FOREWORD Foreword

ISO (the International Organization for Standardization) and IEC (the International Electrotechnical Commission) form the specialized system for worldwide standardization. National bodies that are members of ISO or IEC participate in the development of International Standards through technical committees established by the respective organization to deal with particular fields of technical activity. ISO and IEC technical committees collaborate in fields of mutual interest. Other international organizations, governmental and non-governmental, in liaison with ISO and IEC, also take part in the work.

In the field of information technology, ISO and IEC have established a joint technical committee known as ISO/IEC JTC1. Draft International Standards adopted by the joint technical committee are circulated to the national bodies for voting. Publication as an international standard requires approval by at least 75% of the national bodies that cast a vote.

The ISO/IEC 14651 International Standard has been prepared by the Joint Technical Committee ISO/IEC JTC1, Information Technology.

ISO/IEC 14651:2000(E)

INTRODUCTIONIntroduction

This International Standard provides a <u>world-wide applicable</u> method for ordering text data <u>world-wide</u>, and provides a Common Template Table <u>whose tailoring meetswhich</u>, <u>when tailored</u>, <u>can meet</u> the requirements of <u>given languages and culturesa given language's ordering requirements</u> while retaining reasonable orderingproperties for other scripts.

The Common Template Table requires some tailoring in different local environments. However conformanceConformance to this International Standard requires that all deviations from the Template, called "deltas", be declared to document resultant discrepancies.

This International Standard describes a method to order text data independently of context.

The Draft Technical Report ISO/IEC DTR 14652 (under development) has specifications for ordering that complements the specifications in this International Standard, and where additional information may be sought on ordering keywords defined in this International Standard.

INTERNATIONAL STANDARD ©ISO/IEC ISO/IEC ISO/IEC ISO/IEC ISO/IEC

International string ordering and comparison -

Method for comparing character strings and description of the common template tailorable ordering

1<u>.</u> Scope

This International Standard defines:

- -A reference comparison <u>method. This</u> method <u>is</u> applicable to two character stringsin order to determine their respective order in a sorted list.relative order. The method can be applied to strings containing characters from the full repertoire of ISO/IEC 10646-1. This method is also applicable to subsets of that repertoire, such as those of the different ISO/IEC 8-bit standard character sets, or any other character set, standardized or private,standardised or not, to produce ordering results valid (after tailoring) for a given set of languages for each script. This method uses collation tables derived either from the Common Template Table defined in this International Standard or from one of its tailorings.
- —A reference format, format. The format is described using the Backus-Naur Form (BNF). <u>This format is used</u> to describe the Common Template Table. The format is used normatively within this International Standard.
- —A Common Template <u>Table</u>. A given tailoring of the Common Template Table is used by the reference comparison method. <u>This tableThe Common Template Table</u> describes an order for all characters encoded in the first edition of ISO/IEC 10646-1 up to <u>Amendment</u> <u>7.Amendment 7</u>. It allows for a specification of a fully deterministic ordering. This table enables the specification of an <u>international</u> string ordering adapted to <u>different cultures,local</u> <u>ordering rules</u>, without requiring an <u>implementor to have aimplementer to have</u> knowledge of all the different scripts already encoded in the UCS.
- NOTE 1: This Common Template Table is to be modified to suit the needs of a local environment. The main benefit, worldwide, is that for other scripts, often no modification may be required and that the order will remain as consistent as possible and predictable from an international point of view.
- NOTE 2: The character repertoire used in this International Standard is equivalent to that of the Unicode Standard Versionversion 2.1.
 - A reference name, representingname. The reference name refers to this particular version of the Common Template Table, for use as a reference forwhen tailoring. In particular, this name implies that the table is linked to a particular stage of development of the ISO/IEC 10646 Universal multiple-octet coded character set.
 - Requirements for a declaration of the differences (delta) between the collation table and the Common Template Table.

This International Standard does not mandate:

- A specific comparison method; any equivalent method giving the same results is acceptable.
- A specific format for describing or tailoring tables in a given implementation.
- Specific symbols to be used by implementations except <u>for</u> the name of the Common Template Table.
- _____Any specific user interface for choosing options.

2

- <u>Any</u> specific internal format for intermediate keys used <u>in comparisonswhen comparing</u>, nor for the table used. The use of numeric keys is not mandated either.
- A context-dependent ordering.
- -----Any particular preparation of character strings prior to comparison.
- NOTE 1: It is normally necessary to do preparation of character strings prior to comparison even if it is not prescribed by this International standard (see informative <u>annexAnnex</u> C).
- NOTE 2: Although no user interface is required to choose options or to specify tailoring of the Common Template Table, conformance requires always declaring the applicable delta, a declaration of differences with this table. It is recommended that processes present available tailoring options to users.

2. Conformance

A process is conformant to this International Standard if it meets the requirements prescribed in subclauses 6.2 to 6.5.

A declaration of conformity to this International Standard shall be accompanied by a statement, either directly or by reference, of the following:

- <u>- theThe</u> number of levels that the process <u>supports. Thissupports; this</u> number shall be at least <u>three;three.</u>
- <u>whether Whether</u> the process supports the <u>position parameter;</u>forward, position <u>processing parameter.</u>
- - whether <u>Whether</u> the process supports the backward processing parameter and at which level; level.
- -the<u>The</u> tailoring *delta* described in 6.4 in clause 6.4 and how many levels are defined in the delta.

It is the responsibility of <u>implementors implementers</u> to show how their delta declaration is related to the table syntax described in 6.3, and how the comparison method they use, if different from the one mentioned in clause 6, can be considered as giving the same results as those prescribed by the method specified in clause 6.

3. Normative References references

The following standards contain provisions which, through reference in this text, constitute provisions of this International Standard. At the time of publication, the editions indicated were valid. All standards are subject to revision, and parties to agreements based on this International Standard are encouraged to investigate the possibility of applying the most recent editions of the standards listed below.

Members of IEC and ISO maintain registers of currently valid International Standards.

NOTE concerning Amendment 18: OnlyNOTE: Only the EURO SIGN and the OBJECT REPLACEMENT CHARACTER from Amendment 18 are accounted for in Annex A of this International Standard at this time.

ISO/IEC FCD 14651:2000 (E)

4. Definitions

For the purposes of this International Standard, the following definitions apply:

4.1 character string	a sequence of <u>characters</u>
characters4.2 collation	equivalent to the term "ordering"
4.3 collating symbol	a symbol used to specify weights assigned to a collating element
4.4 collation (weighting	i) <u>table</u> tablea mapping from collating elements to weighting elements
4.5 collating element	a sequence of one or more characters that are considered a single element for ordering
4.6 delta	differences from a given collation table. The given collation table, together with a given delta, forms a new collation table. Unless otherwise specified in this International Standard, the term "delta" always refers to differences from the Common Template Table as defined in this International Standard
4.7 (collation) level	the sequence number for a subkey
4.8 ordering	a process by which two strings are determined to be in exactly one of the relationships of less than , greater than , or equal to one another
4.9 ordering key	a sequence of subkeys used to determine an order
4.10 (collation) prepara	tion preparation a process in which given character strings are mapped to (other) character strings logically before the calculation of the ordering key for each of the strings
4.11 reference compari	son <u>method</u> method the method for establishing an order between two ordering keys (see clause 6)
4.12 subkey	a sequence of weights computed for a character string for a particular level.
4.13 symbol	collating element
4.14 (collation) weight	a positive integer value, used in subkeys, reflecting the relative order of collating elements
4.15 weighting <mark>element</mark>	elementa list of a given number of weights sequentially ordered by level

5. Symbols and abbreviations

Following <u>ISO/IEC_10646-1</u> requirement (Amendment 9)<u>ISO/IEC 10646-1</u>, Amendment 9, characters are referenced as UXXXX where X stands for any hexadecimal digit (using upper case letters where applicable) and refers to the value of that character in ISO/IEC 10646-1. This convention is used throughout this International Standard.

In the Common Template Table arbitrary symbols representing weights are used according to the BNF notation description in <u>clause</u> 6.3.1.

6. String comparison

6.1. Preparation of character strings prior to comparison

It may be necessary to transform character strings before the reference comparison method is applied to them (see annex C for an example of such preparation). Although not part of the scope of this International Standard, preparation may be an important part of the ordering process, as for example in telephone book ordering, a complex case in point.process. See Annex C for some examples of preparation.

Where applicable, it can be an important part of the prehandlingpreparation phase to map characters from a non-UCS encoding scheme to the UCS for input into thereference comparison method. This task can amongst other things encompass the correct handling of escape sequences in the originating encoding scheme, the mapping of characters without an allocated UCS codepoint to an application-defined codepoint in the private zone area and inverting strings which change the sequence of characters in strings that are not stored in logical order. For example, for visual order Arabic code sets, input strings must be put into logical order; and for some bibliographic code sets, strings with combining accents stored before their respective base character require that the sets with accents before base characters require reversal combining accents be put after their base character. The resulting string sequence may then have to be remapped into its original encoding scheme.

- NOTE 1: The Common Template Table is designed so that combining sequences and corresponding single characters (precomposed) will have precisely the same ordering. To avoid inadvertently breaking this invariant (and in the process breaking Unicode conformance), tailoring should reorder combining sequences when corresponding characters are reordered. For example, if Ä is reordered after Z, then the sequence <A>+<combining diaeresis> should also be reordered. To avoid exposing encoding differences that may be invisible to the end-user, it is recommended that strings be normalized according to Unicode normalization to achieve this equivalence see Bibliography, Unicode Technical Report no. 15.
- NOTE 2: Escape sequences and control characters constitute very sensitive data to interpret, and it is highly recommended that preparation should filter out or transform these sequences.
- NOTE <u>3: Since</u> the reference method is a logical statement for the mechanism for string comparison, it does not preclude an implementation from using a non-UCS character encoding only, as long as it produces results as if it were using the reference comparison method.

6.2. Key building and comparison

6.2.1.1. Assumptions

The collation table is a mapping from collating elements to weighting elements. In each weighting element, four levels are described in the Common Template Table. This number of levels can be extended or reduced (but not below 3 levels) reduced, but not below 3 levels, in tailoring.

- In the Common Template Table, levels generally have the following characteristics, although the NOTE: purpose of each level is not absolute:
 - Level 1: This level generally corresponds to the set of common letters of the alphabets for that script, if the script is alphabetic, and to the set of common characters of the script if the script is ideographic or syllabic.
 - Level 2: This level generally corresponds to diacritical marks affecting each basic character of the script. For some languages, letters with diacritics are always considered an integral part of the basic letters of the alphabet, and are not considered at this second level, but rather at the first. For example, in Spanish, N TILDE is considered a basic letter of the Latin script. Therefore, tailoring for Spanish will change the definition of N TILDE from "the weight of an N in the first level and the weight of a TILDE in the second level" to "the weight of an N TILDE (placed after N and before O) in the first level, and indication of the absence of a diacritic in the second level". For some characters, variant letter shapes are also dealt with on level 2. An example of this is ß, the LATIN LETTER SHARP S, which is treated as equivalent to ss on level 1, but traditionally distinguished from it on level 2.
 - Level 3: This level generally corresponds to case distinctions or to distinctions based on variant letter shapes (like the distinction between Hiragana and Katakana).
- NOTE: Normally the last level ____ Level 4: This level generally corresponds to weighting differences that are less significant than those at the other levels. Often the last level (level 4 in the Common Template Table) is intended to specify additional weighting for "special" characters, i.e., characters normally not part of the spelling of words of a language (such as dingbats, punctuation, etc.), sometimes called "ignorable" characters in the context of computerized ordering.

6.2.1.2 6.2.1.2. Processing properties

The whole A given tailored table has specific scanning and ordering properties. These properties may be changed have been changed by the tailoring.

TheA scanning direction (forward or backward) for each level is used to indicate how to process the string. The scanning direction is a global property of each level defined in the tailored table.

An optional property of the last level of comparison is that, comparison, if that level is greater than three, is that before comparing weights of each "ignorable" character, a comparison on the numeric position of each such character in the two strings may be effected. This processing property is known as the position parameter. position' option. In other words, for two strings equivalent at all levels except the last one, the string having an ignorable in the lowest position comes before the other one. In case ignorables share the same positions, thencorresponding "ignorables" are at the same position, then their weights are considered, until a difference is found). This found. Support for this kind of processing is optional and is not necessary to claim conformance.

NOTE: The scanning direction (forward or backward) is not normally related to the natural writing direction of scripts. The scanning direction applies to the logical sequence of the coded character string.

According to ISO/IEC 10646, for scripts written right to left, such as Arabic, the lowest positions in the logical sequence of characters correspond to the rightmost characters of a string (from the point of view of their natural presentation sequence). Conversely, for the Latin script, written left to right, the lowest positions in the logical sequence of characters correspond to the leftmost characters of the string (from the point of view of their natural presentation sequence).

Scanning forward starts with the lowest position in the logical sequence, while scanning backward starts from the highest position, independently of the presentation sequence. The scanning direction for ordering purposes is a global property of each level described in the table.

In ISO/IEC 10646-1, the Arabic script is artificially separated into two pseudo_scripts: 1) the logical, intrinsic Arabic, coded independently of shapes, and 2) the Arabic presentation forms. Both allow the complete coding of Arabic, but intrinsic Arabic is normally preferred for better processing, while presentation-form Arabic is preferred by some presentation-oriented applications. ISO/IEC 10646-1 does not prescribe that the presentation forms be <u>codedstored</u> in any specific order, and in some implementations, the <u>codedstorage</u> order for the latter is <u>exactly the opposite of the one used for</u> <u>"intrinsic Arabic".the reverse of the storage order used for intrinsic Arabic.</u> It is thereforeeventually advisable that prehandling be used to make sure that<u>coded</u> Arabic presentation forms and othercoded Arabic characters be fed to the comparison method inthe same logical order.

