Working Draft, Standard for Programming Language C++

Note: this is an early draft. It’s known to be incomplet and incorrekt, and it has lots of bad formatting.

## CONTENTS

24.1 Iterator requirements .......................................................... 589
24.2 Header `<iterator>` synopsis ................................................. 594
24.3 Iterator primitives .............................................................. 597
24.4 Predefined iterators ............................................................ 600
24.5 Stream iterators .............................................................. 611

### 25 Algorithms library

25.1 Non-modifying sequence operations ........................................ 629
25.2 Mutating sequence operations ............................................... 632
25.3 Sorting and related operations ............................................. 640
25.4 C library algorithms .......................................................... 652

### 26 Numerics library

26.1 Numeric type requirements .................................................. 655
26.2 Complex numbers .............................................................. 656
26.3 Numeric arrays ............................................................... 664
26.4 Generalized numeric operations .......................................... 686
26.5 C Library ........................................................................... 689

### 27 Input/output library

27.1 Iostreams requirements ........................................................ 693
27.2 Forward declarations .......................................................... 693
27.3 Standard iostream objects .................................................... 696
27.4 Iostreams base classes ........................................................ 698
27.5 Stream buffers ................................................................. 716
27.6 Formatting and manipulators ............................................... 726
27.7 String-based streams ......................................................... 751
27.8 File-based streams ............................................................ 760

### A Grammar summary

A.1 Keywords ............................................................................. 773
A.2 Lexical conventions ............................................................ 773
A.3 Basic concepts ..................................................................... 777
A.4 Expressions ......................................................................... 777
A.5 Statements ........................................................................... 780
A.6 Declarations ......................................................................... 781
A.7 Declarators ........................................................................... 784
A.8 Classes ................................................................................ 785
A.9 Derived classes ..................................................................... 786
A.10 Special member functions ................................................... 786
A.11 Overloading ......................................................................... 787
A.12 Templates ............................................................................ 787
A.13 Exception handling ............................................................ 788
A.14 Preprocessing directives ..................................................... 788

Chapter 1   General

1.1 Scope

This International Standard specifies requirements for implementations of the C++ programming language. The first such requirement is that they implement the language, and so this International Standard also defines C++. Other requirements and relaxations of the first requirement appear at various places within this International Standard.

C++ is a general purpose programming language based on the C programming language as described in ISO/IEC 9899:1990 Programming languages - C (1.2). In addition to the facilities provided by C, C++ provides additional data types, classes, templates, exceptions, namespaces, inline functions, operator overloading, function name overloading, references, free store management operators, and additional library facilities.

1.2 Normative references

The following standards contain provisions which, through reference in this text, constitute provisions of this International Standard. At the time of publication, the editions indicated were valid. All standards are subject to revision, and parties to agreements based on this International Standard are encouraged to investigate the possibility of applying the most recent editions of the standards indicated below. Members of IEC and ISO maintain registers of currently valid International Standards.

— ISO/IEC 2382 (all parts), Information technology - Vocabulary
— ISO/IEC 9899:1990, Programming languages - C
— ISO/IEC 9899/Amd.1:1995, Programming languages - C, AMENDMENT 1: C Integrity
— ISO/IEC 10646-1:1993 Information technology - Universal Multiple-Octet Coded Character Set (UCS) - Part 1: Architecture and Basic Multilingual Plane

The library described in clause 7 of ISO/IEC 9899:1990 and clause 7 of ISO/IEC 9899/Amd.1:1995 is hereinafter called the Standard C Library. ¹)

1.3 Definitions

For the purposes of this International Standard, the definitions given in ISO/IEC 2382 and the following definitions apply. 17.1 defines additional terms that are used only in clauses 17 through 27 and Annex D.

¹) With the qualifications noted in clauses 17 through 27, and in C.2, the Standard C library is a subset of the Standard C++ library.
1.3 Definitions

Terms that are used only in a small portion of this International Standard are defined where they are used and italicized where they are defined.

1.3.1 argument

An expression in the comma-separated list bounded by the parentheses in a function call expression, a sequence of preprocessing tokens in the comma-separated list bounded by the parentheses in a function-like macro invocation, the operand of throw, or an expression, type-id or template-name in the comma-separated list bounded by the angle brackets in a template instantiation. Also known as an actual argument or actual parameter.

1.3.2 conditionally-supported

A program construct that an implementation is not required to support. [Note: Each implementation documents all conditionally-supported constructs that it does not support. — end note]

1.3.3 diagnostic message

A message belonging to an implementation-defined subset of the implementation’s output messages.

1.3.4 dynamic type

The type of the most derived object (1.8) to which the lvalue denoted by an lvalue expression refers. [Example: if a pointer (8.3.1) p whose static type is “pointer to class B” is pointing to an object of class D, derived from B (clause 10), the dynamic type of the expression *p is “D.” References (8.3.2) are treated similarly. — end example] The dynamic type of an rvalue expression is its static type.

1.3.5 ill-formed program

Input to a C++ implementation that is not a well-formed program (1.3.15).

1.3.6 implementation-defined behavior

Behavior, for a well-formed program construct and correct data, that depends on the implementation and that each implementation documents.

1.3.7 implementation limits

Restrictions imposed upon programs by the implementation.

1.3.8 locale-specific behavior

Behavior that depends on local conventions of nationality, culture, and language that each implementation documents.

1.3.9 multibyte character

A sequence of one or more bytes representing a member of the extended character set of either the source or the execution environment. The extended character set is a superset of the basic character set (2.2).

1.3.10 parameter

An object or reference declared as part of a function declaration or definition, or in the catch clause of an exception handler, that acquires a value on entry to the function or handler; an identifier from the comma-separated list bounded
by the parentheses immediately following the macro name in a function-like macro definition; or a template-parameter. Parameters are also known as formal arguments or formal parameters.

1.3.11 **signature**

The information about a function that participates in overload resolution (13.3): its parameter-type-list (8.3.5) and, if the function is a class member, the cv-qualifiers (if any) on the function itself and the class in which the member function is declared.\(^2\) The signature of a function template specialization includes the types of its template arguments (14.5.5.1).

1.3.12 **static type**

The type of an expression (3.9), which type results from analysis of the program without considering execution semantics. The static type of an expression depends only on the form of the program in which the expression appears, and does not change while the program is executing.

1.3.13 **undefined behavior**

Behavior, such as might arise upon use of an erroneous program construct or erroneous data, for which this International Standard imposes no requirements. Undefined behavior may also be expected when this International Standard omits the description of any explicit definition of behavior. [Note: permissible undefined behavior ranges from ignoring the situation completely with unpredictable results, to behaving during translation or program execution in a documented manner characteristic of the environment (with or without the issuance of a diagnostic message), to terminating a translation or execution (with the issuance of a diagnostic message). Many erroneous program constructs do not engender undefined behavior; they are required to be diagnosed. — end note ]

1.3.14 **unspecified behavior**

Behavior, for a well-formed program construct and correct data, that depends on the implementation. The implementation is not required to document which behavior occurs. [Note: usually, the range of possible behaviors is delineated by this International Standard. — end note ]

1.3.15 **well-formed program**

A C++ program constructed according to the syntax rules, diagnosable semantic rules, and the One Definition Rule (3.2).

1.4 **Implementation compliance**

The set of diagnosable rules consists of all syntactic and semantic rules in this International Standard except for those rules containing an explicit notation that “no diagnostic is required” or which are described as resulting in “undefined behavior.”

Although this International Standard states only requirements on C++ implementations, those requirements are often easier to understand if they are phrased as requirements on programs, parts of programs, or execution of programs. Such requirements have the following meaning:

— If a program contains no violations of the rules in this International Standard, a conforming implementation shall, within its resource limits, accept and correctly execute\(^3\) that program.

\(^2\) Function signatures do not include return type, because that does not participate in overload resolution.

\(^3\) “Correct execution” can include undefined behavior, depending on the data being processed; see 1.3 and 1.9.
If a program contains a violation of any diagnosable rule or an occurrence of a construct described in this Standard as “conditionally-supported” when the implementation does not support that construct, a conforming implementation shall issue at least one diagnostic message, except that

— If a program contains a violation of a rule for which no diagnostic is required, this International Standard places no requirement on implementations with respect to that program.

For classes and class templates, the library clauses specify partial definitions. Private members (clause 11) are not specified, but each implementation shall supply them to complete the definitions according to the description in the library clauses.

For functions, function templates, objects, and values, the library clauses specify declarations. Implementations shall supply definitions consistent with the descriptions in the library clauses.

The names defined in the library have namespace scope (7.3). A C++ translation unit (2.1) obtains access to these names by including the appropriate standard library header (16.2).

The templates, classes, functions, and objects in the library have external linkage (3.5). The implementation provides definitions for standard library entities, as necessary, while combining translation units to form a complete C++ program (2.1).

Two kinds of implementations are defined: hosted and freestanding. For a hosted implementation, this International Standard defines the set of available libraries. A freestanding implementation is one in which execution may take place without the benefit of an operating system, and has an implementation-defined set of libraries that includes certain language-support libraries (17.4.1.3).

A conforming implementation may have extensions (including additional library functions), provided they do not alter the behavior of any well-formed program. Implementations are required to diagnose programs that use such extensions that are ill-formed according to this International Standard. Having done so, however, they can compile and execute such programs.

Each implementation shall include documentation that identifies all conditionally-supported constructs that it does not support and defines all locale-specific characteristics.

1.5 Structure of this International Standard

Clauses 2 through 16 describe the C++ programming language. That description includes detailed syntactic specifications in a form described in 1.6. For convenience, Annex A repeats all such syntactic specifications.

Clauses 17 through 27 and Annex D (the library clauses) describe the Standard C++ library, which provides definitions for the following kinds of entities: macros (16.3), values (clause 3), types (8.1, 8.3), templates (clause 14), classes (clause 9), functions (8.3.5), and objects (clause 7).

Annex B recommends lower bounds on the capacity of conforming implementations.

Annex C summarizes the evolution of C++ since its first published description, and explains in detail the differences between C++ and C. Certain features of C++ exist solely for compatibility purposes; Annex D describes those features.

Finally, Annex E says what characters are valid in universal-character names in C++ identifiers (2.10).

4) This documentation also defines implementation-defined behavior; see 1.9.

Draft
Throughout this International Standard, each example is introduced by “[Example:” and terminated by “—end example]”. Each note is introduced by “[Note:” and terminated by “—end note]”. Examples and notes may be nested.

1.6 Syntax notation

In the syntax notation used in this International Standard, syntactic categories are indicated by italic type, and literal words and characters in constant width type. Alternatives are listed on separate lines except in a few cases where a long set of alternatives is presented on one line, marked by the phrase “one of.” An optional terminal or nonterminal symbol is indicated by the subscript “opt”, so

{ expression_{opt} }

indicates an optional expression enclosed in braces.

Names for syntactic categories have generally been chosen according to the following rules:

— X-name is a use of an identifier in a context that determines its meaning (e.g. class-name, typedef-name).
— X-id is an identifier with no context-dependent meaning (e.g. qualified-id).
— X-seq is one or more X’s without intervening delimiters (e.g. declaration-seq is a sequence of declarations).
— X-list is one or more X’s separated by intervening commas (e.g. expression-list is a sequence of expressions separated by commas).

1.7 The C++ memory model

The fundamental storage unit in the C++ memory model is the byte. A byte is at least large enough to contain any member of the basic execution character set and is composed of a contiguous sequence of bits, the number of which is implementation-defined. The least significant bit is called the low-order bit; the most significant bit is called the high-order bit. The memory available to a C++ program consists of one or more sequences of contiguous bytes. Every byte has a unique address.

[ Note: the representation of types is described in 3.9. —end note ]

1.8 The C++ object model

The constructs in a C++ program create, destroy, refer to, access, and manipulate objects. An object is a region of storage. [ Note: A function is not an object, regardless of whether or not it occupies storage in the way that objects do. —end note ] An object is created by a definition (3.1), by a new-expression (5.3.4) or by the implementation (12.2) when needed. The properties of an object are determined when the object is created. An object can have a name (clause 3). An object has a storage duration (3.7) which influences its lifetime (3.8). An object has a type (3.9). The term object type refers to the type with which the object is created. Some objects are polymorphic (10.3); the implementation generates information associated with each such object that makes it possible to determine that object’s type during program execution. For other objects, the interpretation of the values found therein is determined by the type of the expressions (clause 5) used to access them.

Objects can contain other objects, called subobjects. A subobject can be a member subobject (9.2), a base class subobject (clause 10), or an array element. An object that is not a subobject of any other object is called a complete object.

For every object x, there is some object called the complete object of x, determined as follows:

— If x is a complete object, then x is the complete object of x.
1.9 Program execution

The semantic descriptions in this International Standard define a parameterized nondeterministic abstract machine. This International Standard places no requirement on the structure of conforming implementations. In particular, they need not copy or emulate the structure of the abstract machine. Rather, conforming implementations are required to emulate (only) the observable behavior of the abstract machine as explained below.\(^5\)

Certain aspects and operations of the abstract machine are described in this International Standard as implementation-defined (for example, \texttt{sizeof(int)}). These constitute the parameters of the abstract machine. Each implementation shall include documentation describing its characteristics and behavior in these respects.\(^7\) Such documentation shall define the instance of the abstract machine that corresponds to that implementation (referred to as the “corresponding instance” below).

Certain other aspects and operations of the abstract machine are described in this International Standard as unspecified (for example, order of evaluation of arguments to a function). Where possible, this International Standard defines a set of allowable behaviors. These define the nondeterministic aspects of the abstract machine. An instance of the abstract machine can thus have more than one possible execution sequence for a given program and a given input.

Certain other operations are described in this International Standard as undefined (for example, the effect of dereferencing the null pointer). [Note: this International Standard imposes no requirements on the behavior of programs that contain undefined behavior. — end note]

A conforming implementation executing a well-formed program shall produce the same observable behavior as one of the possible execution sequences of the corresponding instance of the abstract machine with the same program and the same input. However, if any such execution sequence contains an undefined operation, this International Standard places no requirement on the implementation executing that program with that input (not even with regard to operations preceding the first undefined operation).

The observable behavior of the abstract machine is its sequence of reads and writes to \texttt{volatile} data and calls to library I/O functions.\(^8\)

\(^5\) The acronym POD stands for “plain old data.”

\(^6\) This provision is sometimes called the “as-if” rule, because an implementation is free to disregard any requirement of this International Standard as long as the result is as if the requirement had been obeyed, as far as can be determined from the observable behavior of the program. For instance, an actual implementation need not evaluate part of an expression if it can deduce that its value is not used and that no side effects affecting the observable behavior of the program are produced.

\(^7\) This documentation also includes conditionally-supported constructs and locale-specific behavior. See 1.4.

\(^8\) An implementation can offer additional library I/O functions as an extension. Implementations that do so should treat calls to those functions as
7 Accessing an object designated by a volatile lvalue (3.10), modifying an object, calling a library I/O function, or calling a function that does any of those operations are all side effects, which are changes in the state of the execution environment. Evaluation of an expression might produce side effects. At certain specified points in the execution sequence called sequence points, all side effects of previous evaluations shall be complete and no side effects of subsequent evaluations shall have taken place.\(^9\)

8 Once the execution of a function begins, no expressions from the calling function are evaluated until execution of the called function has completed.\(^{10}\)

9 When the processing of the abstract machine is interrupted by receipt of a signal, the values of objects with type other than volatile std::sig_atomic_t are unspecified, and the value of any object not of volatile std::sig_atomic_t that is modified by the handler becomes undefined.

10 An instance of each object with automatic storage duration (3.7.2) is associated with each entry into its block. Such an object exists and retains its last-stored value during the execution of the block and while the block is suspended (by a call of a function or receipt of a signal).

11 The least requirements on a conforming implementation are:

- At sequence points, volatile objects are stable in the sense that previous evaluations are complete and subsequent evaluations have not yet occurred.
- At program termination, all data written into files shall be identical to one of the possible results that execution of the program according to the abstract semantics would have produced.
- The input and output dynamics of interactive devices shall take place in such a fashion that prompting messages actually appear prior to a program waiting for input. What constitutes an interactive device is implementation-defined.

[Note: more stringent correspondences between abstract and actual semantics may be defined by each implementation. — end note]

12 A full-expression is an expression that is not a subexpression of another expression. If a language construct is defined to produce an implicit call of a function, a use of the language construct is considered to be an expression for the purposes of this definition. Conversions applied to the result of an expression in order to satisfy the requirements of the language construct in which the expression appears are also considered to be part of the full-expression. [Example:

```cpp
struct S {
    S(int i): I(i) { }
    int& v() { return I; }
private:
    int I;
};

S s1(1);  // full-expression is call of S::S(int)
S s2 = 2;  // full-expression is call of S::S(int)"
```

"observable behavior" as well.

\(^9\) Note that some aspects of sequencing in the abstract machine are unspecified; the preceding restriction upon side effects applies to that particular execution sequence in which the actual code is generated. Also note that when a call to a library I/O function returns, the side effect is considered complete, even though some external actions implied by the call (such as the I/O itself) may not have completed yet.

\(^{10}\) In other words, function executions do not "interleave" with each other.
1.9 Program execution

```c
void f() {
  if ( \( S(3).v() \)) { // full-expression includes lvalue-to-rvalue and
    // int to bool conversions, performed before
    // temporary is deleted at end of full-expression
  }
}
```
— end example ]

[ Note: the evaluation of a full-expression can include the evaluation of subexpressions that are not lexically part of the full-expression. For example, subexpressions involved in evaluating default argument expressions (8.3.6) are considered to be created in the expression that calls the function, not the expression that defines the default argument. —end note ]

[ Note: operators can be regrouped according to the usual mathematical rules only where the operators really are associative or commutative.11) For example, in the following fragment

```c
int a, b;
/* ... */
a = a + 32760 + b + 5;
```
the expression statement behaves exactly the same as

```cna
a = (((a + 32760) + b) + 5);
```
due to the associativity and precedence of these operators. Thus, the result of the sum \((a + 32760)\) is next added to \(b\), and that result is then added to \(5\) which results in the value assigned to \(a\). On a machine in which overflows produce an exception and in which the range of values representable by an \(\texttt{int}\) is \([-32768,+32767]\), the implementation cannot rewrite this expression as

```c
a = ((a + b) + 32765);
```
since if the values for \(a\) and \(b\) were, respectively, -32754 and -15, the sum \(a + b\) would produce an exception while the original expression would not; nor can the expression be rewritten either as

```c
a = ((a + 32765) + b);
```
or

```c
a = (a + (b + 32765));
```
since the values for \(a\) and \(b\) might have been, respectively, 4 and -8 or -17 and 12. However on a machine in which overflows do not produce an exception and in which the results of overflows are reversible, the above expression statement can be rewritten by the implementation in any of the above ways because the same result will occur. —end note ]

There is a sequence point at the completion of evaluation of each full-expression12).

When calling a function (whether or not the function is inline), there is a sequence point after the evaluation of all function arguments (if any) which takes place before execution of any expressions or statements in the function body.

---

11) Overloaded operators are never assumed to be associative or commutative.
12) As specified in 12.2, after the “end-of-full-expression” sequence point, a sequence of zero or more invocations of destructor functions for temporary objects takes place, usually in reverse order of the construction of each temporary object.
9 General

There is also a sequence point after the copying of a returned value and before the execution of any expressions outside the function\(^{13}\). Several contexts in C++ cause evaluation of a function call, even though no corresponding function call syntax appears in the translation unit. \([\text{Example: evaluation of a } \text{new} \text{ expression invokes one or more allocation and constructor functions; see 5.3.4. For another example, invocation of a conversion function (12.3.2) can arise in contexts in which no function call syntax appears. } \text{— end example}]\) The sequence points at function-entry and function-exit (as described above) are features of the function calls as evaluated, whatever the syntax of the expression that calls the function might be.

In the evaluation of each of the expressions

\[
\begin{align*}
& a \&\& b \\
& a \mid\mid b \\
& a \ ? \ b : c \\
& a , b
\end{align*}
\]

using the built-in meaning of the operators in these expressions (5.14, 5.15, 5.16, 5.18), there is a sequence point after the evaluation of the first expression\(^{14}\).

1.10 Acknowledgments

All rights in these originals are reserved.

---

\(^{13}\) The sequence point at the function return is not explicitly specified in ISO C, and can be considered redundant with sequence points at full-expressions, but the extra clarity is important in C++. In C++, there are more ways in which a called function can terminate its execution, such as the throw of an exception.

\(^{14}\) The operators indicated in this paragraph are the built-in operators, as described in clause 5. When one of these operators is overloaded (clause 13) in a valid context, thus designating a user-defined operator function, the expression designates a function invocation, and the operands form an argument list, without an implied sequence point between them.
Chapter 2  Lexical conventions

1 The text of the program is kept in units called source files in this International Standard. A source file together with all the headers (17.4.1.2) and source files included (16.2) via the preprocessing directive #include, less any source lines skipped by any of the conditional inclusion (16.1) preprocessing directives, is called a translation unit. [Note: a C++ program need not all be translated at the same time. — end note]

2 [Note: previously translated translation units and instantiation units can be preserved individually or in libraries. The separate translation units of a program communicate (3.5) by (for example) calls to functions whose identifiers have external linkage, manipulation of objects whose identifiers have external linkage, or manipulation of data files. Translation units can be separately translated and then later linked to produce an executable program (3.5). — end note]

2.1 Phases of translation

1 The precedence among the syntax rules of translation is specified by the following phases.

1. Physical source file characters are mapped, in an implementation-defined manner, to the basic source character set (introducing new-line characters for end-of-line indicators) if necessary. Trigraph sequences (2.3) are replaced by corresponding single-character internal representations. Any source file character not in the basic source character set (2.2) is replaced by the universal-character-name that designates that character. (An implementation may use any internal encoding, so long as an actual extended character encountered in the source file, and the same extended character expressed in the source file as a universal-character-name (i.e. using the \uXXXX notation), are handled equivalently.)

2. Each instance of a new-line character and an immediately preceding backslash character is deleted, splicing physical source lines to form logical source lines. If, as a result, a character sequence that matches the syntax of a universal-character-name is produced, the behavior is undefined. If a source file that is not empty does not end in a new-line character, or ends in a new-line character immediately preceded by a backslash character, the behavior is undefined.

3. The source file is decomposed into preprocessing tokens (2.4) and sequences of white-space characters (including comments). A source file shall not end in a partial preprocessing token or partial comment. Each comment is replaced by one space character. New-line characters are retained. Whether each nonempty sequence of white-space characters other than new-line is retained or replaced by one space character is implementation-defined. The process of dividing a source file's characters into preprocessing tokens is context-dependent. [Example: see the handling of < within a #include preprocessing directive. — end example]

---

15) Implementations must behave as if these separate phases occur, although in practice different phases might be folded together.

16) A partial preprocessing token would arise from a source file ending in the first portion of a multi-character token that requires a terminating sequence of characters, such as a header-name that is missing the closing * or >. A partial comment would arise from a source file ending with an unclosed /* comment.
4. Preprocessing directives are executed and macro invocations are expanded. If a character sequence that matches the syntax of a universal-character-name is produced by token concatenation (16.3.3), the behavior is undefined. A `#include` preprocessing directive causes the named header or source file to be processed from phase 1 through phase 4, recursively.

5. Each source character set member, escape sequence, or universal-character-name in character literals and string literals is converted to a member of the execution character set (2.13.2, 2.13.4).

6. Adjacent ordinary string literal tokens are concatenated. Adjacent wide string literal tokens are concatenated.

7. White-space characters separating tokens are no longer significant. Each preprocessing token is converted into a token. (2.6). The resulting tokens are syntactically and semantically analyzed and translated. [Note: Source files, translation units and translated translation units need not necessarily be stored as files, nor need there be any one-to-one correspondence between these entities and any external representation. The description is conceptual only, and does not specify any particular implementation. —end note]

8. Translated translation units and instantiation units are combined as follows: [Note: some or all of these may be supplied from a library. —end note] Each translated translation unit is examined to produce a list of required instantiations. [Note: this may include instantiations which have been explicitly requested (14.7.2). —end note] The definitions of the required templates are located. It is implementation-defined whether the source of the translation units containing these definitions is required to be available. [Note: an implementation could encode sufficient information into the translated translation unit so as to ensure the source is not required here. —end note] All the required instantiations are performed to produce instantiation units. [Note: these are similar to translated translation units, but contain no references to uninstantiated templates and no template definitions. —end note] The program is ill-formed if any instantiation fails.

9. All external object and function references are resolved. Library components are linked to satisfy external references to functions and objects not defined in the current translation. All such translator output is collected into a program image which contains information needed for execution in its execution environment.

2.2 Character sets

1 The basic source character set consists of 96 characters: the space character, the control characters representing horizontal tab, vertical tab, form feed, and new-line, plus the following 91 graphical characters:(\textsuperscript{17})

\begin{verbatim}
abcdefghijklmnopqrstuvwxyz
ABCDEFGHIJKLMNOPQRSTUVWXYZ
0123456789
_.{"[]#()<>%::.?*+-/^&!~=?","
\end{verbatim}

2 The universal-character-name construct provides a way to name other characters.

\texttt{hex-quad:}
\begin{verbatim}
hexadecimal-digit hexadecimal-digit hexadecimal-digit hexadecimal-digit
\end{verbatim}

\textsuperscript{17}) The glyphs for the members of the basic source character set are intended to identify characters from the subset of ISO/IEC 10646 which corresponds to the ASCII character set. However, because the mapping from source file characters to the source character set (described in translation phase 1) is specified as implementation-defined, an implementation is required to document how the basic source characters are represented in source files.

Draft
universal-character-name:
  \u hex-quad
  \U hex-quad hex-quad

The character designated by the universal-character-name \UNNNNNNNN is that character whose character short name in ISO/IEC 10646 is NNNNNNNN; the character designated by the universal-character-name \uNNNN is that character whose character short name in ISO/IEC 10646 is 0000NNNN. If the hexadecimal value for a universal character name is less than 0x20 or in the range 0x7F-0x9F (inclusive), or if the universal character name designates a character in the basic source character set, then the program is ill-formed.

The basic execution character set and the basic execution wide-character set shall each contain all the members of the basic source character set, plus control characters representing alert, backspace, and carriage return, plus a null character (respectively, null wide character), whose representation has all zero bits. For each basic execution character set, the values of the members shall be non-negative and distinct from one another. In both the source and execution basic character sets, the value of each character after 0 in the above list of decimal digits shall be one greater than the value of the previous. The execution character set and the execution wide-character set are supersets of the basic execution character set and the basic execution wide-character set, respectively. The values of the members of the execution character sets are implementation-defined, and any additional members are locale-specific.

2.3 Trigraph sequences

Before any other processing takes place, each occurrence of one of the following sequences of three characters (“trigraph sequences”) is replaced by the single character indicated in Table 1.

<table>
<thead>
<tr>
<th>trigraph replacement</th>
<th>trigraph replacement</th>
<th>trigraph replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td>??=</td>
<td>#</td>
<td>??&lt;</td>
</tr>
<tr>
<td>??/</td>
<td>\</td>
<td>??&gt;</td>
</tr>
<tr>
<td>??’</td>
<td>^</td>
<td>??-</td>
</tr>
</tbody>
</table>

Example:

```c
??= define arraycheck(a,b) a??(b??) ??!!! b??(a??)
```

becomes

```c
#define arraycheck(a,b) a[b] || b[a]
```

—end example

No other trigraph sequence exists. Each ? that does not begin one of the trigraphs listed above is not changed.
2.4 Preprocessing tokens

Each preprocessing token that is converted to a token (2.6) shall have the lexical form of a keyword, an identifier, a literal, an operator, or a punctuator.

A preprocessing token is the minimal lexical element of the language in translation phases 3 through 6. The categories of preprocessing token are: header names, identifiers, preprocessing numbers, character literals, string literals, preprocessing-op-or-punc, and single non-white-space characters that do not lexically match the other preprocessing token categories. If a ' or a " character matches the last category, the behavior is undefined. Preprocessing tokens can be separated by white space; this consists of comments (2.7), or white-space characters (space, horizontal tab, new-line, vertical tab, and form-feed), or both. As described in clause 16, in certain circumstances during translation phase 4, white space (or the absence thereof) serves as more than preprocessing token separation. White space can appear within a preprocessing token only as part of a header name or between the quotation characters in a character literal or string literal.

If the input stream has been parsed into preprocessing tokens up to a given character, the next preprocessing token is the longest sequence of characters that could constitute a preprocessing token, even if that would cause further lexical analysis to fail.

[Example: The program fragment 1Ex is parsed as a preprocessing number token (one that is not a valid floating or integer literal token), even though a parse as the pair of preprocessing tokens 1 and Ex might produce a valid expression (for example, if Ex were a macro defined as +1). Similarly, the program fragment 1E1 is parsed as a preprocessing number (one that is a valid floating literal token), whether or not E is a macro name. — end example ]

[Example: The program fragment x+++++y is parsed as x ++ ++ ++ y, which, if x and y are of built-in types, violates a constraint on increment operators, even though the parse x ++ ++ y might yield a correct expression. — end example ]

2.5 Alternative tokens

Alternative token representations are provided for some operators and punctuators. Alternative token representations are provided for some operators and punctuators. In all respects of the language, each alternative token behaves the same, respectively, as its primary token, except for its...
2.6 Tokens

<td>~</td>
<td>not_eq</td>
<td>!=</td>
</tr>
<tr>
<td>%:%;</td>
<td>##</td>
<td>bitand</td>
<td>&amp;</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

2.6 Tokens

The set of alternative tokens is defined in Table 2.

2.7 Comments

There are five kinds of tokens: identifiers, keywords, literals, operators, and other separators. Blanks, horizontal and vertical tabs, newlines, formfeeds, and comments (collectively, “white space”), as described below, are ignored except as they serve to separate tokens. [Note: Some white space is required to separate otherwise adjacent identifiers, keywords, numeric literals, and alternative tokens containing alphabetic characters. —end note]

2.8 Header names

These include “digraphs” and additional reserved words. The term “digraph” (token consisting of two characters) is not perfectly descriptive, since one of the alternative preprocessing-tokens is %:%; and of course several primary tokens contain two characters. Nonetheless, those alternative tokens that aren’t lexical keywords are colloquially known as “digraphs”.

Thus the “stringized” values (16.3.2) of [ and <: will be different, maintaining the source spelling, but the tokens can otherwise be freely interchanged.

Literals include strings and character and numeric literals.
**2.9 Preprocessing numbers**

- **h-char:** any member of the source character set except new-line and >

- **q-char-sequence:**
  - q-char
  - q-char-sequence q-char

- **q-char:** any member of the source character set except new-line and "

1. Header name preprocessing tokens shall only appear within a `#include` preprocessing directive (16.2). The sequences in both forms of header-names are mapped in an implementation-defined manner to headers or to external source file names as specified in 16.2.

2. If either of the characters ``, ` or `\`, or either of the character sequences `/*` or `//` appears in a q-char-sequence or a h-char-sequence, or the character " appears in a h-char-sequence, the behavior is undefined.\(^{21}\)

### 2.9 Preprocessing numbers

- **pp-number:**
  - digit
  - . digit
  - pp-number digit
  - pp-number nondigit
  - pp-number e sign
  - pp-number E sign
  - pp-number .

1. Preprocessing number tokens lexically include all integral literal tokens (2.13.1) and all floating literal tokens (2.13.3).

2. A preprocessing number does not have a type or a value; it acquires both after a successful conversion (as part of translation phase 7, 2.1) to an integral literal token or a floating literal token.

### 2.10 Identifiers

- **identifier:**
  - nondigit
  - identifier nondigit
  - identifier digit

1. An identifier is an arbitrarily long sequence of letters and digits. Each universal-character-name in an identifier shall designate a character whose encoding in ISO 10646 falls into one of the ranges specified in Annex E. Upper- and lower-case letters are different. All characters are significant.\(^{22}\)

---

\(^{21}\) Thus, sequences of characters that resemble escape sequences cause undefined behavior.

\(^{22}\) On systems in which linkers cannot accept extended characters, an encoding of the universal-character-name may be used in forming valid

---

Draft
2.11 Keywords

The identifiers shown in Table 3 are reserved for use as keywords (that is, they are unconditionally treated as keywords in phase 7):

<table>
<thead>
<tr>
<th>asm</th>
<th>do</th>
<th>if</th>
<th>return</th>
<th>try</th>
</tr>
</thead>
<tbody>
<tr>
<td>auto</td>
<td>double</td>
<td>inline</td>
<td>short</td>
<td>typedef</td>
</tr>
<tr>
<td>bool</td>
<td>dynamic_cast</td>
<td>int</td>
<td>signed</td>
<td>typeid</td>
</tr>
<tr>
<td>break</td>
<td>else</td>
<td>long</td>
<td>sizeof</td>
<td>typename</td>
</tr>
<tr>
<td>case</td>
<td>enum</td>
<td>mutable</td>
<td>static</td>
<td>union</td>
</tr>
<tr>
<td>catch</td>
<td>explicit</td>
<td>namespace</td>
<td>static_assert</td>
<td>unsigned</td>
</tr>
<tr>
<td>char</td>
<td>export</td>
<td>new</td>
<td>static_cast</td>
<td>using</td>
</tr>
<tr>
<td>class</td>
<td>extern</td>
<td>operator</td>
<td>struct</td>
<td>virtual</td>
</tr>
<tr>
<td>const</td>
<td>false</td>
<td>private</td>
<td>switch</td>
<td>void</td>
</tr>
<tr>
<td>const_cast</td>
<td>float</td>
<td>protected</td>
<td>template</td>
<td>volatile</td>
</tr>
<tr>
<td>continue</td>
<td>for</td>
<td>public</td>
<td>this</td>
<td>wchar_t</td>
</tr>
<tr>
<td>default</td>
<td>friend</td>
<td>register</td>
<td>throw</td>
<td>while</td>
</tr>
<tr>
<td>delete</td>
<td>goto</td>
<td>reinterpret_cast</td>
<td>true</td>
<td></td>
</tr>
</tbody>
</table>

Furthermore, the alternative representations shown in Table 4 for certain operators and punctuators (2.5) are reserved and shall not be used otherwise:

<table>
<thead>
<tr>
<th>and</th>
<th>and_eq</th>
<th>bitand</th>
<th>bitor</th>
<th>compl</th>
<th>not</th>
</tr>
</thead>
<tbody>
<tr>
<td>not_eq</td>
<td>or</td>
<td>or_eq</td>
<td>xor</td>
<td>xor_eq</td>
<td></td>
</tr>
</tbody>
</table>

2.12 Operators and punctuators

The lexical representation of C++ programs includes a number of preprocessing tokens which are used in the syntax of the preprocessor or are converted into tokens for operators and punctuators:

---

external identifiers. For example, some otherwise unused character or sequence of characters may be used to encode the \u in a universal-character-name. Extended characters may produce a long external identifier, but C++ does not place a translation limit on significant characters for external identifiers. In C++, upper- and lower-case letters are considered different for all identifiers, including external identifiers.

Draft
preprocessing-op-or-punc: one of

{ } [ ] # ## ( )
<: :> <% %> %: %:%: ; : ...
new delete ? :: . .*
+ - * / % ~ & | ~
!= &= |= << >> >>= <<= == !=
<= >= && || ++ -- , ->* ->
and and_eq bitand bitor compl not not_eq
or or_eq xor xor_eq

Each preprocessing-op-or-punc is converted to a single token in translation phase 7 (2.1).

2.13 Literals

There are several kinds of literals.\(^{23}\)

 literal:
 integer-literal
 character-literal
 floating-literal
 string-literal
 boolean-literal

2.13.1 Integer literals

 integer-literal:
 decimal-literal integer-suffix\(_{opt}\)
 octal-literal integer-suffix\(_{opt}\)
 hexadecimal-literal integer-suffix\(_{opt}\)

decimal-literal:
 nonzero-digit
decimal-literal digit

 octal-literal:
 0
 octal-literal octal-digit

 hexadecimal-literal:
 0x hexadecimal-digit
 0X hexadecimal-digit
 hexadecimal-literal hexadecimal-digit

 nonzero-digit: one of
 1 2 3 4 5 6 7 8 9

 octal-digit: one of
 0 1 2 3 4 5 6 7

 hexadecimal-digit: one of
 0 1 2 3 4 5 6 7 8 9
 a b c d e f
 A B C D E F

---

\(^{23}\) The term “literal” generally designates, in this International Standard, those tokens that are called “constants” in ISO C.
An integer literal is a sequence of digits that has no period or exponent part. An integer literal may have a prefix that specifies its base and a suffix that specifies its type. The lexically first digit of the sequence of digits is the most significant. A decimal integer literal (base ten) begins with a digit other than 0 and consists of a sequence of decimal digits. An octal integer literal (base eight) begins with the digit 0 and consists of a sequence of octal digits. A hexadecimal integer literal (base sixteen) begins with 0x or 0X and consists of a sequence of hexadecimal digits, which include the decimal digits and the letters a through f and A through F with decimal values ten through fifteen. [Example: the number twelve can be written 12, 014, or 0XC. — end example]

The type of an integer literal depends on its form, value, and suffix. If it is decimal and has no suffix, it has the first of these types in which its value can be represented: int, long int; if the value cannot be represented as a long int, the behavior is undefined. If it is octal or hexadecimal and has no suffix, it has the first of these types in which its value can be represented: int, unsigned int, long int, unsigned long int. If it is suffixed by u or U, its type is the first of these types in which its value can be represented: unsigned int, unsigned long int. If it is suffixed by l or L, its type is the first of these types in which its value can be represented: long int, unsigned long int. If it is suffixed by ul, lu, uL, Lu, Ul, lU, or LU, its type is unsigned long int.

A program is ill-formed if one of its translation units contains an integer literal that cannot be represented by any of the allowed types.

### 2.13.2 Character literals

A character literal is a sequence of characters enclosed in single or double quotes. The characters in a character literal are subject to escape sequences.

A program is ill-formed if one of its translation units contains a character literal that is not a valid character sequence.

24) The digits 8 and 9 are not octal digits.
2.13 Literals

Lexical conventions

1. A character literal is one or more characters enclosed in single quotes, as in ‘x’, optionally preceded by the letter L, as in L’x’. A character literal that does not begin with L is an ordinary character literal, also referred to as a narrow-character literal. An ordinary character literal that contains a single c-char has type char, with value equal to the numerical value of the encoding of the c-char in the execution character set. An ordinary character literal that contains more than one c-char is a multicharacter literal. A multicharacter literal has type int and implementation-defined value.

2. A character literal that begins with the letter L, such as L’x’, is a wide-character literal. A wide-character literal has type wchar_t. The value of a wide-character literal containing a single c-char has value equal to the numerical value of the encoding of the c-char in the execution wide-character set. The value of a wide-character literal containing multiple c-chars is implementation-defined.

3. Certain nongraphic characters, the single quote ’, the double quote ”, the question mark ?, and the backslash \, can be represented according to Table 5. The double quote ” and the question mark ?, can be represented as themselves or by the escape sequences \" and \? respectively, but the single quote ’ and the backslash \ shall be represented by the escape sequences \’ and \ respectively. If the character following a backslash is not one of those specified, the behavior is undefined. An escape sequence specifies a single character.

4. The escape \ooo consists of the backslash followed by one, two, or three octal digits that are taken to specify the value of the desired character. The escape \xhh consists of the backslash followed by x followed by one or more hexadecimal digits that are taken to specify the value of the desired character. There is no limit to the number of digits in a hexadecimal sequence. A sequence of octal or hexadecimal digits is terminated by the first character that is not an octal digit or a hexadecimal digit, respectively. The value of a character literal is implementation-defined if it falls outside of the implementation-defined range defined for char (for ordinary literals) or wchar_t (for wide literals).

---

Table 5: escape sequences

<table>
<thead>
<tr>
<th>Escape Sequence</th>

<td>hhh \xhh</td>
</tr>
</tbody>
</table>

---

25) They are intended for character sets where a character does not fit into a single byte.
A universal-character-name is translated to the encoding, in the execution character set, of the character named. If there is no such encoding, the universal-character-name is translated to an implementation-defined encoding. [Note: in translation phase 1, a universal-character-name is introduced whenever an actual extended character is encountered in the source text. Therefore, all extended characters are described in terms of universal-character-names. However, the actual compiler implementation may use its own native character set, so long as the same results are obtained. — end note]

### 2.13.3 Floating literals

```
floating-literal:
  fractional-constant exponent-part_opt floating-suffix_opt
  digit-sequence exponent-part floating-suffix_opt

fractional-constant:
  digit-sequence opt . digit-sequence
  digit-sequence

exponent-part:
  e sign_opt digit-sequence
  E sign_opt digit-sequence

sign: one of
  + -

digit-sequence:
  digit
  digit-sequence digit

floating-suffix: one of
  f F l L
```

A floating literal consists of an integer part, a decimal point, a fraction part, an \( \text{e} \) or \( \text{E} \), an optionally signed integer exponent, and an optional type suffix. The integer and fraction parts both consist of a sequence of decimal (base ten) digits. Either the integer part or the fraction part (not both) can be omitted; either the decimal point or the letter \( \text{e} \) (or \( \text{E} \)) and the exponent (not both) can be omitted. The integer part, the optional decimal point and the optional fraction part form the significant part of the floating literal. The exponent, if present, indicates the power of 10 by which the significant part is to be scaled. If the scaled value is in the range of representable values for its type, the result is the scaled value if representable, else the larger or smaller representable value nearest the scaled value, chosen in an implementation-defined manner. The type of a floating literal is `double` unless explicitly specified by a suffix. The suffixes \( f \) and \( F \) specify `float`, the suffixes \( l \) and \( L \) specify `long double`. If the scaled value is not in the range of representable values for its type, the program is ill-formed.

### 2.13.4 String literals

```
string-literal:
  "s-char-sequence_opt"
  L"s-char-sequence_opt"

s-char-sequence:
  s-char
  s-char-sequence s-char
```

Draft
2.13 Literals

Lexical conventions

$s$-char:
any member of the source character set except
the double-quote "," backslash \, or new-line character

escape-sequence
universal-character-name

1 A string literal is a sequence of characters (as defined in 2.13.2) surrounded by double quotes, optionally beginning with the letter L, as in "..." or L"...". A string literal that does not begin with L is an ordinary string literal, also referred to as a narrow string literal. An ordinary string literal has type “array of \( n \) \texttt{const char}” and \textit{static} storage duration (3.7), where \( n \) is the size of the string as defined below, and is initialized with the given characters. A string literal that begins with L, such as L"asdf", is a wide string literal. A wide string literal has type “array of \( n \) \texttt{const wchar_t}” and has static storage duration, where \( n \) is the size of the string as defined below, and is initialized with the given characters.

2 Whether all string literals are distinct (that is, are stored in nonoverlapping objects) is implementation-defined. The effect of attempting to modify a string literal is undefined.

3 In translation phase 6 (2.1), adjacent narrow string literals are concatenated and adjacent wide string literals are concatenated. If a narrow string literal token is adjacent to a wide string literal token, the behavior is undefined. Characters in concatenated strings are kept distinct. \([\textit{Example:}}"
\textbackslash xA" "B"
contains the two characters 'xA' and 'B' after concatenation (and not the single hexadecimal character 'xAB').

— end example]

4 After any necessary concatenation, in translation phase 7 (2.1), '0' is appended to every string literal so that programs that scan a string can find its end.

5 Escape sequences and universal-character-names in string literals have the same meaning as in character literals (2.13.2), except that the single quote ' is representable either by itself or by the escape sequence \', and the double quote " shall be preceded by a \,. In a narrow string literal, a universal-character-name may map to more than one char element due to \textit{multibyte encoding}. The size of a wide string literal is the total number of escape sequences, universal-character-names, and other characters, plus one for the terminating L' \textbackslash 0'. The size of a narrow string literal is the total number of escape sequences and other characters, plus at least one for the multibyte encoding of each universal-character-name, plus one for the terminating L' \textbackslash 0' .

2.13.5 Boolean literals

\begin{verbatim}
boolean-literal:
  false
  true
\end{verbatim}

1 The Boolean literals are the keywords \texttt{false} and \texttt{true}. Such literals have type \texttt{bool}. They are not lvalues.

Draft
Chapter 3  Basic concepts

[Note: this clause presents the basic concepts of the C++ language. It explains the difference between an object and a name and how they relate to the notion of an lvalue. It introduces the concepts of a declaration and a definition and presents C++’s notion of type, scope, linkage, and storage duration. The mechanisms for starting and terminating a program are discussed. Finally, this clause presents the fundamental types of the language and lists the ways of constructing compound types from these.]

This clause does not cover concepts that affect only a single part of the language. Such concepts are discussed in the relevant clauses. — end note]

3  An entity is a value, object, subobject, base class subobject, array element, variable, function, instance of a function, enumerator, type, class member, template, or namespace.

4  A name is a use of an identifier (2.10) that denotes an entity or label (6.6.4, 6.1). A variable is introduced by the declaration of an object. The variable’s name denotes the object.

5  Every name that denotes an entity is introduced by a declaration. Every name that denotes a label is introduced either by a goto statement (6.6.4) or a labeled-statement (6.1).

6  Some names denote types, classes, enumerations, or templates. In general, it is necessary to determine whether or not a name denotes one of these entities before parsing the program that contains it. The process that determines this is called name lookup (3.4).

7  Two names are the same if
    — they are identifiers composed of the same character sequence; or
    — they are the names of overloaded operator functions formed with the same operator; or
    — they are the names of user-defined conversion functions formed with the same type.

8  An identifier used in more than one translation unit can potentially refer to the same entity in these translation units depending on the linkage (3.5) of the identifier specified in each translation unit.

3.1  Declarations and definitions

[Note: this clause presents the basic concepts of the C++ language. It explains the difference between an object and a name and how they relate to the notion of an lvalue. It introduces the concepts of a declaration and a definition and presents C++’s notion of type, scope, linkage, and storage duration. The mechanisms for starting and terminating a program are discussed. Finally, this clause presents the fundamental types of the language and lists the ways of constructing compound types from these.]

This clause does not cover concepts that affect only a single part of the language. Such concepts are discussed in the relevant clauses. — end note]

3  An entity is a value, object, subobject, base class subobject, array element, variable, function, instance of a function, enumerator, type, class member, template, or namespace.

4  A name is a use of an identifier (2.10) that denotes an entity or label (6.6.4, 6.1). A variable is introduced by the declaration of an object. The variable’s name denotes the object.

5  Every name that denotes an entity is introduced by a declaration. Every name that denotes a label is introduced either by a goto statement (6.6.4) or a labeled-statement (6.1).

6  Some names denote types, classes, enumerations, or templates. In general, it is necessary to determine whether or not a name denotes one of these entities before parsing the program that contains it. The process that determines this is called name lookup (3.4).

7  Two names are the same if
    — they are identifiers composed of the same character sequence; or
    — they are the names of overloaded operator functions formed with the same operator; or
    — they are the names of user-defined conversion functions formed with the same type.

8  An identifier used in more than one translation unit can potentially refer to the same entity in these translation units depending on the linkage (3.5) of the identifier specified in each translation unit.

3.1  Declarations and definitions

A declaration (clause 7) introduces names into a translation unit or redeclares names introduced by previous declarations. A declaration specifies the interpretation and attributes of these names.

A declaration is a definition unless it declares a function without specifying the function’s body (8.4), it contains the
3.1 Declarations and definitions

extern specifier (7.1.1) or a linkage-specification \(^{26}\) (7.5) and neither an initializer nor a function-body, it declares a static data member in a class definition (9.4), it is a class name declaration (9.1), or it is a typedef declaration (7.1.3), a using-declaration (7.3.3), or a using-directive(7.3.4).

[Example: all but one of the following are definitions:

```c
int a;                      // defines a
extern const int c = 1;     // defines c
int f(int x) { return x+a; } // defines f and defines x
struct S { int a; int b; };  // defines S, S::a, and S::b
struct X {
    int x;                   // defines non-static data member x
    static int y;            // declares static data member y
    X(): x(0) {}             // defines a constructor of X
};
int X::y = 1;                // defines X::y
enum { up, down };           // defines up and down
namespace N { int d; }       // defines N and N::d
namespace N1 = N;            // defines N1
X anX;                       // defines anX
```

whereas these are just declarations:

```c
extern int a;                // declares a
extern const int c;          // declares c
int f(int);                  // declares f
struct S;                    // declares S
typedef int Int;             // declares Int
extern X anotherX;           // declares anotherX
using N::d;                   // declares N::d
```

—end example]

[Note: in some circumstances, C++ implementations implicitly define the default constructor (12.1), copy constructor (12.8), assignment operator (12.8), or destructor (12.4) member functions. [Example: given

```c
#include <string>

struct C {
    std::string s;                         // std::string is the standard library class (clause 21)
};

int main() {
    C a;
    C b = a;
    b = a;
}
```

the implementation will implicitly define functions to make the definition of C equivalent to

\(^{26}\) Appearing inside the braced-enclosed declaration-seq in a linkage-specification does not affect whether a declaration is a definition.
struct C {
    std::string s;
    C(): s() { }
    C(const C& x): s(x.s) { }
    C& operator=(const C& x) { s = x.s; return *this; }
    ~C() {} 
};

/* end example */ /* end note */

4 [ Note: a class name can also be implicitly declared by an elaborated-type-specifier (3.3.1). — end note ]

5 A program is ill-formed if the definition of any object gives the object an incomplete type (3.9).

3.2 One definition rule [basic.def.odr]

1 No translation unit shall contain more than one definition of any variable, function, class type, enumeration type or template.

2 An expression is potentially evaluated unless it appears where an integral constant expression is required (see 5.19), is the operand of the sizeof operator (5.3.3), or is the operand of the typeid operator and the expression does not designate an lvalue of polymorphic class type (5.2.8). An object or non-overloaded function is used if its name appears in a potentially-evaluated expression. A virtual member function is used if it is not pure. An overloaded function is used if it is selected by overload resolution when referred to from a potentially-evaluated expression. [ Note: this covers calls to named functions (5.2.2), operator overloading (clause 13), user-defined conversions (12.3.2), allocation function for placement new (5.3.4), as well as non-default initialization (8.5). A copy constructor is used even if the call is actually elided by the implementation. — end note ] An allocation or deallocation function for a class is used by a new expression appearing in a potentially-evaluated expression as specified in 5.3.4 and 12.5. A deallocation function for a class is used by a delete expression appearing in a potentially-evaluated expression as specified in 5.3.5 and 12.5. A non-placement allocation or deallocation function for a class is used by the definition of a constructor of that class. A non-placement deallocation function for a class is used by the definition of the destructor of that class, or by being selected by the lookup at the point of definition of a virtual destructor (12.4). A copy-assignment function for a class is used by an implicitly-defined copy-assignment function for another class as specified in 12.8. A default constructor for a class is used by default initialization or value initialization as specified in 8.5. A constructor for a class is used as specified in 8.5. A destructor for a class is used as specified in 12.4.

3 Every program shall contain exactly one definition of every non-inline function or object that is used in that program; no diagnostic required. The definition can appear explicitly in the program, it can be found in the standard or a user-defined library, or (when appropriate) it is implicitly defined (see 12.1, 12.4 and 12.8). An inline function shall be defined in every translation unit in which it is used.

4 Exactly one definition of a class is required in a translation unit if the class is used in a way that requires the class type to be complete. [ Example: the following complete translation unit is well-formed, even though it never defines X:

```cpp
struct X; // declare X as a struct type
struct X* x1; // use X in pointer formation
X* x2; // use X in pointer formation
```

27) An implementation is not required to call allocation and deallocation functions from constructors or destructors; however, this is a permissible implementation technique.
3.2 One definition rule

— end example ] [ Note: the rules for declarations and expressions describe in which contexts complete class types are required. A class type \( T \) must be complete if:

— an object of type \( T \) is defined (3.1), or

— a non-static class data member of type \( T \) is declared (9.2), or

— \( T \) is used as the object type or array element type in a new-expression (5.3.4), or

— an lvalue-to-rvalue conversion is applied to an lvalue referring to an object of type \( T \) (4.1), or

— an expression is converted (either implicitly or explicitly) to type \( T \) (clause 4, 5.2.3, 5.2.7, 5.2.9, 5.4), or

— an expression that is not a null pointer constant, and has type other than \( \text{void} \star \), is converted to the type pointer to \( T \) or reference to \( T \) using an implicit conversion (clause 4), a dynamic_cast (5.2.7) or a static_cast (5.2.9), or

— a class member access operator is applied to an expression of type \( T \) (5.2.5), or

— the typeid operator (5.2.8) or the sizeof operator (5.3.3) is applied to an operand of type \( T \), or

— a function with a return type or argument type of type \( T \) is defined (3.1) or called (5.2.2), or

— a class with a base class of type \( T \) is defined (10), or

— an lvalue of type \( T \) is assigned to (5.17). — end note ]

There can be more than one definition of a class type (clause 9), enumeration type (7.2), inline function with external linkage (7.1.2), class template (clause 14), non-static function template (14.5.5), static data member of a class template (14.5.1.3), member function of a class template (14.5.1.1), or template specialization for which some template parameters are not specified (14.7, 14.5.4) in a program provided that each definition appears in a different translation unit, and provided the definitions satisfy the following requirements. Given such an entity named \( D \) defined in more than one translation unit, then

— each definition of \( D \) shall consist of the same sequence of tokens; and

— in each definition of \( D \), corresponding names, looked up according to 3.4, shall refer to an entity defined within the definition of \( D \), or shall refer to the same entity, after overload resolution (13.3) and after matching of partial template specialization (14.8.3), except that a name can refer to a const object with internal or no linkage if the object has the same integral or enumeration type in all definitions of \( D \), and the object is initialized with a constant expression (5.19), and the value (but not the address) of the object is used, and the object has the same value in all definitions of \( D \); and

— in each definition of \( D \), the overloaded operators referred to, the implicit calls to conversion functions, constructors, operator new functions and operator delete functions, shall refer to the same function, or to a function defined within the definition of \( D \); and

— in each definition of \( D \), a default argument used by an (implicit or explicit) function call is treated as if its token sequence were present in the definition of \( D \); that is, the default argument is subject to the three requirements described above (and, if the default argument has sub-expressions with default arguments, this requirement applies recursively). 28)

28) 8.3.6 describes how default argument names are looked up.
— if D is a class with an implicitly-declared constructor (12.1), it is as if the constructor was implicitly defined in every translation unit where it is used, and the implicit definition in every translation unit shall call the same constructor for a base class or a class member of D. [Example:

//translation unit 1:
struct X {
    X(int);
    X(int, int);
};
X::X(int = 0) {} class D: public X { };
D d2; // X(int) called by D()

//translation unit 2:
struct X {
    X(int);
    X(int, int);
};
X::X(int = 0, int = 0) {} class D: public X { }; // X(int, int) called by D();
    // D()'s implicit definition
    // violates the ODR

— end example] If D is a template, and is defined in more than one translation unit, then the last four requirements from the list above shall apply to names from the template’s enclosing scope used in the template definition (14.6.3), and also to dependent names at the point of instantiation (14.6.2). If the definitions of D satisfy all these requirements, then the program shall behave as if there were a single definition of D. If the definitions of D do not satisfy these requirements, then the behavior is undefined.

3.3 Declarative regions and scopes

Every name is introduced in some portion of program text called a declarative region, which is the largest part of the program in which that name is valid, that is, in which that name may be used as an unqualified name to refer to the same entity. In general, each particular name is valid only within some possibly contiguous portion of program text called its scope. To determine the scope of a declaration, it is sometimes convenient to refer to the potential scope of a declaration. The scope of a declaration is the same as its potential scope unless the potential scope contains another declaration of the same name. In that case, the potential scope of the declaration in the inner (contained) declarative region is excluded from the scope of the declaration in the outer (containing) declarative region.

[Example: in

    int j = 24;
    int main()
    {
        int i = j, j;
        j = 42;
    }

the identifier j is declared twice as a name (and used twice). The declarative region of the first j includes the entire example. The potential scope of the first j begins immediately after that j and extends to the end of the program, but
3.3 Declarative regions and scopes

The names declared by a declaration are introduced into the scope in which the declaration occurs, except that the presence of a friend specifier (11.4), certain uses of the elaborated-type-specifier (3.3.1), and using-directives (7.3.4) alter this general behavior.

Given a set of declarations in a single declarative region, each of which specifies the same unqualified name,

— they shall all refer to the same entity, or all refer to functions and function templates; or

— exactly one declaration shall declare a class name or enumeration name that is not a typedef name and the other declarations shall all refer to the same object or enumerator, or all refer to functions and function templates; in this case the class name or enumeration name is hidden (3.3.7). [Note: a namespace name or a class template name must be unique in its declarative region (7.3.2, clause 14). — end note]

[Note: these restrictions apply to the declarative region into which a name is introduced, which is not necessarily the same as the region in which the declaration occurs. In particular, elaborated-type-specifiers (3.3.1) and friend declarations (11.4) may introduce a (possibly not visible) name into an enclosing namespace; these restrictions apply to that region. Local extern declarations (3.5) may introduce a name into the declarative region where the declaration appears and also introduce a (possibly not visible) name into an enclosing namespace; these restrictions apply to both regions. — end note]

3.3.1 Point of declaration

The point of declaration for a name is immediately after its complete declarator (clause 8) and before its initializer (if any), except as noted below. [Example:

```c
int x = 12;
{ int x = x; }
```

Here the second x is initialized with its own (indeterminate) value. — end example]

[Note: a nonlocal name remains visible up to the point of declaration of the local name that hides it. [Example:

```c
const int i = 2;
{ int i[i]; }
```

declares a local array of two integers. — end example ] — end note]

The point of declaration for a class first declared by a class-specifier is immediately after the identifier or template-id (if any) in its class-head (Clause 9). The point of declaration for an enumeration is immediately after the identifier (if any) in its enum-specifier (7.2).

The point of declaration for an enumerator is immediately after its enumerator-definition. [Example:

```c
const int x = 12;
{ enum { x = x }; }
```}

Draft
Here, the enumerator \( x \) is initialized with the value of the constant \( x \), namely 12. — end example

After the point of declaration of a class member, the member name can be looked up in the scope of its class. [Note: this is true even if the class is an incomplete class. For example,

```cpp
struct X {
    enum E { z = 16 };
    int b[X::z];  // OK
};
— end note]

The point of declaration of a class first declared in an `elaborated-type-specifier` is as follows:

— for a declaration of the form `class-key identifier` ; the `identifier` is declared to be a `class-name` in the scope that contains the declaration, otherwise

— for an `elaborated-type-specifier` of the form `class-key identifier` if the `elaborated-type-specifier` is used in the `decl-specifier-seq` or `parameter-declaration-clause` of a function defined in namespace scope, the `identifier` is declared as a `class-name` in the namespace that contains the declaration; otherwise, except as a friend declaration, the `identifier` is declared in the smallest non-class, non-function-prototype scope that contains the declaration. [Note: These rules also apply within templates. — end note]

[Note: Other forms of `elaborated-type-specifier` do not declare a new name, and therefore must refer to an existing `type-name`. See 3.4.4 and 7.1.5.3. — end note]

The point of declaration for an `injected-class-name` (9) is immediately following the opening brace of the class definition.

[Note: friend declarations refer to functions or classes that are members of the nearest enclosing namespace, but they do not introduce new names into that namespace (7.3.1.2). Function declarations at block scope and object declarations with the `extern` specifier at block scope refer to declarations that are members of an enclosing namespace, but they do not introduce new names into that scope. — end note]

[Note: For point of instantiation of a template, see 14.6.4.1. — end note]

3.3.2 Local scope

A name declared in a block (6.3) is local to that block. Its potential scope begins at its point of declaration (3.3.1) and ends at the end of its declarative region.

The potential scope of a function parameter name in a function definition (8.4) begins at its point of declaration. If the function has a `function-try-block` the potential scope of a parameter ends at the end of the last associated handler, else it ends at the end of the outermost block of the function definition. A parameter name shall not be redeclared in the outermost block of the function definition nor in the outermost block of any handler associated with a `function-try-block`.

The name in a `catch` exception-declaration is local to the handler and shall not be redeclared in the outermost block of the handler.

Names declared in the `for-init-statement`, and in the `condition` of `if`, `while`, `for`, and `switch` statements are local to the `if`, `while`, `for`, or `switch` statement (including the controlled statement), and shall not be redeclared in a subsequent...
condition of that statement nor in the outermost block (or, for the `if` statement, any of the outermost blocks) of the controlled statement; see 6.4.

### 3.3.3 Function prototype scope

In a function declaration, or in any function declarator except the declarator of a function definition (8.4), names of parameters (if supplied) have function prototype scope, which terminates at the end of the nearest enclosing function declarator.

### 3.3.4 Function scope

Labels (6.1) have function scope and may be used anywhere in the function in which they are declared. Only labels have function scope.

### 3.3.5 Namespace scope

The declarative region of a namespace-definition is its namespace-body. The potential scope denoted by an original-name is the concatenation of the declarative regions established by each of the namespace-declarations in the same declarative region with that original-name. Entities declared in a namespace-body are said to be members of the namespace, and names introduced by these declarations into the declarative region of the namespace are said to be member names of the namespace. A namespace member name has namespace scope. Its potential scope includes its namespace from the name’s point of declaration (3.3.1) onwards; and for each using-directive (7.3.4) that nominates the member’s namespace, the member’s potential scope includes that portion of the potential scope of the using-directive that follows the member’s point of declaration. [Example:

```c
namespace N {
    int i;
    int g(int a) { return a; }  
    int j();
    void q();
}

namespace {} int l=1;  
// the potential scope of l is from its point of declaration
// to the end of the translation unit

namespace N {
    int g(char a)  // overloads N::g(int)  
    {          
        return l+a;  // l is from unnamed namespace
    }

    int i;   // error: duplicate definition
    int j();  // OK: duplicate function declaration

    int j()   // OK: definition of N::j()
    {   
        return g(i);  // calls N::g(int)
    }

    int q();   // error: different return type
}
```

Draft
A namespace member can also be referred to after the :: scope resolution operator (5.1) applied to the name of its namespace or the name of a namespace which nominates the member’s namespace in a using-directive; see 3.4.3.2.

The outermost declarative region of a translation unit is also a namespace, called the global namespace. A name declared in the global namespace has global namespace scope (also called global scope). The potential scope of such a name begins at its point of declaration (3.3.1) and ends at the end of the translation unit that is its declarative region. Names with global namespace scope are said to be global.

3.3.6 Class scope

1) The potential scope of a name declared in a class consists not only of the declarative region following the name’s point of declaration, but also of all function bodies, default arguments, and constructor ctor-initializers in that class (including such things in nested classes).

2) A name \( N \) used in a class \( S \) shall refer to the same declaration in its context and when re-evaluated in the completed scope of \( S \). No diagnostic is required for a violation of this rule.

3) If reordering member declarations in a class yields an alternate valid program under (1) and (2), the program is ill-formed, no diagnostic is required.

4) A name declared within a member function hides a declaration of the same name whose scope extends to or past the end of the member function’s class.

5) The potential scope of a declaration that extends to or past the end of a class definition also extends to the regions defined by its member definitions, even if the members are defined lexically outside the class (this includes static data member definitions, nested class definitions, member function definitions (including the member function body and, for constructor functions (12.1), the ctor-initializer (12.6.2)) and any portion of the declarator part of such definitions which follows the identifier, including a parameter-declaration-clause and any default arguments (8.3.6). [Example:

typedef int c;
enum { i = 1 };

class X {
    char v[i];
    // error: \( i \) refers to ::i
    // but when reevaluated is X::i
    int f() { return sizeof(c); }
    // OK: X::c
    char c;
    enum { i = 2 };  
};

typedef char* T;
struct Y {
    T a;
    // error: \( T \) refers to ::T
    // but when reevaluated is Y::T
    typedef long T;
    T b;
};

Draft
typedef int I;
class D {
    typedef I I;         // error, even though no reordering involved
};

— end example

2 The name of a class member shall only be used as follows:
   — in the scope of its class (as described above) or a class derived (clause 10) from its class,
   — after the . operator applied to an expression of the type of its class (5.2.5) or a class derived from its class,
   — after the -> operator applied to a pointer to an object of its class (5.2.5) or a class derived from its class,
   — after the :: scope resolution operator (5.1) applied to the name of its class or a class derived from its class.

3.3.7 Name hiding

A name can be hidden by an explicit declaration of that same name in a nested declarative region or derived class (10.2).

A class name (9.1) or enumeration name (7.2) can be hidden by the name of an object, function, or enumerator declared in the same scope. If a class or enumeration name and an object, function, or enumerator are declared in the same scope (in any order) with the same name, the class or enumeration name is hidden wherever the object, function, or enumerator name is visible.

In a member function definition, the declaration of a local name hides the declaration of a member of the class with the same name; see 3.3.6. The declaration of a member in a derived class (clause 10) hides the declaration of a member of a base class of the same name; see 10.2.

During the lookup of a name qualified by a namespace name, declarations that would otherwise be made visible by a using-directive can be hidden by declarations with the same name in the namespace containing the using-directive; see (3.4.3.2).

If a name is in scope and is not hidden it is said to be visible.

3.4 Name lookup

The name lookup rules apply uniformly to all names (including typedef-names (7.1.3), namespace-names (7.3) and class-names (9.1)) wherever the grammar allows such names in the context discussed by a particular rule. Name lookup associates the use of a name with a declaration (3.1) of that name. Name lookup shall find an unambiguous declaration for the name (see 10.2). Name lookup may associate more than one declaration with a name if it finds the name to be a function name; the declarations are said to form a set of overloaded functions (13.1). Overload resolution (13.3) takes place after name lookup has succeeded. The access rules (clause 11) are considered only once name lookup and function overload resolution (if applicable) have succeeded. Only after name lookup, function overload resolution (if applicable) and access checking have succeeded are the attributes introduced by the name’s declaration used further in expression processing (clause 5).

A name “looked up in the context of an expression” is looked up as an unqualified name in the scope where the expression is found.
33 Basic concepts

3 The injected-class-name of a class (clause 9) is also considered to be a member of that class for the purposes of name hiding and lookup.

4 [Note: 3.5 discusses linkage issues. The notions of scope, point of declaration and name hiding are discussed in 3.3. —end note]

3.4 Name lookup

3.4.1 Unqualified name lookup [basic.lookup.unqual]

1 In all the cases listed in 3.4.1, the scopes are searched for a declaration in the order listed in each of the respective categories; name lookup ends as soon as a declaration is found for the name. If no declaration is found, the program is ill-formed.

2 The declarations from the namespace nominated by a using-directive become visible in a namespace enclosing the using-directive; see 7.3.4. For the purpose of the unqualified name lookup rules described in 3.4.1, the declarations from the namespace nominated by the using-directive are considered members of that enclosing namespace.

3 The lookup for an unqualified name used as the postfix-expression of a function call is described in 3.4.2. [Note: for purposes of determining (during parsing) whether an expression is a postfix-expression for a function call, the usual name lookup rules apply. The rules in 3.4.2 have no effect on the syntactic interpretation of an expression. For example,

```cpp
typedef int f;
namespace N {
    struct A {
        friend void f(A &);
        operator int();
        void g(A a) {
            int i = f(a);
            // f is the typedef, not the friend function: equivalent to int(a)
        }
    }
}
```

Because the expression is not a function call, the argument-dependent name lookup (3.4.2) does not apply and the friend function f is not found. —end note]

4 A name used in global scope, outside of any function, class or user-declared namespace, shall be declared before its use in global scope.

5 A name used in a user-declared namespace outside of the definition of any function or class shall be declared before its use in that namespace or before its use in a namespace enclosing its namespace.

6 A name used in the definition of a function following the function’s declarator-id that is a member of namespace N (where, only for the purpose of exposition, N could represent the global scope) shall be declared before its use in the block in which it is used or in one of its enclosing blocks (6.3) or, shall be declared before its use in namespace N or, if N is a nested namespace, shall be declared before its use in one of N’s enclosing namespaces.

[Example:

29) This refers to unqualified names that occur, for instance, in a type or default argument expression in the parameter-declaration-clause or used in the function body.
namespace A {
    namespace N {
        void f();
    }
}

void A::N::f () {
    i = 5;
    // The following scopes are searched for a declaration of i:
    // 1) outermost block scope of A::N::f, before the use of i
    // 2) scope of namespace N
    // 3) scope of namespace A
    // 4) global scope, before the definition of A::N::f
}

— end example ]

7 A name used in the definition of a class X outside of a member function body or nested class definition\(^{30}\) shall be declared in one of the following ways:

— before its use in class X or be a member of a base class of X (10.2), or

— if X is a nested class of class Y (9.7), before the definition of X in Y, or shall be a member of a base class of Y (this lookup applies in turn to Y ’s enclosing classes, starting with the innermost enclosing class),\(^{31}\)

— if X is a local class (9.8) or is a nested class of a local class, before the definition of class X in a block enclosing the definition of class X, or

— if X is a member of namespace N, or is a nested class of a class that is a member of N, or is a local class or a nested class within a local class of a function that is a member of N, before the definition of class X in namespace N or in one of N ’s enclosing namespaces.

[ Example:

 namespace M {
     class B { }; 
 } 

 namespace N {
     class Y : public M::B {
         class X {
             int a[i];
         };
     };
 } 

 // The following scopes are searched for a declaration of i:
 // 1) scope of class N::Y::X, before the use of i
 // 2) scope of class N::Y, before the definition of N::Y::X

\(^{30}\) This refers to unqualified names following the class name; such a name may be used in the base-clause or may be used in the class definition. 

\(^{31}\) This lookup applies whether the definition of X is nested within Y ’s definition or whether X ’s definition appears in a namespace scope enclosing Y ’s definition (9.7).
3.4 Name lookup

// 3) scope of \texttt{N::Y}'s base class \texttt{M::B}
// 4) scope of namespace \texttt{N}, before the definition of \texttt{N::Y}
// 5) global scope, before the definition of \texttt{N}

— end example ] [ Note: when looking for a prior declaration of a class or function introduced by a \texttt{friend} declaration, scopes outside of the innermost enclosing namespace scope are not considered; see 7.3.1.2. — end note ] [ Note: 3.3.6 further describes the restrictions on the use of names in a class definition. 9.7 further describes the restrictions on the use of names in nested class definitions. 9.8 further describes the restrictions on the use of names in local class definitions. — end note ]

A name used in the definition of a member function (9.3) of class \texttt{X} following the function’s \texttt{declarator-id} \footnote{That is, an unqualified name that occurs, for instance, in a type or default argument expression in the \texttt{parameter-declaration-clause}, in the function body, or in an expression of a \texttt{mem-initializer} in a constructor definition.} shall be declared in one of the following ways:

— before its use in the block in which it is used or in an enclosing block (6.3), or
— shall be a member of class \texttt{X} or be a member of a base class of \texttt{X} (10.2), or
— if \texttt{X} is a nested class of class \texttt{Y} (9.7), shall be a member of \texttt{Y}, or shall be a member of a base class of \texttt{Y} (this lookup applies in turn to \texttt{Y}’s enclosing classes, starting with the innermost enclosing class),\footnote{This lookup applies whether the member function is defined within the definition of class \texttt{X} or whether the member function is defined in a namespace scope enclosing \texttt{X}’s definition.} or
— if \texttt{X} is a local class (9.8) or is a nested class of a local class, before the definition of class \texttt{X} in a block enclosing the definition of class \texttt{X}, or
— if \texttt{X} is a member of namespace \texttt{N}, or is a nested class of a class that is a member of \texttt{N}, or is a local class or a nested class within a local class of a function that is a member of \texttt{N}, before the member function definition, in namespace \texttt{N} or in one of \texttt{N}’s enclosing namespaces.

\footnotesize{Example:}

```cpp
class B { }
namespace M {
    namespace N {
        class X : public B {
            void f();
        }
    }
    void M::N::X::f() {
        i = 16;
    }
}
```

// The following scopes are searched for a declaration of \texttt{i}:
// 1) outermost block scope of \texttt{M::N::X::f}, before the use of \texttt{i}
// 2) scope of class \texttt{M::N::X}
// 3) scope of \texttt{M::N::X}'s base class \texttt{B}
// 4) scope of namespace \texttt{M::N}
// 5) scope of namespace \texttt{M}
// 6) global scope, before the definition of \texttt{M::N::X::f}
``
3.4 Name lookup

— end example [ Note: 9.3 and 9.4 further describe the restrictions on the use of names in member function definitions. 9.7 further describes the restrictions on the use of names in the scope of nested classes. 9.8 further describes the restrictions on the use of names in local class definitions. — end note ]

Name lookup for a name used in the definition of a friend function (11.4) defined inline in the class granting friendship shall proceed as described for lookup in member function definitions. If the friend function is not defined in the class granting friendship, name lookup in the friend function definition shall proceed as described for lookup in namespace member function definitions.

In a friend declaration naming a member function, a name used in the function declarator and not part of a template-argument in a template-id is first looked up in the scope of the member function’s class. If it is not found, or if the name is part of a template-argument in a template-id, the look up is as described for unqualified names in the definition of the class granting friendship. [ Example:

```c
struct A {
    typedef int AT;
    void f1(AT);
    void f2(float);
};
struct B {
    typedef float BT;
    friend void A::f1(AT); // parameter type is A::AT
    friend void A::f2(BT); // parameter type is B::BT
};
```

— end example ]

During the lookup for a name used as a default argument (8.3.6) in a function parameter-declaration-clause or used in the expression of a mem-initializer for a constructor (12.6.2), the function parameter names are visible and hide the names of entities declared in the block, class or namespace scopes containing the function declaration. [ Note: 8.3.6 further describes the restrictions on the use of names in default arguments. 12.6.2 further describes the restrictions on the use of names in a ctor-initializer. — end note ]

A name used in the definition of a static data member of class X (9.4.2) (after the qualified-id of the static member) is looked up as if the name was used in a member function of X. [ Note: 9.4.2 further describes the restrictions on the use of names in the definition of a static data member. — end note ]

A name used in the handler for a function-try-block (clause 15) is looked up as if the name was used in the outermost block of the function definition. In particular, the function parameter names shall not be redeclared in the exception-declaration nor in the outermost block of a handler for the function-try-block. Names declared in the outermost block of the function definition are not found when looked up in the scope of a handler for the function-try-block. [ Note: but function parameter names are found. — end note ]

[ Note: the rules for name lookup in template definitions are described in 14.6. — end note ]

3.4.2 Argument-dependent name lookup [basic.lookup.argdep]

When an unqualified name is used as the postfix-expression in a function call (5.2.2), other namespaces not considered during the usual unqualified lookup (3.4.1) may be searched, and in those namespaces, namespace-scope friend function
declarations (11.4) not otherwise visible may be found. These modifications to the search depend on the types of the arguments (and for template template arguments, the namespace of the template argument).

For each argument type $T$ in the function call, there is a set of zero or more associated namespaces and a set of zero or more associated classes to be considered. The sets of namespaces and classes is determined entirely by the types of the function arguments (and the namespace of any template template argument). Typedef names and using-declarations used to specify the types do not contribute to this set. The sets of namespces and classes are determined in the following way:

- If $T$ is a fundamental type, its associated sets of namespaces and classes are both empty.
- If $T$ is a class type (including unions), its associated classes are: the class itself; the class of which it is a member, if any; and its direct and indirect base classes. Its associated namespaces are the namespaces in which its associated classes are defined.
- If $T$ is an enumeration type, its associated namespace is the namespace in which it is defined. If it is class member, its associated class is the member’s class; else it has no associated class.
- If $T$ is a pointer to $U$ or an array of $U$, its associated namespaces and classes are those associated with $U$.
- If $T$ is a function type, its associated namespaces and classes are those associated with the function parameter types and those associated with the return type.
- If $T$ is a pointer to a member function of a class $X$, its associated namespaces and classes are those associated with the function parameter types and return type, together with those associated with $X$.
- If $T$ is a pointer to a data member of class $X$, its associated namespaces and classes are those associated with the member type together with those associated with $X$.
- If $T$ is a class template specialization its associated namespaces and classes are the namespace in which the template is defined; for member templates, the member template’s class; the namespaces and classes associated with the types of the template arguments provided for template type parameters (excluding template template parameters); the namespaces in which any template template arguments are defined; and the classes in which any member templates used as template template arguments are defined. [Note: non-type template arguments do not contribute to the set of associated namespaces. — end note]

In addition, if the argument is the name or address of a set of overloaded functions and/or function templates, its associated classes and namespaces are the union of those associated with each of the members of the set: the namespace in which the function or function template is defined and the classes and namespaces associated with its (non-dependent) parameter types and return type.

If the ordinary unqualified lookup of the name finds the declaration of a class member function, or a block-scope function declaration that is not a using-declaration, the associated namespaces are not considered. Otherwise the set of declarations found by the lookup of the function name is the union of the set of declarations found using ordinary unqualified lookup and the set of declarations found in the namespaces associated with the argument types. [Note: the namespaces and classes associated with the argument types can include namespaces and classes already considered by the ordinary unqualified lookup. — end note]

Example:

```cpp
namespace NS {
    class T { }
    void f(T);
    void g(T, int);
}
```
3.4 Name lookup

{ }
NS::T parm;
void g(NS::T, float);
int main() {
    f(parm); // OK: calls NS::f
    extern void g(NS::T, float);
    g(parm, 1); // OK: calls g(NS::T, float)
}

— end example ]

4 When considering an associated namespace, the lookup is the same as the lookup performed when the associated namespace is used as a qualifier (3.4.3.2) except that:

— Any using-directives in the associated namespace are ignored.
— Any namespace-scope friend functions declared in associated classes are visible within their respective namespaces even if they are not visible during an ordinary lookup (11.4).

3.4.3 Qualified name lookup [basic.lookup.qual]

1 The name of a class or namespace member can be referred to after the :: scope resolution operator (5.1) applied to a nested-name-specifier that nominates its class or namespace. During the lookup for a name preceding the :: scope resolution operator, object, function, and enumerator names are ignored. If the name found is not a class-name (clause 9) or namespace-name (7.3.1), the program is ill-formed. [Example:

class A {
    public:
        static int n;
};
int main()
{
    int A;
    A::n = 42; // OK
    A b; // ill-formed: A does not name a type
}

— end example ]

2 [ Note: Multiply qualified names, such as N1::N2::N3::n, can be used to refer to members of nested classes (9.7) or members of nested namespaces. — end note ]

3 In a declaration in which the declarator-id is a qualified-id, names used before the qualified-id being declared are looked up in the defining namespace scope; names following the qualified-id are looked up in the scope of the member’s class or namespace. [Example:

class X { };
class C {
    class X { }
    static const int number = 50;
    static X arr[number];

A name prefixed by the unary scope operator :: (5.1) is looked up in global scope, in the translation unit where it is used. The name shall be declared in global namespace scope or shall be a name whose declaration is visible in global scope because of a using-directive (3.4.3.2). The use of :: allows a global name to be referred to even if its identifier has been hidden (3.3.7).

If a pseudo-destructor-name (5.2.4) contains a nested-name-specifier, the type-names are looked up as types in the scope designated by the nested-name-specifier. Similarly, in a qualified-id of the form:

```
::opt nested-name-specifier opt class-name :: ~ class-name
```

the second class-name is looked up in the same scope as the first. [Example:

```c
struct C {
    typedef int I;
};
typedef int I1, I2;
extern int* p;
extern int* q;
p->C::I::~I(); // I is looked up in the scope of C
q->I1::~I2(); // I2 is looked up in the scope of
               // the postfix-expression
```

```c
struct A {
    ~A();
};
typedef A AB;
int main()
{
    AB *p;
    p->AB::~AB(); // explicitly calls the destructor for A
}
```

— end example ] [Note: 3.4.5 describes how name lookup proceeds after the . and -> operators. — end note ]

### 3.4.3.1 Class members

[class.qual]

1 If the nested-name-specifier of a qualified-id nominates a class, the name specified after the nested-name-specifier is looked up in the scope of the class (10.2), except for the cases listed below. The name shall represent one or more members of that class or of one of its base classes (clause 10). [Note: a class member can be referred to using a qualified-id at any point in its potential scope (3.3.6). — end note ] The exceptions to the name lookup rule above are the following:

— a destructor name is looked up as specified in 3.4.3;
3.4 Name lookup

— a conversion-type-id of an operator-function-id is looked up both in the scope of the class and in the context in which the entire postfix-expression occurs and shall refer to the same type in both contexts;

— the template-arguments of a template-id are looked up in the context in which the entire postfix-expression occurs.

— the lookup for a name specified in a using-declaration (7.3.3) also finds class or enumeration names hidden within the same scope (3.3.7).

In a lookup in which the constructor is an acceptable lookup result, if the nested-name-specifier nominates a class C, and the name specified after the nested-name-specifier, when looked up in C, is the injected-class-name of C (clause 9), the name is instead considered to name the constructor of class C. [Note: For example, the constructor is not an acceptable lookup result in an elaborated-type-specifier so the constructor would not be used in place of the injected-class-name. — end note] Such a constructor name shall be used only in the declarator-id of a declaration that names a constructor. [Example:

```c
struct A { A(); };  
struct B: public A { B(); };  
A::A() {}  
B::B() {};  

B::A ba; // object of type A  
A::A a;  // error; A::A is not a type name  
struct A::A a2; // object of type A
```

— end example]

A class member name hidden by a name in a nested declarative region or by the name of a derived class member can still be found if qualified by the name of its class followed by the :: operator.

3.4.3.2 Namespace members

If the nested-name-specifier of a qualified-id nominates a namespace, the name specified after the nested-name-specifier is looked up in the scope of the namespace, except that the template-arguments of a template-id are looked up in the context in which the entire postfix-expression occurs.

Given X::m (where X is a user-declared namespace), or given ::m (where X is the global namespace), let S be the set of all declarations of m in X in the context in which the entire postfix-expression occurs.

Given X::m (where X is a user-declared namespace), or given ::m (where X is the global namespace), let S be the set of all declarations of m in X and in the transitive closure of all namespaces nominated by using-directives in X and its used namespaces, except that using-directives are ignored in any namespace, including X, directly containing one or more declarations of m. No namespace is searched more than once in the lookup of a name. If S is the empty set, the program is ill-formed. Otherwise, if S has exactly one member, or if the context of the reference is a using-declaration (7.3.3), S is the required set of declarations of m. Otherwise if the use of m is not one that allows a unique declaration to be chosen from S, the program is ill-formed. [Example:

```c
int x;  
namespace Y {  
    void f(float);  
    void h(int);  
}
```

Draft
namespace Z {
    void h(double);
}

namespace A {
    using namespace Y;
    void f(int);
    void g(int);
    int i;
}

namespace B {
    using namespace Z;
    void f(char);
    int i;
}

namespace AB {
    using namespace A;
    using namespace B;
    void g();
}

void h() {
    AB::g();          // g is declared directly in AB, 
    // therefore S is { AB::g() } and AB::g() is chosen
    AB::f(1);         // f is not declared directly in AB so the rules are
    // applied recursively to A and B;
    // namespace Y is not searched and Y::f(float)
    // is not considered;
    // S is { A::f(int), B::f(char) } and overload
    // resolution chooses A::f(int)
    AB::f('c');      // as above but resolution chooses B::f(char)
    AB::x++;        // x is not declared directly in AB, and
    // is not declared in A or B, so the rules are
    // applied recursively to Y and Z,
    // S is {} so the program is ill-formed
    AB::i++;        // i is not declared directly in AB so the rules are
    // applied recursively to A and B,
    // S is { A::i, B::i } so the use is ambiguous
    // and the program is ill-formed
    AB::h(16.8);    // h is not declared directly in AB and
    // not declared directly in A or B so the rules are
    // applied recursively to Y and Z,
    // S is { Y::h(int), Z::h(double) } and overload
    // resolution chooses Z::h(double)
}

Draft
The same declaration found more than once is not an ambiguity (because it is still a unique declaration). For example:

```cpp
namespace A {
    int a;
}

namespace B {
    using namespace A;
}

namespace C {
    using namespace A;
}

namespace BC {
    using namespace B;
    using namespace C;
}

void f()
{
    BC::a ++;
    // OK: S is { A::a, A::a }
}

namespace D {
    using A::a;
}

namespace BD {
    using namespace B;
    using namespace D;
}

void g()
{
    BD::a ++;
    // OK: S is { A::a, A::a }
}
```

Because each referenced namespace is searched at most once, the following is well-defined:

```cpp
namespace B {
    int b;
}

namespace A {
    using namespace B;
    int a;
}

namespace B {
    using namespace A;
```
43 Basic concepts 3.4 Name lookup

```c
void f()
{
    A::a ++; // OK: a declared directly in A, S is {A::a}
    B::a ++; // OK: both A and B searched (once), S is {A::a}
    A::b ++; // OK: both A and B searched (once), S is {B::b}
    B::b ++; // OK: b declared directly in B, S is {B::b}
}
```

— end example ]

5 During the lookup of a qualified namespace member name, if the lookup finds more than one declaration of the member, and if one declaration introduces a class name or enumeration name and the other declarations either introduce the same object, the same enumerator or a set of functions, the non-type name hides the class or enumeration name if and only if the declarations are from the same namespace; otherwise (the declarations are from different namespaces), the program is ill-formed. [ Example:

```c
define namespace A {
    struct x { };  
    int x;
    int y;
}

namespace B {
    struct y { };
}

namespace C {
    using namespace A;
    using namespace B;
    int i = C::x; // OK, A::x (of type int)
    int j = C::y; // ambiguous, A::y or B::y
}
```

— end example ]

6 In a declaration for a namespace member in which the declarator-id is a qualified-id, given that the qualified-id for the namespace member has the form nested-name-specifier unqualified-id the unqualified-id shall name a member of the namespace designated by the nested-name-specifier. [ Example:

```c
define namespace A {
    namespace B {
        void f1(int);
    }
    using namespace B;
}
void A::f1(int) { } // ill-formed, f1 is not a member of A
```

— end example ] However, in such namespace member declarations, the nested-name-specifier may rely on using-directives to implicitly provide the initial part of the nested-name-specifier. [ Example:
3.4 Name lookup

namespace A {
    namespace B {
        void f1(int);
    }
}

namespace C {
    namespace D {
        void f1(int);
    }
}

using namespace A;
using namespace C::D;
void B:: f1( int ){} // OK, defines A::B::f1(int)

—end example

3.4.4 Elaborated type specifiers [basic.lookup.elab]

1 An elaborated-type-specifier (7.1.5.3) may be used to refer to a previously declared class-name or enum-name even though the name has been hidden by a non-type declaration (3.3.7).

2 If the elaborated-type-specifier has no nested-name-specifier, and unless the elaborated-type-specifier appears in a declaration with the following form:

   class-key identifier

the identifier is looked up according to 3.4.1 but ignoring any non-type names that have been declared. If the elaborated-type-specifier is introduced by the enum keyword and this lookup does not find a previously declared type-name, the elaborated-type-specifier is ill-formed. If the elaborated-type-specifier is introduced by the class-key and this lookup does not find a previously declared type-name, or if the elaborated-type-specifier appears in a declaration with the form:

   class-key identifier

the elaborated-type-specifier is a declaration that introduces the class-name as described in 3.3.1.

3 If the elaborated-type-specifier has a nested-name-specifier, qualified name lookup is performed, as described in 3.4.3, but ignoring any non-type names that have been declared. If the name lookup does not find a previously declared type-name, the elaborated-type-specifier is ill-formed. [ Example:

   struct Node {
       struct Node* Next;  // OK: Refers to Node at global scope
       struct Data* Data;  // OK: Declares type Data
                       // at global scope and member Data
   };

   struct Data {
       struct Node* Node;  // OK: Refers to Node at global scope
       friend struct ::Glob; // error: Glob is not declared
                       // cannot introduce a qualified type (7.1.5.3)
       friend struct Glob; // OK: Refers to (as yet) undeclared Glob

Draft
### 3.4.5 Class member access

In a class member access expression (5.2.5), if the . or -> token is immediately followed by an identifier followed by a <, the identifier must be looked up to determine whether the < is the beginning of a template argument list (14.2) or a less-than operator. The identifier is first looked up in the class of the object expression. If the identifier is not found, it is then looked up in the context of the entire postfix-expression and shall name a class or function template. If the lookup in the class of the object expression finds a template, the name is also looked up in the context of the entire postfix-expression and

- if the name is not found, the name found in the class of the object expression is used, otherwise
- if the name is found in the context of the entire postfix-expression and does not name a class template, the name found in the class of the object expression is used, otherwise
- if the name found is a class template, it must refer to the same entity as the one found in the class of the object expression, otherwise the program is ill-formed.

If the id-expression in a class member access (5.2.5) is an unqualified-id, and the type of the object expression is of a class type C (or of pointer to a class type C), the unqualified-id is looked up in the scope of class C. If the type of the object expression is of pointer to scalar type, the unqualified-id is looked up in the context of the complete postfix-expression.

If the unqualified-id is *type-name*, and the type of the object expression is of a class type C (or of pointer to a class type C), the type-name is looked up in the context of the entire postfix-expression and in the scope of class C. The type-name shall refer to a class-name. If type-name is found in both contexts, the name shall refer to the same class type. If the type of the object expression is of scalar type, the type-name is looked up in the scope of the complete postfix-expression. If the id-expression in a class member access is a qualified-id of the form

```
class-name-or-namespace-name::...
```
3.5 Program and linkage [basic.link]

1 A **program** consists of one or more **translation units** (clause 2) linked together. A translation unit consists of a sequence of declarations.

   translation-unit:
   declaration-seq

2 A name is said to have **linkage** when it might denote the same object, reference, function, type, template, namespace or value as a name introduced by a declaration in another scope:

   — When a name has **external linkage**, the entity it denotes can be referred to by names from scopes of other translation units or from other scopes of the same translation unit.

   — When a name has **internal linkage**, the entity it denotes can be referred to by names from other scopes in the same translation unit.

   — When a name has **no linkage**, the entity it denotes cannot be referred to by names from other scopes.

3 A name having namespace scope (3.3.5) has internal linkage if it is the name of

   — an object, reference, function or function template that is explicitly declared **static** or,

   — an object or reference that is explicitly declared **const** and neither explicitly declared **extern** nor previously declared to have external linkage; or

   — a data member of an anonymous union.

4 A name having namespace scope has external linkage if it is the name of

   — an object or reference, unless it has internal linkage; or

Draft
— a function, unless it has internal linkage; or
— a named class (clause 9), or an unnamed class defined in a typedef declaration in which the class has the typedef name for linkage purposes (7.1.3); or
— a named enumeration (7.2), or an unnamed enumeration defined in a typedef declaration in which the enumeration has the typedef name for linkage purposes (7.1.3); or
— an enumerator belonging to an enumeration with external linkage; or
— a template, unless it is a function template that has internal linkage (clause 14); or
— a namespace (7.3), unless it is declared within an unnamed namespace.

5 In addition, a member function, static data member, a named class or enumeration of class scope, or an unnamed class or enumeration defined in a class-scope typedef declaration such that the class or enumeration has the typedef name for linkage purposes (7.1.3), has external linkage if the name of the class has external linkage.

6 The name of a function declared in block scope, and the name of an object declared by a block scope extern declaration, have linkage. If there is a visible declaration of an entity with linkage having the same name and type, ignoring entities declared outside the innermost enclosing namespace scope, the block scope declaration declares that same entity and receives the linkage of the previous declaration. If there is more than one such matching entity, the program is ill-formed. Otherwise, if no matching entity is found, the block scope entity receives external linkage.

    [Example:]
    static void f();
    static int i = 0;                     // 1
    void g() {
        extern void f();               // internal linkage
        int i;                         // 2: i has no linkage
        {
            extern void f();           // internal linkage
            extern int i;              // 3: external linkage
        }
    }

There are three objects named i in this program. The object with internal linkage introduced by the declaration in global scope (line //1), the object with automatic storage duration and no linkage introduced by the declaration on line //2, and the object with static storage duration and external linkage introduced by the declaration on line //3. —end example]

7 When a block scope declaration of an entity with linkage is not found to refer to some other declaration, then that entity is a member of the innermost enclosing namespace. However such a declaration does not introduce the member name in its namespace scope. [Example:

    namespace X {
        void p() {
            q();                     // error: q not yet declared
            extern void q();        // q is a member of namespace X
        }
    }

Draft
void middle()
{
    q();           // error: q not yet declared
}

void q() { /* ... */ } // definition of X::q

void q() { /* ... */ } // some other, unrelated q

— end example ]

8 Names not covered by these rules have no linkage. Moreover, except as noted, a name declared in a local scope (3.3.2) has no linkage. A type is said to have linkage if and only if:

— it is a class or enumeration type that is named (or has a name for linkage purposes (7.1.3) and the name has linkage; or
— it is a specialization of a class template (14)34; or
— it is a fundamental type (3.9.1); or
— it is a compound type (3.9.2) other than a class or enumeration, compounded exclusively from types that have linkage; or
— it is a cv-qualified (3.9.3) version of a type that has linkage.

A type without linkage shall not be used as the type of a variable or function with linkage, unless the variable or function has extern "C" linkage (7.5). [Note: in other words, a type without linkage contains a class or enumeration that cannot be named outside its translation unit. An entity with external linkage declared using such a type could not correspond to any other entity in another translation unit of the program and thus is not permitted. Also note that classes with linkage may contain members whose types do not have linkage, and that typedef names are ignored in the determination of whether a type has linkage. — end note ] [Example:

    void f()
    {
        struct A { int x; };           // no linkage
        extern A a;                    // ill-formed
        typedef A B;
        extern B b;                    // ill-formed
    }

— end example ] This implies that names with no linkage cannot be used as template arguments (14.3).

9 Two names that are the same (clause 3) and that are declared in different scopes shall denote the same object, reference, function, type, enumerator, template or namespace if

— both names have external linkage or else both names have internal linkage and are declared in the same translation unit; and

34) a class template always has external linkage, and the requirements of 14.3.1 and 14.3.2 ensure that the template arguments will also have appropriate linkage.
3.6 Start and termination

3.6.1 Main function

A program shall contain a global function called main, which is the designated start of the program. It is implementation-defined whether a program in a freestanding environment is required to define a main function. [Note: in a freestanding environment, start-up and termination is implementation-defined; start-up contains the execution of constructors for objects of namespace scope with static storage duration; termination contains the execution of destructors for objects with static storage duration. —end note]

An implementation shall not redefine the main function. This function shall not be overloaded. It shall have a return type of type int, but otherwise its type is implementation-defined. All implementations shall allow both of the following definitions of main:

```c
int main () { /* ... */ }
```

and

```c
int main ( int argc , char * argv []) { /* ... */ }
```

In the latter form argc shall be the number of arguments passed to the program from the environment in which the program is run. If argc is nonzero these arguments shall be supplied in argv[0] through argv[argc-1] as pointers to the initial characters of null-terminated multibyte strings (NTMBS) (17.3.2.1.3.2) and argv[0] shall be the pointer to the initial character of a NTMBS that represents the name used to invoke the program or "". The value of argc shall be nonnegative. The value of argv[argc] shall be 0. [Note: it is recommended that any further (optional) parameters be added after argv. —end note]

The function main shall not be used (3.2) within a program. The linkage (3.5) of main is implementation-defined. A program that declares main to be inline or static is ill-formed. The name main is not otherwise reserved. [Example: member functions, classes, and enumerations can be called main, as can entities in other namespaces. —end example]

Calling the function std::exit(int) declared in <cstdlib> (18.3) terminates the program without leaving the current block and hence without destroying any objects with automatic storage duration (12.4). If std::exit is called to end a program during the destruction of an object with static storage duration, the program has undefined behavior.

A return statement in main has the effect of leaving the main function (destroying any objects with automatic storage duration) and calling std::exit with the return value as the argument. If control reaches the end of main without encountering a return statement, the effect is that of executing

```
Draft
```
return 0;

### 3.6.2 Initialization of non-local objects

Objects with static storage duration (3.7.1) shall be zero-initialized (8.5) before any other initialization takes place. A reference with static storage duration and an object of POD type with static storage duration can be initialized with a constant expression (5.19); this is called constant initialization. Together, zero-initialization and constant initialization are called static initialization; all other initialization is dynamic initialization. Static initialization shall be performed before any dynamic initialization takes place. Dynamic initialization of an object is either ordered or unordered. Definitions of explicitly specialized class template static data members have ordered initialization. Other class template static data members (i.e., implicitly or explicitly instantiated specializations) have unordered initialization. Other objects defined in namespace scope have ordered initialization. Objects defined within a single translation unit and with ordered initialization shall be initialized in the order of their definitions in the translation unit. The order of initialization is unspecified for objects with unordered initialization and for objects defined in different translation units. [Note: 8.5.1 describes the order in which aggregate members are initialized. The initialization of local static objects is described in 6.7. — end note]

An implementation is permitted to perform the initialization of an object of namespace scope with static storage duration as a static initialization even if such initialization is not required to be done statically, provided that

- the dynamic version of the initialization does not change the value of any other object of namespace scope with static storage duration prior to its initialization, and
- the static version of the initialization produces the same value in the initialized object as would be produced by the dynamic initialization if all objects not required to be initialized statically were initialized dynamically.

[Note: as a consequence, if the initialization of an object \texttt{obj1} refers to an object \texttt{obj2} of namespace scope with static storage duration potentially requiring dynamic initialization and defined later in the same translation unit, it is unspecified whether the value of \texttt{obj2} used will be the value of the fully initialized \texttt{obj2} (because \texttt{obj2} was statically initialized) or will be the value of \texttt{obj2} merely zero-initialized. For example,

```c
inline double fd() { return 1.0; }
extern double d1;
double d2 = d1; // unspecified:
    // may be statically initialized to 0.0 or
    // dynamically initialized to 1.0

double d1 = fd(); // may be initialized statically to 1.0
```

— end note ]

It is implementation-defined whether or not the dynamic initialization (8.5, 9.4, 12.1, 12.6.1) of an object of namespace scope is done before the first statement of \texttt{main}. If the initialization is deferred to some point in time after the first statement of \texttt{main}, it shall occur before the first use of any function or object defined in the same translation unit as the object to be initialized. [35) \textbf{Example:}

```c
// - File 1 -
#include "a.h"
#include "b.h"
B b;
```

35) An object defined in namespace scope having initialization with side-effects must be initialized even if it is not used (3.7.1).
A::A(){
    b.Use();
}

// - File 2 -
#include "a.h"
A a;

// - File 3 -
#include "a.h"
#include "b.h"
extern A a;
extern B b;

int main() {
    a.Use();
    b.Use();
}

It is implementation-defined whether either a or b is initialized before main is entered or whether the initializations are delayed until a is first used in main. In particular, if a is initialized before main is entered, it is not guaranteed that b will be initialized before it is used by the initialization of a, that is, before A::A is called. If, however, a is initialized at some point after the first statement of main, b will be initialized prior to its use in A::A. — end example ]

4 If construction or destruction of a non-local static object ends in throwing an uncaught exception, the result is to call \texttt{std::terminate} (18.6.3.3).

### 3.6.3 Termination

1 Destructors (12.4) for initialized objects of static storage duration (declared at block scope or at namespace scope) are called as a result of returning from \texttt{main} and as a result of calling \texttt{std::exit} (18.3). These objects are destroyed in the reverse order of the completion of their constructor or of the completion of their dynamic initialization. If an object is initialized statically, the object is destroyed in the same order as if the object was dynamically initialized. For an object of array or class type, all subobjects of that object are destroyed before any local object with static storage duration initialized during the construction of the subobjects is destroyed.

2 If a function contains a local object of static storage duration that has been destroyed and the function is called during the destruction of an object with static storage duration, the program has undefined behavior if the flow of control passes through the definition of the previously destroyed local object.

3 If a function is registered with \texttt{std::atexit} (see \texttt{<cstdlib>}, 18.3) then following the call to \texttt{std::exit}, any objects with static storage duration initialized prior to the registration of that function shall not be destroyed until the registered function is called from the termination process and has completed. For an object with static storage duration constructed after a function is registered with \texttt{std::atexit}, then following the call to \texttt{std::exit}, the registered function is not called until the execution of the object’s destructor has completed. If \texttt{std::atexit} is called during the construction of an object, the complete object to which it belongs shall be destroyed before the registered function is called.

4 Calling the function \texttt{std::abort()} declared in \texttt{<cstdlib>} terminates the program without executing destructors for
3.7 Storage duration

Storage duration is the property of an object that defines the minimum potential lifetime of the storage containing the object. The storage duration is determined by the construct used to create the object and is one of the following:

- static storage duration
- automatic storage duration
- dynamic storage duration

Static and automatic storage durations are associated with objects introduced by declarations (3.1) and implicitly created by the implementation (12.2). The dynamic storage duration is associated with objects created with operator new (5.3.4).

The storage class specifiers static and auto are related to storage duration as described below.

The storage duration categories apply to references as well. The lifetime of a reference is its storage duration.

3.7.1 Static storage duration

All objects which neither have dynamic storage duration nor are local have static storage duration. The storage for these objects shall last for the duration of the program (3.6.2, 3.6.3).

If an object of static storage duration has initialization or a destructor with side effects, it shall not be eliminated even if it appears to be unused, except that a class object or its copy may be eliminated as specified in 12.8.

The keyword static can be used to declare a local variable with static storage duration. [Note: 6.7 describes the initialization of local static variables; 3.6.3 describes the destruction of local static variables. — end note]

The keyword static applied to a class data member in a class definition gives the data member static storage duration.

3.7.2 Automatic storage duration

Local objects explicitly declared auto or register or not explicitly declared static or extern have automatic storage duration. The storage for these objects lasts until the block in which they are created exits.

[Note: these objects are initialized and destroyed as described in 6.7. — end note]

If a named automatic object has initialization or a destructor with side effects, it shall not be destroyed before the end of its block, nor shall it be eliminated as an optimization even if it appears to be unused, except that a class object or its copy may be eliminated as specified in 12.8.

3.7.3 Dynamic storage duration

Objects can be created dynamically during program execution (1.9), using new-expressions (5.3.4), and destroyed using delete-expressions (5.3.5). A C++ implementation provides access to, and management of, dynamic storage via the global allocation functions operator new and operator new[] and the global deallocation functions operator delete and operator delete[].

The library provides default definitions for the global allocation and deallocation functions. Some global allocation and deallocation functions are replaceable (18.4.1). A C++ program shall provide at most one definition of a replaceable
allocation or deallocation function. Any such function definition replaces the default version provided in the library (17.4.3.4). The following allocation and deallocation functions (18.4) are implicitly declared in global scope in each translation unit of a program.

```c
void* operator new (std::size_t) throw(std::bad_alloc);
void* operator new[](std::size_t) throw(std::bad_alloc);
void operator delete(void*) throw();
void operator delete[](void*) throw();
```

These implicit declarations introduce only the function names `operator new`, `operator new[]`, `operator delete`, `operator delete[]`. [Note: the implicit declarations do not introduce the names `std`, `std::bad_alloc`, and `std::size_t`, or any other names that the library uses to declare these names. Thus, a new-expression, delete-expression or function call that refers to one of these functions without including the header `<new>` is well-formed. However, referring to `std`, `std::bad_alloc`, and `std::size_t` is ill-formed unless the name has been declared by including the appropriate header. —end note] Allocation and/or deallocation functions can also be declared and defined for any class (12.5).

Any allocation and/or deallocation functions defined in a C++ program, including the default versions in the library, shall conform to the semantics specified in 3.7.3.1 and 3.7.3.2.

### 3.7.3.1 Allocation functions

1. An allocation function shall be a class member function or a global function; a program is ill-formed if an allocation function is declared in a namespace scope other than global scope or declared static in global scope. The return type shall be `void*`. The first parameter shall have type `std::size_t` (18.1). The first parameter shall not have an associated default argument (8.3.6). The value of the first parameter shall be interpreted as the requested size of the allocation. An allocation function can be a function template. Such a template shall declare its return type and first parameter as specified above (that is, template parameter types shall not be used in the return type and first parameter type). Template allocation functions shall have two or more parameters.

2. The allocation function attempts to allocate the requested amount of storage. If it is successful, it shall return the address of the start of a block of storage whose length in bytes shall be at least as large as the requested size. There are no constraints on the contents of the allocated storage on return from the allocation function. The order, contiguity, and initial value of storage allocated by successive calls to an allocation function is unspecified. The pointer returned shall be suitably aligned so that it can be converted to a pointer of any complete object type and then used to access the object or array in the storage allocated (until the storage is explicitly deallocated by a call to a corresponding deallocation function). Even if the size of the space requested is zero, the request can fail. If the request succeeds, the value returned shall be a non-null pointer value (4.10) p0 different from any previously returned value p1, unless that value p1 was subsequently passed to an `operator delete`. The effect of dereferencing a pointer returned as a request for zero size is undefined. 36)

3. An allocation function that fails to allocate storage can invoke the currently installed new-handler function (18.4.2.2), if any. [Note: A program-supplied allocation function can obtain the address of the currently installed new_handler using the `std::set_new_handler` function (18.4.2.3). —end note] If an allocation function declared with an empty exception-specification (15.4), `throw()`, fails to allocate storage, it shall return a null pointer. Any other allocation function that fails to allocate storage shall only indicate failure by throwing an exception of class `std::bad_alloc` (18.4.2.1) or a class derived from `std::bad_alloc`.

---

36) The intent is to have `operator new()` implementable by calling `std::malloc()` or `std::calloc()`, so the rules are substantially the same. C++ differs from C in requiring a zero request to return a non-null pointer.
3.8 Object Lifetime

The lifetime of an object is a runtime property of the object. The lifetime of an object of type \( T \) begins when:

1. storage with the proper alignment and size for type \( T \) is obtained, and

A global allocation function is only called as the result of a new expression (5.3.4), or called directly using the function call syntax (5.2.2), or called indirectly through calls to the functions in the C++ standard library. [Note: in particular, a global allocation function is not called to allocate storage for objects with static storage duration (3.7.1), for objects of type \( \text{std}::\text{type\_info} \) (5.2.8), for the copy of an object thrown by a throw expression (15.1). — end note]

3.7.3.2 Deallocation functions

Deallocation functions shall be class member functions or global functions; a program is ill-formed if deallocation functions are declared in a namespace scope other than global scope or declared static in global scope.

Each deallocation function shall return \( \text{void} \) and its first parameter shall be \( \text{void}^* \). A deallocation function can have more than one parameter. If a class \( T \) has a member deallocation function named \( \text{operator delete} \) with exactly one parameter, then that function is a usual (non-placement) deallocation function. If class \( T \) does not declare such an \( \text{operator delete} \) but does declare a member deallocation function named \( \text{operator delete} \) with exactly two parameters, the second of which has type \( \text{std}::\text{size\_t} \) (18.1), then this function is a usual deallocation function. Similarly, if a class \( T \) has a member deallocation function named \( \text{operator delete}[] \) with exactly one parameter, then that function is a usual (non-placement) deallocation function. If class \( T \) does not declare such an \( \text{operator delete}[] \) but does declare a member deallocation function named \( \text{operator delete}[] \) with exactly two parameters, the second of which has type \( \text{std}::\text{size\_t} \), then this function is a usual deallocation function. A deallocation function can be an instance of a function template. Neither the first parameter nor the return type shall depend on a template parameter. [Note: that is, a deallocation function template shall have a first parameter of type \( \text{void}^* \) and a return type of \( \text{void} \) (as specified above). — end note] A deallocation function template shall have two or more function parameters. A template instance is never a usual deallocation function, regardless of its signature.

The value of the first argument supplied to one of the deallocation functions provided in the standard library may be a null pointer value; if so, the call to the deallocation function has no effect. Otherwise, the value supplied to \( \text{operator delete} \) in the standard library shall be one of the values returned by a previous invocation of either \( \text{operator new} \) or \( \text{operator new} \) in the standard library, and the value supplied to \( \text{operator delete}[] \) in the standard library shall be one of the values returned by a previous invocation of either \( \text{operator new}[] \) or \( \text{operator new}[] \) in the standard library.

If the argument given to a deallocation function in the standard library is a pointer that is not the null pointer value (4.10), the deallocation function shall deallocate the storage referenced by the pointer, rendering invalid all pointers referring to any part of the deallocated storage. The effect of using an invalid pointer value (including passing it to a deallocation function) is undefined.\(^{37}\)

3.7.4 Duration of subobjects

The storage duration of member subobjects, base class subobjects and array elements is that of their complete object (1.8).

3.8 Object Lifetime

The lifetime of an object is a runtime property of the object. The lifetime of an object of type \( T \) begins when:

\(^{37}\) On some implementations, it causes a system-generated runtime fault.
— if \( \mathcal{T} \) is a class type and the constructor invoked to create the object is non-trivial (12.1), the constructor call has
completed. the initialization is complete. [Note: the initialization can be performed by a constructor call or, in the
case of an aggregate with an implicitly-declared non-trivial default constructor, an aggregate initialization 8.5.1.
— end note]

The lifetime of an object of type \( \mathcal{T} \) ends when:

— if \( \mathcal{T} \) is a class type with a non-trivial destructor (12.4), the destructor call starts, or
— the storage which the object occupies is reused or released.

[Note: the lifetime of an array object or of an object of POD type (3.9) starts as soon as storage with proper size and
alignment is obtained, and its lifetime ends when the storage which the array or object occupies is reused or released.
12.6.2 describes the lifetime of base and member subobjects. — end note]

The properties ascribed to objects throughout this International Standard apply for a given object only during its lifetime.
[Note: in particular, before the lifetime of an object starts and after its lifetime ends there are significant restrictions on
the use of the object, as described below, in 12.6.2 and in 12.7. Also, the behavior of an object under construction and
destruction might not be the same as the behavior of an object whose lifetime has started and not ended. 12.6.2 and 12.7
describe the behavior of objects during the construction and destruction phases. — end note]

A program may end the lifetime of any object by reusing the storage which the object occupies or by explicitly calling
the destructor for an object of a class type with a non-trivial destructor. For an object of a class type with a non-trivial
destructor, the program is not required to call the destructor explicitly before the storage which the object occupies is
reused or released; however, if there is no explicit call to the destructor or if a delete-expression (5.3.5) is not used
to release the storage, the destructor shall not be implicitly called and any program that depends on the side effects
produced by the destructor has undefined behavior.

Before the lifetime of an object has started but after the storage which the object will occupy has been allocated\(^{38}\)
or, after the lifetime of an object has ended and before the storage which the object occupied is reused or released, any
pointer that refers to the storage location where the object will be or was located may be used but only in limited ways.
Such a pointer refers to allocated storage (3.7.3.2), and using the pointer as if the pointer were of type void*, is well-
defined. Such a pointer may be dereferenced but the resulting lvalue may only be used in limited ways, as described
below. If the object will be or was of a class type with a non-trivial destructor, and the pointer is used as the operand
of a delete-expression, the program has undefined behavior. If the object will be or was of a non-POD class type, the
program has undefined behavior if:

— the pointer is used to access a non-static data member or call a non-static member function of the object, or
— the pointer is implicitly converted (4.10) to a pointer to a base class type, or
— the pointer is used as the operand of a static_cast (5.2.9) (except when the conversion is to void*, or to void*
and subsequently to char*, or unsigned char*).
— the pointer is used as the operand of a dynamic_cast (5.2.7). [Example:

\begin{verbatim}
#include <cstdlib>

struct B {
    virtual void f();
};
\end{verbatim}

\(^{38}\) For example, before the construction of a global object of non-POD class type (12.7).

Draft
3.8 Object Lifetime  

```cpp
void mutate();
virtual ~B();

struct D1 : B { void f(); };
struct D2 : B { void f(); };

void B::mutate() {
    new (this) D2; // reuses storage — ends the lifetime of *this
    f(); // undefined behavior
    ... = this; // OK, this points to valid memory
}

void g() {
    void* p = std::malloc(sizeof(D1) + sizeof(D2));
    B* pb = new (p) D1;
    pb->mutate();
    &pb; // OK: pb points to valid memory
    void* q = pb; // OK: pb points to valid memory
    pb->f(); // undefined behavior, lifetime of *pb has ended
}

— end example }
```

6 Similarly, before the lifetime of an object has started but after the storage which the object will occupy has been allocated or, after the lifetime of an object has ended and before the storage which the object occupied is reused or released, any lvalue which refers to the original object may be used but only in limited ways. Such an lvalue refers to allocated storage (3.7.3.2), and using the properties of the lvalue which do not depend on its value is well-defined. If an lvalue-to-rvalue conversion (4.1) is applied to such an lvalue, the program has undefined behavior; if the original object will be or was of a non-POD class type, the program has undefined behavior if:

- the lvalue is used to access a non-static data member or call a non-static member function of the object, or
- the lvalue is implicitly converted (4.10) to a reference to a base class type, or
- the lvalue is used as the operand of a static_cast (5.2.9) except when the conversion is ultimately to cv char& or cv unsigned char&), or
- the lvalue is used as the operand of a dynamic_cast (5.2.7) or as the operand of typeid.

7 If, after the lifetime of an object has ended and before the storage which the object occupied is reused or released, a new object is created at the storage location which the original object occupied, a pointer that pointed to the original object, a reference that referred to the original object, or the name of the original object will automatically refer to the new object and, once the lifetime of the new object has started, can be used to manipulate the new object, if:

- the storage for the new object exactly overlays the storage location which the original object occupied, and
- the new object is of the same type as the original object (ignoring the top-level cv-qualifiers), and
- the type of the original object is not const-qualified, and, if a class type, does not contain any non-static data member whose type is const-qualified or a reference type, and
— the original object was a most derived object (1.8) of type T and the new object is a most derived object of type T (that is, they are not base class subobjects). [Example:

```c
struct C {
  int i;
  void f();
  const C& operator=( const C &);
};

const C& C:: operator=( const C& other)
{
  if ( this != & other ) {
    this->~C(); // lifetime of *this ends
    new (this) C(other); // new object of type C created
    f(); // well-defined
  }
  return * this;
}
```

```c
C c1;
C c2;
c1 = c2; // well-defined
```

```c
// well-defined; c1 refers to a new object of type C
```

— end example]

8 If a program ends the lifetime of an object of type T with static (3.7.1) or automatic (3.7.2) storage duration and if T has a non-trivial destructor, the program must ensure that an object of the original type occupies that same storage location when the implicit destructor call takes place; otherwise the behavior of the program is undefined. This is true even if the block is exited with an exception. [Example:

```c
class T { }
struct B {
  ~B();
};

void h() {
  B b;
  new (&b) T; // undefined behavior at block exit
}
```

— end example]

9 Creating a new object at the storage location that a const object with static or automatic storage duration occupies or, at the storage location that such a const object used to occupy before its lifetime ended results in undefined behavior. [Example:

```c
struct B {
  B();
}
```

[39] that is, an object for which a destructor will be called implicitly—either upon exit of a block for an object with automatic storage duration or upon exit from a program for an object with static storage duration.
3.9 Types

1 [Note: 3.9 and the subclauses thereof impose requirements on implementations regarding the representation of types. There are two kinds of types: fundamental types and compound types. Types describe objects (1.8), references (8.3.2), or functions (8.3.5). — end note]

2 For any object (other than a base-class subobject) of POD type \( T \), whether or not the object holds a valid value of type \( T \), the underlying bytes (1.7) making up the object can be copied into an array of char or unsigned char.\(^{40}\) If the content of the array of char or unsigned char is copied back into the object, the object shall subsequently hold its original value. [Example:

```c
#define N sizeof(T)
char buf[N];
T obj; // obj initialized to its original value
std::memcpy(buf, &obj, N); // between these two calls to std::memcpy,
// obj might be modified
std::memcpy(&obj, buf, N); // at this point, each subobject of obj of scalar type
// holds its original value
```

— end example]

3 For any POD type \( T \), if two pointers to \( T \) point to distinct \( T \) objects \( \text{obj1} \) and \( \text{obj2} \), where neither \( \text{obj1} \) nor \( \text{obj2} \) is a base-class subobject, if the value of \( \text{obj1} \) is copied into \( \text{obj2} \), using the \text{std::memcpy} library function, \( \text{obj2} \) shall subsequently hold the same value as \( \text{obj1} \). [Example:

```c
T* t1p;
T* t2p; // provided that \( t2p \) points to an initialized object...
std::memcpy(t1p, t2p, sizeof(T)); // at this point, every subobject of POD type in *t1p contains
// the same value as the corresponding subobject in *t2p
```

— end example]

4 The object representation of an object of type \( T \) is the sequence of \( N \) unsigned char objects taken up by the object of type \( T \), where \( N \) equals \text{sizeof}(T). The value representation of an object is the set of bits that hold the value of type \( T \).

\(^{40}\) By using, for example, the library functions (17.4.1.2) \text{std::memcpy} or \text{std::memmove}.
For POD types, the value representation is a set of bits in the object representation that determines a value, which is one discrete element of an implementation-defined set of values.\footnote{The intent is that the memory model of C++ is compatible with that of ISO/IEC 9899 Programming Language C.}

5 Object types have alignment requirements (3.9.1, 3.9.2). The alignment of a complete object type is an implementation-defined integer value representing a number of bytes; an object is allocated at an address that meets the alignment requirements of its object type.

6 A class that has been declared but not defined, or an array of unknown size or of incomplete element type, is an incompletely-defined object type.\footnote{The size and layout of an instance of an incompletely-defined object type is unknown.} Incompletely-defined object types and the void types are incomplete types (3.9.1). Objects shall not be defined to have an incomplete type.

7 A class type (such as “\texttt{class X}”) might be incomplete at one point in a translation unit and complete later on; the type “\texttt{class X}” is the same type at both points. The declared type of an array object might be an array of incomplete class type and therefore incomplete; if the class type is completed later on in the translation unit, the array type becomes complete; the array type at those two points is the same type. The declared type of an array object might be an array of unknown size and therefore be incomplete at one point in a translation unit and complete later on; the array types at those two points (“array of unknown bound of \texttt{T}” and “array of \texttt{N T}”) are different types. The type of a pointer to array of unknown size, or of a type defined by a \texttt{typedef} declaration to be an array of unknown size, cannot be completed.

[Example:

```c
class X;
extern X* xp; // X is an incomplete type
extern int arr[]; // xp is a pointer to an incomplete type
typedef int UNKA[]; // the type of arr is incomplete
UNKA* arrp; // UNKA is an incomplete type
UNKA** arrpp; // arrp is a pointer to an incomplete type

void foo()
{
    xp++; // ill-formed: X is incomplete
    arrp++; // ill-formed: incomplete type
    arrpp++; // OK: sizeof UNKA* is known
}

struct X { int i; }; // now X is a complete type
int arr[10]; // now the type of arr is complete

X x;
void bar()
{
    xp = &x; // OK: type is “pointer to X”
    arrp = &arr; // ill-formed: different types
    xp++; // OK: X is complete
    arrp++; // ill-formed: UNKA can’t be completed
}
```
— end example ]

Draft
3.9 Types

[Note: the rules for declarations and expressions describe in which contexts incomplete types are prohibited. —end note]

An object type is a (possibly cv-qualified) type that is not a function type, not a reference type, and not a void type.

Arithmetic types (3.9.1), enumeration types, pointer types, and pointer to member types (3.9.2), and cv-qualified versions of these types (3.9.3) are collectively called scalar types. Scalar types, POD-struct types, POD-union types (clause 9), arrays of such types and cv-qualified versions of these types (3.9.3) are collectively called POD types.

If two types T1 and T2 are the same type, then T1 and T2 are layout-compatible types. [Note: Layout-compatible enumerations are described in 7.2. Layout-compatible POD-structs and POD-unions are described in 9.2. —end note]

3.9.1 Fundamental types

[basic.fundamental]

Objects declared as characters (char) shall be large enough to store any member of the implementation’s basic character set. If a character from this set is stored in a character object, the integral value of that character object is equal to the value of the single character literal form of that character. It is implementation-defined whether a char object can hold negative values. Characters can be explicitly declared unsigned or signed. Plain char, signed char, and unsigned char are three distinct types. A char, a signed char, and an unsigned char occupy the same amount of storage and have the same alignment requirements (3.9); that is, they have the same object representation. For character types, all bits of the object representation participate in the value representation. For unsigned character types, all possible bit patterns of the value representation represent numbers. These requirements do not hold for other types. In any particular implementation, a plain char object can take on either the same values as a signed char or an unsigned char; which one is implementation-defined.

There are four signed integer types: “signed char”, “short int”, “int”, and “long int.” In this list, each type provides at least as much storage as those preceding it in the list. Plain ints have the natural size suggested by the architecture of the execution environment; the other signed integer types are provided to meet special needs.

For each of the signed integer types, there exists a corresponding (but different) unsigned integer type: “unsigned char”, “unsigned short int”, “unsigned int”, and “unsigned long int,” each of which occupies the same amount of storage and has the same alignment requirements (3.9) as the corresponding signed integer type; that is, each signed integer type has the same object representation as its corresponding unsigned integer type. The range of nonnegative values of a signed integer type is a subrange of the corresponding unsigned integer type, and the value representation of each corresponding signed/unsigned type shall be the same.

Unsigned integers, declared unsigned, shall obey the laws of arithmetic modulo 2\(^n\) where \(n\) is the number of bits in the value representation of that particular size of integer.\(^{45}\)

Type wchar_t is a distinct type whose values can represent distinct codes for all members of the largest extended character set specified among the supported locales (22.1.1). Type wchar_t shall have the same size, signedness, and alignment requirements (3.9) as one of the other integral types, called its underlying type.

Values of type bool are either true or false.\(^{46}\) [Note: there are no signed, unsigned, short, or long bool types or values. —end note] As described below, bool values behave as integral types. Values of type bool participate in

\(^{43}\) that is, large enough to contain any value in the range of INT_MIN and INT_MAX, as defined in the header <climits>.

\(^{44}\) See 7.1.5.2 regarding the correspondence between types and the sequences of type-specifiers that designate them.

\(^{45}\) This implies that unsigned arithmetic does not overflow because a result that cannot be represented by the resulting unsigned integer type is reduced modulo that number that is one greater than the largest value that can be represented by the resulting unsigned integer type.

\(^{46}\) Using a bool value in ways described by this International Standard as “undefined,” such as by examining the value of an uninitialized automatic variable, might cause it to behave as if it is neither true nor false.
integral promotions (4.5).

7 Types bool, char, wchar_t, and the signed and unsigned integer types are collectively called integral types.\(^{47}\) A synonym for integral type is integer type. The representations of integral types shall define values by use of a pure binary numeration system.\(^{48}\) [Example: this International Standard permits 2's complement, 1's complement and signed magnitude representations for integral types. —end example]

8 There are three floating point types: float, double, and long double. The type double provides at least as much precision as float, and the type long double provides at least as much precision as double. The set of values of the type float is a subset of the set of values of the type double; the set of values of the type double is a subset of the set of values of the type long double. The value representation of floating-point types is implementation-defined. Integral and floating types are collectively called arithmetic types. Specializations of the standard template std::numeric_limits (18.2) shall specify the maximum and minimum values of each arithmetic type for an implementation.

9 The void type has an empty set of values. The void type is an incomplete type that cannot be completed. It is used as the return type for functions that do not return a value. Any expression can be explicitly converted to type cv void (5.4). An expression of type void shall be used only as an expression statement (6.2), as an operand of a comma expression (5.18), as a second or third operand of ?: (5.16), as the operand of typeid, or as the expression in a return statement (6.6.3) for a function with the return type void.

10 [Note: even if the implementation defines two or more basic types to have the same value representation, they are nevertheless different types. —end note]

3.9.2 Compound types [basic.compound]

1 Compound types can be constructed in the following ways:

- arrays of objects of a given type, 8.3.4;
- functions, which have parameters of given types and return void or references or objects of a given type, 8.3.5;
- pointers to void or objects or functions (including static members of classes) of a given type, 8.3.1;
- references to objects or functions of a given type, 8.3.2;
- classes containing a sequence of objects of various types (clause 9), a set of types, enumerations and functions for manipulating these objects (9.3), and a set of restrictions on the access to these entities (clause 11);
- unions, which are classes capable of containing objects of different types at different times, 9.5;
- enumerations, which comprise a set of named constant values. Each distinct enumeration constitutes a different enumerated type, 7.2;
- pointers to non-static 49\) class members, which identify members of a given type within objects of a given class, 8.3.3.

\(^{47}\) Therefore, enumerations (7.2) are not integral; however, enumerations can be promoted to int, unsigned int, long, or unsigned long, as specified in 4.5.

\(^{48}\) A positional representation for integers that uses the binary digits 0 and 1, in which the values represented by successive bits are additive, begin with 1, and are multiplied by successive integral power of 2, except perhaps for the bit with the highest position. (Adapted from the American National Dictionary for Information Processing Systems.)

\(^{49}\) Static class members are objects or functions, and pointers to them are ordinary pointers to objects or functions.
3.9 Types

These methods of constructing types can be applied recursively; restrictions are mentioned in 8.3.1, 8.3.4, 8.3.5, and 8.3.2.

A pointer to objects of type T is referred to as a “pointer to T.” [Example: a pointer to an object of type int is referred to as “pointer to int.”] and a pointer to an object of class X is called a “pointer to X.” —end example] Except for pointers to static members, text referring to “pointers” does not apply to pointers to members. Pointers to incomplete types are allowed although there are restrictions on what can be done with them (3.9). A valid value of an object pointer type represents either the address of a byte in memory (1.7) or a null pointer (4.10). If an object of type T is located at an address A, a pointer of type cv T* whose value is the address A is said to point to that object, regardless of how the value was obtained. [Note: for instance, the address one past the end of an array (5.7) would be considered to point to an unrelated object of the array’s element type that might be located at that address. —end note] The value representation of pointer types is implementation-defined. Pointers to cv-qualified and cv-unqualified versions (3.9.3) of layout-compatible types shall have the same value representation and alignment requirements (3.9).

Objects of cv-qualified (3.9.3) or cv-unqualified type void* (pointer to void), can be used to point to objects of unknown type. A void* shall be able to hold any object pointer. A cv-qualified or cv-unqualified (3.9.3) void* shall have the same representation and alignment requirements as a cv-qualified or cv-unqualified char*.

3.9.3 CV-qualifiers

A type mentioned in 3.9.1 and 3.9.2 is a cv-unqualified type. Each type which is a cv-unqualified complete or incomplete object type or is void (3.9) has three corresponding cv-qualified versions of its type: a const-qualified version, a volatile-qualified version, and a const-volatile-qualified version. The term object type (1.8) includes the cv-qualifiers specified when the object is created. The presence of a const specifier in a decl-specifier-seq declares an object of const-qualified object type; such object is called a const object. The presence of a volatile specifier in a decl-specifier-seq declares an object of volatile-qualified object type; such object is called a volatile object. The presence of both cv-qualifiers in a decl-specifier-seq declares an object of const-volatile-qualified object type; such object is called a const volatile object. The cv-qualified or cv-unqualified versions of a type are distinct types; however, they shall have the same representation and alignment requirements (3.9).50

A compound type (3.9.2) is not cv-qualified by the cv-qualifiers (if any) of the types from which it is compounded. Any cv-qualifiers applied to an array type affect the array element type, not the array type (8.3.4).

Each non-static, non-mutable, non-reference data member of a const-qualified class object is const-qualified, each non-static, non-reference data member of a volatile-qualified class object is volatile-qualified and similarly for members of a const-volatile class. See 8.3.5 and 9.3.2 regarding cv-qualified function types.

There is a (partial) ordering on cv-qualifiers, so that a type can be said to be more cv-qualified than another. Table 6 shows the relations that constitute this ordering.

In this International Standard, the notation cv (or cv1, cv2, etc.), used in the description of types, represents an arbitrary set of cv-qualifiers, i.e., one of \{const\}, \{volatile\}, \{const, volatile\}, or the empty set. Cv-qualifiers applied to an array type attach to the underlying element type, so the notation “cv T,” where T is an array type, refers to an array whose elements are so-qualified. Such array types can be said to be more (or less) cv-qualified than other types based

50 The same representation and alignment requirements are meant to imply interchangeability as arguments to functions, return values from functions, and members of unions.

Draft
3.10 Lvalues and rvalues [basic.lval]

Every expression is either an lvalue or an rvalue.

An lvalue refers to an object or function. Some rvalue expressions—those of class or cv-qualified class type—also refer to objects.\(^{51}\)

\[\text{Note: some built-in operators and function calls yield lvalues. [Example: if } E \text{ is an expression of pointer type, then } *E \text{ is an lvalue expression referring to the object or function to which } E \text{ points. As another example, the function} \]
\[
\quad \text{int} & f();
\]
\[
\text{yields an lvalue, so the call } f() \text{ is an lvalue expression.} \quad \text{— end example } \quad \text{— end note}\]

Other built-in operators yield rvalues, and some expect them. [Example: the unary and binary \(+\) operators expect rvalue arguments and yield rvalue results. \quad \text{— end example}\]

The discussion of each built-in operator in clause 5 indicates whether it expects lvalue operands and whether it yields an lvalue. \quad \text{— end note}\]

The result of calling a function that does not return a reference is an rvalue. User defined operators are functions, and whether such operators expect or yield lvalues is determined by their parameter and return types.

An expression which holds a temporary object resulting from a cast to a nonreference type is an rvalue (this includes the explicit creation of an object using functional notation (5.2.3)).

Whenever an lvalue appears in a context where an rvalue is expected, the lvalue is converted to an rvalue; see 4.1, 4.2, and 4.3.

The discussion of reference initialization in 8.5.3 and of temporaries in 12.2 indicates the behavior of lvalues and rvalues in other significant contexts.

Class rvalues can have cv-qualified types; non-class rvalues always have cv-unqualified types. Rvalues shall always have complete types or the void type; in addition to these types, lvalues can also have incomplete types.

An lvalue for an object is necessary in order to modify the object except that an rvalue of class type can also be used to modify its referent under certain circumstances. [Example: a member function called for an object (9.3) can modify the object. \quad \text{— end example}\]

Functions cannot be modified, but pointers to functions can be modifiable.

\(^{51}\) Expressions such as invocations of constructors and of functions that return a class type refer to objects, and the implementation can invoke a member function upon such objects, but the expressions are not lvalues.
A pointer to an incomplete type can be modifiable. At some point in the program when the pointed to type is complete, the object at which the pointer points can also be modified.

The referent of a `const`-qualified expression shall not be modified (through that expression), except that if it is of class `mutable` component, that component can be modified (7.1.5.1).

If an expression can be used to modify the object to which it refers, the expression is called *modifiable*. A program that attempts to modify an object through a nonmodifiable lvalue or rvalue expression is ill-formed.

If a program attempts to access the stored value of an object through an lvalue of other than one of the following types the behavior is undefined

- the dynamic type of the object,
- a cv-qualified version of the dynamic type of the object,
- a type similar (as defined in 4.4) to the dynamic type of the object,
- a type that is the signed or unsigned type corresponding to the dynamic type of the object,
- a type that is the signed or unsigned type corresponding to a cv-qualified version of the dynamic type of the object,
- an aggregate or union type that includes one of the aforementioned types among its members (including, recursively, a member of a subaggregate or contained union),
- a type that is a (possibly cv-qualified) base class type of the dynamic type of the object,
- a `char` or `unsigned char` type.

---

52) The intent of this list is to specify those circumstances in which an object may or may not be aliased.
Chapter 4  Standard conversions

Standard conversions are implicit conversions defined for built-in types. Clause 4 enumerates the full set of such conversions. A standard conversion sequence is a sequence of standard conversions in the following order:

- Zero or one conversion from the following set: lvalue-to-rvalue conversion, array-to-pointer conversion, and function-to-pointer conversion.
- Zero or one conversion from the following set: integral promotions, floating point promotion, integral conversions, floating point conversions, floating-integral conversions, pointer conversions, pointer to member conversions, and boolean conversions.
- Zero or one qualification conversion.

[Note: a standard conversion sequence can be empty, i.e., it can consist of no conversions. — end note] A standard conversion sequence will be applied to an expression if necessary to convert it to a required destination type.

Expressions with a given type will be implicitly converted to other types in several contexts:

- When used as operands of operators. The operator’s requirements for its operands dictate the destination type (clause 5).
- When used in the condition of an if statement or iteration statement (6.4, 6.5). The destination type is bool.
- When used in the expression of a switch statement. The destination type is integral (6.4).
- When used as the source expression for an initialization (which includes use as an argument in a function call and use as the expression in a return statement). The type of the entity being initialized is (generally) the destination type. See 8.5, 8.5.3.

[Note: For user-defined types, user-defined conversions are considered as well; see 12.3. In general, an implicit conversion sequence (13.3.3.1) consists of a standard conversion sequence followed by a user-defined conversion followed by another standard conversion sequence.

There are some contexts where certain conversions are suppressed. For example, the lvalue-to-rvalue conversion is not done on the operand of the unary & operator. Specific exceptions are given in the descriptions of those operators and
4.1 Lvalue-to-rvalue conversion

1 An lvalue (3.10) of a non-function, non-array type \( T \) can be converted to an rvalue. If \( T \) is an incomplete type, a program that necessitates this conversion is ill-formed. If the object to which the lvalue refers is not an object of type \( T \) and is not an object of a type derived from \( T \), or if the object is uninitialized, a program that necessitates this conversion has undefined behavior. If \( T \) is a non-class type, the type of the rvalue is the cv-unqualified version of \( T \). Otherwise, the type of the rvalue is \( T \).\(^{53}\)

2 The value contained in the object indicated by the lvalue is the rvalue result. When an lvalue-to-rvalue conversion occurs within the operand of \texttt{sizeof} (5.3.3) the value contained in the referenced object is not accessed, since that operator does not evaluate its operand.

3 \[ \text{Note: See also 3.10.} — \text{end note} \]

4.2 Array-to-pointer conversion

1 An lvalue or rvalue of type “array of \( N \) \( T \)” or “array of unknown bound of \( T \)” can be converted to an rvalue of type “pointer to \( T \)” The result is a pointer to the first element of the array.

2 A string literal (2.13.4) that is not a wide string literal can be converted to an rvalue of type “pointer to char”; a wide string literal can be converted to an rvalue of type “pointer to wchar_t”. In either case, the result is a pointer to the first element of the array. This conversion is considered only when there is an explicit appropriate pointer target type, and not when there is a general need to convert from an lvalue to an rvalue. [\textit{Note}: this conversion is deprecated. See Annex D. — \textit{end note}] For the purpose of ranking in overload resolution (13.3.3.1.1), this conversion is considered an array-to-pointer conversion followed by a qualification conversion (4.4). [\textit{Example}: “abc” is converted to “pointer to \texttt{const char}” as an array-to-pointer conversion, and then to “pointer to \texttt{char}” as a qualification conversion. — \textit{end example}]

4.3 Function-to-pointer conversion

1 An lvalue of function type \( T \) can be converted to an rvalue of type “pointer to \( T \).” The result is a pointer to the function.\(^{54}\)

2 \[ \text{Note: See 13.4 for additional rules for the case where the function is overloaded.} — \text{end note} \]

4.4 Qualification conversions

1 An rvalue of type “pointer to \( cv1 \ T \)” can be converted to an rvalue of type “pointer to \( cv2 \ T \)” if “\( cv2 \ T \)” is more cv-qualified than “\( cv1 \ T \)”.

2 An rvalue of type “pointer to member of \( X \) of type \( cv1 \ T \)” can be converted to an rvalue of type “pointer to member of \( X \) of type \( cv2 \ T \)” if “\( cv2 \ T \)” is more cv-qualified than “\( cv1 \ T \)”.

3 \[ \text{Note: Function types (including those used in pointer to member function types) are never cv-qualified (8.3.5).} — \text{end note} \]

4 A conversion can add cv-qualifiers at levels other than the first in multi-level pointers, subject to the following rules:\(^{55}\)

\(^{53}\) In C++ class rvalues can have cv-qualified types (because they are objects). This differs from ISO C, in which non-lvalues never have cv-qualified types.

\(^{54}\) This conversion never applies to non-static member functions because an lvalue that refers to a non-static member function cannot be obtained.

\(^{55}\) These rules ensure that const-safety is preserved by the conversion.

Draft
Two pointer types $T_1$ and $T_2$ are similar if there exists a type $T$ and integer $n > 0$ such that:

$$T_1 \text{ is } cv_{1,0} \text{ pointer to } cv_{1,1} \text{ pointer to } \cdots \text{ pointer to } cv_{1,n-1} \text{ pointer to } cv_{1,n} T$$

and

$$T_2 \text{ is } cv_{2,0} \text{ pointer to } cv_{2,1} \text{ pointer to } \cdots \text{ pointer to } cv_{2,n-1} \text{ pointer to } cv_{2,n} T$$

where each $cv_{i,j}$ is const, volatile, const volatile, or nothing. The n-tuple of cv-qualifiers after the first in a pointer type, e.g., $cv_{1,1}, cv_{1,2}, \ldots, cv_{1,n}$ in the pointer type $T_1$, is called the cv-qualification signature of the pointer type. An expression of type $T_1$ can be converted to type $T_2$ if and only if the following conditions are satisfied:

- the pointer types are similar.
- for every $j > 0$, if const is in $cv_{1,j}$ then const is in $cv_{2,j}$, and similarly for volatile.
- if the $cv_{1,j}$ and $cv_{2,j}$ are different, then const is in every $cv_{2,k}$ for $0 < k < j$.

[Note: if a program could assign a pointer of type $T**$ to a pointer of type const $T**$ (that is, if line //1 below was allowed), a program could inadvertently modify a const object (as it is done on line //2). For example,

```c
int main() {
    const char c = 'c';
    char* pc;
    const char** pcc = &pc; // 1: not allowed
    *pcc = &c;
    *pc = 'C'; // 2: modifies a const object
}
```

—end note]
An rvalue of type \texttt{wchar}_t (3.9.1) can be converted to an rvalue of the first of the following types that can represent all the values of its underlying type: \texttt{int}, \texttt{unsigned int}, \texttt{long}, or \texttt{unsigned long}. An rvalue of an enumeration type (7.2) can be converted to an rvalue of the first of the following types that can represent all the values of the enumeration (i.e. the values in the range \( b_{\text{min}} \) to \( b_{\text{max}} \) as described in 7.2): \texttt{int}, \texttt{unsigned int}, \texttt{long}, or \texttt{unsigned long}.

An rvalue for an integral bit-field (9.6) can be converted to an rvalue of type \texttt{int} if \texttt{int} can represent all the values of the bit-field; otherwise, it can be converted to \texttt{unsigned int} if \texttt{unsigned int} can represent all the values of the bit-field. If the bit-field is larger yet, no integral promotion applies to it. If the bit-field has an enumerated type, it is treated as any other value of that type for promotion purposes.

An rvalue of type \texttt{bool} can be converted to an rvalue of type \texttt{int}, with \texttt{false} becoming zero and \texttt{true} becoming one.

These conversions are called \textit{integral promotions}.

### 4.6 Floating point promotion [conv.fpprom]

An rvalue of type \texttt{float} can be converted to an rvalue of type \texttt{double}. The value is unchanged.

This conversion is called \textit{floating point promotion}.

### 4.7 Integral conversions [conv.integral]

An rvalue of an integer type can be converted to an rvalue of another integer type. An rvalue of an enumeration type can be converted to an rvalue of an integer type.

If the destination type is unsigned, the resulting value is the least unsigned integer congruent to the source integer (modulo \( 2^n \) where \( n \) is the number of bits used to represent the unsigned type). [\textit{Note}: In a two's complement representation, this conversion is conceptual and there is no change in the bit pattern (if there is no truncation). \textit{— end note}]

If the destination type is signed, the value is unchanged if it can be represented in the destination type (and bit-field width); otherwise, the value is implementation-defined.

If the destination type is \texttt{bool}, see 4.12. If the source type is \texttt{bool}, the value \texttt{false} is converted to zero and the value \texttt{true} is converted to one.

The conversions allowed as integral promotions are excluded from the set of integral conversions.

### 4.8 Floating point conversions [conv.double]

An rvalue of floating point type can be converted to an rvalue of another floating point type. If the source value can be exactly represented in the destination type, the result of the conversion is that exact representation. If the source value is between two adjacent destination values, the result of the conversion is an implementation-defined choice of either of those values. Otherwise, the behavior is undefined.

The conversions allowed as floating point promotions are excluded from the set of floating point conversions.

### 4.9 Floating-integral conversions [conv.fpint]

An rvalue of a floating point type can be converted to an rvalue of an integer type. The conversion truncates; that is, the fractional part is discarded. The behavior is undefined if the truncated value cannot be represented in the destination type. [\textit{Note}: If the destination type is \texttt{bool}, see 4.12. \textit{— end note}]

An rvalue of an integer type or of an enumeration type can be converted to an rvalue of a floating point type. The result is exact if possible. Otherwise, it is an implementation-defined choice of either the next lower or higher representable
value. [Note: loss of precision occurs if the integral value cannot be represented exactly as a value of the floating type. —end note] If the source type is `bool`, the value `false` is converted to zero and the value `true` is converted to one.

### 4.10 Pointer conversions

1. A null pointer constant is an integral constant expression (5.19) rvalue of integer type that evaluates to zero. A null pointer constant can be converted to a pointer type; the result is the null pointer value of that type and is distinguishable from every other value of pointer to object or pointer to function type. Two null pointer values of the same type shall compare equal. The conversion of a null pointer constant to a pointer to cv-qualified type is a single conversion, and not the sequence of a pointer conversion followed by a qualification conversion (4.4).

2. An rvalue of type “pointer to cv T,” where T is an object type, can be converted to an rvalue of type “pointer to cv void”. The result of converting a “pointer to cv T” to a “pointer to cv void” points to the start of the storage location where the object of type T resides, as if the object is a most derived object (1.8) of type T (that is, not a base class subobject).

3. An rvalue of type “pointer to cv D”, where D is a class type, can be converted to an rvalue of type “pointer to cv B”, where B is a base class (clause 10) of D. If B is an inaccessible (clause 11) or ambiguous (10.2) base class of D, a program that necessitates this conversion is ill-formed. The result of the conversion is a pointer to the base class subobject of the derived class object. The null pointer value is converted to the null pointer value of the destination type.

### 4.11 Pointer to member conversions

1. A null pointer constant (4.10) can be converted to a pointer to member type; the result is the null member pointer value of that type and is distinguishable from any pointer to member not created from a null pointer constant. Two null member pointer values of the same type shall compare equal. The conversion of a null pointer constant to a pointer to member of cv-qualified type is a single conversion, and not the sequence of a pointer to member conversion followed by a qualification conversion (4.4).

2. An rvalue of type “pointer to member of B of type cv T”, where B is a class type, can be converted to an rvalue of type “pointer to member of D of type cv T”, where D is a derived class (clause 10) of B. If B is an inaccessible (clause 11), ambiguous (10.2) or virtual (10.1) base class of D, a program that necessitates this conversion is ill-formed. The result of the conversion refers to the same member as the pointer to member before the conversion took place, but it refers to the base class member as if it were a member of the derived class. The result refers to the member in D’s instance of B. Since the result has type “pointer to member of D of type cv T”, it can be dereferenced with a D object. The result is the same as if the pointer to member of B were dereferenced with the B subobject of D. The null member pointer value is converted to the null member pointer value of the destination type.\(^{56}\)

### 4.12 Boolean conversions

1. An rvalue of arithmetic, enumeration, pointer, or pointer to member type can be converted to an rvalue of type `bool`. A zero value, null pointer value, or null member pointer value is converted to `false` any other value is converted to `true`.

---

\(^{56}\) The rule for conversion of pointers to members (from pointer to member of base to pointer to member of derived) appears inverted compared to the rule for pointers to objects (from pointer to derived to pointer to base) (4.10, clause 10). This inversion is necessary to ensure type safety. Note that a pointer to member is not a pointer to object or a pointer to function and the rules for conversions of such pointers do not apply to pointers to members. In particular, a pointer to member cannot be converted to a `void*`. Draft
Chapter 5  Expressions

1  [Note: Clause 5 defines the syntax, order of evaluation, and meaning of expressions. An expression is a sequence of operators and operands that specifies a computation. An expression can result in a value and can cause side effects.]

2  Operators can be overloaded, that is, given meaning when applied to expressions of class type (clause 9) or enumeration type (7.2). Uses of overloaded operators are transformed into function calls as described in 13.5. Overloaded operators obey the rules for syntax specified in clause 5, but the requirements of operand type, lvalue, and evaluation order are replaced by the rules for function call. Relations between operators, such as ++a meaning a+=1, are not guaranteed for overloaded operators (13.5), and are not guaranteed for operands of type bool. — end note ]

3  Clause 5 defines the effects of operators when applied to types for which they have not been overloaded. Operator overloading shall not modify the rules for the built-in operators, that is, for operators applied to types for which they are defined by this Standard. However, these built-in operators participate in overload resolution, and as part of that process user-defined conversions will be considered where necessary to convert the operands to types appropriate for the built-in operator. If a built-in operator is selected, such conversions will be applied to the operands before the operation is considered further according to the rules in clause 5; see 13.3.1.2, 13.6.

4  Except where noted, the order of evaluation of operands of individual operators and subexpressions of individual expressions, and the order in which side effects take place, is unspecified. Between the previous and next sequence point a scalar object shall have its stored value modified at most once by the evaluation of an expression. Furthermore, the prior value shall be accessed only to determine the value to be stored. The requirements of this paragraph shall be met for each allowable ordering of the subexpressions of a full expression; otherwise the behavior is undefined. [Example:

```c
i = v[i++];           // the behavior is undefined
i = 7, i++, i++;      // i becomes 9
i = ++i + 1;          // the behavior is undefined
i = i + 1;            // the value of i is incremented
```
— end example ]

5  If during the evaluation of an expression, the result is not mathematically defined or not in the range of representable values for its type, the behavior is undefined, unless such an expression is a constant expression (5.19), in which case the program is ill-formed. [Note: most existing implementations of C++ ignore integer overflows. Treatment of division by zero, forming a remainder using a zero divisor, and all floating point exceptions vary among machines, and is usually adjustable by a library function. — end note ]

6  If an expression initially has the type “reference to T (8.3.2, 8.5.3), the type is adjusted to T prior to any further analysis, the expression designates the object or function denoted by the reference, and the expression is an lvalue.

57) The precedence of operators is not directly specified, but it can be derived from the syntax.
### 5.1 Primary expressions

#### Expressions

7 An expression designating an object is called an *object-expression*.

8 Whenever an lvalue expression appears as an operand of an operator that expects an rvalue for that operand, the lvalue-to-rvalue (4.1), array-to-pointer (4.2), or function-to-pointer (4.3) standard conversions are applied to convert the expression to an rvalue. [Note: because cv-qualifiers are removed from the type of an expression of non-class type when the expression is converted to an rvalue, an lvalue expression of type `const int` can, for example, be used where an rvalue expression of type `int` is required. — end note]

9 Many binary operators that expect operands of arithmetic or enumeration type cause conversions and yield result types in a similar way. The purpose is to yield a common type, which is also the type of the result. This pattern is called the *usual arithmetic conversions*, which are defined as follows:

- If either operand is of type `long double`, the other shall be converted to `long double`.
- Otherwise, if either operand is `double`, the other shall be converted to `double`.
- Otherwise, if either operand is `float`, the other shall be converted to `float`.
- Otherwise, the integral promotions (4.5) shall be performed on both operands. 58)
- Then, if either operand is `unsigned long`, the other shall be converted to `unsigned long`.
- Otherwise, if one operand is a `long int` and the other `unsigned int`, then if a `long int` can represent all the values of an `unsigned int`, the `unsigned int` shall be converted to a `long int` otherwise both operands shall be converted to `unsigned long int`.
- Otherwise, if either operand is `long`, the other shall be converted to `long`.
- Otherwise, if either operand is `unsigned`, the other shall be converted to `unsigned`.

[Note: otherwise, the only remaining case is that both operands are `int` — end note]

10 The values of the floating operands and the results of floating expressions may be represented in greater precision and range than that required by the type; the types are not changed thereby. 59)

---

58) As a consequence, operands of type `bool`, `uchar_t`, or an enumerated type are converted to some integral type.

59) The cast and assignment operators must still perform their specific conversions as described in 5.4, 5.2.9 and 5.17.
primary-expression:
  literal
  this
    ( expression )
  id-expression

id-expression:
  unqualified-id
  qualified-id

unqualified-id:
  identifier
  operator-function-id
  conversion-function-id
  ~ class-name
template-id

A literal is a primary expression. Its type depends on its form (2.13). A string literal is an lvalue; all other literals are rvalues.

The keyword this names a pointer to the object for which a non-static member function (9.3.2) is invoked. The keyword this shall be used only inside a non-static class member function body (9.3) or in a constructor mem-initializer (12.6.2). The type of the expression is a pointer to the function’s class (9.3.2), possibly with cv-qualifiers on the class type. The expression is an rvalue.

The operator :: followed by an identifier, a qualified-id, or an operator-function-id is a primary-expression. Its type is specified by the declaration of the identifier, qualified-id, or operator-function-id. The result is the entity denoted by the identifier, qualified-id, or operator-function-id. The result is an lvalue if the entity is a function or variable. The identifier, qualified-id, or operator-function-id shall have global namespace scope or be visible in global scope because of a using-directive (7.3.4). [Note: the use of :: allows a type, an object, a function, an enumerator, or a namespace declared in the global namespace to be referred to even if its identifier has been hidden (3.4.3). — end note]

A parenthesized expression is a primary expression whose type and value are identical to those of the enclosed expression. The presence of parentheses does not affect whether the expression is an lvalue. The parenthesized expression can be used in exactly the same contexts as those where the enclosed expression can be used, and with the same meaning, except as otherwise indicated.

An id-expression is a restricted form of a primary-expression. [Note: an id-expression can appear after . and -> operators (5.2.5). — end note]

An identifier is an id-expression provided it has been suitably declared (clause 7). [Note: for operator-function-ids, see 13.5; for conversion-function-ids, see 12.3.2; for template-ids, see 14.2. A class-name prefixed by ~ denotes a destructor; see 12.4. Within the definition of a non-static member function, an identifier that names a non-static member is transformed to a class member access expression (9.3.1). — end note] The type of the expression is the type of the identifier. The result is the entity denoted by the identifier. The result is an lvalue if the entity is a function, variable, or data member.

qualified-id:
  ::opt nested-nameSpecifier template_opt unqualified-id
  :: identifier
  :: operator-function-id
  :: template-id
nested-name-specifier:
  type-name ::
  namespace-name ::
  nested-name-specifier identifier ::
  nested-name-specifier templateopt template-id ::

A nested-name-specifier that names a class, optionally followed by the keyword \texttt{template} (14.2), and then followed by the name of a member of either that class (9.2) or one of its base classes (clause 10), is a qualified-id; 3.4.3.1 describes name lookup for class members that appear in \texttt{qualified-ids}. The result is the member. The type of the result is the type of the member. The result is an lvalue if the member is a static member function or a data member. [\textit{Note}: a class member can be referred to using a qualified-id at any point in its potential scope (3.3.6). — end note] Where \texttt{class-name :: class-name} is used, and the two \textit{class-names} refer to the same class, this notation names the constructor (12.1). Where \texttt{class-name :: \sim class-name} is used, the two \textit{class-names} shall refer to the same class; this notation names the destructor (12.4). [\textit{Note}: a typedef-name that names a class is a \texttt{class-name} (9.1). — end note]

8 A nested-name-specifier that names a namespace (7.3), followed by the name of a member of that namespace (or the name of a member of a namespace made visible by a using-directive ) is a qualified-id; 3.4.3.2 describes name lookup for namespace members that appear in \texttt{qualified-ids}. The result is the member. The type of the result is the type of the member. The result is an lvalue if the member is a function or a variable.

9 In a qualified-id, if the \textit{id-expression} is a conversion-function-id, its \textit{conversion-type-id} shall denote the same type in both the context in which the entire qualified-id occurs and in the context of the class denoted by the nested-name-specifier.

10 An \textit{id-expression} that denotes a non-static data member or non-static member function of a class can only be used:
    — as part of a class member access (5.2.5) in which the object-expression refers to the member’s class or a class derived from that class, or
    — to form a pointer to member (5.3.1), or
    — in the body of a non-static member function of that class or of a class derived from that class (9.3.1), or
    — in a \texttt{mem-initializer} for a constructor for that class or for a class derived from that class (12.6.2).

5.2 Postfix expressions
[expr.post]

Postfix expressions group left-to-right.
postfix-expression:
  primary-expression
  postfix-expression [ expression ]
  postfix-expression ( expression-list_opt )
  simple-type-specifier ( expression-list_opt )
  typename-specifier ( expression-list_opt )
  postfix-expression . template_opt id-expression
  postfix-expression -> template_opt id-expression
  postfix-expression . pseudo-destructor-name
  postfix-expression -> pseudo-destructor-name
  postfix-expression ++
  postfix-expression --
  dynamic_cast < type-id > ( expression )
  static_cast < type-id > ( expression )
  reinterpret_cast < type-id > ( expression )
  const_cast < type-id > ( expression )
  typeid ( expression )
  typeid ( type-id )

expression-list:
  assignment-expression
  expression-list , assignment-expression

pseudo-destructor-name:
  ::opt nested-name-specifier_opt type-name :: ~ type-name
  ::opt nested-name-specifier template template-id :: ~ type-name
  ::opt nested-name-specifier_opt ~ type-name

5.2.1 Subscripting [expr.sub]

A postfix expression followed by an expression in square brackets is a postfix expression. One of the expressions shall have the type ‘pointer to T’ and the other shall have enumeration or integral type. The result is an lvalue of type “T.” The type “T” shall be a completely-defined object type. The expression \( E_1[E_2] \) is identical (by definition) to \( *((E_1)+(E_2)) \) [Note: see 5.3 and 5.7 for details of \* and + and 8.3.4 for details of arrays. — end note]

5.2.2 Function call [expr.call]

There are two kinds of function call: ordinary function call and member function\(^{61}\) (9.3) call. A function call is a postfix expression followed by parentheses containing a possibly empty, comma-separated list of expressions which constitute the arguments to the function. For an ordinary function call, the postfix expression shall be either an lvalue that refers to a function (in which case the function-to-pointer standard conversion (4.3) is suppressed on the postfix expression), or it shall have pointer to function type. Calling a function through an expression whose function type has a language linkage that is different from the language linkage of the function type of the called function’s definition is undefined (7.5). For a member function call, the postfix expression shall be an implicit (9.3.1, 9.4) or explicit class member access (5.2.5) whose id-expression is a function member name, or a pointer-to-member expression (5.5) selecting a function member. The first expression in the postfix expression is then called the object expression, and the call is as a member of the object pointed to or referred to. In the case of an implicit class member access, the implied object is the one pointed to by this [Note: a member function call of the form \( f() \) is interpreted as \((*\text{this}).f()\) (see 9.3.1). — end note] If a function or member function name is used, the name can be overloaded (clause 13), in which case the appropriate function shall be

\(^{60}\) This is true even if the subscript operator is used in the following common idiom: \&x[0].

\(^{61}\) A static member function (9.4) is an ordinary function.
selected according to the rules in 13.3. The function called in a member function call is normally selected according to the static type of the object expression (clause 10), but if that function is virtual and is not specified using a qualified-id then the function actually called will be the final overrider (10.3) of the selected function in the dynamic type of the object expression [Note: the dynamic type is the type of the object pointed or referred to by the current value of the object expression. 12.7 describes the behavior of virtual function calls when the object-expression refers to an object under construction or destruction. — end note]

[Note: if a function or member function name is used, and name lookup (3.4) does not find a declaration of that name, the program is ill-formed. No function is implicitly declared by such a call. — end note]

The type of the function call expression is the return type of the statically chosen function (i.e., ignoring the virtual keyword), even if the type of the function actually called is different. This type shall be a complete object type, a reference type or the type void.

When a function is called, each parameter (8.3.5) shall be initialized (8.5, 12.8, 12.1) with its corresponding argument. If the function is a non-static member function, the this parameter of the function (9.3.2) shall be initialized with a pointer to the object of the call, converted as if by an explicit type conversion (5.4). [Note: There is no access or ambiguity checking on this conversion; the access checking and disambiguation are done as part of the (possibly implicit) class member access operator. See 10.2, 11.2, and 5.2.5. — end note] When a function is called, the parameters that have object type shall have completely-defined object type. [Note: this still allows a parameter to be a pointer or reference to an incomplete class type. However, it prevents a passed-by-value parameter to have an incomplete class type. — end note] During the initialization of a parameter, an implementation may avoid the construction of extra temporaries by combining the conversions on the associated argument and/or the construction of temporaries with the initialization of the parameter (see 12.2). The lifetime of a parameter ends when the function in which it is defined returns. The initialization and destruction of each parameter occurs within the context of the calling function. [Example: the access of the constructor, conversion functions or destructor is checked at the point of call in the calling function. If a constructor or destructor for a function parameter throws an exception, the search for a handler starts in the scope of the calling function; in particular, if the function called has a function-try-block (clause 15) with a handler that could handle the exception, this handler is not considered. — end example] The value of a function call is the value returned by the called function except in a virtual function call if the return type of the final overrider is different from the return type of the statically chosen function, the value returned from the final overrider is converted to the return type of the statically chosen function.

[Note: a function can change the values of its non-const parameters, but these changes cannot affect the values of the arguments except where a parameter is of a reference type (8.3.2); if the reference is to a const-qualified type, const_cast is required to be used to cast away the constness in order to modify the argument’s value. Where a parameter is of const reference type a temporary object is introduced if needed (7.1.5, 2.13, 2.13.4, 8.3.4, 12.2). In addition, it is possible to modify the values of nonconstant objects through pointer parameters. — end note]

A function can be declared to accept fewer arguments (by declaring default arguments (8.3.6)) or more arguments (by using the ellipsis, . . . 8.3.5) than the number of parameters in the function definition (8.4). [Note: this implies that, except where the ellipsis ( . . . ) is used, a parameter is available for each argument. — end note]

When there is no parameter for a given argument, the argument is passed in such a way that the receiving function can obtain the value of the argument by invoking va_arg (18.7). The lvalue-to-rvalue (4.1), array-to-pointer (4.2), and function-to-pointer (4.3) standard conversions are performed on the argument expression. After these conversions, if the argument does not have arithmetic, enumeration, pointer, pointer to member, or class type, the program is ill-formed. If the argument has a non-POD class type (clause 9), the behavior is undefined. If the argument has integral or enumeration type that is subject to the integral promotions (4.5), or a floating point type that is subject to the floating point promotion
Expressions

5.2 Postfix expressions

(4.6), the value of the argument is converted to the promoted type before the call. These promotions are referred to as the default argument promotions.

8 The order of evaluation of arguments is unspecified. All side effects of argument expression evaluations take effect before the function is entered. The order of evaluation of the postfix expression and the argument expression list is unspecified.

9 Recursive calls are permitted, except to the function named main (3.6.1).

10 A function call is an lvalue if and only if the result type is a reference.

5.2.3 Explicit type conversion (functional notation) [expr.type.conv]

1 A simple-type-specifier (7.1.5) followed by a parenthesized expression-list constructs a value of the specified type given the expression list. If the expression list is a single expression, the type conversion expression is equivalent (in definedness, and if defined in meaning) to the corresponding cast expression (5.4). If the simple-type-specifier specifies a class type, the class type shall be complete. If the expression list specifies more than a single value, the type shall be a class with a suitably declared constructor (8.5, 12.1), and the expression \( T(x_1, x_2, \ldots) \) is equivalent in effect to the declaration \( T t(x_1, x_2, \ldots) \); for some invented temporary variable \( t \), with the result being the value of \( t \) as an rvalue.

2 The expression \( T() \), where \( T \) is a simple-type-specifier (7.1.5.2) for a non-array complete object type or the (possibly cv-qualified) void type, creates an rvalue of the specified type, which is value-initialized (8.5; no initialization is done for the void() case). [Note: if \( T \) is a non-class type that is cv-qualified, the cv-qualifiers are ignored when determining the type of the resulting rvalue (3.10). —end note ]

5.2.4 Pseudo destructor call [expr.pseudo]

1 The use of a pseudo-destructor-name after a dot . or arrow \( \rightarrow \) operator represents the destructor for the non-class type named by type-name. The result shall only be used as the operand for the function call operator () , and the result of such a call has type void. The only effect is the evaluation of the postfix-expression before the dot or arrow.

2 The left-hand side of the dot operator shall be of scalar type. The left-hand side of the arrow operator shall be of pointer to scalar type. This scalar type is the object type. The type designated by the pseudo-destructor-name shall be the same as the object type. Furthermore, the two type-names in a pseudo-destructor-name of the form

\[
::opt\text{nested-name-specifier}_{opt}\text{type-name}::\sim\text{type-name}
\]

shall designate the same scalar type. The cv-unqualified versions of the object type and of the type designated by the pseudo-destructor-name shall be the same type.

5.2.5 Class member access [expr.ref]

1 A postfix expression followed by a dot . or an arrow \( \rightarrow \), optionally followed by the keyword template (14.8.1), and then followed by an id-expression, is a postfix expression. The postfix expression before the dot or arrow is evaluated; \(^{62}\) the result of that evaluation, together with the id-expression, determine the result of the entire postfix expression.

2 For the first option (dot) the type of the first expression (the object expression) shall be “class object” (of a complete type). For the second option (arrow) the type of the first expression (the pointer expression) shall be “pointer to class object” (of a complete type). In these cases, the id-expression shall name a member of the class or of one of its base

\(^{62}\) This evaluation happens even if the result is unnecessary to determine the value of the entire postfix expression, for example if the id-expression denotes a static member.
classes. [Note: because the name of a class is inserted in its class scope (clause 9), the name of a class is also considered a nested member of that class. — end note] [Note: 3.4.5 describes how names are looked up after the . and -> operators. — end note]

If E1 has the type “pointer to class X,” then the expression E1->E2 is converted to the equivalent form (* (E1) ). E2; the remainder of 5.2.5 will address only the first option (dot). Abbreviating object-expression.id-expression as E1 . E2, then the type and lvalue properties of this expression are determined as follows. In the remainder of 5.2.5, cq represents either const or the absence of const vq represents either volatile or the absence of volatile. cv represents an arbitrary set of cv-qualifiers, as defined in 3.9.3.

If E2 is declared to have type “reference to T,” then E1 . E2 is an lvalue; the type of E1 . E2 is T. Otherwise, one of the following rules applies.

— If E2 is a static data member, and the type of E2 is T, then E1 . E2 is an lvalue; the expression designates the named member of the class. The type of E1 . E2 is T.

— If E2 is a non-static data member, and the type of E1 is “cq1 vq1 X”, and the type of E2 is “cq2 vq2 T”, the expression designates the named member of the object designated by the first expression. If E1 is an lvalue, then E1 . E2 is an lvalue; otherwise, it is an rvalue. Let the notation vq12 stand for the “union” of vq1 and vq2; that is, if vq1 or vq2 is volatile, then vq12 is volatile. Similarly, let the notation cq12 stand for the “union” of cq1 and cq2; that is, if cq1 or cq2 is const, then cq12 is const. If E2 is declared to be a mutable member, then the type of E1 . E2 is “vq12 T”. If E2 is not declared to be a mutable member, then the type of E1 . E2 is “cq12 vq12 T”.

— If E2 is a (possibly overloaded) member function, function overload resolution (13.3) is used to determine whether E1 . E2 refers to a static or a non-static member function.

— If it refers to a static member function, and the type of E2 is “function of parameter-type-list returning T”, then E1 . E2 is an lvalue; the expression designates the static member function. The type of E1 . E2 is the same type as that of E2, namely “function of parameter-type-list returning T”.

— Otherwise, if E1 . E2 refers to a non-static member function, and the type of E2 is “function of parameter-type-list cv returning T”, then E1 . E2 is not an lvalue. The expression designates a non-static member function. The expression can be used only as the left-hand operand of a member function call (9.3). [Note: any redundant set of parentheses surrounding the expression is ignored (5.1). — end note] The type of E1 . E2 is “function of parameter-type-list cv returning T”.

— If E2 is a nested type, the expression E1 . E2 is ill-formed.

— If E2 is a member enumerator, and the type of E2 is T, the expression E1 . E2 is not an lvalue. The type of E1 . E2 is T.

[Note: “class objects” can be structures (9.2) and unions (9.5). Classes are discussed in clause 9. — end note]

If E2 is a non-static data member or a non-static member function, the program is ill-formed if the class of which E2 is directly a member is an ambiguous base (10.2) of the naming class (11.2) of E2.

63) Note that if E1 has the type “pointer to class X,” then (* (E1) ) is an lvalue.
5.2.6 Increment and decrement

The value obtained by applying a postfix ++ is the value that the operand had before applying the operator. [Note: the value obtained is a copy of the original value — end note] The operand shall be a modifiable lvalue. The type of the operand shall be an arithmetic type or a pointer to a complete object type. After the result is noted, the value of the object is modified by adding 1 to it, unless the object is of type bool, in which case it is set to true. [Note: this use is deprecated, see Annex D. — end note] The result is an rvalue. The type of the result is the cv-unqualified version of the type of the operand. See also 5.7 and 5.17.

The operand of postfix -- is decremented analogously to the postfix ++ operator, except that the operand shall not be of type bool. [Note: For prefix increment and decrement, see 5.3.2. — end note]

5.2.7 Dynamic cast

The result of the expression dynamic_cast<T>(v) is the result of converting the expression v to type T. T shall be a pointer or reference to a complete class type, or “pointer to cv void.” Types shall not be defined in a dynamic_cast. The dynamic_cast operator shall not cast away constness (5.2.11).

2 If T is a pointer type, v shall be an rvalue of a pointer to complete class type, and the result is an rvalue of type T. If T is a reference type, v shall be an lvalue of a complete class type, and the result is an lvalue of the type referred to by T.

3 If the type of v is the same as the required result type (which, for convenience, will be called R in this description), or it is the same as R except that the class object type in R is more cv-qualified than the class object type in v, the result is v (converted if necessary).

4 If the value of v is a null pointer value in the pointer case, the result is the null pointer value of type R.

5 If T is “pointer to cv1 B” and v has type “pointer to cv2 D” such that B is a base class of D, the result is a pointer to the unique B subobject of the D object pointed to by v. Similarly, if T is “reference to cv1 B” and v has type cv2 D such that B is a base class of D, the result is an lvalue for the unique B subobject of the D object referred to by v. 64) In both the pointer and reference cases, cv1 shall be the same cv-qualification as, or greater cv-qualification than, cv2, and B shall be an accessible unambiguous base class of D. [Example:

```c
struct B {};  
struct D : B {};  
void foo(D* dp)  
{  
    B* bp = dynamic_cast<B*>(dp);  // equivalent to B* bp = dp;  
}  
```

— end example]

6 Otherwise, v shall be a pointer to or an lvalue of a polymorphic type (10.3).

7 If T is “pointer to cv void,” then the result is a pointer to the most derived object pointed to by v. Otherwise, a run-time check is applied to see if the object pointed or referred to by v can be converted to the type pointed or referred to by T.

8 The run-time check logically executes as follows:

64) The most derived object (1.8) pointed or referred to by v can contain other B objects as base classes, but these are ignored.
If, in the most derived object pointed (referred) to by v, v points (refers) to a public base class subobject of a T object, and if only one object of type T is derived from the subobject pointed (referred) to by v the result is a pointer (an lvalue referring) to that T object.

Otherwise, if v points (refers) to a public base class subobject of the most derived object, and the type of the most derived object has a base class, of type T, that is unambiguous and public, the result is a pointer (an lvalue referring) to the T subobject of the most derived object.

Otherwise, the run-time check fails.

The value of a failed cast to pointer type is the null pointer value of the required result type. A failed cast to reference type throws std::bad_cast (18.5.2).

Example:

```cpp
class A { virtual void f(); };  
class B { virtual void g(); };  
class D : public virtual A, private B {};  
void g()
{
    D d;  
    B* bp = (B*)&d;  // cast needed to break protection
    A* ap = &d;  // public derivation, no cast needed
    D& dr = dynamic_cast<D&>(*bp);  // fails
    ap = dynamic_cast<A*>(bp);  // fails
    bp = dynamic_cast<B*>(ap);  // fails
    ap = dynamic_cast<A*>(&d);  // succeeds
    bp = dynamic_cast<B*>(&d);  // fails
}

class E : public D, public B {};  
class F : public E, public D {};  
void h()
{
    F f;  
    A* ap = &f;  // succeeds: finds unique A
    D* dp = dynamic_cast<D*>(ap);  // fails: yields 0
       // f has two D subobjects
    E* ep = (E*)ap;  // ill-formed:
       // cast from virtual base
    E* ep1 = dynamic_cast<E*>(ap);  // succeeds
}
```

— end example ] [ Note: 12.7 describes the behavior of a dynamic_cast applied to an object under construction or destruction. — end note ]

5.2.8 Type identification

The result of a typeid expression is an lvalue of static type const std::type_info (18.5.1) and dynamic type const std::type_info or const name where name is an implementation-defined class derived from std::type_info
which preserves the behavior described in 18.5.1.\(^{65}\) The lifetime of the object referred to by the lvalue extends to the end of the program. Whether or not the destructor is called for the std::type_info object at the end of the program is unspecified.

2 When typeid is applied to an lvalue expression whose type is a polymorphic class type (10.3), the result refers to a std::type_info object representing the type of the most derived object (1.8) (that is, the dynamic type) to which the lvalue refers. If the lvalue expression is obtained by applying the unary * operator to a pointer\(^{66}\) and the pointer is a null pointer value (4.10), the typeid expression throws the std::bad_typeid exception (18.5.3).

3 When typeid is applied to an expression other than an lvalue of a polymorphic class type, the result refers to a std::type_info object representing the static type of the expression. Lvalue-to-rvalue (4.1), array-to-pointer (4.2), and function-to-pointer (4.3) conversions are not applied to the expression. If the type of the expression is a class type, the class shall be completely-defined. The expression is not evaluated.

4 When typeid is applied to a type-id, the result refers to a std::type_info object representing the type of the type-id. If the type of the type-id is a reference type, the result of the typeid expression refers to a std::type_info object representing the referenced type. If the type of the type-id is a class type or a reference to a class type, the class shall be completely-defined. Types shall not be defined in the type-id.

5 The top-level cv-qualifiers of the lvalue expression or the type-id that is the operand of typeid are always ignored.

[Example:

```cpp
    class D { ... };  
    D d1;  
    const D d2;  

    typeid(d1) == typeid(d2); // yields true  
    typeid(D)  == typeid(const D); // yields true  
    typeid(D)  == typeid(d2);     // yields true  
    typeid(D)  == typeid(const D&); // yields true  
```

—end example]

6 If the header <typeinfo> (18.5.1) is not included prior to a use of typeid, the program is ill-formed.

7 [Note: 12.7 describes the behavior of typeid applied to an object under construction or destruction. —end note]

5.2.9 Static cast

[expr.static.cast]

1 The result of the expression static_cast<T>(v) is the result of converting the expression v to type T. If T is a reference type, the result is an lvalue; otherwise, the result is an rvalue. Types shall not be defined in a static_cast. The static_cast operator shall not cast away constness (5.2.11).

2 An lvalue of type cv1 B, where B is a class type, can be cast to type “reference to cv2 D, where D is a class derived (clause 10) from B, if a valid standard conversion from “pointer to D” to “pointer to B” exists (4.10), cv2 is the same cv-qualification as, or greater cv-qualification than, cv1, and B is not a virtual base class of D. The result is an lvalue of type cv2 D. If the lvalue of type cv1 B is actually a subobject of an object of type D, the lvalue refers to the enclosing object of type D. Otherwise, the result of the cast is undefined. [Example:

---

\(^{65}\) The recommended name for such a class is extended_type_info.

\(^{66}\) If p is an expression of pointer type, then *p, (**p), *(*p), ((*p)), and so on all meet this requirement.
5.2 Postfix expressions

Expressions

```cpp
struct B {}
struct D : public B {}
D d;
B &br = d;

static_cast<D&>(br); // produces lvalue to the original d object

— end example ]
```

3 Otherwise, an expression e can be explicitly converted to a type T using a `static_cast` of the form `static_cast<T>(e)` if the declaration T t(e); is well-formed, for some invented temporary variable t (8.5). The effect of such an explicit conversion is the same as performing the declaration and initialization and then using the temporary variable as the result of the conversion. The result is an lvalue if T is a reference type (8.3.2), and an rvalue otherwise. The expression e is used as an lvalue if and only if the initialization uses it as an lvalue.

4 Otherwise, the `static_cast` shall perform one of the conversions listed below. No other conversion shall be performed explicitly using a `static_cast`.

5 Any expression can be explicitly converted to type `cv void`. The expression value is discarded. [Note: however, if the value is in a temporary variable (12.2), the destructor for that variable is not executed until the usual time, and the value of the variable is preserved for the purpose of executing the destructor. —end note] The lvalue-to-rvalue (4.1), array-to-pointer (4.2), and function-to-pointer (4.3) standard conversions are not applied to the expression.

6 The inverse of any standard conversion sequence (clause 4), other than the lvalue-to-rvalue (4.1), array-to-pointer (4.2), function-to-pointer (4.3), and boolean (4.12) conversions, can be performed explicitly using `static_cast`. A program is ill-formed if it uses `static_cast` to perform the inverse of an ill-formed standard conversion sequence. [Example:

```cpp
struct B {}
struct D : private B {}
void f() {
    static_cast<D*>(B*)0); // Error: B is a private base of D.
    static_cast<int B::*>(int D::*0); // Error: B is a private base of D.
}

— end example ]
```

7 The lvalue-to-rvalue (4.1), array-to-pointer (4.2), and function-to-pointer (4.3) conversions are applied to the operand. Such a `static_cast` is subject to the restriction that the explicit conversion does not cast away constness (5.2.11), and the following additional rules for specific cases:

8 A value of integral or enumeration type can be explicitly converted to an enumeration type. The value is unchanged if the original value is within the range of the enumeration values (7.2). Otherwise, the resulting enumeration value is unspecified.

9 An rvalue of type “pointer to cvl B,” where B is a class type, can be converted to an rvalue of type “pointer to cv2 D,” where D is a class derived (clause 10) from B, if a valid standard conversion from “pointer to D” to “pointer to B” exists (4.10), cv2 is the same cv-qualification as, or greater cv-qualification than, cvl, and B is not a virtual base class of D. The null pointer value (4.10) is converted to the null pointer value of the destination type. If the rvalue of type “pointer to cvl B” points to a B that is actually a subobject of an object of type D, the resulting pointer points to the enclosing object of type D. Otherwise, the result of the cast is undefined.

Draft
An rvalue of type “pointer to member of D of type cvl T” can be converted to an rvalue of type “pointer to member of B” of type cv2 T, where B is a base class (clause 10) of D, if a valid standard conversion from “pointer to member of B of type T” to “pointer to member of D of type T” exists (4.11), and cv2 is the same cv-qualification as, or greater cv-qualification than, cvl.67) The null member pointer value (4.11) is converted to the null member pointer value of the destination type. If class B contains the original member, or is a base or derived class of the class containing the original member, the resulting pointer to member points to the original member. Otherwise, the result of the cast is undefined. [Note: although class B need not contain the original member, the dynamic type of the object on which the pointer to member is dereferenced must contain the original member; see 5.5. — end note]

An rvalue of type “pointer to cvl void” can be converted to an rvalue of type “pointer to cv2 T,” where T is an object type and cv2 is the same cv-qualification as, or greater cv-qualification than, cvl. A value of type pointer to object converted to “pointer to cv void” and back, possibly with different cv-qualification, shall have its original value.[Example:

```cpp
    T* p1 = new T;
    const T* p2 = static_cast< const T*>(static_cast< void*>(p1));
    bool b = p1 == p2;    // b will have the value true.
```

— end example ]

5.2.10 Reinterpret cast [expr.reinterpret.cast]

The result of the expression reinterpret_cast<T>(v) is the result of converting the expression v to type T. If T is a reference type, the result is an lvalue; otherwise, the result is an rvalue and the lvalue-to-rvalue (4.1), array-to-pointer (4.2), and function-to-pointer (4.3) standard conversions are performed on the the expression v. Types shall not be defined in a reinterpret_cast. Conversions that can be performed explicitly using reinterpret_cast are listed below. No other conversion can be performed explicitly using reinterpret_cast.

2 The reinterpret_cast operator shall not cast away constness. [Note: see 5.2.11 for the definition of “casting away constness”. Subject to the restrictions in this section, an expression may be cast to its own type using a reinterpret_cast operator. — end note]

3 The mapping performed by reinterpret_cast is implementation-defined. [Note: it might, or might not, produce a representation different from the original value. — end note]

4 A pointer can be explicitly converted to any integral type large enough to hold it. The mapping function is implementation-defined. [Note: it is intended to be unsurprising to those who know the addressing structure of the underlying machine. — end note]

5 A value of integral type or enumeration type can be explicitly converted to a pointer.68) A pointer converted to an integer of sufficient size (if any such exists on the implementation) and back to the same pointer type will have its original value; mappings between pointers and integers are otherwise implementation-defined.

6 A pointer to a function can be explicitly converted to a pointer to a function of a different type. The effect of calling a function through a pointer to a function type (8.3.5) that is not the same as the type used in the definition of the function is undefined. Except that converting an rvalue of type “pointer to T1” to the type “pointer to T2” (where T1 and T2 are function types) and back to its original type yields the original pointer value, the result of such a pointer conversion is unspecified. [Note: see also 4.10 for more details of pointer conversions. — end note]

67) Function types (including those used in pointer to member function types) are never cv-qualified; see 8.3.5.

68) Converting an integral constant expression (5.19) with value zero always yields a null pointer (4.10), but converting other expressions that happen to have value zero need not yield a null pointer.
A pointer to an object can be explicitly converted to a pointer to an object of different type. Except that converting an rvalue of type “pointer to T1” to the type “pointer to T2” (where T1 and T2 are object types and where the alignment requirements of T2 are no stricter than those of T1) and back to its original type yields the original pointer value, the result of such a pointer conversion is unspecified.

Converting a pointer to a function into a pointer to an object type or vice versa is conditionally-supported. The meaning of such a conversion is implementation defined, except that if an implementation supports conversions in both directions, converting an rvalue of one type to the other type and back, possibly with different cv-qualification, shall yield the original pointer value.

The null pointer value (4.10) is converted to the null pointer value of the destination type.

An rvalue of type “pointer to member of X of type T1” can be explicitly converted to an rvalue of type “pointer to member of Y of type T2” if T1 and T2 are both function types or both object types. The null member pointer value (4.11) is converted to the null member pointer value of the destination type. The result of this conversion is unspecified, except in the following cases:

- converting an rvalue of type “pointer to member function” to a different pointer to member function type and back to its original type yields the original pointer to member value.
- converting an rvalue of type “pointer to data member of X of type T1” to the type “pointer to data member of Y of type T2 (where the alignment requirements of T2 are no stricter than those of T1) and back to its original type yields the original pointer to member value.

An lvalue expression of type T1 can be cast to the type “reference to T2” if an expression of type “pointer to T1” can be explicitly converted to the type “pointer to T2” using a reinterpret_cast. That is, a reference cast reinterpret_cast<T&>(x) has the same effect as the conversion *reinterpret_cast<T*>(&x) with the built-in & and * operators. The result is an lvalue that refers to the same object as the source lvalue, but with a different type. No temporary is created, no copy is made, and constructors (12.1) or conversion functions (12.3) are not called.

The result of the expression const_cast<T>(v) is of type T. If T is a reference type, the result is an lvalue; otherwise, the result is an rvalue and, the lvalue-to-rvalue (4.1), array-to-pointer (4.2), and function-to-pointer (4.3) standard conversions are performed on the expression v. Types shall not be defined in a const_cast. Conversions that can be performed explicitly using const_cast are listed below. No other conversion shall be performed explicitly using const_cast.

For two pointer types T1 and T2 where

\[ T1 \text{ is } cv_{1,0} \text{ pointer to } cv_{1,1} \text{ pointer to } \cdots cv_{1,n-1} \text{ pointer to } cv_{1,n} \ T \]

and

\[ T2 \text{ is } cv_{2,0} \text{ pointer to } cv_{2,1} \text{ pointer to } \cdots cv_{2,n-1} \text{ pointer to } cv_{2,n} \ T \]

The types may have different cv-qualifiers, subject to the overall restriction that a reinterpret_cast cannot cast away constness.

T1 and T2 may have different cv-qualifiers, subject to the overall restriction that a reinterpret_cast cannot cast away constness.

This is sometimes referred to as a type pun.
where \( T \) is any object type or the \( \text{void} \) type and where \( cv_{1,k} \) and \( cv_{2,k} \) may be different cv-qualifications, an rvalue of type \( T_1 \) may be explicitly converted to the type \( T_2 \) using a \( \text{const\_cast} \). The result of a pointer \( \text{const\_cast} \) refers to the original object.

4 An lvalue of type \( T_1 \) can be explicitly converted to an lvalue of type \( T_2 \) using the cast \( \text{const\_cast}<T2\&> \) (where \( T_1 \) and \( T_2 \) are object types) if a pointer to \( T_1 \) can be explicitly converted to the type pointer to \( T_2 \) using a \( \text{const\_cast} \). The result of a reference \( \text{const\_cast} \) refers to the original object.

5 For a \( \text{const\_cast} \) involving pointers to data members, multi-level pointers to data members and multi-level mixed pointers and pointers to data members (4.4), the rules for \( \text{const\_cast} \) are the same as those used for pointers; the “member” aspect of a pointer to member is ignored when determining where the cv-qualifiers are added or removed by the \( \text{const\_cast} \). The result of a pointer to data member \( \text{const\_cast} \) refers to the same member as the original (uncast) pointer to data member.

6 A null pointer value (4.10) is converted to the null pointer value of the destination type. The null member pointer value (4.11) is converted to the null member pointer value of the destination type.

7 [Note: Depending on the type of the object, a write operation through the pointer, lvalue or pointer to data member resulting from a \( \text{const\_cast} \) that casts away a const-qualifier\(^{72}\) may produce undefined behavior (7.1.5.1). — end note]

8 The following rules define the process known as casting away constness. In these rules \( T_n \) and \( X_n \) represent types. For two pointer types:

\[
\begin{align*}
X1 & = T1cv_{1,1} \cdots cv_{1,N} * \quad \text{where } T1 \text{ is not a pointer type} \\
X2 & = T2cv_{2,1} \cdots cv_{2,M} * \quad \text{where } T2 \text{ is not a pointer type} \\
K & = \min(N, M)
\end{align*}
\]

casting from \( X_1 \) to \( X_2 \) casts away constness if, for a non-pointer type \( T \) there does not exist an implicit conversion (clause 4) from:

\[
Tcv_{1,(N-K+1)} \cdots cv_{1,N} *
\]

to

\[
Tcv_{2,(M-K+1)} \cdots cv_{2,M} *
\]

9 Casting from an lvalue of type \( T_1 \) to an lvalue of type \( T_2 \) using a reference cast casts away constness if a cast from an rvalue of type “pointer to \( T_1 \)” to the type “pointer to \( T_2 \)” casts away constness.

10 Casting from an rvalue of type “pointer to data member of \( X \) of type \( T_1 \)” to the type “pointer to data member of \( Y \) of type \( T_2 \)” casts away constness if a cast from an rvalue of type “pointer to \( T_1 \)” to the type “pointer to \( T_2 \)” casts away constness.

11 For multi-level pointer to members and multi-level mixed pointers and pointer to members (4.4), the “member” aspect of a pointer to member level is ignored when determining if a \( \text{const cv-qualifier} \) has been cast away.

12 [Note: some conversions which involve only changes in cv-qualification cannot be done using \( \text{const\_cast} \). For instance, conversions between pointers to functions are not covered because such conversions lead to values whose use causes undefined behavior. For the same reasons, conversions between pointers to member functions, and in particular,

\(^{72}\) \( \text{const\_cast} \) is not limited to conversions that cast away a const-qualifier.\]
5.3 Unary expressions

Expressions with unary operators group right-to-left.

unary-expression:
  postfix-expression
  ++ cast-expression
  -- cast-expression
  unary-operator cast-expression
  sizeof unary-expression
  sizeof ( type-id )
  new-expression
  delete-expression

unary-operator: one of
  * & + - ! ~

5.3.1 Unary operators

The unary * operator performs *indirection*: the expression to which it is applied shall be a pointer to an object type, or a pointer to a function type and the result is an lvalue referring to the object or function to which the expression points. If the type of the expression is “pointer to T,” the type of the result is “T.” [Note: a pointer to an incomplete type (other than cv void) can be dereferenced. The lvalue thus obtained can be used in limited ways (to initialize a reference, for example); this lvalue must not be converted to an rvalue, see 4.1. — end note]

2 The result of the unary & operator is a pointer to its operand. The operand shall be an lvalue or a qualified-id. In the first case, if the type of the expression is “T,” the type of the result is “pointer to T.” In particular, the address of an object of type “cv T” is “pointer to cv T,” with the same cv-qualifiers. For a qualified-id, if the member is a static member of type “T”, the type of the result is plain “pointer to T.” If the member is a non-static member of class C of type T, the type of the result is “pointer to member of class C of type T.” [Example:

```c
struct A { int i; };  
struct B : A { };  
... &B::i ... // has type int A::*
```

— end example] [Note: a pointer to member formed from a mutable non-static data member (7.1.1) does not reflect the mutable specifier associated with the non-static data member. — end note]

3 A pointer to member is only formed when an explicit & is used and its operand is a qualified-id not enclosed in parentheses. [Note: that is, the expression &(qualified-id), where the qualified-id is enclosed in parentheses, does not form an expression of type “pointer to member.” Neither does qualified-id, because there is no implicit conversion from a qualified-id for a non-static member function to the type “pointer to member function” as there is from an lvalue of function type to the type “pointer to function” (4.3). Nor is &unqualified-id a pointer to member, even within the scope of the unqualified-id’s class. — end note]

4 The address of an object of incomplete type can be taken, but if the complete type of that object is a class type that declares operator&() as a member function, then the behavior is undefined (and no diagnostic is required). The operand of & shall not be a bit-field.
The address of an overloaded function (clause 13) can be taken only in a context that uniquely determines which version of the overloaded function is referred to (see 13.4). [Note: since the context might determine whether the operand is a static or non-static member function, the context can also affect whether the expression has type “pointer to function” or “pointer to member function.” — end note ]

The operand of the unary + operator shall have arithmetic, enumeration, or pointer type and the result is the value of the argument. Integral promotion is performed on integral or enumeration operands. The type of the result is the type of the promoted operand.

The operand of the unary − operator shall have arithmetic or enumeration type and the result is the negation of its operand. Integral promotion is performed on integral or enumeration operands. The negative of an unsigned quantity is computed by subtracting its value from 2^n, where n is the number of bits in the promoted operand. The result of the type is the type of the promoted operand.

The operand of the logical negation operator ! is implicitly converted to bool (clause 4); its value is true if the converted operand is false and false otherwise. The type of the result is bool.

The operand of ~ shall have integral or enumeration type; the result is the one’s complement of its operand. Integral promotions are performed. The type of the result is the type of the promoted operand. There is an ambiguity in the unary-expression ~X(), where X is a class-name. The ambiguity is resolved in favor of treating ~ as a unary complement rather than treating ~X as referring to a destructor.

5.3.2 Increment and decrement [expr.pre.incr]

The operand of prefix ++ is modified by adding 1, or set to true if it is bool (this use is deprecated). The operand shall be a modifiable lvalue. The type of the operand shall be an arithmetic type or a pointer to a completely-defined object type. The result is the updated operand; it is an lvalue, and it is a bit-field if the operand is a bit-field. If x is not of type bool, the expression ++x is equivalent to x+=1 [Note: see the discussions of addition (5.7) and assignment operators (5.17) for information on conversions. — end note ]

The operand of prefix − is modified by subtracting 1. The operand shall not be of type bool. The requirements on the operand of prefix − and the properties of its result are otherwise the same as those of prefix ++. [Note: For postfix increment and decrement, see 5.2.6. — end note ]

5.3.3 Sizeof [expr.sizeof]

The sizeof operator yields the number of bytes in the object representation of its operand. The operand is either an expression, which is not evaluated, or a parenthesized type-id. The sizeof operator shall not be applied to an expression that has function or incomplete type, or to an enumeration type before all its enumerators have been declared, or to the parenthesized name of such types, or to an lvalue that designates a bit-field. sizeof(char), sizeof(signed char) and sizeof(unsigned char) are 1. The result of sizeof applied to any other fundamental type (3.9.1) is implementation-defined. [Note: in particular, sizeof(bool) and sizeof(wchar_t) are implementation-defined. — end note ] [Note: See 1.7 for the definition of byte and 3.9 for the definition of object representation. — end note ]

When applied to a reference or a reference type, the result is the size of the referenced type. When applied to a class, the result is the number of bytes in an object of that class including any padding required for placing objects of that type in an array. The size of a most derived class shall be greater than zero (1.8). The result of applying sizeof to a base

73) sizeof(bool) is not required to be 1.
class subobject is the size of the base class type.\(^\text{74)}\) When applied to an array, the result is the total number of bytes in the array. This implies that the size of an array of \(n\) elements is \(n\) times the size of an element.

3 The \texttt{sizeof} operator can be applied to a pointer to a function, but shall not be applied directly to a function.

4 The lvalue-to-rvalue (4.1), array-to-pointer (4.2), and function-to-pointer (4.3) standard conversions are not applied to the operand of \texttt{sizeof}.

5 Types shall not be defined in a \texttt{sizeof} expression.

6 The result is a constant of type \texttt{std::size_t}. [\textit{Note:} \texttt{std::size_t} is defined in the standard header \texttt{<cassert>} (18.1). — end note]

5.3.4 New \(\text{[expr.new]}\)

1 The \texttt{new-expression} attempts to create an object of the \textit{type-id} (8.1) or \textit{new-type-id} to which it is applied. The type of that object is the \textit{allocated type}. This type shall be a complete object type, but not an abstract class type or array thereof (1.8, 3.9, 10.4). [\textit{Note:} because references are not objects, references cannot be created by \texttt{new-expression}s. — end note] [\textit{Note:} the \textit{type-id} may be a cv-qualified type, in which case the object created by the \texttt{new-expression} has a cv-qualified type. — end note]

\begin{verbatim}
new-expression:
  ::opt new new-placement\_opt new-type-id new-initializer\_opt
  ::opt new new-placement\_opt (type-id) new-initializer\_opt

new-placement:
  (expression-list)

new-type-id:
  type-specifier-seq new-declarator\_opt

new-declarator:
  ptr-operator new-declarator\_opt
direct-new-declarator

  [expression]
direct-new-declarator [constant-expression]

new-initializer:
  (expression-list\_opt)
\end{verbatim}

Entities created by a \texttt{new-expression} have dynamic storage duration (3.7.3). [\textit{Note:} the lifetime of such an entity is not necessarily restricted to the scope in which it is created. — end note] If the entity is a non-array object, the \texttt{new-expression} returns a pointer to the object created. If it is an array, the \texttt{new-expression} returns a pointer to the initial element of the array.

2 The \textit{new-type-id} in a \texttt{new-expression} is the longest possible sequence of \texttt{new-declarators}. [\textit{Note:} this prevents ambiguities between declarator operators &\texttt{,} *, \texttt{[]} , and their expression counterparts. — end note] [\textit{Example:}]

\begin{verbatim}
new int * i;
  // syntax error: parsed as (new int*) i
  // not as (new int)*i
\end{verbatim}

\(\text{74)}\) The actual size of a base class subobject may be less than the result of applying \texttt{sizeof} to the subobject, due to virtual base classes and less strict padding requirements on base class subobjects.

Draft
The * is the pointer declarator and not the multiplication operator. — end example ]

3 [ Note: parentheses in a new-type-id of a new-expression can have surprising effects. [Example:
new int(*[10])(); // error

is ill-formed because the binding is
(new int)(*[10])(); // error

Instead, the explicitly parenthesized version of the new operator can be used to create objects of compound types (3.9.2):
new (int (*[10])());

allocates an array of 10 pointers to functions (taking no argument and returning int. — end example] — end note ]

4 The type-specifier-seq shall not contain class declarations, or enumeration declarations.

5 When the allocated object is an array (that is, the direct-new-declarator syntax is used or the new-type-id or type-id
denotes an array type), the new-expression yields a pointer to the initial element (if any) of the array. [Note: both new
int and new int[10] have type int* and the type of new int[i][10] is int (*)[10] — end note ]

6 Every constant-expression in a direct-new-declarator shall be an integral constant expression (5.19) and evaluate to a
strictly positive value. The expression in a direct-new-declarator shall have integral or enumeration type (3.9.1) with a
non-negative value. [Example: if n is a variable of type int, then new float[n][5] is well-formed (because n is the
expression of a direct-new-declarator), but new float[5][n] is ill-formed (because n is not a constant-expression). If
n is negative, the effect of new float[n][5] is undefined. — end example ]

7 When the value of the expression in a direct-new-declarator is zero, the allocation function is called to allocate an array
with no elements.

8 A new-expression obtains storage for the object by calling an allocation function (3.7.3.1). If the new-expression termi-
nates by throwing an exception, it may release storage by calling a deallocation function (3.7.3.2). If the allocated type
is a non-array type, the allocation function’s name is operator new and the deallocation function’s name is operator
delete. If the allocated type is an array type, the allocation function’s name is operator new[] and the deallocation
function’s name is operator delete[]. [Note: an implementation shall provide default definitions for the global
allocation functions (3.7.3, 18.4.1.1, 18.4.1.2). A C++ program can provide alternative definitions of these functions
(17.4.3.4) and/or class-specific versions (12.5). — end note ]

9 If the new-expression begins with a unary :: operator, the allocation function’s name is looked up in the global scope.
Otherwise, if the allocated type is a class type T or array thereof, the allocation function’s name is looked up in the scope
of T If this lookup fails to find the name, or if the allocated type is not a class type, the allocation function’s name is
looked up in the global scope.

10 A new-expression passes the amount of space requested to the allocation function as the first argument of type std::
size_t. That argument shall be no less than the size of the object being created; it may be greater than the size of the
object being created only if the object is an array. For arrays of char and unsigned char, the difference between the
result of the new-expression and the address returned by the allocation function shall be an integral multiple of the most
stringent alignment requirement (3.9) of any object type whose size is no greater than the size of the array being created.
[ Note: Because allocation functions are assumed to return pointers to storage that is appropriately aligned for objects
of any type, this constraint on array allocation overhead permits the common idiom of allocating character arrays into
which objects of other types will later be placed. — end note ]
5.3 Unary expressions  Expressions 90

The *new-placement* syntax is used to supply additional arguments to an allocation function. If used, overload resolution is performed on a function call created by assembling an argument list consisting of the amount of space requested (the first argument) and the expressions in the *new-placement* part of the *new-expression* (the second and succeeding arguments). The first of these arguments has type `std::size_t` and the remaining arguments have the corresponding types of the expressions in the *new-placement*.

Example:

- `new T` results in a call of `operator new(sizeof(T))`,
- `new(2,f) T` results in a call of `operator new(sizeof(T),2,f)`,
- `new T[5]` results in a call of `operator new[](sizeof(T)*5+x)`, and
- `new(2,f) T[5]` results in a call of `operator new[](sizeof(T)*5+y,2,f)`.

Here, `x` and `y` are non-negative unspecified values representing array allocation overhead: the result of the *new-expression* will be offset by this amount from the value returned by `operator new[]`. This overhead may be applied in all array *new-expressions*, including those referencing the library function `operator new[](std::size_t, void*)` and other placement allocation functions. The amount of overhead may vary from one invocation of `new` to another. — end example]

Note: unless an allocation function is declared with an empty *exception-specification* (15.4), `throw()`, it indicates failure to allocate storage by throwing a `bad_alloc` exception (clause 15, 18.4.2.1); it returns a non-null pointer otherwise. If the allocation function is declared with an empty *exception-specification*, `throw()`, it returns null to indicate failure to allocate storage and a non-null pointer otherwise. — end note]

If the allocation function returns null, initialization shall not be done, the deallocation function shall not be called, and the value of the *new-expression* shall be null. — end note]

Note: when the allocation function returns a value other than null, it must be a pointer to a block of storage in which space for the object has been reserved. The block of storage is assumed to be appropriately aligned and of the requested size. The address of the created object will not necessarily be the same as that of the block if the object is an array. — end note]

A *new-expression* that creates an object of type `T` initializes that object as follows:

- If the *new-initializer* is omitted:
  - If `T` is a (possibly cv-qualified) non-POD class type (or array thereof), the object is default-initialized (8.5). If `T` is a const-qualified type, the underlying class type shall have a user-declared default constructor.
  - Otherwise, the object created has indeterminate value. If `T` is a const-qualified type, or a (possibly cv-qualified) POD class type (or array thereof) containing (directly or indirectly) a member of const-qualified type, the program is ill-formed;

- If the *new-initializer* is of the form `()`, the item is value-initialized (8.5);

- If the *new-initializer* is of the form *expression-list* and `T` is a class type, the appropriate constructor is called, using *expression-list* as the arguments (8.5);

- If the *new-initializer* is of the form *expression-list* and `T` is an arithmetic, enumeration, pointer, or pointer-to-member type and *expression-list* comprises exactly one expression, then the object is initialized to the (possibly converted) value of the expression (8.5);

- Otherwise the *new-expression* is ill-formed.
If the new-expression creates an object or an array of objects of class type, access and ambiguity control are done for the allocation function, the deallocation function (12.5), and the constructor (12.1). If the new expression creates an array of objects of class type, access and ambiguity control are done for the destructor (12.4).

If any part of the object initialization described above\textsuperscript{25} terminates by throwing an exception and a suitable deallocation function can be found, the deallocation function is called to free the memory in which the object was being constructed, after which the exception continues to propagate in the context of the new-expression. If no unambiguous matching deallocation function can be found, propagating the exception does not cause the object’s memory to be freed. [Note: This is appropriate when the called allocation function does not allocate memory; otherwise, it is likely to result in a memory leak. — end note]

If the new-expression begins with a unary :: operator, the deallocation function’s name is looked up in the global scope. Otherwise, if the allocated type is a class type T or an array thereof, the deallocation function’s name is looked up in the scope of T. If this lookup fails to find the name, or if the allocated type is not a class type or array thereof, the deallocation function’s name is looked up in the global scope.

A declaration of a placement deallocation function matches the declaration of a placement allocation function if it has the same number of parameters and, after parameter transformations (8.3.5), all parameter types except the first are identical. Any non-placement deallocation function matches a non-placement allocation function. If the lookup finds a single matching deallocation function, that function will be called; otherwise, no deallocation function will be called. If the lookup finds the two-parameter form of a usual deallocation function (3.7.3.2) and that function, considered as a placement deallocation function, would have been selected as a match for the allocation function, the program is ill-formed. [Example:

```c
struct S {
    // Placement allocation function:
    static void* operator new(std::size_t, std::size_t);

    // Usual (non-placement) deallocation function:
    static void operator delete(void*, std::size_t);
};

S* p = new (0) S; // ill-formed: non-placement deallocation function matches
    // placement allocation function
```

— end example]

If a new-expression calls a deallocation function, it passes the value returned from the allocation function call as the first argument of type void*. If a placement deallocation function is called, it is passed the same additional arguments as were passed to the placement allocation function, that is, the same arguments as those specified with the new-placement syntax. If the implementation is allowed to make a copy of any argument as part of the call to the allocation function, it is allowed to make a copy (of the same original value) as part of the call to the deallocation function or to reuse the copy made as part of the call to the allocation function. If the copy is elided in one place, it need not be elided in the other.

Whether the allocation function is called before evaluating the constructor arguments or after evaluating the constructor arguments but before entering the constructor is unspecified. It is also unspecified whether the arguments to a constructor are evaluated if the allocation function returns the null pointer or exits using an exception.

\textsuperscript{25} This may include evaluating a new-initializer and/or calling a constructor.
5.3 Unary expressions

5.3.5 Delete

The delete-expression operator destroys a most derived object (1.8) or array created by a new-expression.

\[ \text{delete-expression:} \]
\[ \quad \text{::opt delete cast-expression} \]
\[ \quad \text{::opt delete [ ] cast-expression} \]

The first alternative is for non-array objects, and the second is for arrays. The operand shall have a pointer type, or a class type having a single conversion function (12.3.2) to a pointer type. The result has type \text{void}.

If the operand has a class type, the operand is converted to a pointer type by calling the above-mentioned conversion function, and the converted operand is used in place of the original operand for the remainder of this section. In either alternative, if the value of the operand of delete is the null pointer the operation has no effect. In the first alternative (delete object), the value of the operand of delete shall be a pointer to a non-array object or a pointer to a subobject (1.8) representing a base class of such an object (clause 10). If not, the behavior is undefined. In the second alternative (delete array), the value of the operand of delete shall be the pointer value which resulted from a previous array new-expression.\(^{76}\) If not, the behavior is undefined. [ Note: this means that the syntax of the delete-expression must match the type of the object allocated by new, not the syntax of the new-expression. — end note ] [ Note: a pointer to a \texttt{const} type can be the operand of a delete-expression; it is not necessary to cast away the constness (5.2.11) of the pointer expression before it is used as the operand of the delete-expression. — end note ]

In the first alternative (delete object), if the static type of the operand is different from its dynamic type, the static type shall be a base class of the operand’s dynamic type and the static type shall have a virtual destructor or the behavior is undefined. In the second alternative (delete array) if the dynamic type of the object to be deleted differs from its static type, the behavior is undefined.

The cast-expression in a delete-expression shall be evaluated exactly once. If the delete-expression calls the implementation deallocation function (3.7.3.2), and if the operand of the delete expression is not the null pointer constant, the deallocation function will deallocate the storage referenced by the pointer thus rendering the pointer invalid. [ Note: the value of a pointer that refers to deallocated storage is indeterminate. — end note ]

If the object being deleted has incomplete class type at the point of deletion and the complete class has a non-trivial destructor or a deallocation function, the behavior is undefined.

The delete-expression will invoke the destructor (if any) for the object or the elements of the array being deleted. In the case of an array, the elements will be destroyed in order of decreasing address (that is, in reverse order of the completion of their constructor; see 12.6.2).

The delete-expression will call a deallocation function (3.7.3.2). [ Note: The deallocation function is called regardless of whether the destructor for the object or some element of the array throws an exception. — end note ]

\[ \text{[ Note: An implementation provides default definitions of the global deallocation functions \texttt{operator delete}()} \] for non-arrays (18.4.1.1) and \texttt{operator delete[]} () for arrays (18.4.1.2). A C++ program can provide alternative definitions of these functions (17.4.3.4), and/or class-specific versions (12.5). — end note ] When the keyword delete in a delete-expression is preceded by the unary :: operator, the global deallocation function is used to deallocate the storage.

\(^{76}\) For non-zero-length arrays, this is the same as a pointer to the first element of the array created by that new-expression. Zero-length arrays do not have a first element.

\(^{77}\) This implies that an object cannot be deleted using a pointer of type \texttt{void*} because there are no objects of type \texttt{void}.
Access and ambiguity control are done for both the deallocation function and the destructor (12.4, 12.5).

### 5.4 Explicit type conversion (cast notation)

The result of the expression \((T)\) \[\text{cast-expression}\] is of type \(T\). The result is an lvalue if \(T\) is a reference type, otherwise the result is an rvalue. [Note: if \(T\) is a non-class type that is cv-qualified, the cv-qualifiers are ignored when determining the type of the resulting rvalue; see 3.10. — end note]

An explicit type conversion can be expressed using functional notation (5.2.3), a type conversion operator (dynamic_cast, static_cast, reinterpret_cast, const_cast), or the \textit{cast} notation.

\[
\text{cast-expression:}
\begin{align*}
\text{unary-expression} \\
\text{(} \text{type-id} \text{)}\text{ cast-expression}
\end{align*}
\]

Types shall not be defined in casts.

Any type conversion not mentioned below and not explicitly defined by the user (12.3) is ill-formed.

The conversions performed by

- a \textit{const_cast} (5.2.11),
- a \textit{static_cast} (5.2.9),
- \textit{a static cast} followed by a \textit{const_cast},
- \textit{a reinterpret_cast} (5.2.10), or
- \textit{a reinterpret_cast} followed by a \textit{const_cast},

can be performed using the cast notation of explicit type conversion. The same semantic restrictions and behaviors apply, with the exception that in performing a \textit{static_cast} in the following situations the conversion is valid even if the base class is inaccessible:

- a pointer to an object of derived class type or an lvalue of derived class type may be explicitly converted to a pointer or reference to an unambiguous base class type, respectively;
- a pointer to member of derived class type may be explicitly converted to a pointer to member of an unambiguous non-virtual base class type;
- a pointer to an object of an unambiguous non-virtual base class type, an lvalue of an unambiguous non-virtual base class type, or a pointer to member of an unambiguous non-virtual base class type may be explicitly converted to a pointer, a reference, or a pointer to member of a derived class type, respectively.

If a conversion can be interpreted in more than one of the ways listed above, the interpretation that appears first in the list is used, even if a cast resulting from that interpretation is ill-formed. If a conversion can be interpreted in more than one way as a \textit{static_cast} followed by a \textit{const_cast}, the conversion is ill-formed. [Example:

```cpp
struct A {}
struct I1 : A {}
struct I2 : A {}
struct D : I1, I2 {}
A *foo( D *p ) {
    return (A*)( p );
    // ill-formed static_cast interpretation
}
```
The operand of a cast using the cast notation can be an rvalue of type “pointer to incomplete class type”. The destination type of a cast using the cast notation can be “pointer to incomplete class type”. In such cases, even if there is an inheritance relationship between the source and destination classes, whether the static_cast or reinterpret_cast interpretation is used is unspecified.

5.5 Pointer-to-member operators

The pointer-to-member operators →* and .* group left-to-right.

pm-expression:
cast-expression
pm-expression .* cast-expression
pm-expression ->* cast-expression

The binary operator .* binds its second operand, which shall be of type “pointer to member of T” (where T is a completely-defined class type) to its first operand, which shall be of class T or of a class of which T is an unambiguous and accessible base class. The result is an object or a function of the type specified by the second operand.

The binary operator ->* binds its second operand, which shall be of type “pointer to member of T” (where T is a completely-defined class type) to its first operand, which shall be of type “pointer to T” or “pointer to a class of which T is an unambiguous and accessible base class.” The result is an object or a function of the type specified by the second operand.

If the dynamic type of the object does not contain the member to which the pointer refers, the behavior is undefined.

The restrictions on cv-qualification, and the manner in which the cv-qualifiers of the operands are combined to produce the cv-qualifiers of the result, are the same as the rules for E1.E2 given in 5.2.5. [Note: it is not possible to use a pointer to member that refers to a mutable member to modify a const class object. For example,

```c
class S {
  mutable int i;
};
const S cs;
int S::* pm = &S::i; // pm refers to mutable member S::i
cs.*pm = 88; // ill-formed: cs is a const object
```

— end note ]

If the result of .* or ->* is a function, then that result can be used only as the operand for the function call operator ().

[Example:

```c
(ptr_to_obj->*ptr_to_mfct)(10);
```

calls the member function denoted by ptr_to_mfct for the object pointed to by ptr_to_obj. — end example ]

The result of a .* expression is an lvalue only if its first operand is an lvalue and its second operand is a pointer to data member. The result of an ->* expression is an lvalue only if its second operand is a pointer to data member. If the second operand is the null pointer to member value (4.11), the behavior is undefined.

5.6 Multiplicative operators

The multiplicative operators *, /, and % group left-to-right.
5.7 Additive operators

The multiplicative operators * and / shall have arithmetic or enumeration type; the operands of % shall have integral or enumeration type. The usual arithmetic conversions are performed on the operands and determine the type of the result.

The binary * operator indicates multiplication.

The binary / operator yields the quotient, and the binary % operator yields the remainder from the division of the first expression by the second. If the second operand of / or % is zero the behavior is undefined; otherwise (a/b) * b + a % b is equal to a. If both operands are nonnegative then the remainder is nonnegative; if not, the sign of the remainder is implementation-defined.

The binary + operator yields the sum of the operands. The result of the binary - operator is the difference resulting from the subtraction of the second operand from the first.

For addition, either both operands shall have arithmetic or enumeration type, or one operand shall be a pointer to a completely defined object type and the other shall have integral or enumeration type.

For subtraction, one of the following shall hold:

— both operands have arithmetic or enumeration type; or
— both operands are pointers to cv-qualified or cv-unqualified versions of the same completely defined object type; or
— the left operand is a pointer to a completely defined object type and the right operand has integral or enumeration type.

The result of the binary + operator is the sum of the operands. The result of the binary - operator is the difference resulting from the subtraction of the second operand from the first.

For the purposes of these operators, a pointer to a nonarray object behaves the same as a pointer to the first element of an array of length one with the type of the object as its element type.

When an expression that has integral type is added to or subtracted from a pointer, the result has the type of the pointer operand. If the pointer operand points to an element of an array object, and the array is large enough, the result points to an element offset from the original element such that the difference of the subscripts of the resulting and original array elements equals the integral expression. In other words, if the expression P points to the i-th element of an array object, the expressions (P) + n (equivalently, n + (P)) and (P) - n (where n has the value n) point to, respectively, the i + n-th and

780 According to work underway toward the revision of ISO C, the preferred algorithm for integer division follows the rules defined in the ISO Fortran standard, ISO/IEC 1539:1991, in which the quotient is always rounded toward zero.

Draft
5.8 Shift operators

Expressions 96

5.8 Shift operators

The shift operators \(<\) and \(\text{>>}\) group left-to-right.

\[
\begin{align*}
\text{shift-expression:} & \\
\text{additive-expression} & \\
\text{shift-expression} \ < \ \text{additive-expression} & \\
\text{shift-expression} \ > \ > \ \text{additive-expression} & 
\end{align*}
\]

The operands shall be of integral or enumeration type and integral promotions are performed. The type of the result is that of the promoted left operand. The behavior is undefined if the right operand is negative, or greater than or equal to the length in bits of the promoted left operand.

1 The value of \(E1 \ < \ E2\) is \(E1\) (interpreted as a bit pattern) left-shifted \(E2\) bit positions; vacated bits are zero-filled. If \(E1\) has an unsigned type, the value of the result is \(E1\) multiplied by the quantity \(2\) raised to the power \(E2\), reduced modulo \(\text{ULONG\_MAX}+1\) if \(E1\) has type unsigned long, \(\text{UINT\_MAX}+1\) otherwise. [Note: the constants \(\text{ULONG\_MAX}\) and \(\text{UINT\_MAX}\) are defined in the header \(<\text{climits}>\). — end note ]

2 The value of \(E1 \ > \ > \ E2\) is \(E1\) right-shifted \(E2\) bit positions. If \(E1\) has an unsigned type or if \(E1\) has a signed type and a nonnegative value, the value of the result is the integral part of the quotient of \(E1\) divided by the quantity \(2\) raised to the

\[79\] Another way to approach pointer arithmetic is first to convert the pointer(s) to character pointer(s): In this scheme the integral value of the expression added to or subtracted from the converted pointer is first multiplied by the size of the object originally pointed to, and the resulting pointer is converted back to the original type. For pointer subtraction, the result of the difference between the character pointers is similarly divided by the size of the object originally pointed to.

When viewed in this way, an implementation need only provide one extra byte (which might overlap another object in the program) just after the end of the object in order to satisfy the “one past the last element” requirements.
power E2. If E1 has a signed type and a negative value, the resulting value is implementation-defined.

5.9 Relational operators

The relational operators group left-to-right. [Example: \(a<b<c\) means \((a<b)<c\) and not \((a<b) && (b<c)\). — end example]

```
relational-expression:
  shift-expression
  relational-expression < shift-expression
  relational-expression > shift-expression
  relational-expression <= shift-expression
  relational-expression >= shift-expression
```

The operands shall have arithmetic, enumeration or pointer type. The operators \(<\) (less than), \(>\) (greater than), \(<=\) (less than or equal to), and \(>=\) (greater than or equal to) all yield \texttt{false} or \texttt{true}. The type of the result is \texttt{bool}.

The usual arithmetic conversions are performed on operands of arithmetic or enumeration type. Pointer conversions (4.10) and qualification conversions (4.4) are performed on pointer operands (or on a pointer operand and a null pointer constant) to bring them to their \textit{composite pointer type}. If one operand is a null pointer constant, the composite pointer type is the type of the other operand. Otherwise, if one of the operands has type “pointer to cv1 \texttt{void},” then the other has type “pointer to cv2 T” and the composite pointer type is “pointer to cv12 \texttt{void},” where cv12 is the union of cv1 and cv2. Otherwise, the composite pointer type is a pointer type similar (4.4) to the type of one of the operands, with a cv-qualification signature (4.4) that is the union of the cv-qualification signatures of the operand types. [Note: this implies that any pointer can be compared to a null pointer constant and that any object pointer can be compared to a pointer to (possibly cv-qualified) \texttt{void}. — end note] [Example:

```c
void *p;
const int *q;
int **pi;
const int *const *pci;
void ct()
{
  p <= q; // Both converted to const void* before comparison
  pi <= pci; // Both converted to const int *const * before comparison
}
```

— end example] Pointers to objects or functions of the same type (after pointer conversions) can be compared, with a result defined as follows:

— If two pointers \(p\) and \(q\) of the same type point to the same object or function, or both point one past the end of the same array, or are both null, then \(p<q\) and \(p>q\) both yield \texttt{true} and \(p<q\) and \(p>q\) both yield \texttt{false}.

— If two pointers \(p\) and \(q\) of the same type point to different objects that are not members of the same object or elements of the same array or to different functions, or if only one of them is null, the results of \(p<q\), \(p>q\), \(p<q\), and \(p>q\) are unspecified.

— If two pointers point to non-static data members of the same object, or to subobjects or array elements of such members, recursively, the pointer to the later declared member compares greater provided the two members are not separated by an \textit{access-specifier} label (11.1) and provided their class is not a union.
5.10 Equality operators

— If two pointers point to non-static data members of the same object separated by an access-specifier label (11.1) the result is unspecified.

— If two pointers point to data members of the same union object, they compare equal (after conversion to void*, if necessary). If two pointers point to elements of the same array or one beyond the end of the array, the pointer to the object with the higher subscript compares higher.

— Other pointer comparisons are unspecified.

5.10 Equality operators
[expr.eq]

equality-expression:
relational-expression
equality-expression == relational-expression
equality-expression != relational-expression

1 The == (equal to) and the != (not equal to) operators have the same semantic restrictions, conversions, and result type as the relational operators except for their lower precedence and truth-value result. [Note: \texttt{a<b == c<d} is \texttt{true} whenever \texttt{a<b} and \texttt{c<d} have the same truth-value. — end note] Pointers to objects or functions of the same type (after pointer conversions) can be compared for equality. Two pointers of the same type compare equal if and only if they are both null, both point to the same function, or both represent the same address (3.9.2).

2 In addition, pointers to members can be compared, or a pointer to member and a null pointer constant. Pointer to member conversions (4.11) and qualification conversions (4.4) are performed to bring them to a common type. If one operand is a null pointer constant, the common type is the type of the other operand. Otherwise, the common type is a pointer to member type similar (4.4) to the type of one of the operands, with a cv-qualification signature (4.4) that is the union of the cv-qualification signatures of the operand types. [Note: this implies that any pointer to member can be compared to a null pointer constant. —end note] If both operands are null, they compare equal. Otherwise if only one is null, they compare unequal. Otherwise if either is a pointer to a virtual member function, the result is unspecified. Otherwise they compare equal if and only if they would refer to the same member of the same most derived object (1.8) or the same subobject if they were dereferenced with a hypothetical object of the associated class type. [Example:

```
struct B {
    int f();
};
struct L : B {
};
struct R : B {
};
struct D : L, R {
};

int (B::*pb)() = &B::f;
int (L::*pl)() = pb;
int (R::*pr)() = pb;
int (D::*pdl)() = pl;
int (D::*pdr)() = pr;
bool x = (pdl == pdr); // false
```
5.11 Bitwise AND operator

```
and-expression:
  equality-expression
  and-expression & equality-expression
```

1 The usual arithmetic conversions are performed; the result is the bitwise AND function of the operands. The operator applies only to integral or enumeration operands.

5.12 Bitwise exclusive OR operator

```
exclusive-or-expression:
  and-expression
  exclusive-or-expression ^ and-expression
```

1 The usual arithmetic conversions are performed; the result is the bitwise exclusive OR function of the operands. The operator applies only to integral or enumeration operands.

5.13 Bitwise inclusive OR operator

```
inclusive-or-expression:
  exclusive-or-expression
  inclusive-or-expression | exclusive-or-expression
```

1 The usual arithmetic conversions are performed; the result is the bitwise inclusive OR function of its operands. The operator applies only to integral or enumeration operands.

5.14 Logical AND operator

```
logical-and-expression:
  inclusive-or-expression
  logical-and-expression && inclusive-or-expression
```

1 The `&&` operator groups left-to-right. The operands are both implicitly converted to type `bool` (clause 4). The result is `true` if both operands are `true` and `false` otherwise. Unlike `&`, `&&` guarantees left-to-right evaluation: the second operand is not evaluated if the first operand is `false`.
2 The result is a `bool`. All side effects of the first expression except for destruction of temporaries (12.2) happen before the second expression is evaluated.

5.15 Logical OR operator

```
logical-or-expression:
  logical-and-expression
  logical-or-expression || logical-and-expression
```

1 The `||` operator groups left-to-right. The operands are both implicitly converted to `bool` (clause 4). It returns `true` if either of its operands is `true`, and `false` otherwise. Unlike `|`, `||` guarantees left-to-right evaluation; moreover, the second operand is not evaluated if the first operand evaluates to `true`.
2 The result is a `bool`. All side effects of the first expression except for destruction of temporaries (12.2) happen before
5.16 Conditional operator

Conditional expressions group right-to-left. The first expression is implicitly converted to `bool` (clause 4). It is evaluated and if it is `true`, the result of the conditional expression is the value of the second expression, otherwise that of the third expression. All side effects of the first expression except for destruction of temporaries (12.2) happen before the second or third expression is evaluated. Only one of the second and third expressions is evaluated.

If either the second or the third operand has type (possibly cv-qualified) `void`, then the lvalue-to-rvalue (4.1), array-to-pointer (4.2), and function-to-pointer (4.3) standard conversions are performed on the second and third operands, and one of the following shall hold:

- The second or the third operand (but not both) is a `throw-expression` (15.1); the result is of the type of the other and is an rvalue.
- Both the second and the third operands have type `void` the result is of type `void` and is an rvalue. [Note: this includes the case where both operands are `throw-expressions`. — end note]

Otherwise, if the second and third operand have different types, and either has (possibly cv-qualified) class type, an attempt is made to convert each of those operands to the type of the other. The process for determining whether an operand expression `E1` of type `T1` can be converted to match an operand expression `E2` of type `T2` is defined as follows:

- If `E2` is an lvalue: `E1` can be converted to match `E2` if `E1` can be implicitly converted (clause 4) to the type “reference to `T2`”, subject to the constraint that in the conversion the reference must bind directly (8.5.3) to `E1`.
- If `E2` is an rvalue, or if the conversion above cannot be done:
  - if `E1` and `E2` have class type, and the underlying class types are the same or one is a base class of the other: `E1` can be converted to match `E2` if the class of `T2` is the same type as, or a base class of, the class of `T1`, and the cv-qualification of `T2` is the same cv-qualification as, or a greater cv-qualification than, the cv-qualification of `T1`. If the conversion is applied, `E1` is changed to an rvalue of type `T2` that still refers to the original source class object (or the appropriate subobject thereof). [Note: that is, no copy is made. — end note]
  - Otherwise (i.e., if `E1` or `E2` has a nonclass type, or if they both have class types but the underlying classes are not either the same or one a base class of the other): `E1` can be converted to match `E2` if `E1` can be implicitly converted to the type that expression `E2` would have if `E2` were converted to an rvalue (or the type it has, if `E2` is an rvalue).

Using this process, it is determined whether the second operand can be converted to match the third operand, and whether the third operand can be converted to match the second operand. If both can be converted, or one can be converted but the conversion is ambiguous, the program is ill-formed. If neither can be converted, the operands are left unchanged and further checking is performed as described below. If exactly one conversion is possible, that conversion is applied to the chosen operand and the converted operand is used in place of the original operand for the remainder of this section.

If the second and third operands are lvalues and have the same type, the result is of that type and is an lvalue and it is a bit-field if the second or the third operand is a bit-field, or if both are bit-fields.
Otherwise, the result is an rvalue. If the second and third operand do not have the same type, and either has (possibly cv-qualified) class type, overload resolution is used to determine the conversions (if any) to be applied to the operands (13.3.1.2, 13.6). If the overload resolution fails, the program is ill-formed. Otherwise, the conversions thus determined are applied, and the converted operands are used in place of the original operands for the remainder of this section.

Lvalue-to-rvalue (4.1), array-to-pointer (4.2), and function-to-pointer (4.3) standard conversions are performed on the second and third operands. After those conversions, one of the following shall hold:

— The second and third operands have the same type; the result is of that type.
— The second and third operands have arithmetic or enumeration type; the usual arithmetic conversions are performed to bring them to a common type, and the result is of that type.
— The second and third operands have pointer type, or one has pointer type and the other is a null pointer constant; pointer conversions (4.10) and qualification conversions (4.4) are performed to bring them to their composite pointer type (5.9). The result is of the composite pointer type.
— The second and third operands have pointer to member type, or one has pointer to member type and the other is a null pointer constant; pointer to member conversions (4.11) and qualification conversions (4.4) are performed to bring them to a common type, whose cv-qualification shall match the cv-qualification of either the second or the third operand. The result is of the common type.

5.17 Assignment and compound assignment operators

The assignment operator (=) and the compound assignment operators all group right-to-left. All require a modifiable lvalue as their left operand and return an lvalue with the type and value of the left operand after the assignment has taken place. The result in all cases is a bit-field if the left operand is a bit-field.

Assignment-expression:
conditional-expression
logical-or-expression assignment-operator assignment-expression
throw-expression

Assignment-operator: one of

= += /= %= += -= >>= <<= &= ^= |=

In simple assignment (=), the value of the expression replaces that of the object referred to by the left operand.

If the left operand is not of class type, the expression is implicitly converted (clause 4) to the cv-unqualified type of the left operand.

If the left operand is of class type, the class shall be complete. Assignment to objects of a class is defined by the copy assignment operator (12.8, 13.5.3).

[ Note: For class objects, assignment is not in general the same as initialization (8.5, 12.1, 12.6, 12.8). — end note ]

When the left operand of an assignment operator denotes a reference to T, the operation assigns to the object of type T denoted by the reference.

The behavior of an expression of the form E1 op= E2 is equivalent to E1 = E1 op E2 except that E1 is evaluated only once. In += and -=, E1 shall either have arithmetic type or be a pointer to a possibly cv-qualified completely defined object type. In all other cases, E1 shall have arithmetic type.
5.18 Comma operator

If the value being stored in an object is accessed from another object that overlaps in any way the storage of the first object, then the overlap shall be exact and the two objects shall have the same type, otherwise the behavior is undefined.

5.18 Comma operator

The comma operator groups left-to-right.

\[
\text{expression:} \\
\quad \text{assignment-expression} \\
\quad \text{expression, assignment-expression}
\]

A pair of expressions separated by a comma is evaluated left-to-right and the value of the left expression is discarded. The lvalue-to-rvalue (4.1), array-to-pointer (4.2), and function-to-pointer (4.3) standard conversions are not applied to the left expression. All side effects (1.9) of the left expression, except for the destruction of temporaries (12.2), are performed before the evaluation of the right expression. The type and value of the result are the type and value of the right operand; the result is an lvalue if its right operand is an lvalue, and is a bit-field if its right operand is an lvalue and a bit-field.

In contexts where comma is given a special meaning, [Example: in lists of arguments to functions (5.2.2) and lists of initializers (8.5) — end example] the comma operator as described in clause 5 can appear only in parentheses. [Example:
\[
f(a, (t=3, t+2), c);
\]
has three arguments, the second of which has the value 5. — end example]

5.19 Constant expressions

In several places, C++ requires expressions that evaluate to an integral or enumeration constant: as array bounds (8.3.4, 5.3.4), as case expressions (6.4.2), as bit-field lengths (9.6), as enumerator initializers (7.2), as static member initializers (9.4.2), and as integral or enumeration non-type template arguments (14.3).

\[
\text{constant-expression:} \\
\quad \text{conditional-expression}
\]

An integral constant-expression can involve only literals of arithmetic types (2.13, 3.9.1), enumerators, non-volatile const variables or static data members of integral or enumeration types initialized with constant expressions (8.5), non-type template parameters of integral or enumeration types, and sizeof expressions. Floating literals (2.13.3) can appear only if they are cast to integral or enumeration types. Only type conversions to integral or enumeration types can be used. In particular, except in sizeof expressions, functions, class objects, pointers, or references shall not be used, and assignment, increment, decrement, function-call, or comma operators shall not be used.

Other expressions are considered constant-expressions only for the purpose of non-local static object initialization (3.6.2). Such constant expressions shall evaluate to one of the following:

- a null pointer value (4.10),
- a null member pointer value (4.11),
- an arithmetic constant expression,
- an address constant expression,
- a reference constant expression,
— an address constant expression for a complete object type, plus or minus an integral constant expression, or
— a pointer to member constant expression.

An arithmetic constant expression shall satisfy the requirements for an integral constant expression, except that
— floating literals need not be cast to integral or enumeration type, and
— conversions to floating point types are permitted.

An address constant expression is a pointer to an lvalue designating an object of static storage duration, a string literal (2.13.4), or a function. The pointer shall be created explicitly, using the unary & operator, or implicitly using a non-type template parameter of pointer type, or using an expression of array (4.2) or function (4.3) type. The subscripting operator [], the class member access . and operator, the & and * unary operators, and pointer casts (except dynamic_casts, 5.2.7) can be used in the creation of an address constant expression, but the value of an object shall not be accessed by the use of these operators. If the subscripting operator is used, one of its operands shall be an integral constant expression. An expression that designates the address of a subobject of a non-POD class object (clause 9) is not an address constant expression (12.7). Function calls shall not be used in an address constant expression, even if the function is inline and has a reference return type.

A reference constant expression is an lvalue designating an object of static storage duration, a non-type template parameter of reference type, or a function. The subscripting operator [], the class member access . and operator, the & and * unary operators, and reference casts (except those invoking user-defined conversion functions (12.3.2) and except dynamic_casts (5.2.7)) can be used in the creation of a reference constant expression, but the value of an object shall not be accessed by the use of these operators. If the subscripting operator is used, one of its operands shall be an integral constant expression. An lvalue expression that designates a member or base class of a non-POD class object (clause 9) is not a reference constant expression (12.7). Function calls shall not be used in a reference constant expression, even if the function is inline and has a reference return type.

A pointer to member constant expression shall be created using the unary & operator applied to a qualified-id operand (5.3.1), optionally preceded by a pointer to member cast (5.2.9).
Chapter 6  Statements

1 Except as indicated, statements are executed in sequence.

    statement:
    labeled-statement
    expression-statement
    compound-statement
    selection-statement
    iteration-statement
    jump-statement
    declaration-statement
    try-block

6.1 Labeled statement

1 A statement can be labeled.

    labeled-statement:
    identifier : statement
    case constant-expression : statement
    default : statement

An identifier label declares the identifier. The only use of an identifier label is as the target of a goto. The scope of a label is the function in which it appears. Labels shall not be redeclared within a function. A label can be used in a goto statement before its definition. Labels have their own name space and do not interfere with other identifiers.

2 Case labels and default labels shall occur only in switch statements.

6.2 Expression statement

1 Expression statements have the form

    expression-statement:
    expression_opt ;

The expression is evaluated and its value is discarded. The lvalue-to-rvalue (4.1), array-to-pointer (4.2), and function-to-pointer (4.3) standard conversions are not applied to the expression. All side effects from an expression statement are completed before the next statement is executed. An expression statement with the expression missing is called a null statement. [Note: Most statements are expression statements — usually assignments or function calls. A null statement is useful to carry a label just before the } of a compound statement and to supply a null body to an iteration statement such as a while statement (6.5.1). — end note]

6.3 Compound statement or block

1 So that several statements can be used where one is expected, the compound statement (also, and equivalently, called
“block”) is provided.

```plaintext
compound-statement:
  { statement-seq_opt }
statement-seq:
  statement
  statement-seq statement
```

A compound statement defines a local scope (3.3). \[ Note: a declaration is a statement (6.7). — end note \]

### 6.4 Selection statements

Selection statements choose one of several flows of control.

