New wording for C++0x Lambdas (rev. 2)

Introduction
During the meeting of March 2009 in Summit, a large number of issues relating to C++0x Lambdas were raised and reviewed by the core working group (CWG). After deciding on a clear direction for most of these issues, CWG concluded that it was preferable to rewrite the section on Lambdas to implement that direction. This paper presents this rewrite.

Open issue
There are known problems with move constructors that might have to deal with an exception after some subobjects have already been moved. When that general issue is addressed, the move constructor for closure types will likely require some treatment.

Resolved issues
The following CWG issues are addressed by this rewrite:

- 680: What is a move constructor?
- 720: Need examples of lambda-expressions
- 732: Late-specified return types in function definitions
- 750: Implementation constraints on reference-only closure objects
- 751: Deriving from closure classes
- 752: Name lookup in nested lambda-expressions
- 753: Array names in lambda capture sets
- 754: Lambda expressions in default arguments of block-scope function declarations
- 756: Dropping cv-qualification on members of closure objects
- 759: Destruction of closure objects
- 761: Inferred return type of closure object call operator
- 762: Name lookup in the compound-statement of a lambda-expression
- 763: Is a closure object's `operator()` inline?
- 764: Capturing unused variables in a lambda expression
- 766: Where may lambda expressions appear?
- 767: `void` parameter for lambdas
- 768: Ellipsis in a lambda parameter list
- 769: Initialization of closure objects
- 770: Ambiguity in late-specified return type
- 771: Move-construction of reference members of closure objects
- 772: `capture-default` in lambdas in local default arguments
- 774: Can a closure class be a POD?
- 775: Capturing references to functions
- 779: Rvalue reference members of closure objects?
In addition, this rewrite adds the restriction that lambda expressions cannot be used in the operand of a `sizeof` operator, `alignof` operator, or `decltype` specifier. That restriction—suggested by Doug Gregor and John Spicer—avoids severe implementation difficulties with template argument deduction (e.g., this avoids the need to encode arbitrary statement sequences in mangled names).

**Key concepts in the new wording**

The new wording no longer relies on lookup to remap uses of captured entities. It more clearly denies the interpretations that a lambda's `compound-statement` is processed in two passes or that any names in that `compound-statement` might resolve to a member of the closure type.

The new wording no longer specifies any rewrite or closure members for "by reference" capture. Uses of entities captured "by reference" affect the original entities, and the mechanism to achieve this is left entirely to the implementation.

The term "late-specified return type" has been dropped in favor of a nonterminal `trailing-return-type`.

**Wording changes**

The following changes are relative to N2798.

In 3.3.3 [basic.scope.local] paragraph 2 replace `lambda-parameter-declaration-clause` by `lambda-declarator` (one occurrence).

Replace subsection 5.1.1 [expr.prim.lambda] by the following:

5.1.1 Lambda expressions

Lambda expressions provide a concise way to create simple function objects. [Example:

```cpp
#include <algorithm>
#include <cmath>
void abssort(float *x, unsigned N) {
    std::sort(x, x+N,
        [](float a, float b) {
            return std::abs(a) < std::abs(b);
        });
}
```
—end example]

```
lambda-expression:
    lambda-introducer lambda-declarator_opt compound-statement

lambda-introducer:
    [ lambda-capture_opt ]
```
lambda-capture:
capture-default
capture-list
capture-default , capture-list
capture-default:
 & = capture-list:
capture
capture-list , capture
capture:
 identifier
 & identifier this

lambda-declarator,
( parameter-declaration-clause ) attribute-specifier_opt mutable_opt
exception-specification_opt trailing-return-type_opt

2 The evaluation of a lambda-expression results in an rvalue temporary (_class.temporary_ 12.2). This temporary is called the closure object. A lambda-expression shall not appear in an unevaluated operand (_expr_Clause 5). [Note: A closure object behaves like a function object (_function.objects_ 20.7). —end note]

3 The type of the lambda-expression (which is also the type of the closure object) is a unique, unnamed non-union class type—called the closure type—whose properties are described below. This class type is not an aggregate (_dcl.init.aggr_ 8.5.1). The closure type is declared in the smallest block scope, class scope, or namespace scope that contains the corresponding lambda-expression. [Note: This determines the set of namespaces and classes associated with the closure type (_basic.lookup.argdep_ 3.4.2). The parameter types of a lambda-declarator do not affect these associated namespaces and classes. —end note] An implementation may define the closure type differently from what is described below provided this does not alter the observable behavior of the program other than by changing:
— the size and/or alignment of the closure type
— whether the closure type is trivially copyable (_class_Clause 9)
— whether the closure type is a standard-layout class (_class_Clause 9)
— whether the closure type is a POD class (_class_Clause 9)
An implementation shall not add members of rvalue reference type to the closure type.