A tailored table may be separated into sections for ease of tailoring. Each section is then assigned a name consistent with the specification in subclause 6.3.1. One of the tailoring possibilities is to assign a given order to each section and to change the relative order of an entire section relative to other sections.

6.2.2 Ordering 6.2.2. Reference ordering key formation

When two strings are <u>to be</u> compared to determine their relative order, the two strings are first broken up into a sequence of collating <u>elements</u>, <u>making use of any applicableelements</u> <u>taking into account</u>, in the tailored table <u>used</u>, the multi-character collating elements that have been declared by a 'collating' element' statement in the tailored table.

declared by "collating-element" statements in a tailored table (*if* the syntax of clause 6.3.1 is used). For the syntax used for expressing the Common Template Table, the name of a collating element consisting of a single character, is formed by the UCS value of the character, expressed as a hexadecimal string, prefixed with "U". For multi-character collating elements, the name and association to characters can be found via the collating elements declarations.

-Then a sequence of m intermediary subkeys is formed out of a character string, where m is the number of levels described in a tailored collation weighting table. The following subclauses describe the formation of an ordering key.

Each ordering key is a sequence of subkeys. Each subkey is a list of numeric weights. A subkey is formed by successively appending the list of the weights assigned, at the level of the subkey, to each collating element of the string. The keyword "IGNORE" IGNORE" in the Common Template Table at the place of a sequence of collating symbols at a level, indicates that the sequence of weights at that level for that collating element is an empty sequence of weights.

There are three <u>typesways</u> of <u>forming</u> subkeys: subkeys <u>formed</u> using the <u>"forward" forward"</u> <u>processing</u> parameter; subkeys <u>formed</u> using the <u>"backward" backward" processing</u> parameter; and subkeys <u>formed</u> using the <u>"forward, position" forward, position" processing</u> parameter. Subkeys that use the <u>position parameter "position" option</u> can only occur at the last <u>level</u>. Support of the position parameter is not required for conformance but shall be declared if used.

<u>level</u>, and only if that level is greater than three. The special keyword "ICNORE" as a weight indicates that when strings are compared using the weights at the level where "ICNORE" is specified, the collating element shall be ignored; i.e., as if the string did not contain the collating element. Support of the "position" option is not required for conformance.

ISO/IEC FCD 14651:2000 (E)

If there is no entry in the tailored table for a character of the input string, then the character's weights are undefined. Characters with undefined weights are orderedshould be ordered, with respect to characters that have defined weights as if theyweights, as if the undefined ones were given the weight "UNDEFINED" at each level in the Common Template Table.named "UNDEFINED" at the first level. If there is no weight assignedassignment to the symbol "UNDEFINED" in the "UNDEFINED" before the symbol <SFFFF>'s weight assignment in a given tailored table, then the table isshall be interpreted as if there were one at the very end. "UNDEFINED" was weighted just before <SFFFF> (the maximal level 1 weight). The ordering of characters with undefined weights with respect to other characters with undefined weights is not specified in this standard."

NOTE: there are two common treatments of undefined characters. The first is to sort among them as if their level one weight differences were based upon their UCS character code. The second is to sort them as if they all had the same level one weight, and their second-level weights were the same as their UCS character codes. A possible way to order characters with undefined weights is as if there were tailoring lines like this one added to the table, in UCS code point order (call the maximal level 4 weight <PLAIN> here):

<UXXXX> "<UNDEFINED><UXXXX>";<BASE>;<MIN>;<PLAIN>

6.2.2.1<u>.</u> Formation of a subkey with the <u>forward parameter "forward" level processing</u> parameter

Subkeys with the <u>forward</u>Subkeys, at a particular level, formed with the <u>forward</u> level processing parameter are formed in the following way at a particular level:

During forward scanning of each collating element of the input character string, one or more weights are obtained. These weights are obtained by matching the <u>name of collating element</u> the <u>collating element</u> in <u>athe given</u> tailored collation weighting table, and then obtaining the list of weights assigned at the particular level to the collating element. the collating element at the particular level. The obtained weight list is appended to the end of the subkey.

For the syntax used for expressing the Common Template Table, the name of a collating element consisting of a single character, is formed by the UCS value of the character, expressed as a hexadecimal string, prefixed with "U" For multi-character collating elements, the name and association to characters can be found via the collating elements declarations.6.2.2.2 Formation of a subkey with the backward parameter

Subkeys with the backward parameter are formed by forming a subkey with the forward parameter at a particular level, then reversing that subkey.

6.2.2.3 Formation of a subkey which uses the forward position parameter

Subkeys using the forward position parameter are formed at a particular level in the following way:

During forward scanning of each collating element of the input character string, two weights are appended to the end of the subkey. The first weight corresponds to the logical position in the original character string of the collating element being processed. The second weight corresponds to the weight assigned to that collating element at the subkey's level in the table.

NOTE: In the Common Template Table, levels generally have the following characteristics, although the purpose of each level is not absolute:

Level 1: This level generally corresponds to the set of common letters of the alphabets for that script, if the script is alphabetic, and to the set of common characters of the script if the script is ideographic or syllabic.

Level 2:	This level generally corresponds to diacritical marks affecting each basic character of the script. For
	some languages, letters with diacritics are always considered an integral part of the basic letters of
	the alphabet, and are not considered at this second level, but rather at the first. For example, in Spanish, N TILDE is considered a basic letter of the Latin script. Therefore, tailoring for Spanish will
	change the definition of N TILDE from "the weight of an N in the first level and the weight of a TILDE
	in the second level" to "the weight of an N TILDE (placed after N and before O) in the first level, and
	indication of the absence of a diacritic in the second level". For some characters, variant letter
	shapes are also dealt with on level 2. An example of this is 8, the LATIN LETTER SHARP S, which
	is treated as equivalent to ss on level 1, but traditionally distinguished from it on level 2.
1	This local second by second to see distinctions on mainty is used of the second to the second to the second s
Level 3: -	This level generally corresponds to case distinctions or, mainly in non-Latin scripts, to distinctions based on variant character shapes.
Level 4:	This level generally corresponds to weighting differences that are less significant than those at the other levels.
6.2.3 Re	ference comparison method for ordering character strings
The	following describes the reference comparison method:
<u>1.ln</u>	considering a table describing weights (each instance a of weight is noted wt(a) below) at m
	levels (an instance of a subkey at a given level b is noted sk(b) below) for each of n
	characters in the implementation character set, build an ordering key for each of two
	arbitrary character strings being compared, according to the algorithm of key formation
	described in sub-clause 6.2.2of this International Standard.
2.4.	a ordering key wie leas then an ordering key wat level a where dhenn if and only if there
2.A	n ordering key x is less than an ordering key y at level s where 1PsPn if and only if there
	exists some integer i where 1PiPs such that xsk(i) < ysk(i) and xsk(i) = ysk(i) for all integers j
	where 1PjPi .
— An or	dering key x is greater than an ordering key y if and only if y is less than x ;
— An or	dering key x is equal to an ordering key y if neither x is less than y nor y is less than x .
3.A	subkey v of length Iv is less than a subkey w of length Iw if and only if Iv=0 and Iw>0 or if
	there exists some integer p where pPly and pP ly such that for all integers q, where 1PqPp,
	V_{wt(q)}=w_{wt(q)} and either I_v=p and I_wΣp and v_{wt(p)}=w_{wt(p)} or₋v_{wt(p)}<w<sub>wt(p).</w<sub>
<u> </u>	wey v is greater than a subkey w if and only if w is less than v ;
— A sut	wey v is equal to a subkey w if neither v is less than w nor w is less than v.
	table used in this reference comparison method is the result of the numeric interpretation of the in a tailored table.
NOTE: Ti strings to different differenc ordered,	he comparison may be made "on-the-fly" while generating the ordering keys for two b be compared, stopping the comparison when two collating elements have got weights at a given level. This avoids generating the full ordering key, when a e may be found in the beginning of the strings. When a bigger set of strings are to be it is advisable to generate the full ordering keys before comparison. <u>6.2.2.2. Formation</u> (ey with the "backward" level processing parameter
.	

Subkeys, at a particular level, formed with the "backward" level processing parameter are formed by forming a subkey as with the "forward" parameter, then reversing that subkey weight by weight. 10

©ISO/IEC ISO/IEC FCD 14651:2000 (E) 6.2.2.3. Formation of a subkey with the "forward, position" level processing parameter

Subkeys, at the last level, formed with the "forward, position" level processing parameter are formed by forming a subkey as with the "forward" parameter, but for collating elements that are not "IGNORE"d at all levels but the last one, their last level weighting (list of weights) is replaced by a single weight (call it <PLAIN> here) that is larger than all other weights at the last level in the given tailored table. Collating elements that are "IGNORE"d at all levels but the are "IGNORE"d at all levels but the subkey as the last level in the given tailored table. Collating elements that are "IGNORE"d at all levels but the last one, retain their weighting according to the given tailored table. Finally, any trailing sequence of the maximal weight (<PLAIN>) is removed from the subkey, effectively replacing each trailing maximal weight with a zero weight.

 NOTE:
 For any level, implementations are allowed to apply an order-preserving reduction of all subkeys at that level (see, e.g., Annex E). Such an order-preserving subkey reduction is useful for levels 2, 3, and 4. Level 2 often has long stretches of the weight named <BASE> in Annex A. Level 3 often has long stretches of the weight named <MIN> in Annex A. Level 4 often has long stretches of the weight named <PLAIN> here. One such ordering preserving subkey reduction technique effectively encodes, in the last level subkey, the (relative) position, as single number each, of each otherwise ignored character; hence the name of the "position" option.

6.2.3. Reference comparison method for ordering character strings

The reference comparison method for ordering two given character strings (*after* collation preparation, which is not part of the reference comparison method itself) is to compare ordering keys generated by the reference key formation method described in subclause 6.2.2 of this International Standard:

- Begin by building an ordering key, using a given tailored collation weighting table, for each of the two given character strings being compared.
- Then compare the resulting keys according to the key ordering definition below in this subclause. Keys can be compared either up to a given level, or up to the last level of the given tailored collation weighting table.
- <u>NOTE 1:</u> The comparison may be made while generating the ordering keys for two strings to be compared, stopping the key generation when the order of the strings can be determined. Such a technique is sometimes termed lazy evaluation, and some systems support it by default. This avoids generating the full ordering key, when an ordering difference may be found early in the keys. When a bigger set of strings are to be ordered, it may be advisable to generate the ordering keys, and store each key or an initial segment of each, before comparing the keys.

Weights for different levels should not be compared, which implies that subkeys at different levels should not be compared. Nor should keys generated from different tailored tables be compared.

<u>NOTE 2:</u> This allows implementations to assign weightings at each level independently of the other levels, and independently of other tailorings.

<u>*m* is the maximal level of a given tailored table. Recall that a key is a list, of length *m*, of subkeys; a subkey is a list of weights; and a weight is a positive integer. Other notations used below are:</u>

• L_z is the length of the subkey z, i.e., the number of weights in the subkey.

- $z_{wt(a)}$, where $1 \le a \le L_z$, is the weight at index position a (an integer > 0) of the subkey z.
- $u_{\mathbf{sk}(b)}$, where $1 \le b \le m$, is the subkey at level b (an integer > 0) of the key u.

The orderings of weights, subkeys, and ordering keys (up to a given level, or up to the last level) are total orders, defined for a given tailored collation table as follows:

Weights are positive integer values (in the reference method), and are compared as such for the purposes of collation.

A subkey v is less than a subkey w (written v < w) if and only if there exists an integer i, where $1 \le i \le L_{\underline{v}}+1$ and $i \le L_{\underline{w}}$ such that for all integers j, where $1 \le j < i$, the equality $\underline{v_{wt(j)}} = w_{wt(j)}$ holds; and either $i \le L_{\underline{v}}$ and $v_{wt(i)} < w_{wt(i)}$, or $i = L_{\underline{v}}+1$ and $0 < w_{wt(j)}$.

A subkey v is greater than a subkey w (written v > w) if and only if w is less than v. A subkey v is equal to a subkey w (written v = w) if and only if neither v is less than w, nor w is less than v.

An ordering key x is *less than* an ordering key y at level s (written $x \leq_s y$) **if and only if** there exists an integer i, where $1 \leq i \leq s$ and $i \leq m$, such that for all integers j, where $1 \leq j < i$, the equality $x_{sk(j)} = y_{sk(j)}$ holds; and $x_{sk(i)} < y_{sk(j)}$.

An ordering key x is greater than an ordering key y at level s (written $x \ge_{s} y$) if and only if y is less than x at level s. An ordering key x is equal to an ordering key y at level s (written $x =_{s} y$) if and only if neither x is less than y at level s, nor y is less than x at level s.

For ordering keys, <, >, and = are defined as $<_m$, $>_m$, and $=_m$ respectively.

NOTE 3: For ordering keys, $x <_{\underline{t}} y$ implies $x <_{\underline{t}+1} y$, $x >_{\underline{t}} y$ implies $x >_{\underline{t}+1} y$, $x =_{\underline{t}} y$ implies $x =_{\underline{t}-1} y$, $x <_{\underline{0}} y$ is false, $x >_{\underline{0}} y$ is false, and $x =_{\underline{0}} y$ is true. Above level m, for a given tailored table, there are no further ordering distinctions. Note that this definition implies that if two ordering keys are in the 'less than' relationship at level 1, they will also be in the 'less than' relationship at levels 2, 3, 4, etc. In general, whenever two ordering keys are less than at a given level, they will also automatically be less than at all subsequent, higher levels. Conversely, if two ordering keys are equal at a given level, they will also automatically be equal at all preceding, lower levels.