```plaintext
selection-statement:
  if ( condition ) statement
  if ( condition ) statement else statement
  switch ( condition ) statement
condition:
  expression
type-specifier-seq declarator = assignment-expression
```

In clause 6, the term substatement refers to the contained statement or statements that appear in the syntax notation. The substatement in a selection-statement (each substatement, in the else form of the if statement) implicitly defines a local scope (3.3). If the substatement in a selection-statement is a single statement and not a compound-statement, it is as if it was rewritten to be a compound-statement containing the original substatement. \[ Example:\]

```plaintext
if (x)
  int i;
```

can be equivalently rewritten as

```plaintext
if (x) {
  int i;
}
```

Thus after the if statement, i is no longer in scope. \[ end example \]

2 The rules for conditions apply both to selection-statements and to the for and while statements (6.5). The declarator shall not specify a function or an array. The type-specifier-seq shall not contain typedef and shall not declare a new class or enumeration.

3 A name introduced by a declaration in a condition (either introduced by the type-specifier-seq or the declarator of the condition) is in scope from its point of declaration until the end of the substatements controlled by the condition. If the name is re-declared in the outermost block of a substatement controlled by the condition, the declaration that re-declares the name is ill-formed. \[ Example:\]

```plaintext
if (int x = f()) {
  int x;       // ill-formed, redeclaration of x
}
else {
  int x;       // ill-formed, redeclaration of x
}
```

Draft
4 The value of a condition that is an initialized declaration in a statement other than a switch statement is the value of the declared variable implicitly converted to type bool. If that conversion is ill-formed, the program is ill-formed. The value of a condition that is an initialized declaration in a switch statement is the value of the declared variable if it has integral or enumeration type, or of that variable implicitly converted to integral or enumeration type otherwise. The value of a condition that is an expression is the value of the expression, implicitly converted to bool for statements other than switch if that conversion is ill-formed, the program is ill-formed. The value of the condition will be referred to as simply “the condition” where the usage is unambiguous.

5 If a condition can be syntactically resolved as either an expression or the declaration of a local name, it is interpreted as a declaration.

6.4.1 The if statement

If the condition (6.4) yields true the first substatement is executed. If the else part of the selection statement is present and the condition yields false, the second substatement is executed. In the second form of if statement (the one including else), if the first substatement is also an if statement then that inner if statement shall contain an else part.

6.4.2 The switch statement

The switch statement causes control to be transferred to one of several statements depending on the value of a condition.

1 The condition shall be of integral type, enumeration type, or of a class type for which a single conversion function to integral or enumeration type exists (12.3). If the condition is of class type, the condition is converted by calling that conversion function, and the result of the conversion is used in place of the original condition for the remainder of this section. Integral promotions are performed. Any statement within the switch statement can be labeled with one or more case labels as follows:

```
  case constant-expression :
```

where the constant-expression shall be an integral constant-expression. The integral constant-expression (5.19) is implicitly converted to the promoted type of the switch condition. No two of the case constants in the same switch shall have the same value after conversion to the promoted type of the switch condition.

2 There shall be at most one label of the form

```
  default :
```

within a switch statement.

3 Switch statements can be nested; a case or default label is associated with the smallest switch enclosing it.

4 When the switch statement is executed, its condition is evaluated and compared with each case constant. If one of the case constants is equal to the value of the condition, control is passed to the statement following the matched case label. If no case constant matches the condition, and if there is a default label, control passes to the statement labeled by the default label. If no case matches and if there is no default then none of the statements in the switch is executed.

5 case and default labels in themselves do not alter the flow of control, which continues unimpeded across such labels. To exit from a switch, see break, 6.6.1. [Note: usually, the substatement that is the subject of a switch is compound and

--- end example ]

80) In other words, the else is associated with the nearest un-elsed if.
case and default labels appear on the top-level statements contained within the (compound) substatement, but this is not required. Declarations can appear in the substatement of a switch-statement. — end note]

6.5 Iteration statements

Iteration statements specify looping.

iteration-statement:
   while (condition) statement
   do statement while (expression);
   for (for-init-statement condition; expression; opt) statement
   for-init-statement:
      expression-statement
      simple-declaration
   [Note: a for-init-statement ends with a semicolon. — end note]

The substatement in an iteration-statement implicitly defines a local scope (3.3) which is entered and exited each time through the loop.

If the substatement in an iteration-statement is a single statement and not a compound-statement, it is as if it was rewritten to be a compound-statement containing the original statement. [Example:

\[
\text{while} (--x >= 0) \\
\text{int } i;
\]

can be equivalently rewritten as

\[
\text{while} (--x >= 0) \\
\text{int } i; \\
\}
\]

Thus after the while statement, \(i\) is no longer in scope. — end example]

[Note: The requirements on conditions in iteration statements are described in 6.4. — end note]

6.5.1 The while statement

In the while statement the substatement is executed repeatedly until the value of the condition (6.4) becomes false. The test takes place before each execution of the substatement.

When the condition of a while statement is a declaration, the scope of the variable that is declared extends from its point of declaration (3.3.1) to the end of the while statement. A while statement of the form

\[
\text{while} (T \ t = x) \ statement
\]

is equivalent to

\[
\text{label:} \\
\{ \\
\text{T } t = x; \\
\text{if } (t) \{ \\
\text{statement} \\
\text{goto} \ label;
\}
\]

Draft
The object created in a condition is destroyed and created with each iteration of the loop. [Example:

```c
struct A {
    int val;
    A(int i) : val(i) { }
    ~A() { }
    operator bool() { return val != 0; }
};
int i = 1;
while (A a = i) {
    // ...
    i = 0;
}
```

In the while-loop, the constructor and destructor are each called twice, once for the condition that succeeds and once for the condition that fails. — end example]

6.5.2 The do statement [stmt.do]

1 The expression is implicitly converted to bool; if that is not possible, the program is ill-formed.

2 In the do statement the substatement is executed repeatedly until the value of the expression becomes false. The test takes place after each execution of the statement.

6.5.3 The for statement [stmt.for]

1 The for statement

```c
for (for-init-statement condition_opt ; expression_opt) statement
```

is equivalent to

```c
{
    for-init-statement
    while (condition) {
        statement
        expression;
    }
}
```

except that names declared in the for-init-statement are in the same declarative-region as those declared in the condition, and except that a continue in statement (not enclosed in another iteration statement) will execute expression before re-evaluating condition. [Note: Thus the first statement specifies initialization for the loop; the condition (6.4) specifies a test, made before each iteration, such that the loop is exited when the condition becomes false; the expression often specifies incrementing that is done after each iteration. — end note]

2 Either or both of the condition and the expression can be omitted. A missing condition makes the implied while clause equivalent to while(true).
If the `for-init-statement` is a declaration, the scope of the name(s) declared extends to the end of the `for-statement`.

[Example:

```cpp
int i = 42;
int a[10];

for (int i = 0; i < 10; i++)
    a[i] = i;

int j = i; // j = 42
```
—end example]

### 6.6 Jump statements

Jump statements unconditionally transfer control.

- **break**;
- **continue**;
- `return expression`opt;
- `goto` `identifier`;

On exit from a scope (however accomplished), destructors (12.4) are called for all constructed objects with automatic storage duration (3.7.2) (named objects or temporaries) that are declared in that scope, in the reverse order of their declaration. Transfer out of a loop, out of a block, or back past an initialized variable with automatic storage duration involves the destruction of variables with automatic storage duration that are in scope at the point transferred from but not at the point transferred to. (See 6.7 for transfers into blocks). [Note: However, the program can be terminated (by calling `std::exit()` or `std::abort()` (18.3), for example) without destroying class objects with automatic storage duration. —end note]

#### 6.6.1 The break statement

The `break` statement shall occur only in an `iteration-statement` or a switch statement and causes termination of the smallest enclosing `iteration-statement` or switch statement; control passes to the statement following the terminated statement, if any.

#### 6.6.2 The continue statement

The `continue` statement shall occur only in an `iteration-statement` and causes control to pass to the loop-continuation portion of the smallest enclosing `iteration-statement`, that is, to the end of the loop. More precisely, in each of the statements

```cpp
while (foo) {
    // ... 
    continue; 
} // ... 
```

```cpp
do {
    // ... 
    continue; 
} while (foo); // ...
```

```cpp
for (;;) {
    // ... 
    continue; 
} // ...
```
a `continue` not contained in an enclosed iteration statement is equivalent to `goto continue`.

**6.6.3 The `return` statement**

1. A function returns to its caller by the `return` statement.

2. A return statement without an expression can be used only in functions that do not return a value, that is, a function with the return type `void`, a constructor (12.1), or a destructor (12.4). A return statement with an expression of non-void type can be used only in functions returning a value; the value of the expression is returned to the caller of the function. The expression is implicitly converted to the return type of the function in which it appears. A return statement can involve the construction and copy of a temporary object (12.2). Flowing off the end of a function is equivalent to a `return` with no value; this results in undefined behavior in a value-returning function.

3. A return statement with an expression of type “`cv void`” can be used only in functions with a return type of `cv void`; the expression is evaluated just before the function returns to its caller.

**6.6.4 The `goto` statement**

1. The `goto` statement unconditionally transfers control to the statement labeled by the identifier. The identifier shall be a label (6.1) located in the current function.

**6.7 Declaration statement**

1. A declaration statement introduces one or more new identifiers into a block; it has the form

   ```
   declaration-statement:
   block-declaration
   ```

   If an identifier introduced by a declaration was previously declared in an outer block, the outer declaration is hidden for the remainder of the block, after which it resumes its force.

2. Variables with automatic storage duration (3.7.2) are initialized each time their `declaration-statement` is executed. Variables with automatic storage duration declared in the block are destroyed on exit from the block (6.6).

3. It is possible to transfer into a block, but not in a way that bypasses declarations with initialization. A program that jumps\(^{81}\) from a point where a local variable with automatic storage duration is not in scope to a point where it is in scope is ill-formed unless the variable has POD type (3.9) and is declared without an `initializer` (8.5).

   [Example:
   ```
   void f()
   {
      // ...
      goto lx;          // ill-formed: jump into scope of a
      // ...
      ly:
      X a = 1;
      // ...
      lx:
      goto ly;          // OK, jump implies destructor
      // call for a followed by construction
      // again immediately following label ly
   }
   ```
   \(^{81}\) The transfer from the condition of a `switch` statement to a `case` label is considered a jump in this respect.

Draft
6.8 Ambiguity resolution

There is an ambiguity in the grammar involving expression-statements and declarations: An expression-statement with a function-style explicit type conversion (5.2.3) as its leftmost subexpression can be indistinguishable from a declaration where the first declarator starts with a ( . In those cases the statement is a declaration. [Note: To disambiguate, the whole statement might have to be examined to determine if it is an expression-statement or a declaration. This disambiguates many examples. [Example: assuming T is a simple-type-specifier (7.1.5),

\[
T(a) \rightarrow m = 7; \quad \text{// expression-statement} \\
T(a)++; \quad \text{// expression-statement} \\
T(a,5) << c; \quad \text{// expression-statement} \\
T(*d)(int); \quad \text{// declaration} \\
T(e)[5]; \quad \text{// declaration} \\
T(f) = \{ 1, 2 \}; \quad \text{// declaration} \\
T(*g)(double(3)); \quad \text{// declaration}
\]

In the last example above, g, which is a pointer to T, is initialized to double(3). This is of course ill-formed for semantic reasons, but that does not affect the syntactic analysis. — end example ]

The remaining cases are declarations. [Example:

```cpp
class T {
  // ...
public:
  T();
  T(int);
  T(int, int);
};
```

Draft
The disambiguation is purely syntactic; that is, the meaning of the names occurring in such a statement, beyond whether they are type-names or not, is not generally used in or changed by the disambiguation. Class templates are instantiated as necessary to determine if a qualified name is a type-name. Disambiguation precedes parsing, and a statement disambiguated as a declaration may be an ill-formed declaration. If, during parsing, a name in a template parameter is bound differently than it would be bound during a trial parse, the program is ill-formed. No diagnostic is required. [Note: This can occur only when the name is declared earlier in the declaration. —end note] [Example:

```cpp
struct T1 {
    T1 operator()(int x) { return T1(x); }
    int operator=(int x) { return x; }
}

struct T2 { T2(int){ } }; int a, (*(*(b)(T2)))(int), c, d;

void f() {
    // disambiguation requires this to be parsed
    // as a declaration
    T1(a) = 3,
    T2(4),  // T2 will be declared as
    (*(*(b)(T2(c)))(int(d)));  // a variable of type T1
    // but this will not allow
    // the last part of the
    // declaration to parse
    // properly since it depends
    // on T2 being a type-name
}
```

—end example]
Chapter 7  Declarations

1 Declarations specify how names are to be interpreted. Declarations have the form

\[
\text{declaration-seq:}
\]

\[\begin{align*}
\text{declaration} \\
\text{declaration-seq declaration}
\end{align*}\]

\[
\text{declaration:}
\]

\[\begin{align*}
\text{block-declaration} \\
\text{function-definition} \\
\text{template-declaration} \\
\text{explicit-instantiation} \\
\text{explicit-specialization} \\
\text{linkage-specification} \\
\text{namespace-definition}
\end{align*}\]

\[
\text{block-declaration:}
\]

\[\begin{align*}
\text{simple-declaration} \\
\text{asm-definition} \\
\text{namespace-alias-definition} \\
\text{using-declaration} \\
\text{using-directive} \\
\text{static_assert-declaration}
\end{align*}\]

\[
\text{simple-declaration:}
\]

\[\begin{align*}
\text{decl-specifier-seq}_{\text{opt}} \text{ init-declarator-list}_{\text{opt}} ;
\end{align*}\]

\[
\text{static_assert-declaration:}
\]

\[\begin{align*}
\text{static_assert} ( \text{constant-expression} , \text{string-literal} ) ;
\end{align*}\]

\[\text{decl-specifier-seq}_{\text{opt}} \text{ init-declarator-list}_{\text{opt}} ;\]

[Note: \text{asm-definition}s are described in 7.4, and \text{linkage-specification}s are described in 7.5. \text{Function-definition}s are described in 8.4 and \text{template-declaration}s are described in clause 14. \text{Namespace-definition}s are described in 7.3.1, \text{using-declaration}s are described in 7.3.3 and \text{using-directive}s are described in 7.3.4. — end note] The \text{simple-declaration}

\[\text{decl-specifier-seq}_{\text{opt}} \text{ init-declarator-list}_{\text{opt}} ;\]

is divided into two parts: \text{decl-specifiers}, the components of a \text{decl-specifier-seq}, are described in 7.1 and \text{declarators}, the components of an \text{init-declarator-list}, are described in clause 8.

2 A declaration occurs in a scope (3.3); the scope rules are summarized in 3.4. A declaration that declares a function or defines a class, namespace, template, or function also has one or more scopes nested within it. These nested scopes, in turn, can have declarations nested within them. Unless otherwise stated, utterances in clause 7 about components in, of, or contained by a declaration or subcomponent thereof refer only to those components of the declaration that are not nested within scopes nested within the declaration.
7.1 Specifiers

3 In a simple-declaration, the optional init-declarator-list can be omitted only when declaring a class (clause 9) or enumeration (7.2), that is, when the decl-specifier-seq contains either a class-specifier, an elaborated-type-specifier with a class-key (9.1), or an enum-specifier. In these cases and whenever a class-specifier or enum-specifier is present in the decl-specifier-seq, the identifiers in these specifiers are among the names being declared by the declaration (as class-names, enum-names, or enumerators, depending on the syntax). In such cases, and except for the declaration of an unnamed bit-field (9.6), the decl-specifier-seq shall introduce one or more names into the program, or shall redeclare a name introduced by a previous declaration. [Example:

```c
enum { }; // ill-formed
typedef class { }; // ill-formed
```

— end example ]

4 In a static_assert-declaration the constant-expression shall be an integral constant expression (5.19). If the value of the expression when converted to bool is true, the declaration has no effect. Otherwise, the program is ill-formed, and the resulting diagnostic message (1.4) shall include the text of the string-literal, except that characters not in the basic source character set (2.2) are not required to appear in the diagnostic message. [Example:

```
static_assert(sizeof(long) >= 8, "64-bit code generation not supported.");
```

— end example ]

5 Each init-declarator in the init-declarator-list contains exactly one declarator-id, which is the name declared by that init-declarator and hence one of the names declared by the declaration. The type-specifiers (7.1.5) in the decl-specifier-seq and the recursive declarator structure of the init-declarator describe a type (8.3), which is then associated with the name being declared by the init-declarator.

6 If the decl-specifier-seq contains the typedef specifier, the declaration is called a typedef declaration and the name of each init-declarator is declared to be a typedef-name, synonymous with its associated type (7.1.3). If the decl-specifier-seq contains no typedef specifier, the declaration is called a function declaration if the type associated with the name is a function type (8.3.5) and an object declaration otherwise.

7 Syntactic components beyond those found in the general form of declaration are added to a function declaration to make a function-definition. An object declaration, however, is also a definition unless it contains the extern specifier and has no initializer (3.1). A definition causes the appropriate amount of storage to be reserved and any appropriate initialization (8.5) to be done.

8 Only in function declarations for constructors, destructors, and type conversions can the decl-specifier-seq be omitted.\(^{82}\)

7.1 Specifiers

1 The specifiers that can be used in a declaration are

```c
decl-specifier:
   storage-class-specifier
   type-specifier
   function-specifier
   friend
   typedef
```

\(^{82}\) The “implicit int” rule of C is no longer supported.
The longest sequence of decl-specifiers that could possibly be a type name is taken as the decl-specifier-seq of a declaration. The sequence shall be self-consistent as described below. [Example:

```c
typedef char* Pc;
static Pc;  // error: name missing
```

Here, the declaration static Pc is ill-formed because no name was specified for the static variable of type Pc. To get a variable called Pc, a type-specifier (other than const or volatile) has to be present to indicate that the typedef-name Pc is the name being (re)declared, rather than being part of the decl-specifier sequence. For another example,

```c
void f(const Pc);
void g(const int Pc);
```

— end example ]

2 [Note: since signed, unsigned, long, and short by default imply int, a type-name appearing after one of those specifiers is treated as the name being (re)declared. [Example:

```c
void h(unsigned Pc);
void k(unsigned int Pc);
```

— end example ] — end note ]

### 7.1.1 Storage class specifiers

The storage class specifiers are

```c
storage-class-specifier:
 auto
 register
 static
 extern
 mutable
```

At most one storage-class-specifier shall appear in a given decl-specifier-seq. If a storage-class-specifier appears in a decl-specifier-seq, there can be no typedef specifier in the same decl-specifier-seq and the init-declarator-list of the declaration shall not be empty (except for global anonymous unions, which shall be declared static (9.5)). The storage-class-specifier applies to the name declared by each init-declarator in the list and not to any names declared by other specifiers. A storage-class-specifier shall not be specified in an explicit specialization (14.7.3) or an explicit instantiation (14.7.2) directive.

2 The auto or register specifiers can be applied only to names of objects declared in a block (6.3) or to function parameters (8.4). They specify that the named object has automatic storage duration (3.7.2). An object declared without a storage-class-specifier at block scope or declared as a function parameter has automatic storage duration by default. [Note: hence, the auto specifier is always redundant and not often used; one use of auto is to distinguish a declaration-statement from an expression-statement explicitly rather than relying on the disambiguation rules (6.8), which may aid readers. — end note ]

3 A register specifier has the same semantics as an auto specifier together with a hint to the implementation that the object so declared will be heavily used. [Note: the hint can be ignored and in most implementations it will be ignored if the address of the object is taken. — end note ]
4 The `static` specifier can be applied only to names of objects and functions and to anonymous unions (9.5). There can be no `static` function declarations within a block, nor any `static` function parameters. A `static` specifier used in the declaration of an object declares the object to have static storage duration (3.7.1). A `static` specifier can be used in declarations of class members; 9.4 describes its effect. For the linkage of a name declared with a `static` specifier, see 3.5.

5 The `extern` specifier can be applied only to the names of objects and functions. The `extern` specifier cannot be used in the declaration of class members or function parameters. For the linkage of a name declared with an `extern` specifier, see 3.5.

6 A name declared in a namespace scope without a `storage-class-specifier` has external linkage unless it has internal linkage because of a previous declaration and provided it is not declared `const`. Objects declared `const` and not explicitly declared `extern` have internal linkage.

7 The linkages implied by successive declarations for a given entity shall agree. That is, within a given scope, each declaration declaring the same object name or the same overloading of a function name shall imply the same linkage. Each function in a given set of overloaded functions can have a different linkage, however. [Example:

```c
static char* f(); // f() has internal linkage
cchar* f()       // f() still has internal linkage
     { /* ... */ }

char* g();       // g() has external linkage
static char* g() // error: inconsistent linkage
     { /* ... */ }

void h();
inline void h(); // external linkage

inline void l(); // external linkage
void l();

inline void m(); // external linkage
extern void m();

static void n(); // internal linkage
inline void n();

static int a;    // a has internal linkage
int a;           // error: two definitions

static int b;    // b has internal linkage
extern int b;    // b still has internal linkage

int c;           // c has external linkage
static int c;    // error: inconsistent linkage

extern int d;    // d has external linkage
static int d;    // error: inconsistent linkage
```

Draft
The name of a declared but undefined class can be used in an `extern` declaration. Such a declaration can only be used in ways that do not require a complete class type. [Example:

```c
struct S;
extern S a;
extern S f();
extern void g(S);

void h()
{
    g(a); // error: S is incomplete
    f(); // error: S is incomplete
}
```

— end example ]

The `mutable` specifier can be applied only to names of class data members (9.2) and cannot be applied to names declared `const` or `static`, and cannot be applied to reference members. [Example:

```c
class X {
    mutable const int* p; // OK
    mutable int* const q; // ill-formed
};
```

— end example ]

The `mutable` specifier on a class data member nullifies a `const` specifier applied to the containing class object and permits modification of the mutable class member even though the rest of the object is `const` (7.1.5.1).

**7.1.2 Function specifiers**

Function specifiers can be used only in function declarations.

```c
function-specifier:
    inline
    virtual
    explicit
```

A function declaration (8.3.5, 9.3, 11.4) with an `inline` specifier declares an `inline function`. The `inline` specifier indicates to the implementation that inline substitution of the function body at the point of call is to be preferred to the usual function call mechanism. An implementation is not required to perform this inline substitution at the point of call; however, even if this inline substitution is omitted, the other rules for inline functions defined by 7.1.2 shall still be respected.

A function defined within a class definition is an inline function. The `inline` specifier shall not appear on a block scope function declaration.\(^3\) If the `inline` specifier is used in a friend declaration, that declaration shall be a definition or the function shall have previously been declared inline.

An inline function shall be defined in every translation unit in which it is used and shall have exactly the same definition in every case (3.2). [Note: a call to the inline function may be encountered before its definition appears in the translation unit. — end note] If a function with external linkage is declared inline in one translation unit, it shall be declared inline

---

\(^3\) The inline keyword has no effect on the linkage of a function.
7.1 Specifiers

in all translation units in which it appears; no diagnostic is required. An inline function with external linkage shall have the same address in all translation units. A static local variable in an extern inline function always refers to the same object. A string literal in an extern inline function is the same object in different translation units.

5 The virtual specifier shall only be used in declarations of non-static class member functions that appear within a member-specification of a class definition; see 10.3.

6 The explicit specifier shall be used only in declarations of constructors within a class definition; see 12.3.1.

7.1.3 The typedef specifier

Declarations containing the decl-specifier typedef declare identifiers that can be used later for naming fundamental (3.9.1) or compound (3.9.2) types. The typedef specifier shall not be used in a function-definition (8.4), and it shall not be combined in a decl-specifier-seq with any other kind of specifier except a type-specifier.

typedef-name:
  identifier

A name declared with the typedef specifier becomes a typedef-name. Within the scope of its declaration, a typedef-name is syntactically equivalent to a keyword and names the type associated with the identifier in the way described in clause 8. A typedef-name is thus a synonym for another type. A typedef-name does not introduce a new type the way a class declaration (9.1) or enum declaration does. [Example: after
typedef int MILES, *KLICKSP;
the constructions
MILES distance;
extern KLICKSP metricp;
are all correct declarations; the type of distance is int that of metricp is “pointer to int.” — end example]

2 In a given non-class scope, a typedef specifier can be used to redefine the name of any type declared in that scope to refer to the type to which it already refers. [Example:
typedef struct { /* ... */ } s;
typedef int I;
typedef int I;
typedef I I;
— end example]

3 In a given class scope, a typedef specifier can be used to redefine any class-name declared in that scope that is not also a typedef-name to refer to the type to which it already refers.

[Example:
struct S {
  typedef struct A {} A; // OK
  typedef struct B B; // OK
  typedef A A; // error

— end example]
In a given scope, a typedef specifier shall not be used to redefine the name of any type declared in that scope to refer to a different type. [Example:

```c
class complex { /* ... */
typedef int complex;          // error: redefinition
```

— end example ]

Similarly, in a given scope, a class or enumeration shall not be declared with the same name as a typedef-name that is declared in that scope and refers to a type other than the class or enumeration itself. [Example:

```c
typedef int complex;
class complex { /* ... */};     // error: redefinition
```

— end example ]

[ Note: A typedef-name that names a class type, or a cv-qualified version thereof, is also a class-name (9.1). If a typedef-name is used to identify the subject of an elaborated-type-specifier (7.1.5.3), a class definition (clause 9), a constructor declaration (12.1), or a destructor declaration (12.4), the program is ill-formed. — end note ]

```c
struct S {
    S();
    ~S();
};
typedef struct S T;
S a = T();          // OK
struct T * p;     // error
```

— end example ]

If the typedef declaration defines an unnamed class (or enum), the first typedef-name declared by the declaration to be that class type (or enum type) is used to denote the class type (or enum type) for linkage purposes only (3.5). [Example:

```c
typedef struct { } *ps, S;     // S is the class name for linkage purposes
```

— end example ]

[ Note: if the typedef-name is used where a class-name (or enum-name) is required, the program is ill-formed. For example,

```c
typedef struct {
    S();
} S;
```

— end note ]

If a typedef TD names a type “reference to cv1 S”, an attempt to create the type “reference to cv2 TD” creates the type “reference to cv12 S”, where cv12 is the union of the cv-qualifiers cv1 and cv2. Redundant qualifiers are ignored. [Example:

Draft
7.1 Specifiers

```c
int i;
typedef int & RI;
RI & r1 = i;  // r1 has the type int&
const RI & r2 = i; // r2 has the type const int&
```
— end example ]

7.1.4 The friend specifier

The friend specifier is used to specify access to class members; see 11.4.

7.1.5 Type specifiers

1 The type-specifiers are

```
type-specifier:
simple-type-specifier
class-specifier
enum-specifier
elaborated-type-specifier
typename-specifier
cv-qualifier
```

2 As a general rule, at most one type-specifier is allowed in the complete decl-specifier-seq of a declaration. The only exceptions to this rule are the following:

---
const or volatile can be combined with any other type-specifier. However, redundant cv-qualifiers are prohibited except when introduced through the use of typedefs (7.1.3) or template type arguments (14.3), in which case the redundant cv-qualifiers are ignored.

---
signed or unsigned can be combined with char, long, short, or int.

---
short or long can be combined with int.

---
long can be combined with double.

3 At least one type-specifier that is not a cv-qualifier is required in a declaration unless it declares a constructor, destructor or conversion function. [Note: 3.9.3 describes how cv-qualifiers affect object and function types. — end note ]

7.1.5.1 The cv-qualifiers

1 There are two cv-qualifiers, const and volatile. If a cv-qualifier appears in a decl-specifier-seq, the init-declarator-list of the declaration shall not be empty. [Note: 3.9.3 describes how cv-qualifiers affect object and function types. — end note ]

2 An object declared in namespace scope with a const-qualified type has internal linkage unless it is explicitly declared extern or unless it was previously declared to have external linkage. A variable of non-volatile const-qualified integral

---
[84] There is no special provision for a decl-specifier-seq that lacks a type-specifier or that has a type-specifier that only specifies cv-qualifiers. The “implicit int” rule of C is no longer supported.

Draft
or enumeration type initialized by an integral constant expression can be used in integral constant expressions (5.19).

[Note: as described in 8.5, the definition of an object or subobject of const-qualified type must specify an initializer or be subject to default-initialization. — end note]

A pointer or reference to a cv-qualified type need not actually point or refer to a cv-qualified object, but it is treated as if it does; a const-qualified access path cannot be used to modify an object even if the object referenced is a non-const object and can be modified through some other access path. [Note: cv-qualifiers are supported by the type system so that they cannot be subverted without casting (5.2.11). — end note]

Except that any class member declared mutable (7.1.1) can be modified, any attempt to modify a const object during its lifetime (3.8) results in undefined behavior.

[Example:

```cpp
const int ci = 3; // cv-qualified (initialized as required)
ci = 4; // ill-formed: attempt to modify const

int i = 2; // not cv-qualified
const int* cip; // pointer to const int
cip = &i; // OK: cv-qualified access path to unqualified
*cip = 4; // ill-formed: attempt to modify through ptr to const

int* ip;
ip = const_cast<int*>(cip); // cast needed to convert const int* to int*
*iip = 4; // defined: *ip points to i, a non-const object

cost int* ciq = new const int (3); // initialized as required
int* iq = const_cast<int*>(ciq); // cast required
*iq = 4; // undefined: modifies a const object
```

For another example

```cpp
class X {
    public:
        mutable int i;
        int j;
};
class Y {
    public:
        X x;
        Y();
};

cost Y y;
y.x.i++; // well-formed: mutable member can be modified
y.x.j++; // ill-formed: const-qualified member modified
Y* p = const_cast<Y*>(y); // cast away const-ness of y
p->x.i = 99; // well-formed: mutable member can be modified
p->x.j = 99; // undefined: modifies a const member
```

—end example]
If an attempt is made to refer to an object defined with a volatile-qualified type through the use of an lvalue with a non-volatile-qualified type, the program behaviour is undefined.

[Note: volatile is a hint to the implementation to avoid aggressive optimization involving the object because the value of the object might be changed by means undetectable by an implementation. See 1.9 for detailed semantics. In general, the semantics of volatile are intended to be the same in C++ as they are in C. — end note]

7.1.5.2 Simple type specifiers

The simple type specifiers are

```
simple-type-specifier:
   ::opt nested-name-specifier, opt type-name
   ::opt nested-name-specifier template template-id
   char
   wchar_t
   bool
   short
   int
   long
   signed
   unsigned
   float
   double
   void

type-name:
   class-name
   enum-name
   typedef-name
```

The `simple-type-specifiers` specify either a previously-declared user-defined type or one of the fundamental types (3.9.1). Table 7 summarizes the valid combinations of `simple-type-specifiers` and the types they specify.

<table>
<thead>
<tr>
<th>Specifier(s)</th>

<td>“unsigned short int”</td>
</tr>
<tr>
<td>unsigned long int</td>
<td>“unsigned long int”</td>
</tr>
<tr>
<td>unsigned long</td>
<td>“unsigned long int”</td>
</tr>
</tbody>
</table>

Draft
When multiple simple-type-specifiers are allowed, they can be freely intermixed with other decl-specifiers in any order. It is implementation-defined whether bit-fields and objects of char type are represented as signed or unsigned quantities. The signed specifier forces char objects and bit-fields to be signed; it is redundant with other integral types.

### Table 7.1 Specifiers

</tbody>
</table>

7.1.5.3 Elaborated type specifiers

If an elaborated-type-specifier is the sole constituent of a declaration, the declaration is ill-formed unless it is an explicit specialization (14.7.3), an explicit instantiation (14.7.2) or it has one of the following forms:

- `class-key identifier ;`
- `friend class-key ::opt identifier ;`
- `friend class-key ::opt template-id ;`
- `friend class-key ::opt nested-name-specifier identifier ;`
- `friend class-key ::opt nested-name-specifier template ::opt template-id ;`

3.4.4 describes how name lookup proceeds for the identifier in an elaborated-type-specifier. If the identifier resolves to a class-name or enum-name, the elaborated-type-specifier introduces it into the declaration the same way a simple-type-specifier introduces its type-name. If the identifier resolves to a typedef-name, the elaborated-type-specifier is ill-formed. [Note: this implies that, within a class template with a template type-parameter T, the declaration

```
friend class T;
```

is ill-formed. — end note ]

The class-key or enum keyword present in the elaborated-type-specifier shall agree in kind with the declaration to which the name in the elaborated-type-specifier refers. This rule also applies to the form of elaborated-type-specifier that declares a class-name or friend class since it can be construed as referring to the definition of the class. Thus, in any elaborated-type-specifier, the enum keyword shall be used to refer to an enumeration (7.2), the union class-key shall be
used to refer to a union (clause 9), and either the class or struct class-key shall be used to refer to a class (clause 9) declared using the class or struct class-key.

### 7.2 Enumeration declarations

1. An enumeration is a distinct type (3.9.1) with named constants. Its name becomes an enum-name, within its scope.

   ```
   enum-name:
      identifier
   enum-specifier:
      enum identifier-opt{ enumerator-list_opt}
   enumerator-list:
      enumerator-definition
      enumerator-list , enumerator-definition
   enumerator-definition:
      enumerator
      enumerator = constant-expression
   enumerator:
      identifier
   ```

2. The identifiers in an enumerator-list are declared as constants, and can appear wherever constants are required. An enumerator-definition with = gives the associated enumerator the value indicated by the constant-expression. The constant-expression shall be of integral or enumeration type. If the first enumerator has no initializer, the value of the corresponding constant is zero. An enumerator-definition without an initializer gives the enumerator the value obtained by increasing the value of the previous enumerator by one.

   **Example:**
   ```
   enum { a , b , c=0 };
   enum { d , e , f=e+2 };
   ```
   defines a, c, and d to be zero, b and e to be 1, and f to be 3. —end example]

3. The point of declaration for an enumerator is immediately after its enumerator-definition. **Example:**

   ```
   const int x = 12;
   { enum { x = x }; } 
   ```
   Here, the enumerator x is initialized with the value of the constant x, namely 12. —end example]

4. Each enumeration defines a type that is different from all other types. Following the closing brace of an enum-specifier, each enumerator has the type of its enumeration. Prior to the closing brace, the type of each enumerator is the type of its initializing value. If an initializer is specified for an enumerator, the initializing value has the same type as the expression. If no initializer is specified for the first enumerator, the type is an unspecified integral type. Otherwise the type is the same as the type of the initializing value of the preceding enumerator unless the incremented value is not representable in that type, in which case the type is an unspecified integral type sufficient to contain the incremented value.

5. The underlying type of an enumeration is an integral type that can represent all the enumerator values defined in the enumeration. If no integral type can represent all the enumerator values, the enumeration is ill-formed. It is implementation-defined which integral type is used as the underlying type for an enumeration except that the underlying type shall not be larger than int unless the value of an enumerator cannot fit in an int or unsigned int. If the enumerator-list
is empty, the underlying type is as if the enumeration had a single enumerator with value 0. The value of `sizeof()` applied to an enumeration type, an object of enumeration type, or an enumerator, is the value of `sizeof()` applied to the underlying type.

7 For an enumeration where $e_{\text{min}}$ is the smallest enumerator and $e_{\text{max}}$ is the largest, the values of the enumeration are the values of the underlying type in the range $b_{\text{min}}$ to $b_{\text{max}}$, where $b_{\text{min}}$ and $b_{\text{max}}$ are, respectively, the smallest and largest values of the smallest bit-field that can store $e_{\text{min}}$ and $e_{\text{max}}$.\(^{85}\) It is possible to define an enumeration that has values not defined by any of its enumerators.

8 Two enumeration types are layout-compatible if they have the same underlying type.

9 The value of an enumerator or an object of an enumeration type is converted to an integer by integral promotion (4.5). [Example:

```c
enum color { red, yellow, green=20, blue };  
color col = red;  
color* cp = &col;  
if (*cp == blue) // ...
```

makes `color` a type describing various colors, and then declares `col` as an object of that type, and `cp` as a pointer to an object of that type. The possible values of an object of type `color` are `red`, `yellow`, `green`, `blue` these values can be converted to the integral values 0, 1, 20, and 21. Since enumerations are distinct types, objects of type `color` can be assigned only values of type `color`.

```c
color c = 1; // error: type mismatch.  
// no conversion from int to color

int i = yellow; // OK: yellow converted to integral value 1  
// integral promotion
```

—end example —

10 An expression of arithmetic or enumeration type can be converted to an enumeration type explicitly. The value is unchanged if it is in the range of enumeration values of the enumeration type; otherwise the resulting enumeration value is unspecified.

11 The enum-name and each enumerator declared by an enum-specifier is declared in the scope that immediately contains the enum-specifier. These names obey the scope rules defined for all names in (3.3) and (3.4). An enumerator declared in class scope can be referred to using the class member access operators (::, . (dot) and -> (arrow)), see 5.2.5. [Example:

```c
class X {
public:
enum direction { left='l', right='r' };  
int f(int i)  
    { return i==left ? 0 : i==right ? 1 : 2; }
};

void g(X* p)  
{
```

\(^{85}\) On a two's-complement machine, $b_{\text{max}}$ is the smallest value greater than or equal to $\max(|e_{\text{min}}| - 1, |e_{\text{max}}|)$ of the form $2^{M-1}; b_{\text{min}}$ is zero if $e_{\text{min}}$ is non-negative and $-(b_{\text{max}} + 1)$ otherwise.
direction d;  // error: direction not in scope
int i;
i = p->f(left);  // error: left not in scope
i = p->f(X::right);  // OK
i = p->f(p->left);  // OK
// ...
}
namespace Outer {
    int i;
    namespace Inner {
        void f() { i++; }  // Outer::i
        int i;
        void g() { i++; }  // Inner::i
    }
}

7.3.1.1 Unnamed namespaces

An unnamed-namespace-definition behaves as if it were replaced by

namespace unique { /* empty body */ }
using namespace unique;
namespace unique { namespace-body }

where all occurrences of unique in a translation unit are replaced by the same identifier and this identifier differs from all other identifiers in the entire program. 86) [Example:

namespace { int i; }  // unique::i
void f() { i++; }  // unique::i++

namespace A {
    namespace {
        int i;  // A::unique::i
        int j;  // A::unique::j
    }
    void g() { i++; }  // A::unique::i++
}

using namespace A;
void h() {
    i++;  // error: unique::i or A::unique::i
    A::i++;  // A::unique::i
    j++;  // A::unique::j
}

—end example ]

The use of the static keyword is deprecated when declaring objects in a namespace scope (see annex D); the unnamed-namespace provides a superior alternative.

7.3.1.2 Namespace member definitions

Members (including explicit specializations of templates (14.7.3)) of a namespace can be defined within that namespace. [Example:

86) Although entities in an unnamed namespace might have external linkage, they are effectively qualified by a name unique to their translation unit and therefore can never be seen from any other translation unit.

Draft
7.3 Namespaces

Members (including explicit specializations of templates (14.7.3)) of a named namespace can also be defined outside that namespace by explicit qualification (3.4.3.2) of the name being defined, provided that the entity being defined was already declared in the namespace and the definition appears after the point of declaration in a namespace that encloses the declaration’s namespace. [Example:]

```cpp
namespace Q {
    namespace V {
        void f();
    }
    void V::f() { /* ... */ } // OK
    void V::g() { /* ... */ } // error: g() is not yet a member of V
    namespace V {
        void g();
    }
}
namespace R {
    void Q::V::g() { /* ... */ } // error: R doesn’t enclose Q
}
```

Every name first declared in a namespace is a member of that namespace. If a friend declaration in a non-local class first declares a class or function\(^{87}\) the friend class or function is a member of the innermost enclosing namespace. The name of the friend is not found by simple name lookup until a matching declaration is provided in that namespace scope (either before or after the class definition granting friendship). If a friend function is called, its name may be found by the name lookup that considers functions from namespaces and classes associated with the types of the function arguments (3.4.2). When looking for a prior declaration of a class or a function declared as a friend, and when the name of the friend class or function is neither a qualified name nor a template-id, scopes outside the innermost enclosing namespace scope are not considered. [Example:]

```cpp
// Assume f and g have not yet been defined.
void h(int);
template <class T> void f2(T);
namespace A {
    class X {
        friend void f(X); // A::f(X) is a friend
    class Y {
        friend void g(); // A::g is a friend
        friend void h(int); // A::h is a friend
        // ::h not considered
        friend void f2<(int)>; // ::f2<(int)> is a friend
    }
};
```

\(^{87}\) this implies that the name of the class or function is unqualified.

Draft
A::f, A::g and A::h are not visible here

X x;

void g() { f(x); }  // definition of A::g
void f(X) { /* ... */}  // definition of A::f
void h(int) { /* ... */ }  // definition of A::h

// A::f, A::g and A::h are visible here and known to be friends

using A::x;

void h()
{
    A::f(x);
    A::X::f(x);  // error: f is not a member of A::X
    A::X::Y::g();  // error: g is not a member of A::X::Y
}

— end example ]

7.3.2 Namespace alias

A namespace-alias-definition declares an alternate name for a namespace according to the following grammar:

namespace-alias:
    identifier
namespace-alias-definition:
    namespace
    identifier = qualified-namespace-specifier ;
qualified-namespace-specifier:
    ::opt nested-name-specifier opt namespace-name

The identifier in a namespace-alias-definition is a synonym for the name of the namespace denoted by the qualified-namespace-specifier and becomes a namespace-alias. [Note: when looking up a namespace-name in a namespace-alias-definition, only namespace names are considered, see 3.4.6. —end note ]

In a declarative region, a namespace-alias-definition can be used to redefine a namespace-alias declared in that declarative region to refer only to the namespace to which it already refers. [Example: the following declarations are well-formed:

namespace Company_with_very_long_name { /* ... */}
namespace CWVLN = Company_with_very_long_name;
namespace CWVLN = Company_with_very_long_name;  // OK: duplicate
namespace CWVLN = CWVLN;

— end example ]

A namespace-name or namespace-alias shall not be declared as the name of any other entity in the same declarative region. A namespace-name defined at global scope shall not be declared as the name of any other entity in any global...
scope of the program. No diagnostic is required for a violation of this rule by declarations in different translation units.

### 7.3.3 The using declaration

A *using-declaration* introduces a name into the declarative region in which the *using-declaration* appears. That name is a synonym for the name of some entity declared elsewhere.

```
using-declaration:
    using typename_opt ::opt nested-name-specifier unqualified-id ;
    using :: unqualified-id ;
```

The member name specified in a *using-declaration* is declared in the declarative region in which the *using-declaration* appears. [*Note: only the specified name is so declared; specifying an enumeration name in a *using-declaration* does not declare its enumerators in the *using-declaration*’s declarative region. — end note*]

Every *using-declaration* is a *declaration* and a *member-declaration* and so can be used in a class definition. [*Example:*

```c
struct B {
    void f(char);
    void g(char);
    enum E { e };
    union { int x; };
};

struct D : B {
    using B::f;
    void f(int) { f('c'); } // calls B::f(char)
    void g(int) { g('c'); } // recursively calls D::g(int)
};
```

— end example ]

In a *using-declaration* used as a *member-declaration*, the *nested-name-specifier* shall name a base class of the class being defined. Such a *using-declaration* introduces the set of declarations found by member name lookup (10.2, 3.4.3.1). [*Example:*

```c
class C {
    int g();
};

class D2 : public B {
    using B::f; // OK: B is a base of D2
    using B::e; // OK: e is an enumerator of base B
    using B::x; // OK: x is a union member of base B
    using C::g; // error: C isn’t a base of D2
};
```

— end example ]

[*Note: since constructors and destructors do not have names, a *using-declaration* cannot refer to a constructor or a destructor for a base class. Since specializations of member templates for conversion functions are not found by name lookup, they are not considered when a *using-declaration* specifies a conversion function (14.5.2). — end note*] If an assignment operator brought from a base class into a derived class scope has the signature of a copy-assignment
operator for the derived class (12.8), the using-declaration does not by itself suppress the implicit declaration of the derived class copy-assignment operator; the copy-assignment operator from the base class is hidden or overridden by the implicitly-declared copy-assignment operator of the derived class, as described below.

5 A using-declaration shall not name a template-id. [Example:

```cpp
class A {
public:
    template <class T> void f(T);
    template <class T> struct X { };
};
class B : public A {
public:
    using A::f<double>;    // ill-formed
    using A::X<int>;       // ill-formed
};

— end example ]
```

6 A using-declaration shall not name a namespace.

7 A using-declaration for a class member shall be a member-declaration. [Example:

```cpp
struct X {
    int i;
    static int s;
};

void f()
{
    using X::i;               // error: X::i is a class member
    using X::s;               // error: X::s is a class member
}

— end example ]
```

8 Members declared by a using-declaration can be referred to by explicit qualification just like other member names (3.4.3.2). In a using-declaration, a prefix :: refers to the global namespace. [Example:

```cpp
void f();

namespace A {
    void g();
}

namespace X {
    using ::f;                 // global f
    using A::g;                // A's g
}
```

Draft
void h()
{
    X::f();       // calls :\f
    X::g();       // calls A::g
}

— end example ]

A using-declaration is a declaration and can therefore be used repeatedly where (and only where) multiple declarations are allowed. [Example:

namespace A {
    int i;
}

namespace A1 {
    using A::i;
    using A::i;        // OK: double declaration
}

void f()
{
    using A::i;
    using A::i;       // error: double declaration
}

class B {
public:
    int i;
};

class X : public B {
    using B::i;
    using B::i;       // error: double member declaration
};

— end example ]

The entity declared by a using-declaration shall be known in the context using it according to its definition at the point of the using-declaration. Definitions added to the namespace after the using-declaration are not considered when a use of the name is made. [Example:

namespace A {
    void f(int);
}

using A::f;                        // f is a synonym for A::f;
using A::f;                        // that is, for A::f(int).

namespace A {
    void f(char);
}
void foo()
{
    f('a');  // calls f(int).
}  // even though f(char) exists.

void bar()
{
    using A::f;  // f is a synonym for A::f;
    // that is, for A::f(int) and A::f(char).
    f('a');  // calls f(char)
}

— end example ]

[ Note: partial specializations of class templates are found by looking up the primary class template and then considering all partial specializations of that template. If a using-declaration names a class template, partial specializations introduced after the using-declaration are effectively visible because the primary template is visible (14.5.4). — end note ]

Since a using-declaration is a declaration, the restrictions on declarations of the same name in the same declarative region (3.3) also apply to using-declarations. [ Example: ]

namespace A {
    int x;
}

namespace B {
    int i;
    struct g { };  // OK: hides struct g
    struct x { };  // OK: hides struct g
    void f(int);
    void f(double);
    void g(char);  // OK: hides struct g
}

void func()
{
    int i;
    using B::i;  // error: i declared twice
    void f(char);
    using B::f;  // OK: each f is a function
    f(3.5);  // calls B::f(double)
    using B::g;
    g('a');  // calls B::g(char)
    struct g g1;  // g1 has class type B::g
    using B::x;
    using A::x;  // OK: hides struct B::x
    x = 99;  // assigns to A::x
    struct x x1;  // x1 has class type B::x
}
If a function declaration in namespace scope or block scope has the same name and the same parameter types as a function introduced by a using-declaration, and the declarations do not declare the same function, the program is ill-formed.  

\[\text{[Note: two using-declarations may introduce functions with the same name and the same parameter types. If, for a call to an unqualified function name, function overload resolution selects the functions introduced by such using-declarations, the function call is ill-formed.]}\]

\[\text{Example:}\]

```cpp
namespace B {
    void f(int);
    void f(double);
}
namespace C {
    void f(int);
    void f(double);
    void f(char);
}

void h() {
    using B::f; // B::f(int) and B::f(double)
    using C::f; // C::f(int), C::f(double), and C::f(char)
    f('h');    // calls C::f(char)
    f(1);      // error: ambiguous: B::f(int) or C::f(int)?
    void f(int); // error:
                  // f(int) conflicts with C::f(int) and B::f(int)
}
```

When a using-declaration brings names from a base class into a derived class scope, member functions and member function templates in the derived class override and/or hide member functions and member function templates with the same name, parameter-type-list (8.3.5), and cv-qualification in a base class (rather than conflicting).

\[\text{Example:}\]

```cpp
struct B {
    virtual void f(int);
    virtual void f(char);
    void g(int);
    void h(int);
};

struct D : B {
    using B::f; // OK: D::f(int) overrides B::f(int):
    void f(int);

    using B::g; // OK
    void g(char);
};
```
using B::h;
void h(int);       // OK: D::h(int) hides B::h(int)
);

void k(D* p)
{
    p->f(1);        // calls D::f(int)
    p->f('a');      // calls B::f(char)
    p->g(1);        // calls B::g(int)
    p->g('a');      // calls D::g(char)
}
— end example ]

[ Note: two using-declarations may introduce functions with the same name and the same parameter types. If, for a call to an unqualified function name, function overload resolution selects the functions introduced by such using-declarations, the function call is ill-formed. — end note ]

For the purpose of overload resolution, the functions which are introduced by a using-declaration into a derived class will be treated as though they were members of the derived class. In particular, the implicit this parameter shall be treated as if it were a pointer to the derived class rather than to the base class. This has no effect on the type of the function, and in all other respects the function remains a member of the base class.

All instances of the name mentioned in a using-declaration shall be accessible. In particular, if a derived class uses a using-declaration to access a member of a base class, the member name shall be accessible. If the name is that of an overloaded member function, then all functions named shall be accessible. The base class members mentioned by a using-declaration shall be visible in the scope of at least one of the direct base classes of the class where the using-declaration is specified. [ Note: because a using-declaration designates a base class member (and not a member subobject or a member function of a base class subobject), a using-declaration cannot be used to resolve inherited member ambiguities. For example,

    struct A { int x(); };  
    struct B : A { };      
    struct C : A {
        using A::x; 
        int x(int);;
    };
    
    struct D : B, C {
        using C::x;
        int x(double);
    };
    int f(D* d) {
        return d->x();        // ambiguous: B::x or C::x
    }
— end note ]

The alias created by the using-declaration has the usual accessibility for a member-declaration. [ Example:

    class A {

Draft
private:
    void f(char);
public:
    void f(int);
protected:
    void g();
};

class B : public A {
    using A::f; // error: A::f(char) is inaccessible
public:
    using A::g; // B::g is a public synonym for A::g
};

— end example ]

[ Note: use of access-declarations (11.3) is deprecated; member using-declarations provide a better alternative. — end note ]

If a using-declaration uses the keyword typename and specifies a dependent name (14.6.2), the name introduced by the using-declaration is treated as a typedef-name (7.1.3).

7.3.4 Using directive [namespace.udir]

using-directive:

using namespace ::opt nested-name-specifier, opt namespace-name;

1 A using-directive shall not appear in class scope, but may appear in namespace scope or in block scope. [ Note: when looking up a namespace-name in a using-directive, only namespace names are considered, see 3.4.6. — end note ]

2 A using-directive specifies that the names in the nominated namespace can be used in the scope in which the using-directive appears after the using-directive. During unqualified name lookup (3.4.1), the names appear as if they were declared in the nearest enclosing namespace which contains both the using-directive and the nominated namespace. [ Note: in this context, “contains” means “contains directly or indirectly”. — end note ]

3 A using-directive does not add any members to the declarative region in which it appears. [ Example:

namespace A {
    int i;
    namespace B {
        namespace C {
            int i;
        }
        using namespace A::B::C;
        void f1() {
            i = 5; // OK, C::i visible in B and hides A::i
        }
    }
    namespace D {
        using namespace B;
        using namespace C;
        void f2() {

Draft
i = 5;        // ambiguous, B::C::i or A::i?
}

void f3() {
    i = 5;       // uses A::i
}

void f4() {
    i = 5;       // ill-formed; neither i is visible
}

— end example

The using-directive is transitive: if a scope contains a using-directive that nominates a second namespace that itself contains using-directives, the effect is as if the using-directives from the second namespace also appeared in the first. [Example:

namespace M {
    int i;
}

namespace N {
    int i;
    using namespace M;
}

void f() {
    using namespace N;
    i = 7;        // error: both M::i and N::i are visible
}

For another example,

namespace A {
    int i;
}
namespace B {
    int i;
    int j;
    namespace C {
        namespace D {
            using namespace A;
            int j;
            int k;
            int a = i;       // B::i hides A::i
        }
        using namespace D;
        int k = 89;       // no problem yet
        int l = k;        // ambiguous: C::k or D::k
        int m = i;        // B::i hides A::i
    }
}
5 If a namespace is extended by an extension-namespace-definition after a using-directive for that namespace is given, the additional members of the extended namespace and the members of namespaces nominated by using-directives in the extension-namespace-definition can be used after the extension-namespace-definition.

If name lookup finds a declaration for a name in two different namespaces, and the declarations do not declare the same entity and do not declare functions, the use of the name is ill-formed. [Note: in particular, the name of an object, function or enumerator does not hide the name of a class or enumeration declared in a different namespace. For example,

```cpp
define A {  
class X {  
extern "C" int g();  
extern "C++" int h();  
}  
define B {  
void X(int);  
extern "C" int g();  
extern "C++" int h();  
}  
using namespace A;  
using namespace B;  
void f() {  
    X(1);  // error: name X found in two namespaces  
g();  // okay: name g refers to the same entity  
h();  // error: name h found in two namespaces  
}  

— end note —
```

6 During overload resolution, all functions from the transitive search are considered for argument matching. The set of declarations found by the transitive search is unordered. [Note: in particular, the order in which namespaces were considered and the relationships among the namespaces implied by the using-directives do not cause preference to be given to any of the declarations found by the search. — end note] An ambiguity exists if the best match finds two functions with the same signature, even if one is in a namespace reachable through using-directives in the namespace of the other.88) [Example:

```cpp
define D {  
int d1;  
void f(char);  
}  
```

88) During name lookup in a class hierarchy, some ambiguities may be resolved by considering whether one member hides the other along some paths (10.2). There is no such disambiguation when considering the set of names found as a result of following using-directives.

Draft
using namespace D;

int d1; // OK: no conflict with D::d1

namespace E {
    int e;
    void f(int);
}

namespace D { // namespace extension
    int d2;
    using namespace E;
    void f(int);
}

void f()
{
    d1 ++; // error: ambiguous ::d1 or D::d1?
    ::d1 ++; // OK
    D::d1 ++; // OK
    d2 ++;    // OK: D::d2
    e ++;     // OK: E::e
    f(1);     // error: ambiguous: D::f(int) or E::f(int)?
    f('a');  // OK: D::f(char)
}

— end example ]

7.4 The asm declaration [dcl.asm]

An asm declaration has the form

\[
\text{asm-definition:}
\text{asm (string-literal) ;}
\]

The \texttt{asm} declaration is conditionally-supported; its meaning is implementation-defined. [Note: Typically it is used to pass information through the implementation to an assembler. — end note]

7.5 Linkage specifications [dcl.link]

All function types, function names with external linkage, and variable names with external linkage have a \textit{language linkage}. [Note: Some of the properties associated with an entity with language linkage are specific to each implementation and are not described here. For example, a particular language linkage may be associated with a particular form of representing names of objects and functions with external linkage, or with a particular calling convention, etc. — end note] The default language linkage of all function types, function names, and variable names is C++ language linkage. Two function types with different language linkages are distinct types even if they are otherwise identical.

2 Linkage (3.5) between C++ and non-C++ code fragments can be achieved using a \textit{linkage-specification}:

\[
\text{linkage-specification:}
\text{extern string-literal } \{\text{declaration-seq_{opt}}\}
\text{extern string-literal declaration}
\]
The string-literal indicates the required language linkage. This International Standard specifies the semantics for the string-literals "C" and "C++". Use of a string-literal other than "C" or "C++" is conditionally-supported, with implementation-defined semantics. [Note: Therefore, a linkage-specification with a string-literal that is unknown to the implementation requires a diagnostic. — end note] [Note: It is recommended that the spelling of the string-literal be taken from the document defining that language. For example, Ada (not ADA) and Fortran or FORTRAN, depending on the vintage. — end note]

3 Every implementation shall provide for linkage to functions written in the C programming language, "C", and linkage to C++ functions, "C++". [Example:

```c
complex sqrt(complex);          // C++ linkage by default
extern "C" {
    double sqrt(double);       // C linkage
}
```

— end example ]

4 Linkage specifications nest. When linkage specifications nest, the innermost one determines the language linkage. A linkage specification does not establish a scope. A linkage-specification shall occur only in namespace scope (3.3). In a linkage-specification, the specified language linkage applies to the function types of all function declarators, function names with external linkage, and variable names with external linkage declared within the linkage-specification. [Example:

```c
extern "C" void f1(void*(pf)(int)); // the name f1 and its function type have C language linkage; pf is a pointer to a C function
extern "C" typedef void FUNC();
    FUNC f2;                     // the name f2 has C++ language linkage and the function's type has C language linkage
extern "C" FUNC f3;             // the name of function f3 and the function's type have C language linkage
void (*pf2)(FUNC*);            // the name of the variable pf2 has C++ linkage and the type of pf2 is pointer to C++ function that takes one parameter of type pointer to C function
extern "C" {
    static void f4();          // the name of the function f4 has internal linkage (not C language linkage) and the function's type has C language linkage.
}

extern "C" void f5() {        // OK: Name linkage (internal) and function type linkage (C language linkage) gotten from previous declaration.
    extern void f4();
}

extern void f4();            // OK: Name linkage (internal) and function type linkage (C
```

Draft
-- end example ] A C language linkage is ignored for the names of class members and the member function type of class member functions. [Example:

    extern "C" typedef void FUNC_c();

    class C {
      void mf1(FUNC_c*);
      // the name of the function mf1 and the member
      // function’s type have C++ language linkage: the
      // parameter has type pointer to C function
      FUNC_c mf2;
      // the name of the function mf2 and the member
      // function’s type have C++ language linkage
      static FUNC_c* q;
      // the name of the data member q has C++ language
      // linkage and the data member’s type is pointer to
      // C function
    };

    extern "C" {
      class X {
        void mf();
        // the name of the function mf and the member
        // function’s type have C++ language linkage
        void mf2(void(*)());
        // the name of the function mf2 has C++ language
        // linkage; the parameter has type pointer to
        // C function
      };
    }

    -- end example ]

5 If two declarations of the same function or object specify different linkage-specifications (that is, the linkage-specifications of these declarations specify different string-literals), the program is ill-formed if the declarations appear in the same translation unit, and the one definition rule (3.2) applies if the declarations appear in different translation units. Except for functions with C++ linkage, a function declaration without a linkage specification shall not precede the first linkage specification for that function. A function can be declared without a linkage specification after an explicit linkage specification has been seen; the linkage explicitly specified in the earlier declaration is not affected by such a function declaration.

6 At most one function with a particular name can have C language linkage. Two declarations for a function with C language linkage with the same function name (ignoring the namespace names that qualify it) that appear in different namespace scopes refer to the same function. Two declarations for an object with C language linkage with the same name (ignoring the namespace names that qualify it) that appear in different namespace scopes refer to the same object.
7.5 Linkage specifications

[Note: because of the one definition rule (3.2), only one definition for a function or object with C linkage may appear in the program; that is, such a function or object must not be defined in more than one namespace scope. For example,

```cpp
namespace A {
    extern "C" int f();
    extern "C" int g() { return 1; }
    extern "C" int h();
}

namespace B {
    extern "C" int f();       // A::f and B::f refer
    // to the same function
    extern "C" int g() { return 1; } // ill-formed, the function g
    // with C language linkage
    // has two definitions
}

int A::f() { return 98; }  // definition for the function f
    // with C language linkage
extern "C" int h() { return 97; }  // definition for the function h
    // with C language linkage
    // k::h and ::h refer to the same function

— end note ]

7 A declaration directly contained in a linkage-specification is treated as if it contains the extern specifier (7.1.1) for the purpose of determining the linkage of the declared name and whether it is a definition. Such a declaration shall not specify a storage class. [Example:

```cpp
extern "C" double f();
static double f();  // error
extern "C" int i;        // declaration
extern "C" {
    int i;              // definition
}
extern "C" static void g();  // error

— end example ]

8 [Note: because the language linkage is part of a function type, when a pointer to C function (for example) is dereferenced, the function to which it refers is considered a C function. — end note ]

9 Linkage from C++ to objects defined in other languages and to objects defined in C++ from other languages is implementation-defined and language-dependent. Only where the object layout strategies of two language implementations are similar enough can such linkage be achieved.
Chapter 8  Declarators

1. A declarator declares a single object, function, or type, within a declaration. The *init-declarator-list* appearing in a declaration is a comma-separated sequence of declarators, each of which can have an initializer.

   init-declarator-list:
   
   init-declarator
   
   init-declarator-list , init-declarator

   init-declarator:
   declarator initializer_opt

2. The two components of a *declaration* are the specifiers (*decl-specifier-seq*; 7.1) and the declarators (*init-declarator-list*). The specifiers indicate the type, storage class or other properties of the objects, functions or typedefs being declared. The declarators specify the names of these objects, functions or typedefs, and (optionally) modify the type of the specifiers with operators such as * (pointer to) and () (function returning). Initial values can also be specified in a declarator; initializers are discussed in 8.5 and 12.6.

3. Each *init-declarator* in a declaration is analyzed separately as if it was in a declaration by itself.\(^{89}\)

4. Declarators have the syntax

   declarator:
   
   direct-declarator
   
   ptr-operator declarator

   direct-declarator:
   declarator-id
   
   direct-declarator ( parameter-declaration-clause ) cv-qualifier-seq_opt exception-specification_opt
   
   direct-declarator [ constant-expression_opt ]
   
   ( declarator )

---

\(^{89}\) A declaration with several declarators is usually equivalent to the corresponding sequence of declarations each with a single declarator. That is

T D1, D2, ... Dn;

is usually equivalent to

T D1; T D2; ... T Dn;

where T is a *decl-specifier-seq* and each Di is an *init-declarator*. The exception occurs when a name introduced by one of the *declarators* hides a type name used by the *decl-specifiers*, so that when the same *decl-specifiers* are used in a subsequent declaration, they do not have the same meaning, as in

struct S { ... };

S S, T; // declare two instances of struct S

which is not equivalent to

struct S { ... };

S S;

S T; // error
8.1 Type names

ptr-operator:
  * cv-qualifier-seq
  &
  :: opt nested-name-specifier * cv-qualifier-seq

cv-qualifier-seq:
  cv-qualifier cv-qualifier-seq

cv-qualifier:
  const
  volatile
declarator-id:
  id-expression
  :: opt nested-name-specifier opt class-name

A class-name has special meaning in a declaration of the class of that name and when qualified by that name using the scope resolution operator :: (5.1, 12.1, 12.4).

8.1 Type names

1 To specify type conversions explicitly, and as an argument of sizeof, new, or typeid, the name of a type shall be specified. This can be done with a type-id, which is syntactically a declaration for an object or function of that type that omits the name of the object or function.

type-id:
  type-specifier-seq abstract-declarator

type-specifier-seq:
  type-specifier type-specifier-seq

abstract-declarator:
  ptr-operator abstract-declarator

direct-abstract-declarator:
  direct-abstract-declarator

abstract-declarator:
  direct-abstract-declarator

It is possible to identify uniquely the location in the abstract-declarator where the identifier would appear if the construction were a declarator in a declaration. The named type is then the same as the type of the hypothetical identifier.

[Example:

```c
int i; // int i
int *pi; // int *pi
int *p[3]; // int *p[3]
int (*p3i)[3]; // int (*p3i)[3]
int *f(); // int *f()
int *(double); // int *(double)
```

name respectively the types “int,” “pointer to int,” “array of 3 pointers to int,” “pointer to array of 3 int,” “function of (no parameters) returning pointer to int,” and “pointer to a function of (double) returning int.” — end example]
A type can also be named (often more easily) by using a `typedef` (7.1.3).

### 8.2 Ambiguity resolution

The ambiguity arising from the similarity between a function-style cast and a declaration mentioned in 6.8 can also occur in the context of a declaration. In that context, the choice is between a function declaration with a redundant set of parentheses around a parameter name and an object declaration with a function-style cast as the initializer. Just as for the ambiguities mentioned in 6.8, the resolution is to consider any construct that could possibly be a declaration a declaration.  

**Note:** a declaration can be explicitly disambiguated by a nonfunction-style cast, by an `=` to indicate initialization or by removing the redundant parentheses around the parameter name.  

```c
struct S {
    S(int);
};

void foo(double a) {
    S w(int(a));       // function declaration
    S x(int());        // function declaration
    S y((int)a);       // object declaration
    S z = int(a);      // object declaration
}
```

---

The ambiguity arising from the similarity between a function-style cast and a *type-id* can occur in different contexts. The ambiguity appears as a choice between a function-style cast expression and a declaration of a type. The resolution is that any construct that could possibly be a *type-id* in its syntactic context shall be considered a *type-id*.

```c
#include <cstdlib>
char *p;
void *operator new(std::size_t, int);
void foo() {
    const int x = 63;
    new (int(*p)) int;       // new-placement expression
    new (int(*[x]));         // new type-id
}
```

For another example,

```c
#include <cstddef>

template <class T>
struct S {
    T *p;
};

S<int()> x;           //type-id
S<int(1)> y;          // expression (ill-formed)
```

For another example,
8.3 Meaning of declarators

```c
void foo()
{
    sizeof(int(1));  // expression
    sizeof(int());   // type-id (ill-formed)
}
```

6 For another example,

```c
void foo()
{
    (int(1));        // expression
    (int())1;        // type-id (ill-formed)
}
```

—end example—

7 Another ambiguity arises in a parameter-declaration-clause of a function declaration, or in a type-id that is the operand of a sizeof or typeid operator, when a type-name is nested in parentheses. In this case, the choice is between the declaration of a parameter of type pointer to function and the declaration of a parameter with redundant parentheses around the declarator-id. The resolution is to consider the type-name as a simple-type-specifier rather than a declarator-id. [Example:

```c
class C { };    
void f(int(C)) { }  // void f(int(*fp)(C c)) { }
                   // not: void f(int C);

int g(C);

void foo()
{
    f(1);          // error: cannot convert 1 to function pointer
    f(g);          // OK
}
```

For another example,

```c
class C { };    
void h(int *(C[10]));  // void h(int *(fp)(C _parm[10]));
                      // not: void h(int *C[10]);
```

—end example—

8.3 Meaning of declarators

A list of declarators appears after an optional (clause 7) decl-specifier-seq (7.1). Each declarator contains exactly one declarator-id; it names the identifier that is declared. An unqualified-id occurring in a declarator-id shall be a simple identifier except for the declaration of some special functions (12.3, 12.4, 13.5) and for the declaration of template specializations or partial specializations (14.7). A declarator-id shall not be qualified except for the definition of a member function (9.3) or static data member (9.4) outside of its class, the definition or explicit instantiation of a function or variable member of a namespace outside of its namespace, or the definition of a previously declared explicit specialization outside of its namespace, or the declaration of a friend function that is a member of another class or namespace (11.4). When the declarator-id is qualified, the declaration shall refer to a previously declared member
of the class or namespace to which the qualifier refers, and the member shall not have been introduced by a using-declaration in the scope of the class or namespace nominated by the nested-name-specifier of the declarator-id. [Note: if the qualifier is the global :: scope resolution operator, the declarator-id refers to a name declared in the global namespace scope. — end note]

2 An auto, static, extern, register, mutable, friend, inline, virtual, or typedef specifier applies directly to each declarator-id in an init-declarator-list; the type specified for each declarator-id depends on both the decl-specifier-seq and its declarator.

3 Thus, a declaration of a particular identifier has the form

\[ T \ D \]

where \( T \) is a decl-specifier-seq and \( D \) is a declarator. Following is a recursive procedure for determining the type specified for the contained declarator-id by such a declaration.

4 First, the decl-specifier-seq determines a type. In a declaration

\[ T \ D \]

the decl-specifier-seq \( T \) determines the type \( T \). [Example: in the declaration

\[ \text{int unsigned i;} \]

the type specifiers \text{int unsigned} determine the type “\text{unsigned int}” (7.1.5.2). — end example ]

5 In a declaration \( T \ D \) where \( D \) is an unadorned identifier the type of this identifier is “\( T \).”

6 In a declaration \( T \ D \) where \( D \) has the form

\[ (D1) \]

the type of the contained declarator-id is the same as that of the contained declarator-id in the declaration

\[ T \ D1 \]

Parentheses do not alter the type of the embedded declarator-id, but they can alter the binding of complex declarators.

8.3.1 Pointers [dcl.ptr]

1 In a declaration \( T \ D \) where \( D \) has the form

\[ * \text{cv-qualifier-seq} \text{opt} \ D1 \]

and the type of the identifier in the declaration \( T \ D1 \) is “derived-declarator-type-list \( T \)” then the type of the identifier of \( D \) is “derived-declarator-type-list cv-qualifier-seq pointer to \( T \).” The cv-qualifiers apply to the pointer and not to the object pointed to.

2 [Example: the declarations

\[ \text{const int ci} = 10, *pc = &ci, *\text{const cpc} = \text{pc}, **ppc; } \\
\text{int i, *p, } *\text{\textbf{const cp} = &i;} \]
declare \texttt{ci}, a constant integer; \texttt{pc}, a pointer to a constant integer; \texttt{cpc}, a constant pointer to a constant integer; \texttt{ppc}, a pointer to a pointer to a constant integer; \texttt{i}, an integer; \texttt{p}, a pointer to integer; and \texttt{cp}, a constant pointer to integer. The value of \texttt{ci}, \texttt{cpc}, and \texttt{cp} cannot be changed after initialization. The value of \texttt{pc} can be changed, and so can the object pointed to by \texttt{cp}. Examples of some correct operations are

\begin{verbatim}
i = ci;
*cp = ci;
pc++;
pc = cpc;
 pc = p;
ppc = &pc;
\end{verbatim}

Examples of ill-formed operations are

\begin{verbatim}
 ci = 1; \hspace{1cm} // error
 ci++; \hspace{1cm} // error
 *pc = 2; \hspace{1cm} // error
 cp = &ci; \hspace{1cm} // error
 cpc++; \hspace{1cm} // error
 p = pc; \hspace{1cm} // error
 ppc = &p; \hspace{1cm} // error
\end{verbatim}

Each is unacceptable because it would either change the value of an object declared \texttt{const} or allow it to be changed through a cv-unqualified pointer later, for example:

\begin{verbatim}
*ppc = &ci; \hspace{1cm} // OK, but would make \texttt{p} point to \texttt{ci} ...
\end{verbatim}

\begin{verbatim}
*p = 5; \hspace{1cm} // clobber \texttt{ci}
\end{verbatim}

— end example ]

3 See also 5.17 and 8.5.

4 [ \textit{Note:} there are no pointers to references; see 8.3.2. Since the address of a bit-field (9.6) cannot be taken, a pointer can never point to a bit-field. — end note ]

8.3.2 References [dcl.ref]

1 In a declaration \texttt{T D} where \texttt{D} has the form

\begin{verbatim}
& D1
\end{verbatim}

and the type of the identifier in the declaration \texttt{T D1} is “\textit{derived-declarator-type-list \texttt{T}},” then the type of the identifier of \texttt{D} is “\textit{derived-declarator-type-list reference to \texttt{T}}.” Cv-qualified references are ill-formed except when the cv-qualifiers are introduced through the use of a typedef (7.1.3) or of a template type argument (14.3), in which case the cv-qualifiers are ignored. [ \textit{Example:} in

\begin{verbatim}
typedef int& A;
const A aref = 3; \hspace{1cm} // ill-formed;
\end{verbatim}

\begin{verbatim}
\hspace{1cm} // non-const reference initialized with rvalue
\end{verbatim}

Draft
the type of `&ref` is “reference to int”, not “const reference to int”. — end example] [Note: a reference can be thought of as a name of an object. — end note] A declarator that specifies the type “reference to cv void” is ill-formed.

[Example:
```c
void f(double& a) { a += 3.14; }
// ...
double d = 0;
f(d);
```
dejures a to be a reference parameter of `f` so the call `f(d)` will add 3.14 to `d`.

```c
int v[20];
// ...
int& g(int i) { return v[i]; }
// ...
g(3) = 7;
```
dejures the function `g()` to return a reference to an integer so `g(3)=7` will assign 7 to the fourth element of the array `v`. For another example,

```c
struct link {
    link* next;
};
link* first;
void h(link*& p) // p is a reference to pointer
{
    p->next = first;
    first = p;
    p = 0;
}
void k()
{
    link* q = new link;
    h(q);
}
```
dejures `p` to be a reference to a pointer to `link` so `h(q)` will leave `q` with the value zero. See also 8.5.3. — end example]

3 It is unspecified whether or not a reference requires storage (3.7).

4 There shall be no references to references, no arrays of references, and no pointers to references. The declaration of a reference shall contain an initializer (8.5.3) except when the declaration contains an explicit extern specifier (7.1.1), is a class member (9.2) declaration within a class definition, or is the declaration of a parameter or a return type (8.3.5); see 3.1. A reference shall be initialized to refer to a valid object or function. [Note: in particular, a null reference cannot exist in a well-defined program, because the only way to create such a reference would be to bind it to the “object”
obtained by dereferencing a null pointer, which causes undefined behavior. As described in 9.6, a reference cannot be bound directly to a bit-field. — end note ]

8.3.3 Pointers to members

In a declaration T D where D has the form

\[ D_1 \]

and the nested-name-specifier names a class, and the type of the identifier in the declaration T D1 is “derived-declarator-type-list T,” then the type of the identifier of D is “derived-declarator-type-list cv-qualifier-seq pointer to member of class nested-name-specifier of type T.”

\[ Example: \]

```c
class X {
  public:
    void f(int);
    int a;
};

class Y;

int X::* pmi = &X::a;
void (X::* pmf)(int) = &X::f;
double X::* pmd;
char Y::* pmc;
```

declares pmi, pmf, pmd and pmc to be a pointer to a member of X of type int, a pointer to a member of X of type void(int), a pointer to a member of X of type double and a pointer to a member of Y of type char respectively. The declaration of pmd is well-formed even though X has no members of type double. Similarly, the declaration of pmc is well-formed even though Y is an incomplete type. pmi and pmf can be used like this:

\[ X \ obj;
// ...
obj.*pmi = 7; \quad \text{ // assign 7 to an integer}
\quad \text{ // member of obj}
(obj.*pmf)(7); \quad \text{ // call a function member of obj}
\quad \text{ // with the argument 7}
```

— end example ]

A pointer to member shall not point to a static member of a class (9.4), a member with reference type, or “cv void.” [Note: see also 5.3 and 5.5. The type “pointer to member” is distinct from the type “pointer”, that is, a pointer to member is declared only by the pointer to member declarator syntax, and never by the pointer declarator syntax. There is no “reference-to-member” type in C++. — end note ]

8.3.4 Arrays

In a declaration T D where D has the form

\[ D_1 \]

Draft
and the type of the identifier in the declaration \( T \ D1 \) is “derived-declarator-type-list \( T \),” then the type of the identifier of \( D \) is an array type. \( T \) is called the array element type; this type shall not be a reference type, the (possibly cv-qualified) type \( \text{void} \), a function type or an abstract class type. If the constant-expression (5.19) is present, it shall be an integral constant expression and its value shall be greater than zero. The constant expression specifies the bound of (number of elements in) the array. If the value of the constant expression is \( N \), the array has \( N \) elements numbered 0 to \( N-1 \), and the type of the identifier of \( D \) is “derived-declarator-type-list array of \( N \ T \).” An object of array type contains a contiguously allocated non-empty set of \( N \) subobjects of type \( T \). If the constant expression is omitted, the type of the identifier of \( D \) is “derived-declarator-type-list array of unknown bound of \( T \),” an incomplete object type. If the value of the constant expression is \( N \), the array has \( N \) elements numbered 0 to \( N-1 \), and the type of the identifier of \( D \) is “derived-declarator-type-list array of \( N \ T \).” An object of array type contains a contiguously allocated non-empty set of \( N \) subobjects of type \( T \). If the constant expression is omitted, the type of the identifier of \( D \) is “derived-declarator-type-list array of unknown bound of \( T \),” an incomplete object type. The type “derived-declarator-type-list array of \( N \ T \)” is a different type from the type “array of \( N \ cv-qualifier-seq \ T \),” see 3.9. Any type of the form “cv-qualifier-seq array of \( N \ T \)” is adjusted to “array of \( N \ cv-qualifier-seq \ T \),” and similarly for “array of unknown bound of \( T \).” [Example:

typedef int A[5], AA[2][3];
typedef const A CA; // type is “array of 5 const int”
typedef const AA CAA; // type is “array of 2 array of 3 const int”

— end example ] [ Note: an “array of \( N \ cv-qualifier-seq \ T \)” has cv-qualified type; see 3.9.3. — end note ]

2 An array can be constructed from one of the fundamental types (except \( \text{void} \)), from a pointer, from a pointer to member, from a class, from an enumeration type, or from another array.

3 When several “array of” specifications are adjacent, a multidimensional array is created; the constant expressions that specify the bounds of the arrays can be omitted only for the first member of the sequence. [ Note: this elision is useful for function parameters of array types, and when the array is external and the definition, which allocates storage, is given elsewhere. — end note ] The first constant-expression can also be omitted when the declarator is followed by an initializer (8.5). In this case the bound is calculated from the number of initial elements (say, \( N \)) supplied (8.5.1), and the type of the identifier of \( D \) is “array of \( N \ T \).”

[ Example:

float fa[17], *afp[17];

declares an array of \( \text{float} \) numbers and an array of pointers to \( \text{float} \) numbers. For another example,

static int x3d[3][5][7];

declares a static three-dimensional array of integers, with rank \( 3 \times 5 \times 7 \). In complete detail, \( x3d \) is an array of three items; each item is an array of five arrays; each of the latter arrays is an array of seven integers. Any of the expressions \( x3d, x3d[i], x3d[i][j], x3d[i][j][k] \) can reasonably appear in an expression. — end example ]

[ Note: conversions affecting lvalues of array type are described in 4.2. Objects of array types cannot be modified, see 3.10. — end note ]

6 Except where it has been declared for a class (13.5.5), the subscript operator [ ] is interpreted in such a way that \( E1[E2] \) is identical to \( \ast((E1)+(E2)) \). Because of the conversion rules that apply to \( \ast \), if \( E1 \) is an array and \( E2 \) an integer, then \( E1[E2] \) refers to the \( E2\)-th member of \( E1 \). Therefore, despite its asymmetric appearance, subscripting is a commutative operation.

7 A consistent rule is followed for multidimensional arrays. If \( E \) is an \( n \)-dimensional array of rank \( i \times j \times \ldots \times k \), then \( E \) appearing in an expression is converted to a pointer to an \( (n-1) \)-dimensional array with rank \( j \times \ldots \times k \). If the \( \ast \)
operator, either explicitly or implicitly as a result of subscripting, is applied to this pointer, the result is the pointed-to
\((n-1)\)-dimensional array, which itself is immediately converted into a pointer.

[Example: consider

```c
int x[3][5];
```

Here \(x\) is a \(3 \times 5\) array of integers. When \(x\) appears in an expression, it is converted to a pointer to (the first of three)
five-membered arrays of integers. In the expression \(x[i]\) which is equivalent to \(*(x+i)\), \(x\) is first converted to a pointer
as described; then \(x+i\) is converted to the type of \(x\), which involves multiplying \(i\) by the length of the object to which
the pointer points, namely five integer objects. The results are added and indirection applied to yield an array (of five
integers), which in turn is converted to a pointer to the first of the integers. If there is another subscript the same argument
applies again; this time the result is an integer. — end example]

9 [Note: it follows from all this that arrays in C++ are stored row-wise (last subscript varies fastest) and that the first
subscript in the declaration helps determine the amount of storage consumed by an array but plays no other part in
subscript calculations. — end note]

8.3.5 Functions [dcl.fct]

1 In a declaration \(T\ D\) where \(D\) has the form

\[
D1 (\text{parameter-declaration-clause}) \text{cv-qualifier-seq}_{opt} \text{exception-specification}_{opt}
\]

and the type of the contained declarator-id in the declaration \(T\ D1\) is “derived-declarator-type-list \(T\),” the type of the declarator-
id in \(D\) is “derived-declarator-type-list function of (parameter-declaration-clause) \text{cv-qualifier-seq}_{opt} \text{returning } T\”; a type of
this form is a function type\(^{90}\).

```
parameter-declaration-clause:
 parameter-declaration-list_{opt} \ldots_{opt}
 parameter-declaration-list , ... 
parameter-declaration-list:
 parameter-declaration 
 parameter-declaration-list , parameter-declaration
parameter-declaration:
 decl-specifier-seq declarator 
 decl-specifier-seq declarator = assignment-expression 
 decl-specifier-seq abstract-declarator_{opt} 
 decl-specifier-seq abstract-declarator_{opt} = assignment-expression
```

2 The parameter-declaration-clause determines the arguments that can be specified, and their processing, when the function
is called. [Note: the parameter-declaration-clause is used to convert the arguments specified on the function call;
see 5.2.2. — end note] If the parameter-declaration-clause is empty, the function takes no arguments. The parameter
list (void) is equivalent to the empty parameter list. Except for this special case, void shall not be a parameter type
(though types derived from void, such as void*, can). If the parameter-declaration-clause terminates with an ellipsis,
the number of arguments shall be equal to or greater than the number of parameters that do not have a default argument.
Where syntactically correct, “\ldots” is synonymous with “\ldots.” [Example: the declaration

```c
int printf(const char*, ...);
```

declares a function that can be called with varying numbers and types of arguments.

\(^{90}\) As indicated by the syntax, cv-qualifiers are a significant component in function return types.
printf("hello world");
printf("a=%d b=%d", a, b);

However, the first argument must be of a type that can be converted to a const char* — end example] [Note: the standard header `<stdarg>` contains a mechanism for accessing arguments passed using the ellipsis (see 5.2.2 and 18.7). — end note]

3 A single name can be used for several different functions in a single scope; this is function overloading (clause 13). All declarations for a function shall agree exactly in both the return type and the parameter-type-list. The type of a function is determined using the following rules. The type of each parameter is determined from its own `decl-specifier-seq` and `declarator`. After determining the type of each parameter, any parameter of type “array of T” or “function returning T” is adjusted to be “pointer to T” or “pointer to function returning T,” respectively. After producing the list of parameter types, several transformations take place upon these types to determine the function type. Any `cv-qualifier` modifying a parameter type is deleted. [Example: the type `void(*)(const int)` becomes `void(*)(int)` — end example] Such `cv-qualifiers` affect only the definition of the parameter within the body of the function; they do not affect the function type. If a `storage-class-specifier` modifies a parameter type, the specifier is deleted. [Example: `register char*` becomes `char*` — end example] Such `storage-class-specifiers` affect only the definition of the parameter within the body of the function; they do not affect the function type. The resulting list of transformed parameter types and the presence or absence of the ellipsis is the function’s `parameter-type-list`.