4 If a lambda-expression does not include a lambda-declarator, it is as if the lambda-declarator were (). If a lambda-expression does not include a trailing-return-type, it is as if the trailing-return-type denotes the following type:
— if the compound-statement is of the form
   
   { return attribute-specifier_opt expression ; }

   the type of the returned expression after lvalue-to-rvalue conversion (_conv.lval_ 4.1), array-to-pointer conversion (_conv.array_ 4.2), and function-to-pointer conversion (_conv.func_ 4.3);

— otherwise, **void**.

[ Example:

```cpp
auto x1 = [](int i) { return i; };
// OK: return type is int
auto x2 = []( ) { return { 1, 2 }; };
// error: the return type is void (a braced-init-list is not an expression)
```

—end example ]

5 The closure type for a lambda-expression has a public **inline** function call operator (_over.call_ 13.5.4) whose parameters and return type are described by the lambda-expression's parameter-declaration-clause and trailing-return-type respectively. This function call operator is declared **const** (_class.mfct.non-static_ 9.3.1) if and only if the lambda-expression's parameter-declaration-clause is not followed by **mutable**. It is not declared **volatile**. Default arguments (_decl.fct.default_ 8.3.6) shall not be specified in the parameter-declaration-clause of a lambda-declarator. Any exception-specification specified on a lambda-expression applies to the corresponding function call operator. [ Note: Names referenced in the lambda-declarator are looked up in the context in which the lambda-expression appears. —end note ]

6 The lambda-expression's compound-statement yields the function-body (_dcl.fct.def_ 8.4) of the function call operator, but for purposes of name lookup (_basic.lookup_ 3.4), determining the type and value of **this** (_class.this_ 9.3.2), and transforming id-expressions referring to non-static class members into class member access expressions using (*this) (_class.mfct.non-static_ 9.3.1), the compound-statement is considered in the context of the lambda-expression. [ Example:

```cpp
struct S1 {
  int x, y;
  int operator()(int);
  void f() {
    [=]()->int {
      return operator()(this->x+y);
      // equivalent to: S1::operator()(this->x+(*this).y)
      // and this has type S1*
    }
  }
};
```

—end example ]

7 For the purpose of describing the behavior of lambda-expressions below, **this** is considered to be "used" if replacing **this** by an invented variable **v** with automatic
storage duration and the same type as \texttt{this} would result in \texttt{v} being used (_basic.def.odr_ 3.2).

8 If a lambda-capture includes a capture-default that is \&, the identifiers in the lambda-capture shall not be preceded by \&. If a lambda-capture includes a capture-default that is =, the lambda-capture shall not contain \texttt{this} and each identifier it contains shall be preceded by \&. An identifier or \texttt{this} shall not appear more than once in a lambda-capture. [ Example:

```c
struct S2 { void f(int i); };  
void S2::f(int i) {
    [&, i]{};      // OK
    [&, &i]{};     // error: i preceded by & when & is the default
    [=, this]{};   // error: this when = is the default
    [i, i]{};      // error: i is repeated
}
```

—end example ]

9 A lambda-expression's compound-statement can use (see above) \texttt{this} from an immediately-enclosing member function definition, as well as variables and references with automatic storage duration from an immediately-enclosing function definition or lambda-expression, provided these entities are captured (as described below). Any other use (_basic.def.odr_ 3.2) of a variable or reference with automatic storage duration declared outside the lambda-expression is ill-formed. [ Example:

```c
void f1(int i) {
    int const N = 20;
    [=]{
        int const M = 30;
        [=]{
            int x[N][M]; // OK: N and M are not "used"
            x[0][0] = i; // error: i is not declared in the immediately enclosing lambda-expression
        };
    }
}
```

—end example ]

10 The identifiers in a capture-list are looked up using the usual rules for unqualified name lookup (_basic.lookup.unqual_ 3.4.1); each such lookup shall find a variable or reference with automatic storage duration. An entity (i.e., a variable, a reference, or \texttt{this}) is said to be explicitly captured if it appears in the lambda-expression's capture-list. An explicitly captured entity is used (_basic.def.odr_ 3.2).