6.3. Common Template Table: formation and interpretation

This clause specifies:

- <u>the The</u> syntax used to form the Common Template Table in <u>annexAnnex</u> A of this International Standard or a tailored table based upon the Common Template Table<u>as</u> <u>expressed in Annex A.</u>
- <u>conditions</u> of well-formedness of a table using this syntax.
- <u>interpretation of Interpretation of tailoring statements in deltas for</u> tables formed using this syntax.
- Evaluation from symbols to weights of tailored tables formed using this syntax.
- <u>conditions</u> for considering two tables as equivalent.
- <u>conditions</u> for considering comparison results as equivalent.

6.3.1. BNF syntax rules for the Common Template Table in Annex A

Definitions between <angle brackets> make use of terms not defined in this BNF syntax, and assume general English usage.

Other conventions:

- * indicates 0 or more repetitions of a token or a group of tokens;
- + indicates 1 or more repetitions of a token or a group of tokens

? indicates optional occurrence of a token or a group of tokens (0 or 1 occurrences)

parentheses are used to group tokens

6.3.1.1 Keyword usage

The following keywords were inherited from POSIX locale syntax. Theoriginal usage of these keywords is as follows:

©ISO/IEC	1	SO/IEC FCD 14651:2000 (E)
collating-element	Define a collating-elementcollating-symbol representing a weight.	Define a collating symbol
collating-element	Define a collating element symbol representing charactermulticharacter collating element. This	
order_start	Define collation rules. This statement is <u>(after re</u> one or more collation order statements, assigni and collation weights to collating elements. <u>mult</u> collating elements. A collating element is either <u>substring</u> .	ng character collation values i-level collation weightings to
order_end	Specify the end of the collation-order statement	S.
reorder-after	Redefine collating rules. Specify after which coll of collation order shall take order. This statement the lines between the reorder-after and the next moved. This statement is followed by one or more reassigning character collation values and collat elementstable lines. The result is to reassign of collating elements's weightings.	nt <u>collating symbol weighting</u> t (or reorder-end) are to be ore collation order statements, tion weights to collating
reorder-end	Specify the end of the "reorder-after" collating o	rder statements.
section	Define a section of the table. A section can be r section-after.	moved as a whole by reorder-
reorder-section-after	Redefine the order of sections. This statement section symbols, reassigning character collation to collating elements. statement is followed by a symbol. The result is to reassign collating symbol elements's weightings.	a values and collation weights a section symbol and a target ol's values or collating
reorder-section-end	Specify the end of the "rec statements.	order-sections" section order

6.3.2. Well-formedness conditions

WF1. AnyWF 1. Any simple_symbol occurring in a weight_list shall also occur in the initial symbol_element of the symbol_weight in which that that weight_list occurs, or in a symbol_definition that occurs earlier in the sequence of lines that constitute a weight_table.

NOTE: All simple_symbols shallmust be "defined" before they are "used".

WF2. NoWF 2. No symbol that occurs in a symbol_definition in a weight_table that contains no tailoring_line's may occur in another symbol_definition in the same weight_table.

NOTE: Duplication<u>NOTE: Duplication</u> of collation weighting symbols is prohibited. This is true for the Common Template Table itself, and must also itself. It must remain true for a tailored_table, once the results of tailored_table after all reordering of lines has been applied.

©ISO/IEC

WF3. All weight_list'sWF 3. All weight_lists in a tailored_table shall contain the same number of level_token's. An empty level_token shall be interpreted as the collating_element itself.

NOTE: A tailorable table shall be consistent in its use of levels throughout.

WF4. A tailored_table shall contain one order_start statement..

NOTE: This statement shall appear after symbol_definition entries and before the symbol_weight entries.

WF5. A *multiple_level_direction* in a *tailored_table* shall contain the same number of *direction's* as the number of *level_token's* of any *weight_list* in that *tailored_table*.

NOTE: Any order_start shall have the same number of levels as is generally used in the table.

WF6. If a *level_token* in a *weight_list* consists of a *symbol_group*, all successive *level_token*'s in that *weight_list* shall also consist of a *symbol_group*.

NOTE: 'IGNORE' shall not be used at a level after an explicit symbol for a weighting.

WF7. Any section_identifier occurring in a reorder_section_after shall occur in a section_definition which occurs earlier in the sequence of table_lines that constitutes a tailored_table. All section_identifiers_shall be "defined" before they are "used".

WF8. No two section_definition_entrys in a tailored_table shall contain the same values in their section_identifiers.

NOTE: Multiple definition of sections is prohibited; section_identifiers shall be unique.

WF9. Each *reorder_after* in a *tailored_table* shall be followed at a later point in that tailored table by a *reorder_end* or another *reorder_after*.

WF10. A tailored_table shall contain one order_start and one order_end.

WF11. No reorder_section_after shall contain a target_symbol whose value is the same as any symbol in the section_definition_list whose section_identifier is the same as the section_identifier in that reorder_section_after.

NOTE: A section shall not be reordered after a line which the section itself contains; attempts at recursive relocation of lines are prohibited.

WF12. Any *symbol_range* shall contain two *symbol's* which meet the following conditions: Each *symbol* shall contain a common prefix; the portions of *identifier* of each *symbol* following the common prefix shall be a *hex_numeric_string;* and when interpreted as numeric values, the *hex_numeric_string* of the first *symbol* shall be less than the *hex_numeric_string* of the second *symbol.* The positive integral difference between the *hex_numeric_string* of the second *symbol,* interpreted as a 18

numeric value, and the hex_numeric_string of the first symbol, interpreted as a numeric value, constitutes the range of values of the symbol_range.

NOTE: A well-formed symbol_range is of a form such as <S4E00>...<S9FA5>, where the common prefix is "S", and the rest of the identifier portion of each symbol is a hex_numeric_string.

WF13. Any symbol_weight which contains more than one symbol_range shall contain only symbol_range's that meet the following requirement: Each symbol_range following the first symbol_range shall have the same number of values in the range as that of the first symbol_range.

NOTE: This condition guarantees that all expanded ranges will be well-formed, since for any one symbol_weight, all of the range expansions will have the same number of values.

6.3.3 Interpretation of tailored tables

I1. A section consists either 1) of the list of simple_lines which contain a symbol_definition whose value is equal to any symbol contained in the symbol_list in a section_definition_list_entry, or 2) of the list of simple_line's following a section_definition_simple in a tailored_table.

NOTE: A section is defined 1) by a specific symbol_list, or 2) by taking all the lines following the section_definition until another tailoring line such as an order_start, a reorder_section_after, another section_definition, or the end of the entire table is encountered.

I2. A simple_line consisting of a symbol_definition containing a symbol_range is equivalent to a sequence of simple_line's, each containing a symbol in place of the symbol_range, where the symbol for each successive simple_line is generated by concatenating a hex_numeric_string to the common prefix of the symbol_range, in numeric order, starting with the hex value associated with the hex_numeric_string of the first symbol, and ending with the hex value associated with the hex_numeric_string of the second symbol. The hex_numeric_string concaneted to the common prefix must contain the same number of digits as the hex_numeric_string of the first symbol. The number of simple_line's thus generated is equal to the number of symbols in the symbol_range.

NOTE: A tailorable table must be consistent in its use of levels throughout.

- WF 4. A tailored_table shall contain one order_start statement. This statement shall appear after the symbol_definition entries and before the symbol_weight entries after all reordering of lines has been applied.
- <u>WF 5.</u> A multiple_level_direction in a tailored_table shall contain the same number of directions as the number of level_tokens of any weight_list in that tailored_table.
 - NOTE: Any order start must have the same number of levels as is generally used in the table.

NOTE: IGNORE *must not be used at a level after an explicit symbol for a weighting.*

WF 7. Any section identifier occurring in a reorder section after shall occur in a section definition that occurs earlier in the sequence of table lines that constitutes a tailored table.

NOTE: All section identifiers must be "defined" before they are "used".

- WF 8. No two section definitions in a tailored table shall contain the same values in their section identifiers.
 - NOTE: Multiple definitions of sections are prohibited; section identifiers must be unique.

WF 9. Each reorder after in a tailored table shall be followed at a later point in that tailored table by a reorder end or another reorder after.

- WF 10. A tailored table shall contain one order start and one order end.
- WF 11. No reorder section after shall contain a target symbol whose value is the same as any symbol in the section definition list whose section identifier is the same as the section identifier in that reorder section after.
 - A section must not be reordered after a line which the section itself contains; attempts at recursive NOTE: relocation of lines are prohibited.
- WF 12. Any symbol range shall contain two symbols which meet the following conditions: 1) Each of the two symbols shall contain a common prefix. 2) The portions of identifier of each of the two symbols following the common prefix shall be a hex numeric string. 3) When interpreted as numeric values, the hex numeric string of the first symbol shall be less than the hex numeric string of the second symbol. One plus the positive integral difference between the hex numeric string of the second symbol, interpreted as a numeric value, and the hex numeric string of the first symbol, interpreted as a numeric value, constitutes the range of *values* of the *symbol* range.
 - A well-formed symbol_range is of a form such as <S4E00>..<S9FA5>, where the common prefix is NOTE: "S", and the rest of the identifier portion of each symbol is a hex numeric string.
- WF 13. Any symbol weight that contains more than one symbol range shall contain only symbol ranges that meet the following requirement: Each symbol range following the first symbol range shall have the same number of values in its range as that of the first symbol range.

NOTE: This condition guarantees that all expanded ranges will be well-formed, since for any one symbol weight, all of the range expansions will have the same number of values.

6.3.3. Interpretation of tailored tables

I 1. A section consists either 1) of the list of simple lines which contain a symbol definition whose value is equal to any symbol contained in the symbol list in a section definition list, or 2) of the list of simple lines following a section definition simple in a tailored table.

©ISO/IEC

ISO/IEC FCD 14651:2000 (E)

- <u>NOTE:</u> A section is defined 1) by a specific symbol_list, or 2) by taking all the lines following the section_definition until another tailoring line such as an order_start, a reorder_section_after, another section_definition, or the end of the entire table is encountered.
- I 2. A simple line consisting of a symbol definition containing a symbol range is equivalent to a sequence of simple lines, where each of those lines contain a symbol in place of the symbol range. The symbol for each successive simple line is generated by concatenating a hex numeric string to the common prefix of the symbol range, in numeric order, starting with the hex value associated with the hex numeric string of the first symbol the range, and ending with the hex value associated with the hex numeric string of the second symbol. The hex numeric string concatenated to the common prefixes must contain the same number of digits as the hex numeric string of the first symbol. The number of simple lines thus generated is equal to the number of symbols in the symbol range.

NOTE: A<u>NOTE: A</u> symbol_definition of the form "collating-symbol <S0301>..<S0303>" is equivalent to the three lines: collating-symbol <S0301> collating-symbol <S0302> collating-symbol <S0303>

I3. A simple_line consisting of a symbol_weight containing one or more symbol_range's is equivalent to a sequence of simple_line's, where each symbol_range has been expanded into a sequence of symbol's, as described in I2 for symbol_definition's.I 2 for symbol_definitions.

NOTE: A<u>NOTE: A</u> symbol_weight of the form "<U2000>..<U2002> <S0301>..<S0303>;<BLANK>;<MIN>; <U2000>..<U2002>" is equivalent to the three lines: <U2000> <S0301>;<BLANK>;<MIN>;<U2000> <U2001> <S0302>;<BLANK>;<MIN>;<U2001> <U2002> <S0303>;<BLANK>;<MIN>;<U2001>

<u>14a. AI 4a.</u> *A tailored_table* containing a *reorder_after* is equivalent to the *tailored_table* where:

1)have been removed all *table_line*'s all *table_lines* that were ahead of the *reorder_after* and that contained *symbol_definition*'s whose *symbol* matches the *symbol* of any *symbol_definition* in the *table_line*'s between the *reorder_after* and *reorder_end*,

2)1. reorder end have been reordered removed,

2)the table_lines between that reorder_after and the first subsequent reorder_end to immediately follow the first table_line in the tailored_table containing a symbol_definition whose symbol is the same as the target_symbol in the reorder_after, and

3) reorder after have been reordered, and

<u>3.2. have been removed</u> that *reorder_after* and that *reorder_end*. <u>reorder_end</u> have been <u>removed</u>.

NOTE: MoveNOTE: Move the block of lines between the reorder_after and the reorder_end to follow the target_symbol, delete any prior lines that duplicate the symbol_definition's of the reordered lines, and remove the reorder_after and reorder_end themselves.

©ISO/IEC

I4b.: When I 4b. When a tailored_table contains multiple groups of lines to be reordered, the table is interpreted by processing each reorder_after sequentially, starting from the first line of the table.

NOTE: Subsequent<u>NOTE: Subsequent</u> line reorderings may impact lines that themselves were reordered by prior reorderings.

- I5. A tailored_table containing a <u>section_reorder_after_reorder_section_after</u> is equivalent to the tailored_table with the section associated with that section-reorder_after reordered (in the same relative order as the table_lines have in that section) to immediately follow the last table_line in the tailored_table containing a symbol_definition whose symbol is the same as the target_symbol in the <u>section_reorder_after</u>, and with that <u>section_after</u>.
- <u>I6. AI 6.</u> <u>A</u> weight_table is said to be in normal form when it contains no <u>reorder_after's or</u> <u>section_reorder_after's reorder afters or reorder section afters.</u>
 - NOTE: A<u>NOTE: A</u> tailored_table can be put into normal form by the operations implied by <u>I4 and I5.[4 and I</u> <u>5.</u>

6.3.4. Evaluation of weight tables

- E1. AE 1. A weight_table in normal form is said to be evaluated when each weight_assignment in the weight_table is mapped to a positive integer value (a weight) such that those values increase monotonically by the order in which the weight_assignment's occur in the weight_table.
 - NOTE <u>1:The table_line's1</u>: <u>The table lines</u> of the weight_table <u>arecan</u> first <u>be</u> mapped to the set of positive integers, by sequential order in the table. This mapping defines an ordered set of line numbers. The weight_assignment's are then mapped to a set of positive integers (weights) that varies monotonically with the set of line numbers.
 - NOTE 2: <u>this</u> <u>this</u> does not restrict the starting number for the weight of the first weight_assignment,weight assignment (other than it must be positive)</u> nor does it require that the numbers for these weights be immediately consecutive.
- E2. An evaluated weight_table is said to be collation-element-weighted when each simple_symbol occurring in each weight_list in that evaluated weight_table has been mapped to the weight whichthat corresponds to the weight_assignment whichthat contains the same simple_symbol.
 - NOTE <u>1: Each3: Each</u> weight_list can be interpreted as containing either symbol's mapped to integral weight values, or as instances of the string <u>'IGNORE'. At this point'IGNORE', which denotes the empty</u> <u>sequence of weights. At this point</u>, the mathematical injection of strings can be defined using the weight_table. The string 'IGNORE' is equivalent to an empty list of weight symbols.