4 A `cv-qualifier-seq` shall only be part of the function type for a non-static member function, the function type to which a pointer to member refers, or the top-level function type of a function typedef declaration. The effect of a `cv-qualifier-seq` in a function declarator is not the same as adding cv-qualification on top of the function type. In the latter case, the cv-qualifiers are ignored. [Example:
```
typedef void F();
struct S {
    const F f;
    // OK: equivalent to: void f();
};
— end example] The return type, the parameter-type-list and the `cv-qualifier-seq`, but not the default arguments (8.3.6) or the exception specification (15.4), are part of the function type. [Note: function types are checked during the assignments and initializations of pointer-to-functions, reference-to-functions, and pointer-to-member-functions. — end note]

5 [Example: the declaration
```
int fseek(FILE*, long, int);
```
declares a function taking three arguments of the specified types, and returning int (7.1.5). — end example]

6 If the type of a parameter includes a type of the form “pointer to array of unknown bound of T” or “reference to array of unknown bound of T,” the program is ill-formed. Functions shall not have a return type of type array or function, although they may have a return type of type pointer or reference to such things. There shall be no arrays of functions, although there can be arrays of pointers to functions. Types shall not be defined in return or parameter types. The type of a parameter or the return type for a function definition shall not be an incomplete class type (possibly cv-qualified)

91) This excludes parameters of type “ptr-arr-seq T2” where T2 is “pointer to array of unknown bound of T” and where `ptr-arr-seq` means any sequence of “pointer to” and “array of” derived declarator types. This exclusion applies to the parameters of the function, and if a parameter is a pointer to function or pointer to member function then to its parameters also, etc.
8.3 Meaning of declarators

unless the function definition is nested within the *member-specification* for that class (including definitions in nested classes defined within the class).

A typedef of function type may be used to declare a function but shall not be used to define a function (8.4). [Example:

typedef void F();
F fv;        // OK: equivalent to void fv();
F fv {}      // ill-formed
void fv() {} // OK: definition of fv

— end example] A typedef of a function type whose declarator includes a *cv-qualifier-seq* shall be used only to declare the function type for a non-static member function, to declare the function type to which a pointer to member refers, or to declare the top-level function type of another function typedef declaration. [Example:

typedef int FIC(int) const;
FIN f;        // ill-formed: does not declare a member function
struct S {
    FIC f;    // OK
}
FIN S::*pm = &S::*f; // OK

— end example]

An identifier can optionally be provided as a parameter name; if present in a function definition (8.4), it names a parameter (sometimes called “formal argument”). [Note: in particular, parameter names are also optional in function definitions and names used for a parameter in different declarations and the definition of a function need not be the same. If a parameter name is present in a function declaration that is not a definition, it cannot be used outside of the *parameter-declaration-clause* since it goes out of scope at the end of the function declarator (3.3). — end note]

[Example: the declaration

int i,
    *pi,
    f(),
    *(fpi(int)),
    (*fpi)(const char*, const char*),
    (*fpi(int))(int);

declares an integer i, a pointer pi to an integer, a function f taking no arguments and returning an integer, a function fpi taking an integer argument and returning a pointer to an integer, a pointer pif to a function which takes two pointers to constant characters and returns an integer, a function fpif taking an integer argument and returning a pointer to a function that takes an integer argument and returns an integer. It is especially useful to compare fpi and pif. The binding of *(fpi(int)) is *(fpi(int)), so the declaration suggests, and the same construction in an expression requires, the calling of a function fpi, and then using indirectness through the (pointer) result to yield an integer. In the declarator (*(fpi(const char*, const char*)), the extra parentheses are necessary to indicate that indirectness through a pointer to a function yields a function, which is then called. — end example] [Note: typedefs are sometimes convenient when the return type of a function is complex. For example, the function fpif above could have been declared

typedef int IFUNC(int);
IFUNC* fpif(int);
8.3.6 Default arguments

If an expression is specified in a parameter declaration this expression is used as a default argument. Default arguments will be used in calls where trailing arguments are missing.

Example: the declaration

```c
void point(int = 3, int = 4);
```

declares a function that can be called with zero, one, or two arguments of type `int`. It can be called in any of these ways:

```c
point(1,2);  point(1);  point();
```

The last two calls are equivalent to `point(1,4)` and `point(3,4),` respectively. — end example ]

A default argument expression shall be specified only in the `parameter-declaration-clause` of a function declaration or in a template-parameter (14.1). If it is specified in a `parameter-declaration-clause`, it shall not occur within a declarator or abstract-declarator of a parameter-declaration.

For non-template functions, default arguments can be added in later declarations of a function in the same scope. Declarations in different scopes have completely distinct sets of default arguments. That is, declarations in inner scopes do not acquire default arguments from declarations in outer scopes, and vice versa. In a given function declaration, all parameters subsequent to a parameter with a default argument shall have default arguments supplied in this or previous declarations. A default argument shall not be redefined by a later declaration (not even to the same value). [ Example:

```c
void g(int = 0, ...);
void f(int, int);
void f(int, int = 7);
void h()
{
    f(3);
    void f(int = 1, int);
    // error: does not use default
    // from surrounding scope
}
void m()
{
    void f(int, int);
    // has no defaults
    f(4);
    // error: wrong number of arguments
    void f(int, int = 5);
    // OK
    f(4);
    // OK, calls f(4, 5);
    void f(int, int = 5);
    // error: cannot redefine, even to
    // same value
}
void n()
{
```

92) This means that default arguments cannot appear, for example, in declarations of pointers to functions, references to functions, or `typedef` declarations.
8.3 Meaning of declarators

Declarators 158

```c
f(6); // OK, calls f(6, 7)
}

— end example] For a given inline function defined in different translation units, the accumulated sets of default arguments at the end of the translation units shall be the same; see 3.2. If a friend declaration specifies a default argument expression, that declaration must be a definition and shall be the only declaration of the function or function template in the translation unit.

5 A default argument expression is implicitly converted (clause 4) to the parameter type. The default argument expression has the same semantic constraints as the initializer expression in a declaration of a variable of the parameter type, using the copy-initialization semantics (8.5). The names in the expression are bound, and the semantic constraints are checked, at the point where the default argument expression appears. Name lookup and checking of semantic constraints for default arguments in function templates and in member functions of class templates are performed as described in 14.7.1. [Example: in the following code, g will be called with the value f(2):

```c
int a = 1;
int f(int);
int g(int x = f(a)); // default argument: f(a)

void h() {
  a = 2;
  {
    int a = 3;
    g(); // g(f(a))
  }
}
```

— end example] [Note: in member function declarations, names in default argument expressions are looked up as described in 3.4.1. Access checking applies to names in default argument expressions as described in clause 11. — end note]

6 Except for member functions of class templates, the default arguments in a member function definition that appears outside of the class definition are added to the set of default arguments provided by the member function declaration in the class definition. Default arguments for a member function of a class template shall be specified on the initial declaration of the member function within the class template. [Example:

```c
class C {
  void f(int i = 3);
  void g(int i, int j = 99);
};

void C::f(int i = 3) // error: default argument already
{} // specified in class scope
void C::g(int i = 88, int j) // in this translation unit,
{} // C::g can be called with no argument

— end example ]

7 Local variables shall not be used in default argument expressions. [Example:
void f()
{
    int i;
    extern void g(int x = i);  //error
    // ...
}

— end example }

8 The keyword this shall not be used in a default argument of a member function. [Example:

    class A {
        void f(A* p = this) { }  // error
    };

— end example ]

9 Default arguments are evaluated each time the function is called. The order of evaluation of function arguments is unspecified. Consequently, parameters of a function shall not be used in default argument expressions, even if they are not evaluated. Parameters of a function declared before a default argument expression are in scope and can hide namespace and class member names. [Example:

    int a;
    int f(int a, int b = a);  // error: parameter a
    // used as default argument
    typedef int I;
    int g(float I, int b = I(2));  // error: parameter I found
    int h(int a, int b = sizeof(a)); // error: parameter a used
    // in default argument

— end example ] Similarly, a non-static member shall not be used in a default argument expression, even if it is not evaluated, unless it appears as the id-expression of a class member access expression (5.2.5) or unless it is used to form a pointer to member (5.3.1). [Example: the declaration of X::mem1() in the following example is ill-formed because no object is supplied for the non-static member X::a used as an initializer.

    int b;
    class X {
        int a;
        int mem1(int i = a);  // error: non-static member a
        // used as default argument
        int mem2(int i = b);  // OK; use X::b
        static int b;
    };

The declaration of X::mem2() is meaningful, however, since no object is needed to access the static member X::b. Classes, objects, and members are described in clause 9. — end example ] A default argument is not part of the type of a function. [Example:

    int f(int = 0);

    void h()

When a declaration of a function is introduced by way of a using-declaration (7.3.3), any default argument information associated with the declaration is made known as well. If the function is redeclared thereafter in the namespace with additional default arguments, the additional arguments are also known at any point following the redeclaration where the using-declaration is in scope.

A virtual function call (10.3) uses the default arguments in the declaration of the virtual function determined by the static type of the pointer or reference denoting the object. An overriding function in a derived class does not acquire default arguments from the function it overrides. [Example:

```cpp
struct A {
    virtual void f(int a = 7);
};
struct B : public A {
    void f(int a);
};
void m()
{
    B* pb = new B;
    A* pa = pb;
    pa->f();
    // OK, calls pa->B::f(7)
    pb->f();
    // error: wrong number of arguments for B::f()
}
```

— end example ]

Function definitions have the form

```plaintext
function-definition:
    decl-specifier-seqopt declarator ctor-initializeropt function-body
    decl-specifier-seqopt declarator function-try-block

function-body:
    compound-statement
```

The declarator in a function-definition shall have the form

```plaintext
D1 ( parameter-declaration-clause ) cv-qualifier-seqopt exception-specificationopt
```

as described in 8.3.5. A function shall be defined only in namespace or class scope.

[Example: a simple example of a complete function definition is

```cpp
int max(int a, int b, int c)
{
```

Draft
A declarator can specify an initial value for the identifier being declared. The identifier designates an object or reference being initialized. The process of initialization described in the remainder of 8.5 applies also to initializations specified by other syntactic contexts, such as the initialization of function parameters with argument expressions (5.2.2) or the initialization of return values (6.6.3).

\[ \text{initializer:} \]
\[ \quad \text{= initializer-clause} \]
\[ \quad \langle \text{expression-list} \rangle \]
\[ \text{initializer-clause:} \]
\[ \quad \text{assignment-expression} \]
\[ \quad \langle \text{initializer-list}, \text{opt} \rangle \]
\[ \quad \{ \} \]
\[ \text{initializer-list:} \]
\[ \quad \text{initializer-clause} \]
\[ \quad \text{initializer-list}, \text{opt}, \text{initializer-clause} \]

Automatic, register, static, and external variables of namespace scope can be initialized by arbitrary expressions involving literals and previously declared variables and functions. [Example:

\[ \text{int } f(\text{int}); \]
\[ \text{int } a = 2; \]
\[ \text{int } b = f(a); \]
\[ \text{int } c(b); \]

— end example]

3 [Note: default argument expressions are more restricted; see 8.3.6.

The order of initialization of static objects is described in 3.6 and 6.7. — end note]
To **zero-initialize** an object of type \( T \) means:

- if \( T \) is a scalar type (3.9), the object is set to the value 0 (zero), taken as an integral constant expression, converted to \( T \);\(^{93}\)
- if \( T \) is a non-union class type, each non-static data member and each base-class subobject is zero-initialized;
- if \( T \) is a union type, the object’s first named data member\(^ {94}\) is zero-initialized;
- if \( T \) is an array type, each element is zero-initialized;
- if \( T \) is a reference type, no initialization is performed.

To **default-initialize** an object of type \( T \) means:

- if \( T \) is a non-POD class type (clause 9), the default constructor for \( T \) is called (and the initialization is ill-formed if \( T \) has no accessible default constructor);
- if \( T \) is an array type, each element is default-initialized;
- otherwise, the object is zero-initialized.

To **value-initialize** an object of type \( T \) means:

- if \( T \) is a class type (clause 9) with a user-declared constructor (12.1), then the default constructor for \( T \) is called (and the initialization is ill-formed if \( T \) has no accessible default constructor);
- if \( T \) is a non-union class type without a user-declared constructor, then every non-static data member and base-class component of \( T \) is value-initialized;\(^ {95}\)
- if \( T \) is an array type, then each element is value-initialized;
- otherwise, the object is zero-initialized

A program that calls for default-initialization or value-initialization of an entity of reference type is ill-formed. If \( T \) is a cv-qualified type, the cv-unqualified version of \( T \) is used for these definitions of zero-initialization, default-initialization, and value-initialization.

Every object of static storage duration shall be zero-initialized at program startup before any other initialization takes place. \( \text{[Note: in some cases, additional initialization is done later. — end note]} \)

An object whose initializer is an empty set of parentheses, i.e., \((\)\), shall be value-initialized.

\( \text{[Note: since } (\) \text{ is not permitted by the syntax for initializer,} \)

\( X \ a () ; \)

is not the declaration of an object of class \( X \), but the declaration of a function taking no argument and returning an \( X \). The form \( (\) \) is permitted in certain other initialization contexts (5.3.4, 5.2.3, 12.6.2). \( \text{— end note} \)

If no initializer is specified for an object, and the object is of (possibly cv-qualified) non-POD class type (or array thereof), the object shall be default-initialized; if the object is of const-qualified type, the underlying class type shall have a user-declared default constructor. Otherwise, if no initializer is specified for a non-static object, the object and

\(^{93}\) As specified in 4.10, converting an integral constant expression whose value is 0 to a pointer type results in a null pointer value.

\(^{94}\) This member must not be static, by virtue of the requirements in 9.5.

\(^{95}\) Value-initialization for such a class object may be implemented by zero-initializing the object and then calling the default constructor.
its subobjects, if any, have an indeterminate initial value\textsuperscript{96}; if the object or any of its subobjects are of const-qualified type, the program is ill-formed.

10 An initializer for a static member is in the scope of the member’s class. [Example:

```c
int a;

struct X {
    static int a;
    static int b;
};

int X::a = 1;
int X::b = a; // X::b = X::a
```
— end example ]

11 The form of initialization (using parentheses or =) is generally insignificant, but does matter when the entity being initialized has a class type; see below. A parenthesized initializer can be a list of expressions only when the entity being initialized has a class type.

12 The initialization that occurs in argument passing, function return, throwing an exception (15.1), handling an exception (15.3), and brace-enclosed initializer lists (8.5.1) is called \textit{copy-initialization} and is equivalent to the form

\[ T x = a; \]

13 The initialization that occurs in \texttt{new} expressions (5.3.4), \texttt{static\_cast} expressions (5.2.9), functional notation type conversions (5.2.3), and base and member initializers (12.6.2) is called \textit{direct-initialization} and is equivalent to the form

\[ T x(a); \]

14 If \( T \) is a scalar type, then a declaration of the form

\[ T x = \{ a \}; \]

is equivalent to

\[ T x = a; \]

15 The semantics of initializers are as follows. The \textit{destination type} is the type of the object or reference being initialized and the \textit{source type} is the type of the initializer expression. The source type is not defined when the initializer is brace-enclosed or when it is a parenthesized list of expressions.

\begin{itemize}
  \item If the destination type is a reference type, see 8.5.3.
  \item If the destination type is an array of characters or an array of wchar\_t, and the initializer is a string literal, see 8.5.2.
  \item Otherwise, if the destination type is an array, see 8.5.1.
  \item If the destination type is a (possibly cv-qualified) class type:
\end{itemize}

\textsuperscript{96} This does not apply to aggregate objects with automatic storage duration initialized with an incomplete brace-enclosed \texttt{initializer\_list}; see 8.5.1.
8.5 Initializers

— If the class is an aggregate (8.5.1), and the initializer is a brace-enclosed list, see 8.5.1.

— If the initialization is direct-initialization, or if it is copy-initialization where the cv-unqualified version of
the source type is the same class as, or a derived class of, the class of the destination, constructors are
considered. The applicable constructors are enumerated (13.3.1.3), and the best one is chosen through
overload resolution (13.3). The constructor so selected is called to initialize the object, with the initializer
expression(s) as its argument(s). If no constructor applies, or the overload resolution is ambiguous, the
initialization is ill-formed.

— Otherwise (i.e., for the remaining copy-initialization cases), user-defined conversion sequences that can
convert from the source type to the destination type or (when a conversion function is used) to a derived
class thereof are enumerated as described in 13.3.1.4, and the best one is chosen through overload resolution
(13.3). If the conversion cannot be done or is ambiguous, the initialization is ill-formed. The function
selected is called with the initializer expression as its argument; if the function is a constructor, the call
initializes a temporary of the cv-unqualified version of the destination type. The temporary is an rvalue.
The result of the call (which is the temporary for the constructor case) is then used to direct-initialize,
according to the rules above, the object that is the destination of the copy-initialization. In certain cases,
an implementation is permitted to eliminate the copying inherent in this direct-initialization by constructing
the intermediate result directly into the object being initialized; see 12.2, 12.8.

— Otherwise, if the source type is a (possibly cv-qualified) class type, conversion functions are considered. The
applicable conversion functions are enumerated (13.3.1.5), and the best one is chosen through overload resolution
(13.3). The user-defined conversion so selected is called to convert the initializer expression into the object being
initialized. If the conversion cannot be done or is ambiguous, the initialization is ill-formed.

— Otherwise, the initial value of the object being initialized is the (possibly converted) value of the initializer ex-
expression. Standard conversions (clause 4) will be used, if necessary, to convert the initializer expression to the
cv-unqualified version of the destination type; no user-defined conversions are considered. If the conversion can-
not be done, the initialization is ill-formed. [Note: an expression of type “cv1 T” can initialize an object of type
“cv2 T” independently of the cv-qualifiers cv1 and cv2.

    int a;
    const int b = a;
    int c = b;

— end note ]

8.5.1 Aggregates

1 An aggregate is an array or a class (clause 9) with no user-declared constructors (12.1), no private or protected non-static
data members (clause 11), no base classes (clause 10), and no virtual functions (10.3).

2 When an aggregate is initialized the initializer can contain an initializer-clause consisting of a brace-enclosed, comma-
separated list of initializer-clauses for the members of the aggregate, written in increasing subscript or member order. If
the aggregate contains subaggregates, this rule applies recursively to the members of the subaggregate. [Example:

    struct A {
      int x;
    } struct B {

Draft
An aggregate that is a class can also be initialized with a single expression not enclosed in braces, as described in 8.5. An array of unknown size initialized with a brace-enclosed *initializer-list* containing \( n \) *initializers*, where \( n \) shall be greater than zero, is defined as having \( n \) elements (8.3.4). [Example:

```c
int x[] = { 1, 3, 5 };  
```

declares and initializes \( x \) as a one-dimensional array that has three elements since no size was specified and there are three initializers. — *end example*

An empty *initializer-list* `{}` shall not be used as the initializer for an array of unknown bound.\(^{97}\)

Static data members are not considered members of the class for purposes of aggregate initialization. [Example:

```c
struct A {
    int i;
    static int s;
    int j;
} a = { 1, 2 };  
```

Here, the second initializer 2 initializes \( a.j \) and not the static data member \( A::s \) — *end example*

An *initializer-list* is ill-formed if the number of *initializers* exceeds the number of members or elements to initialize. [Example:

```c
char cv[4] = { 'a', 's', 'd', 'f', 0 };  // error 
```

is ill-formed. — *end example*

If there are fewer *initializers* in the list than there are members in the aggregate, then each member not explicitly initialized shall be value-initialized (8.5). [Example:

```c
struct S { int a; char* b; int c; }; S ss = { 1, "asdf" };  
```

initializes \( ss.a \) with 1, \( ss.b \) with "asdf", and \( ss.c \) with the value of an expression of the form \( \text{int()} \), that is, 0. — *end example*

An *initializer* for an aggregate member that is an empty class shall have the form of an empty *initializer-list* `{}`. [Example:

```c
struct S { }; struct A {
    S s;
    int i;
} a = { { }, 3 };  
```

\(^{97}\) The syntax provides for empty *initializer-lists*, but nonetheless C++ does not have zero length arrays.
An empty initializer-list can be used to initialize any aggregate. If the aggregate is not an empty class, then each member of the aggregate shall be initialized with a value of the form $T()$ (5.2.3), where $T$ represents the type of the uninitialized member.

If an incomplete or empty initializer-list leaves a member of reference type uninitialized, the program is ill-formed. When initializing a multi-dimensional array, the initializers initialize the elements with the last (rightmost) index of the array varying the fastest (8.3.4). [Example:

```c
int x[2][2] = { 3, 1, 4, 2 };
```

initializes $x[0][0]$ to 3, $x[0][1]$ to 1, $x[1][0]$ to 4, and $x[1][1]$ to 2. On the other hand,

```c
float y[4][3] = {
    { 1 }, { 2 }, { 3 }, { 4 }
};
```

initializes the first column of $y$ (regarded as a two-dimensional array) and leaves the rest zero. — end example ]

Braces can be elided in an initializer-list as follows. If the initializer-list begins with a left brace, then the succeeding comma-separated list of initializers initializes the members of a subaggregate; it is erroneous for there to be more initializers than members. If, however, the initializer-list for a subaggregate does not begin with a left brace, then only enough initializers from the list are taken to initialize the members of the subaggregate; any remaining initializers are left to initialize the next member of the aggregate of which the current subaggregate is a member. [Example:

```c
float y[4][3] = {
    { 1, 3, 5 },
    { 2, 4, 6 },
    { 3, 5, 7 },
};
```

is a completely-braced initialization: 1, 3, and 5 initialize the first row of the array $y[0]$, namely $y[0][0]$, $y[0][1]$, and $y[0][2]$. Likewise the next two lines initialize $y[1]$ and $y[2]$. The initializer ends early and therefore $y[3]$s elements are initialized as if explicitly initialized with an expression of the form `float()`, that is, are initialized with 0.0. In the following example, braces in the initializer-list are elided; however the initializer-list has the same effect as the completely-braced initializer-list of the above example.

```c
float y[4][3] = {
    1, 3, 5, 2, 4, 6, 3, 5, 7
};
```

The initializer for $y$ begins with a left brace, but the one for $y[0]$ does not, therefore three elements from the list are used. Likewise the next three are taken successively for $y[1]$ and $y[2]$. — end example ]

All implicit type conversions (clause 4) are considered when initializing the aggregate member with an initializer from an initializer-list. If the initializer can initialize a member, the member is initialized. Otherwise, if the member is itself a non-empty subaggregate, brace elision is assumed and the initializer is considered for the initialization of the first member of the subaggregate.

[Example:
struct A {
    int i;
    operator int();
};
struct B {
    A a1, a2;
    int z;
};
A a;
B b = {4, a, a};

Braces are elided around the initializer for b.a1.i. b.a1.i is initialized with 4, b.a2 is initialized with a, b.z is initialized with whatever a.operator int() returns. — end example]

[Note: An aggregate array or an aggregate class may contain members of a class type with a user-declared constructor (12.1). Initialization of these aggregate objects is described in 12.6.1. — end note]

When an aggregate with static storage duration is initialized with a brace-enclosed initializer-list, if all the member initializer expressions are constant expressions, and the aggregate is a POD type, the initialization shall be done during the static phase of initialization (3.6.2); otherwise, it is unspecified whether the initialization of members with constant expressions takes place during the static phase or during the dynamic phase of initialization.

When a union is initialized with a brace-enclosed initializer, the braces shall only contain an initializer for the first member of the union. [Example:

    union u { int a; char* b; };
    u a = {1};
    u b = a;
    u c = 1;           // error
    u d = {0, "asdf"}; // error
    u e = {"asdf"};    // error

— end example]

[Note: as described above, the braces around the initializer for a union member can be omitted if the union is a member of another aggregate. — end note]

8.5.2 Character arrays [dcl.init.string]

A char array (whether plain char, signed char, or unsigned char) can be initialized by a string-literal (optionally enclosed in braces); a wchar_t array can be initialized by a wide string-literal (optionally enclosed in braces); successive characters of the string-literal initialize the members of the array. [Example:

    char msg[] = "Syntax error on line %s\n";

shows a character array whose members are initialized with a string-literal. Note that because '\n' is a single character and because a trailing '\0' is appended, sizeof(msg) is 25. — end example]

There shall not be more initializers than there are array elements. [Example:

    char cv[4] = "asdf"; // error

Draft
is ill-formed since there is no space for the implied trailing \(\backslash 0\). — end example]

8.5.3 References [dcl.init.ref]

1 A variable declared to be a \texttt{T&}, that is “reference to type \texttt{T} (8.3.2), shall be initialized by an object, or function, of type \texttt{T} or by an object that can be converted into a \texttt{T}. [Example:

```c
int g(int);
void f()
{
    int i;
    int& r = i;  // \texttt{r} refers to \texttt{i}
    r = 1;       // the value of \texttt{i} becomes 1
    int* p = &r; // \texttt{p} points to \texttt{i}
    int& rr = r; // \texttt{rr} refers to what \texttt{r} refers to, that is, to \texttt{i}
    int (&rg)(int) = g; // \texttt{rg} refers to the function \texttt{g}
    rg(i); // calls function \texttt{g}
    int a[3];
    int (&ra)[3] = a; // \texttt{ra} refers to the array \texttt{a}
    ra[1] = i; // modifies \texttt{a}[1]
}

— end example ]

A reference cannot be changed to refer to another object after initialization. Note that initialization of a reference is treated very differently from assignment to it. Argument passing (5.2.2) and function value return (6.6.3) are initializations.

3 The initializer can be omitted for a reference only in a parameter declaration (8.3.5), in the declaration of a function return type, in the declaration of a class member within its class definition (9.2), and where the \texttt{extern} specifier is explicitly used. [Example:

```c
int& r1; // error: initializer missing
extern int& r2; // OK

— end example ]

4 Given types “\texttt{cv1} \texttt{T1}” and “\texttt{cv2} \texttt{T2}, “\texttt{cv1} \texttt{T1}” is reference-related to “\texttt{cv2} \texttt{T2}” if \texttt{T1} is the same type as \texttt{T2}, or \texttt{T1} is a base class of \texttt{T2}. “\texttt{cv1} \texttt{T1}” is reference-compatible with “\texttt{cv2} \texttt{T2}” if \texttt{T1} is reference-related to \texttt{T2} and \texttt{cv1} is the same cv-qualification as, or greater cv-qualification than, \texttt{cv2}. For purposes of overload resolution, cases for which \texttt{cv1} is greater cv-qualification than \texttt{cv2} are identified as reference-compatible with added qualification (see 13.3.3.2). In all cases where the reference-related or reference-compatible relationship of two types is used to establish the validity of a reference binding, and \texttt{T1} is a base class of \texttt{T2}, a program that necessitates such a binding is ill-formed if \texttt{T1} is an inaccessible (clause 11) or ambiguous (10.2) base class of \texttt{T2}.

A reference to type “\texttt{cv1} \texttt{T1}” is initialized by an expression of type “\texttt{cv2} \texttt{T2}” as follows:

— If the initializer expression

— is an lvalue (but is not a bit-field), and “\texttt{cv1} \texttt{T1}” is reference-compatible with “\texttt{cv2} \texttt{T2},” or
— has a class type (i.e., $T_2$ is a class type) and can be implicitly converted to an lvalue of type “$cv_3 T_3$,” where “$cv_1 T_1$” is reference-compatible with “$cv_3 T_3$”\(^\text{[98]}\) (this conversion is selected by enumerating the applicable conversion functions (13.3.1.6) and choosing the best one through overload resolution (13.3)),

then the reference is bound directly to the initializer expression lvalue in the first case, and the reference is bound to the lvalue result of the conversion in the second case. In these cases the reference is said to bind directly to the initializer expression. [Note: the usual lvalue-to-rvalue (4.1), array-to-pointer (4.2), and function-to-pointer (4.3) standard conversions are not needed, and therefore are suppressed, when such direct bindings to lvalues are done. — end note]

[Example:

double d = 2.0;
double& rd = d; // rd refers to d
const double& rcd = d; // rcd refers to d

struct A {};
struct B : public A {} b;
A& ra = b; // ra refers to A subobject in b
const A& rca = b; // rca refers to A subobject in b

— end example]

— Otherwise, the reference shall be to a non-volatile const type (i.e., $cv_1$ shall be const). [Example:

double& rd2 = 2.0; // error: not an lvalue and reference not const
int i = 2;
double& rd3 = i; // error: type mismatch and reference not const

— end example]

— If the initializer expression is an rvalue, with $T_2$ a class type, and “$cv_1 T_1$” is reference-compatible with “$cv_2 T_2$,” the reference is bound in one of the following ways (the choice is implementation-defined):

— The reference is bound to the object represented by the rvalue (see 3.10) or to a subobject within that object.

— A temporary of type “$cv_1 T_2$” [sic] is created, and a constructor is called to copy the entire rvalue object into the temporary. The reference is bound to the temporary or to a subobject within the temporary.\(^\text{[99]}\)

The constructor that would be used to make the copy shall be callable whether or not the copy is actually done. [Example:

struct A {};
struct B : public A {} b;
extern B f();
const A& rca = f(); // Either bound to the A subobject of the B rvalue,
// or the entire B object is copied and the reference
// is bound to the A subobject of the copy

\(^{98}\) This requires a conversion function (12.3.2) returning a reference type.

\(^{99}\) Clearly, if the reference initialization being processed is one for the first argument of a copy constructor call, an implementation must eventually choose the first alternative (binding without copying) to avoid infinite recursion.

Draft
Otherwise, a temporary of type “cv1 T1” is created and initialized from the initializer expression using the rules for a non-reference copy initialization (8.5). The reference is then bound to the temporary. If T1 is reference-related to T2, cv1 must be the same cv-qualification as, or greater cv-qualification than, cv2; otherwise, the program is ill-formed. [Example:

```cpp
const double& rcd2 = 2; // rcd2 refers to temporary with value 2.0
const volatile int cvi = 1;
const int& r = cvi;     // error: type qualifiers dropped
```

— end example ]

Note: 12.2 describes the lifetime of temporaries bound to references. — end note ]
A class is a type. Its name becomes a class-name (9.1) within its scope.

```
class-name:
  identifier
  template-id
```

Class-specifiers and elaborated-type-specifiers (7.1.5.3) are used to make class-names. An object of a class consists of a (possibly empty) sequence of members and base class objects.

```
class-specifier:
  class-head { member-specification opt }

class-head:
  class-key identifier opt
  base-clause opt
  class-key nested-name-specifier
  identifier base-clause opt
  class-key nested-name-specifier opt template-id base-clause opt

class-key:
  class
  struct
  union
```

A class-specifier where the class-head omits the optional identifier defines an unnamed class.

2 A class-name is inserted into the scope in which it is declared immediately after the class-name is seen. The class-name is also inserted into the scope of the class itself; this is known as the injected-class-name. For purposes of access checking, the injected-class-name is treated as if it were a public member name. A class-specifier is commonly referred to as a class definition. A class is considered defined after the closing brace of its class-specifier has been seen even though its member functions are in general not yet defined.

3 Complete objects and member subobjects of class type shall have nonzero size.\[100\] [Note: class objects can be assigned, passed as arguments to functions, and returned by functions (except objects of classes for which copying has been restricted; see 12.8). Other plausible operators, such as equality comparison, can be defined by the user; see 13.5. — end note]

4 A structure is a class defined with the class-key struct; its members and base classes (clause 10) are public by default (clause 11). A union is a class defined with the class-key union; its members are public by default and it holds only one data member at a time (9.5). [Note: aggregates of class type are described in 8.5.1. — end note] A POD-struct is an aggregate class that has no non-static data members of type non-POD-struct, non-POD-union (or array of such types) or reference, and has no user-declared copy assignment operator and no user-declared destructor. Similarly, a POD-union

---

\[100\] Base class subobjects are not so constrained.
is an aggregate union that has no non-static data members of type non-POD-struct, non-POD-union (or array of such types) or reference, and has no user-declared copy assignment operator and no user-declared destructor. A POD class is a class that is either a POD-struct or a POD-union.

If a class-head contains a nested-name-specifier, the class-specifier shall refer to a class that was previously declared directly in the class or namespace to which the nested-name-specifier refers (i.e., neither inherited nor introduced by a using-declaration), and the class-specifier shall appear in a namespace enclosing the previous declaration.

9.1 Class names

1 A class definition introduces a new type. [Example:

```c
struct X { int a; };
struct Y { int a; };
X a1;
Y a2;
int a3;
```

declares three variables of three different types. This implies that

```c
a1 = a2;  // error: Y assigned to X
a1 = a3;  // error: int assigned to X
```

are type mismatches, and that

```c
int f(X);
int f(Y);
```

declare an overloaded (clause 13) function f() and not simply a single function f() twice. For the same reason,

```c
struct S { int a; };
struct S { int a; };  // error, double definition
```

is ill-formed because it defines S twice. — end example ]

2 A class declaration introduces the class name into the scope where it is declared and hides any class, object, function, or other declaration of that name in an enclosing scope (3.3). If a class name is declared in a scope where an object, function, or enumerator of the same name is also declared, then when both declarations are in scope, the class can be referred to only using an elaborated-type-specifier (3.4.4). [Example:

```c
struct stat {
  // ...
};

stat gstat;  // use plain stat to
             // define variable

int stat(struct stat*);  // redeclare stat as function

void f()
{
  struct stat* ps;  // struct prefix needed
```

Draft
A declaration consisting solely of class-key identifier; is either a redeclaration of the name in the current scope or a forward declaration of the identifier as a class name. It introduces the class name into the current scope. [Example:

```c
struct s { int a; }

void g()
{
    struct s; // hide global struct s
    // with a local declaration
    s* p; // refer to local struct s
    struct s { char* p; }; // define local struct s
    struct s; // redeclaration, has no effect
}
```

—end example] [Note: Such declarations allow definition of classes that refer to each other. [Example:

```c
class Vector;

class Matrix {
    // ...
    friend Vector operator*(Matrix&, Vector&);
};

class Vector {
    // ...
    friend Vector operator*(Matrix&, Vector&);
};
```

Declaration of friends is described in 11.4, operator functions in 13.5. —end example] —end note]

[Note: An elaborated-type-specifier (7.1.5.3) can also be used as a type-specifier as part of a declaration. It differs from a class declaration in that if a class of the elaborated name is in scope the elaborated name will refer to it. —end note] [Example:

```c
struct s { int a; }

void g(int s)
{
    struct s* p = new struct s; // global s
    p->a = s; // local s
}
```

—end example]
4 [Note: The declaration of a class name takes effect immediately after the identifier is seen in the class definition or elaborated-type-specifier. For example,

```c
class A * A;
```

first specifies A to be the name of a class and then redefines it as the name of a pointer to an object of that class. This means that the elaborated form `class A` must be used to refer to the class. Such artistry with names can be confusing and is best avoided. — end note]

5 A typedef-name (7.1.3) that names a class type, or a cv-qualified version thereof, is also a class-name, but shall not be used as the identifier in a class-head.

9.2 Class members

```
member-specification:
    member-declaration member-specificationopt
access-specifier : member-specificationopt

member-declaration:
    decl-specifier-seqopt member-declarator-listopt ;
    function-definition ;opt
    ::opt nested-name-specifier templateopt unqualified-id ;
using-declaration
static_assert-declaration
template-declaration

member-declarator-list:
    member-declarator
    member-declarator-list , member-declarator

member-declarator:
    declarator pure-specifieropt
    declarator constant-initializeropt
    identifieropt : constant-expression

pure-specifier:
    = 0

constant-initializer:
    = constant-expression
```

1 The `member-specification` in a class definition declares the full set of members of the class; no member can be added elsewhere. Members of a class are data members, member functions (9.3), nested types, and enumerators. Data members and member functions are static or non-static; see 9.4. Nested types are classes (9.1, 9.7) and enumerations (7.2) defined in the class, and arbitrary types declared as members by use of a typedef declaration (7.1.3). The enumerators of an enumeration (7.2) defined in the class are members of the class. Except when used to declare friends (11.4) or to introduce the name of a member of a base class into a derived class (7.3.3,11.3), `member-declarations` declare members of the class, and each such `member-declaration` shall declare at least one member name of the class. A member shall not be declared twice in the `member-specification`, except that a nested class or member class template can be declared and then later defined.

2 A class is considered a completely-defined object type (3.9) (or complete type) at the closing `}` of the `class-specifier`. Within the class `member-specification`, the class is regarded as complete within function bodies, default arguments,
exception-specifications, and constructor ctor-initializers (including such things in nested classes). Otherwise it is regarded as incomplete within its own class member-specification.

[Note: a single name can denote several function members provided their types are sufficiently different (clause 13). — end note]

A member-declarator can contain a constant-initializer only if it declares a static member (9.4) of const integral or const enumeration type, see 9.4.2.

A member can be initialized using a constructor; see 12.1. [Note: see clause 12 for a description of constructors and other special member functions. — end note]

A member shall not be auto, extern, or register.

The decl-specifier-seq is omitted in constructor, destructor, and conversion function declarations only. The member-declarator-list can be omitted only after a class-specifier, an enum-specifier, or a decl-specifier-seq of the form friend elaborated-type-specifier. A pure-specifier shall be used only in the declaration of a virtual function (10.3).

Non-static (9.4) data members shall not have incomplete types. In particular, a class C shall not contain a non-static member of class C, but it can contain a pointer or reference to an object of class C.

Each occurrence in an expression of the name of a non-static data member or non-static member function of a class shall be expressed as a class member access (5.2.5), except when it appears in the formation of a pointer to member (5.3.1), when it appears in the body of a non-static member function of its class or of a class derived from its class (9.3.1), or when it appears in a mem-initializer for a constructor for its class or for a class derived from its class (12.6.2).

[Note: the type of a non-static member function is an ordinary function type, and the type of a non-static data member is an ordinary object type. There are no special member function types or data member types. — end note]

Example: A simple example of a class definition is

```c
struct tnode {
    char tword[20];
    int count;
    tnode *left;
    tnode *right;
};
```

which contains an array of twenty characters, an integer, and two pointers to similar structures. Once this definition has been given, the declaration

```c
tnode s, *sp;
```

declares s to be a tnode and sp to be a pointer to a tnode. With these declarations, sp->count refers to the count member of the structure to which sp points; s.left refers to the left subtree pointer of the structure s; and s.right->tword[0] refers to the initial character of the tword member of the right subtree of s. — end example]

Nonstatic data members of a (non-union) class declared without an intervening access-specifier are allocated so that later members have higher addresses within a class object. The order of allocation of non-static data members separated by an access-specifier is unspecified (11.1). Implementation alignment requirements might cause two adjacent members not to be allocated immediately after each other; so might requirements for space for managing virtual functions (10.3) and virtual base classes (10.1).
If \( T \) is the name of a class, then each of the following shall have a name different from \( T \):

- every static data member of class \( T \);
- every member function of class \( T \) \[ Note: this restriction does not apply to constructors, which do not have names (12.1) \] ;
- every member of class \( T \) that is itself a type;
- every enumerator of every member of class \( T \) that is an enumerated type; and
- every member of every anonymous union that is a member of class \( T \).

In addition, if class \( T \) has a user-declared constructor (12.1), every non-static data member of class \( T \) shall have a name different from \( T \).

Two POD-struct (clause 9) types are layout-compatible if they have the same number of non-static data members, and corresponding non-static data members (in order) have layout-compatible types (3.9).

Two POD-union (clause 9) types are layout-compatible if they have the same number of non-static data members, and corresponding non-static data members (in any order) have layout-compatible types (3.9).

If a POD-union contains two or more POD-structs that share a common initial sequence, and if the POD-union object currently contains one of these POD-structs, it is permitted to inspect the common initial part of any of them. Two POD-structs share a common initial sequence if corresponding members have layout-compatible types (and, for bit-fields, the same widths) for a sequence of one or more initial members.

A pointer to a POD-struct object, suitably converted using a reinterpret_cast, points to its initial member (or if that member is a bit-field, then to the unit in which it resides) and vice versa. \[ Note: There might therefore be unnamed padding within a POD-struct object, but not at its beginning, as necessary to achieve appropriate alignment. \] — end note

### 9.3 Member functions

Functions declared in the definition of a class, excluding those declared with a friend specifier (11.4), are called member functions of that class. A member function may be declared static in which case it is a static member function of its class (9.4); otherwise it is a non-static member function of its class (9.3.1, 9.3.2).

A member function may be defined (8.4) in its class definition, in which case it is an inline member function (7.1.2), or it may be defined outside of its class definition if it has already been declared but not defined in its class definition. A member function definition that appears outside of the class definition shall appear in a namespace scope enclosing the class definition. Except for member function definitions that appear outside of a class definition, and except for explicit specializations of member functions of class templates and member function templates (14.7) appearing outside of the class definition, a member function shall not be redeclared.

An inline member function (whether static or non-static) may also be defined outside of its class definition provided either its declaration in the class definition or its definition outside of the class definition declares the function as inline. \[ Note: member functions of a class in namespace scope have external linkage. Member functions of a local class (9.8) have no linkage. See 3.5. \] — end note

There shall be at most one definition of a non-inline member function in a program; no diagnostic is required. There may be more than one inline member function definition in a program. See 3.2 and 7.1.2.
If the definition of a member function is lexically outside its class definition, the member function name shall be qualified by its class name using the :: operator. [Note: a name used in a member function definition (that is, in the parameter-declaration-clause including the default arguments (8.3.6), or in the member function body, or, for a constructor function (12.1), in a mem-initializer expression (12.6.2)) is looked up as described in 3.4. —end note] [Example:

```c
struct X {
    typedef int T;
    static T count;
    void f(T);
};
void X::f(T t = count) {
}
```

The member function f of class X is defined in global scope; the notation X::f specifies that the function f is a member of class X and in the scope of class X. In the function definition, the parameter type T refers to the typedef member T declared in class X and the default argument count refers to the static data member count declared in class X. —end example]

A static local variable in a member function always refers to the same object, whether or not the member function is inline.

Member functions may be mentioned in friend declarations after their class has been defined.

Member functions of a local class shall be defined inline in their class definition, if they are defined at all.

[Note: a member function can be declared (but not defined) using a typedef for a function type. The resulting member function has exactly the same type as it would have if the function declarator were provided explicitly, see 8.3.5. For example,

```c
typedef void fv(void);
typedef void fvc(void) const;
struct S {
    fv memfunc1; // equivalent to: void memfunc1(void);
    void memfunc2();
    fvc memfunc3; // equivalent to: void memfunc3(void) const;
};
fv S::* pmfv1 = &S::memfunc1;
fv S::* pmfv2 = &S::memfunc2;
fvc S::* pmfv3 = &S::memfunc3;
```

Also see 14.3. —end note]

### 9.3.1 Nonstatic member functions

A non-static member function may be called for an object of its class type, or for an object of a class derived (clause 10) from its class type, using the class member access syntax (5.2.5, 13.3.1.1). A non-static member function may also be called directly using the function call syntax (5.2.2, 13.3.1.1)

— from within the body of a member function of its class or of a class derived from its class, or
— from a mem-initializer (12.6.2) for a constructor for its class or for a class derived from its class.

If a non-static member function of a class X is called for an object that is not of type X, or of a type derived from X, the behavior is undefined.
When an id-expression (5.1) that is not part of a class member access syntax (5.2.5) and not used to form a pointer to member (5.3.1) is used in the body of a non-static member function of class X or used in the mem-initializer for a constructor of class X, if name lookup (3.4.1) resolves the name in the id-expression to a non-static non-type member of class X or of a base class of X, the id-expression is transformed into a class member access expression (5.2.5) using (*this) (9.3.2) as the postfix-expression to the left of the . operator. The member name then refers to the member of the object for which the function is called. Similarly during name lookup, when an unqualified-id (5.1) used in the definition of a member function for class X resolves to a static member, an enumerator or a nested type of class X or of a base class of X, the unqualified-id is transformed into a qualified-id (5.1) in which the nested-name-specifier names the class of the member function. [Example:

```c
struct tnode {
    char tword[20];
    int count;
    tnode *left;
    tnode *right;
    void set(char*, tnode* l, tnode* r);
};

void tnode::set(char* w, tnode* l, tnode* r) {
    count = strlen(w)+1;
    if (sizeof(tword)<=count)
        perror("tnode string too long");
    strcpy(tword,w);
    left = l;
    right = r;
}

void f(tnode n1, tnode n2) {
    n1.set("abc",&n2,0);
    n2.set("def",0,0);
}
```

In the body of the member function tnode::set, the member names tword, count, left, and right refer to members of the object for which the function is called. Thus, in the call n1.set("abc",&n2,0), tword refers to n1.tword, and in the call n2.set("def",0,0), it refers to n2.tword. The functions strlen, perror, and strcpy are not members of the class tnode and should be declared elsewhere.101] — end example]

A non-static member function may be declared const, volatile, or const volatile. These cv-qualifiers affect the type of the this pointer (9.3.2). They also affect the function type (8.3.5) of the member function; a member function declared const is a const member function, a member function declared volatile is a volatile member function and a member function declared const volatile is a const volatile member function. [Example:

```c
struct X {
    void g() const;
    void h() const volatile;
};
```

101] See, for example, <cstring> (21.4).
X::g is a const member function and X::h is a const volatile member function. — end example]

5 A non-static member function may be declared virtual (10.3) or pure virtual (10.4).

### 9.3.2 The this pointer

1 In the body of a non-static (9.3) member function, the keyword this is a non-lvalue expression whose value is the address of the object for which the function is called. The type of this in a member function of a class X is X*. If the member function is declared const, the type of this is const X*, if the member function is declared volatile, the type of this is volatile X*, and if the member function is declared const volatile, the type of this is const volatile X*.

2 In a const member function, the object for which the function is called is accessed through a const access path; therefore, a const member function shall not modify the object and its non-static data members. [Example:

```c
struct s {
    int a;
    int f() const;
    int g() { return a++; }
    int h() const { return a++; } // error
};

int s::f() const { return a; }
```

The a++ in the body of s::h is ill-formed because it tries to modify (a part of) the object for which s::h() is called. This is not allowed in a const member function because this is a pointer to const; that is, *this has const type. — end example]

3 Similarly, volatile semantics (7.1.5.1) apply in volatile member functions when accessing the object and its non-static data members.

4 A cv-qualified member function can be called on an object-expression (5.2.5) only if the object-expression is as cv-qualified or less-cv-qualified than the member function. [Example:

```c
void k(s& x, const s& y)
{
    x.f();
    x.g();
    y.f();
    y.g(); // error
}
```

The call y.g() is ill-formed because y is const and s::g() is a non-const member function, that is, s::g() is less-qualified than the object-expression y. — end example]

5 Constructors (12.1) and destructors (12.4) shall not be declared const, volatile or const volatile. [Note: However, these functions can be invoked to create and destroy objects with cv-qualified types, see (12.1) and (12.4). — end

Draft
9.4 Static members

A data or function member of a class may be declared `static` in a class definition, in which case it is a `static member` of the class.

A static member `s` of class `X` may be referred to using the `qualified-id` expression `X::s`; it is not necessary to use the class member access syntax (5.2.5) to refer to a static member. A static member may be referred to using the class member access syntax, in which case the `object-expression` is evaluated. [Example:

```cpp
class process {
public:
    static void reschedule();
};

process & g();

void f()
{
    process::reschedule();       // OK: no object necessary
    g().reschedule();            // g() is called
}
```
—end example]

A static member may be referred to directly in the scope of its class or in the scope of a class derived (clause 10) from its class; in this case, the static member is referred to as if a `qualified-id` expression was used, with the `nested-name-specifier` of the `qualified-id` naming the class scope from which the static member is referenced. [Example:

```cpp
int g();
struct X {
    static int g();
};
struct Y : X {
    static int i;
};
int Y::i = g();                           // equivalent to Y::g();
```
—end example]

If an `unqualified-id` (5.1) is used in the definition of a static member following the member’s `declarator-id`, and name lookup (3.4.1) finds that the `unqualified-id` refers to a static member, enumerator, or nested type of the member’s class (or of a base class of the member’s class), the `unqualified-id` is transformed into a `qualified-id` expression in which the `nested-name-specifier` names the class scope from which the member is referenced. The definition of a static member shall not use directly the names of the non-static members of its class or of a base class of its class (including as operands of the `sizeof` operator). The definition of a static member may only refer to these members to form pointer to members (5.3.1) or with the class member access syntax (5.2.5).

Static members obey the usual class member access rules (clause 11). When used in the declaration of a class member, the `static` specifier shall only be used in the member declarations that appear within the `member-specification` of the
9.4 Static members

9.4.1 Static member functions

1 [Note: the rules described in 9.3 apply to static member functions. — end note] A static member function shall not be virtual. There shall not be a static and a non-static member function with the same name and the same parameter types (13.1). A static member function shall not be declared const, volatile, or const volatile.

9.4.2 Static data members

1 A static data member is not part of the subobjects of a class. There is only one copy of a static data member shared by all the objects of the class.

The declaration of a static data member in its class definition is not a definition and may be of an incomplete type other than cv-qualified void. The definition for a static data member shall appear in a namespace scope enclosing the member’s class definition. In the definition at namespace scope, the name of the static data member shall be qualified by its class name using the :: operator. The initializer expression in the definition of a static data member is in the scope of its class (3.3.6). [Example:

```cpp
class process {
    static process* run_chain;
    static process* running;
};

process* process::running = get_main();
process* process::run_chain = running;
```

The static data member `run_chain` of class `process` is defined in global scope; the notation `process::run_chain` specifies that the member `run_chain` is a member of class `process` and in the scope of class `process`. In the static data member definition, the initializer expression refers to the static data member `running` of class `process`. — end example]

[Note: once the static data member has been defined, it exists even if no objects of its class have been created. [Example: in the example above, `run_chain` and `running` exist even if no objects of class `process` are created by the program. — end example] — end note]

2 If a static data member is of const integral or const enumeration type, its declaration in the class definition can specify a constant-initializer which shall be an integral constant expression (5.19). In that case, the member can appear in integral constant expressions. The member shall still be defined in a namespace scope if it is used in the program and the namespace scope definition shall not contain an initializer.

3 There shall be exactly one definition of a static data member that is used in a program; no diagnostic is required; see 3.2. Unnamed classes and classes contained directly or indirectly within unnamed classes shall not contain static data members.

4 Static data members of a class in namespace scope have external linkage (3.5). A local class shall not have static data members.

5 Static data members are initialized and destroyed exactly like non-local objects (3.6.2, 3.6.3).
A static data member shall not be mutable (7.1.1).

### 9.5 Unions

In a union, at most one of the data members can be active at any time, that is, the value of at most one of the data members can be stored in a union at any time. [Note: a special guarantee is made in order to simplify the use of unions: If a POD-union contains several POD-structs that share a common initial sequence (9.2), and if an object of this POD-union type contains one of the POD-structs, it is permitted to inspect the common initial sequence of any of the POD-struct members; see 9.2. — end note] The size of a union is sufficient to contain the largest of its data members. Each data member is allocated as if it were the sole member of a struct. A union can have member functions (including constructors and destructors), but not virtual (10.3) functions. A union shall not have base classes. A union shall not be used as a base class. An object of a class with a non-trivial default constructor (12.1), a non-trivial copy constructor (12.8), a non-trivial destructor (12.4), or a non-trivial copy assignment operator (13.5.3, 12.8) cannot be a member of a union, nor can an array of such objects. If a union contains a static data member, or a member of reference type, the program is ill-formed.

A union of the form

```c
union { member-specification };
```

is called an anonymous union; it defines an unnamed object of unnamed type. The member-specification of an anonymous union shall only define non-static data members. [Note: nested types and functions cannot be declared within an anonymous union. — end note] The names of the members of an anonymous union shall be distinct from the names of any other entity in the scope in which the anonymous union is declared. For the purpose of name lookup, after the anonymous union definition, the members of the anonymous union are considered to have been defined in the scope in which the anonymous union is declared. [Example:

```c
void f()
{
    union { int a; char* p; };
    a = 1;
    // ...
    p = "Jennifer";
    // ...
}
```

Here `a` and `p` are used like ordinary (nonmember) variables, but since they are union members they have the same address. — end example]

Anonymous unions declared in a named namespace or in the global namespace shall be declared static. Anonymous unions declared at block scope shall be declared with any storage class allowed for a block-scope variable, or with no storage class. A storage class is not allowed in a declaration of an anonymous union in a class scope. An anonymous union shall not have private or protected members (clause 11). An anonymous union shall not have function members.

A union for which objects or pointers are declared is not an anonymous union. [Example:

```c
union { int aa; char* p; } obj, *ptr = &obj;
    aa = 1;                       // error
    ptr->aa = 1;                  // OK
```
The assignment to plain `aa` is ill-formed since the member name is not visible outside the union, and even if it were visible, it is not associated with any particular object. — end example] [Note: Initialization of unions with no user-declared constructors is described in (8.5.1). — end note]

### 9.6 Bit-fields

1 A member-declarator of the form

```plaintext
identifier_{opt} : constant-expression
```

specifies a bit-field; its length is set off from the bit-field name by a colon. The bit-field attribute is not part of the type of the class member. The `constant-expression` shall be an integral constant-expression with a value greater than or equal to zero. The constant-expression may be larger than the number of bits in the object representation (3.9) of the bit-field’s type; in such cases the extra bits are used as padding bits and do not participate in the value representation (3.9) of the bit-field. Allocation of bit-fields within a class object is implementation-defined. Alignment of bit-fields is implementation-defined. Bit-fields are packed into some addressable allocation unit. [Note: bit-fields straddle allocation units on some machines and not on others. Bit-fields are assigned right-to-left on some machines, left-to-right on others. — end note]

2 A declaration for a bit-field that omits the `identifier` declares an unnamed bit-field. Unnamed bit-fields are not members and cannot be initialized. [Note: an unnamed bit-field is useful for padding to conform to externally-imposed layouts. — end note] As a special case, an unnamed bit-field with a width of zero specifies alignment of the next bit-field at an allocation unit boundary. Only when declaring an unnamed bit-field may the `constant-expression` be a value equal to zero.

3 A bit-field shall not be a static member. A bit-field shall have integral or enumeration type (3.9.1). It is implementation-defined whether a plain (neither explicitly signed nor unsigned) `char`, `short`, `int` or `long` bit-field is signed or unsigned. A `bool` value can successfully be stored in a bit-field of any nonzero size. The address-of operator `&` shall not be applied to a bit-field, so there are no pointers to bit-fields. A non-const reference shall not be bound to a bit-field (8.5.3). [Note: if the initializer for a reference of type `const T&` is an lvalue that refers to a bit-field, the reference is not bound to the bit-field directly. See 8.5.3. — end note]

4 If the value `true` or `false` is stored into a bit-field of type `bool` of any size (including a one bit bit-field), the original `bool` value and the value of the bit-field shall compare equal. If the value of an enumerator is stored into a bit-field of the same enumeration type and the number of bits in the bit-field is large enough to hold all the values of that enumeration type, the original enumerator value and the value of the bit-field shall compare equal. [Example:

```c
enum BOOL { FALSE=0, TRUE=1 };  
struct A {
    BOOL b:1;
};  
A a; 
void f() {  
a.b = TRUE;  
if (a.b == TRUE) // shall yield true
    { /* ... */  
}
```
A class can be declared within another class. A class declared within another is called a *nested* class. The name of a nested class is local to its enclosing class. The nested class is in the scope of its enclosing class. [Note: In accordance with 9.2, except by using explicit pointers, references, and object names, declarations in a nested class shall not use non-static data members or non-static member functions from the enclosing class. This restriction applies in all constructs including the operands of the `sizeof` operator. — end note]

**Example:**

```cpp
class enclose {
public:
    int x;
    static int s;

class inner {
    void f(int i) {
        int a = sizeof(x); // error: direct use of enclose::x even in sizeof
        x = i; // error: assign to enclose::x
        s = i; // OK: assign to enclose::s
        ::x = i; // OK: assign to global x
        y = i; // OK: assign to global y
    }

    void g(enclose* p, int i) {
        p->x = i; // OK: assign to enclose::x
    }

};

inner* p = 0; // error: inner not in scope
```

— end example ]

Member functions and static data members of a nested class can be defined in a namespace scope enclosing the definition of their class. [Example:

```cpp
class enclose {
public:
    class inner {
        static int x;
        void f(int i);
    }

class inner {
    static int x;
    void f(int i);

Draft
If class \( X \) is defined in a namespace scope, a nested class \( Y \) may be declared in class \( X \) and later defined in the definition of class \( X \) or be later defined in a namespace scope enclosing the definition of class \( X \). [Example:

```c
class E {
    class I1;  // forward declaration of nested class
    class I2;
    class I1 {};  // definition of nested class
};
class E::I2 {};  // definition of nested class

— end example ]
```

Like a member function, a friend function (11.4) defined within a nested class is in the lexical scope of that class; it obeys the same rules for name binding as a static member function of that class (9.4) and has no special access rights to members of an enclosing class.

### 9.8 Local class declarations

A class can be declared within a function definition; such a class is called a local class. The name of a local class is local to its enclosing scope. The local class is in the scope of the enclosing scope, and has the same access to names outside the function as does the enclosing function. Declarations in a local class can use only type names, static variables, extern variables and functions, and enumerators from the enclosing scope. [Example:

```c
int x;
void f() {
    static int s;
    int x;
    extern int g();

    struct local {
        int g() { return x; }  // error: x is auto
        int h() { return s; }  // OK
        int k() { return ::x; }  // OK
        int l() { return g(); }  // OK
    };
    // ...
}

local* p = 0;  // error: local not in scope

— end example ]
```
2 An enclosing function has no special access to members of the local class; it obeys the usual access rules (clause 11). Member functions of a local class shall be defined within their class definition, if they are defined at all.

3 If class X is a local class a nested class Y may be declared in class X and later defined in the definition of class X or be later defined in the same scope as the definition of class X. A class nested within a local class is a local class.

4 A local class shall not have static data members.

9.9 Nested type names

Type names obey exactly the same scope rules as other names. In particular, type names defined within a class definition cannot be used outside their class without qualification. 

Example:

```cpp
class X {
public:
    typedef int I;
    class Y { /* ... */ };
    I a;
};

I b; // error
Y c; // error
X::Y d; // OK
X::I e; // OK
```

— end example —
Chapter 10  Derived classes

1 A list of base classes can be specified in a class definition using the notation:

   base-clause:
      : base-specifier-list

   base-specifier-list:
      base-specifier
      base-specifier-list , base-specifier

   base-specifier:
      :: opt nested-name-specifier opt class-name
      virtual access-specifier opt :: opt nested-name-specifier opt class-name
      access-specifier virtual opt :: opt nested-name-specifier opt class-name

   access-specifier:
      private
      protected
      public

2 The class-name in a base-specifier shall not be an incompletely defined class (clause 9); this class is called a direct base class for the class being defined. During the lookup for a base class name, non-type names are ignored (3.3.7). If the name found is not a class-name, the program is ill-formed. A class B is a base class of a class D if it is a direct base class of D or a direct base class of one of D’s base classes. A class is an indirect base class of another if it is a base class but not a direct base class. A class is said to be (directly or indirectly) derived from its (direct or indirect) base classes. [ Note: See clause 11 for the meaning of access-specifier. — end note ] Unless redeclared in the derived class, members of a base class are also considered to be members of the derived class. The base class members are said to be inherited by the derived class. Inherited members can be referred to in expressions in the same manner as other members of the derived class, unless their names are hidden or ambiguous (10.2). [ Note: the scope resolution operator :: (5.1) can be used to refer to a direct or indirect base member explicitly. This allows access to a name that has been redeclared in the derived class. A derived class can itself serve as a base class subject to access control; see 11.2. A pointer to a derived class can be implicitly converted to a pointer to an accessible unambiguous base class (4.10). An lvalue of a derived class type can be bound to a reference to an accessible unambiguous base class (8.5.3). — end note ]

3 The base-specifier-list specifies the type of the base class subobjects contained in an object of the derived class type. [ Example: ]

   class Base {
      public:
         int a, b, c;
   };
10.1 Multiple base classes

A class can be derived from any number of base classes. [Note: the use of more than one direct base class is often called multiple inheritance. —end note] [Example:

```cpp
class A { /* ... */ ;
class B { /* ... */ ;
class C { /* ... */ ;
class D : public A, public B, public C { /* ... */ ;

—end example]
```

2 [Note: the order of derivation is not significant except as specified by the semantics of initialization by constructor (12.6.2), cleanup (12.4), and storage layout (9.2, 11.1). —end note]
A class shall not be specified as a direct base class of a derived class more than once. \[ Note: \] a class can be an indirect base class more than once and can be a direct and an indirect base class. There are limited things that can be done with such a class. The non-static data members and member functions of the direct base class cannot be referred to in the scope of the derived class. However, the static members, enumerations and types can be unambiguously referred to. \[ — end note \] \[ Example: \]

```cpp
class X { /* ... */ };
class Y : public X, public X { /* ... */ }; // ill-formed

class L { public: int next; /* ... */ };
class A : public L { /* ... */ };
class B : public L { /* ... */ };
class C : public A, public B { void f(); /* ... */ }; // well-formed
class D : public A, public L { void f(); /* ... */ }; // well-formed

— end example \]
```

A base class specifier that does not contain the keyword `virtual`, specifies a non-virtual base class. A base class specifier that contains the keyword `virtual`, specifies a virtual base class. For each distinct occurrence of a non-virtual base class in the class lattice of the most derived class, the most derived object (1.8) shall contain a corresponding distinct base class subobject of that type. For each distinct base class that is specified virtual, the most derived object shall contain a single base class subobject of that type. \[ Example: \] for an object of class type C, each distinct occurrence of a (non-virtual) base class L in the class lattice of C corresponds one-to-one with a distinct L subobject within the object of type C. Given the class C defined above, an object of class C will have two subobjects of class L as shown below.

```
L
A
L
B
C
```

In such lattices, explicit qualification can be used to specify which subobject is meant. The body of function C::f could refer to the member next of each L subobject:

```cpp
void C::f() { A::next = B::next; } // well-formed
```

Without the A:: or B:: qualifiers, the definition of C::f above would be ill-formed because of ambiguity (10.2).

For another example,

```cpp
class V { /* ... */ };
class A : virtual public V { /* ... */ };
class B : virtual public V { /* ... */ };
class C : public A, public B { /* ... */ };
```

for an object c of class type C, a single subobject of type V is shared by every base subobject of c that has a virtual base class of type V. Given the class C defined above, an object of class C will have one subobject of class V, as shown below.

Draft
A class can have both virtual and non-virtual base classes of a given type.

```cpp
class B { /* ... */ };
class X : virtual public B { /* ... */ };
class Y : virtual public B { /* ... */ };
class Z : public B { /* ... */ };
class AA : public X, public Y, public Z { /* ... */ };
```

For an object of class `AA`, all virtual occurrences of base class `B` in the class lattice of `AA` correspond to a single `B` subobject within the object of type `AA`, and every other occurrence of a (non-virtual) base class `B` in the class lattice of `AA` corresponds one-to-one with a distinct `B` subobject within the object of type `AA`. Given the class `AA` defined above, class `AA` has two subobjects of class `B`: `Z`'s `B` and the virtual `B` shared by `X` and `Y`, as shown below.

---

10.2 Member name lookup

Member name lookup determines the meaning of a name (id-expression) in a class scope (3.3.6). Name lookup can result in an ambiguity, in which case the program is ill-formed. For an id-expression, name lookup begins in the class scope of this; for a qualified-id, name lookup begins in the scope of the nested-name-specifier. Name lookup takes place before access control (3.4, clause 11).

The following steps define the result of name lookup for a member name `f` in a class scope `C`.

1. The lookup set for `f` in `C`, called `S(f, C)`, consists of two component sets: the declaration set, a set of members named `f`; and the subobject set, a set of subobjects where declarations of these members (possibly including using-declarations) were found. In the declaration set, using-declarations are replaced by the members they designate, and type declarations (including injected-class-names) are replaced by the types they designate. `S(f, C)` is calculated as follows:

2. If `C` contains a declaration of the name `f`, the declaration set contains every declaration of `f` declared in `C` that satisfies the requirements of the language construct in which the lookup occurs. [Note: Looking up a name in an elaborated-type-specifier (3.4.4) or base-specifier (clause 10), for instance, ignores all non-type declarations, while looking up a name in
a nested-name-specifier (3.4.3) ignores function, object, and enumerator declarations. As another example, looking up a name in a using-declaration (7.3.3) includes the declaration of a class or enumeration that would ordinarily be hidden by another declaration of that name in the same scope. — end note] If the resulting declaration set is not empty, the subobject set contains C itself, and calculation is complete.

5 Otherwise (i.e., C does not contain a declaration of f or the resulting declaration set is empty), S(f, C) is initially empty. If C has base classes, calculate the lookup set for f in each direct base class subobject Bi, and merge each such lookup set S(f, Bi) in turn into S(f, C).

6 The following steps define the result of merging lookup set S(f, Bi) into the intermediate S(f, C):

— If each of the subobject members of S(f, Bi) is a base class subobject of at least one of the subobject members of S(f, C), or if S(f, Bi) is empty, S(f, C) is unchanged and the merge is complete. Conversely, if each of the subobject members of S(f, C) is a base class subobject of at least one of the subobject members of S(f, Bi), or if S(f, C) is empty, the new S(f, C) is a copy of S(f, Bi).

— Otherwise, if the declaration sets of S(f, Bi) and S(f, C) differ, the merge is ambiguous: the new S(f, C) is a lookup set with an invalid declaration set and the union of the subobject sets. In subsequent merges, an invalid declaration set is considered different from any other.

— Otherwise, the new S(f, C) is a lookup set with the shared set of declarations and the union of the subobject sets.

7 The result of name lookup for f in C is the declaration set of S(f, C). If it is an invalid set, the program is ill-formed.

[Example:

```c
struct A { int x; }; // S(x,A) = { { A::x }, { A } }
struct B { float x; }; // S(x,B) = { { B::x }, { B } }
struct C: public A, public B { }; // S(x,C) = { invalid, { A in C, B in C } }
struct D: public virtual C { }; // S(x,D) = S(x,C)
struct E: public virtual C { char x; }; // S(x,E) = { { E::x }, { E } }
struct F: public D, public E { }; // S(x,F) = S(x,E)
int main() {
    F f;
    f.x = 0; // OK, lookup finds E::x
}
```

S(x,F) is unambiguous because the A and B base subobjects of D are also base subobjects of E, so S(x,D) is discarded in the first merge step. — end example]

8 If the name of an overloaded function is unambiguously found, overloading resolution (13.3) also takes place before access control. Ambiguities can often be resolved by qualifying a name with its class name. [Example:

```c
class A {
public:
    int f();
};
class B {
public:
    int f();
};
```

Draft
10.2 Member name lookup

```cpp
class C : public A, public B {
    int f() { return A::f() + B::f(); }
};

— end example ]
```

[Note: A static member, a nested type or an enumerator defined in a base class T can unambiguously be found even if an object has more than one base class subobject of type T. Two base class subobjects share the non-static member subobjects of their common virtual base classes. — end note ]

```cpp
class V { public: int v; }
class A {
public:
    int a;
    static int s;
    enum { e };
};
class B : public A, public virtual V {};
class C : public A, public virtual V {};
class D : public B, public C {}; 

template class t;
void f(D* pd)
{
    pd->v++; // OK: only one v (virtual)
    pd->s++; // OK: only one s (static)
    int i = pd->e; // OK: only one e (enumerator)
    pd->a++; // error, ambiguous: two a's in D
}

— end example ]
```

[Note: When virtual base classes are used, a hidden declaration can be reached along a path through the subobject lattice that does not pass through the hiding declaration. This is not an ambiguity. The identical use with non-virtual base classes is an ambiguity; in that case there is no unique instance of the name that hides all the others. — end note ]

```cpp
class V { public: int f(); int x; }
class W { public: int g(); int y; }
class B : public virtual V, public W {
public:
    int f(); int x;
    int g(); int y;
};
class C : public virtual V, public W {};
class D : public B, public C { void glorp(); }; 

— end example ]
```

Draft
11 [Note: The names declared in V and the left-hand instance of W are hidden by those in B, but the names declared in the right-hand instance of W are not hidden at all. — end note]

```cpp
void D::glorp()
{
  x ++;
  // OK: B::x hides V::x
  f();
  // OK: B::f() hides V::f()
  y ++;
  // error: B::y and C's W::y
  g();
  // error: B::g() and C's W::g()
}
```

— end example ]

12 An explicit or implicit conversion from a pointer to or an lvalue of a derived class to a pointer or reference to one of its base classes shall unambiguously refer to a unique object representing the base class. [Example:

```cpp
class V { };
class A { };
class B : public A, public virtual V { };
class C : public A, public virtual V { };
class D : public B, public C { };

void g()
{
  D d;
  B* pb = &d;
  A* pa = &d;
  // error, ambiguous: C's A or B's A?
  V* pv = &d;
  // OK: only one V subobject
}
```

— end example ]

13 [Note: Even if the result of name lookup is unambiguous, use of a name found in multiple subobjects might still be ambiguous (4.11, 5.2.5, 11.2). — end note ] Example:

```cpp
struct B1 {
  void f();
  static void f(int);
  int i;
};
struct B2 {
  void f(double);
};
```
Virtual functions support dynamic binding and object-oriented programming. A class that declares or inherits a virtual function is called a polymorphic class.

If a virtual member function \(vf\) is declared in a class \(Base\) and in a class \(Derived\), derived directly or indirectly from \(Base\), a member function \(vf\) with the same name, parameter-type-list (8.3.5), and cv-qualification as \(Base::vf\) is declared, then \(Derived::vf\) is also virtual (whether or not it is so declared) and it overrides \(Base::vf\). For convenience we say that any virtual function overrides itself. Then in any well-formed class, for each virtual function declared in that class or any of its direct or indirect base classes there is a unique final overrider that overrides that function and every other overrider of that function. The rules for member lookup (10.2) are used to determine the final overrider for a virtual function in the scope of a derived class but ignoring names introduced by using-declarations.

[Example:

```cpp
struct A {
    virtual void f();
};
struct B : virtual A {
    virtual void f();
};

struct C : B, virtual A {
    using A::f;
};
void foo() {
    C c;
    c.f(); // calls B::f, the final overrider
    c.C::f(); // calls A::f because of the using-declaration
}
```

A function with the same name but a different parameter list (clause 13) as a virtual function is not necessarily virtual and does not override. The use of the virtual specifier in the declaration of an overriding function is legal but redundant (has empty semantics). Access control (clause 11) is not considered in determining overriding.
3 [ Note: a virtual member function does not have to be visible to be overridden, for example,

\[
\begin{align*}
\text{struct B} & \{ \\
\phantom{\text{struct B}} & \quad \text{virtual void f();} \\
\phantom{\text{struct B}} & \}; \\
\text{struct D : B} & \{ \\
\phantom{\text{struct D : B}} & \quad \text{void f(int);} \\
\phantom{\text{struct D : B}} & \}; \\
\text{struct D2 : D} & \{ \\
\phantom{\text{struct D2 : D}} & \quad \text{void f();} \\
\phantom{\text{struct D2 : D}} & \};
\end{align*}
\]

the function \text{f(int)} in class D hides the virtual function \text{f()} in its base class B: \text{D::f(int)} is not a virtual function. However, \text{f()} declared in class D2 has the same name and the same parameter list as \text{B::f()}, and therefore is a virtual function that overrides the function \text{B::f()} even though \text{B::f()} is not visible in class D2. — end note ]

4 Even though destructors are not inherited, a destructor in a derived class overrides a base class destructor declared virtual; see 12.4 and 12.5.

5 The return type of an overriding function shall be either identical to the return type of the overridden function or covariant with the classes of the functions. If a function \text{D::f} overrides a function \text{B::f}, the return types of the functions are covariant if they satisfy the following criteria:

\begin{itemize}
\item both are pointers to classes or references to classes\(^{03}\)
\item the class in the return type of \text{B::f} is the same class as the class in the return type of \text{D::f}, or is an unambiguous and accessible direct or indirect base class of the class in the return type of \text{D::f}
\item both pointers or references have the same cv-qualification and the class type in the return type of \text{D::f} has the same cv-qualification as or less cv-qualification than the class type in the return type of \text{B::f}.
\end{itemize}

6 If the return type of \text{D::f} differs from the return type of \text{B::f}, the class type in the return type of \text{D::f} shall be complete at the point of declaration of \text{D::f} or shall be the class type \text{D}. When the overriding function is called as the final overrider of the overridden function, its result is converted to the type returned by the (statically chosen) overridden function (5.2.2). [ Example:

\[
\begin{align*}
\text{class B} & \{ \} ; \\
\text{class D : private B} & \{ \text{friend class Derived; } \} ; \\
\text{struct Base} & \{ \\
\phantom{\text{struct Base}} & \quad \text{virtual void vf1();} \\
\phantom{\text{struct Base}} & \quad \text{virtual void vf2();} \\
\phantom{\text{struct Base}} & \quad \text{virtual void vf3();} \\
\phantom{\text{struct Base}} & \quad \text{virtual B* vf4();} \\
\phantom{\text{struct Base}} & \quad \text{virtual B* vf5();} \\
\phantom{\text{struct Base}} & \quad \text{void f();} \\
\phantom{\text{struct Base}} & \};
\end{align*}
\]

\(^{03}\) Multi-level pointers to classes or references to multi-level pointers to classes are not allowed.

Draft
struct No_good : public Base {
    D* vf4();    // error: B (base class of D) inaccessible
};

class A;
struct Derived : public Base {
    void vf1();    // virtual and overrides Base::vf1()
    void vf2(int); // not virtual, hides Base::vf2()
    char vf3();    // error: invalid difference in return type only
    D* vf4();      // OK: returns pointer to derived class
    A* vf5();     // error: returns pointer to incomplete class
    void f();
};

void g()
{
    Derived d;
    Base* bp = &d;     // standard conversion:
        // Derived* to Base*
    bp->vf1();        // calls Derived::vf1()
    bp->vf2();        // calls Base::vf2()
    bp->f();          // calls Base::f() (not virtual)
    B* p = bp->vf4(); // calls Derived::pf() and converts the
    // result to B*

    Derived* dp = &d;
    D* q = dp->vf4(); // calls Derived::pf() and does not
       // convert the result to B*
    dp->vf2();       // ill-formed: argument mismatch
}

— end example ]

7 [Note: the interpretation of the call of a virtual function depends on the type of the object for which it is called (the dynamic type), whereas the interpretation of a call of a non-virtual member function depends only on the type of the pointer or reference denoting that object (the static type) (5.2.2). — end note ]

8 [Note: the virtual specifier implies membership, so a virtual function cannot be a nonmember (7.1.2) function. Nor can a virtual function be a static member, since a virtual function call relies on a specific object for determining which function to invoke. A virtual function declared in one class can be declared a friend in another class. — end note ]

9 A virtual function declared in a class shall be defined, or declared pure (10.4) in that class, or both; but no diagnostic is required (3.2).

10 [Example: here are some uses of virtual functions with multiple base classes:

    struct A {
        virtual void f();
    }

    struct B1 : A {          // note non-virtual derivation
        void f();
    }

    Draft
struct B2 : A {
    void f();
};

struct D : B1, B2 { // D has two separate A subobjects
};

void foo ()
{
    D d;
    // A* ap = &d; // would be ill-formed: ambiguous
    B1* b1p = &d;
    A* ap = b1p;
    D* dp = &d;
    ap->f (); // calls D::B1::f
    dp->f (); // ill-formed: ambiguous
}

In class D above there are two occurrences of class A and hence two occurrences of the virtual member function A::f. The final overrider of B1::A::f is B1::f and the final overrider of B2::A::f is B2::f.

11 The following example shows a function that does not have a unique final overrider:

struct A {
    virtual void f();
};

struct VB1 : virtual A { // note virtual derivation
    void f();
};

struct VB2 : virtual A {
    void f();
};

struct Error : VB1, VB2 { // ill-formed
};

struct Okay : VB1, VB2 {
    void f();
};

Both VB1::f and VB2::f override A::f but there is no overrider of both of them in class Error. This example is therefore ill-formed. Class Okay is well formed, however, because Okay::f is a final overrider.

12 The following example uses the well-formed classes from above.

struct VB1a : virtual A { // does not declare f
};
10.4 Abstract classes

The abstract class mechanism supports the notion of a general concept, such as a shape, of which only more concrete variants, such as circle and square, can actually be used. An abstract class can also be used to define an interface for which derived classes provide a variety of implementations.