11 If a lambda-expression has an associated capture-default and its compound-statement uses (_basic.def.odr_ 3.2) \texttt{this} or a variable or reference with automatic storage duration declared in an enclosing function or lambda-expression and the used entity is not explicitly captured, then the used entity is said to be implicitly captured. [ Note: Implicit uses of \texttt{this} can result in implicit capture. —end note ]
12 If \texttt{this} is captured, either explicitly or implicitly, the \textit{lambda-expression} shall appear directly in the definition of a non-static member function, i.e., not in another \textit{lambda-expression}. [Note: This rule prevents access from a nested \textit{lambda-expression} to the members of the enclosing \textit{lambda-expression}'s closure object. —end note]

13 A \textit{lambda-expression} appearing in a default argument shall not implicitly or explicitly capture any entity. [Example:

```cpp
void f2() {
    int i = 1;
    void g1(int = ([i]{ return i; }())()); // ill-formed
    void g2(int = ([i]{ return 0; }())()); // ill-formed
    void g3(int = ([=]{ return i; }())()); // ill-formed
    void g4(int = ([=]{ return 0; }())()); // OK
    void g5(int = ([]{ return sizeof i; }())()); // OK
}
—end example]

14 An entity is \textit{captured by copy} if it is implicitly captured and the \textit{capture-default} is \texttt{=}, or if it is explicitly captured with a \textit{capture} that does not include a \texttt{&}. For each entity captured by copy, an unnamed non-static data member is declared in the closure type. The declaration order of these members is unspecified. The type of such a data member is the type of the corresponding captured entity if the entity is not a reference to an object, or the referenced type otherwise. [Note: If the captured entity is a reference to a function, the corresponding data member is also a reference to a function. —end note]

15 An entity is \textit{captured by reference} if it is implicitly or explicitly captured, but not captured by copy. It is unspecified whether additional unnamed non-static data members are declared in the closure type for entities captured by reference.

16 Every \textit{id-expression} that is a use \cite{basic.def.odr_3.2} of an entity captured by copy is transformed into an access to the corresponding unnamed data member of the closure type. If \texttt{this} is captured, each use of \texttt{this} is transformed into an access to the corresponding unnamed data member of the closure type cast \cite{expr.cast_5.4} to the type of \texttt{this}. [Note: The cast ensures that the transformed expression is an rvalue. —end note]

17 Every occurrence of \texttt{decltype((x))} where \texttt{x} is a possibly parenthesized \textit{id-expression} that names an entity of automatic storage duration is treated as if \texttt{x} were transformed into an access to a corresponding data member of the closure type that would have been declared if \texttt{x} were a use of the denoted entity. [Example:
```cpp
void f3() {
    float x, &r = x;
    [=] // x and r are not captured (appearance in a
            // decltype operand is not a "use")
    decltype(x) y1;  // y1 has type float
    decltype((x)) y2 = y1; // y2 has type float const & because this
                            // lambda is not mutable and x is an lvalue
                            // even after the hypothetical transformation
    decltype(r) r1 = y1;  // r1 has type float & (transformation not
                             // considered)
    decltype((r)) r2 = y2; // r2 has type float const &
}
};
@end example

18 The closure type associated with a lambda-expression has a deleted default constructor
and a deleted copy assignment operator. It has an implicitly-declared copy constructor (_class.copy_ 12.8). [ Note: The copy constructor is implicitly defined in the same way as any other implicitly declared copy constructor would be implicitly defined. —end note ]

19 The closure type C associated with a lambda-expression has an additional public
inline constructor with a single parameter of type C&&. Given an argument object x,
this constructor initializes each non-static data member m of *this as follows:
— if m is an array, each element of this->m is direct-initialized with an
  expression equivalent to std::move(e) where e is the corresponding element of
  x.m. Otherwise,
— if m is an lvalue reference, this->m is initialized with x.m. [ Note: m cannot be
  an rvalue reference. —end note ] Otherwise,
— this->m is direct-initialized with an expression equivalent to
  std::move(x.m).
[ Note: The notations are for exposition only; the members of a closure type are
  unnamed and std::move need not be called. —end note ]

20 The closure type associated with a lambda-expression has an implicitly-declared
destructor (_class.dtor_ 12.4).

21 When the lambda-expression is evaluated, the entities that are captured by copy are
used to direct-initialize each corresponding non-static data member of the resulting
closure object. (For array members, the array elements are direct-initialized in
increasing subscript order.) These initializations are performed in the (unspecified)
order in which the non-static data members are declared. [ Note: This ensures that the
destructions will occur in the reverse order of the constructions. —end note ]

22 [ Note: If an entity is implicitly or explicitly captured by reference, invoking the function
call operator of the corresponding lambda-expression after the lifetime of the entity has
ended is likely to result in undefined behavior. —end note ]

In 7.1.6 [dcl.type] replace in paragraph 1
In 7.1.6 [decl.type] replace the first sentence of paragraph 2

2 As a general rule, at most one type-specifier is allowed in the complete decl-specifier-seq of a declaration or in a type-specifier-seq.

by

2 As a general rule, at most one type-specifier is allowed in the complete decl-specifier-seq of a declaration or in a type-specifier-seq or trailing-type-specifier-seq.