NOTE <u>2: In4: In</u> a tailored table the value of any hex_numeric_string associated with a symbol typically does not reflect the numeric weighting of the symbol.

6.3.5. Conditions for considering specific table equivalences

A weight_table <u>W1TBL1</u> and a weight_table <u>W2TBL2</u> are said to be equivalent at a particular level if any comparison of strings using those tables up to that level results in the same ordering.

NOTE: If one takes two strings, builds keys for each based on <u>W1TBL1</u> and compares them, one should always get the same results as when one builds keys for those strings based on <u>W2TBL2</u> and compares them, if those two tables are claimed to be equivalent.

6.3.6. Conditions for results to be considered equivalent

An implementation of international string ordering is conformant with this International Standard if, for any set of strings S defined on a repertoire R, the implementation can duplicate the same comparisons as those resulting from comparison of the numbers from an injection constructed according to the rules of clause 6.2.3 of this International Standard.

6.4. Declaration of a delta

Tailoring shall be based upon the Common Template Table described in annex A. Tailoring may be accomplished using any syntax that is equivalent to the one described in this International Standard.

NOTE<u>1</u>: For example, ISO/IEC DTR 14652, uses a compatible extension of the syntax used in this International Standard for tailoring_ A tailoring delta can also be expressed using the syntax of the Unicode collation algorithm (see Bibliography - Unicode Technical Report no. 10). It has also been demonstrated that a tailoring delta can also be expressed using an XML-conformant mark_up scheme.

Any declaration of conformance to this International Standard shall be accompanied with a declaration of the differences between the collation weighting table and the Common Template Table. A delta shall contain the equivalent of:

- 1. At least one valid *order_start* entry described in clause 6.3.1; an unlimited number of sections containing an *order_start* entry and an *order_end* entry may be declared.
- 2. The number of levels used for comparison.
- 3. The list of *symbol_definition* weights (as defined in 6.2.1) added and after which *symbol_definition* entry each insertion is made.
- 4. The list of *simple_line* entries (as defined in 6.2.1) deleted or inserted, referencing after which *simple_line* entry in the Common Template Table the insertions are made

NOTE: It is recommended that a delta should not be bigger than necessary.

In cases where a process has provision to allow the end-user to tailor the table himself or herself, a statement of conformance shall indicate which of the 4 elements of the previous list are tailorable and

©ISO/IEC

which of those 4 elements are not tailorable. For those which are not tailorable, the delta of fixed elements relative to the Common Template Table shall be declared.

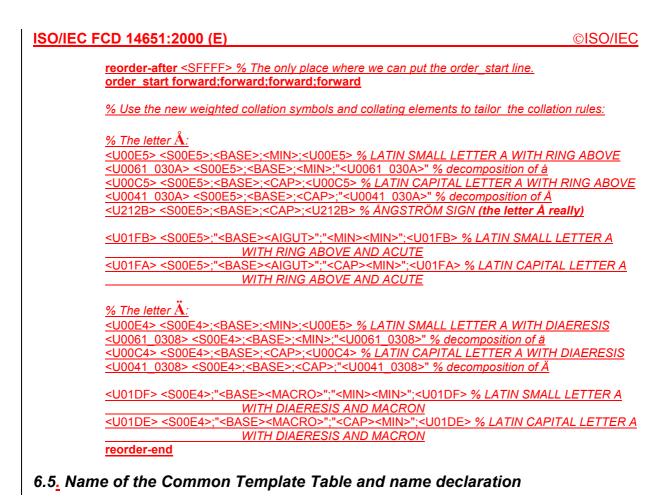

NOTE<u>3</u>: The declaration may use a different syntax from the one specified in 6.3 provided that the relationship with this syntax can be reasonably established. For example, the following declarations are valid:

"Collate U+00E5 after <u>U+007AU+00FE</u> at the primary level. Collate U+00E4 after U+00E5 at the primary level. "

Of
The primary alphabet order is modified so that in all cases $z < b < a < z$ (to be noted that the letters a and z are sorted after Icelandic letter thorn (b), itself already coming after all the variants of the letter z, i.e. they have a weight value higher at level 1 than the one for thorn (b), which itself comes after the one for all variants of the letter z.
These two notations can reasonably be considered to be equivalent to the following more precise expressions (which also give weights at levels 2 and 3 and take care of accented å's, acccented ä's and Angström sign):
collation-element <u0041_0308> from "<u0041><u0308>" % decomposition of Ä</u0308></u0041></u0041_0308>

24

	collation-element <u0041 030a=""> from "<u0041><u030a>" % decomposition of Å</u030a></u0041></u0041>
	<u>collation-element <u0061_0308> from "<u0061><u0308>" % decomposition of ä</u0308></u0061></u0061_0308></u> collation-element <u0041_0308> from "<u0041><u0308>" % decomposition of Ä</u0308></u0041></u0041_0308>
	<u>% Assign weights to the new collation symbols (after THORN):</u>
	<u><\$00E5> % for å</u> <\$00E4> % for ä
	reorder-end

Whenever the Common Template Table is referred externally as a base point in a given context, whether in a process, contract, or procurement requirement, it shall be referenced using the name ISO14651_2000_TABLE1. If another name is used due to practical constraints, a declaration of conformance shall indicate how the correspondence between this other name and the name ISO14651_2000_TABLE1 is taken care of.

The use of a defined name is necessary to manage the different stages of development of this table. This follows from the nature of the reference character repertoire, for which development will be ongoing for a number of years or even decades.

Annex A ---- Common Template Table (normative)

In this ordering table, a number of characters and scripts of the world are missing, due to the fact that because those characters or scripts have not yet been encoded in the reference character set repertoire, ISO/IEC 10646-1 (Universal multiple-octet coded Character Set, or UCS) at time of the preparation of this International Standard.

It is the intent of ISO/IEC to include the ordering of those scripts explicitly in the Common Template Table when data becomes available, by way of amendments to this International Standard. If the Common Template Table is not tailored for unspecified characters, then an implicit order is assigned in the following table, which may not meet the user requirements of a particular community. Any delta with this table shall be declared in a statement of conformance to this International Standard as per the specifications of the conformance clause.

Name used for referring to this table in this version of this International standard: **ISO14651_2000_TABLE1**

ISO14651 2000 TABLE1.

****** TEXT TO BE MODIFIED WHEN WE KNOW THE PERMANENT URL OF THE <u>MACHINE_READABLE TABLE ON</u><u>MACHINE-READABLE TABLE ON</u> <u>THE</u> ITTF SITE *****

NOTE: Some lines in the following table spill in presentation has automatic line wrap applied because of long line lengths. An eventual <u>The</u> machine-readable table using this format shall be corrected to avoid this minor presentation problem. In case of doubt a copy of the source file (which does not present this presentation problem as it is a machine-readable file) is available from the SC22/WG20 convenor or from the editor of this International has no extra end-of-line characters because of this. A plain text copy of the Common Template Table file is available at <htps://www.iso.ch/?????>.

Standard. At time of publishing of the International Standard, it is currently the intent that the machine-readable table will be assigned a permanent URL which will be refered in the final document in addition to being reproduced fully in the International Standard.

Annex B – Example tailoring deltas (informative)

B.1. Example 1 – Minimal tailoring

The following is a minimal tailoring of the Common Template Table:

```
reorder_after <SFFFF>
order_start forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward;forward
```

B.2. Example 2 – Reversing the order of lowercase and uppercase letters

The following is a simple tailoring example to show how to reverse the order of uppercase versus lowercase from the order specified in the Common Template Table.

```
% Make uppercase letters sort before lowercase
% and scanning of accents done forward at level 2.
```

```
% The entire range of tertiary weight symbols
% <MIN>..<CIRCLE> are moved after <CIRCLECAP>, so that they order after
% <CAP> <WIDECAP> <COMPATCAP <FONTCAP> <CIRCLECAP> in the same
% relative order with respect to themselves. This has the effect of
% also making all the compatibility uppercase letters sort before
% their respective compatibility lowercase letters. (For example,
% U+24B6 CIRCLED LATIN CAPITAL LETTER A will sort before
% U+24D0 CIRCLED LATIN SMALL LETTER A.
```

```
% To do this correctly, an order_start is
% inserted to make the delta conformant.
```

reorder-after <CIRCLECAP>
<MIN>
<WIDE>
<COMPAT>

<CIRCLE>

reorder_after <SFFF>
order_start forward;forward;forward;forward;forward;position
reorder-end

% End of the uppercase/lowercase tailoring

B.1 Example 1B.3. Example 3 – Canadian delta and benchmark

This annex describes benchmark 1, based on Canadian standard CAN/CSA Z243.4.1-1998 (and - 1992). The delta that precedes the benchmark *has been simplified* for illustration here; a larger delta is required, mainly for special characters, for full conformance to this Canadian standard, and is given here as an example only, limited to what is required for the benchmark. For complete information, the Canadian standard CAN/CSA Z243.4.1 should be consulted. The example's specifications are to be performed usingexample tailoring is to be applied to the Common Template Table of annex A, with the following delta:

```
1.Processing properties:
```

```
order_start <TABLE>;forward;backward;forward;forward,position
2.Number of levels unchanged to 4.
```

3.No symbol change.

4.No other insertion, deletion or redefinition than: 1. Level processing properties:

forward; backward; forward; forward, position

2. Number of levels: 4 (unchanged).

3. No symbol changes.

-4. The following ordering changes are done:

- æ sorted as if it were separate letters "ae" at level 1. The letters "ae" are distinguished at level 2 from the character "æ" and are sorted before it. Upper case is distinguished from lower case at level 3.is ordered before it.
- _____ð sorted as if it were the letter "d" at level 1. The letter "ð" is distinguished at level 2 from the letter "d" and is sorted after it. Upper case is distinguished from lower case at level 3.ordered after it.
- _____b sorted as if it were separate letters "th" at level 1. The letters "th" are is distinguished at level 2 from the letter "b" and are sorted before it. Upper case is distinguished from lower case at level 3 is ordered before it.

Alternate formal ISO/IEC DTR 14652 tailoring equivalent

% copy IS014651_2000_TABLE1

reorder_after <<u>SFFFF></u> <u>A</u> Canadian tailoring expressed in the tailoring syntax for this International Standard (normative only for Annex A) can be:

% copy ISO14651_2000_TABLE1

C --- <u>Annex C -</u> Preparation (informative)

C.1. General considerations

Preparation is necessary only for modification and/or duplication of original strings to render them context-independent prior to the comparison phase. Examples are:

<u>A non-duplicating preparation maps a given string to one string. A non-duplicating preparation</u> <u>can be composed with the key generation and comparison, as e.g. is needed for Lao</u> <u>and Thai (see Annex C.2), or</u> <u>- duplication of a string such as "41" for as it is spelled</u> <u>out in different languages (Irish Gaelic, German, English, and French):</u>

daichead a haon

einundvierzig

forty-one

quarante et un

removal or rotation of characters that are a nuisance for special requirements of ordering; for example, removing articles in sorting book names as in

Tale of two cities, A

- transformation of abbreviated data into a fuller form; for example, transformation of "McArthur" to give "MacArthur"proper ordering of numerals (see Annex C.3). A duplicating preparation can map a given string to several strings (to be sorted).

Examples of non-duplicating preparations are:

- <u>Vowel-consonant rearrangement, as is needed for Thai (see C.2) and Lao.</u>
- transformation<u>Transformation</u> of numbers so that the result will be ordered in numerical order, as opposed to positional order (see <u>below).C.3).</u> Numeric ordering is particularly delicate and requires special consideration in many cases.
- Removal or rotation of characters that are a nuisance for special requirements of ordering; for example, removing articles (language dependent) in sorting book names as in:

Tale of two cities, A

Transformation of abbreviated data into a fuller form. For example: transformation of
 "McArthur" to give "MacArthur".