An abstract class is a class that can be used only as a base class of some other class; no objects of an abstract class can be created except as subobjects of a class derived from it. A class is abstract if it has at least one pure virtual function. [Note: such a function might be inherited: see below. —end note] A virtual function is specified pure by using a pure-specifier (9.2) in the function declaration in the class definition. A pure virtual function need be defined only if called with, or as if with (12.4), the qualified-id syntax (5.1). [Example:

```cpp
class point { /* . . . */
};
class shape { // abstract class
    point center; // ...
    public:
        point where() { return center; }
        void move(point p) { center=p; draw(); }
        virtual void rotate(int) = 0; // pure virtual
        virtual void draw() = 0; // pure virtual
    // ...
};
```

—end example] [Note: a function declaration cannot provide both a pure-specifier and a definition —end note] [Example:

```cpp
struct C {
    virtual void f() = 0 {}; // ill-formed
};
```

Draft
An abstract class shall not be used as a parameter type, as a function return type, or as the type of an explicit conversion. Pointers and references to an abstract class can be declared. [Example:

```cpp
shape x;       // error: object of abstract class
shape* p;     // OK
shape f();    // error
void g(shape); // error
shape& h(shape&); // OK
```

— end example ]

A class is abstract if it contains or inherits at least one pure virtual function for which the final overrider is pure virtual. [ Example:

```cpp
class ab_circle : public shape {
    int radius;
    public:
        void rotate(int) {} // ab_circle::draw() is a pure virtual
}
```

Since shape::draw() is a pure virtual function ab_circle::draw() is a pure virtual by default. The alternative declaration,

```cpp
class circle : public shape {
    int radius;
    public:
        void rotate(int) {} // a definition is required somewhere
        void draw();
}
```

would make class circle nonabstract and a definition of circle::draw() must be provided. — end example ]

[ Note: an abstract class can be derived from a class that is not abstract, and a pure virtual function may override a virtual function which is not pure. — end note ]

Member functions can be called from a constructor (or destructor) of an abstract class; the effect of making a virtual call (10.3) to a pure virtual function directly or indirectly for the object being created (or destroyed) from such a constructor (or destructor) is undefined.
Chapter 11 Member access control [class.access]

1 A member of a class can be
   — private; that is, its name can be used only by members and friends of the class in which it is declared.
   — protected; that is, its name can be used only by members and friends of the class in which it is declared, and by
     members and friends of classes derived from this class (see 11.5).
   — public; that is, its name can be used anywhere without access restriction.

2 A member of a class can also access all the names declared in the class of which it is a member. A local class of a
   member function may access the same names that the member function itself may access.\(^{104}\)

3 Members of a class defined with the keyword class are private by default. Members of a class defined with the
   keywords struct or union are public by default. [Example:

   ```c
   class X {
   int a;  // X::a is private by default
   };

   struct S {
   int a;  // S::a is public by default
   };
   ```

   — end example]

4 Access control is applied uniformly to all names, whether the names are referred to from declarations or expressions.
   [Note: access control applies to names nominated by friend declarations (11.4) and using-declarations (7.3.3). — end
   note] In the case of overloaded function names, access control is applied to the function selected by overload resolution.
   [Note: because access control applies to names, if access control is applied to a typedef name, only the accessibility of
   the typedef name itself is considered. The accessibility of the entity referred to by the typedef is not considered. For
   example,

   ```c
   class A
   {
   class B { };  // class B is protected
   public:
       typedef B BB;  // typedef BB is public
   };
   ```

\(^{104}\)Access permissions are thus transitive and cumulative to nested and local classes.
11.1 Access specifiers

void f()
{
    A::BB x; // OK, typedef name A::BB is public
    A::B y; // access error, A::B is private
}

— end note —

5 It should be noted that it is access to members and base classes that is controlled, not their visibility. Names of members are still visible, and implicit conversions to base classes are still considered, when those members and base classes are inaccessible. The interpretation of a given construct is established without regard to access control. If the interpretation established makes use of inaccessible member names or base classes, the construct is ill-formed.

6 All access controls in clause 11 affect the ability to access a class member name from a particular scope. The access control for names used in the definition of a class member that appears outside of the member’s class definition is done as if the entire member definition appeared in the scope of the member’s class. In particular, access controls apply as usual to member names accessed as part of a function return type, even though it is not possible to determine the access privileges of that use without first parsing the rest of the function declarator. Similarly, access control for implicit calls to the constructors, the conversion functions, or the destructor called to create and destroy a static data member is performed as if these calls appeared in the scope of the member’s class. [Example:

```cpp
class A {
    typedef int I; // private member
    I f();
    friend I g(I);
    static I x;
};

A::I A::f() { return 0; }
A::I g(A::I p = A::x);
A::I g(A::I p) { return 0; }
A::I A::x = 0;
```

7 Here, all the uses of A::I are well-formed because A::f and A::x are members of class A and g is a friend of class A. This implies, for example, that access checking on the first use of A::I must be deferred until it is determined that this use of A::I is as the return type of a member of class A. —end example —

8 The names in a default argument expression (8.3.6) are bound at the point of declaration, and access is checked at that point rather than at any points of use of the default argument expression. Access checking for default arguments in function templates and in member functions of class templates is performed as described in 14.7.1.

11.1 Access specifiers

Member declarations can be labeled by an access-specifier (clause 10):

An access-specifier specifies the access rules for members following it until the end of the class or until another access-specifier is encountered. [Example:

```cpp
class X {
    int a; // X::a is private by default: class used
    public:
```

Draft
11.2 Accessibility of base classes and base class members

If a class is declared to be a base class (clause 10) for another class using the public access specifier, the public members of the base class are accessible as public members of the derived class and protected members of the base class are accessible as protected members of the derived class. If a class is declared to be a base class for another
class using the protected access specifier, the public and protected members of the base class are accessible as protected members of the derived class. If a class is declared to be a base class for another class using the private access specifier, the public and protected members of the base class are accessible as private members of the derived class.\(^{105}\)

In the absence of an access-specifier for a base class, public is assumed when the derived class is declared struct and private is assumed when the class is declared class. [Example:

```cpp
class B { /* ... */};
class D1 : private B { /* ... */};
class D2 : public B { /* ... */};
class D3 : B { /* ... */};  // B private by default
struct D4 : public B { /* ... */};
struct D5 : private B { /* ... */};
struct D6 : B { /* ... */};  // B public by default
class D7 : protected B { /* ... */};
struct D8 : protected B { /* ... */};
```

Here B is a public base of D2, D4, and D6, a private base of D1, D3, and D5, and a protected base of D7 and D8. —end example]

3  [Note: A member of a private base class might be inaccessible as an inherited member name, but accessible directly. Because of the rules on pointer conversions (4.10) and explicit casts (5.4), a conversion from a pointer to a derived class to a pointer to an inaccessible base class might be ill-formed if an implicit conversion is used, but well-formed if an explicit cast is used. For example,

```cpp
class B {
public:
    int mi;  // non-static member
    static int si; // static member
};
class D : private B {
};
class DD : public D {
    void f();
};

void DD::f() {
    mi = 3;  // error: mi is private in D
    si = 3;  // error: si is private in D
    ::B b;
    b.mi = 3;   // OK (b.mi is different from this->mi)
    b.si = 3;   // OK (b.si is different from this->si)
    ::B::si = 3; // OK
    ::B* bp1 = this;  // error: B is a private base class
    ::B* bp2 = (::B*)this; // OK with cast
    bp2->mi = 3;  // OK: access through a pointer to B.
}
```

\(^{105}\) As specified previously in clause 11, private members of a base class remain inaccessible even to derived classes unless friend declarations within the base class definition are used to grant access explicitly.
4 A base class B of N is accessible at R, if
   — an invented public member of B would be a public member of N, or
   — R occurs in a member or friend of class N, and an invented public member of B would be a private or protected member of N, or
   — R occurs in a member or friend of a class P derived from N, and an invented public member of B would be a private or protected member of P, or
   — there exists a class S such that B is a base class of S accessible at R and S is a base class of N accessible at R.

[Example:
class B {
 public:
  int m;
};

class S: private B {
  friend class N;
};
class N: private S {
  void f() {
    B* p = this;  // OK because class S satisfies the fourth condition
    // above: B is a base class of N accessible in f() because
    // B is an accessible base class of S and S is an accessible
    // base class of N.
  }
};

— end example ]

5 If a base class is accessible, one can implicitly convert a pointer to a derived class to a pointer to that base class (4.10, 4.11). [Note: it follows that members and friends of a class X can implicitly convert an X* to a pointer to a private or protected immediate base class of X. — end note] The access to a member is affected by the class in which the member is named. This naming class is the class in which the member name was looked up and found. [Note: this class can be explicit, e.g., when a qualified-id is used, or implicit, e.g., when a class member access operator (5.2.5) is used (including cases where an implicit “this->” is added). If both a class member access operator and a qualified-id are used to name the member (as in p->T::m), the class naming the member is the class named by the nested-name-specifier of the qualified-id (that is, T). — end note] A member m is accessible at the point R when named in class N if
   — m as a member of N is public, or
   — m as a member of N is private, and R occurs in a member or friend of class N, or
   — m as a member of N is protected, and R occurs in a member or friend of class N, or in a member or friend of a class P derived from N, where m as a member of P is public, private, or protected, or
   — there exists a base class B of N that is accessible at R, and m is accessible at R when named in class B. [Example:
11.3 Access declarations

class B;
class A {
private:
    int i;
    friend void f(B*);
};
class B : public A {};
void f(B* p) {
    p->i = 1;       // OK: B* can be implicitly cast to A*,
    // and i has access to i in A
}

— end example

If a class member access operator, including an implicit “this->,” is used to access a non-static data member or non-static member function, the reference is ill-formed if the left operand (considered as a pointer in the “.” operator case) cannot be implicitly converted to a pointer to the naming class of the right operand. [Note: this requirement is in addition to the requirement that the member be accessible as named. — end note]

11.3 Access declarations

The access of a member of a base class can be changed in the derived class by mentioning its qualified-id in the derived class definition. Such mention is called an access declaration. The effect of an access declaration qualified-id ; is defined to be equivalent to the declaration using qualified-id ;.  

[Example:

class A {
    public:
        int z;
        int z1;
};

class B : public A {
    int a;
    public:
        int b, c;
        int bf();
    protected:
        int x;
        int y;
};

class D : private B {
    int d;
    public:
        B::c;       // adjust access to B::c

106) Access declarations are deprecated; member using-declarations (7.3.3) provide a better means of doing the same things. In earlier versions of the C++ language, access declarations were more limited; they were generalized and made equivalent to using-declarations in the interest of simplicity. Programmers are encouraged to use using-declarations, rather than the new capabilities of access declarations, in new code.
A friend of a class is a function or class that is given permission to use the private and protected member names from the class. A class specifies its friends, if any, by way of friend declarations. Such declarations give special access rights to the friends, but they do not make the nominated friends members of the befriending class. [Example: the following example illustrates the differences between members and friends:

```cpp
class X {
    int a;
    friend void friend_set(X*, int);
public:
    void member_set(int);
};

void friend_set(X* p, int i) { p->a = i; }
void X::member_set(int i) { a = i; }

void f()
{
    X obj;
    friend_set(&obj,10);
    obj.member_set(10);
}
```

— end example ]

2 Declaring a class to be a friend implies that the names of private and protected members from the class granting friend-
ship can be accessed in declarations of members of the befriended class. [Note: this means that access to private and protected names is also granted to member functions of the friend class (as if the functions were each friends) and to the static data member definitions of the friend class. This also means that private and protected type names from the class granting friendship can be used in the base-clause of a nested class of the friend class. However, the declarations of members of classes nested within the friend class cannot access the names of private and protected members from the class granting friendship. Also, because the base-clause of the friend class is not part of its member declarations, the base-clause of the friend class cannot access the names of the private and protected members from the class granting friendship. For example,

```cpp
class A {
    class B { };    
    friend class X;
};
class X : A::B {       // ill-formed: A::B cannot be accessed
    A::B mx;
    friend class Y {      // OK: A::B used to declare member of X
        A::B my;
    };
};
```

— end note ] An elaborated-type-specifier shall be used in a friend declaration for a class.\(^\text{\textsuperscript{107}}\) A class shall not be defined in a friend declaration. [Example:

```cpp
class X {
    enum { a=100 };    
    friend class Y;
};
class Y {
    int v[X::a];        // OK, Y is a friend of X
};
class Z {
    int v[X::a];        // error: X::a is private
};
```

— end example ]

3 A function first declared in a friend declaration has external linkage (3.5). Otherwise, the function retains its previous linkage (7.1.1).

4 When a friend declaration refers to an overloaded name or operator, only the function specified by the parameter types becomes a friend. A member function of a class \(X\) can be a friend of a class \(Y\). [Example:

```cpp
class Y {
    friend char* X::foo(int);
    friend X::X(char);      // constructors can be friends
```

\(^{107}\) The class-key of the elaborated-type-specifier is required.
friend X::~X(); // destructors can be friends

};

— end example ]

5 A function can be defined in a friend declaration of a class if and only if the class is a non-local class (9.8), the function name is unqualified, and the function has namespace scope. [Example:

```c++
class M {
    friend void f() { } // definition of global f, a friend of M,
    // not the definition of a member function
};
— end example ]
```

6 Such a function is implicitly inline. A friend function defined in a class is in the (lexical) scope of the class in which it is defined. A friend function defined outside the class is not (3.4.1).

7 No storage-class-specifier shall appear in the decl-specifier-seq of a friend declaration.

8 A name nominated by a friend declaration shall be accessible in the scope of the class containing the friend declaration. The meaning of the friend declaration is the same whether the friend declaration appears in the private, protected or public (9.2) portion of the class member-specification.

9 Friendship is neither inherited nor transitive. [Example:

```c++
class A {
    friend class B;
    int a;
};

class B {
    friend class C;
};

class C {
    void f(A* p)
    {
        p->a++; // error: C is not a friend of A
    }
};

class D : public B {
    void f(A* p)
    {
        p->a++; // error: D is not a friend of A
    }
};
```

Draft
11.5 Protected member access

An additional access check beyond those described earlier in clause 11 is applied when a non-static data member or non-static member function is a protected member of its naming class (11.2)\(^{108}\). As described earlier, access to a protected member is granted because the reference occurs in a friend or member of some class \(C\). If the access is to form a pointer to member (5.3.1), the nested-nameSpecifier shall name \(C\) or a class derived from \(C\). All other accesses involve a (possibly implicit) object expression (5.2.5). In this case, the class of the object expression shall be \(C\) or a class derived from \(C\). [Example:

```cpp
class B {
    protected:
    int i;
    static int j;
};

class D1 : public B {
};

class D2 : public B {
    friend void fr(B*, D1*, D2*);
    void mem(B*, D1*);
};
```  

\(^{108}\) This additional check does not apply to other members, e.g. static data members or enumerator member constants.
void fr(B* pb, D1* p1, D2* p2)
{
    pb->i = 1; // ill-formed
    p1->i = 2; // ill-formed
    p2->i = 3; // OK (access through a D2)
    p2->B::i = 4; // OK (access through a D2, even though
                   // naming class is B)
    int B::* pmi_B = &B::i; // ill-formed
    int B::* pmi_B2 = &D2::i; // OK (type of &D2::i is int B::*)
    B::j = 5; // OK (because refers to static member)
    D2::j = 6; // OK (because refers to static member)
}

void D2::mem(B* pb, D1* p1)
{
    pb->i = 1; // ill-formed
    p1->i = 2; // ill-formed
    i = 3; // OK (access through this)
    B::i = 4; // OK (access through this, qualification ignored)
    int B::* pmi_B = &B::i; // ill-formed
    int B::* pmi_B2 = &D2::i; // OK
    j = 5; // OK (because j refers to static member)
    B::j = 6; // OK (because B::j refers to static member)
}

void g(B* pb, D1* p1, D2* p2)
{
    pb->i = 1; // ill-formed
    p1->i = 2; // ill-formed
    p2->i = 3; // ill-formed
}

— end example ]

11.6 Access to virtual functions [class.access.virt]

The access rules (clause 11) for a virtual function are determined by its declaration and are not affected by the rules for a function that later overrides it. [Example:

```cpp
class B {
public:
    virtual int f();
};

class D : public B {
private:
    int f();
};
```
void f()
{
    D d;
    B* pb = &d;
    D* pd = &d;

    pb->f();       // OK: B::f() is public,
                   // D::f() is invoked
    pd->f();       // error: D::f() is private
}
— end example 

Access is checked at the call point using the type of the expression used to denote the object for which the member
function is called (B* in the example above). The access of the member function in the class in which it was defined (D
in the example above) is in general not known.

11.7 Multiple access

1 If a name can be reached by several paths through a multiple inheritance graph, the access is that of the path that gives
most access. [Example:

class W { public: void f(); };  
class A : private virtual W { };  
class B : public virtual W { }; 
class C : public A, public B {
    void f() { W::f(); }    // OK
};

2 Since W::f() is available to C::f() along the public path through B, access is allowed. — end example 

11.8 Nested classes

1 A nested class is a member and as such has the same access rights as any other member. The members of an enclosing
class have no special access to members of a nested class; the usual access rules (clause 11) shall be obeyed. [Example:

class E {
    int x;
    class B { }; 
};

    class I { 
        B b;          // OK: E::I can access E::B
        int y;
        void f(E* p, int i)
        {
            p->x = i;    // OK: E::I can access E::x
        }
    };

Draft
int g(I* p)
{
    return p->y;  // error: I::y is private
}
};

— end example ]
Chapter 12  Special member functions

The default constructor (12.1), copy constructor and copy assignment operator (12.8), and destructor (12.4) are special member functions. The implementation will implicitly declare these member functions for a class type when the program does not explicitly declare them, except as noted in 12.1. The implementation will implicitly define them if they are used, as specified in 12.1, 12.4 and 12.8. Programs shall not define implicitly-declared special member functions. Programs may explicitly refer to implicitly declared special member functions. [Example: a program may explicitly call, take the address of or form a pointer to member to an implicitly declared special member function.

```cpp
struct A { };     // implicitly-declared A::operator=
struct B : A {
    B& operator=(const B&); 
};
B& B::operator=(const B& s) {
    this->A::operator=(s);    // well-formed
    return *this;
}
— end example ]
```

[Note: the special member functions affect the way objects of class type are created, copied, and destroyed, and how values can be converted to values of other types. Often such special member functions are called implicitly. — end note]

Special member functions obey the usual access rules (clause 11). [Example: declaring a constructor protected ensures that only derived classes and friends can create objects using it. — end example]

12.1 Constructors

Constructors do not have names. A special declarator syntax using an optional sequence of function-specifiers (7.1.2) followed by the constructor’s class name followed by a parameter list is used to declare or define the constructor. In such a declaration, optional parentheses around the constructor class name are ignored. [Example:

```cpp
class C {
    public:
        C();          // declares the constructor
};
C::C() {}        // defines the constructor
— end example ]
```
A constructor is used to initialize objects of its class type. Because constructors do not have names, they are never found during name lookup; however an explicit type conversion using the functional notation (5.2.3) will cause a constructor to be called to initialize an object. [Note: for initialization of objects of class type see 12.6. — end note]

A typedef-name shall not be used as the class-name in the declarator-id for a constructor declaration.

A constructor shall not be virtual (10.3) or static (9.4). A constructor can be invoked for a const, volatile or const volatile object. A constructor shall not be declared const, volatile, or const volatile (9.3.2). const and volatile semantics (7.1.5.1) are not applied on an object under construction. They come into effect when the constructor for the most derived object (1.8) ends.

A default constructor for a class X is a constructor of class X that can be called without an argument. If there is no user-declared constructor for class X, a default constructor is implicitly declared. An implicitly-declared default constructor is an inline public member of its class. A default constructor is trivial if it is implicitly-declared and if:

- its class has no virtual functions (10.3) and no virtual base classes (10.1), and
- all the direct base classes of its class have trivial default constructors, and
- for all the non-static data members of its class that are of class type (or array thereof), each such class has a trivial default constructor.

Otherwise, the default constructor is non-trivial.

An implicitly-declared default constructor for a class is implicitly defined when it is used (3.2) to create an object of its class type (1.8). The implicitly-defined default constructor performs the set of initializations of the class that would be performed by a user-written default constructor for that class with an empty mem-initializer-list (12.6.2) and an empty function body. If that user-written default constructor would be ill-formed, the program is ill-formed. Before the implicitly-declared default constructor for a class is implicitly defined, all the implicitly-declared default constructors for its base classes and its non-static data members shall have been implicitly defined. [Note: an implicitly-declared default constructor has an exception-specification (15.4). — end note]

Default constructors are called implicitly to create class objects of static or automatic storage duration (3.7.1, 3.7.2) defined without an initializer (8.5), are called to create class objects of dynamic storage duration (3.7.3) created by a new-expression in which the new-initializer is omitted (5.3.4), or are called when the explicit type conversion syntax (5.2.3) is used. A program is ill-formed if the default constructor for an object is implicitly used and the constructor is not accessible (clause 11).

[Note: 12.6.2 describes the order in which constructors for base classes and non-static data members are called and describes how arguments can be specified for the calls to these constructors. — end note]

A copy constructor (12.8) is used to copy objects of class type.

A union member shall not be of a class type (or array thereof) that has a non-trivial constructor.

No return type (not even void) shall be specified for a constructor. A return statement in the body of a constructor shall not specify a return value. The address of a constructor shall not be taken.

A functional notation type conversion (5.2.3) can be used to create new objects of its type. [Note: The syntax looks like an explicit call of the constructor. — end note] [Example:

```cpp
complex zz = complex(1,2.3);
cprint( complex(7.8,1.2) );
```
An object created in this way is unnamed. [Note: 12.2 describes the lifetime of temporary objects. — end note] [Note: explicit constructor calls do not yield lvalues, see 3.10. — end note]

[Note: some language constructs have special semantics when used during construction; see 12.6.2 and 12.7. — end note]

During the construction of a const object, if the value of the object or any of its subobjects is accessed through an lvalue that is not obtained, directly or indirectly, from the constructor’s this pointer, the value of the object or subobject thus obtained is unspecified. [Example:

```cpp
struct C;
void no_opt(C*);

struct C {
  int c;
  C() : c(0) { no_opt(this); }
};

const C cobj;

void no_opt(C* cptr) {
  int i = cobj.c * 100;  // value of cobj.c is unspecified
  cptr->c = 1;
  cout << cobj.c * 100  // value of cobj.c is unspecified
    << '\n';
}
```
— end example]

12.2 Temporary objects

Temporaries of class type are created in various contexts: binding an rvalue to a reference (8.5.3), returning an rvalue (6.6.3), a conversion that creates an rvalue (4.1, 5.2.9, 5.2.11, 5.4), throwing an exception (15.1), entering a handler (15.3), and in some initializations (8.5). [Note: the lifetime of exception objects is described in 15.1. — end note] Even when the creation of the temporary object is avoided (12.8), all the semantic restrictions must be respected as if the temporary object was created. [Example: even if the copy constructor is not called, all the semantic restrictions, such as accessibility (clause 11), shall be satisfied. — end example]

```cpp
class X {
  // ...
public:
  // ...
  X(int);
  X(const X&);
  ~X();
};
```
12.2 Temporary objects

\begin{verbatim}
X f(X);
void g()
{
    X a(1);
    X b = f(X(2));
    a = f(a);
}
\end{verbatim}

2 Here, an implementation might use a temporary in which to construct \(X(2)\) before passing it to \(f()\) using \(X\)'s copy-constructor; alternatively, \(X(2)\) might be constructed in the space used to hold the argument. Also, a temporary might be used to hold the result of \(f(X(2))\) before copying it to \(b\) using \(X\)'s copy-constructor; alternatively, \(f()\)'s result might be constructed in \(b\). On the other hand, the expression \(a = f(a)\) requires a temporary for the result of \(f(a)\), which is then assigned to \(a\). — end example 

3 When an implementation introduces a temporary object of a class that has a non-trivial constructor (12.1, 12.8), it shall ensure that a constructor is called for the temporary object. Similarly, the destructor shall be called for a temporary with a non-trivial destructor (12.4). Temporary objects are destroyed as the last step in evaluating the full-expression (1.9) that (lexically) contains the point where they were created. This is true even if that evaluation ends in throwing an exception.

4 There are two contexts in which temporaries are destroyed at a different point than the end of the full-expression. The first context is when a default constructor is called to initialize an element of an array. If the constructor has one or more default arguments, any temporaries created in the default argument expressions are destroyed immediately after return from the constructor.

5 The second context is when a reference is bound to a temporary. The temporary to which the reference is bound or the temporary that is the complete object of a subobject to which the reference is bound persists for the lifetime of the reference except as specified below. A temporary bound to a reference member in a constructor's ctor-initializer (12.6.2) persists until the constructor exits. A temporary bound to a reference parameter in a function call (5.2.2) persists until the completion of the full expression containing the call. A temporary bound to the returned value in a function return statement (6.6.3) persists until the function exits. In all these cases, the temporaries created during the evaluation of the expression initializing the reference, except the temporary to which the reference is bound, are destroyed at the end of the full-expression in which they are created and in the reverse order of the completion of their construction. If the lifetime of two or more temporaries to which references are bound ends at the same point, these temporaries are destroyed at that point in the reverse order of the completion of their construction. In addition, the destruction of temporaries bound to references shall take into account the ordering of destruction of objects with static or automatic storage duration (3.7.1, 3.7.2); that is, if \(obj1\) is an object with static or automatic storage duration created before the temporary is created, the temporary shall be destroyed before \(obj1\) is destroyed; if \(obj2\) is an object with static or automatic storage duration created after the temporary is created, the temporary shall be destroyed after \(obj2\) is destroyed. [Example: 

\begin{verbatim}
class C {
    // ...
    public:
    C();
    C(int);
    friend C operator+(const C&, const C&);
    ~C();
};
\end{verbatim}

Draft
the expression \( C(16) + C(23) \) creates three temporaries. A first temporary \( T_1 \) to hold the result of the expression \( C(16) \), a second temporary \( T_2 \) to hold the result of the expression \( C(23) \), and a third temporary \( T_3 \) to hold the result of the addition of these two expressions. The temporary \( T_3 \) is then bound to the reference \( cr \). It is unspecified whether \( T_1 \) or \( T_2 \) is created first. On an implementation where \( T_1 \) is created before \( T_2 \), it is guaranteed that \( T_2 \) is destroyed before \( T_1 \). The temporaries \( T_1 \) and \( T_2 \) are bound to the reference parameters of \( \text{operator+} \); these temporaries are destroyed at the end of the full expression containing the call to \( \text{operator+} \). The temporary \( T_3 \) bound to the reference \( cr \) is destroyed at the end of \( cr \)’s lifetime, that is, at the end of the program. In addition, the order in which \( T_3 \) is destroyed takes into account the destruction order of other objects with static storage duration. That is, because \( \text{obj1} \) is constructed before \( T_3 \), and \( T_3 \) is constructed before \( \text{obj2} \), it is guaranteed that \( \text{obj2} \) is destroyed before \( T_3 \), and that \( T_3 \) is destroyed before \( \text{obj1} \). — end example ]

12.3 Conversions [class.conv]

1 Type conversions of class objects can be specified by constructors and by conversion functions. These conversions are called user-defined conversions and are used for implicit type conversions (clause 4), for initialization (8.5), and for explicit type conversions (5.4, 5.2.9).

2 User-defined conversions are applied only where they are unambiguous (10.2, 12.3.2). Conversions obey the access control rules (clause 11). Access control is applied after ambiguity resolution (3.4).

3 [ Note: See 13.3 for a discussion of the use of conversions in function calls as well as examples below. — end note ]

4 At most one user-defined conversion (constructor or conversion function) is implicitly applied to a single value.

[Example:

```cpp
class X {
    // ...
    public:
    operator int();
};

class Y {
    // ...
    public:
    operator X();
};

Y a;
int b = a;       // error
                // a.operator X().operator int() not tried
int c = X(a);    // OK: a.operator X().operator int()

— end example ]

5 User-defined conversions are used implicitly only if they are unambiguous. A conversion function in a derived class does not hide a conversion function in a base class unless the two functions convert to the same type. Function overload
12.3 Conversions

resolution (13.3.3) selects the best conversion function to perform the conversion. [Example:

```cpp
class X {
public:
  // ...
  operator int();
};

class Y : public X {
public:
  // ...
  operator char();
};

void f(Y& a)
{
  if (a) {
    // ill-formed:
    // X::operator int() or Y::operator char() // ...
  }
}
```
— end example ]

12.3.1 Conversion by constructor [class.convctor]

A constructor declared without the function-specifier explicit that can be called with a single parameter specifies a conversion from the type of its first parameter to the type of its class. Such a constructor is called a converting constructor. [Example:

```cpp
class X {
  // ...
  public:
    X(int);
    X(const char*, int =0);
};

void f(X arg)
{
  X a = 1; // a = X(1)
  X b = "Jessie"; // b = X("Jessie",0)
  a = 2; // a = X(2)
  f(3); // f(X(3))
}
```
— end example ]

An explicit constructor constructs objects just like non-explicit constructors, but does so only where the direct-initialization syntax (8.5) or where casts (5.2.9, 5.4) are explicitly used. A default constructor may be an explicit constructor; such a constructor will be used to perform default-initialization or value-initialization (8.5). [Example:

```cpp
class Z {

```
public:
    explicit Z();
    explicit Z(int);
    // ...
};

Z a;           // OK: default-initialization performed
Z a1 = 1;      // error: no implicit conversion
Z a3 = Z(1);   // OK: direct initialization syntax used
Z a2(1);      // OK: direct initialization syntax used
Z* p = new Z(1);  // OK: direct initialization syntax used
Z a4 = (Z)1;      // OK: explicit cast used
Z a5 = static_cast<Z>(1); // OK: explicit cast used

— end example ]

A non-explicit copy-constructor (12.8) is a converting constructor. An implicitly-declared copy constructor is not an explicit constructor; it may be called for implicit type conversions.

12.3.2 Conversion functions [class.conv.fct]

A member function of a class X with a name of the form

    conversion-function-id:
    operator conversion-type-id
    conversion-type-id:
    type-specifier-seq conversion-declarator_opt
    conversion-declarator:
    ptr-operator conversion-declarator_opt

specifies a conversion from X to the type specified by the conversion-type-id. Such member functions are called conversion functions. Classes, enumerations, and typedef-names shall not be declared in the type-specifier-seq. Neither parameter types nor return type can be specified. The type of a conversion function (8.3.5) is “function taking no parameter returning conversion-type-id.” A conversion function is never used to convert a (possibly cv-qualified) object to the (possibly cv-qualified) same object type (or a reference to it), to a (possibly cv-qualified) base class of that type (or a reference to it), or to (possibly cv-qualified) void.109

[ Example:

    class X {
        // ...
        public:
            operator int();
    };

    void f(X a) {
        int i = int(a);
        i = (int)a;
    }

109] Even though never directly called to perform a conversion, such conversion functions can be declared and can potentially be reached through a call to a virtual conversion function in a base class

Draft
12.4 Destructors

A special declarator syntax using an optional function-specifier (7.1.2) followed by ~ followed by the destructor's class name followed by an empty parameter list is used to declare the destructor in a class definition. In such a declaration, the ~ followed by the destructor’s class name can be enclosed in optional parentheses; such parentheses are ignored. A typedef-name shall not be used as the class-name following the ~ in the declarator for a destructor declaration.

A destructor is used to destroy objects of its class type. A destructor takes no parameters, and no return type can be specified for it (not even void). The address of a destructor shall not be taken. A destructor shall not be static. A destructor can be invoked for a const, volatile or const volatile object. A destructor shall not be declared const, volatile or const volatile (9.3.2). const and volatile semantics (7.1.5.1) are not applied on an object under destruction. They stop being in effect when the destructor for the most derived object (1.8) starts.

If a class has no user-declared destructor, a destructor is declared implicitly. An implicitly-declared destructor is an inline public member of its class. A destructor is trivial if it is implicitly-declared and if:

— all of the direct base classes of its class have trivial destructors and

— for all of the non-static data members of its class that are of class type (or array thereof), each such class has a trivial destructor.
Otherwise, the destructor is non-trivial.

An implicitly-declared destructor is implicitly defined when it is used to destroy an object of its class type (3.7). A program is ill-formed if the class for which a destructor is implicitly defined has:

- a non-static data member of class type (or array thereof) with an inaccessible destructor, or
- a base class with an inaccessible destructor.

Before the implicitly-declared destructor for a class is implicitly defined, all the implicitly-declared destructors for its base classes and its non-static data members shall have been implicitly defined. [Note: an implicitly-declared destructor has an exception-specification (15.4). — end note]

After executing the body of the destructor and destroying any automatic objects allocated within the body, a destructor for class X calls the destructors for X’s direct members, the destructors for X’s direct base classes and, if X is the type of the most derived class (12.6.2), its destructor calls the destructors for X’s virtual base classes. All destructors are called as if they were referenced with a qualified name, that is, ignoring any possible virtual overriding destructors in more derived classes. Bases and members are destroyed in the reverse order of the completion of their constructor (see 12.6.2). A return statement (6.6.3) in a destructor might not directly return to the caller; before transferring control to the caller, the destructors for the members and bases are called. Destructors for elements of an array are called in reverse order of their construction (see 12.6).

A destructor can be declared virtual (10.3) or pure virtual (10.4); if any objects of that class or any derived class are created in the program, the destructor shall be defined. If a class has a base class with a virtual destructor, its destructor (whether user- or implicitly-declared) is virtual.

[Note: some language constructs have special semantics when used during destruction; see 12.7. — end note]

A union member shall not be of a class type (or array thereof) that has a non-trivial destructor.

Destructors are invoked implicitly (1) for a constructed object with static storage duration (3.7.1) at program termination (3.6.3), (2) for a constructed object with automatic storage duration (3.7.2) when the block in which the object is created exits (6.7), (3) for a constructed temporary object when the lifetime of the temporary object ends (12.2), (4) for a constructed object allocated by a new-expression (5.3.4), through use of a delete-expression (5.3.5), (5) in several situations due to the handling of exceptions (15.3). A program is ill-formed if an object of class type or array thereof is declared and the destructor for the class is not accessible at the point of the declaration. Destructors can also be invoked explicitly.

At the point of definition of a virtual destructor (including an implicit definition (12.8)), the non-array deallocation function is looked up in the scope of the destructor’s class (10.2), and, if no declaration is found, the function is looked up in the global scope. If the result of this lookup is ambiguous or inaccessible, or if the lookup selects a placement deallocation function, the program is ill-formed. [Note: this assures that a deallocation function corresponding to the dynamic type of an object is available for the delete-expression (12.5). — end note]

In an explicit destructor call, the destructor name appears as a ~ followed by a type-name that names the destructor’s class type. The invocation of a destructor is subject to the usual rules for member functions (9.3), that is, if the object is not of the destructor’s class type and not of a class derived from the destructor’s class type, the program has undefined behavior (except that invoking delete on a null pointer has no effect). [Example:

```c
struct B {
    virtual ~B() { }  
};
```

Draft
struct D : B {
  ~D() { }
};

D D_object;
typedef B B_alias;
B* B_ptr = &D_object;

void f () {
  D_object.B::~B();                          // calls B's destructor
  B_ptr->~B();                               // calls D's destructor
  B_ptr->~B_alias();                         // calls D's destructor
  B_ptr->B_alias::~B();                      // calls B's destructor
  B_ptr->B_alias::~B_alias();                // calls B's destructor
}

— end example ] [ Note: an explicit destructor call must always be written using a member access operator (5.2.5) or a qualified-id (5.1); in particular, the unaary-expression ~X() in a member function is not an explicit destructor call (5.3.1). — end note ]

Note: explicit calls of destructors are rarely needed. One use of such calls is for objects placed at specific addresses using a new-expression with the placement option. Such use of explicit placement and destruction of objects can be necessary to cope with dedicated hardware resources and for writing memory management facilities. For example,

```cpp
void* operator new(std::size_t, void* p) { return p; }
struct X {
  // ...
  X(int);
  ~X();
};
void f(X* p);

void g()                              // rare, specialized use:
{
  char* buf = new char[sizeof(X)];
  X* p = new(buf) X(222);            // use buf[] and initialize
  f(p);
  p->X::~X();                        // cleanup
}

— end note ]

Once a destructor is invoked for an object, the object no longer exists; the behavior is undefined if the destructor is invoked for an object whose lifetime has ended (3.8). [ Example: if the destructor for an automatic object is explicitly invoked, and the block is subsequently left in a manner that would ordinarily invoke implicit destruction of the object, the behavior is undefined. — end example ]

Note: the notation for explicit call of a destructor can be used for any scalar type name (5.2.4). Allowing this makes it possible to write code without having to know if a destructor exists for a given type. For example,

```cpp
typedef int I;
```
225 Special member functions

I* p;
// ...
p->I::~I();

— end note ]

12.5 Free store [class.free]

1 Any allocation function for a class T is a static member (even if not explicitly declared static).

2 [Example:

```c
class Arena;
struct B {
    void* operator new(std::size_t, Arena*);
};
struct D1 : B {
};

Arena* ap;
void foo(int i)
{
    new (ap) D1;       // calls B::operator new(std::size_t, Arena*)
    new D1[i];         // calls ::operator new[](std::size_t)
    new D1;            // ill-formed: ::operator new(std::size_t) hidden
}
```

— end example ]

3 When an object is deleted with a delete-expression (5.3.5), a deallocation function (operator delete() for non-array objects or operator delete[]() for arrays) is (implicitly) called to reclaim the storage occupied by the object (3.7.3.2).

4 If a delete-expression begins with a unary :: operator, the deallocation function’s name is looked up in global scope. Otherwise, if the delete-expression is used to deallocate a class object whose static type has a virtual destructor, the deallocation function is the one selected at the point of definition of the dynamic type’s virtual destructor (12.4). Otherwise, if the delete-expression is used to deallocate an object of class T or array thereof, the static and dynamic types of the object shall be identical and the deallocation function’s name is looked up in the scope of T. If this lookup fails to find the name, the name is looked up in the global scope. If the result of the lookup is ambiguous or inaccessible, or if the lookup selects a placement deallocation function, the program is ill-formed.

5 When a delete-expression is executed, the selected deallocation function shall be called with the address of the block of storage to be reclaimed as its first argument and (if the two-parameter style is used) the size of the block as its second argument.  

6 Any deallocation function for a class X is a static member (even if not explicitly declared static). [Example:

---

110) A similar provision is not needed for the array version of operator delete because 5.3.5 requires that in this situation, the static type of the delete-expression’s operand be the same as its dynamic type.

111) If the static type in the delete-expression is different from the dynamic type and the destructor is not virtual the size might be incorrect, but that case is already undefined; see 5.3.5.
class X {
    // ...
    void operator delete(void*);
    void operator delete[](void*, std::size_t);
};

class Y {
    // ...
    void operator delete(void*, std::size_t);
    void operator delete[](void*);
};

— end example ]

7 Since member allocation and deallocation functions are static they cannot be virtual.  [Note: however, when the cast-expression of a delete-expression refers to an object of class type, because the deallocation function actually called is looked up in the scope of the class that is the dynamic type of the object, if the destructor is virtual, the effect is the same. For example,

```cpp
struct B {
    virtual ~B();
    void operator delete(void*, std::size_t);
};

struct D : B {
    void operator delete(void*);
};

void f()
{
    B* bp = new D;
    delete bp;    // 1: uses D::operator delete(void*)
}
```

Here, storage for the non-array object of class D is deallocated by D::operator delete(), due to the virtual destructor. — end note ] [Note: virtual destructors have no effect on the deallocation function actually called when the cast-expression of a delete-expression refers to an array of objects of class type. For example,

```cpp
struct B {
    virtual ~B();
    void operator delete[](void*, std::size_t);
};

struct D : B {
    void operator delete[](void*, std::size_t);
};

void f(int i)
{
    D* dp = new D[i];
```
12.6 Initialization

When no initializer is specified for an object of (possibly cv-qualified) class type (or array thereof), or the initializer has the form (), the object is initialized as specified in 8.5. The object is default-initialized if there is no initializer, or value-initialized if the initializer is ()

An object of class type (or array thereof) can be explicitly initialized; see 12.6.1 and 12.6.2.

When an array of class objects is initialized (either explicitly or implicitly), the constructor shall be called for each element of the array, following the subscript order; see 8.3.4. [Note: destructors for the array elements are called in reverse order of their construction. — end note]

12.6.1 Explicit initialization

An object of class type can be initialized with a parenthesized expression-list, where the expression-list is construed as an argument list for a constructor that is called to initialize the object. Alternatively, a single assignment-expression can be specified as an initializer using the = form of initialization. Either direct-initialization semantics or copy-initialization semantics apply; see 8.5. [Example: class complex {
    // ...
    public:
        complex();
        complex(double);
        complex(double,double);
    // ...
};

complex sqrt(complex,complex);

complex a(1); // initialize by a call of
    // complex(double)
complex b = a; // initialize by a copy of a
complex c = complex(1,2); // construct complex(1,2)
    // using complex(double,double)
    // copy it into c
complex d = sqrt(b,c); // call sqrt(complex,complex)
    // and copy the result into d
complex e; // initialize by a call of
    // complex()
complex f = 3; // construct complex(3) using

Draft
complex g = { 1, 2 };  // error: constructor is required

— end example ] [ Note: overloading of the assignment operator (13.5.3) has no effect on initialization. — end note ]

When an aggregate (whether class or array) contains members of class type and is initialized by a brace-enclosed initializer-list (8.5.1), each such member is copy-initialized (see 8.5) by the corresponding assignment-expression. If there are fewer initializers in the initializer-list than members of the aggregate, each member not explicitly initialized shall be value-initialized (8.5). [ Note: 8.5.1 describes how assignment-expressions in an initializer-list are paired with the aggregate members they initialize. — end note ] [ Example:

complex v[6] = { 1, complex(1,2), complex(), 2 };

Here, complex::complex(double) is called for the initialization of v[0] and v[3], complex::complex(double, double) is called for the initialization of v[1], complex::complex() is called for the initialization v[2], v[4], and v[5]. For another example,

class X {
public:
  int i;
  float f;
  complex c;
} x = { 99, 88.8, 77.7 };

Here, x.i is initialized with 99, x.f is initialized with 88.8, and complex::complex(double) is called for the initialization of x.c. — end example ] [ Note: braces can be elided in the initializer-list for any aggregate, even if the aggregate has members of a class type with user-defined type conversions; see 8.5.1. — end note ]

[ Note: if T is a class type with no default constructor, any declaration of an object of type T (or array thereof) is ill-formed if no initializer is explicitly specified (see 12.6 and 8.5). — end note ]

[ Note: the order in which objects with static storage duration are initialized is described in 3.6.2 and 6.7. — end note ]

12.6.2 Initializing bases and members [class.base.init]

In the definition of a constructor for a class, initializers for direct and virtual base subobjects and non-static data members can be specified by a ctor-initializer, which has the form

cctor-initializer:
  : mem-initializer-list
mem-initializer-list:
  mem-initializer
  mem-initializer , mem-initializer-list
mem-initializer:
  mem-initializer-id ( expression-listopt )
mem-initializer-id:
  ::opt nested-name-specifieropt class-name
  identifier

Draft
Names in a \textit{mem-initializer-id} are looked up in the scope of the constructor’s class and, if not found in that scope, are looked up in the scope containing the constructor’s definition. [\textit{Note:} if the constructor’s class contains a member with the same name as a direct or virtual base class of the class, a \textit{mem-initializer-id} naming the member or base class and composed of a single identifier refers to the class member. A \textit{mem-initializer-id} for the hidden base class may be specified using a qualified name. — \textit{end note}] Unless the \textit{mem-initializer-id} names a non-static data member of the constructor’s class or a direct or virtual base of that class, the \textit{mem-initializer} is ill-formed. A \textit{mem-initializer-list} can initialize a base class using any name that denotes that base class type. [\textit{Example:}

\begin{verbatim}
struct A { A(); }; typedef A global_A;
struct B { }; struct C: public A, public B { C(); }; C::C(): global_A() {} // mem-initializer for base A
\end{verbatim}

— \textit{end example}] If a \textit{mem-initializer-id} is ambiguous because it designates both a direct non-virtual base class and an inherited virtual base class, the \textit{mem-initializer} is ill-formed. [\textit{Example:}

\begin{verbatim}
struct A { A(); }; struct B: public virtual A { }; struct C: public A, public B { C(); }; C::C(): A() {} // ill-formed: which A?
\end{verbatim}

— \textit{end example}] A \textit{ctor-initializer} may initialize the member of an anonymous union that is a member of the constructor’s class. If a \textit{ctor-initializer} specifies more than one \textit{mem-initializer} for the same member, for the same base class or for multiple members of the same union (including members of anonymous unions), the \textit{ctor-initializer} is ill-formed.

The \textit{expression-list} in a \textit{mem-initializer} is used to initialize the base class or non-static data member subobject denoted by the \textit{mem-initializer-id}. The semantics of a \textit{mem-initializer} are as follows:

— if the \textit{expression-list} of the \textit{mem-initializer} is omitted, the base class or member subobject is value-initialized (see \ref{8.5});
— otherwise, the subobject indicated by \textit{mem-initializer-id} is direct-initialized using \textit{expression-list} as the \textit{initializer} (see \ref{8.5}).

[\textit{Example:}

\begin{verbatim}
struct B1 { B1(int); /* ... */}; struct B2 { B2(int); /* ... */}; struct D : B1, B2 {
    D(int);
    B1 b;
    const int c;
};
D::D(int a) : B2(a+1), B1(a+2), c(a+3), b(a+4)
{ /* ... */ } D d(10);
\end{verbatim}

— \textit{end example}] There is a sequence point (1.9) after the initialization of each base and member. The \textit{expression-list} of a \textit{mem-initializer} is evaluated as part of the initialization of the corresponding base or member.
4 If a given non-static data member or base class is not named by a *mem-initializer-id* (including the case where there is no *mem-initializer-list* because the constructor has no *ctor-initializer*), then

— If the entity is a non-static data member of (possibly cv-qualified) class type (or array thereof) or a base class, and the entity class is a non-POD class, the entity is default-initialized (8.5). If the entity is a non-static data member of a const-qualified type, the entity class shall have a user-declared default constructor.

— Otherwise, the entity is not initialized. If the entity is of const-qualified type or reference type, or of a (possibly cv-qualified) POD class type (or array thereof) containing (directly or indirectly) a member of a const-qualified type, the program is ill-formed.

After the call to a constructor for class X has completed, if a member of X is neither specified in the constructor’s *mem-initializers*, nor default-initialized, nor value-initialized, nor given a value during execution of the body of the constructor, the member has indeterminate value.

5 Initialization shall proceed in the following order:

— First, and only for the constructor of the most derived class as described below, virtual base classes shall be initialized in the order they appear on a depth-first left-to-right traversal of the directed acyclic graph of base classes, where “left-to-right” is the order of appearance of the base class names in the derived class *base-specifier-list*.

— Then, direct base classes shall be initialized in declaration order as they appear in the *base-specifier-list* (regardless of the order of the *mem-initializers*).

— Then, non-static data members shall be initialized in the order they were declared in the class definition (again regardless of the order of the *mem-initializers*).

— Finally, the body of the constructor is executed.

[Note: the declaration order is mandated to ensure that base and member subobjects are destroyed in the reverse order of initialization. —end note]

6 All subobjects representing virtual base classes are initialized by the constructor of the most derived class (1.8). If the constructor of the most derived class does not specify a *mem-initializer* for a virtual base class V, then V’s default constructor is called to initialize the virtual base class subobject. If V does not have an accessible default constructor, the initialization is ill-formed. A *mem-initializer* naming a virtual base class shall be ignored during execution of the constructor of any class that is not the most derived class. [Example:

```cpp
class V {
public:
    V();
    V(int);
    // ...
};

class A : public virtual V {
public:
    A();
    A(int);
    // ...
};
```

Draft
class B : public virtual V {
public:
    B();
    B(int);
    // ...  
};

class C : public A, public B, private virtual V {
public:
    C();
    C(int);
    // ...  
};

A::A(int i) : V(i) { /* ... */ }
B::B(int i) { /* ... */ }
C::C(int i) { /* ... */ }

V v1;  // use V(int)
A a2;  // use V(int)
B b3;  // use V()
C c4;  // use V()

/* end example */

Names in the expression-list of a mem-initializer are evaluated in the scope of the constructor for which the mem-initializer is specified. [Example:

class X {
    int a;
    int b;
    int i;
    int j;
public:
    const int& r;
    X(int i): r(a), b(i), i(i), j(this->i) {} 
};

initializes X::r to refer to X::a, initializes X::b with the value of the constructor parameter i, initializes X::i with the value of the constructor parameter i, and initializes X::j with the value of X::i; this takes place each time an object of class X is created. —end example] [Note: because the mem-initializer are evaluated in the scope of the constructor, the this pointer can be used in the expression-list of a mem-initializer to refer to the object being initialized. —end note]

Member functions (including virtual member functions, 10.3) can be called for an object under construction. Similarly, an object under construction can be the operand of the typeid operator (5.2.8) or of a dynamic_cast (5.2.7). However, if these operations are performed in a ctor-initializer (or in a function called directly or indirectly from a ctor-initializer) before all the mem-initializers for base classes have completed, the result of the operation is undefined. [Example:

class A {
public:

Draft
A(int);
}

class B : public A {
    int j;
public:
    int f();
    B() : A(f()), // undefined: calls member function
        j(f()) {} // well-defined: bases are all initialized
};

class C {
public:
    C(int);
};

class D : public B, C {
    int i;
public:
    D() : C(f()), // undefined: calls member function
          i(f()) {} // well-defined: bases are all initialized
};

— end example ]

[ Note: 12.7 describes the result of virtual function calls, typeid and dynamic_casts during construction for the well-defined cases; that is, describes the polymorphic behavior of an object under construction. — end note ]

12.7 Construction and destruction

For an object of non-POD class type (clause 9), before the constructor begins execution and after the destructor finishes execution, referring to any non-static member or base class of the object results in undefined behavior. [ Example:

    struct X { int i; };  
    struct Y : X { };  
    struct A { int a; };  
    struct B : public A { int j; Y y; };  

    extern B bobj;
    B* pb = &bobj; // OK
    int* p1 = &bobj.a; // undefined, refers to base class member
    int* p2 = &bobj.y.i; // undefined, refers to member’s member

    A* pa = &bobj; // undefined, upcast to a base class type
    B bobj; // definition of bobj

    extern X xobj;
    int* p3 = &xobj.i; // OK, X is a POD class

Draft
233 Special member functions

2 For another example,

```cpp
struct W { int j; };
struct X : public virtual W { };
struct Y {
    int *p;
    X x;
    Y() : p(&x.j) // undefined, x is not yet constructed
    { }
};
```

— end example ]

3 To explicitly or implicitly convert a pointer (an lvalue) referring to an object of class X to a pointer (reference) to a direct or indirect base class B of X, the construction of X and the construction of all of its direct or indirect bases that directly or indirectly derive from B shall have started and the destruction of these classes shall not have completed, otherwise the conversion results in undefined behavior. To form a pointer to (or access the value of) a direct non-static member of an object obj, the construction of obj shall have started and its destruction shall not have completed, otherwise the computation of the pointer value (or accessing the member value) results in undefined behavior. [ Example:

```cpp
struct A { };
struct B : virtual A { };
struct C : B { };
struct D : virtual A { D(A*); };
struct X { X(A*); };

struct E : C, D, X {
    E() : D(this), // undefined: upcast from E* to A*
        // might use path E* → D* → A*
        // but D is not constructed
        // D((C*this)).// defined:
        // E* → C* defined because E() has started
        // and C* → A* defined because
        // C fully constructed
    X(this) // defined: upon construction of X,
        // C/B/D/A sublattice is fully constructed
    { }
};
```

— end example ]

4 Member functions, including virtual functions (10.3), can be called during construction or destruction (12.6.2). When a virtual function is called directly or indirectly from a constructor (including from the mem-initializer for a data member) or from a destructor, and the object to which the call applies is the object under construction or destruction, the function called is the one defined in the constructor or destructor’s own class or in one of its bases, but not a function overriding it in a class derived from the constructor or destructor’s class, or overriding it in one of the other base classes of the most derived object (1.8). If the virtual function call uses an explicit class member access (5.2.5) and the object-expression
refers to the object under construction or destruction but its type is neither the constructor or destructor’s own class or one of its bases, the result of the call is undefined. [Example:

class V {
  public:
    virtual void f();
    virtual void g();
};

class A : public virtual V {
  public:
    virtual void f();
};

class B : public virtual V {
  public:
    virtual void g();
    B(V*, A*);
};

class D : public A, B {
  public:
    virtual void f();
    virtual void g();
    D() : B((A*) this, this) { }
};

B::B(V* v, A* a) {
  f();          // calls V::f, not A::f
  g();          // calls B::g, not D::g
  v->g();       // v is base of B, the call is well-defined, calls B::g
  a->f();       // undefined behavior, a’s type not a base of B
}

— end example ]

5 The typeid operator (5.2.8) can be used during construction or destruction (12.6.2). When typeid is used in a constructor (including from the mem-initializer for a data member) or in a destructor, or used in a function called (directly or indirectly) from a constructor or destructor, if the operand of typeid refers to the object under construction or destruction, typeid yields the std::type_info object representing the constructor or destructor’s class. If the operand of typeid refers to the object under construction or destruction and the static type of the operand is neither the constructor or destructor’s class nor one of its bases, the result of typeid is undefined.

6 Dynamic_casts (5.2.7) can be used during construction or destruction (12.6.2). When a dynamic_cast is used in a constructor (including from the mem-initializer for a data member) or in a destructor, or used in a function called (directly or indirectly) from a constructor or destructor, if the operand of the dynamic_cast refers to the object under construction or destruction, this object is considered to be a most derived object that has the type of the constructor or destructor’s class. If the operand of the dynamic_cast refers to the object under construction or destruction and the static type of the operand is not a pointer to or object of the constructor or destructor’s own class or one of its bases, the dynamic_cast results in undefined behavior.
Example:

```cpp
class V {
public:
    virtual void f();
};

class A : public virtual V { }

class B : public virtual V {
public:
    B(V* , A*);
};
class D : public A , B {
public:
    D() : B((A*) this , this) { }
};

B::B(V* v , A* a) {
    typeid(*this);            // type_info for B
    typeid(*v);               // well-defined: *v has type V, a base of B
                                // yields type_info for B
    typeid(*a);               // undefined behavior: type A not a base of B
    dynamic_cast<B*>(v);     // well-defined: *v of type V*, V base of B
                                // results in B*
    dynamic_cast<B*>(a);     // undefined behavior,
                                // a has type A*, A not a base of B
}
```

— end example

12.8 Copying class objects

A class object can be copied in two ways, by initialization (12.1, 8.5), including for function argument passing (5.2.2) and for function value return (6.6.3), and by assignment (5.17). Conceptually, these two operations are implemented by a copy constructor (12.1) and copy assignment operator (13.5.3).

A non-template constructor for class X is a copy constructor if its first parameter is of type X&, const X&, volatile X& or const volatile X&, and either there are no other parameters or else all other parameters have default arguments (8.3.6). Example: X::X(const X&) and X::X(X&, int=1) are copy constructors.

112) Because a template constructor is never a copy constructor, the presence of such a template does not suppress the implicit declaration of a copy constructor. Template constructors participate in overload resolution with other constructors, including copy constructors, and a template constructor may be used to copy an object if it provides a better match than other constructors.

X a(1); // calls X(int);
X b(a, 0); // calls X(const X&, int);
X c = b; // calls X(const X&, int);

— end example ] [ Note: all forms of copy constructor may be declared for a class. [ Example:

class X {
    public:
        X(const X&); // OK
        X(X&); // OK
    }

— end example ] — end note ] [ Note: if a class X only has a copy constructor with a parameter of type X&, an initializer of type const X or volatile X cannot initialize an object of type (possibly cv-qualified) X. [ Example:

struct X {
    X(); // default constructor
    X(X&); // copy constructor with a nonconst parameter
};
const X cx;
X x = cx; // error — X::X(X&) cannot copy cx into x

— end example ] — end note]

3 A declaration of a constructor for a class X is ill-formed if its first parameter is of type (optionally cv-qualified) X and either there are no other parameters or else all other parameters have default arguments. A member function template is never instantiated to perform the copy of a class object to an object of its class type. [ Example:

struct S {
    template<typename T> S(T);
};
S f();

void g() {
    S a( f() ); // does not instantiate member template
}

— end example ]

4 If the class definition does not explicitly declare a copy constructor, one is declared implicitly. Thus, for the class definition

struct X {
    X(const X&, int); // OK
};

a copy constructor is implicitly-declared. If the user-declared constructor is later defined as

X::X(const X& x, int i =0) { /* ... */ }

Draft
then any use of \( X \)'s copy constructor is ill-formed because of the ambiguity; no diagnostic is required.

5 The implicitly-declared copy constructor for a class \( X \) will have the form

\[
X::X(const X &) 
\]

if

- each direct or virtual base class \( B \) of \( X \) has a copy constructor whose first parameter is of type \( const B & \) or \( const volatile B & \), and
- for all the non-static data members of \( X \) that are of a class type \( M \) (or array thereof), each such class type has a copy constructor whose first parameter is of type \( const M & \) or \( const volatile M & \). *(13)*

Otherwise, the implicitly declared copy constructor will have the form

\[
X::X(X &) 
\]

An implicitly-declared copy constructor is an inline public member of its class.

6 A copy constructor for class \( X \) is trivial if it is implicitly declared and if

- class \( X \) has no virtual functions (10.3) and no virtual base classes (10.1), and
- each direct base class of \( X \) has a trivial copy constructor, and
- for all the non-static data members of \( X \) that are of class type (or array thereof), each such class type has a trivial copy constructor;

otherwise the copy constructor is non-trivial.

7 An implicitly-declared copy constructor is implicitly defined if it is used to initialize an object of its class type from a copy of an object of its class type or of a class type derived from its class type. *(14)* [Note: the copy constructor is implicitly defined even if the implementation elided its use (12.2). — end note] A program is ill-formed if the class for which a copy constructor is implicitly defined has:

- a non-static data member of class type (or array thereof) with an inaccessible or ambiguous copy constructor, or
- a base class with an inaccessible or ambiguous copy constructor.

Before the implicitly-declared copy constructor for a class is implicitly defined, all implicitly-declared copy constructors for its direct and virtual base classes and its non-static data members shall have been implicitly defined. [Note: an implicitly-declared copy constructor has an exception-specification (15.4). — end note]

8 The implicitly-defined copy constructor for class \( X \) performs a memberwise copy of its subobjects. The order of copying is the same as the order of initialization of bases and members in a user-defined constructor (see 12.6.2). Each subobject is copied in the manner appropriate to its type:

- if the subobject is of class type, the copy constructor for the class is used;
- if the subobject is an array, each element is copied, in the manner appropriate to the element type;
- if the subobject is of scalar type, the built-in assignment operator is used.

---

*(13)* This implies that the reference parameter of the implicitly-declared copy constructor cannot bind to a volatile lvalue; see C.1.8.

*(14)* See 8.5 for more details on direct and copy initialization.
Virtual base class subobjects shall be copied only once by the implicitly-defined copy constructor (see 12.6.2).

A user-declared copy assignment operator X::operator= is a non-static non-template member function of class X with exactly one parameter of type X, X&, const X& or const volatile X& or const volatile X&. [Note: an overloaded assignment operator must be declared to have only one parameter; see 13.5.3. —end note] [Note: more than one form of copy assignment operator may be declared for a class. —end note] [Note: if a class X only has a copy assignment operator with a parameter of type X&, an expression of type const X cannot be assigned to an object of type X. [Example:

```c
struct X {
    X();
    X& operator=(X&);
};
const X cx;
X x;
void f () {
    x = cx; // error:
    // X::operator=(X&) cannot assign cx into x
}
```

—end example] —end note]

If the class definition does not explicitly declare a copy assignment operator, one is declared implicitly. The implicitly-declared copy assignment operator for a class X will have the form

```
X& X::operator=(const X&)
```

if

— each direct base class B of X has a copy assignment operator whose parameter is of type const B&, const volatile B& or B, and

— for all the non-static data members of X that are of a class type M (or array thereof), each such class type has a copy assignment operator whose parameter is of type const M&, const volatile M& or M. [116]116

Otherwise, the implicitly declared copy assignment operator will have the form

```
X& X::operator=(X&)
```

The implicitly-declared copy assignment operator for class X has the return type X&; it returns the object for which the assignment operator is invoked, that is, the object assigned to. An implicitly-declared copy assignment operator is an inline public member of its class. Because a copy assignment operator is implicitly declared for a class if not declared by the user, a base class copy assignment operator is always hidden by the copy assignment operator of a derived class (13.5.3). A using-declaration (7.3.3) that brings in from a base class an assignment operator with a parameter type that could be that of a copy-assignment operator for the derived class is not considered an explicit declaration of a copy-assignment operator and does not suppress the implicit declaration of the derived class copy-assignment operator;

---

115) Because a template assignment operator is never a copy assignment operator, the presence of such a template does not suppress the implicit declaration of a copy assignment operator. Template assignment operators participate in overload resolution with other assignment operators, including copy assignment operators, and a template assignment operator may be used to assign an object if it provides a better match than other assignment operators.

116) This implies that the reference parameter of the implicitly-declared copy assignment operator cannot bind to a volatile lvalue; see C.1.8.
the operator introduced by the using-declaration is hidden by the implicitly-declared copy-assignment operator in the derived class.

11 A copy assignment operator for class \( X \) is trivial if it is implicitly declared and if

- class \( X \) has no virtual functions (10.3) and no virtual base classes (10.1), and
- each direct base class of \( X \) has a trivial copy assignment operator, and
- for all the non-static data members of \( X \) that are of class type (or array thereof), each such class type has a trivial copy assignment operator;

otherwise the copy assignment operator is non-trivial.

12 An implicitly-declared copy assignment operator is implicitly defined when an object of its class type is assigned a value of its class type or a value of a class type derived from its class type. A program is ill-formed if the class for which a copy assignment operator is implicitly defined has:

- a non-static data member of const type, or
- a non-static data member of reference type, or
- a non-static data member of class type (or array thereof) with an inaccessible copy assignment operator, or
- a base class with an inaccessible copy assignment operator.

Before the implicitly-declared copy assignment operator for a class is implicitly defined, all implicitly-declared copy assignment operators for its direct base classes and its non-static data members shall have been implicitly defined. [Note: an implicitly-declared copy assignment operator has an exception-specification (15.4).—end note]

13 The implicitly-defined copy assignment operator for class \( X \) performs memberwise assignment of its subobjects. The direct base classes of \( X \) are assigned first, in the order of their declaration in the base-specifier-list, and then the immediate non-static data members of \( X \) are assigned, in the order in which they were declared in the class definition. Each subobject is assigned in the manner appropriate to its type:

- if the subobject is of class type, the copy assignment operator for the class is used (as if by explicit qualification; that is, ignoring any possible virtual overriding functions in more derived classes);
- if the subobject is an array, each element is assigned, in the manner appropriate to the element type;
- if the subobject is of scalar type, the built-in assignment operator is used.

It is unspecified whether subobjects representing virtual base classes are assigned more than once by the implicitly-defined copy assignment operator. [Example:

```c
struct V {};
struct A : virtual V {};
struct B : virtual V {};
struct C : B, A {};
```

it is unspecified whether the virtual base class subobject \( V \) is assigned twice by the implicitly-defined copy assignment operator for \( C \).—end example]
A program is ill-formed if the copy constructor or the copy assignment operator for an object is implicitly used and the special member function is not accessible (clause 11). [\textit{Note: Copying one object into another using the copy constructor or the copy assignment operator does not change the layout or size of either object.} — end note ]

When certain criteria are met, an implementation is allowed to omit the copy construction of a class object, even if the copy constructor and/or destructor for the object have side effects. In such cases, the implementation treats the source and target of the omitted copy operation as simply two different ways of referring to the same object, and the destruction of that object occurs at the later of the times when the two objects would have been destroyed without the optimization.\footnote{Because only one object is destroyed instead of two, and one copy constructor is not executed, there is still one object destroyed for each one constructed.} This elision of copy operations is permitted in the following circumstances (which may be combined to eliminate multiple copies):

— in a \texttt{return} statement in a function with a class return type, when the expression is the name of a non-volatile automatic object with the same cv-unqualified type as the function return type, the copy operation can be omitted by constructing the automatic object directly into the function’s return value

— when a temporary class object that has not been bound to a reference (12.2) would be copied to a class object with the same cv-unqualified type, the copy operation can be omitted by constructing the temporary object directly into the target of the omitted copy

[\textit{Example:}]

```cpp
class Thing {
public:
    Thing();
    ~Thing();
    Thing(const Thing&);  
};

Thing f() {
    Thing t;
    return t;
}

Thing t2 = f();
```

Here the criteria for elision can be combined to eliminate two calls to the copy constructor of class \texttt{Thing}: the copying of the local automatic object \texttt{t} into the temporary object for the return value of function \texttt{f()} and the copying of that temporary object into object \texttt{t2}. Effectively, the construction of the local object \texttt{t} can be viewed as directly initializing the global object \texttt{t2}, and that object’s destruction will occur at program exit. — end example ]
Chapter 13  Overloading

When two or more different declarations are specified for a single name in the same scope, that name is said to be overloaded. By extension, two declarations in the same scope that declare the same name but with different types are called overloaded declarations. Only function declarations can be overloaded; object and type declarations cannot be overloaded.

When an overloaded function name is used in a call, which overloaded function declaration is being referenced is determined by comparing the types of the arguments at the point of use with the types of the parameters in the overloaded declarations that are visible at the point of use. This function selection process is called overload resolution and is defined in 13.3. [Example:

double abs(double);
int abs(int);

abs(1);  // call abs(int);
abs(1.0);  // call abs(double);

— end example ]

13.1 Overloadable declarations

Not all function declarations can be overloaded. Those that cannot be overloaded are specified here. A program is ill-formed if it contains two such non-overloadable declarations in the same scope. [Note: this restriction applies to explicit declarations in a scope, and between such declarations and declarations made through a using-declaration (7.3.3). It does not apply to sets of functions fabricated as a result of name lookup (e.g., because of using-directives) or overload resolution (e.g., for operator functions). — end note ]

Certain function declarations cannot be overloaded:

— Function declarations that differ only in the return type cannot be overloaded.

— Member function declarations with the same name and the same parameter-type-list cannot be overloaded if any of them is a static member function declaration (9.4). Likewise, member function template declarations with the same name, the same parameter-type-list, and the same template parameter lists cannot be overloaded if any of them is a static member function template declaration. The types of the implicit object parameters constructed for the member functions for the purpose of overload resolution (13.3.1) are not considered when comparing parameter-type-lists for enforcement of this rule. In contrast, if there is no static member function declaration among a set of member function declarations with the same name and the same parameter-type-list, then these member function declarations can be overloaded if they differ in the type of their implicit object parameter. [Example: the following illustrates this distinction:
class X {
    static void f();
    void f(); // ill-formed
    void f() const; // ill-formed
    void f() const volatile; // ill-formed
    void g();
    void g() const; // OK: no static g
    void g() const volatile; // OK: no static g
};

— end example

[Note: as specified in 8.3.5, function declarations that have equivalent parameter declarations declare the same function and therefore cannot be overloaded:

— Parameter declarations that differ only in the use of equivalent typedef “types” are equivalent. A typedef is not a separate type, but only a synonym for another type (7.1.3). [Example:

typedef int Int;

    void f(int i);
    void f(Int i); // OK: redeclaration of f(int)
    void f(int i) { /* ... */ } // error: redefinition of f(int)
    void f(Int i) { /* ... */ } // error: redefinition of f(int)

— end example]

Enumerations, on the other hand, are distinct types and can be used to distinguish overloaded function declarations. [Example:

    enum E { a };

    void f(int i) { /* ... */ }
    void f(E i) { /* ... */ }

— end example]

— Parameter declarations that differ only in a pointer * versus an array [] are equivalent. That is, the array declaration is adjusted to become a pointer declaration (8.3.5). Only the second and subsequent array dimensions are significant in parameter types (8.3.4). [Example:

    int f(char*);
    int f(char[]); // same as f(char*);
    int f(char[7]); // same as f(char*);
    int f(char[9]); // same as f(char*);

    int g(char(*)[10]);
    int g(char[5][10]); // same as g(char(*)[10]);
    int g(char[7][10]); // same as g(char(*)[10]);
    int g(char(*)[20]); // different from g(char(*)[10]);

— end example]
— Parameter declarations that differ only in that one is a function type and the other is a pointer to the same function type are equivalent. That is, the function type is adjusted to become a pointer to function type (8.3.5). [Example:]

```c
void h(int());
void h(int (*)(()));       // redeclaration of h(int())
void h(int x()); { }       // definition of h(int())
void h(int (*)(x)()); { }  // ill-formed: redeclaration of h(int())

— end example ]

— Parameter declarations that differ only in the presence or absence of const and/or volatile are equivalent. That is, the const and volatile type-specifiers for each parameter type are ignored when determining which function is being declared, defined, or called. [Example:]

typedef const int cInt;

int f (int);
int f (const int);  // redeclaration of f(int)
int f (int) { ... }  // definition of f(int)
int f (cInt) { ... } // error: redefinition of f(int)

— end example ]

Only the const and volatile type-specifiers at the outermost level of the parameter type specification are ignored in this fashion; const and volatile type-specifiers buried within a parameter type specification are significant and can be used to distinguish overloaded function declarations.\(^{118}\) In particular, for any type \(T\), “pointer to \(T\),” “pointer to const \(T\),” and “pointer to volatile \(T\)” are considered distinct parameter types, as are “reference to \(T\),” “reference to const \(T\),” and “reference to volatile \(T\).”

— Two parameter declarations that differ only in their default arguments are equivalent. [Example: consider the following:]

```c
void f (int i, int j);
void f (int i, int j = 99);       // OK: redeclaration of f(int, int)
void f (int i = 88, int j);       // OK: redeclaration of f(int, int)
void f ();                          // OK: overloaded declaration of f

void prog ()
{
    f (1, 2);                  // OK: call f(int, int)
    f (1);                    // OK: call f(int, int)
    f ();                     // Error: f(int, int) or f()?  
}

— end example ] — end note ]

\(^{118}\) When a parameter type includes a function type, such as in the case of a parameter type that is a pointer to function, the const and volatile type-specifiers at the outermost level of the parameter type specifications for the inner function type are also ignored.
13.2 Declaration matching

Two function declarations of the same name refer to the same function if they are in the same scope and have equivalent parameter declarations (13.1). A function member of a derived class is not in the same scope as a function member of the same name in a base class. [Example:

```c++
class B {
    public:
        int f(int);
};

class D : public B {
    public:
        int f(char*);
};
```

Here `D::f(char*)` hides `B::f(int)` rather than overloading it.

```c++
void h(D* pd)
{
    pd->f(1); // error:
               // D::f(char*) hides B::f(int)
    pd->B::f(1); // OK
    pd->f("Ben"); // OK, calls D::f
}
```

— end example ]

2 A locally declared function is not in the same scope as a function in a containing scope. [Example:

```c++
int f(char*);
void g()
{
    extern f(int);
    f("asdf"); // error: f(int) hides f(char*)
    // so there is no f(char*) in this scope
}

void caller ()
{
    extern void callee(int, int);
    {
        extern void callee(int); // hides callee(int, int)
        callee(88, 99); // error: only callee(int) in scope
    }
}
```

— end example ]

3 Different versions of an overloaded member function can be given different access rules. [Example:

Draft
class buffer {
private:
    char* p;
    int size;

protected:
    buffer(int s, char* store) { size = s; p = store; }
    // ...
public:
    buffer(int s) { p = new char[size = s]; }
    // ...
};

— end example ]

13.3 Overload resolution

Overload resolution is a mechanism for selecting the best function to call given a list of expressions that are to be the arguments of the call and a set of candidate functions that can be called based on the context of the call. The selection criteria for the best function are the number of arguments, how well the arguments match the parameter-type-list of the candidate function, how well (for non-static member functions) the object matches the implied object parameter, and certain other properties of the candidate function. [Note: the function selected by overload resolution is not guaranteed to be appropriate for the context. Other restrictions, such as the accessibility of the function, can make its use in the calling context ill-formed. — end note ]

Overload resolution selects the function to call in seven distinct contexts within the language:

— invocation of a function named in the function call syntax (13.3.1.1.1);
— invocation of a function call operator, a pointer-to-function conversion function, a reference-to-pointer-to-function conversion function, or a reference-to-function conversion function on a class object named in the function call syntax (13.3.1.1.2);
— invocation of the operator referenced in an expression (13.3.1.2);
— invocation of a constructor for direct-initialization (8.5) of a class object (13.3.1.3);
— invocation of a user-defined conversion for copy-initialization (8.5) of a class object (13.3.1.4);
— invocation of a conversion function for initialization of an object of a nonclass type from an expression of class type (13.3.1.5); and
— invocation of a conversion function for conversion to an lvalue to which a reference (8.5.3) will be directly bound (13.3.1.6).

Each of these contexts defines the set of candidate functions and the list of arguments in its own unique way. But, once the candidate functions and argument lists have been identified, the selection of the best function is the same in all cases:

— First, a subset of the candidate functions (those that have the proper number of arguments and meet certain other conditions) is selected to form a set of viable functions (13.3.2).
13.3 Overload resolution

— Then the best viable function is selected based on the implicit conversion sequences (13.3.3.1) needed to match each argument to the corresponding parameter of each viable function.

3 If a best viable function exists and is unique, overload resolution succeeds and produces it as the result. Otherwise overload resolution fails and the invocation is ill-formed. When overload resolution succeeds, and the best viable function is not accessible (clause 11) in the context in which it is used, the program is ill-formed.

13.3.1 Candidate functions and argument lists

1 The subclauses of 13.3.1 describe the set of candidate functions and the argument list submitted to overload resolution in each of the seven contexts in which overload resolution is used. The source transformations and constructions defined in these subclauses are only for the purpose of describing the overload resolution process. An implementation is not required to use such transformations and constructions.

2 The set of candidate functions can contain both member and non-member functions to be resolved against the same argument list. So that argument and parameter lists are comparable within this heterogeneous set, a member function is considered to have an extra parameter, called the implicit object parameter, which represents the object for which the member function has been called. For the purposes of overload resolution, both static and non-static member functions have an implicit object parameter, but constructors do not.

3 Similarly, when appropriate, the context can construct an argument list that contains an implied object argument to denote the object to be operated on. Since arguments and parameters are associated by position within their respective lists, the convention is that the implicit object parameter, if present, is always the first parameter and the implied object argument, if present, is always the first argument.

4 For non-static member functions, the type of the implicit object parameter is “reference to cv X” where X is the class of which the function is a member and cv is the cv-qualification on the member function declaration. [Example: for a const member function of class X, the extra parameter is assumed to have type “reference to const X”. — end example] For conversion functions, the function is considered to be a member of the class of the implicit object argument for the purpose of defining the type of the implicit object parameter. For non-conversion functions introduced by a using-declaration into a derived class, the function is considered to be a member of the derived class for the purpose of defining the type of the implicit object parameter. For static member functions, the implicit object parameter is considered to match any object (since if the function is selected, the object is discarded). [Note: no actual type is established for the implicit object parameter of a static member function, and no attempt will be made to determine a conversion sequence for that parameter (13.3.3). — end note]

5 During overload resolution, the implied object argument is indistinguishable from other arguments. The implicit object parameter, however, retains its identity since conversions on the corresponding argument shall obey these additional rules:

— no temporary object can be introduced to hold the argument for the implicit object parameter;

— no user-defined conversions can be applied to achieve a type match with it; and

— even if the implicit object parameter is not const-qualified, an rvalue temporary can be bound to the parameter as long as in all other respects the temporary can be converted to the type of the implicit object parameter.

6 Because only one user-defined conversion is allowed in an implicit conversion sequence, special rules apply when selecting the best user-defined conversion (13.3.3, 13.3.3.1). [Example:
class T {
public:
    T();
    // ...
};

class C : T {
public:
    C(int);
    // ...
};

T a = 1; // ill-formed: T(C(1)) not tried

--- end example ---

In each case where a candidate is a function template, candidate function template specializations are generated using template argument deduction (14.8.3, 14.8.2). Those candidates are then handled as candidate functions in the usual way. A given name can refer to one or more function templates and also to a set of overloaded non-template functions. In such a case, the candidate functions generated from each function template are combined with the set of non-template candidate functions.

13.3.1.1 Function call syntax

Recall from 5.2.2, that a function call is a postfix-expression, possibly nested arbitrarily deep in parentheses, followed by an optional expression-list enclosed in parentheses: ( ... (opt postfix-expression) ... )opt (expression-listopt)

Overload resolution is required if the postfix-expression is the name of a function, a function template (14.5.5), an object of class type, or a set of pointers-to-function. 2

13.3.1.1.1 describes how overload resolution is used in the first two of the above cases to determine the function to call. 13.3.1.1.2 describes how overload resolution is used in the third of the above cases to determine the function to call.

The fourth case arises from a postfix-expression of the form &F, where F names a set of overloaded functions. In the context of a function call, &F is treated the same as the name F by itself. Thus, (&F) (expression-listopt) is simply (F) (expression-listopt), which is discussed in 13.3.1.1.1. If the function selected by overload resolution according to 13.3.1.1.1 is a non-static member function, the program is ill-formed. (The resolution of &F in other contexts is described in 13.4.)

13.3.1.1.1 Call to named function

Of interest in 13.3.1.1.1 are only those function calls in which the postfix-expression ultimately contains a name that denotes one or more functions that might be called. Such a postfix-expression, perhaps nested arbitrarily deep in parentheses, has one of the following forms:

--- end example ---

119) The process of argument deduction fully determines the parameter types of the function template specializations, i.e., the parameters of function template specializations contain no template parameter types. Therefore the function template specializations can be treated as normal (non-template) functions for the remainder of overload resolution.