In 7.1.6.4 [dcl.spec.auto] replace the introductory paragraphs

The auto type-specifier signifies that the type of an object being declared shall be deduced from its initializer or specified explicitly at the end of a function declarator.

The auto type-specifier may appear with a function declarator with a late-specified return type (8.3.5) in any context where such a declarator is valid, and the use of auto is replaced by the type specified at the end of the declarator.
The **auto** type-specifier signifies that the type of a variable or reference being declared shall be deduced from its initializer or that a function declarator shall include a **trailing-return-type**.

The **auto** type-specifier may appear with a function declarator with a **trailing-return-type** (_dcl.fct_ 8.3.5) in any context where such a declarator is valid.

In 8 [dcl.decl] paragraph 4 replace the grammar line

\[\text{noptr-declarator parameters-and-qualifiers} \rightarrow \text{attribute-specifier}_{\text{opt}} \text{ type-id}\]

by

\[\text{noptr-declarator parameters-and-qualifiers trailing-return-type}\]

and add before the grammar rule for **ptr-operator**:

\[\text{trailing-return-type:}\]

\[\rightarrow \text{attribute-specifier}_{\text{opt}} \text{ trailing-type-specifier-seq}\]

\[\text{attribute-specifier}_{\text{opt}} \text{ abstract-declarator}_{\text{opt}}\]

In 8.1 [dcl.name] paragraph 1 replace the grammar line

\[\text{noptr-abstract-declarator}_{\text{opt}} \text{ parameters-and-qualifiers} \rightarrow \text{attribute-specifier}_{\text{opt}} \text{ type-id}\]

by

\[\text{noptr-abstract-declarator}_{\text{opt}} \text{ parameters-and-qualifiers trailing-return-type}\]

Add a new paragraph with the following content at the end of 8 [dcl.decl]:

5 The optional **attribute-specifier** in a **trailing-return-type** appertains to the indicated return type. The **type-id** in a **trailing-return-type** includes the longest possible sequence of **abstract-declarators**. [Note: This resolves the ambiguous binding of array and function declarators. [Example:

\[\text{auto f() \rightarrow int(*)[4]; // function returning a pointer to array[4] of int}\]

\[\text{not function returning array[4] of pointer to int}\]

—end example ] —end note ]

In 8.3.5 [dcl.fct] paragraph 2 replace the grammatical form

\[D1 \ (\text{parameter-declaration-clause}) \ \text{attribute-specifier}\_{\text{opt}} \text{ cv-qualifier-seq}_{\text{opt}}\]

\[\text{ref-qualifier}_{\text{opt}} \text{ exception-specification}_{\text{opt}} \rightarrow \text{attribute-specifier}_{\text{opt}} \text{ type-id}\]

by

\[D1 \ (\text{parameter-declaration-clause}) \ \text{attribute-specifier}_{\text{opt}} \text{ cv-qualifier-seq}_{\text{opt}}\]

\[\text{ref-qualifier}_{\text{opt}} \text{ exception-specification}_{\text{opt}} \text{ trailing-return-type}\]

and replace the sentences
Such a function type has a *late-specified return type*. The first optional *attribute-specifier* appertains to the function type. The second optional *attribute-specifier* appertains to the return type.

By

The optional *attribute-specifier* appertains to the function type.

In 8.3.5 [dcl.fct] delete paragraph 3. The first sentence of this paragraph currently reads

The *type-id* in this form includes the longest possible sequence of *abstract-declarators*.

In the last note of 8.3.5 [dcl.fct] paragraph 12 replace *late-specified return type* by *trailing-return-type* (two occurrences: one plural and one singular).

In 8.4 [dcl.fct.def] paragraph 2, replace

```
D1 ( parameter-declaration-clause ) cv-qualifier-seqopt ref-qualifieropt
    exception-specificationopt
```

by

```
D1 ( parameter-declaration-clause ) cv-qualifier-seqopt ref-qualifieropt
    exception-specificationopt trailing-return-typeopt
```