Some examples of a duplicating preparation are:

 Duplicating a string into several 'rotations', like when producing a keyword-in-context index:

	Inter	mational	string	ordering
International s	string o rder	ring		
International	s trir	ng orderin	ıg	

Duplication of a string such as "41" for as it is spelled out in different languages (Irish Gaelic, German, English, and French):

daichead a haon einundvierzig forty-one quarante-et-un

<u>C.2. Thai string ordering – a case involving preparation required to get</u> <u>the proper ordering</u>

C.2.1. Thai Ordering Principle

The widely accepted standard for Thai lexicographical ordering is defined in the Royal Institute Dictionary 2525 B.E. Edition (1982 A.D.), the official standard Thai dictionary. The
ordering principles are:
Words are ordered alphabetically, not phonetically. Consonants order is:
<u>กขฃคฅฆงจฉชํฃํฌญฏฏฐฑฒณด</u>
ตถทธน
บ ป ผ ฝ พ ฟ ภ ม ย ร ฤ ฤ ๅ ล ฦ ฦ ๅ ว ศ ษ
<u>ส ห ฟ้ อ ฮ</u>
(ฤฤ၇၃) அதி வாச vowels and ligatures, but put in the order according
to the sounds they represent.)
 Vowels are also ordered by written forms, not by sounds. Vowels order is:
<u>ະ ຳ ຳ ີ </u>
(2 う む are always ordered as consonants, although they sometimes act as <u>vowels.)</u>
String comparison is performed from left to right, but considering initial consonants before vowels in the same syllable.
 Tones and diacritics are ignored at level 1, at level 2 the order is:
ເພັ ບ ຍາ +
Here is an ordering example:

Example for Thai (sorted order)

	1		
<u>ก ก</u>	<u>โกน</u>	<u>แข่งข</u> ั	<u>ผ ั ด</u>
<u>กรรม</u>	<u>โกร๋น</u>	<u>u</u>	<u>ฯ พณฯ</u>
<u>กรรม์</u>	<u>ใกล้</u>	<u>แขน</u>	<u>พณิชย์</u>
z	<u>ไก่</u>	<u>ครรภ-</u>	<u>ย่อง</u>
<u>กระแย่</u>	<u>ไกล</u>	ครรภ์	<u>รอง</u>
<u>v</u>	<u>ข้น</u>	<u>จุมพล</u>	ฤทธิ์
<u>กราบ</u>	<u>ขนาบ</u>	<u>จุํพล</u>	<u>ព្ឋ</u>
<u>กะเกณฑ</u>	<u>ข้าง</u>	<u>ข้าย</u>	<u>ฤๅษ</u> ี
<i>σ</i>	<u>ข้างๆ</u>	<u>เฒ่า</u>	<u>ลลิตา</u>
<u>ก ~ ก</u>	<u>ข้างกร</u>	<u>เณร</u>	<u>ฦๅขำ</u>
<u>ก้าว</u>	<u>ะดาน</u>	<u>ตลาด</u>	<u>ว ก</u>
<u>กำ</u>	<u>ข้างข</u> ึ	<u>ทูลเกล</u>	<u>ศาล</u>
<u>กิน</u>	<u>้ น</u>	<u></u>	<u>หริภุญ</u>
<u>ก</u> ึ่	<u>ข้างคว</u>	<u>ทูลเกล</u>	<u>ขั ย</u>
<u>ก ึ ำ น</u>	<u>าย</u>	<u>้าฯ</u>	<u>หฤท ัย</u>
<u>กุน</u>	<u>ข้างๆ</u>	<u>ทูลเกล</u>	<u>หลง</u>
<u>กูด</u>	<u>ค ู ๆ</u>	<u>้าทูลก</u>	<u>แหง่</u>
<u>เก้ง</u>	<u>ข้างเง</u>	<u>ระหม่อ</u>	<u>แห่ง</u>
<u>เกล้า</u>	<u>ิ น</u>	<u>ม</u>	<u>แหนม</u>
<u>เกลียว</u>	<u>ข้างออ</u>	<u>น้ำ</u>	<u>แหนหวง</u>

54 <mark>แกะ</mark>	<u>แข่ง</u>	<u>ป้า</u>	
	แ ดเ้ ง	้ ป ็ ก	

C.2.2 Algorithmic Aspect

These are the only two mandatory requirements for Thai string collation algorithms.

- Leading vowels (l- ll- l- l- l-, corresponding to characters U+0E40-U+0E44), which are written before consonants, must be considered after the initial consonant. Therefore, the rearrangement is needed before comparison.

No syllable structure or word boundary analysis is required, as Thai lexicons are ordered alphabetically, not phonetically.

C.2.2.1. Leading Vowel Rearrangement

To fullfill this requirement, either a collation preparation or collating-element grouping is required. The collation preparation scans the string once and swaps every leading vowel with its succeeding letter. The prepared string is then passed to the normal weight calculation process. Another way to manage this is by means of collating-element formation. Every possible pair of leading vowel and consonant is defined as a collating-element, whose weight equals to that of the rearranged substring.

Note that the rearrangement of each leading vowel is simply performed with its immediate succeeding consonant. No consonant cluster analysis is needed. Indeed, doing so would result in ambiguities or yield a different order than that specified in the Royal Institute Dictionary. For example:

- 1. Ambiguities: The problem with ambiguity is illustrated by the word "l N A ?". It has two potential pronunciations: either as a two-syllable word, "phe-la" (meaning "time"), or as a one-syllable word, "phlao" (meaning "axle" or "abate"). A rearrangement algorithm which follows the distinct pronunciation of the potential cluster 'W A ' in this string would result in distinct keys, "W L A ?" and "W A L ?", and therefore different weights, which are equally legal. Both words need to have the same weight to be sortable, however.
- 2. Non-conforming ordering: To illustrate the difference in ordering caused by the treatment of consonant clusters, consider these words, shown in conforming order: " **L N A** , **L N A V** , **L N A** ". The correct rearrangement ignores any clusters and results in the following: "**N L A** , **W L A V** , **W L A** ", which sorts in the order shown.

If, however, pairs of consonants that form legal clusters were grouped as singlecollation elements (regardless of actual pronunciation where the potential pronunciationis ambiguous), then the results of rearrangement would be "<\N a > l,<\N a > l v, M l r ", which would yield the (non-conforming) ordering"L W r , L W a , L W a v".

<u>Again, if a</u>	ctual clusters	were group	ed as single	e collation elei	ments (with some
disambiguation	effort), then	the results	of rearrang	gement would	be "ฟิเล
<พล>เง	์ , พิเศ	", which	would yield	the (non-con	forming) ordering
แพล,เ	พศ,เ	พลง '			

C.2.2.2. The Multiple Levels of Character Weights

The second requirement of the algorithm, relating to the treatment of diacritics and tone marks, implies multiple levels of weights. Tone marks and diacritics must be ignored in the first level, and weigh more than consonants and vowels in the second level.

There are ten Thai decimal digits (O (\circ) \Box (\circ) α (\circ) α) α (\circ), each semantically equivalent to Arabic digit 0-9, respectively. Their weights are then equal to their corresponding Arabic digits in the first level, and are different in the second level, to distinguish languages.

When punctuation marks ($\P \ \P \ B \ \odot \ \Pi \ Cw$) are concerned, another level of weights is required for them. This corresponds to the fourth level in the Common Template Table. In string ordering, punctuation marks are less significant than any tone marks and diacritics, and must be ignored in all the first three levels.

"For example, " ໃ ້	างๆ	, ข ้	างก	กบ,ข้า	งๆ คູๆ,
<u>ข างจะน</u>	" is a valid	order in t	the Royal	Institute Dictionary	 In the first level, the
considered weights	are 1	าง	, ๆ	างกบ,	ขางคู,
ี <mark>ขางจ</mark> ัน re	spectively.				

The third level is not needed for Thai string ordering, but is reserved for tailoring.

C.2C.3. Handling of numeral substrings in collation

A numeral is a string representing a number. The examples here deal with numerals which that represent values in *R*, the real numbers, or, really, subsets of *R*, as these have a predetermined order. Only decimal numerals are dealt with in the examples given here.

The presentation below will first give positional system decimal numerals for natural numbers using the digits 0-9. It will progress to numerals for whole numbers, numerals with a fraction part, a fraction part and an exponent. There is also a brief discussion on numerals with digits from other scripts, scripts whichthat sometimes uses another syntax with digits for numerals (such as Hàn numerals), and Roman numerals. There are circumstances where digits do not represent numerical values, such as in part numbers. These cases are not discussed below. Caution: preparatory stepsnumbers and telephone numbers. The preparations described below have undesirable consequences insome cases where apparent numerals do not represent numerical values, such as when the ordering telephone numbers in telephone books, or part 'numbers', and should be avoided in those cases.

C.2.1C.3.1. Handling of 'ordinary' numerals for natural numbers

The Common Template Table has no means of <u>sortingordering</u> strings with numbers in such a way that the resulting order reflects the number values represented by the numerals. For example, given the following randomly-arranged strings:

Release 1 Release 20 Release 12 Release 2 Release 9

<u>9</u>

the method described in the this International Standard yields the following list of <u>"sorted"order for these</u> strings:

> Release 1 Release 12 Release 2 Release 20 Release 9

<u>9</u>

(It is sufficient simply to look positionally at just the first digit in each numeral to see why this ordering results.) A more acceptable ordering is: is:

> Release 1 Release 2 Release 9 Release 12 Release 20

The Common Template Table defined in this International Standard cannot be tailored to give this result. However, preparation can be done prior to the basic collation step to achieve the desired results when numeric value order is desired. The prepared strings are normally not presented to the user; only the original strings are. The prepared strings are normally only used for the collation key construction. A simple, but not very general, way of preparing numerals for natural ordering is to pad them with zeroes to a given number of digits. If one pads the numerals in our original example strings up to three digits, the following will result:

Release 001 Release 020 Release 012 Release 002 Release 009

Using the Common Template Table defined in this International Standard one then obtains the strings in a better order (here showing the strings as they are after preparation, which are normally not shown in the result):

Release 001 Release 002 Release 009 Release 012 Release 020

However, there are two problems with this approach:

 One must determine beforehand a (usually small) number of digits to pad up to. If the number of digits to pad up to is too large, the strings after preparation can become rather long, especially if there are several numerals in each string. If the number of digits to pad up to is too small, however, the risk is greater that there are actually occurring numerals with more digits than one has padded up to, which results in partially getting back to the original situation, where the numerals' values are not taken entirely into account. Determinacy is lost, if some of the original numerals were already partially zeropadded. For example, if the original strings were:

Release 01 Release 1

the strings after preparation are identical, and the end result (as the user would normally see it) could be either

Release 01 Release 1

or

<u>or</u>

Release 1 Release 01

and the relative order may come out differently for different occurrences of numerals, or different runs of the collation process applying the same rules. Indeterminacy in collation is not desirable. This kind of indeterminacy is undesirable.

There are many ways to deal with these problems. The following is one such way.

To each maximal digit subsequence prepend a fixed-number-of-digits numeral which represents the original number of digits in the numeral. For most cases a two-digit count would suffice (allowing up to 99 digits in the original integer numerals). For example, given the original strings:

Release 1 Release 01 Release 20 Release 12 Release 2 Release 09 Release 9

Oneone obtains after this preparation the following strings:

Release 011 Release 0201 Release 0220 Release 0212 Release 012 Release 0209 Release 019

Which would be collated which would be ordered by the basic mechanism of this International Standard to:

Release 011 Release 012 Release 019 Release 0201 Release 0209 Release 0212 Release 0220

Asand are normally presented to the user as:

Release 1 Release 2 Release 9 Release 01 Release 09 Release 12 Release 20

This particular method puts numerals with a like original number of digits close to each other, even if the actual value represented is smaller due to the original zero-padding. If the represented *values* should be kept close together, one should instead duplicate the numeral: first a count of digits for the leading-zero-stripped numeral, the leading-zero-stripped numeral itself, followed by the original numeral. The duplication is needed to get determinacy relative to the original strings. For example, using the same original strings as above:

Which would be collated which would be ordered by the basic mechanism of this standard to:

Asand normally be presented to the user as:

Release 01 Release 1 Release 2 Release 09 Release 9 Release 12 Release 20

The originally zero-padded numerals consistently come before the numeral without (or with less) original zero-padding. The preparation processing could move the original numerals (in order of occurrence) to the very end of each string, if one wants to give the original zero-padding lesser significance than the text following the numerals.

The presence of several natural numerals in each string causes no additional problem.

Taking care of the natural number numerals is in most cases sufficient, and it is recommended that it be included as part of the usual preparation of strings to be collated. However, such preparation is not required by this International Standard.

C.2.2C.3.2. Handling of positional numerals in other scripts

ISO/IEC 10646 encodes decimal digits for a number of scripts. In most cases these are used in a positional system, just like 0-9 usually are. However, one should not regard a sequence of numerals mixed from different scripts as a single numeral; rather, one should consider each maximal substring of digits of the same script to be a numeral.

C.2.3C.3.3. Handling of other non-pure positional system numerals or non-positional system numerals (e.g. Roman numerals)

Chinese and some other languages can use decimal digits (in the Han script, for instance) interspersed with ideographs for "one thousand", "ten", etc. If such numerals are to be collated according to the value they represent, one can proceed as above, adding a step just after the initial duplication: convert the copy to the corresponding positional system numeral in the syntax used here for whole numerals.

Roman numerals, if handled, can be handled in a similar fashion to that described above. Duplicate, and replace the first copy with the same natural number expressed in the decimal positional system. E.g. "Louis V", where the V is determined to be a Roman numeral, can be modified to "Louis 5 V".

Caveat: In this case human interactive intervention or an expert system may be required, as in the following example involving the French language: CHAPITRE DIX might mean CHAPTER 10 or CHAPTER 509 ("dix" is the French word for 10, it is also the Roman numeral for 509).

C.2.4C.3.4. Handling of numerals for whole numbers

If <u>numerals for</u> negative whole numbers are also to be <u>sortedordered</u> according to their value, there are a number of issues to be considered. Most frequently, negative whole values are given numerals that begin with a negation sign. The negation sign may be HYPHEN-MINUS U+002D (<u>caveat:(but</u> this character may <u>often</u> represent a true hyphen, rather than a negation), or MINUS SIGN U+2212. <u>ButHowever</u>, there are other conventions also, like using a SOLIDUS U+002F or a PERCENT SIGN U+0025 to indicate negativeness; or the negation indicator can come *after* the digits rather than before; or negativeness can be indicated by putting the digits between parenthesis, and/or putting the digits in a contrasting colo<u>u</u>r (often red). In the examples here, only the case that negativeness is indicated by an immediately prepended MINUS SIGN is dealt with. Positiveness is indicated by either the absence of a MINUS SIGN, or the presence of a PLUS SIGN U+002B.