120) When F is a non-static member function, a reference of the form &A::f is a pointer-to-member, which cannot be used with the function-call syntax, and a reference of the form &F is an invalid use of the "&" operator on a non-static member function.
13.3 Overload resolution

In unqualified function calls, the name is not qualified by an \texttt{->} or \texttt{.} operator. Since the construct \texttt{A->B} is generally equivalent to \texttt{(*A).B}, the rest of clause 13 assumes, without loss of generality, that all member function calls have been normalized to the form that uses an object and the \texttt{.} operator. Furthermore, clause 13 assumes that the \texttt{postfix-expression} that is the left operand of the \texttt{.} operator has type \texttt{"cv T"} where \texttt{T} denotes a class.\footnote{Note that \texttt{cv} -qualifiers on the type of objects are significant in overload resolution for both lvalue and class rvalue objects.} Under this assumption, the \texttt{id-expression} in the call is looked up as a member function of \texttt{T} following the rules for looking up names in classes (10.2). The function declarations found by that lookup constitute the set of candidate functions. The argument list is the \texttt{expression-list} in the call augmented by the addition of the left operand of the \texttt{.} operator in the normalized member function call as the implied object argument (13.3.1).

In qualified function calls, the name to be resolved is an \texttt{id-expression} and is preceded by an \texttt{->} or \texttt{.} operator. The name is looked up in the context of the function call following the normal rules for name lookup in function calls (3.4). The function declarations found by that lookup constitute the set of candidate functions. Because of the rules for name lookup, the set of candidate functions consists (1) entirely of non-member functions or (2) entirely of member functions of some class \texttt{T}. In case (1), the argument list is the same as the \texttt{expression-list} in the call. In case (2), the argument list is the \texttt{expression-list} in the call augmented by the addition of an implied object argument as in a qualified function call. If the keyword \texttt{this} (9.3.2) is in scope and refers to class \texttt{T}, or a derived class of \texttt{T}, then the implied object argument is \texttt{(*this)}. If the keyword \texttt{this} is not in scope or refers to another class, then a contrived object of type \texttt{T} becomes the implied object argument\footnote{An implied object argument must be contrived to correspond to the implicit object parameter attributed to member functions during overload resolution. It is not used in the call to the selected function. Since the member functions all have the same implicit object parameter, the contrived object will not be the cause to select or reject a function.}. If the argument list is augmented by a contrived object and overload resolution selects one of the non-static member functions of \texttt{T}, the call is ill-formed.

13.3.1.1.2 Call to object of class type

If the \texttt{primary-expression} \texttt{E} in the function call syntax evaluates to a class object of type \texttt{"cv T"}, then the set of candidate functions includes at least the function call operators of \texttt{T}. The function call operators of \texttt{T} are obtained by ordinary lookup of the name \texttt{operator()} in the context of \texttt{(E).operator()}. In addition, for each conversion function declared in \texttt{T} of the form

\begin{verbatim}
operator conversion-type-id () cv-qualifier ;
\end{verbatim}

where \texttt{cv-qualifier} is the same cv-qualification as, or a greater cv-qualification than, \texttt{cv}, and where \texttt{conversion-type-id} denotes the type “pointer to function of (P1,...,Pn) returning R”, or the type “reference to pointer to function of (P1,...,Pn) returning R”, or the type “reference to function of (P1,...,Pn) returning R”, a surrogate call function with the unique name \texttt{call-function} and having the form

\begin{verbatim}
R call-function (conversion-type-id F, P1 a1, ..., Pn an) { return F(a1,...,an); }
\end{verbatim}

is also considered as a candidate function. Similarly, surrogate call functions are added to the set of candidate functions for each conversion function declared in a base class of \texttt{T} provided the function is not hidden within \texttt{T} by another intervening declaration\footnote{Note that this construction can yield candidate call functions that cannot be differentiated one from the other by overload resolution because they have identical declarations or differ only in their return type. The call will be ambiguous if overload resolution cannot select a match to the call that is uniquely better than such undifferentiable functions.}.
3 If such a surrogate call function is selected by overload resolution, the corresponding conversion function will be called to convert E to the appropriate function pointer or reference, and the function will then be invoked with the arguments of the call. If the conversion function cannot be called (e.g., because of an ambiguity), the program is ill-formed.

4 The argument list submitted to overload resolution consists of the argument expressions present in the function call syntax preceded by the implied object argument (E). [Note: when comparing the call against the function call operators, the implied object argument is compared against the implicit object parameter of the function call operator. When comparing the call against a surrogate call function, the implied object argument is compared against the first parameter of the surrogate call function. The conversion function from which the surrogate call function was derived will be used in the conversion sequence for that parameter since it converts the implied object argument to the appropriate function pointer or reference required by that first parameter. — end note] [Example:

```c
int f1(int);
int f2(float);
typedef int (*fp1)(int);
typedef int (*fp2)(float);
struct A {
    operator fp1() { return f1; }
    operator fp2() { return f2; }
} a;
int i = a(1);  // Calls f1 via pointer returned from
              // conversion function
```

— end example ]

13.3.1.2 Operators in expressions [over.match.oper]

1 If no operand of an operator in an expression has a type that is a class or an enumeration, the operator is assumed to be a built-in operator and interpreted according to clause 5. [Note: because . . . , and :: cannot be overloaded, these operators are always built-in operators interpreted according to clause 5. ? cannot be overloaded, but the rules in this subclause are used to determine the conversions to be applied to the second and third operands when they have class or enumeration type (5.16). — end note] [Example:

```c
class String {
    public:
        String (const String &);
        String (char *);
        operator char * ();
    };
String operator + (const String &, const String &);

void f( void )
{
   char* p = "one" + "two";  // ill-formed because neither
   int I = 1 + 1;           // operand has user-defined type
   // Always evaluates to 2 even if
   // user-defined types exist which
   // would perform the operation.
}
```

— end example ]

Draft
If either operand has a type that is a class or an enumeration, a user-defined operator function might be declared that implements this operator or a user-defined conversion can be necessary to convert the operand to a type that is appropriate for a built-in operator. In this case, overload resolution is used to determine which operator function or built-in operator is to be invoked to implement the operator. Therefore, the operator notation is first transformed to the equivalent function-call notation as summarized in Table 8 (where \( \oplus \) denotes one of the operators covered in the specified subclause).

### Table 8: relationship between operator and function call notation

</table>

For a unary operator \( \oplus \) with an operand of a type whose cv-unqualified version is T1, and for a binary operator \( \oplus \) with a left operand of a type whose cv-unqualified version is T1 and a right operand of a type whose cv-unqualified version is T2, three sets of candidate functions, designated member candidates, non-member candidates and built-in candidates, are constructed as follows:

- If T1 is a complete class type, the set of member candidates is the result of the qualified lookup of T1::operator\( \oplus \) (13.3.1.1.1); otherwise, the set of member candidates is empty.
- The set of non-member candidates is the result of the unqualified lookup of operator\( \oplus \) in the context of the expression according to the usual rules for name lookup in unqualified function calls (3.4.2) except that all member functions are ignored. However, if no operand has a class type, only those non-member functions in the lookup set that have a first parameter of type T1 or “reference to (possibly cv-qualified) T1”, when T1 is an enumeration type, or (if there is a right operand) a second parameter of type T2 or “reference to (possibly cv-qualified) T2”, when T2 is an enumeration type, are candidate functions.
- For the operator \( , \), the unary operator \&, or the operator ->, the built-in candidates set is empty. For all other operators, the built-in candidates include all of the candidate operator functions defined in 13.6 that, compared to the given operator,
  - have the same operator name, and
  - accept the same number of operands, and
  - accept operand types to which the given operand or operands can be converted according to 13.3.3.1, and
  - do not have the same parameter-type-list as any non-template non-member candidate.

For the built-in assignment operators, conversions of the left operand are restricted as follows:

- no temporaries are introduced to hold the left operand, and
- no user-defined conversions are applied to the left operand to achieve a type match with the left-most parameter of a built-in candidate.

For all other operators, no such restrictions apply.
The set of candidate functions for overload resolution is the union of the member candidates, the non-member candidates, and the built-in candidates. The argument list contains all of the operands of the operator. The best function from the set of candidate functions is selected according to 13.3.2 and 13.3.3. 

Example:

```c
struct A {
    operator int();
};
A operator+(const A&, const A&);
void m() {
    A a, b;
    a + b; // operator+(a,b) chosen over int(a) + int(b)
}
```

— end example —

If a built-in candidate is selected by overload resolution, the operands are converted to the types of the corresponding parameters of the selected operation function. Then the operator is treated as the corresponding built-in operator and interpreted according to clause 5.

The second operand of operator `->` is ignored in selecting an `operator->` function, and is not an argument when the `operator->` function is called. When `operator->` returns, the operator `->` is applied to the value returned, with the original second operand.

If the operator is the operator `,`, the unary operator `&`, or the operator `->`, and there are no viable functions, then the operator is assumed to be the built-in operator and interpreted according to clause 5.

[ Note: the lookup rules for operators in expressions are different than the lookup rules for operator function names in a function call, as shown in the following example:

```c
struct A {};
void operator + (A, A);

struct B {
    void operator + (B);
    void f ();
};

A a;

void B::f() {
    operator+ (a,a); // ERROR — global operator hidden by member
    a + a; // OK — calls global operator+
}
```

— end note —

124) If the set of candidate functions is empty, overload resolution is unsuccessful.

125) If the value returned by the `operator->` function has class type, this may result in selecting and calling another `operator->` function. The process repeats until an `operator->` function returns a value of non-class type.
13.3 Overload resolution

13.3.1.3 Initialization by constructor

When objects of class type are direct-initialized (8.5), or copy-initialized from an expression of the same or a derived class type (8.5), overload resolution selects the constructor. For direct-initialization, the candidate functions are all the constructors of the class of the object being initialized. For copy-initialization, the candidate functions are all the converting constructors (12.3.1) of that class. The argument list is the expression-list within the parentheses of the initializer.

13.3.1.4 Copy-initialization of class by user-defined conversion

Under the conditions specified in 8.5, as part of a copy-initialization of an object of class type, a user-defined conversion can be invoked to convert an initializer expression to the type of the object being initialized. Overload resolution is used to select the user-defined conversion to be invoked. Assuming that “cv1 T” is the type of the object being initialized, with T a class type, the candidate functions are selected as follows:

— The converting constructors (12.3.1) of T are candidate functions.

— When the type of the initializer expression is a class type “cv S”, the conversion functions of S and its base classes are considered. Those that are not hidden within S and yield a type whose cv-unqualified version is the same type as T or is a derived class thereof are candidate functions. Conversion functions that return “reference to X” return lvalues of type X and are therefore considered to yield X for this process of selecting candidate functions.

2 In both cases, the argument list has one argument, which is the initializer expression. [Note: this argument will be compared against the first parameter of the constructors and against the implicit object parameter of the conversion functions. — end note ]

13.3.1.5 Initialization by conversion function

Under the conditions specified in 8.5, as part of an initialization of an object of nonclass type, a conversion function can be invoked to convert an initializer expression of class type to the type of the object being initialized. Overload resolution is used to select the conversion function to be invoked. Assuming that “cv1 T” is the type of the object being initialized, and “cv S” is the type of the initializer expression, with S a class type, the candidate functions are selected as follows:

— The conversion functions of S and its base classes are considered. Those that are not hidden within S and yield type T or a type that can be converted to type T via a standard conversion sequence (13.3.3.1.1) are candidate functions. Conversion functions that return a cv-qualified type are considered to yield the cv-unqualified version of that type for this process of selecting candidate functions. Conversion functions that return “reference to cv2 X” return lvalues of type cv2 X” and are therefore considered to yield X for this process of selecting candidate functions.

2 The argument list has one argument, which is the initializer expression. [Note: this argument will be compared against the implicit object parameter of the conversion functions. — end note ]

13.3.1.6 Initialization by conversion function for direct reference binding

Under the conditions specified in 8.5.3, a reference can be bound directly to an lvalue that is the result of applying a conversion function to an initializer expression. Overload resolution is used to select the conversion function to be

Draft
invoked. Assuming that “cv1 T” is the underlying type of the reference being initialized, and “cv S” is the type of the initializer expression, with S a class type, the candidate functions are selected as follows:

— The conversion functions of S and its base classes are considered. Those that are not hidden within S and yield type “reference to cv2 T2”, where “cv1 T” is reference-compatible (8.5.3) with “cv2 T2”, are candidate functions.

2 The argument list has one argument, which is the initializer expression. [Note: this argument will be compared against the implicit object parameter of the conversion functions. — end note ]

13.3.2 Viable functions [over.match.viable]

1 From the set of candidate functions constructed for a given context (13.3.1), a set of viable functions is chosen, from which the best function will be selected by comparing argument conversion sequences for the best fit (13.3.3). The selection of viable functions considers relationships between arguments and function parameters other than the ranking of conversion sequences.

2 First, to be a viable function, a candidate function shall have enough parameters to agree in number with the arguments in the list.

— If there are m arguments in the list, all candidate functions having exactly m parameters are viable.

— A candidate function having fewer than m parameters is viable only if it has an ellipsis in its parameter list (8.3.5). For the purposes of overload resolution, any argument for which there is no corresponding parameter is considered to “match the ellipsis” (13.3.3.1.3).

— A candidate function having more than m parameters is viable only if the (m+1)-st parameter has a default argument (8.3.6). For the purposes of overload resolution, the parameter list is truncated on the right, so that there are exactly m parameters.

3 Second, for F to be a viable function, there shall exist for each argument an implicit conversion sequence (13.3.3.1) that converts that argument to the type of the i-th parameter of viable function F. If the parameter has reference type, the implicit conversion sequence includes the operation of binding the reference, and the fact that a reference to non-const cannot be bound to an rvalue can affect the viability of the function (see 13.3.3.1.4).

13.3.3 Best Viable Function [over.match.best]

1 Define ICSi(F) as follows:

— if F is a static member function, ICSi(F) is defined such that ICSi(F) is neither better nor worse than ICSi(G) for any function G, and, symmetrically, ICSi(G) is neither better nor worse than ICSi(F); otherwise,

— let ICSi(F) denote the implicit conversion sequence that converts the i-th argument in the list to the type of the i-th parameter of viable function F. 13.3.3.1 defines the implicit conversion sequences and 13.3.3.2 defines what it means for one implicit conversion sequence to be a better conversion sequence or worse conversion sequence than another.

126 According to 8.3.6, parameters following the (m+1)-st parameter must also have default arguments.

127 If a function is a static member function, this definition means that the first argument, the implied object parameter, has no effect in the determination of whether the function is better or worse than any other function.
Given these definitions, a viable function \( F_1 \) is defined to be a better function than another viable function \( F_2 \) if for all arguments \( i \), \( \text{ICS}_i(F_1) \) is not a worse conversion sequence than \( \text{ICS}_i(F_2) \), and then

- for some argument \( j \), \( \text{ICS}_j(F_1) \) is a better conversion sequence than \( \text{ICS}_j(F_2) \), or, if not that,
- \( F_1 \) is a non-template function and \( F_2 \) is a function template specialization, or, if not that,
- \( F_1 \) and \( F_2 \) are function template specializations, and the function template for \( F_1 \) is more specialized than the template for \( F_2 \) according to the partial ordering rules described in 14.5.5.2, or, if not that,
- the context is an initialization by user-defined conversion (see 8.5, 13.3.1.5, and 13.3.1.6) and the standard conversion sequence from the return type of \( F_1 \) to the destination type (i.e., the type of the entity being initialized) is a better conversion sequence than the standard conversion sequence from the return type of \( F_2 \) to the destination type. [Example:

```c
struct A {
    A();
    operator int();
    operator double();
} a;
int i = a;       // a.operator int() followed by no conversion
                // is better than a.operator double() followed by
                // a conversion to int
float x = a;    // ambiguous: both possibilities require conversions,
                // and neither is better than the other
```

— end example]

If there is exactly one viable function that is a better function than all other viable functions, then it is the one selected by overload resolution; otherwise the call is ill-formed\(^{(128)}\).

[Example:

```c
void Fcn(const int*, short);
void Fcn(int*, int);

int i;
short s = 0;

void f() {
    Fcn(&i, s);       // is ambiguous because
                      // &i -> int* is better than &i -> const int*
                      // but s -> short is also better than s -> int
    Fcn(&i, 1L);      // calls Fcn(int*, int), because
                      // &i -> int* is better than &i -> const int*
                      // and 1L -> short and 1L -> int are indistinguishable
```

\(^{(128)}\) The algorithm for selecting the best viable function is linear in the number of viable functions. Run a simple tournament to find a function \( W \) that is not worse than any opponent it faced. Although another function \( F \) that \( W \) did not face might be at least as good as \( W \), \( F \) cannot be the best function because at some point in the tournament \( F \) encountered another function \( G \) such that \( F \) was not better than \( G \). Hence, \( W \) is either the best function or there is no best function. So, make a second pass over the viable functions to verify that \( W \) is better than all other functions.
If the best viable function resolves to a function for which multiple declarations were found, and if at least two of these declarations — or the declarations they refer to in the case of using-declarations — specify a default argument that made the function viable, the program is ill-formed. [Example:

```cpp
namespace A {
    extern "C" void f(int = 5);
}
namespace B {
    extern "C" void f(int = 5);
}
using A::f;
using B::f;

void use() {
    f(3);            // OK, default argument was not used for viability
    f();             // Error: found default argument twice
}
```
— end example]

### 13.3.3.1 Implicit conversion sequences [over.best.ics]

1 An *implicit conversion sequence* is a sequence of conversions used to convert an argument in a function call to the type of the corresponding parameter of the function being called. The sequence of conversions is an implicit conversion as defined in clause 4, which means it is governed by the rules for initialization of an object or reference by a single expression (8.5, 8.5.3).

2 Implicit conversion sequences are concerned only with the type, cv-qualification, and lvalue-ness of the argument and how these are converted to match the corresponding properties of the parameter. Other properties, such as the lifetime, storage class, alignment, or accessibility of the argument and whether or not the argument is a bit-field are ignored. So, although an implicit conversion sequence can be defined for a given argument-parameter pair, the conversion from the argument to the parameter might still be ill-formed in the final analysis.

3 A well-formed implicit conversion sequence is one of the following forms:

   — a *standard conversion sequence* (13.3.3.1.1),
   — a *user-defined conversion sequence* (13.3.3.1.2), or
   — an *ellipsis conversion sequence* (13.3.3.1.3).
4 However, when considering the argument of a user-defined conversion function that is a candidate by 13.3.1.3 when invoked for the copying of the temporary in the second step of a class copy-initialization, or by 13.3.1.4, 13.3.1.5, or 13.3.1.6 in all cases, only standard conversion sequences and ellipsis conversion sequences are allowed.

5 For the case where the parameter type is a reference, see 13.3.3.1.4.

6 When the parameter type is not a reference, the implicit conversion sequence models a copy-initialization of the parameter from the argument expression. The implicit conversion sequence is the one required to convert the argument expression to an rvalue of the type of the parameter. [Note: when the parameter has a class type, this is a conceptual conversion defined for the purposes of clause 13; the actual initialization is defined in terms of constructors and is not a conversion. —end note] Any difference in top-level cv-qualification is subsumed by the initialization itself and does not constitute a conversion. [Example: a parameter of type A can be initialized from an argument of type const A. The implicit conversion sequence for that case is the identity sequence; it contains no “conversion” from const A to A. —end example] When the parameter has a class type and the argument expression has the same type, the implicit conversion sequence is an identity conversion. When the parameter has a class type and the argument expression has a derived class type, the implicit conversion sequence is a derived-to-base Conversion from the derived class to the base class. [Note: there is no such standard conversion; this derived-to-base Conversion exists only in the description of implicit conversion sequences. —end note] A derived-to-base Conversion has Conversion rank (13.3.3.1.1).

7 In all contexts, when converting to the implicit object parameter or when converting to the left operand of an assignment operation only standard conversion sequences that create no temporary object for the result are allowed.

8 If no conversions are required to match an argument to a parameter type, the implicit conversion sequence is the standard conversion sequence consisting of the identity conversion (13.3.3.1.1).

9 If no sequence of conversions can be found to convert an argument to a parameter type or the conversion is otherwise ill-formed, an implicit conversion sequence cannot be formed.

10 If several different sequences of conversions exist that each convert the argument to the parameter type, the implicit conversion sequence associated with the parameter is defined to be the unique conversion sequence designated the ambiguous conversion sequence. For the purpose of ranking implicit conversion sequences as described in 13.3.3.2, the ambiguous conversion sequence is treated as a user-defined sequence that is indistinguishable from any other user-defined conversion sequence. If a function that uses the ambiguous conversion sequence is selected as the best viable function, the call will be ill-formed because the conversion of one of the arguments in the call is ambiguous.

129) The ambiguous conversion sequence is ranked with user-defined conversion sequences because multiple conversion sequences for an argument can exist only if they involve different user-defined conversions. The ambiguous conversion sequence is indistinguishable from any other user-defined conversion sequence because it represents at least two user-defined conversion sequences, each with a different user-defined conversion, and any other user-defined conversion sequence must be indistinguishable from at least one of them.

This rule prevents a function from becoming non-viable because of an ambiguous conversion sequence for one of its parameters. Consider this example.

```cpp
class B;
class A { A (B&); };  // class B has a constructor
class B { operator A (); };  // class B has an operator A()
class C { C (B&); };        // class C has a constructor
void f(A) { }
void f(C) { }
B b;                        // ambiguos because b → C via constructor and
f(b);                       // b → A via constructor or conversion function.
```

If it were not for this rule, f(A) would be eliminated as a viable function for the call f(b) causing overload resolution to select f(C) as the function to call even though it is not clearly the best choice. On the other hand, if an f(B) were to be declared then f(b) would resolve to that f(B) because the exact match with f(B) is better than any of the sequences required to match f(A).
The three forms of implicit conversion sequences mentioned above are defined in the following subclauses.

13.3.3.1 Standard conversion sequences

Table 9 summarizes the conversions defined in clause 4 and partitions them into four disjoint categories: Lvalue Transformation, Qualification Adjustment, Promotion, and Conversion. [Note: these categories are orthogonal with respect to lvalue-ness, cv-qualification, and data representation: the Lvalue Transformations do not change the cv-qualification or data representation of the type; the Qualification Adjustments do not change the lvalue-ness or data representation of the type; and the Promotions and Conversions do not change the lvalue-ness or cv-qualification of the type. — end note]

[Note: As described in clause 4, a standard conversion sequence is either the Identity conversion by itself (that is, no conversion) or consists of one to three conversions from the other four categories. At most one conversion from each category is allowed in a single standard conversion sequence. If there are two or more conversions in the sequence, the conversions are applied in the canonical order: Lvalue Transformation, Promotion or Conversion, Qualification Adjustment. — end note]

Each conversion in Table 9 also has an associated rank (Exact Match, Promotion, or Conversion). These are used to rank standard conversion sequences (13.3.3.2). The rank of a conversion sequence is determined by considering the rank of each conversion in the sequence and the rank of any reference binding (13.3.3.1.4). If any of those has Conversion rank, the sequence has Conversion rank; otherwise, if any of those has Promotion rank, the sequence has Promotion rank; otherwise, the sequence has Exact Match rank.

13.3.3.1.2 User-defined conversion sequences

A user-defined conversion sequence consists of an initial standard conversion sequence followed by a user-defined conversion (12.3) followed by a second standard conversion sequence. If the user-defined conversion is specified by a constructor (12.3.1), the initial standard conversion sequence converts the source type to the type required by the
argument of the constructor. If the user-defined conversion is specified by a conversion function (12.3.2), the initial standard conversion sequence converts the source type to the implicit object parameter of the conversion function.

2. The second standard conversion sequence converts the result of the user-defined conversion to the target type for the sequence. Since an implicit conversion sequence is an initialization, the special rules for initialization by user-defined conversion apply when selecting the best user-defined conversion for a user-defined conversion sequence (see 13.3.3 and 13.3.3.1).

3. If the user-defined conversion is specified by a template conversion function, the second standard conversion sequence must have exact match rank.

4. A conversion of an expression of class type to the same class type is given Exact Match rank, and a conversion of an expression of class type to a base class of that type is given Conversion rank, in spite of the fact that a copy constructor (i.e., a user-defined conversion function) is called for those cases.

13.3.3.1.3 Ellipsis conversion sequences

An ellipsis conversion sequence occurs when an argument in a function call is matched with the ellipsis parameter specification of the function called.

13.3.3.1.4 Reference binding

When a parameter of reference type binds directly (8.5.3) to an argument expression, the implicit conversion sequence is the identity conversion, unless the argument expression has a type that is a derived class of the parameter type, in which case the implicit conversion sequence is a derived-to-base Conversion (13.3.3.1). [Example:

```c
struct A {};  
struct B : public A {} b;  
int f(A&);  
int f(B&);  
int i = f(b); // Calls f(B&), an exact match, rather than  
// f(A&), a conversion
```

— end example] If the parameter binds directly to the result of applying a conversion function to the argument expression, the implicit conversion sequence is a user-defined conversion sequence (13.3.3.1.2), with the second standard conversion sequence either an identity conversion or, if the conversion function returns an entity of a type that is a derived class of the parameter type, a derived-to-base Conversion.

2. When a parameter of reference type is not bound directly to an argument expression, the conversion sequence is the one required to convert the argument expression to the underlying type of the reference according to 13.3.3.1. Conceptually, this conversion sequence corresponds to copy-initializing a temporary of the underlying type with the argument expression. Any difference in top-level cv-qualification is subsumed by the initialization itself and does not constitute a conversion.

3. A standard conversion sequence cannot be formed if it requires binding a reference to non-const to an rvalue (except when binding an implicit object parameter; see the special rules for that case in 13.3.1). [Note: this means, for example, that a candidate function cannot be a viable function if it has a non-const reference parameter (other than the implicit object parameter) and the corresponding argument is a temporary or would require one to be created to initialize the reference (see 8.5.3). — end note]

4. Other restrictions on binding a reference to a particular argument that are not based on the types of the reference and the argument do not affect the formation of a standard conversion sequence, however. [Example: a function with a... Draft
“reference to int” parameter can be a viable candidate even if the corresponding argument is an int bit-field. The formation of implicit conversion sequences treats the int bit-field as an int lvalue and finds an exact match with the parameter. If the function is selected by overload resolution, the call will nonetheless be ill-formed because of the prohibition on binding a non-const reference to a bit-field (8.5.3). —end example

The binding of a reference to an expression that is reference-compatible with added qualification influences the rank of a standard conversion; see 13.3.3.2 and 8.5.3.

13.3.3.2 Ranking implicit conversion sequences

13.3.3.2 defines a partial ordering of implicit conversion sequences based on the relationships better conversion sequence and better conversion. If an implicit conversion sequence S1 is defined by these rules to be a better conversion sequence than S2, then it is also the case that S2 is a worse conversion sequence than S1. If conversion sequence S1 is neither better than nor worse than conversion sequence S2, S1 and S2 are said to be indistinguishable conversion sequences.

When comparing the basic forms of implicit conversion sequences (as defined in 13.3.3.1)

— a standard conversion sequence (13.3.3.1.1) is a better conversion sequence than a user-defined conversion sequence or an ellipsis conversion sequence, and

— a user-defined conversion sequence (13.3.3.1.2) is a better conversion sequence than an ellipsis conversion sequence (13.3.3.1.3).

Two implicit conversion sequences of the same form are indistinguishable conversion sequences unless one of the following rules apply:

— Standard conversion sequence S1 is a better conversion sequence than standard conversion sequence S2 if

— S1 is a proper subsequence of S2 (comparing the conversion sequences in the canonical form defined by 13.3.3.1.1, excluding any Lvalue Transformation; the identity conversion sequence is considered to be a subsequence of any non-identity conversion sequence) or, if not that,

— the rank of S1 is better than the rank of S2, or S1 and S2 have the same rank and are distinguishable by the rules in the paragraph below, or, if not that,

— S1 and S2 differ only in their qualification conversion and yield similar types T1 and T2 (4.4), respectively, and the cv-qualification signature of type T1 is a proper subset of the cv-qualification signature of type T2, and S1 is not the deprecated string literal array-to-pointer conversion (4.2). [Example:

```
int f(const int *);
int f(int *);
int i;
int j = f(&i);  // Calls f(int*)
```

— end example] or, if not that,

— S1 and S2 are reference bindings (8.5.3), and the types to which the references refer are the same type except for top-level cv-qualifiers, and the type to which the reference initialized by S2 refers is more cv-qualified than the type to which the reference initialized by S1 refers. [Example:

```
int f(const int &);
int f(int &);
int g(const int &);
```

Draft
13.3 Overload resolution

```c
int g(int);
int i;
int j = f(i);  // Calls f(int k)
int k = g(i);  // ambiguous

class X {
public:
  void f() const;
  void f();
};

void g(const X& a, X b)
{
  a.f();  // Calls X::f() const
  b.f();  // Calls X::f()
}
```

— end example }

User-defined conversion sequence U1 is a better conversion sequence than another user-defined conversion sequence U2 if they contain the same user-defined conversion function or constructor and if the second standard conversion sequence of U1 is better than the second standard conversion sequence of U2. [Example:

```c
struct A {
  operator short();
} a;
int f(int);
int f(float);
int i = f(a);  // Calls f(int), because short → int is
               // better than short → float.
```

— end example ]

4 Standard conversion sequences are ordered by their ranks: an Exact Match is a better conversion than a Promotion, which is a better conversion than a Conversion. Two conversion sequences with the same rank are indistinguishable unless one of the following rules applies:

— A conversion that is not a conversion of a pointer, or pointer to member, to bool is better than another conversion that is such a conversion.

— If class B is derived directly or indirectly from class A, conversion of B* to A* is better than conversion of B* to void*, and conversion of A* to void* is better than conversion of B* to void*.

— If class B is derived directly or indirectly from class A and class C is derived directly or indirectly from B, conversion of C* to B* is better than conversion of C* to A*. [Example:

```c
struct A {};
struct B : public A {};
struct C : public B {};
C *pc;
int f(A *);
```

Draft
int f(B *);
int i = f(pc);

// Calls f(B*)

— end example]  
— binding of an expression of type C to a reference of type B& is better than binding an expression of type C to a reference of type A&,
— conversion of A::* to B::* is better than conversion of A::* to C::*,
— conversion of C to B is better than conversion of C to A,
— conversion of B* to A* is better than conversion of C* to A*,
— binding of an expression of type B to a reference of type A& is better than binding an expression of type C to a reference of type A&,
— conversion of B::* to C::* is better than conversion of A::* to C::* , and
— conversion of B to A is better than conversion of C to A.

[Note: compared conversion sequences will have different source types only in the context of comparing the second standard conversion sequence of an initialization by user-defined conversion (see 13.3.3); in all other contexts, the source types will be the same and the target types will be different. —end note]

13.4 Address of overloaded function [over.over]

1 A use of an overloaded function name without arguments is resolved in certain contexts to a function, a pointer to function or a pointer to member function for a specific function from the overload set. A function template name is considered to name a set of overloaded functions in such contexts. The function selected is the one whose type matches the target type required in the context. The target can be
— an object or reference being initialized (8.5, 8.5.3),
— the left side of an assignment (5.17),
— a parameter of a function (5.2.2),
— a parameter of a user-defined operator (13.5),
— the return value of a function, operator function, or conversion (6.6.3),
— an explicit type conversion (5.2.3, 5.2.9, 5.4), or
— a non-type template-parameter (14.3.2).

The overloaded function name can be preceded by the & operator. An overloaded function name shall not be used without arguments in contexts other than those listed. [Note: any redundant set of parentheses surrounding the overloaded function name is ignored (5.1). —end note]

2 If the name is a function template, template argument deduction is done (14.8.2.2), and if the argument deduction succeeds, the resulting template argument list is used to generate a single function template specialization, which is added to the set of overloaded functions considered. [Note: As described in 14.8.1, if deduction fails and the function template name is followed by an explicit template argument list, the template-id is then examined to see whether it
identifies a single function template specialization. If it does, the template-id is considered to be an Ivalue for that
function template specialization. The target type is not used in that determination. — end note ]

3 Non-member functions and static member functions match targets of type “pointer-to-function” or “reference-to-func-
tion.” Nonstatic member functions match targets of type “pointer-to-member-function;” the function type of the pointerto member is used to select the member function from the set of overloaded member functions. If a non-static member
function is selected, the reference to the overloaded function name is required to have the form of a pointer to member
as described in 5.3.1.

4 If more than one function is selected, any function template specializations in the set are eliminated if the set also
contains a non-template function, and any given function template specialization F1 is eliminated if the set contains a
second function template specialization whose function template is more specialized than the function template of F1
according to the partial ordering rules of 14.5.5.2. After such eliminations, if any, there shall remain exactly one selected
function.

5 [ Example:

```c
int f(double);
int f(int);
int (*pfd)(double) = &f; // selects f(double)
int (*pfi)(int) = &f; // selects f(int)
int (*pfe)(...) = &f; // error: type mismatch
int (&rfi)(int) = f; // selects f(int)
int (&rfd)(double) = f; // selects f(double)
void g() {
  (int (*)(int))&f; // cast expression as selector
}
```

The initialization of pfe is ill-formed because no f() with type int(...) has been declared, and not because of any
ambiguity. For another example,

```c
struct X {
  int f(int);
  static int f(long);
};

int (X::*p1)(int) = &X::*f; // OK
int (*p2)(int) = &X::*f; // error: mismatch
int (*p3)(long) = &X::*f; // OK
int (X::*p4)(long) = &X::*f; // error: mismatch
int (X::*p5)(int) = &X::*f; // error: wrong syntax for
                           // pointer to member
int (*p6)(long) = &X::*f; // OK
```

— end example ]

6 [ Note: if f() and g() are both overloaded functions, the cross product of possibilities must be considered to resolve
f(&g), or the equivalent expression f(g). — end note ]

7 [ Note: there are no standard conversions (clause 4) of one pointer-to-function type into another. In particular, even if B
is a public base of D, we have

Draft
A function declaration having one of the following `operator-function-ids` as its name declares an operator function. An operator function is said to implement the operator named in its `operator-function-id`.

```plaintext
operator-function-id:
  operator operator < template-argument-list_opt >

operator: one of
new delete new[] delete[]
+  -  *  /  %  ^  &  |  ~
i  =  <  >  +=  -=  *=  /=  %=
/=  *=  &=  |=  <<=  >>=  <<=
<  <=  >=  &&  ||  ++  --  ,  ->
()  []
```

[Note: the last two operators are function call (5.2.2) and subscripting (5.2.1). The operators new[], delete[], (), and [] are formed from more than one token. —end note]

2 Both the unary and binary forms of
   +  -  *  &

can be overloaded.

3 The following operators cannot be overloaded:
   .*  ::  ??

   nor can the preprocessing symbols # and ## (clause 16).

4 Operator functions are usually not called directly; instead they are invoked to evaluate the operators they implement (13.5.1 - 13.5.7). They can be explicitly called, however, using the `operator-function-id` as the name of the function in the function call syntax (5.2.2). [Example:]

```plaintext
complex z = a.operator+(b);  // complex z = a+b;
void* p = operator new(sizeof(int)*n);
```

[Example:]

5 The allocation and deallocation functions, `operator new`, `operator new[]`, `operator delete` and `operator delete[]`, are described completely in 3.7.3. The attributes and restrictions found in the rest of this subclause do not apply to them unless explicitly stated in 3.7.3.

Draft
An operator function shall either be a non-static member function or be a non-member function and have at least one parameter whose type is a class, a reference to a class, an enumeration, or a reference to an enumeration. It is not possible to change the precedence, grouping, or number of operands of operators. The meaning of the operators =, (unary) &, and , (comma), predefined for each type, can be changed for specific class and enumeration types by defining operator functions that implement these operators. Operator functions are inherited in the same manner as other base class functions.

The identities among certain predefined operators applied to basic types (for example, ++a ≡ a+=1) need not hold for operator functions. Some predefined operators, such as +=, require an operand to be an lvalue when applied to basic types; this is not required by operator functions.

An operator function cannot have default arguments (8.3.6), except where explicitly stated below. Operator functions cannot have more or fewer parameters than the number required for the corresponding operator, as described in the rest of this subclause.

Operators not mentioned explicitly in subclauses 13.5.3 through 13.5.7 act as ordinary unary and binary operators obeying the rules of 13.5.1 or 13.5.2.

### 13.5.1 Unary operators

A prefix unary operator shall be implemented by a non-static member function (9.3) with no parameters or a non-member function with one parameter. Thus, for any prefix unary operator @, @x can be interpreted as either x.operator@() or operator@x. If both forms of the operator function have been declared, the rules in 13.3.1.2 determine which, if any, interpretation is used. See 13.5.7 for an explanation of the postfix unary operators ++ and –.

The unary and binary forms of the same operator are considered to have the same name. [Note: consequently, a unary operator can hide a binary operator from an enclosing scope, and vice versa. — end note]

### 13.5.2 Binary operators

A binary operator shall be implemented either by a non-static member function (9.3) with one parameter or by a non-member function with two parameters. Thus, for any binary operator @, x@y can be interpreted as either x.operator@y() or operator@x,y. If both forms of the operator function have been declared, the rules in 13.3.1.2 determine which, if any, interpretation is used.

### 13.5.3 Assignment

An assignment operator shall be implemented by a non-static member function with exactly one parameter. Because a copy assignment operator operator= is implicitly declared for a class if not declared by the user (12.8), a base class assignment operator is always hidden by the copy assignment operator of the derived class.

Any assignment operator, even the copy assignment operator, can be virtual. [Note: for a derived class D with a base class B for which a virtual copy assignment has been declared, the copy assignment operator in D does not override B’s virtual copy assignment operator. [Example:

```c
struct B {
    virtual int operator= (int);
    virtual B& operator= (const B&);
};
struct D : B {
    virtual int operator= (int);
    virtual D& operator= (const B&);
}
```

Draft
};
D dobj1;
D dobj2;
B* bptr = &dobj1;
void f() {
    bptr->operator=(99); // calls D::operator=(int)
    *bptr = 99; // ditto
    bptr->operator=(dobj2); // calls D::operator=(const B&)
    *bptr = dobj2; // ditto
    dobj1 = dobj2; // calls implicitly-declared
                    // D::operator=(const D&)
}

— end example ] — end note ]

13.5.4 Function call [over.call]
operator() shall be a non-static member function with an arbitrary number of parameters. It implements the function call syntax

postfix-expression ( expression-list_opt )

where the postfix-expression evaluates to a class object and the possibly empty expression-list matches the parameter list of an operator() member function of the class. Thus, a call x(arg1,...) is interpreted as x.operator()(arg1,

...) for a class object x of type T if T::operator()(T1, T2, T3) exists and if the operator is selected as the best match function by the overload resolution mechanism (13.3.3).

13.5.5 Subscripting [over.sub]
operator[] shall be a non-static member function with exactly one parameter. It implements the subscripting syntax

postfix-expression [ expression ]

Thus, a subscripting expression x[y] is interpreted as x.operator[](y) for a class object x of type T if T::operator[](T1) exists and if the operator is selected as the best match function by the overload resolution mechanism (13.3.3).

13.5.6 Class member access [over.ref]
operator-> shall be a non-static member function taking no parameters. It implements class member access using ->

postfix-expression -> id-expression

An expression x->m is interpreted as (x.operator->())->m for a class object x of type T if T::operator->() exists and if the operator is selected as the best match function by the overload resolution mechanism (13.3).

13.5.7 Increment and decrement [over.inc]
The user-defined function called operator++ implements the prefix and postfix ++ operator. If this function is a member function with no parameters, or a non-member function with one parameter of class or enumeration type, it defines the prefix increment operator ++ for objects of that type. If the function is a member function with one parameter (which shall be of type int) or a non-member function with two parameters (the second of which shall be of type int), it
defines the postfix increment operator ++ for objects of that type. When the postfix increment is called as a result of using the ++ operator, the int argument will have value zero.\footnote{Calling \texttt{operator++} explicitly, as in expressions like \texttt{a.operator++(2)}, has no special properties. The argument to \texttt{operator++} is 2.}

\begin{verbatim}
example:

```cpp
class X {
public:
  X& operator++();    // prefix ++a
  X operator++(int);  // postfix a++
};

class Y {
  Y& operator++(Y&);  // prefix ++b
  Y operator++(Y&, int); // postfix b++

  void f(X a, Y b) {
    ++a;                // a.operator++();
    a++;                // a.operator++(0);
    ++b;                // operator++(b);
    b++;                // operator++(b, 0);

    a.operator++();     // explicit call: like ++a;
    a.operator++(0);    // explicit call: like a++;
    operator++(b);      // explicit call: like ++b;
    operator++(b, 0);   // explicit call: like b++;
  }

  // end example }
```

\end{verbatim}

--- end example ]

2 The prefix and postfix decrement operators – are handled analogously.

13.6 Built-in operators

The candidate operator functions that represent the built-in operators defined in clause 5 are specified in this subclause. These candidate functions participate in the operator overload resolution process as described in 13.3.1.2 and are used for no other purpose. [Note: because built-in operators take only operands with non-class type, and operator overload resolution occurs only when an operand expression originally has class or enumeration type, operator overload resolution can resolve to a built-in operator only when an operand has a class type that has a user-defined conversion to a non-class type appropriate for the operator, or when an operand has an enumeration type that can be converted to a type appropriate for the operator. Also note that some of the candidate operator functions given in this subclause are more permissive than the built-in operators themselves. As described in 13.3.1.2, after a built-in operator is selected by overload resolution the expression is subject to the requirements for the built-in operator given in clause 5, and therefore to any additional semantic constraints given there. If there is a user-written candidate with the same name and parameter types as a built-in candidate operator function, the built-in operator function is hidden and is not included in the set of candidate functions. —end note]

2 In this subclause, the term \textit{promoted integral type} is used to refer to those integral types which are preserved by integral promotion (including e.g. \texttt{int} and \texttt{long} but excluding e.g. \texttt{char}). Similarly, the term \textit{promoted arithmetic type} refers to floating types plus promoted integral types. [Note: in all cases where a promoted integral type or promoted arithmetic type is required, an operand of enumeration type will be acceptable by way of the integral promotions. —end note]
For every pair \((T, VQ)\), where \(T\) is an arithmetic type, and \(VQ\) is either \texttt{volatile} or empty, there exist candidate operator functions of the form
\[
VQ T \& \text{operator}++(VQ T \&);
T \text{operator}++(VQ T \&, \text{int});
\]

For every pair \((T, VQ)\), where \(T\) is an arithmetic type other than \texttt{bool}, and \(VQ\) is either \texttt{volatile} or empty, there exist candidate operator functions of the form
\[
VQ T \& \text{operator}--(VQ T \&);
T \text{operator}--(VQ T \&, \text{int});
\]

For every pair \((T, VQ)\), where \(T\) is a cv-qualified or cv-unqualified object type, and \(VQ\) is either \texttt{volatile} or empty, there exist candidate operator functions of the form
\[
T*VQ \& \text{operator}++(T*VQ \&);
T*VQ \& \text{operator}--(T*VQ \&);
T* \text{operator}++(T*VQ \&, \text{int});
T* \text{operator}--(T*VQ \&, \text{int});
\]

For every cv-qualified or cv-unqualified object type \(T\), there exist candidate operator functions of the form
\[
T \& \text{operator}*(T*);
\]

For every function type \(T\), there exist candidate operator functions of the form
\[
T \& \text{operator}*(T*);
\]

For every type \(T\), there exist candidate operator functions of the form
\[
T* \text{operator}+(T*);
\]

For every promoted arithmetic type \(T\), there exist candidate operator functions of the form
\[
T \text{operator}+(T);
T \text{operator}-(T);
\]

For every promoted integral type \(T\), there exist candidate operator functions of the form
\[
T \text{operator}~(T);
\]

For every quintuple \((C1, C2, T, CV1, CV2)\), where \(C2\) is a class type, \(C1\) is the same type as \(C2\) or is a derived class of \(C2\), \(T\) is an object type or a function type, and \(CV1\) and \(CV2\) are \texttt{cv-qualifier-seqs}, there exist candidate operator functions of the form
\[
CV12 T \& \text{operator}-->*(CV1 C1\*, CV2 T C2::\*);
\]

where \(CV12\) is the union of \(CV1\) and \(CV2\).

For every pair of promoted arithmetic types \(L\) and \(R\), there exist candidate operator functions of the form

Draft
13.6 Built-in operators

Overloading 268

LR operator *(L, R);
LR operator /(L, R);
LR operator *(L, R);
LR operator -(L, R);
bool operator <(L, R);
bool operator >(L, R);
bool operator <=(L, R);
bool operator >=(L, R);
bool operator ==(L, R);
bool operator !=(L, R);

where LR is the result of the usual arithmetic conversions between types L and R.

13 For every cv-qualified or cv-unqualified object type T there exist candidate operator functions of the form

T* operator *(T*, std::ptrdiff_t);
T& operator [] (T*, std::ptrdiff_t);
T* operator -(T*, std::ptrdiff_t);
T* operator *(std::ptrdiff_t, T*);
T& operator [] (std::ptrdiff_t, T*);

14 For every T, where T is a pointer to object type, there exist candidate operator functions of the form

std::ptrdiff_t operator -(T, T);

15 For every pointer or enumeration type T, there exist candidate operator functions of the form

bool operator <(T, T);
bool operator >(T, T);
bool operator <=(T, T);
bool operator >=(T, T);
bool operator ==(T, T);
bool operator !=(T, T);

16 For every pointer to member type T, there exist candidate operator functions of the form

bool operator ==(T, T);
bool operator !=(T, T);

17 For every pair of promoted integral types L and R, there exist candidate operator functions of the form

LR operator % (L, R);
LR operator &(L, R);
LR operator ^(L, R);
LR operator |(L, R);
L operator <<(L, R);
L operator >> (L, R);

where LR is the result of the usual arithmetic conversions between types L and R.

18 For every triple (L, VQ, R), where L is an arithmetic type, VQ is either volatile or empty, and R is a promoted arithmetic type, there exist candidate operator functions of the form

Draft
For every pair \((T, VQ)\), where \(T\) is any type and \(VQ\) is either volatile or empty, there exist candidate operator functions of the form
\[ T \ast VQ \& \text{ operator} = (T \ast VQ \&, \ T \ast); \]

For every pair \((T, VQ)\), where \(T\) is an enumeration or pointer to member type and \(VQ\) is either volatile or empty, there exist candidate operator functions of the form
\[ VQ \ T \& \text{ operator} = (VQ \ T \&, \ T); \]

For every pair \((T, VQ)\), where \(T\) is a cv-qualified or cv-unqualified object type and \(VQ\) is either volatile or empty, there exist candidate operator functions of the form
\[ T \ast VQ \& \text{ operator} += (T \ast VQ \&, \ std::ptrdiff_t); \]
\[ T \ast VQ \& \text{ operator} -= (T \ast VQ \&, \ std::ptrdiff_t); \]

For every triple \((L, VQ, R)\), where \(L\) is an integral type, \(VQ\) is either volatile or empty, and \(R\) is a promoted integral type, there exist candidate operator functions of the form
\[ VQ \ L \& \text{ operator} %= (VQ \ L \&, \ R); \]
\[ VQ \ L \& \text{ operator} <= (VQ \ L \&, \ R); \]
\[ VQ \ L \& \text{ operator} >= (VQ \ L \&, \ R); \]
\[ VQ \ L \& \text{ operator} &= (VQ \ L \&, \ R); \]
\[ VQ \ L \& \text{ operator} ^= (VQ \ L \&, \ R); \]
\[ VQ \ L \& \text{ operator} |= (VQ \ L \&, \ R); \]

There also exist candidate operator functions of the form
\[ \text{bool } \text{ operator}(\text{bool}); \]
\[ \text{bool } \text{ operator}&&(\text{bool}, \text{ bool}); \]
\[ \text{bool } \text{ operator}||(|(\text{bool}, \text{ bool}); \]

For every pair of promoted arithmetic types \(L\) and \(R\), there exist candidate operator functions of the form
\[ LR \text{ operator}? (\text{bool}, \ L, \ R); \]

where \(LR\) is the result of the usual arithmetic conversions between types \(L\) and \(R\). [Note: as with all these descriptions of candidate functions, this declaration serves only to describe the built-in operator for purposes of overload resolution. The operator “?” cannot be overloaded. —end note]

For every type \(T\), where \(T\) is a pointer or pointer-to-member type, there exist candidate operator functions of the form
\[ T \text{ operator}? (\text{bool}, \ T, \ T); \]
A template defines a family of classes or functions.

```plaintext
template-declaration:
  exportopt template < template-parameter-list > declaration

template-parameter-list:
  template-parameter
  template-parameter-list , template-parameter
```

The declaration in a template-declaration shall

- declare or define a function or a class, or
- define a member function, a member class or a static data member of a class template or of a class nested within a class template, or
- define a member template of a class or class template.

A template-declaration is a declaration. A template-declaration is also a definition if its declaration defines a function, a class, or a static data member.

2 A template-declaration can appear only as a namespace scope or class scope declaration. In a function template declaration, the declarator-id shall be a template-name (i.e., not a template-id). [Note: in a class template declaration, if the class name is a template-id, the declaration declares a class template partial specialization (14.5.4). — end note]

3 In a template-declaration, explicit specialization, or explicit instantiation the init-declarator-list in the declaration shall contain at most one declarator. When such a declaration is used to declare a class template, no declarator is permitted.

4 A template name has linkage (3.5). A non-member function template can have internal linkage; any other template name shall have external linkage. Entities generated from a template with internal linkage are distinct from all entities generated in other translation units. A template, a template explicit specialization (14.7.3), and a class template partial specialization shall not have C linkage. Use of a linkage specification other than C or C++ with any of these constructs is conditionally-supported, with implementation-defined semantics. Template definitions shall obey the one definition rule (3.2). [Note: default arguments for function templates and for member functions of class templates are considered definitions for the purpose of template instantiation (14.5) and must also obey the one definition rule. — end note]

5 A class template shall not have the same name as any other template, class, function, object, enumeration, enumerator, namespace, or type in the same scope (3.3), except as specified in (14.5.4). Except that a function template can be overloaded either by (non-template) functions with the same name or by other function templates with the same name (14.8.3), a template name declared in namespace scope or in class scope shall be unique in that scope.
A template-declaration may be preceded by the export keyword. Such a template is said to be exported. Declaring exported a class template is equivalent to declaring exported all of its non-inline member functions, static data members, member classes, member class templates, and non-inline member function templates.

If a template is exported in one translation unit, it shall be exported in all translation units in which it appears; no diagnostic is required. A declaration of an exported template shall appear with the export keyword before any point of instantiation (14.6.4.1) of that template in that translation unit. In addition, the first declaration of an exported template containing the export keyword must not follow the definition of that template. The export keyword shall not be used in a friend declaration.

Templates defined in an unnamed namespace, inline functions, and inline function templates shall not be exported. An exported non-class template shall be defined only once in a program; no diagnostic is required. An exported non-class template need only be declared (and not necessarily defined) in a translation unit in which it is instantiated.

A non-exported non-class template must be defined in every translation unit in which it is implicitly instantiated (14.7.1), unless the corresponding specialization is explicitly instantiated (14.7.2) in some translation unit; no diagnostic is required.

[Note: an implementation may require that a translation unit containing the definition of an exported template be compiled before any translation unit containing an instantiation of that template. — end note]

14.1 Template parameters

The syntax for template-parameters is:

```
template-parameter:
  type-parameter
parameter-declaration

type-parameter:
  class identifier_opt
  class identifier_opt = type-id
  typename identifier_opt
  typename identifier_opt = type-id
  template < template-parameter-list > class identifier_opt
template < template-parameter-list > class identifier_opt = id-expression
```

There is no semantic difference between class and typename in a template-parameter. typename followed by an unqualified-id names a template type parameter. typename followed by a qualified-id denotes the type in a non-type parameter-declaration. A storage class shall not be specified in a template-parameter declaration. [Note: a template parameter may be a class template. For example,

```
template<class T> class myarray { /* ... */

template<class K, class V, template<class T> class C = myarray>
class Map {
  C<K> key;
  C<V> value;
  // ...
```

131) Since template template-parameters and template template-arguments are treated as types for descriptive purposes, the terms non-type parameter and non-type argument are used to refer to non-type, non-template parameters and arguments.
A type-parameter defines its identifier to be a typedef-name (if declared with class or typename) or template-name (if declared with template) in the scope of the template declaration. [Note: because of the name lookup rules, a template-parameter that could be interpreted as either a non-type template-parameter or a type-parameter (because its identifier is the name of an already existing class) is taken as a type-parameter. For example,

```c++
class T { /* ... */ ];
int i;

template<class T, T i> void f(T t)
{
    T t1 = i;  // template-parameters T and i
    ::T t2 = ::i;  // global namespace members T and i
}
```

Here, the template f has a type-parameter called T, rather than an unnamed non-type template-parameter of class T. [end note]

A non-type template-parameter shall have one of the following (optionally cv-qualified) types:

- integral or enumeration type,
- pointer to object or pointer to function,
- reference to object or reference to function,
- pointer to member.

[Note: other types are disallowed either explicitly below or implicitly by the rules governing the form of template-arguments (14.3).] [end note] The top-level cv-qualifiers on the template-parameter are ignored when determining its type.

A non-type non-reference template-parameter is not an lvalue. It shall not be assigned to or in any other way have its value changed. A non-type non-reference template-parameter cannot have its address taken. When a non-type non-reference template-parameter is used as an initializer for a reference, a temporary is always used. [Example:

```c++
template<const X& x, int i> void f()
{
    i++;  // error: change of template-parameter value
    &x;  // OK
    &i;  // error: address of non-reference template-parameter

    int& ri = i;  // error: non-const reference bound to temporary
    const int& cri = i;  // OK: const reference bound to temporary
}
```

[end example]

A non-type template-parameter shall not be declared to have floating point, class, or void type. [Example: Draft]
A non-type \textit{template-parameter} of type “array of \( T \)” or “function returning \( T \)” is adjusted to be of type “pointer to \( T \)” or “pointer to function returning \( T \)\), respectively.\[\text{Example:}\]

\begin{verbatim}
template<int *a> struct R { /* ... */ };  
template<int b[5]> struct S { /* ... */ };  
int p;  
R<&p> w;  // OK  
S<&p> x;  // OK due to parameter adjustment  
int v[5];  
R<&v> y;  // OK due to implicit argument conversion  
S<&v> z;  // OK due to both adjustment and conversion
\end{verbatim}

A \textit{default template-argument} is a \textit{template-argument} (14.3) specified after = in a \textit{template-parameter}. A default \textit{template-argument} may be specified for any kind of \textit{template-parameter} (type, non-type, template). A default \textit{template-argument} may be specified in a template declaration. A default \textit{template-argument} shall not be specified in the \textit{template-parameter-lists} of the definition of a member of a class template that appears outside of the member’s class. A default \textit{template-argument} shall not be specified in a friend class template declaration. If a friend function template declaration specifies a default \textit{template-argument}, that declaration shall be a definition and shall be the only declaration of the function template in the translation unit.

The set of default \textit{template-arguments} available for use with a template declaration or definition is obtained by merging the default arguments from the definition (if in scope) and all declarations in scope in the same way default function arguments are (8.3.6).\[\text{Example:}\]

\begin{verbatim}
template<class T1 , class T2 = int > class A;  
template<class T1 = int , class T2 > class A;
\end{verbatim}

is equivalent to

\begin{verbatim}
template<class T1 = int , class T2 = int > class A;
\end{verbatim}

If a \textit{template-parameter} of a class template has a default \textit{template-argument}, all subsequent \textit{template-parameters} shall have a default \textit{template-argument} supplied. \[\text{Note:}\] This is not a requirement for function templates because template arguments might be deduced (14.8.2).\[\text{Example:}\]

\begin{verbatim}
template<class T1 = int , class T2> class B;  // error
\end{verbatim}

A \textit{template-parameter} shall not be given default arguments by two different declarations in the same scope.\[\text{Example:}\]

\begin{verbatim}
template<class T = int > class X;  
template<class T = int > class X { /* ... */ };  // error
\end{verbatim}
The scope of a `template-parameter` extends from its point of declaration until the end of its template. In particular, a `template-parameter` can be used in the declaration of subsequent `template-parameters` and their default arguments. [Example:
```
template<class T, T* p, class U = T> class X { /* ... */ };
template<class T> void f(T* p = new T);
```
— end example ]

A `template-parameter` shall not be used in its own default argument.

When parsing a default `template-argument` for a non-type `template-parameter`, the first non-nested `>` is taken as the end of the `template-parameter-list` rather than a greater-than operator. [Example:
```
template<int i = 3 > 4 > // syntax error
   class X { /* ... */ };

template<int i = (3 > 4) > // OK
   class Y { /* ... */ };
```
— end example ]

A `template-parameter` of a template `template-parameter` is permitted to have a default `template-argument`. When such default arguments are specified, they apply to the template `template-parameter` in the scope of the template `template-parameter`. [Example:
```
template <class T = float> struct B {}

template <template <class TT = float> class T> struct A {
   inline void f();
   inline void g();
};
template <template <class TT> class T> void A<T>::f() {
   T t; // error - TT has no default template argument
}
template <template <class TT = char> class T> void A<T>::g() {
   T t; // OK - T<char>
```
— end example ]

# 14.2 Names of template specializations

A template specialization (14.7) can be referred to by a `template-id`:
```
template-id:
   template-name < template-argument-list opt >
```
```
template-name:
   identifier
```
```
template-argument-list:
   template-argument
template-argument-list , template-argument
```

Draft
14.2 Names of template specializations

```
template-argument:
    assignment-expression
    type-id
    id-expression
```

[Note: the name lookup rules (3.4) are used to associate the use of a name with a template declaration; that is, to identify a name as a template-name. — end note]

2 For a template-name to be explicitly qualified by the template arguments, the name must be known to refer to a template.

3 After name lookup (3.4) finds that a name is a template-name, if this name is followed by a <, the < is always taken as the beginning of a template-argument-list and never as a name followed by the less-than operator. When parsing a template-id, the first non-nested >\[132\] is taken as the end of the template-argument-list rather than a greater-than operator. [Example:

```
template<int i> class X { /* ... */ };  
X< 1>2 > x1; // syntax error  
X<(1>2)> x2; // OK

template<class T> class Y { /* ... */ };  
Y< X<i> > x3; // OK  
Y<X<6>> 1> > x4; // OK: Y < X < (6>>1) >
```

— end example]

4 When the name of a member template specialization appears after . or -> in a postfix-expression, or after a nested-name-specifier in a qualified-id, and the postfix-expression or qualified-id explicitly depends on a template-parameter (14.6.2) but does not refer to a member of the current instantiation (14.6.2.1), the member template name must be prefixed by the keyword template. Otherwise the name is assumed to name a non-template. [Example:

```
class X {
    public:
        template<std::size_t> X* alloc();
        template<std::size_t> static X* adjust();
    };
    template<class T> void f(T* p) {
        T* p1 = p->alloc<200>();
        // ill-formed: < means less than
        T* p2 = p->template alloc<200>();
        // OK: < starts template argument list
        T::adjust<100>();
        // ill-formed: < means less than
        T::template adjust<100>();
        // OK: < starts template argument list
    }
```

\[132\]: A > that encloses the type-id of a dynamic_cast, static_cast, reinterpret_cast or const_cast, or which encloses the template-arguments of a subsequent template-id, is considered nested for the purpose of this description.

Draft
If a name prefixed by the keyword `template` is not the name of a template, the program is ill-formed. [Note: the keyword `template` may not be applied to non-template members of class templates. — end note] Furthermore, names of member templates shall not be prefixed by the keyword `template` if the `postfix-expression` or `qualified-id` does not appear in the scope of a template. [Note: just as is the case with the `typename` prefix, the `template` prefix is allowed in cases where it is not strictly necessary; i.e., when the expression on the left of the `->` or `.`, or the `nested-name-specifier` is not dependent on a `template-parameter`. — end note]

A `template-id` that names a class template specialization is a `class-name` (clause 9).

### 14.3 Template arguments

There are three forms of `template-argument`, corresponding to the three forms of `template-parameter`: type, non-type and template. The type and form of each `template-argument` specified in a `template-id` shall match the type and form specified for the corresponding parameter declared by the template in its `template-parameter-list`. [Example:
```cpp
template<class T> class Array {
  T* v;
  int sz;
public:
  explicit Array(int);
  T& operator[](int);
  T& elem(int i) { return v[i]; }
  // ...
};

Array<int> v1(20);
typeof std::complex<double> dcomplex; // std::complex is a standard library template
Array<dcomplex> v2(30);
Array<dcomplex> v3(40);

void bar() {
  v1[3] = 7;
  v2[3] = v3.elem(4) = dcomplex(7,8);
}
```
— end example]

In a `template-argument`, an ambiguity between a `type-id` and an expression is resolved to a `type-id`, regardless of the form of the corresponding `template-parameter`. [Example:
```cpp
template<class T> void f();
template<int I> void f();

void g() {
  f<int>(); // int() is a `type-id`: call the first f()
```

There is no such ambiguity in a default `template-argument` because the form of the `template-parameter` determines the allowable forms of the `template-argument`.
The name of a template-argument shall be accessible at the point where it is used as a template-argument. [Note: if the name of the template-argument is accessible at the point where it is used as a template-argument, there is no further access restriction in the resulting instantiation where the corresponding template-parameter name is used. —end note]

Example:

```cpp
template<class T> class X {
    static T t;
};

class Y {
    private:
        struct S { /* ... */ };
    X<S> x;          // OK: S is accessible
    // X<Y::S> has a static member of type Y::S
    // OK: even though Y::S is private
};

X<Y::S> y;         // error: S not accessible
```

—end example] For a template-argument of class type, the template definition has no special access rights to the inaccessible members of the template argument type.

4 When default template-arguments are used, a template-argument list can be empty. In that case the empty <> brackets shall still be used as the template-argument-list. [Example:

```cpp
template<class T = char> class String;
String<>* p;          // OK: String<char>
String* q;            // syntax error
```

—end example]

5 An explicit destructor call (12.4) for an object that has a type that is a class template specialization may explicitly specify the template-arguments. [Example:

```cpp
template<class T> struct A {
    ~A();
};

void f(A<int>* p, A<int>* q) {
    p->A<int>::~A();      // OK: destructor call
    q->A<int>::~A<int>();  // OK: destructor call
}
```

—end example]

6 If the use of a template-argument gives rise to an ill-formed construct in the instantiation of a template specialization, the program is ill-formed.
When the template in a template-id is an overloaded function template, both non-template functions in the overload set and function templates in the overload set for which the template-arguments do not match the template-parameters are ignored. If none of the function templates have matching template-parameters, the program is ill-formed.

### 14.3.1 Template type arguments

1. A template-argument for a template-parameter which is a type shall be a type-id.

2. A type without linkage (3.5) shall not be used as a template-argument for a template type-parameter.

#### Example:
```
template <class T> class X { /* ... */};
void f()
{
    struct S { /* ... */};
    X<S> x3;        // error: local type used as template-argument
    X<S*> x4;       // error: pointer to local type used as template-argument
}
```

--- end example ] [ Note: a template type argument may be an incomplete type (3.9). — end note ]

3. If a declaration acquires a function type through a type dependent on a template-parameter and this causes a declaration that does not use the syntactic form of a function declarator to have function type, the program is ill-formed. [ Example:
```
template<class T> struct A {
    static T t;
};
typedef int function();
A<function> a;        // ill-formed: would declare A<function>::t
                      // as a static member function
```

--- end example ]

4. If a template-argument for a template-parameter T names a type “reference to cv1 S”, an attempt to create the type “reference to cv2 T” creates the type “reference to cv12 S”, where cv12 is the union of the cv-qualifiers cv1 and cv2. Redundant cv-qualifiers are ignored. [ Example:
```
template <class T> class X {
    void f(const T&);
    /* ... */
};
X<int&> x;        // X<int&>::f has the parameter type const int&
```

--- end example ]

### 14.3.2 Template non-type arguments

1. A template-argument for a non-type, non-template template-parameter shall be one of:
   - an integral constant-expression of integral or enumeration type; or
   - the name of a non-type template-parameter; or
14.3 Template arguments

— the address of an object or function with external linkage, including function templates and function template-ids but excluding non-static class members, expressed as & id-expression where the & is optional if the name refers to a function or array, or if the corresponding template-parameter is a reference; or

— a pointer to member expressed as described in 5.3.1.

2 [Note: A string literal (2.13.4) does not satisfy the requirements of any of these categories and thus is not an acceptable template-argument. [Example:

```cpp
template<class T, char* p> class X {
   // ...
   X();
   X(const char* q) { /* ... */ }
};

X<int,"Studebaker"> x1; // error: string literal as template-argument
char p[] = "Vivisectionist";
X<int,p> x2; // OK
```

— end example] — end note]

3 [Note: Addresses of array elements and names or addresses of non-static class members are not acceptable template-arguments. [Example:

```cpp
template<int* p> class X { };

int a[10];
struct S { int m; static int s; } s;

X<&a[2]> x3; // error: address of array element
X<&s.m> x4; // error: address of non-static member
X<&s.s> x5; // error: &S::s must be used
X<&S::s> x6; // OK: address of static member
```

— end example] — end note]

4 [Note: Temporaries, unnamed lvalues, and named lvalues that do not have external linkage are not acceptable template-arguments when the corresponding template-parameter has reference type. [Example:

```cpp
template<const int& CRI> struct B { /* ... */ };

B<1> b2; // error: temporary would be required for template argument

int c = 1;
B<c> b1; // OK
```

— end example] — end note]

5 The following conversions are performed on each expression used as a non-type template-argument. If a non-type template-argument cannot be converted to the type of the corresponding template-parameter then the program is ill-formed.
— for a non-type `template-parameter` of integral or enumeration type, integral promotions (4.5) and integral conversions (4.7) are applied.

— for a non-type `template-parameter` of type pointer to object, qualification conversions (4.4) and the array-to-pointer conversion (4.2) are applied. [Note: In particular, neither the null pointer conversion (4.10) nor the derived-to-base conversion (4.10) are applied. Although 0 is a valid `template-argument` for a non-type `template-parameter` of integral type, it is not a valid `template-argument` for a non-type `template-parameter` of pointer type. — end note]

— For a non-type `template-parameter` of type reference to object, no conversions apply. The type referred to by the reference may be more cv-qualified than the (otherwise identical) type of the `template-argument`. The `template-parameter` is bound directly to the `template-argument`, which must be an lvalue.

— For a non-type `template-parameter` of type pointer to function, only the function-to-pointer conversion (4.3) is applied. If the `template-argument` represents a set of overloaded functions (or a pointer to such), the matching function is selected from the set (13.4).

— For a non-type `template-parameter` of type reference to function, no conversions apply. If the `template-argument` represents a set of overloaded functions, the matching function is selected from the set (13.4).

— For a non-type `template-parameter` of type pointer to member function, no conversions apply. If the `template-argument` represents a set of overloaded member functions, the matching member function is selected from the set (13.4).

— For a non-type `template-parameter` of type pointer to data member, qualification conversions (4.4) are applied.

[Example:

```cpp
    template< const int* pci > struct X { /* ... */ };  
    int ai[10];  
    X<ai> xi;  
    // array to pointer and qualification conversions

    struct Y { /* ... */ };  
    template< const Y& b > struct Z { /* ... */ };  
    Y y;  
    Z<y> z;  
    // no conversion, but note extra cv-qualification

    template< int (&pa)[5] > struct W { /* ... */ };  
    int b[5];  
    W<b> w;  
    // no conversion

    void f(char);  
    void f(int);  

    template< void (*pf)(int) > struct A { /* ... */ };  
    A<&f> a;  
    // selects f(int)

    — end example ]
```
14.3.3 Template template arguments

A template-argument for a template template-parameter shall be the name of a class template, expressed as id-expression. Only primary class templates are considered when matching the template template argument with the corresponding parameter; partial specializations are not considered even if their parameter lists match that of the template template parameter.

Any partial specializations (14.5.4) associated with the primary class template are considered when a specialization based on the template template-parameter is instantiated. If a specialization is not visible at the point of instantiation, and it would have been selected had it been visible, the program is ill-formed; no diagnostic is required. [Example:

```cpp
template<class T> class A { // primary template
    int x;
};
template<class T> class A<T*> { // partial specialization
    long x;
};
template<template<class U> class V> class C {
    V<int> y;
    V<int*> z;
};
C<A> c; // V<int> within C<A> uses the primary template,
        // V<int*> within C<A> uses the partial specialization,
        // so c.y.x has type int
        // so c.z.x has type long
```

— end example ]

14.4 Type equivalence

Two template-ids refer to the same class or function if their template names are identical, they refer to the same template, their type template-arguments are the same type, their non-type template-arguments of integral or enumeration type have identical values, their non-type template-arguments of pointer or reference type refer to the same external object or function, and their template template-arguments refer to the same template. [Example:

```cpp
template<class E, int size> class buffer { /* ... */ }; 
buffer<char,2*512> x;
buffer<char,1024> y;
```

declares x and y to be of the same type, and

```cpp
template<class T, void(*err_fct)()> class list { /* ... */ };
list<int,&error_handler1> x1;
list<int,&error_handler2> x2;
list<int,&error_handler2> x3;
list<char,&error_handler2> x4;
```

declares x2 and x3 to be of the same type. Their type differs from the types of x1 and x4. — end example ]

14.5 Template declarations

A template-id, that is, the template-name followed by a template-argument-list shall not be specified in the declaration
of a primary template declaration. [Example:

```cpp
template<class T1, class T2, int I> class A<T1, T2, I> { }; // error

template<class T1, int I> void sort<T1, I>(T1 data[I]); // error
```
— end example] [Note: however, this syntax is allowed in class template partial specializations (14.5.4). — end note]

For purposes of name lookup and instantiation, default arguments of function templates and default arguments of member functions of class templates are considered definitions; each default argument is a separate definition which is unrelated to the function template definition or to any other default arguments.

14.5.1 Class templates

A class template defines the layout and operations for an unbounded set of related types. [Example: a single class template List might provide a common definition for list of int, list of float, and list of pointers to Shapes. — end example]

[Example: An array class template might be declared like this:

```cpp
template<class T> class Array {
  T* v;
  int sz;
public:
  explicit Array(int);
  T& operator[](int);
  T& elem(int i) { return v[i]; } // ...
};
```

The prefix template <class T> specifies that a template is being declared and that a type-name T will be used in the declaration. In other words, Array is a parameterized type with T as its parameter. — end example]

When a member function, a member class, a static data member or a member template of a class template is defined outside of the class template definition, the member definition is defined as a template definition in which the template parameters are those of the class template. The names of the template parameters used in the definition of the member may be different from the template parameter names used in the class template definition. The template argument list following the class template name in the member definition shall name the parameters in the same order as the one used in the template parameter list of the member. [Example:

```cpp
template<class T1, class T2> struct A {
  void f1();
  void f2();
};
```

```cpp
template<class T2, class T1> void A<T2,T1>::f1() { } // OK

template<class T2, class T1> void A<T1,T2>::f2() { } // error
```
— end example]
In a redeclaration, partial specialization, explicit specialization or explicit instantiation of a class template, the class-key shall agree in kind with the original class template declaration (7.1.5.3).

14.5.1.1 Member functions of class templates

A member function of a class template may be defined outside of the class template definition in which it is declared. [Example:

```cpp
template<class T> class Array {
    T* v;
    int sz;
public:
    explicit Array(int);
    T& operator[](int); // 7.1.3.1.2.1
    T& elem(int i) { return v[i]; }
    // ...
};
```

declares three function templates. The subscript function might be defined like this:

```cpp
template<class T> T& Array<T>::operator[](int i) {
    if (i<0 || sz<=i) error("Array: range error");
    return v[i];
}
```

— end example ]

The template-arguments for a member function of a class template are determined by the template-arguments of the type of the object for which the member function is called. [Example: the template-argument for Array<T>::operator[]() will be determined by the Array to which the subscripting operation is applied.

```cpp
Array<int> v1(20);
Array<dcomplex> v2(30);

v1[3] = 7;     // Array<int>::operator[]()
v2[3] = dcomplex(7,8);     // Array<dcomplex>::operator[]()
```

— end example ]

14.5.1.2 Member classes of class templates

A class member of a class template may be defined outside the class template definition in which it is declared. [Note: the class member must be defined before its first use that requires an instantiation (14.7.1). For example,

```cpp
template<class T> struct A {
    class B;
};
A<int>::B* b1;     // OK: requires A to be defined but not A::B
```

```cpp
template<class T> class A<T>::B { }
A<int>::B b2;     // OK: requires A::B to be defined
```
14.5.1.3 Static data members of class templates

A definition for a static data member may be provided in a namespace scope enclosing the definition of the static member's class template. [Example:]

```cpp
template<class T> class X {
    static T s;
};
template<class T> T X<T>::s = 0;
```

— end example ]

14.5.2 Member templates

A template can be declared within a class or class template; such a template is called a member template. A member template can be defined within or outside its class definition or class template definition. A member template of a class template that is defined outside of its class template definition shall be specified with the template-parameter s of the class template followed by the template-parameter s of the member template. [Example:]

```cpp
template<class T> class string {
    public:
        template<class T2> int compare(const T2&);
        template<class T2> string(const string<T2>& s) {
            /* ... */
        }
        // ...
    };

template<class T> template<class T2> int string<T>::compare(const T2& s)
    {
        /* ... */
    }

    — end example ]

2 A local class shall not have member templates. Access control rules (clause 11) apply to member template names. A destructor shall not be a member template. A normal (non-template) member function with a given name and type and a member function template of the same name, which could be used to generate a specialization of the same type, can both be declared in a class. When both exist, a use of that name and type refers to the non-template member unless an explicit template argument list is supplied. [Example:]

```cpp
template <class T> void f(int)
    {
    }

template <class T> struct A
    {
        void f(int);
        template <class T2> void f(T2);
    };

    template <> void A<int>::f(int) { } // non-template member
    template <> template <> void A<int>::f<(int) { } // template member

    int main()
    {
        A<char> ac;
    }
```

Draft
A member function template shall not be virtual. [Example:

```c++
template < class T > struct AA {
    template < class C > virtual void g(C );  // error
    virtual void f();  // OK
};
```

— end example ]

A specialization of a member function template does not override a virtual function from a base class. [Example:

```c++
class B {
    virtual void f(int);
};

class D : public B {
    template < class T > void f(T );  // does not override B::f(int)
    void f(int i) { f<(i)>; }  // overriding function that calls
    // the template instantiation
};
```

— end example ]

A specialization of a template conversion function is referenced in the same way as a non-template conversion function that converts to the same type. [Example:

```c++
struct A {
    template < class T > operator T*();
};
template < class T > A::operator T*(){ return 0; }
template <> A::operator char*(){ return 0; }  // specialization
template A::operator void*();  // explicit instantiation

int main()
{
    A a;
    int* ip;

    ip = a.operator int*();  // explicit call to template operator
    // A::operator int*()
}
```

— end example ] [ Note: because the explicit template argument list follows the function template name, and because conversion member function templates and constructor member function templates are called without using a function name, there is no way to provide an explicit template argument list for these function templates. — end note ]
A specialization of a template conversion function is not found by name lookup. Instead, any template conversion functions visible in the context of the use are considered. For each such operator, if argument deduction succeeds (14.8.2.3), the resulting specialization is used as if found by name lookup.

A using-declaration in a derived class cannot refer to a specialization of a template conversion function in a base class.

Overload resolution (13.3.3.2) and partial ordering (14.5.5.2) are used to select the best conversion function among multiple template conversion functions and/or non-template conversion functions.

### 14.5.3 Friends

A friend of a class or class template can be a function template or class template, a specialization of a function template or class template, or an ordinary (non-template) function or class. For a friend function declaration that is not a template declaration:

- if the name of the friend is a qualified or unqualified template-id, the friend declaration refers to a specialization of a function template, otherwise
- if the name of the friend is a qualified-id and a matching non-template function is found in the specified class or namespace, the friend declaration refers to that function, otherwise,
- if the name of the friend is a qualified-id and a matching specialization of a function template is found in the specified class or namespace, the friend declaration refers to that function template specialization, otherwise,
- the name shall be an unqualified-id that declares (or redeclares) an ordinary (non-template) function.

**Example:**

```cpp
template<class T> class task;
template<class T> task<T>* preempt(task<T>*,

```template<class T> class task {
    // ...
    friend void next_time();
    friend void process(task<T>*);
    friend task<T>* preempt(<T>(task<T>*));
    template<class C> friend int func(C);

    friend class task<int>;
    template<class P> friend class frd;
    // ...
};
```

Here, each specialization of the `task` class template has the function `next_time` as a friend; because `process` does not have explicit `template-arguments`, each specialization of the `task` class template has an appropriately typed function `process` as a friend, and this friend is not a function template specialization; because the friend `preempt` has an explicit `template-argument` `<T>`, each specialization of the `task` class template has the appropriate specialization of the function template `preempt` as a friend; and each specialization of the `task` class template has all specializations of the function template `func` as friends. Similarly, each specialization of the `task` class template has the class template specialization `task<int>` as a friend, and has all specializations of the class template `frd` as friends. —end example]
A friend template may be declared within a class or class template. A friend function template may be defined within a class or class template, but a friend class template may not be defined in a class or class template. In these cases, all specializations of the friend class or friend function template are friends of the class or class template granting friendship.

Example:

```cpp
class A {
    template<class T> friend class B; // OK
    template<class T> friend void f(T){ /* ... */ } // OK
};
```

A template friend declaration specifies that all specializations of that template, whether they are implicitly instantiated (14.7.1), partially specialized (14.5.4) or explicitly specialized (14.7.3), are friends of the class containing the template friend declaration.

Example:

```cpp
class X {
    template<class T> friend struct A;
    class Y { }
};

template<class T> struct A { X::Y ab; }; // OK
template<class T> struct A<T*> { X::Y ab; }; // OK
```

When a function is defined in a friend function declaration in a class template, the function is instantiated when the function is used. The same restrictions on multiple declarations and definitions that apply to non-template function declarations and definitions also apply to these implicit definitions.

A member of a class template may be declared to be a friend of a non-template class. In this case, the corresponding member of every specialization of the class template is a friend of the class granting friendship.

