Adopt source_location from Library Fundamentals V3 for C++20

Robert Douglas, Corentin Jabot

2019-06-17

1 Class `source_location` [reflection.src_loc]

1.1 Header <source_location> Synopsis [reflection.src_loc.intro]

```
namespace std {
  struct source_location {
    constexpr source_location() noexcept;

    constexpr uint_least32_t line() const noexcept;
    constexpr uint_least32_t column() const noexcept;
    constexpr const char* file_name() const noexcept;
    constexpr const char* function_name() const noexcept;

    static consteval source_location current() noexcept;
  };
}
```

[*Note:* The intent of `source_location` is to have a small size and efficient copying.– *end note*]

`constexpr source_location() noexcept;`

1   *Effects:* Constructs an object of class `source_location`.

2   *Remark:* The values are implementation-defined.

`constexpr uint_least32_t line() const noexcept;`

3   *Returns:* The presumed line number (16.8) represented by this object.

Remark: Line numbers are presumed to be 1-indexed however an implementation is encouraged to return 0 when the line number is unknown.

```
constexpr uint_least32_t column() const noexcept;
```

4   *Returns:* An implementation-defined value representing some offset from the start of the line represented by this object.

Remark: Column numbers are presumed to be 1-indexed however an implementation is encouraged to return 0 when the column number is unknown.

```
constexpr const char* file_name() const noexcept;
```

5   *Returns:* The presumed name of the current source file (14.2) represented by this object as an NTBS.

```
constexpr const char* function_name() const noexcept;
```

6   *Returns:* If this object represents a position in the body of a function, returns an implementation-defined NTBS that should correspond to the function name. Otherwise, returns an empty string.

```
static consteval source_location current() noexcept;
```

7   *Returns:* When invoked by a function call whose *postfix-expression* is a (possibly parenthesized) *id-expression* naming `current`, returns a `source_location` with an implementation-defined value. The value should be affected by `#line` (14.4) in the same manner as for `__LINE__` and `__FILE__`. If invoked in some other way, the value returned is unspecified.

8   *Remark:* When a *brace-or-equal-initializer* is used to initialize a non-static data member, any calls to `current` should correspond to the location of the constructor or aggregate initialization that initializes the member.

9   [*Note:* When used as a default argument (9.3.6), the value of the `source_location` will be the location of the call to `current` at the call site. – *end note*]

[*Example:*
```
struct s {
  source_location member = source_location::current();
  int other_member;
  s(source_location loc = source_location::current())
    : member(loc) // values of member will be from call-site
  {}
  s(int blather) : // values of member should be hereabouts
    other_member(blather)
  {}
  s(double) // values of member should be hereabouts
  {}
};
void f(source_location a = source_location::current()) {
  source_location b = source_location::current(); // values in b represent
this line
```

```
  }

  void g() {
    f(); // f's first argument corresponds to this line of code

    source_location c = source_location::current();
    f(c); // f's first argument gets the same values as c, above
  }
```
– end example]

2   Feature macro

We recommend the feature macro `__cpp_lib_source_location` for this feature.