Example strings:

Temperature: -9 °C Temperature: 0 °C Temperature: -14 °C Temperature: 05 °C Temperature: +5 °C Temperature: -0 °C Temperature: -09 °C Temperature: 105 °C Temperature: +05 °C Temperature: 5 °C One preparation to get an acceptable and determinate order for numerals (in this syntax) for whole numbers is as follows (actual implementations should do something equivalent, but more efficient):

- <u>1</u>. Duplicate the numerals in the string (including sign indications), putting the 'original' ones (not to be touched by the following steps) in order of original occurrence at the end or the string, leaving the copies <u>to be modified</u> at the original positions. This step ensures determinacy.
- 2. Ensure that all of the copies have an explicit initial sign indicator.
- 3. Remove leading zeroes in the copies of the numerals (systematically either leaving one zero digit for zero or representing 0 by the empty string of digits); alternatively, let all numeral copies have exactly one leading zero.
- <u>4.</u> Between the sign indicator and the digits in the copies of the numerals, insert a (two-digit) count of how many digits there were (after removing the leading zeroes).
- 5. Do 9's complement on each digit in each copy of a negated numeral. 9's complement of a digit that individually represents the value x, is 9-x. That is, 9's complement of 0 is 9, of 9 is 0, of 5 is 4, etc.

8.Done with this (part of the) preparation.

For the basic collation step, use a tailoring of the template given in this standard, namely, a tailoring where the PLUS SIGN and the MINUS SIGN are significant at the same level as the digits, and where the MINUS SIGN has less weight than the PLUS SIGN. (In the example below, it is assumed that the weight of PLUS SIGN is less than the weight of 0, but this is not a prerequisite for getting an acceptable ordering.)

Our example strings after this prehanding:preparation:

Temperature: -980 °C -9Temperature: +00 °C 0Temperature: -9785 °C -14Temperature: +015 °C 05Temperature: +015 °C +5Temperature: -99 °C -0Temperature: -980 °C -09Temperature: +03105 °C 105Temperature: +015 °C +05Temperature: +015 °C 5

Sort The ordering for these, using the basic mechanism of this standard, is:

Temperature: -9785 °C - 14Temperature: -980 °C - 09Temperature: -980 °C - 9Temperature: -99 °C - 0Temperature: +00 °C 0Temperature: +015 °C + 05Temperature: +015 °C + 5Temperature: +015 °C 5Temperature: +015 °C 5

Asand normally presented to the user as:

Temperature: -14 °C Temperature: -09 °C Temperature: -9 °C Temperature: 0 °C Temperature: +05 °C Temperature: +5 °C Temperature: 5 °C Temperature: 5 °C Temperature: 105 °C

This preparation results in a determinate ordering of strings which may have that have zero or more numerals for whole numbers in them (also if there are several such numerals in some of the strings), such that the numerals are ordered according to the integer value they represent.

The process for other syntaxes for whole numbers can be similar. Just add a step to convert the copies to the syntax used here for whole numbers.

This technique for handling negative numerals can be used also for numerals with a fractional part, and so on (see below).

C.2.5C.3.5. Handling of positive positional numerals with fractional parts

The method presented above can easily be adapted to the case where fraction parts may occur and are to be taken into account. A problem is, however, that the characters often used to delimit the integer part from the fraction part are also used for other purposes. The separator character is generally either FULL STOP U+002E, or COMMA U+002C. These characters also have other uses, also in conjunction with digits.

For the examples here, assume that FULL STOP is used (only) as a fraction part delimiter.

Do as above, but count only the digits in the integer part of the numeral for the count of digits to be prepended. The fraction part delimiter character (here: FULL STOP) can be removed.

For example:

 $\begin{array}{r} -12.34 \\

C.2.6C.3.6. Handling of positive positional numerals with fraction parts and exponent parts

For very large, or very small, values, one often uses formats like $2.5*10^7$ (to illustrate just one possible way of writing these for the purposes of the examples here). Here there is already an exponent, which must be combined with the "number of integer part digits" (here: digits before the decimal point), by adding those two numbers to get a resulting fixed-number-of-digits exponent to prepend just before the first digit. For this example, with a three-digit exponent: we get +00825. One problem here is that the resulting exponent may be negative. To handle this, use an exponent bias. For a three-digit exponent a bias of 500 may be suitable, which gives us for this example numeral: +50825, and for the numeral $2.5*10^{-7}$ we get +49425. Negative values are handled as before, with 9's complement. $-2.5*10^7$ gives -49174, and $-2.5*10^{-7}$ gives -50574.

<u>-50574.</u> This method should be familiar to anyone with knowledge about (radix 10) floating point arithmetic.

Thus:

 $2.5*10^{-7}$ -2.5*10⁷ 2.5*10⁷ -2.5*10⁻⁷

After preparation (including a duplicate of the original, for determinacy):

 $\begin{array}{r} +49425\ 2.5^{*}10^{-7}\\ -49174\ ^{-}2.5^{*}10^{7}\\ +50825\ 2.5^{*}10^{7}\\ -50574\ ^{-}2.5^{*}10^{-7}\end{array}$

After sorting:Ordered:

-49174 ⁻2.5*10⁷ -50574 ⁻2.5*10⁻⁷ +49425 2.5*10⁻⁷ +50825 2.5*10⁷

As presented to the user:

```
\begin{array}{r} -2.5*10^{7} \\ -2.5*10^{-7} \\ 2.5*10^{-7} \\ 2.5*10^{7} \end{array}
```

C.2.8C.3.7. Handling of date and time of day indications

Going a bit beyond plain numerals, date and time-of-day indications often employ numerals (as well as names for months, weekdays, etc.) for the parts of the date and time-of-day indication. It is not uncommon to want to <u>sortorder</u> this kind of information also when it occurs within strings.

The preparation needed to obtain date and time-of-day indications, of some predetermined syntaxes, sortedordered according to point in time is similar to what has been described above.

- 1. Duplicate all date and time-of-day indications to maintain determinacy of collation when the original strings differ, but point in time identical. Leave the originals at the end of the strings, untouched by the following steps.
- 2. Convert the copies of the date and time indications to the same calendar system, if there are several calendar (sub)systems used and handled. The calendar (sub)system converted to, must be suitable for being able to get proper time order. We will here use the Gregorian calendar system and the subsystem of year, month, day-of-month.
- 3.3. Put the date and time-of-day elements in order of decreasing significance (to the resolution taken into <u>account)</u>.-<u>account)</u>. Full year, month, day-of-month, hour, minute, second, fraction of second.
- <u>4.</u> Use a 24-hour/day clock for the time-of-day indications. Remove A.M. or P.M. indications, if present and handled, in the date-time indication copies.
- 5. Use the UTC (Co-ordinated Universal Time) time zone for the date and time-ofday indications. Remove time zone indications, if present, in the date-time indication copies.
- 6. Use month numbers, rather than month names. Use two digits each for month, day-of-month, hour, minute, second.
- 7. Use full year number representation, as many digits as needed. Take abbreviations into account so that the full year number is used. E.g. '98' might denote year 98 or year 1998, or 1898, etc. No indeterminacy regarding year due to abbreviations like these may be present after the preparation step.
- 8. For years AD, use an initial PLUS SIGN. For years BC, use an initial MINUS SIGN. Remove the original AD or BC indication from the copies. (To nitpick, year n BC should be represented by year (1-n), which is less or equal to zero if n is positive.)
- 9. For the year indications, insert between the sign indication and the first digit for the year indication a digit telling how many digits there are in the full year indication. One digit for this should suffice.

- <u>10.</u> For negative years, replace the each digit in the year indication (including the digit telling the number of digits in the original full year indication) with its 9's complement digit.
- <u>11.</u> Make sure the textual format for all of the date indication copies is the same (paying attention to hyphens, spaces, etc.). (This is most easily accomplished by printing them in the same format from an internal, non-string, representation.)
- <u>12.</u> Alternatively, use a number indicating the point of time on a linear time scale (for example, hours, milliseconds, or days from a predetermined point in time), to the resolution desired, and handle this as an ordinary numeral (see above).

13.Done with this (part of the) preparation.

For the basic collation step, use a tailoring of the template given in this standard. Use a tailoring where the PLUS SIGN and the MINUS SIGN are significant at the same level as the digits, and where the MINUS SIGN has less weight than the PLUS SIGN.

For example:

Dated: July 19, 1955, at 1 p.m. GMT Dated: January, 20 BC Dated: Sept. 20, 1995, at 1 p.m. PST Dated: 11-june/345 AD

After preparation:

Dated: +41955-07-19T13:00Z July 19, 1955, at 1 p.m. GMT Dated: -780-01 January, 20 BC Dated: +1995-09-20T10:00Z Sept. 20, 1995, at 1 p.m. PST Dated: +3345-06-11 11-june/345 AD

After sorting:Ordered:

Dated: -780-01 January, 20 BC Dated: +3345-06-11 11-june/345 AD Dated: +41955-07-19T13:00Z July 19, 1955, at 1 p.m. GMT Dated: +41995-09-20T10:00Z Sept. 20, 1995, at 1 p.m. PST

As presented to the user:

Dated: January, 20 BC Dated: 11-june/345 AD Dated: July 19, 1955, at 1 p.m. GMT Dated: Sept. 20, 1995, at 1 p.m. PST

C.2.9C.3.8. Making numbers less significant than letters

In many cases, numerals preceding letters should be considered as less significant than the following alphabetic part. ButHowever, the Common Template Table specifies digits to be level 1 significant. To make numerals less significant than letters, either tailor the weight table so that numerals are ignored at level 1 (but significant at level 2 or 3), or alternatively leave them significant at level 1, but prepare the strings so that numerals are moved to the end of the string or moved to a less significant field. When doing such a move, one must pay attention not to map different strings to identical strings (or identical string fields), so that determinacy is maintained (see C.2.10).C.3.9).

Some examples where it is appropriate to consider numerals as less significant than letters: Street or block names with one or more numbers to indicate where in the street/block, if that/those number(s) precede the street or block name (common for example in the US and in Japan); chemical compound names which have prepended numerals, e.g., 1,2-diclorobenzol.

C.2.10C.3.9. Maintaining determinacy

As noted above in several cases, part of the string has been duplicated to maintain determinacy in collation, when the original strings are different, but when preparation may otherwise turn different strings into identical strings.

This method of <u>duplication forconcatenating a copy of a substring in order to maintain</u> determinacy can be used more generally, so if there are several preparations affecting different parts of the strings, one may simply duplicate the original strings to begin with, and only perform the preparation (without additional <u>duplication</u>) on the first half of the "doubled" string.

copying) on the given string, then concatenating on the initial copy.

One disadvantage with just concatenating the two copies is that the base letters of the second half of the "doubled" string count as more significant than the accents and case of the resulting first half of the "doubled" string. This International Standard has no mechanism for handling this in a better way, where the "original" (the second half of the "doubled" string) would count as less significant than the *entire* first half of the "doubled" string. This may be handled better by having the original and copy in different 'fields', and construct the collation key by combining the full keys for each 'field'. Such processing is beyond the scope of this International Standard, however.

Note that the string after preparation is used only for the collation key construction. The original string is not intended to be retrievable from the modified string, though this is possible with this way of attaining determinacy. The strings to be presented to the user are the original, by preparation untouched, strings.

Maintenance of determinacy when some of the original strings to be collated are identical, is out of the scope of this International Standard. A <u>collationsorting</u> processor should, <u>however</u>, document if it is 'stable' (maintaining initial relative order of identical strings) or not. This is useful to know when <u>collatingsorting</u> on one field of multi-field data.

C.3 Thai string ordering – a case involving special preparation

Thai Ordering Principle

The widely accepted standard for Thai lexicographical ordering is defined in the Royal Institute Dictionary 2525 B.E. Edition (1982 A.D.), the official standard Thai dictionary. The ordering principles are:

Words are ordered alphabetically, not phonetically. Consonants order is:

กขฃคฅฆงจฉข์ฃํฌญฏฏฐฑฒณด ตถทธน บปผฝพฟภมยรถถๅลฦฦๅวศษ สหพือฮ (ถิถุๅฦฦๅ-are vowels and ligatures, but put in the order according

(유 위 기 위 기 - are vowels and ligatures, but put in the order according to the sounds they represent.)

(a) are always ordered as consonants, although they sometimes act

as vowels.)

Consonants always precede vowels. String comparison is performed from left to right, considering initial consonants before vowels in the same syllable. Tones and diacritics are normally ignored, unless all other parts are equal, in which case the order is:

Here is an ordering example:

 กก
 กระแย่ง

 กรรม
 ก้าว

 กรรม
 กำาว

 กรรม
 กำาว

 กรรม
 กำาว

 กรรม
 กำาว

গু- ়ু- ১-	በ 5 5 ภ -	ปาน
ข้าง ๆ	ក 5 5 ភ ័	ผ ั ด
	จ ุมพล	ฯ พ ณ ฯ

พณิขัย ์ 8 ' 8 % 5 8 1 ត្ ឃ ី ถา ชี ลลิตา រា។ វា ว ก-ศ า ล ۳ ا ห ล ง แหง่ แห่ง แหนม แหนหวง แหบ แ หม อาน ฮ-า-

Algorithmic Aspect

The above principle, with appropriate character code assignment such as TIS-620 and ISO/IEC 10646, almost allows C standard library function **strcmp()** to collate Thai strings without much more complication, except:

Leading vowels (L - L - โ - ใ - L -, corresponding to characters

U0E40-U0E44), which are written before consonants, must be considered after the initial consonant. Therefore, the rearrangement is needed before comparison.

ignored in the first pass, and be considered at later pass if the first pass yields equality.

And these are the only two mandatory requirements for Thai string collation algorithms. No syllable structure nor word boundary analysis is required, as Thai lexicons are ordered alphabetically, not phonetically.

Leading Vowel Rearrangement

To fullfill this requirement, either a preprocessing or collating-element grouping is required. The preprocessor scans the string once and swaps every leading vowel with its succeeding letter. The preprocessed string is then passed to the normal weight calculation process. Another way to manage this is by means of collating-element formation. Every possible pair of leading vowel and consonant is defined as a collating element, whose weight equals to that of the rearranged substring. Note that the rearrangement of a leading vowel is simply performed with its immediate succeeding consonant. No consonant cluster analysis is needed. Indeed, doing so would result in ambiguities or yield a different order than that specified in the Royal Institute Dictionary. For example:

1. Ambiguities. The problem with ambiguity is illustrated by the word " ዛ ብ ገ ...

It has two potential pronunciations: either as a two syllable word, "phe-la" (meaning "time"), or as a one syllable word, "phlao" (meaning "axle" or "abate"). A rearrangement algorithm which follows the distinct pronunciation of the potential

cluster 'ฟ ล ' in this string would result in distinct keys, "ฟ เ ล า " and

"ዝ ର ዜ ጉ ", and therefore different weights, which are equally legal. Both words need to have the same weight to be sortable, however.

2. Non-conforming Ordering. To illustrate the difference in ordering caused by the treatment of consonant clusters, consider these words, shown in conforming order:

<u>"L พ ล , L พ ล ง , L พ ศ ". The correct rearrangement ignores any clusters</u>

and results in the following: "ฟ เ ล , ฟ เ ล ง , ฟ เ ค์ ", which sorts in the

order shown.

If, however, pairs of consonants that form legal clusters were grouped as single collation elements (regardless of actual pronunciation where the potential pronunciation is ambiguous), then the results of rearrangement would be

<u>"<₩ล>L, <₩ล>L, (non-conforming)</u>

ordering " 내 위 서 , 내 원 유 가 ".

Again, if actual clusters were grouped as single collation elements (with some disambiguation effort), then the results of rearrangement would be

<u>"พเล, <พล>เง, พเค which would yield the (non-conforming)</u>

ordering " <mark>W ล , W ศ , W ล ง</mark> ".

The Multiple Levels of Character Weights

The second requirement of the algorithm, relating to the treatment of diacritics and tone marks, implies multiple levels of weights. Tone marks and diacritics must be ignored in the first level, and weigh more than consonants and vowels in the second level.

There are ten Thai decimal digits (ு ை b ள ச ச ் ஸ க ஸ), each

semantically equivalent to Arabic digit 0-9, respectively. Their weights are then equal to their corresponding Arabic digits in the first level, and are different in the second level, to distinguish languages.

When punctuation marks (^{eff} ¶ B o eff Correct, another level of

weights is required for them. This corresponds to the fourth level in the Common Template Table. In string ordering, punctuation marks are less significant than any tone marks and diacritics, and must be ignored in all the first three levels.

<u>ข้างจะน</u>" is a valid order in the Royal Institute Dictionary. In the first

The third level is not defined for Thai string ordering, but is reserved for tailoring.

Why aren't existing standard codes, character by character comparisons, and commercial sort programs appropriate for sorting, and what must be done to solve the problem? For clarity, does not existing standard character codes, with character-by-character comparisons, give appropriate resulting ordering of strings? What must be done in order to get appropriate resulting orderings? In this discussion will start with illustrate this with examples the Latin script.

D.1. Problems

i.1. Sorting, in any language using the Latin script, including English, using standardusing, e.g., ISO/IEC 646 coding, does not follow traditional dictionary sequence, which is the minimum the average user needs.

Example: SortingFor example: Ordering the list "august", "August", "container", "coop", "co-op", "co-op", "co-op", "Vice-president", "Vice versa" gives the following order, if ISO/IEC 646 coding is used and a simple sort following binary order is performed:

August Vice versa Vice-president august co-op container coop

This ordering is obviously incorrect.

ii. <u>Transforming lower case to upper case2. Transforming uppercase to lowercase</u> and removing special characters yields a sorted list acceptable to users, but also yields unpredictable results.

Example: For example: Sorting the list "August", "august", "coop", "co-op" gives the following order:

August august coop co-op

------Sorting the same list with a different initial order, say, "august", "co-op", "August", "coop" may give a different order with this method:

- august August co-op coop
- iii.3. If accented characters are introduced using for example any ISO/IEC 8-bit character set, the same problems <u>as</u> encountered in examples i and ii above are amplified but they share the same causes.

ISO/IEC FCD 14651:2000 (E)

iv. If <u>4</u>. If character code point tables arewere reorganized to make all related characters contiguous, one might think that a simplified single-character sort would result, but this does not work either. Take upper and lower case upper- and lowercase unaccented letters as an example. If code position 01 is assigned to "a", code position 02 assigned to "A", code position 03 to "b", code position 04 to "B" and so on, a list sorted directly according to these rearranged values will yield the following:

 Sorted List
 Internal Values

 aaaa
 01010101

 abbb
 01030303

 Aaaa
 02010101

 Abbb
 02030303

This is also predictable, but remains obviously incorrect for any country with regard to cultural expectations.

D.2. Solution

v.—The only solution is to decompose to the above problems is to consider the initial data in a way which multiple levels in a way that will respect traditional lexical order, and at the same time ensure absolute predictability. For the Latin script, this necessitates at least four can be achieved by comparing in four (or more) levels:

1. The first decomposition renders information<u>1</u>. The first level renders the texts to be sorted case-insensitive and insensitive to diacritical marks, removingand to all special characters (which have no pre-established traditional order).

An example usingfor English:

"résumé" ('curriculum vitae') becomes "resume" ('begin again'), without any accent.

An example usingfor French:

"Vice-légation" becomes "vicelegation", with no accent, no upper-case and no hyphen.

An example <u>usingfor</u> German:

"groß" becomes "gross", with the sharp-s being converted to double-s to render it case insensitive.for the ordering.

In some languages, including Spanish or and the Nordic languages, some extra letters are added to the 26fixed letters of the English, French, and German alphabets, which alphabets. The additional letters are not ordered according to the expectations of those in other languages. This demonstrates the need for adaptability.

2. The second decomposition 2. The second level breaks ties on quasi-homographs, that is, strings that differ only because they have different diacritical marks.

marks. In In English, "resumé" and "résumé" are quasi-homographs. Traditional English lexical order requires that "resume" always comes before "résumé" (which sorting using only the first level would not guarantee). In this case, the tradition does not explicitly specify whether "resumé" should come before "résumé", though this would seem logical: most English and German dictionaries only state that unaccented words precede the accented words - However German dictionarywords. However, German dictionaries generally employ the German standard DIN 5007, which states more precise rules rules that are more precise.

Here another characteristic is introduced. In French, because of the large number of multiple quasi-homograph groups formed of more than 2 instances, the most important dictionaries follow the following rule: accentsAccents are generally not taken into account for sorting, but in case of homographic ties, the *last* difference in the word determines the correct order between two given words, awords. A priority order being then is assigned to each type of accent. According to this, "coté" should be sorted after "côte" but before "côté". This is easy to implement with "backwards" tailoring: aA number is assigned to each character of the data to be sorted, representing either a letter with an accent or a letter with no accent at all, but these numbers are stackedprepended instead of being added to a linear list: inappended to the result being constructed. In other words, the resulting string is made starting from the last character of the original data and processing in a backwards direction.

Example: to For example: To obtain an order respecting this rule: "cote, "côte", "coté", "côté", numbers could be assigned indicating respectively "****", "<u>**c*</u>", "<u>a***</u>", "<u>a*c*</u>", "<u>**C*</u>", "<u>a***</u>", "<u>a*c*</u>", "<u>**C*</u>", "<u>a***</u>", "<u>a*c*</u>", "<u>**C*</u>", "<u>a***</u>", "<u>a*c*</u>", "

3. The third decomposition3. The third level breaks ties for quasi-homographs whichthat differ only because upper-case and lower-case uppercase and lower-case characters are used.

used. This <u>time</u>, the tradition is well established in German dictionaries, where lower case always precedes upper-case in homographs, while the tradition is not well established in French dictionaries, which generally use only accented capital letters for common word entries. In known French dictionaries where <u>upper and lower</u> case<u>upper and lower</u> case <u>upper and lower</u> case<u>upper and lower</u> case <u>upper and lower</u> case<u>upper and lower</u> case<u>upper</u> case<u>upper and lower</u> case<u>upper</u> case<u>upper</u> case is specified to precede lower case<u>upper</u> and lower case<u>upper</u> caseupper case<u>upper</u> case<u>upper</u> case<u>upper</u> case<u>uppe</u> ca

Example: to have the following order: "august", "August", numbers could be assigned indicating respectively "IIIIII", "uIIIII", where "I" means lower case and "u" upper case.

4. The fourth decomposition breaks the final tie which, in general, does not correspond to any strong tradition, namely, the tie between quasi-homographs differing only because they contain special characters. Breaking this tie is essential to ensure the absolute predictability of ordering as well as enabling the ordering of strings composed only of special characters. Since the traces of special characters were removed from the original data to form the three first orders of decomposition, simply putting them sequentially in the fourth order of decomposition would mean that their position would be lost. These positions are quite important to solve remaining ties and in consequence the original positions of these special characters must be retained: two quasi homographs could each contain a common special character in different positions and thus be strictly different (example: "ab*cd" is different from "a*bcd" despite they share one and only one common special character).

Example: to obtain the following order: "coop", "coop", "coop ", numbers could be assigned respectively according to the following pattern: "d", "d3 " and "d5 ", where "d" is an ever-present delimiter separating this decomposition from the first three in case all four decompositions are to be concatenated to form a single sorting key based on numeric values (see discussion in the next paragraph). "3 " means a hyphen in position 3 of the original string. "5 " means a hyphen in position 5, and so on.

These four decompositions can be structured using a four-level key, concatenating the subkeys from the highest significance to the lowest. If the coded assignment of numbers is done properly, instead of necessitating a cumbersome exception process for dealing with homographs, all decompositions may be made at once and resulting strings concatenated and passed through a standard ordering program sorting in numeric order. To attain this result, it is sufficient that the numbers chosen for the first decomposition code set be greater than numbers chosen for the second one, the second one's greater than the third one's, and that the delimiter chosen for the fourth decomposition be less than the lowest possible number coded elsewhere for the sort (a delimiter called logical zero), in which case no restriction applies to the content of the fourth decomposition. An easier implementation might just choose to put the lowest value possible as a delimiter between each subkey, in which case no restriction ever applies.

 This method was fully described with tables in Règles du classement alphabétique en langue française et procédure informatisée pour le tri, Alain LaBonté, Ministère des Communications du Québec, 1988-08-19, ISBN 2-550-19046-7.

Reduction techniques have been designed to considerably shorten space requirements. As no implementation is required to use specific numbers for weights and neither reduction nor compression is required, this issue is outside the scope of this International Standard. Nevertheless, it is interesting to note that implementation can be optimized. This has been improved over time and is easy to accomplish, some methods being more efficient than others.

- A public domain reduction technique is described in details (with numerous examples) in *Technique de réduction Tris informatiques à quatre clés,* Alain LaBonté, Ministère des Communications du Québec, 1989-06 (ISBN 2-550-19965-0).
- vi. For a number of languages, the Common Template presented in this standard will need to be adapted, both in the table values for the four orders of keys (which can require redefining characters or introducing multicharacter collating elements into the table) and in the potential context analysis processing necessary to achieve culturally correct results for users of these languages. To illustrate this (without discussing context analysis which is not necessary in what follows), examples of dictionary sequences are given here for two languages which native order is not in the Common Template table:
- Traditional Spanish (where "ch" is greater than "cu" and "ña" is greater than "no"):

cuneo<cúneo<chapeo<nodo<ñaco

- (Comparative French/English/German sort: chapeo<cuneo<cúneo<ñaco<nodo)</p>
- Danish (where "a" is less than "c", "cz" is less than "cæ" and "cø", and "aa" is equivalent to "å", which is greater than "z", even in cases where it is pronounced differently):

Alzheimer<czar<cæsium<cølibat< Aachen<Aalborg<Århus

- (Comparative French/English/German sort:

— Aachen<Aalborg< Alzheimer<Århus<cæsium<cølibat<czar)</p>

Annex E – BIBLIOGRAPHY (informative)

- without affecting others. Note that in Denmark, uppercase is specified to precede lowercase, a different but well-established rule. This is a second fact that demonstrates the need for adaptability in the model used in this International Standard.
 - For example: to have the following order: "august", "August", numbers could be assigned indicating respectively "LLLLL", "ULLLL", where "L" means lowercase and "U" uppercase.
- 4. The fourth level breaks the final tie that, in general, does not correspond to any strong tradition, namely, the tie between quasi-homographs differing only because they contain special characters.
 - Breaking this tie is essential to ensure the predictability of ordering as well as enabling the ordering of strings composed only of special characters. Since the traces of special characters were removed from the original data to form the three first levels, simply putting them sequentially in the fourth order of decomposition would mean that their position would be lost. These positions are needed to resolve remaining ties, so the original positions of these special characters must be retained somehow. E.g., two quasi-homographs could each contain a common special character in different positions and thus be strictly different (example: "ab*cd" is different from "a*bcd" despite they share one and only one common special character).
 - For example: To obtain the following order: "coop", "coop", "coop-", numbers could be assigned respectively according to the following pattern: "", "3-", and "5-"; where "3-" means a hyphen in (relative) position 3 of the original string. "5-" means a hyphen in (relative) position 5, and so on. Note that "coop.", "coop..", "coop-." (adding a period at the end of each string) get the numbers assigned as "5.", "3-3.", and "5-1.", and are thus ordered: "co-op.", "coop.", "coop-.".

<u>These four levels can be composed to a four-level key, concatenating the subkeys from the most</u> significant to the least significant, putting the lowest value possible as a delimiter between each subkey. <u>The ordering result can then be obtained through the numeric order of the keys.</u>

If the assignment of weight numbers is done properly, one can eliminate some of the delimiter weights. To eliminate the level delimiter between the first and second level subkeys, choose the numbers for the second level weights be less than numbers for the first level weights. To eliminate the level delimiter between the second and third level subkeys, choose the numbers for the third level weights be less than numbers for the second level weights.

Subkey reduction techniques have been designed to considerably shorten space requirements. As no implementation is required to use specific numbers for weights and reduction is not required, this issue is outside the scope of this International Standard. Nevertheless, it is interesting to note that implementation can be optimised. This has been improved over time and is easy to accomplish, some methods being more efficient than others. Annex E below describes two example order-preserving subkey reduction techniques.

This method for string collation was described with tables in *Règles du classement alphabétique en langue française et procédure informatisée pour le tri*, Alain LaBonté, Ministère des Communications du Québec, 1988-08-19, ISBN 2-550-19046-7. A public-domain subkey reduction technique is described (with several examples) in *Technique de réduction - Tris informatiques à quatre clés*, Alain LaBonté, Ministère des Communications du Québec, 1989-06, ISBN 2-550-19965-0. See also the paper by Rolf Gavare, *Alphabetic ordering in a lexicological perspective*, Studies in Computer-Aided Lexicology, 1988, pp. 63–102, which also describes a multi-level string collation technique, with subkey compression.

D.3. Tailoring

For a number of languages, the Common Template Table presented in this standard will need to be adapted. Adaptation may be needed both in the table values for the four levels of subkeys, which can require redefining weightings for characters or introducing multi-character collating elements into the table; as well as changes in the potential context analysis processing necessary to achieve culturally correct results for users of these languages.

To illustrate this, without discussing context analysis which is not necessary in what follows, examples of dictionary sequences are given here for two languages whose expected ordering rules are not covered the Common Template Table:

For traditional Spanish, where "ch" is greater than "cu" and "ña" is greater than "no":

<u>cuneo < cúneo < chapeo < nodo < ñaco</u>

Comparative French/English/German sort of the same strings:

<u>chapeo < cuneo < cúneo < ñaco< nodo</u>

For Danish, where "a" is less than "c", "cz" is less than "cæ" and "cø", and "aa" is equivalent to "å", which is greater than "z", even in cases where it is pronounced differently:

Alzheimer < czar < cæsium < cølibat < Aachen < Aalborg < Århus

Comparative French/English/German sort of the same strings:

<u>Aachen < Aalborg < Alzheimer < Århus < cæsium < cølibat < czar</u>

Similarly, Japanese will need tailoring in order to handle the length mark properly; Thai and Lao will need preparation or tailoring to handle vowel-consonant rearrangement properly (see C.2). For may other orthographies, some degree of tailoring will be necessary.

Annex E – Order-preserving subkey reduction (informative)

The template table of collation weights has four levels. When applied to a string, each level nominally produces a subkey that is about as long, in number of weights, as the number of characters in the string itself. There are, however, a number of ways to reduce the size of the subkeys without changing the ordering as determined by the nominal key. This international standard neither specifies normatively, and even less requires the use of, any subkey reduction technique. However, for conformity, any key size reduction method must preserve the order between strings as determined by the nominal key produced by the given tailoring of the template table.

In order to illustrate what can be done in terms of subkey reduction, we here present two example reduction methods. Good implementations of these methods produce the reduced key directly, without producing the nominal key first.

Applied correctly to each nominal key, these reduction methods keep the order between the strings, since each is a strictly monotonically increasing mapping, i.e.,

<u>if nominal_key1 < nominal_key2, then</u> <u>reduce1(nominal_key1) < reduce1(nominal_key2), and</u> <u>reduce2(nominal_key1) < reduce2(nominal_key2).</u>

Each subkey reduction method that results in a strictly monotonically increasing mapping can be applied at any level. Moreover, different reduction methods can be applied at different levels, as long as it is done consistently for all keys. E.g., example method 1 below can be used for levels 2 and 4, while using example method 2 below for level 3, while no reduction method need be applied to level 1.

These example methods are not normative, and can probably be improved upon to reduce the subkey sizes further (e.g., one may first remove trailing weights that are minimal at levels 2 and 3).

E.1. Example subkey reduction method 1: interleaved counts and weights

This method can be applied for a single selected weight at each level this method is used, preferably a weight that is very commonly occurring at that level.

This method uses a count value, which may be stored in the subkey using different number of digits from what the weights uses at that level. The transformed value (see below) of the count need be not related to any of the weight values. In this illustration, we will use integer values between 00 and FF (in hexadecimal), the latter is the *maxcnt*_g. A practical implementation may of course use a wider range of values.

The reduction method works as follows, described in principle, not in implementation terms: Each maximal subrun of the for that level selected weight to be reduced, including subruns of length 0, is replaced by a transformed count value, as follows:

- Consider each subkey to be terminated by a less than minimal (at that level), or zero, weight.
- swaq is the selected reduction weight at level q.
- *wb* is the weight (including subkey terminator weight) that follows the (empty or not) maximal subrun, of the weight *swa*_g, currently processed.
- *cnt* is the length (\geq 0) of the subrun currently processed.
- maxcnt_g is the value (≥ 0) that is the largest value that can be stored as a count in the subkey, given the number of digits used for the storage of a (transformed) count in a subkey at that level.
- $guardcnt_q$ is a value ≥ 0 and $\leq maxcnt_q$ (e.g. $maxcnt_q$ div 2 can be used as $guardcnt_q$).
- *lowcntsize*_q = guardcnt_q + 1.

- $highcntsize_q = maxcnt_q guardcnt_q + 1.$
- If *swa_g* > *wb*: Replace the subrun with the count/weight-pair (*guardcnt_g*, *swa_g*) repeated (*cnt* **div** *lowcntsize_g*) times, followed by the count (*cnt* **mod** *lowcntsize_g*).
- If *swa_g* < *wb*: Replace the subrun with the count/weight-pair (*guardcnt_g*, *swa_g*) repeated (*cnt* **div** *highcntsize_g*) times, followed by the count (*maxcnt_g* (*cnt* **mod** *highcntsize_g*)).

Note that if the limits are set reasonably high, the count/weight-pairs will be repeated zero times in practical cases. In the other extreme, if $maxcnt_q$ is zero, the subkey is not changed.

The reason this method works only for one weight per level is that subruns otherwise would cause ambiguous key reductions.

This reduction method can be applied to level 2, where <BASE> can be expected to be a very common weight. It can also be used for level 3, where <MIN> (minuscule, i.e. lowercase, or caseless) can be expected to be very common. This reduction method can also be applied to level 4, if one uses a tailoring that gives one very common weight on level 4. Note that if the selected weight is not very common in a string, the resulting key by this method may be longer than the nominal key, since empty subruns of the selected weight must be replaced by another subrun that is non-empty.

Below is an example reduction using this method on level 2 (selecting the weight <BASE>), on level 3 (selecting the weight <MIN>), and on level 4 (selecting a maximal weight called <PLAIN>; for a tailoring of the template table). For readability, we will in this example write <a>, , etc. for the weights of the letters, <-> for <BLANK>, <1> for <MIN>, <u> for <CAP>, <*> for <PLAIN>, <A> for <ACUTE>, <H> for the level 4 weight of a hyphen, and <P> for the level 4 weight of an apostrophe. The example character string is "Vice-Président's". The nominal key, according to the template table, can be expressed as a number in *R*, expressed as a hexadecimal fractional number; <v> etc. really stands for digit sequences; spaces are used for alignment for clarity, they are in no way part the actual key; the 0000 at the end of the subkeys is the subkey termination weight):

0. <v><i><c><e></e></c></i></v>	<r><e></e></r>	<s><i><d><e><n><t></t></n></e></d></i></s>	<s></s>	0000
<-><-><->	<-><-><	<-><-><-><-><-><-><-><	<->	0000
<u><l><l><l>></l></l></l></u>	<u><l><l></l></l></u>	<l><l><l><l><l><l><l><l><l><l><l><l><l><</l></l></l></l></l></l></l></l></l></l></l></l></l>	<1>	0000
<*><*><*><*> <h< td=""><td>[><*><*></td><td><*><*><*><*><*><*><*><*><*><</td><td>°><*></td><td>0000</td></h<>	[><*><*>	<*><*><*><*><*><*><*><*><*><	°><*>	0000

Do the reduction as described above (note that here: <-> (and <1>) is smaller than any other level 2 (level 3) weight, but greater than 0 (the subkey termination weight), and <*> is greater than any other level 4 weight):

0. <v><i:< th=""><th>><c><e></e></c></th><th><</th><th><r><e></e></r></th><th><s><i><d><e><n><t></t></n></e></d></i></s></th><th><s></s></th><th>0000</th></i:<></v>	> <c><e></e></c>	<	<r><e></e></r>	<s><i><d><e><n><t></t></n></e></d></i></s>	<s></s>	0000
F8			<	A> 07		0000
FF <u:< td=""><td>> FC</td><td><u></u></td><td>0B</td><td></td><td></td><td>0000</td></u:<>	> FC	<u></u>	0B			0000
04	<h></h>	09			<p> 01</p>	0000

Note that "count" values are at the beginning and end of the reduced subkeys, as well as between each non-selected weight. This key is significantly shorter than the nominal key, in this example as well as for most (not all) other strings that one can expect to normally occur.

E.2. Example subkey reduction method 2: each count integrated in a weight

This method can be applied for a set of weights at each level, preferably the ones that are commonly used at that level.

This method also uses a count value, but the transformed weight value must have the same number of digits as all other weights at that level uses. The transformed values (see below) for the count must have values that are in the neighborhood of the weight in the subrun that is replaced. This neighborhood of a weight must not overlap with any other weights or neighborhoods of weights.

The reduction method works as follows, described in principle, not in implementation terms: Each non-empty maximal subrun of a weight selected for reduction is replaced as follows:

- Consider each subkey to be terminated by a less than minimal (at that level), or zero, weight.
- wa is the weight in the subrun.
- *wb* is the weight (including subkey terminator) that follows the non-empty maximal subrun of wa currently processed.
- cnt is the length (≥ 1) of the subrun currently processed.
- minnbhwa is the minimum value that constitutes the neighborhood of wa.
- maxnbhwa is the maximum value that constitutes the neighborhood of wa.
- lownbhsize_{wa} = wa minnbh_{wa} + 1.
- highnbhsize_{wa} = maxnbh_{wa} wa + 1.
- If wa > wb: Replace the subrun with the weight wa repeated (cnt div lownbhsize_{wa}) times, and, if (cnt mod lownbhsize_{wa}) is non-zero, followed by the weight (minnbh_{wa} + (cnt mod lownbhsize_{wa}) - 1).
- If wa < wb: Replace the subrun with the weight wa repeated (cnt div highnbhsize_{wa}) times, and, if (cnt mod highnbhsize_{wa}) is non-zero, followed by the weight (maxnbh_{wa} - (cnt mod highnbhsize_{wa}) + 1).

Note that if the neighborhood of wa consists of wa only, the subrun is not changed.

This reduction method can be applied to level 2, for <BASE>. It can also be used for level 3, e.g. for <MIN>, <CAP>, <HIRA>, and <KATA>. It can also be applied to level 4, for <PLAIN> (for a tailoring that uses <PLAIN> as a maximal weight at level 4). Note that even if the weight reduced is not common, the resulting subkey is never longer than the nominal subkey. A nontrivial neighborhood is needed around each of the selected weights for a shortening of the subkey to actually take place.

We do an example reduction using this method on level 2 (for <BASE>), on level 3 (for <MIN> and <CAP>), and on level 4 (for <PLAIN>). For this we make the following assumptions:

- <-> (level 2): weight: 0026; minimum maximum of neighborhood: 0022 002A.
- <1> (level 3): weight: 0005; minimum maximum of neighborhood: 0002 0007.
- <u> (level 3): weight: 0017; minimum maximum of neighborhood: 0015 001A.
- <*> (level 4): weight: 0F80; minimum maximum of neighborhood: 0F00 0FFE.

For the same example string as in the description of example reduction method 1, we still have the nominal key:

0. <v><i><c><e></e></c></i></v>	<r><e></e></r>	<s><i><d><e><n><t></t></n></e></d></i></s>	<s></s>	0000
<-><-><-><->	<-><-><->	A><-><-><-><-><-><	<->	0000
<u><1><1><1></u>	<u><l><l></l></l></u>	<l><l><l><l><l><l><l><l><l><l><l><l><l><</l></l></l></l></l></l></l></l></l></l></l></l></l>	<1>	0000
<*><*><*><	H><*><*>	<*><*><*><*><*><*><*><	P><*>	0000

Do the reduction as described above:

0. <v><i><c><e< th=""><th>> <r></r></th><th><e></e></th><th><s><</s></th><th><i><d><e></e></d></i></th><th><n><t></t></n></th><th><s></s></th><th>0000</th></e<></c></i></v>	> <r></r>	<e></e>	<s><</s>	<i><d><e></e></d></i>	<n><t></t></n>	<s></s>	0000
0024		<7	A>0028	3			0000
0015 0005	0015	0005	0005	0002			0000
0F03	<h>0F08</h>				<	P>0F00	0000

If the lower neighborhood of <1> had been a bit bigger, we could have used only one weight (or two), instead of three, for the sequence of nine <1> weights.

<u>This key is also significantly shorter than the nominal key, and this method never lengthens the key, since every subrun replaced is replaced by one that is shorter or at most as long as the original subrun.</u> <u>This method can also be applied to several weights at each level, which example method 1 cannot. On the other hand, example method 2 is a bit more complex than example method 1, since it needs to keep track of non-overlapping neighborhoods around some of the weights.</u>

E.3. Remapping of weights to a common weight for better subkey reduction

In many cases, at level 2 and up, differing weights don't convey a real difference for the ordering, since subkeys that are more significant may contain a necessary ordering difference already. This is especially common for the fourth level, where the Common Template Table has different weights for every collating element. Since there are usually other more significant differences, it is rarely this difference at the fourth level matters. Implementers are in such cases allowed to map several nominally different weights to the same actual weight, in such a way that the resulting ordering is unchanged, in order to enable better subkey reduction.