Example:

```cpp
template<class T> struct A {
    struct B { }
    void f();
};

class C {
    template<class T> friend struct A<T>::B;
    template<class T> friend void A<T>::f();
};
```

Note: a friend declaration may first declare a member of an enclosing namespace scope (14.6.5).

A friend template shall not be declared in a local class.

Friend declarations shall not declare partial specializations.

Example:

```cpp
template<class T> class A { }
class X {
```

Draft
template< class T > friend class A<T*>;  // error
};

— end example ]

When a friend declaration refers to a specialization of a function template, the function parameter declarations shall not include default arguments, nor shall the inline specifier be used in such a declaration.

14.5.4 Class template partial specializations [temp.class.spec]

A primary class template declaration is one in which the class template name is an identifier. A template declaration in which the class template name is a template-id, is a partial specialization of the class template named in the template-id. A partial specialization of a class template provides an alternative definition of the template that is used instead of the primary definition when the arguments in a specialization match those given in the partial specialization (14.5.4.1). The primary template shall be declared before any specializations of that template. If a template is partially specialized then that partial specialization shall be declared before the first use of that partial specialization that would cause an implicit instantiation to take place, in every translation unit in which such a use occurs; no diagnostic is required.

When a partial specialization is used within the instantiation of an exported template, and the unspecialized template name is non-dependent in the exported template, a declaration of the partial specialization must be declared before the definition of the exported template, in the translation unit containing that definition. A similar restriction applies to explicit specialization; see 14.7.

Each class template partial specialization is a distinct template and definitions shall be provided for the members of a template partial specialization (14.5.4.3).

[ Example:

        template< class T1 , class T2 , int I > class A { };  // #1
        template< class T , int I > class A<T , T* , I > { };  // #2
        template< class T1 , class T2 , int I > class A<T1* , T2 , I > { };  // #3
        template< class T > class A<int , T* , 5 > { };  // #4
        template< class T1 , class T2 , int I > class A<T1 , T2* , I > { };  // #5

The first declaration declares the primary (unspecialized) class template. The second and subsequent declarations declare partial specializations of the primary template. — end example ]

The template parameters are specified in the angle bracket enclosed list that immediately follows the keyword template. For partial specializations, the template argument list is explicitly written immediately following the class template name. For primary templates, this list is implicitly described by the template parameter list. Specifically, the order of the template arguments is the sequence in which they appear in the template parameter list. [ Example: the template argument list for the primary template in the example above is <T1, T2, I>. — end example ] [ Note: the template argument list shall not be specified in the primary template declaration. For example,

        template< class T1 , class T2 , int I > class A<T1 , T2 , I > { };  // error

— end note ]

A class template partial specialization may be declared or redeclared in any namespace scope in which its definition may be defined (14.5.1 and 14.5.2). [ Example:
Partial specialization declarations themselves are not found by name lookup. Rather, when the primary template name is used, any previously declared partial specializations of the primary template are also considered. One consequence is that a using-declaration which refers to a class template does not restrict the set of partial specializations which may be found through the using-declaration. [Example:

```cpp
namespace N {
    template < class T1 , class T2 > class A { }; // primary template
}
using N::A; // refers to the primary template
namespace N {
    template < class T > class A<T , T* > { }; // partial specialization
}
A<int , int* > a; // uses the partial specialization, which is found through
                 // the using declaration which refers to the primary template
```
— end example ]

A non-type argument is non-specialized if it is the name of a non-type parameter. All other non-type arguments are specialized.

Within the argument list of a class template partial specialization, the following restrictions apply:

— A partially specialized non-type argument expression shall not involve a template parameter of the partial specialization except when the argument expression is a simple identifier. [Example:

```cpp
template < int I , int J > struct A {};
template < int I > struct A<I+5 , I*2> {}; // error

template < int I , int J > struct B {};
template < int I > struct B<I , I> {}; // OK
```
— end example ]

— The type of a template parameter corresponding to a specialized non-type argument shall not be dependent on a parameter of the specialization. [Example:
template <class T, T t> struct C {};  
// error

template <class T> struct C<T, 1>;        
// error

template <int X, int (*array_ptr)[X] > class A {};  
int array[5];                      
template <int X > class A<X,&array> {};   
// error

— end example

— The argument list of the specialization shall not be identical to the implicit argument list of the primary template.
The template parameter list of a specialization shall not contain default template argument values.\(^{134}\)

14.5.4.1 Matching of class template partial specializations \(\text{[temp.class.spec.match]}\)

1 When a class template is used in a context that requires an instantiation of the class, it is necessary to determine whether the instantiation is to be generated using the primary template or one of the partial specializations. This is done by matching the template arguments of the class template specialization with the template argument lists of the partial specializations.

— If exactly one matching specialization is found, the instantiation is generated from that specialization.

— If more than one matching specialization is found, the partial order rules (14.5.4.2) are used to determine whether one of the specializations is more specialized than the others. If none of the specializations is more specialized than all of the other matching specializations, then the use of the class template is ambiguous and the program is ill-formed.

— If no matches are found, the instantiation is generated from the primary template.

2 A partial specialization matches a given actual template argument list if the template arguments of the partial specialization can be deduced from the actual template argument list (14.8.2). [Example:

\[
\begin{align*}
\text{A<int, int, 1> a1;} & \quad \text{ // uses #1} \\
\text{A<int, int*, 1> a2;} & \quad \text{ // uses #2, T is int, I is 1} \\
\text{A<int, char*, 5> a3;} & \quad \text{ // uses #4, T is char} \\
\text{A<int, char*, 1> a4;} & \quad \text{ // uses #5, T1 is int, T2 is char, I is 1} \\
\text{A<int*, int*, 2> a5;} & \quad \text{ // ambiguous: matches #3 and #5} \\
\end{align*}
\]

— end example ]

3 A non-type template argument can also be deduced from the value of an actual template argument of a non-type parameter of the primary template. [Example: the declaration of a2 above. — end example]

4 In a type name that refers to a class template specialization, (e.g., A<int, int, 1>) the argument list must match the template parameter list of the primary template. The template arguments of a specialization are deduced from the arguments of the primary template.

\(^{134}\) There is no way in which they could be used.
14.5.4.2 Partial ordering of class template specializations

For two class template partial specializations, the first is at least as specialized as the second if, given the following rewrite to two function templates, the first function template is at least as specialized as the second according to the ordering rules for function templates (14.5.5.2):

- the first function template has the same template parameters as the first partial specialization and has a single function parameter whose type is a class template specialization with the template arguments of the first partial specialization, and
- the second function template has the same template parameters as the second partial specialization and has a single function parameter whose type is a class template specialization with the template arguments of the second partial specialization.

[Example:

```cpp
template < int I , int J , class T > class X { };  // #1
template < int I , int J > class X<I , J , int > { };  // #2

template < int I > class X<I , I , int > { };  // #A
template < int I > void f(X<I , I , int >);  // #B
```

The partial specialization #2 is more specialized than the partial specialization #1 because the function template #B is more specialized than the function template #A according to the ordering rules for function templates. — end example ]

14.5.4.3 Members of class template specializations

The template parameter list of a member of a class template partial specialization shall match the template parameter list of the class template partial specialization. The template argument list of a member of a class template partial specialization shall match the template argument list of the class template partial specialization. A class template specialization is a distinct template. The members of the class template partial specialization are unrelated to the members of the primary template. Class template partial specialization members that are used in a way that requires a definition shall be defined; the definitions of members of the primary template are never used as definitions for members of a class template partial specialization. An explicit specialization of a member of a class template partial specialization is declared in the same way as an explicit specialization of the primary template. [ Example:

```cpp
// primary template
template<class T , int I > struct A {  
   void f();
};

template<class T , int I > void A<T,I>::f() {} 

// class template partial specialization
template<class T> struct A<T,2> {  
   void f();
   void g();
   void h();
};
```

Draft
If a member template of a class template is partially specialized, the member template partial specializations are member templates of the enclosing class template; if the enclosing class template is instantiated (14.7.1, 14.7.2), a declaration for every member template partial specialization is also instantiated as part of creating the members of the class template specialization. If the primary member template is explicitly specialized for a given (implicit) specialization of the enclosing class template, the partial specializations of the member template are ignored for this specialization of the enclosing class template. If a partial specialization of the member template is explicitly specialized for a given (implicit) specialization of the enclosing class template, the primary member template and its other partial specializations are still considered for this specialization of the enclosing class template. [Example:

```c++
template<class T> struct A {
    template<class T2> struct B {}; // #1
    template<class T2> struct B<T2*> {}; // #2
};

template<> template<class T2> struct A<short>::B {}; // #3

A<char>::B<int*> abcip; // uses #2
A<short>::B<int*> absip; // uses #3
A<char>::B<int> abci; // uses #1
```

— end example ]

14.5.5 Function templates

A function template defines an unbounded set of related functions. [Example: a family of sort functions might be declared like this:

```c++
template<class T> class Array { };  
template<class T> void sort(Array<T>&);
```
A function template can be overloaded with other function templates and with normal (non-template) functions. A normal function is not related to a function template (i.e., it is never considered to be a specialization), even if it has the same name and type as a potentially generated function template specialization.

**14.5.5.1 Function template overloading**

It is possible to overload function templates so that two different function template specializations have the same type.

```c
// file1.c
// template< class T>
// void f(T*);
// void g(int* p) {
//   f(p); // call
//   // f<int>(int*)
// }

// file2.c
// template< class T>
// void f(T);
// void h(int* p) {
//   f(p); // call
//   // f<int*>(int*)
// }
```

Such specializations are distinct functions and do not violate the one definition rule (3.2).

The signature of a function template specialization consists of the signature of the function template and of the actual template arguments (whether explicitly specified or deduced).

The signature of a function template consists of its function signature, its return type and its template parameter list. The names of the template parameters are significant only for establishing the relationship between the template parameters and the rest of the signature. [Note: two distinct function templates may have identical function return types and function parameter lists, even if overload resolution alone cannot distinguish them.]

```c
// file1.c
// template< class T> void f();
// template< int I> void f(); // OK: overloads the first template
//   // distinguishable with an explicit template argument list

// file2.c
// template< class T> void f();
```

When an expression that references a template parameter is used in the function parameter list or the return type in the declaration of a function template, the expression that references the template parameter is part of the signature of the function template. This is necessary to permit a declaration of a function template in one translation unit to be linked with another declaration of the function template in another translation unit and, conversely, to ensure that function templates that are intended to be distinct are not linked with one another. [Example:

```c
template <int I, int J> A<i+J> f(A<i>, A<j>); // #1
template <int K, int L> A<K+L> f(A<K>, A<L>); // same as #1
template <int I, int J> A<i-J> f(A<i>, A<j>); // different from #1
```

[Note: Most expressions that use template parameters use non-type template parameters, but it is possible for an expression to reference a type parameter. For example, a template type parameter can be used in the `sizeof` operator. — end note]

---

That is, declarations of non-template functions do not merely guide overload resolution of function template specializations with the same name. If such a non-template function is used in a program, it must be defined; it will not be implicitly instantiated using the function template definition.
Two expressions involving template parameters are considered *equivalent* if two function definitions containing the expressions would satisfy the one definition rule (3.2), except that the tokens used to name the template parameters may differ as long as a token used to name a template parameter in one expression is replaced by another token that names the same template parameter in the other expression. [Example:

```c++
template <int I, int J> void f(A<I+J>); // #1
template <int K, int L> void f(A<K+L>); // same as #1
```

— end example ] Two expressions involving template parameters that are not equivalent are *functionally equivalent* if, for any given set of template arguments, the evaluation of the expression results in the same value.

Two function templates are *equivalent* if they are declared in the same scope, have the same name, have identical template parameter lists, and have return types and parameter lists that are equivalent using the rules described above to compare expressions involving template parameters. Two function templates are *functionally equivalent* if they are equivalent except that one or more expressions that involve template parameters in the return types and parameter lists are functionally equivalent using the rules described above to compare expressions involving template parameters. If a program contains declarations of function templates that are functionally equivalent but not equivalent, the program is ill-formed; no diagnostic is required.

[Note: This rule guarantees that equivalent declarations will be linked with one another, while not requiring implementations to use heroic efforts to guarantee that functionally equivalent declarations will be treated as distinct. For example, the last two declarations are functionally equivalent and would cause a program to be ill-formed:]

```c++
// Guaranteed to be the same
template <int I> void f(A<I>, A<I+10>);
template <int I> void f(A<I>, A<I+10>);

// Guaranteed to be different
template <int I> void f(A<I>, A<I+10>);
template <int I> void f(A<I>, A<I+11>);

// Ill-formed, no diagnostic required
template <int I> void f(A<I>, A<I+10>);
template <int I> void f(A<I>, A<I+1+2+3+4>);
```

— end note ]

### 14.5.5.2 Partial ordering of function templates

[temp.func.order]

If a function template is overloaded, the use of a function template specialization might be ambiguous because template argument deduction (14.8.2) may associate the function template specialization with more than one function template declaration. *Partial ordering* of overloaded function template declarations is used in the following contexts to select the function template to which a function template specialization refers:

— during overload resolution for a call to a function template specialization (13.3.3);
— when the address of a function template specialization is taken;
— when a placement operator delete that is a function template specialization is selected to match a placement operator new (3.7.3.2, 5.3.4);
14.5 Template declarations

— when a friend function declaration (14.5.3), an explicit instantiation (14.7.2) or an explicit specialization (14.7.3) refers to a function template specialization.

2 Partial ordering selects which of two function templates is more specialized than the other by transforming each template in turn (see next paragraph) and performing template argument deduction using the function parameter types, or in the case of a conversion function the return type. The deduction process determines whether one of the templates is more specialized than the other. If so, the more specialized template is the one chosen by the partial ordering process.

3 To produce the transformed template, for each type, non-type, or template template parameter synthesize a unique type, value, or class template respectively and substitute it for each occurrence of that parameter in the function type of the template.

4 Using the transformed function template’s function parameter list, or in the case of a conversion function its transformed return type, perform type deduction against the function parameter list (or return type) of the other function. The mechanism for performing these deductions is given in 14.8.2.4.

[Example:

```cpp
template< class T > struct A { A(); }

template< class T > void f(T);
template< class T > void f(T*);
template< class T > void f(const T*);

template< class T > void g(T);
template< class T > void g(T&);

void m () {
    const int *p;
    f(p);  // f(const T*) is more specialized than f(T) or f(T*)
    float x;
    g(x);  // Ambiguous: g(T) or g(T&)
    A<int> z;
    h(z);  // overload resolution selects h(A<T>&)
    const A<int> z2;
    h(z2);  // h(const T&) is called because h(A<T>&) is not callable
}
```

— end example ]

5 The presence of unused ellipsis and default arguments has no effect on the partial ordering of function templates.

[Example:

```cpp
template< class T > void f(T);  // #1
template< class T > void f(T*, int=1); // #2
template< class T > void g(T); // #3
template< class T > void g(T*, ...); // #4
```

Draft
int main() {
    int* ip;
    f(ip); // calls #2
    g(ip); // calls #4
}

— end example ]

14.6 Name resolution

Three kinds of names can be used within a template definition:

— The name of the template itself, and names declared within the template itself.
— Names dependent on a template-parameter (14.6.2).
— Names from scopes which are visible within the template definition.

A name used in a template declaration or definition and that is dependent on a template-parameter is assumed not to name a type unless the applicable name lookup finds a type name or the name is qualified by the keyword typename.

[Example:
 // no B declared here

class X;

template<class T> class Y {
    class Z; // forward declaration of member class
    void f() {
        X* a1; // declare pointer to X
        T* a2; // declare pointer to T
        Y* a3; // declare pointer to Y<T>
        Z* a4; // declare pointer to Z
        typedef typename T::A TA;
        TA* a5; // declare pointer to T's A
typename T::A* a6; // declare pointer to T's A
        T::A* a7; // T::A is not a type name:
        // multiply T::A by a7; ill-formed,
        // no visible declaration of a7
        B* a8; // B is not a type name:
        // multiply B by a8; ill-formed,
        // no visible declarations of B and a8
    }
};

— end example ]

A qualified-id that refers to a type and in which the nested-name-specifier depends on a template-parameter (14.6.2) but does not refer to a member of the current instantiation (14.6.2.1) shall be prefixed by the keyword typename to indicate that the qualified-id denotes a type, forming a typename-specifier.

Draft
If a specialization of a template is instantiated for a set of template-arguments such that the qualified-id prefixed by typename does not denote a type, the specialization is ill-formed. The usual qualified name lookup (3.4.3) is used to find the qualified-id even in the presence of typename. [Example:

```
struct A {
    struct X { };  // OK: T::X refers to B::X
    int X;
};
struct B {
    struct X { };  // error: T::X refers to the data member A::X not the struct A::X
    template<class T> void f(T t) {
        typename T::X x;
    }
    void foo() {
        A a;
        B b;
        f(b);       // OK: T::X refers to B::X
        f(a);       // error: T::X refers to the data member A::X not the struct A::X
    }
}
```

— end example ]

5 The keyword typename shall only be used in template declarations and definitions, including in the return type of a function template or member function template, in the return type for the definition of a member function of a class template or of a class nested within a class template, and in the type-specifier for the definition of a static member of a class template or of a class nested within a class template. The keyword typename shall be applied only to qualified names, but those names need not be dependent. The keyword typename shall be used only in contexts in which dependent names can be used. This includes template declarations and definitions but excludes explicit specialization declarations and explicit instantiation declarations. A qualified name used as the name in a mem-initializer-id, a base-specifier, or an elaborated-type-specifier is implicitly assumed to name a type, without the use of the typename keyword. [ Note: the typename keyword is not permitted by the syntax of these constructs. — end note ]

6 Within the definition of a class template or within the definition of a member of a class template, the keyword typename is not required when referring to the unqualified name of a previously declared member of the class template that declares a type. [Example:

```
template<class T> struct A {
    typedef int B;
    B b;   // OK, no typename required
};
```

— end example ]

7 Knowing which names are type names allows the syntax of every template definition to be checked. No diagnostic shall be issued for a template definition for which a valid specialization can be generated. If no valid specialization can be generated for a template definition, and that template is not instantiated, the template definition is ill-formed, no
diagnostic required. If a type used in a non-dependent name is incomplete at the point at which a template is defined but is complete at the point at which an instantiation is done, and if the completeness of that type affects whether or not the program is well-formed or affects the semantics of the program, the program is ill-formed; no diagnostic is required. 

[Note: if a template is instantiated, errors will be diagnosed according to the other rules in this Standard. Exactly when these errors are diagnosed is a quality of implementation issue. — end note] [Example:

```c++
int j;
template<class T> class X {
    // ...
    void f(T t, int i, char* p)
    {
        t = i; // diagnosed if X::f is instantiated
            // and the assignment to t is an error
        p = i; // may be diagnosed even if X::f is
            // not instantiated
        p = j; // may be diagnosed even if X::f is
            // not instantiated
    }
    void g(T t) {
        +; // may be diagnosed even if X::g is
            // not instantiated
    }
};

— end example]
```

8 When looking for the declaration of a name used in a template definition, the usual lookup rules (3.4.1, 3.4.2) are used for non-dependent names. The lookup of names dependent on the template parameters is postponed until the actual template-argument is known (14.6.2). [Example:

```c++
#include <iostream>
using namespace std;

template<class T> class Set {
    T* p;
    int cnt;
public:
    Set();
    Set<T>(const Set<T>&);
    void printall()
    {
        for (int i = 0; i<cnt; i++)
            cout << p[i] << '\n';
    }
    // ...
};
```

in the example, i is the local variable i declared in printall, cnt is the member cnt declared in Set, and cout is the standard output stream declared in iostream. However, not every declaration can be found this way; the resolution of some names must be postponed until the actual template-arguments are known. For example, even though the name

Draft
operator<< is known within the definition of printall() and a declaration of it can be found in <iostream>, the actual declaration of operator<< needed to print p[i] cannot be known until it is known what type T is (14.6.2).

— end example ]

9 If a name does not depend on a template-parameter (as defined in 14.6.2), a declaration (or set of declarations) for that name shall be in scope at the point where the name appears in the template definition; the name is bound to the declaration (or declarations) found at that point and this binding is not affected by declarations that are visible at the point of instantiation. [ Example: 

```cpp
void f(char);

template<class T> void g(T t)
{
    f(1); // f(char)
    f(T(1)); // dependent
    f(t); // dependent
    dd++;
    // error: declaration for dd not found
}

void f(int);

double dd;
void h()
{
    g(2); // will cause one call of f(char) followed
    // by two calls of f(int)
    g('a'); // will cause three calls of f(char)
}
```

— end example ]

[ Note: for purposes of name lookup, default arguments of function templates and default arguments of member functions of class templates are considered definitions (14.5). — end note ]

### 14.6.1 Locally declared names  [temp.local]

1 Like normal (non-template) classes, class templates have an injected-class-name (clause 9). The injected-class-name can be used with or without a template-argument-list. When it is used without a template-argument-list, it is equivalent to the injected-class-name followed by the template-parameters of the class template enclosed in <>. When it is used with a template-argument-list, it refers to the specified class template specialization, which could be the current specialization or another specialization.

2 Within the scope of a class template specialization or partial specialization, when the injected-class-name is not followed by a <, it is equivalent to the injected-class-name followed by the template-arguments of the class template specialization or partial specialization enclosed in <>. [ Example: 

```cpp
template<class T> class Y;
template<> class Y<int> { // meaning Y<int>
    Y* p;
}
```

Draft
The injected-class-name of a class template or class template specialization can be used either with or without a template-argument-list wherever it is in scope. [Example:

```
template <class T> struct Base {
    Base* p;
};

template <class T> struct Derived: public Base<T> {
    typename Derived::Base* p; // meaning Derived::Base<T>
};
```

— end example ]

A lookup that finds an injected-class-name (10.2) can result in an ambiguity in certain cases (for example, if it is found in more than one base class). If all of the injected-class-names that are found refer to specializations of the same class template, and if the name is followed by a template-argument-list, the reference refers to the class template itself and not a specialization thereof, and is not ambiguous. [Example:

```
template <class T> struct Base { };
template <class T> struct Derived: public Base<int>, Base<char> {
    typename Derived::Base b; // error: ambiguous
    typename Derived::Base<double> d; // OK
};
```

— end example ]

When the normal name of the template (i.e., the name from the enclosing scope, not the injected-class-name) is used without a template-argument-list, it refers to the class template itself and not a specialization of the template. [Example:

```
template <class T> class X {
    X* p; // meaning X<T>
    X<T>* p2;
    X<int>* p3;
    ::X* p4; // error: missing template argument list
            // ::X does not refer to the injected-class-name
};
```

— end example ]

The scope of a template-parameter extends from its point of declaration until the end of its template. A template-parameter hides any entity with the same name in the enclosing scope. [Note: this implies that a template-parameter can be used in the declaration of subsequent template-parameters and their default arguments but cannot be used in preceding template-parameters or their default arguments. For example,

```
template<class T, T* p, class U = T> class X { /* ... */ };
template<class T> void f(T* p = new T);
```
This also implies that a template-parameter can be used in the specification of base classes. For example,

```cpp
template<class T> class X : public Array<T> { /* ... */ };
template<class T> class Y : public T { /* ... */ };
```

The use of a template-parameter as a base class implies that a class used as a template-argument must be defined and not just declared when the class template is instantiated. —end note]

7 A template-parameter shall not be redeclared within its scope (including nested scopes). A template-parameter shall not have the same name as the template name. [Example:

```cpp
template<class T, int i> class Y {
    int T; // error: template-parameter redeclared
    void f() {
        char T; // error: template-parameter redeclared
    }
};

template<class X> class X; // error: template-parameter redeclared
```

—end example]

8 In the definition of a member of a class template that appears outside of the class template definition, the name of a member of this template hides the name of a template-parameter. [Example:

```cpp
template<class T> struct A {
    struct B { /* ... */ };
    void f();
};

template<class B> void A<B>::f() {
    B b; // A's B, not the template parameter
}
```

—end example]

9 In the definition of a member of a class template that appears outside of the namespace containing the class template definition, the name of a template-parameter hides the name of a member of this namespace. [Example:

```cpp
namespace N {
    class C {}
    template<class T> class B {
        void f(T);
    }
}
template<class C> void N::B<C>::f(C) {
    C b; // C is the template parameter, not N::C
}
```

—end example]

10 In the definition of a class template or in the definition of a member of such a template that appears outside of the template definition, for each base class which does not depend on a template-parameter (14.6.2), if the name of the base
class or the name of a member of the base class is the same as the name of a template-parameter, the base class name or member name hides the template-parameter name (3.3.7).  [Example:

```c
struct A {
    struct B { /* ... */};
    int a;
    int Y;
};

template<class B, class a> struct X : A {
    B b;   // A's B
    a b;   // error: A's a isn't a type name
};
```
— end example ]

### 14.6.2 Dependent names  [temp.dep]

Inside a template, some constructs have semantics which may differ from one instantiation to another. Such a construct depends on the template parameters. In particular, types and expressions may depend on the type and/or value of template parameters (as determined by the template arguments) and this determines the context for name lookup for certain names. Expressions may be type-dependent (on the type of a template parameter) or value-dependent (on the value of a non-type template parameter). In an expression of the form:

```
postfix-expression ( expression-listopt )
```

where the postfix-expression is an identifier, the identifier denotes a dependent name if and only if any of the expressions in the expression-list is a type-dependent expression (14.6.2.2). If an operand of an operator is a type-dependent expression, the operator also denotes a dependent name. Such names are unbound and are looked up at the point of the template instantiation (14.6.4.1) in both the context of the template definition and the context of the point of instantiation.

[Example:

```c
template<class T> struct X : B<T> {
    typename T::A* pa;
    void f(B<T>* pb) {
        static int i = B<T>::i;
        pb->j++;
    }
};
```
the base class name B<T>, the type name T::A, the names B<T>::i and pb->j explicitly depend on the template-parameter. — end example ]

In the definition of a class template or a member of a class template, if a base class of the class template depends on a template-parameter, the base class scope is not examined during unqualified name lookup either at the point of definition of the class template or member or during an instantiation of the class template or member.  [Example:

```c
typedef double A;
template<class T> class B {
    typedef int A;
};
```

Draft
template< class T > struct X : B<T> {
   A a; // a has type double
};

The type name A in the definition of X<T> binds to the typedef name defined in the global namespace scope, not to the typedef name defined in the base class B<T>. — end example ] [Example:

struct A {
   struct B { /* ... */ };  
   int a;
   int Y;
};

int a;

template< class T > struct Y : T {
   struct B { /* ... */ };      // The B defined in Y
   B b;                          // Y<T>
   void f(int i) { a = i; }      // ::a
   Y* p;                         // Y<T>
};

Y<A> ya;

The members A::B, A::a, and A::Y of the template argument A do not affect the binding of names in Y<A>. — end example ]

14.6.2.1 Dependent types [temp.dep.type]

1 In the definition of a class template, a nested class of a class template, a member of a class template, or a member of a nested class of a class template, a name refers to the current instantiation if it is
   — the injected-class-name (9) of the class template or nested class,
   — in the definition of a primary class template, the name of the class template followed by the template argument list of the primary template (as described below) enclosed in <>,
   — in the definition of a nested class of a class template, the name of the nested class referenced as a member of the current instantiation, or
   — in the definition of a partial specialization, the name of the class template followed by the template argument list of the partial specialization enclosed in <>.

2 The template argument list of a primary template is a template argument list in which the nth template argument has the value of the nth template parameter of the class template.

3 A template argument that is equivalent to a template parameter (i.e., has the same constant value or the same type as the template parameter) can be used in place of that template parameter in a reference to the current instantiation. In the case of a non-type template argument, the argument must have been given the value of the template parameter and not an expression involving the template parameter. [Example:

   template <class T> class A {

Draft
4 A name is a member of the current instantiation if it is
   — An unqualified name that, when looked up, refers to a member of a class template. [ Note: this can only occur when looking up a name in a scope enclosed by the definition of a class template. — end note ]
   — A qualified-id in which the nested-name-specifier refers to the current instantiation.
   — [ Example:}

```
template <class T> class A {
  static const int i = 5;
  int n1[i];             // i refers to a member of the current instantiation
  int n2[A::i];          // A::i refers to a member of the current instantiation
  int n3[A<T>::i];       // A<T>::i refers to a member of the current instantiation
  int f();
};

template <class T> int A<T>::f()
{
  return i;             // i refers to a member of the current instantiation
}
```
A name is a member of an unknown specialization if the name is a qualified-id in which the nested-name-specifier names a dependent type that is not the current instantiation.

A type is dependent if it is

- a template parameter,
- a member of an unknown specialization,
- a nested class that is a member of the current instantiation,
- a cv-qualified type where the cv-unqualified type is dependent,
- a compound type constructed from any dependent type,
- an array type constructed from any dependent type or whose size is specified by a constant expression that is value-dependent, or
- a template-id in which either the template name is a template parameter or any of the template arguments is a dependent type or an expression that is type-dependent or value-dependent.

[Note: because typedefs do not introduce new types, but instead simply refer to other types, a name that refers to a typedef that is a member of the current instantiation is dependent only if the type referred to is dependent. —end note]

### 14.6.2.2 Type-dependent expressions

Except as described below, an expression is type-dependent if any subexpression is type-dependent.

This is type-dependent if the class type of the enclosing member function is dependent (14.6.2.1).

An id-expression is type-dependent if it contains:

- an identifier that was declared with a dependent type,
- a template-id that is dependent,
- a conversion-function-id that specifies a dependent type,
- a nested-name-specifier or a qualified-id that names a member of an unknown specialization.

Expressions of the following forms are type-dependent only if the type specified by the type-id, simple-type-specifier or new-type-id is dependent, even if any subexpression is type-dependent:

```
simple-type-specifier ( expression-listopt )
::opt new new-placementopt new-typeid new-initializeropt
::opt new new-placementopt ( type-id ) new-initializeropt
dynamic_cast < type-id > ( expression )
static_cast < type-id > ( expression )
const_cast < type-id > ( expression )
reinterpret_cast < type-id > ( expression )
(type-id ) cast-expression
```

Expressions of the following forms are never type-dependent (because the type of the expression cannot be dependent):
A class member access expression (5.2.5) is type-dependent if the type of the referenced member is dependent. [Note: in an expression of the form \(x.y\) or \(xp->y\) the type of the expression is usually the type of the member \(y\) of the class of \(x\) (or the class pointed to by \(xp\)). However, if \(x\) or \(xp\) refers to a dependent type that is not the current instantiation, the type of \(y\) is always dependent. If \(x\) or \(xp\) refers to a non-dependent type or refers to the current instantiation, the type of \(y\) is the type of the class member access expression. — end note ]

### 14.6.2.3 Value-dependent expressions

Except as described below, a constant expression is value-dependent if any subexpression is value-dependent.

1. An identifier is value-dependent if it is:
   1. a name declared with a dependent type,
   2. the name of a non-type template parameter,
   3. a constant with integral or enumeration type and is initialized with an expression that is value-dependent.

Expressions of the following form are value-dependent if the unary-expression is type-dependent or the type-id is dependent (even if sizeof unary-expression and sizeof (type-id) are not type-dependent):

```
sizeof unary-expression
sizeof (type-id)
```

3. Expressions of the following form are value-dependent if either the type-id or simple-type-specifier is dependent or the expression or cast-expression is value-dependent:

```
simple-type-specifier (expression-list_opt)
static_cast <type-id> (expression)
const_cast <type-id> (expression)
reinterpret_cast <type-id> (expression)
(type-id) cast-expression
```

### 14.6.2.4 Dependent template arguments

1. A type template-argument is dependent if the type it specifies is dependent.
2. An integral non-type template-argument is dependent if the constant expression it specifies is value-dependent.
3. A non-integral non-type template-argument is dependent if its type is dependent or it has either of the following forms

Draft
4 A template template-argument is dependent if it names a template-parameter or is a qualified-id with a nested-name-specifier which contains a class-name that names a dependent type.

14.6.3 Non-dependent names [temp.nondep]

1 Non-dependent names used in a template definition are found using the usual name lookup and bound at the point they are used. [Example:

```cpp
void g(double);
void h();

template<class T> class Z {
public:
    void f() {
        g(1); // calls g(double)
        h++; // ill-formed: cannot increment function;
        // this could be diagnosed either here or
        // at the point of instantiation
    }
};

g(int); // not in scope at the point of the template
    // definition, not considered for the call g(1)

— end example ]

14.6.4 Dependent name resolution [temp.dep.res]

1 In resolving dependent names, names from the following sources are considered:

— Declarations that are visible at the point of definition of the template.
— Declarations from namespaces associated with the types of the function arguments both from the instantiation context (14.6.4.1) and from the definition context.

14.6.4.1 Point of instantiation [temp.point]

1 For a function template specialization, a member function template specialization, or a specialization for a member function or static data member of a class template, if the specialization is implicitly instantiated because it is referenced from within another template specialization and the context from which it is referenced depends on a template parameter, the point of instantiation of the specialization is the point of instantiation of the enclosing specialization. Otherwise, the point of instantiation for such a specialization immediately follows the namespace scope declaration or definition that refers to the specialization.

2 If a function template or member function of a class template is called in a way which uses the definition of a default argument of that function template or member function, the point of instantiation of the default argument is the point of instantiation of the function template or member function specialization.
For a class template specialization, a class member template specialization, or a specialization for a class member of a class template, if the specialization is implicitly instantiated because it is referenced from within another template specialization, if the context from which the specialization is referenced depends on a template parameter, and if the specialization is not instantiated previously to the instantiation of the enclosing template, the point of instantiation is immediately before the point of instantiation of the enclosing template. Otherwise, the point of instantiation for such a specialization immediately precedes the namespace scope declaration or definition that refers to the specialization.

If a virtual function is implicitly instantiated, its point of instantiation is immediately following the point of instantiation of its enclosing class template specialization.

An explicit instantiation directive is an instantiation point for the specialization or specializations specified by the explicit instantiation directive.

The instantiation context of an expression that depends on the template arguments is the set of declarations with external linkage declared prior to the point of instantiation of the template specialization in the same translation unit.

A specialization for a function template, a member function template, or of a member function or static data member of a class template may have multiple points of instantiations within a translation unit. A specialization for a class template has at most one point of instantiation within a translation unit. A specialization for any template may have points of instantiation in multiple translation units. If two different points of instantiation give a template specialization different meanings according to the one definition rule (3.2), the program is ill-formed, no diagnostic required.

### 14.6.4.2 Candidate functions

For a function call that depends on a template parameter, if the function name is an unqualified-id but not a template-id, the candidate functions are found using the usual lookup rules (3.4.1, 3.4.2) except that:

— For the part of the lookup using unqualified name lookup (3.4.1), only function declarations with external linkage from the template definition context are found.

— For the part of the lookup using associated namespaces (3.4.2), only function declarations with external linkage found in either the template definition context or the template instantiation context are found.

If the call would be ill-formed or would find a better match had the lookup within the associated namespaces considered all the function declarations with external linkage introduced in those namespaces in all translation units, not just considering those declarations found in the template definition and template instantiation contexts, then the program has undefined behavior.

### 14.6.5 Friend names declared within a class template

Friend classes or functions can be declared within a class template. When a template is instantiated, the names of its friends are treated as if the specialization had been explicitly declared at its point of instantiation.

As with non-template classes, the names of namespace-scope friend functions of a class template specialization are not visible during an ordinary lookup unless explicitly declared at namespace scope (11.4). Such names may be found under the rules for associated classes (3.4.2).

### Example:

```cpp
template<typename T> class number {
public:
```

---

[136] Friend declarations do not introduce new names into any scope, either when the template is declared or when it is instantiated.
14.7 Template instantiation and specialization

The act of instantiating a function, a class, a member of a class template or a member template is referred to as template instantiation.

A function instantiated from a function template is called an instantiated function. A class instantiated from a class template is called an instantiated class. A member function, a member class, or a static data member of a class template instantiated from the member definition of the class template is called, respectively, an instantiated member function, member class or static data member. A member function instantiated from a member function template is called an instantiated member function. A member class instantiated from a member class template is called an instantiated member class.

An explicit specialization may be declared for a function template, a class template, a member of a class template or a member template. An explicit specialization declaration is introduced by template<>. In an explicit specialization declaration for a class template, a member of a class template or a class member template, the name of the class that is explicitly specialized shall be a template-id. In the explicit specialization declaration for a function template or a member function template, the name of the function or member function explicitly specialized may be a template-id.

[Example:

template<class T = int> struct A {
  static int x;
};
template<class U> void g(U) {

  template<> struct A<double> { };
  // specialize for T == double
  template<> struct A<> { };
  // specialize for T == int
  template<> void g(char) { }
  // specialize for U == char
  // U is deduced from the parameter type
  template<> void g<int>(int) { }
  // specialize for U == int
  template<> int A<char>::x = 0;
  // specialize for T == char

}
4 An instantiated template specialization can be either implicitly instantiated (14.7.1) for a given argument list or be explicitly instantiated (14.7.2). A specialization is a class, function, or class member that is either instantiated or explicitly specialized (14.7.3).

5 For a given template and a given set of template-arguments,

— an explicit instantiation shall appear at most once in a program,
— an explicit specialization shall be defined at most once in a program (according to 3.2), and
— both an explicit instantiation and a declaration of an explicit specialization shall not appear in a program unless the explicit instantiation follows a declaration of the explicit specialization.

An implementation is not required to diagnose a violation of this rule.

6 Each class template specialization instantiated from a template has its own copy of any static members. [Example:

```cpp
template< class T > struct B {
    static int x;
};
template<> int B<>::x = 1; // specialize for T == int

— end example ]
```

14.7.1 Implicit instantiation [temp.inst]

1 Unless a class template specialization has been explicitly instantiated (14.7.2) or explicitly specialized (14.7.3), the class template specialization is implicitly instantiated when the specialization is referenced in a context that requires a completely-defined object type or when the completeness of the class type affects the semantics of the program. The implicit instantiation of a class template specialization causes the implicit instantiation of the declarations, but not of the definitions or default arguments, of the class member functions, member classes, static data members and member templates; and it causes the implicit instantiation of the definitions of member anonymous unions. Unless a member of a class template or a member template has been explicitly instantiated or explicitly specialized, the specialization of the member is implicitly instantiated when the specialization is referenced in a context that requires the member definition to exist; in particular, the initialization (and any associated side-effects) of a static data member does not occur unless the static data member is itself used in a way that requires the definition of the static data member to exist.

2 Unless a function template specialization has been explicitly instantiated or explicitly specialized, the function template specialization is implicitly instantiated when the specialization is referenced in a context that requires a function
definition to exist. Unless a call is to a function template explicit specialization or to a member function of an explicitly specialized class template, a default argument for a function template or a member function of a class template is implicitly instantiated when the function is called in a context that requires the value of the default argument.

Example:

```c++
template<class T> class Z {
public:
    void f();
    void g();
};

void h() {
    Z<int> a;           // instantiation of class Z<int> required
    Z<char>* p;        // instantiation of class Z<char> not required
    Z<double>* q;      // instantiation of class Z<double> not required

    a.f();            // instantiation of Z<int>::f() required
    p->g();           // instantiation of Z<char>::g() required
    // instantiation of Z<char>::g() required
}
```

Nothing in this example requires class Z<double>, Z<int>::g(), or Z<char>::f() to be implicitly instantiated. — end example

A class template specialization is implicitly instantiated if the class type is used in a context that requires a completely-defined object type or if the completeness of the class type might affect the semantics of the program. [Note: in particular, if the semantics of an expression depend on the member or base class lists of a class template specialization, the class template specialization is implicitly generated. For instance, deleting a pointer to class type depends on whether or not the class declares a destructor, and conversion between pointer to class types depends on the inheritance relationship between the two classes involved. — end note] Example:

```c++
template<class T> class B { /* ... */ };
template<class T> class D : public B<T> { /* ... */ };

void f(void*);
void f(B<int>*);

void g(D<int>* p, D<char>* pp, D<double> ppp) {
    f(p);            // instantiation of D<int> required: call f(B<int>*)
    B<char>* q = pp;  // instantiation of D<char> required:
                     // convert D<char>* to B<char>*
    delete ppp;       // instantiation of D<double> required
}
```
If the overload resolution process can determine the correct function to call without instantiating a class template definition, it is unspecified whether that instantiation actually takes place. [Example:

```cpp
template <class T> struct S {
    operator int();
};

void f(int);
void f(S<int>&);
void f(S<float>);

void g(S<int>& sr) {
    f(sr);
    // instantiation of S<int> allowed but not required
    // instantiation of S<float> allowed but not required
}
```

— end example ]

If an implicit instantiation of a class template specialization is required and the template is declared but not defined, the program is ill-formed. [Example:

```cpp
template <class T> class X;

X<char> ch;  // error: definition of X required
```

— end example ]

The implicit instantiation of a class template does not cause any static data members of that class to be implicitly instantiated.

If a function template or a member function template specialization is used in a way that involves overload resolution, a declaration of the specialization is implicitly instantiated (14.8.3).

An implementation shall not implicitly instantiate a function template, a member template, a non-virtual member function, a member class or a static data member of a class template that does not require instantiation. It is unspecified whether or not an implementation implicitly instantiates a virtual member function of a class template if the virtual member function would not otherwise be instantiated. The use of a template specialization in a default argument shall not cause the template to be implicitly instantiated except that a class template may be instantiated where its complete type is needed to determine the correctness of the default argument. The use of a default argument in a function call causes specializations in the default argument to be implicitly instantiated.

Implicitly instantiated class and function template specializations are placed in the namespace where the template is defined. Implicitly instantiated specializations for members of a class template are placed in the namespace where the enclosing class template is defined. Implicitly instantiated member templates are placed in the namespace where the enclosing class or class template is defined. [Example:

```cpp
namespace N {
    template <class T> class List {
    public:
        T* get();
    }
```
template < class K , class V > class Map {
    N::List<V> lt;
    V get(K);
    // ...
};

void g(Map<char*,int>& m)
{
    int i = m.get("Nicholas");
    // ...
}

14.6.4.1 defines the point of instantiation of a template specialization.
— end note

There is an implementation-defined quantity that specifies the limit on the total depth of recursive instantiations, which could involve more than one template. The result of an infinite recursion in instantiation is undefined.

Example:

template < class T > class X {
    X<T*>* p; // OK
    X<T*> a; // implicit generation of X<T> requires
    // the implicit instantiation of X<T*> which requires

14.7 Template instantiation and specialization

14.7.2 Explicit instantiation

A class, a function or member template specialization can be explicitly instantiated from its template. A member function, member class or static data member of a class template can be explicitly instantiated from the member definition associated with its class template.

1 The syntax for explicit instantiation is:

```
explicit-instantiation:
    template declaration
```

If the explicit instantiation is for a class, a function or a member template specialization, the `unqualified-id` in the `declaration` shall be either a `template-id` or, where all template arguments can be deduced, a `template-name`. [Note: the declaration may declare a `qualified-id`, in which case the `unqualified-id` of the `qualified-id` must be a `template-id`. — end note] If the explicit instantiation is for a member function, a member class or a static data member of a class template specialization, the name of the class template specialization in the `qualified-id` for the member name shall be a `template-id`. An explicit instantiation shall appear in an enclosing namespace of its template. If the name declared in the explicit instantiation is an unqualified name, the explicit instantiation shall appear in the namespace where its template is declared. [Note: regarding qualified names in declarators, see 8.3. — end note] [Example:

```
template< class T> class Array { void mf(); };  
template class Array<char>;  
template void Array<int>::mf();

template< class T> void sort(Array<T>& v) { /* ... */ }  
template void sort(Array<char>&);    // argument is deduced here
```

2 A declaration of a function template shall be in scope at the point of the explicit instantiation of the function template. A definition of the class or class template containing a member function template shall be in scope at the point of the explicit instantiation of the member function template. A definition of a class template or class member template shall be in scope at the point of the explicit instantiation of the class template or class member template. A definition of a class template shall be in scope at the point of an explicit instantiation of a member function or a static data member of the class template. A definition of a member class of a class template shall be in scope at the point of an explicit instantiation of the member class. If the `declaration` of the explicit instantiation names an implicitly-declared special member function (clause 12), the program is ill-formed.

3 For a given set of template parameters, if an explicit instantiation of a template appears after a declaration of an explicit specialization for that template, the explicit instantiation has no effect. Otherwise, the definition of a non-exported
function template, a non-exported member function template, or a non-exported member function or static data member of a class template shall be present in every translation unit in which it is explicitly instantiated.

5 An explicit instantiation of a class or function template specialization is placed in the namespace in which the template is defined. An explicit instantiation for a member of a class template is placed in the namespace where the enclosing class template is defined. An explicit instantiation for a member template is placed in the namespace where the enclosing class or class template is defined. [Example:

```cpp
namespace N {
    template<class T> class Y { void mf() { } };  // error: class template Y not visible
}

template class Y<int>;  // in the global namespace
using N::Y;
template class Y<int>;  // OK: explicit instantiation in namespace N
	template class N::Y<char*>;  // OK: explicit instantiation in namespace N

template class Y<double>::mf();  // OK: explicit instantiation

— end example ]
```

6 A trailing template-argument can be left unspecified in an explicit instantiation of a function template specialization or of a member function template specialization provided it can be deduced from the type of a function parameter (14.8.2). [Example:

```cpp
template<class T> class Array { /* ... */ };  
template<class T> void sort(Array<T>& v);  

// instantiate sort(Array<int>&) - template-argument deduced

template void sort<T>(Array<int>&);  // in namespace N

— end example ]
```

7 The explicit instantiation of a class template specialization implies the instantiation of all of its members not previously explicitly specialized in the translation unit containing the explicit instantiation.

8 The usual access checking rules do not apply to names used to specify explicit instantiations. [Note: In particular, the template arguments and names used in the function declarator (including parameter types, return types and exception specifications) may be private types or objects which would normally not be accessible and the template may be a member template or member function which would not normally be accessible. — end note]

9 An explicit instantiation does not constitute a use of a default argument, so default argument instantiation is not done. [Example:

```cpp
char* p = 0;
template<class T> T g(T = &p);  // OK even though &p isn’t an int.
template int g<int>(int);  // OK even though &p isn’t an int.
```

Draft
14.7.3 Explicit specialization

An explicit specialization of any of the following:

- function template
- class template
- member function of a class template
- static data member of a class template
- member class of a class template
- member class template of a class template
- member function template of a class template

can be declared by a declaration introduced by \texttt{template<>}; that is:

\begin{verbatim}
    explicit-specialization:
    template <> declaration
\end{verbatim}

[Example:

\begin{verbatim}
    template<class T> class stream;

    template<> class stream<char> { /* ... */ };

    template<class T> class Array { /* ... */ };
    template<class T> void sort(Array<T>& v) { /* ... */ }

    template<> void sort<char*>(Array<char*>&); 
\end{verbatim}

Given these declarations, \texttt{stream<char>} will be used as the definition of streams of \texttt{char}s; other streams will be handled by class template specializations instantiated from the class template. Similarly, \texttt{sort<char*>>} will be used as the sort function for arguments of type \texttt{Array<char*>}; other \texttt{Array} types will be sorted by functions generated from the template. — end example ]

An explicit specialization shall be declared in the namespace of which the template is a member, or, for member templates, in the namespace of which the enclosing class or enclosing class template is a member. An explicit specialization of a member function, member class or static data member of a class template shall be declared in the namespace of which the class template is a member. Such a declaration may also be a definition. If the declaration is not a definition, the specialization may be defined later (7.3.1.2).

2 A declaration of a function template or class template being explicitly specialized shall be in scope at the point of declaration of an explicit specialization. [Note: a declaration, but not a definition of the template is required. —end note ] The definition of a class or class template shall be in scope at the point of declaration of an explicit specialization for a member template of the class or class template. [Example:

\begin{verbatim}
    template<> class X<int> { /* ... */ };
    // error: X not a template

    template<class T> class X;
\end{verbatim}
A member function, a member class or a static data member of a class template may be explicitly specialized for a class specialization that is implicitly instantiated; in this case, the definition of the class template shall be in scope at the point of declaration of the explicit specialization for the member of the class template. If such an explicit specialization for the member of a class template names an implicitly-declared special member function (clause 12), the program is ill-formed.

A member of an explicitly specialized class is not implicitly instantiated from the member declaration of the class template; instead, the member of the class template specialization shall itself be explicitly defined. In this case, the definition of the class template explicit specialization shall be in scope at the point of declaration of the explicit specialization of the member. The definition of an explicitly specialized class is unrelated to the definition of a generated specialization. That is, its members need not have the same names, types, etc. as the members of a generated specialization. Definitions of members of an explicitly specialized class are defined in the same manner as members of normal classes, and not using the explicit specialization syntax. [Example:

```cpp
template< class T > struct A {
    template<>
    struct A<T> { void f(T); }
};

template<>
void A<int>::f() { /* ... */ }

void A<int>::f() { /* ... */ }
```

— end example ]

If a template, a member template or the member of a class template is explicitly specialized then that specialization shall be declared before the first use of that specialization that would cause an implicit instantiation to take place, in every translation unit in which such a use occurs; no diagnostic is required. If the program does not provide a definition for an explicit specialization and either the specialization is used in a way that would cause an implicit instantiation to take place or the member is a virtual member function, the program is ill-formed, no diagnostic required. An implicit instantiation is never generated for an explicit specialization that is declared but not defined. [Example:

```cpp
void f(Array<String>& v)
```

Draft
{  
    sort(v);  // use primary template
    // sort(Array<T>&), T is String
}

template<> void sort<String>(Array<String>& v); // error: specialization
    // after use of primary template

template<> void sort<char*>(Array<char*>& v);        // OK: sort<char*> not yet used

— end example ]

6 The placement of explicit specialization declarations for function templates, class templates, member functions of class
templates, static data members of class templates, member classes of class templates, member class templates of class
templates, member function templates of class templates, member functions of member templates of class templates,
member functions of member templates of non-template classes, member function templates of member classes of class
templates, etc., and the placement of partial specialization declarations of class templates, member class templates of
non-template classes, member class templates of class templates, etc., can affect whether a program is well-formed
according to the relative positioning of the explicit specialization declarations and their points of instantiation in the
translation unit as specified above and below. When writing a specialization, be careful about its location; or to make it
compile will be such a trial as to kindle its self-immolation.

7 When a specialization for which an explicit specialization exists is used within the instantiation of an exported template,
and the unspecialized template name is non-dependent in the exported template, a declaration of the explicit special-
ization shall be declared before the definition of the exported template, in the translation unit containing that definition.

[ Example:

// file #1
#include <vector>
// Primary class template vector
export template<class T> void f(t) {
    std::vector<T>; vec;    // should match the specialization
    /* ... */
}

// file #2
#include <vector>
class B { };  
// Explicit specialization of vector for vector<B>
namespace std {
    template<> class vector<B> { /* ... */ };
}
template<class T> void f(T);
void g(B b) {
    f(b);        // ill-formed:
        // f<B> should refer to vector<B>, but the
        // specialization was not declared with the
        // definition of f in file #1
}

— end example ]

Draft
A template explicit specialization is in the scope of the namespace in which the template was defined.

```cpp
namespace N {
  template<class T> class X { /* ... */ };  // OK: specialization
  template<class T> class Y { /* ... */ };  // in same namespace
  template<> class X<int> { /* ... */ };   // OK: specialization
      // in same namespace
  template<> class Y<double>;            // forward declare intent to
      // specialize for double
}

template<> class N::Y<double> { /* ... */ };  // OK: specialization
      // in same namespace
```

A template-id that names a class template explicit specialization that has been declared but not defined can be used exactly like the names of other incompletely-defined classes (3.9).

```cpp
template<class T> class X;  // X is a class template
template<> class X<int>;

X<int>* p;    // OK: pointer to declared class X<int>
X<int> x;     // error: object of incomplete class X<int>
```

A trailing template-argument can be left unspecified in the template-id naming an explicit function template specialization provided it can be deduced from the function argument type.

```cpp
template<class T> class Array { /* ... */ };  // explicit specialization for sort(Array<int>&)
    // with deduces template-argument of type int
  template<> void sort(Array<int>&);
```

A function with the same name as a template and a type that exactly matches that of a template specialization is not an explicit specialization (14.5.5).

```cpp
template<class T> void f(T) { /* ... */ }
```

An explicit specialization of a function template is inline only if it is explicitly declared to be, and independently of whether its function template is.

```cpp
template<class T> inline T g(T) { /* ... */ }
```
An explicit specialization of a static data member of a template is a definition if the declaration includes an initializer; otherwise, it is a declaration. [Note: there is no syntax for the definition of a static data member of a template that requires default initialization.]

```cpp
template<> X Q<int>::x;
```

This is a declaration regardless of whether X can be default initialized (8.5). — end note]

A member or a member template of a class template may be explicitly specialized for a given implicit instantiation of the class template, even if the member or member template is defined in the class template definition. An explicit specialization of a member or member template is specified using the template specialization syntax. [Example:

```cpp
template<class T> struct A {
    void f(T);
    template<class X1> void g1(T, X1);
    template<class X2> void g2(T, X2);
    void h(T) {}
};

// specialization
template<> void A<int>::f(int);

// out of class member template definition
template<class T> template<class X1> void A<T>::g1(T, X1) {
}

// member template specialization
template<> template<class X1> void A<int>::g1(int, X1);

// member template specialization
template<> template<>
    void A<int>::g1(int, char); // X1 deduced as char
template<> template<>
    void A<int>::g2<char>(int, char); // X2 specified as char

// member specialization even if defined in class definition
template<> void A<int>::h(int) {}
```

— end example]

A member or a member template may be nested within many enclosing class templates. In an explicit specialization for such a member, the member declaration shall be preceded by a `template<>` for each enclosing class template that is explicitly specialized. [Example:

```cpp
template<class T1> class A {
    template<class T2> class B {
        void mf();
    };
};
template<> template<> class A<int>::B<double>;
template<> template<> void A<char>::B<char>::mf();
```

Draft
18 In an explicit specialization declaration for a member of a class template or a member template that appears in namespace scope, the member template and some of its enclosing class templates may remain unspecialized, except that the declaration shall not explicitly specialize a class member template if its enclosing class templates are not explicitly specialized as well. In such explicit specialization declaration, the keyword `template` followed by a `template-parameter-list` shall be provided instead of the `template<>` preceding the explicit specialization declaration of the member. The types of the `template-parameters` in the `template-parameter-list` shall be the same as those specified in the primary template definition. [Example:

```cpp
template < class T1 > class A {
    template < class T2 > class B {
        template < class T3 > void mf1(T3);
        void mf2();
    };
    template <> template < class X>
    class A<int>::B {
        template < class T > void mf1(T);
    };
    template < template <> template < class T>
    void A<int>::B<double>::mf1(T) { } // ill-formed; B<double> is specialized but
    template < class Y > template <>
    void A<Y>::B<double>::mf2() { } // its enclosing class template A is not
```

— end example ]

19 A specialization of a member function template or member class template of a non-specialized class template is itself a template.

20 An explicit specialization declaration shall not be a friend declaration.

21 Default function arguments shall not be specified in a declaration or a definition for one of the following explicit specializations:

   — the explicit specialization of a function template;
   — the explicit specialization of a member function template;
   — the explicit specialization of a member function of a class template where the class template specialization to which the member function specialization belongs is implicitly instantiated. [Note: default function arguments may be specified in the declaration or definition of a member function of a class template specialization that is explicitly specialized. —end note ]

14.8 Function template specializations [temp.fct.spec]

1 A function instantiated from a function template is called a function template specialization; so is an explicit specialization of a function template. Template arguments can be explicitly specified when naming the function template specialization, deduced from the context (e.g., deduced from the function arguments in a call to the function template specialization, see 14.8.2), or obtained from default template arguments.
Each function template specialization instantiated from a template has its own copy of any static variable. [Example:

```cpp
template<class T> void f(T* p)
{
    static T s;
    // ...
};

void g(int a, char* b)
{
    f(&a); // call f<int>(int*)
    f(&b); // call f<char*>(char**)  
}
```

Here \( f\texttt{<int>}(\texttt{int}*) \) has a static variable \( s \) of type \( \texttt{int} \) and \( f\texttt{<char*>(char**)} \) has a static variable \( s \) of type \( \texttt{char*} \). — end example]

### 14.8.1 Explicit template argument specification

Template arguments can be specified when referring to a function template specialization by qualifying the function template name with the list of template-arguments in the same way as template-arguments are specified in uses of a class template specialization. [Example:

```cpp
template<class T> void sort(Array<T>& v);
void f(Array<dcomplex>& cv, Array<int>& ci)
{
    sort<dcomplex>(cv); // sort(Array<dcomplex>&)
    sort<int>(ci); // sort(Array<int>&)
}
```

and

```cpp
template<class U, class V> U convert(V v);
```

```cpp
void g(double d)
{
    int i = convert<int,double>(d); // int convert(double)
    char c = convert<char,double>(d); // char convert(double)
}
```

— end example]

A template argument list may be specified when referring to a specialization of a function template

— when a function is called,
— when the address of a function is taken, when a function initializes a reference to function, or when a pointer to member function is formed,
— in an explicit specialization,
— in an explicit instantiation, or
— in a friend declaration.

3 Trailing template arguments that can be deduced (14.8.2) or obtained from default template-arguments may be omitted from the list of explicit template-arguments. If all of the template arguments can be deduced, they may all be omitted; in this case, the empty template argument list <> itself may also be omitted. In contexts where deduction is done and fails, or in contexts where deduction is not done, if a template argument list is specified and it, along with any default template arguments, identifies a single function template specialization, then the template-id is an lvalue for the function template specialization. [Example:]

```cpp
template<class X, class Y> X f(Y);
void g()
{
    int i = f<int>(5.6); // Y is deduced to be double
    int j = f(5.6); // ill-formed: X cannot be deduced
    f<void>(f<int, bool>); // Y for outer f deduced to be
                           // int (*)(bool)
    f<void>(f<int>); // ill-formed: f<int> does not denote a
                     // single function template specialization
}
```

— end example ]

4 [Note: An empty template argument list can be used to indicate that a given use refers to a specialization of a function template even when a normal (i.e., non-template) function is visible that would otherwise be used. For example:

```cpp
template < class T > int f(T ); // #1
int f(int); // #2
int k = f(1); // uses #2
int l = f<> (1); // uses #1
```

— end note ]

5 Template arguments that are present shall be specified in the declaration order of their corresponding template-parameters. The template argument list shall not specify more template-arguments than there are corresponding template-parameters. [Example:]

```cpp
template<class X, class Y, class Z> X f(Y,Z);
void g()
{
    f<int,char*,double>("aa",3.0);
    f<int,char*>("aa",3.0); // Z is deduced to be double
    f<int>("aa",3.0); // Y is deduced to be char*, and
                      // Z is deduced to be double
    f("aa",3.0); // error: X cannot be deduced
}
```

— end example ]

6 Implicit conversions (clause 4) will be performed on a function argument to convert it to the type of the corresponding function parameter if the parameter type contains no template-parameters that participate in template argument deduction. [Note: template parameters do not participate in template argument deduction if they are explicitly specified. For example,
template<class T> void f(T);

class Complex {
    // ...
    Complex(double);
};

void g()
{
    f<Complex>(1);     // OK, means f<Complex>(Complex(1))
}

— end note ]

[ Note: because the explicit template argument list follows the function template name, and because conversion member function templates and constructor member function templates are called without using a function name, there is no way to provide an explicit template argument list for these function templates. — end note ]

[ Note: For simple function names, argument dependent lookup (3.4.2) applies even when the function name is not visible within the scope of the call. This is because the call still has the syntactic form of a function call (3.4.1). But when a function template with explicit template arguments is used, the call does not have the correct syntactic form unless there is a function template with that name visible at the point of the call. If no such name is visible, the call is not syntactically well-formed and argument-dependent lookup does not apply. If some such name is visible, argument dependent lookup applies and additional function templates may be found in other namespaces. [ Example:

    namespace A {
        struct B {    };
        template<int X> void f(B);
    }
    namespace C {
        template<class T> void f(T t);
    }
    void g(A::B b) {
        f<3>(b);       // ill-formed: not a function call
        A::f<3>(b);    // well-formed
        C::f<3>(b);    // ill-formed; argument dependent lookup
        // applies only to unqualified names
        using C::f;
        f<3>(b);       // well-formed because C::f is visible; then
                          // A::f is found by argument dependent lookup
    }

— end example ] — end note ]

14.8.2 Template argument deduction [temp.deduct]

When a function template specialization is referenced, all of the template arguments must have values. The values can be explicitly specified or, in some cases, be deduced from the use or obtained from default template-arguments. [ Example:
void f(Array<dcomplex>& cv, Array<int>& ci)
{
    sort(cv);          // call sort(Array<dcomplex>&)
    sort(ci);          // call sort(Array<int>&)
}

and

void g(double d)
{
    int i = convert<int>(d);       // call convert<int,double>(double)
    int c = convert<char>(d);      // call convert<char,double>(double)
}

— end example ]

When an explicit template argument list is specified, the template arguments must be compatible with the template parameter list and must result in a valid function type as described below; otherwise type deduction fails. Specifically, the following steps are performed when evaluating an explicitly specified template argument list with respect to a given function template:

— The specified template arguments must match the template parameters in kind (i.e., type, non-type, template), and there must not be more arguments than there are parameters; otherwise type deduction fails.

— Non-type arguments must match the types of the corresponding non-type template parameters, or must be convertible to the types of the corresponding non-type parameters as specified in 14.3.2, otherwise type deduction fails.

— All references in the function type of the function template to the corresponding template parameters are replaced by the specified template argument values. If a substitution in a template parameter or in the function type of the function template results in an invalid type, type deduction fails. [Note: The equivalent substitution in exception specifications is done only when the function is instantiated, at which point a program is ill-formed if the substitution results in an invalid type.] Type deduction may fail for the following reasons:

— Attempting to create an array with an element type that is void, a function type, a reference type, or an abstract class type, or attempting to create an array with a size that is zero or negative. [ Example:

    template <class T> int f(T[5]);
    int I = f<int>(0);
    int j = f<void>(0);       // invalid array

    — end example ]

— Attempting to use a type that is not a class type in a qualified name. [ Example:

    template <class T> int f(typename T::B*);
    int i = f<int>(0);

    — end example ]

— Attempting to use a type in a nested-name-specifier of a qualified-id when that type does not contain the specified member, or

Draft
— the specified member is not a type where a type is required, or
— the specified member is not a template where a template is required, or
— the specified member is not a non-type where a non-type is required.

[Example:

template <int I> struct X {}

template <template <class T> class> struct Z {}

template <class T> void f(typename T::*{}

template <class T> void g(X<T::N>*){}

template <class T> void h(Z<T::template TT>*){}

struct A {};

struct B { int Y; };

struct C {
    typedef int N;
}

struct D {
    typedef int TT;
}

int main()
{
    // Deduction fails in each of these cases:
    f<A>(0); // A does not contain a member Y
    f<B>(0); // The Y member of B is not a type
    g<C>(0); // The N member of C is not a non-type
    h<D>(0); // The TT member of D is not a template
}

— end example ]

— Attempting to create a pointer to reference type.

— Attempting to create a reference to void.

— Attempting to create “pointer to member of T” when T is not a class type. [Example:

template <class T> int f(int T::*);

int i = f<int>(0);

— end example ]

— Attempting to give an invalid type to a non-type template parameter. [Example:

template <class T, T> struct S {};

template <class T> int f(S<T, T>()*);

struct X {};

int i0 = f<X>(0);

— end example ]
— Attempting to perform an invalid conversion in either a template argument expression, or an expression used in the function declaration. [*Example:*

```cpp
template <class T, T*> int f(int);
ext int i2 = f<int,1>(0);    // can't conv 1 to int*
```

— end example ]

— Attempting to create a function type in which a parameter has a type of `void`.

After this substitution is performed, the function parameter type adjustments described in §8.3.5 are performed. [*Example: A parameter type of “void ()(const int, int[5])” becomes “void(*)(int,int*)”. — end example][Note: A top-level qualifier in a function parameter declaration does not affect the function type but still affects the type of the function parameter variable within the function. — end note] [*Example:*

```cpp
template <class T> void f(T t);
template <class X> void g(const X x);
template <class Z> void h(Z, Z*);

int main()
{
    // #1: function type is f(int), t is non const
    f<int>(1);

    // #2: function type is f(int), t is const
    f<const int>(1);

    // #3: function type is g(int), x is const
    g<int>(1);

    // #4: function type is g(int), x is const
    g<const int>(1);

    // #5: function type is h(int, const int*)
    h<const int>(1,0);
}
```

— end example ]

[Note: f<int>(1) and f<const int>(1) call distinct functions even though both of the functions called have the same function type. — end note ]

The resulting substituted and adjusted function type is used as the type of the function template for template argument deduction. If a template argument has not been deduced, its default template argument, if any, is used. [*Example:*

```cpp
template <class T, class U = double>
void f(T t = 0, U u = 0);

void g()
{
    f(1, 'c');    // f<int,char>(1,'c')
    f(1);         // f<int,double>(1,0)
```
Templates

14.8 Function template specializations

```cpp
f();               // error: T cannot be deduced
f<int>();         // f<int,double>(0,0)
f<int,char>();    // f<int,char>(0,0)
}
```

— end example ]

When all template arguments have been deduced or obtained from default template arguments, all uses of template parameters in non-deduced contexts are replaced with the corresponding deduced or default argument values. If the substitution results in an invalid type, as described above, type deduction fails.

6 Except as described above, the use of an invalid value shall not cause type deduction to fail. [Example: In the following example 1000 is converted to `signed char` and results in an implementation-defined value as specified in (4.7). In other words, both templates are considered even though 1000, when converted to `signed char`, results in an implementation-defined value.]

```cpp
template <int> int f(int);
template <signed char> int f(int);
int i1 = f<1>(0);    // ambiguous
int i2 = f<1000>(0); // ambiguous
```

— end example ]

14.8.2.1 Deducing template arguments from a function call [temp.deduct.call]

Template argument deduction is done by comparing each function template parameter type (call it \( P \)) with the type of the corresponding argument of the call (call it \( A \)) as described below.

2 If \( P \) is not a reference type:
   
   — If \( A \) is an array type, the pointer type produced by the array-to-pointer standard conversion (4.2) is used in place of \( A \) for type deduction; otherwise,
   
   — If \( A \) is a function type, the pointer type produced by the function-to-pointer standard conversion (4.3) is used in place of \( A \) for type deduction; otherwise,
   
   — If \( A \) is a cv-qualified type, the top level cv-qualifiers of \( A \)’s type are ignored for type deduction.

3 If \( P \) is a cv-qualified type, the top level cv-qualifiers of \( P \)’s type are ignored for type deduction. If \( P \) is a reference type, the type referred to by \( P \) is used for type deduction.

4 In general, the deduction process attempts to find template argument values that will make the deduced \( A \) identical to \( A \) (after the type \( A \) is transformed as described above). However, there are three cases that allow a difference:
   
   — If the original \( P \) is a reference type, the deduced \( A \) (i.e., the type referred to by the reference) can be more cv-qualified than \( A \).
   
   — \( A \) can be another pointer or pointer to member type that can be converted to the deduced \( A \) via a qualification conversion (4.4).
   
   — If \( P \) is a class, and \( P \) has the form `template-id`, then \( A \) can be a derived class of the deduced \( A \). Likewise, if \( P \) is a pointer to a class of the form `template-id`, \( A \) can be a pointer to a derived class pointed to by the deduced \( A \).
14.8 Function template specializations

These alternatives are considered only if type deduction would otherwise fail. If they yield more than one possible deduced A, the type deduction fails. [Note: if a template-parameter is not used in any of the function parameters of a function template, or is used only in a non-deduced context, its corresponding template-argument cannot be deduced from a function call and the template-argument must be explicitly specified. — end note]

When P is a function type, pointer to function type, or pointer to member function type:

— If the argument is an overload set containing one or more function templates, the parameter is treated as a non-deduced context.

— If the argument is an overload set (not containing function templates), trial argument deduction is attempted using each of the members of the set. If deduction succeeds for only one of the overload set members, that member is used as the argument value for the deduction. If deduction succeeds for more than one member of the overload set the parameter is treated as a non-deduced context.

[Example:

// Only one function of an overload set matches the call so the function // parameter is a deduced context.
template <class T> int f(T (*p)(T));
int g(int);
int g(char);
int i = f(g); // calls f(int (*)(int))

— end example]

[Example:

// Ambiguous deduction causes the second function parameter to be a // non-deduced context.
template <class T> int f(T, T (*p)(T));
int g(int);
char g(char);
int i = f(1, g); // calls f(int, int (*)(int))

— end example]

[Example:

// The overload set contains a template, causing the second function // parameter to be a non-deduced context.
template <class T> int f(T, T (*p)(T));
char g(char);
template <class T> T g(T);
int i = f(1, g); // calls f(int, int (*)(int))

— end example]

14.8.2.2 Deducing template arguments taking the address of a function template [temp.deduct.funcaddr]

Template arguments can be deduced from the type specified when taking the address of an overloaded function (13.4).
The function template’s function type and the specified type are used as the types of \( P \) and \( A \), and the deduction is done as described in 14.8.2.5.

14.8.2.3 Deducing conversion function template arguments

Template argument deduction is done by comparing the return type of the template conversion function (call it \( P \)) with the type that is required as the result of the conversion (call it \( A \)) as described in 14.8.2.5.

1 If \( A \) is not a reference type:
   - If \( P \) is an array type, the pointer type produced by the array-to-pointer standard conversion (4.2) is used in place of \( P \) for type deduction; otherwise,
   - If \( P \) is a function type, the pointer type produced by the function-to-pointer standard conversion (4.3) is used in place of \( P \) for type deduction; otherwise,
   - If \( P \) is a cv-qualified type, the top level cv-qualifiers of \( P \)’s type are ignored for type deduction.

2 If \( A \) is a cv-qualified type, the top level cv-qualifiers of \( A \)’s type are ignored for type deduction. If \( A \) is a reference type, the type referred to by \( A \) is used for type deduction. If \( P \) is a reference type, the type referred to by \( P \) is used for type deduction.

3 In general, the deduction process attempts to find template argument values that will make the deduced \( A \) identical to \( A \). However, there are two cases that allow a difference:
   - If the original \( A \) is a reference type, \( A \) can be more cv-qualified than the deduced \( A \) (i.e., the type referred to by the reference)
   - The deduced \( A \) can be another pointer or pointer to member type that can be converted to \( A \) via a qualification conversion.

4 These alternatives are considered only if type deduction would otherwise fail. If they yield more than one possible deduced \( A \), the type deduction fails.

5 When the deduction process requires a qualification conversion for a pointer or pointer to member type as described above, the following process is used to determine the deduced template argument values:

If \( A \) is a type
\[ cv_{1,0} \text{ “pointer to ...” } cv_{1,n-1} \text{ “pointer to” } cv_{1,n} T1 \]
and \( P \) is a type
\[ cv_{2,0} \text{ “pointer to ...” } cv_{2,n-1} \text{ “pointer to” } cv_{2,n} T2 \]
The cv-unqualified \( T1 \) and \( T2 \) are used as the types of \( A \) and \( P \) respectively for type deduction. [Example:

```c
struct A {
    template < class T > operator T***();
};
A a;
const int * const * const * p1 = a; // T is deduced as int, not const int
```

— end example ]
14.8 Function template specializations

14.8.2.4 Deducing template arguments during partial ordering

Template argument deduction is done by comparing certain types associated with the two function templates being compared.

Two sets of types are used to determine the partial ordering. For each of the templates involved there is the original function type and the transformed function type. [Note: the creation of the transformed type is described in 14.5.5.2. — end note] The deduction process uses the transformed type as the argument template and the original type of the other template as the parameter template. This process is done twice for each type involved in the partial ordering comparison: once using the transformed template-1 as the argument template and template-2 as the parameter template and again using the transformed template-2 as the argument template and template-1 as the parameter template.

The types used to determine the ordering depend on the context in which the partial ordering is done:

— In the context of a function call, the function parameter types are used.
— In the context of a call to a conversion operator, the return types of the conversion function templates are used.
— In other contexts (14.5.5.2) the function template’s function type is used.

Each type from the parameter template and the corresponding type from the argument template are used as the types of P and A.

Before the partial ordering is done, certain transformations are performed on the types used for partial ordering:

— If P is a reference type, P is replaced by the type referred to.
— If A is a reference type, A is replaced by the type referred to.

If both P and A were reference types (before being replaced with the type referred to above), determine which of the two types (if any) is more cv-qualified than the other; otherwise the types are considered to be equally cv-qualified for partial ordering purposes. The result of this determination will be used below.

Remove any top-level cv-qualifiers:

— If P is a cv-qualified type, P is replaced by the cv-unqualified version of P.
— If A is a cv-qualified type, A is replaced by the cv-unqualified version of A.

Using the resulting types P and A the deduction is then done as described in 14.8.2.5. If deduction succeeds for a given type, the type from the argument template is considered to be at least as specialized as the type from the parameter template.

If, for a given type, deduction succeeds in both directions (i.e., the types are identical after the transformations above) and if the type from the argument template is more cv-qualified than the type from the parameter template (as described above) that type is considered to be more specialized than the other. If neither type is more cv-qualified than the other then neither type is more specialized than the other.

If for each type being considered a given template is at least as specialized for all types and more specialized for some set of types and the other template is not more specialized for any types or is not at least as specialized for any types, then the given template is more specialized than the other template. Otherwise, neither template is more specialized than the other.
11 In most cases, all template parameters must have values in order for deduction to succeed, but for partial ordering purposes a template parameter may remain without a value provided it is not used in the types being used for partial ordering. \[Note: a template parameter used in a non-deduced context is considered used. — end note\] \[Example:\]

```cpp
template <class T> T f(int); // #1
template <class T, class U> T f(U); // #2
void g () {
    f<int>(1); // Calls #1
}
— end example ]
```

### 14.8.2.5 Deducing template arguments from a type \[temp.deduct.type\]

1 Template arguments can be deduced in several different contexts, but in each case a type that is specified in terms of template parameters (call it \(P\)) is compared with an actual type (call it \(A\)), and an attempt is made to find template argument values (a type for a type parameter, a value for a non-type parameter, or a template for a template parameter) that will make \(P\), after substitution of the deduced values (call it the deduced \(A\)), compatible with \(A\).

2 In some cases, the deduction is done using a single set of types \(P\) and \(A\), in other cases, there will be a set of corresponding types \(P\) and \(A\). Type deduction is done independently for each \(P/A\) pair, and the deduced template argument values are then combined. If type deduction cannot be done for any \(P/A\) pair, or if for any pair the deduction leads to more than one possible set of deduced values, or if different pairs yield different deduced values, or if any template argument remains neither deduced nor explicitly specified, template argument deduction fails.

3 A given type \(P\) can be composed from a number of other types, templates, and non-type values:

   — A function type includes the types of each of the function parameters and the return type.

   — A pointer to member type includes the type of the class object pointed to and the type of the member pointed to.

   — A type that is a specialization of a class template (e.g., \(A<int>\)) includes the types, templates, and non-type values referenced by the template argument list of the specialization.

   — An array type includes the array element type and the value of the array bound.

4 In most cases, the types, templates, and non-type values that are used to compose \(P\) participate in template argument deduction. That is, they may be used to determine the value of a template argument, and the value so determined must be consistent with the values determined elsewhere. In certain contexts, however, the value does not participate in type deduction, but instead uses the values of template arguments that were either deduced elsewhere or explicitly specified. If a template parameter is used only in non-deduced contexts and is not explicitly specified, template argument deduction fails.

5 The non-deduced contexts are:

   — The `nested-name-specifier` of a type that was specified using a `qualified-id`.

   — A non-type template argument or an array bound that is an expression that references a template parameter.

   — A template parameter used in the parameter type of a function parameter that has a default argument that is being used in the call for which argument deduction is being done.
— A function parameter for which argument deduction cannot be done because the associated function argument is a function, or a set of overloaded functions (13.4), and one or more of the following apply:

— more than one function matches the function parameter type (resulting in an ambiguous deduction), or
— no function matches the function parameter type, or
— the set of functions supplied as an argument contains one or more function templates.

— An array bound that is an expression that references a template-parameter.

6 When a type name is specified in a way that includes a non-deduced context, all of the types that comprise that type name are also non-deduced. However, a compound type can include both deduced and non-deduced types. [Example: If a type is specified as \( A<T>::B<T2> \), both \( T \) and \( T2 \) are non-deduced. Likewise, if a type is specified as \( A\langle I+J\rangle::X<T>, I, J, \) and \( T \) are non-deduced. If a type is specified as \( \text{void } f(\text{typename } A<T>::B, A<T>) \), the \( T \) in \( A<T>::B \) is non-deduced but the \( T \) in \( A<T> \) is deduced. — end example]

7 [Example: Here is an example in which different parameter/argument pairs produce inconsistent template argument deductions:

```c
#include <iostream>

template <class T> void f(T x, T y) { /* ... */ }
struct A { /* ... */};
struct B : A { /* ... */};
int g(A a, B b)
{
    f(a,b); // error: T could be A or B
    f(b,a); // error: T could be A or B
    f(a,a); // OK: T is A
    f(b,b); // OK: T is B
}
```

Here is an example where two template arguments are deduced from a single function parameter/argument pair. This can lead to conflicts that cause type deduction to fail:

```c
#include <iostream>

template <class T, class U> void f( T (*)( T , U , U ) );

int g1( int , float , float );
char g2( int , float , float );
int g3( int , char , float );

void r()
{
    f(g1); // OK: T is int and U is float
    f(g2); // error: T could be char or int
    f(g3); // error: U could be char or float
}
```

Here is an example where a qualification conversion applies between the argument type on the function call and the deduced template argument type:

```c
#include <iostream>

template<class T> void f(const T*) {}
int *p;
```
Here is an example where the template argument is used to instantiate a derived class type of the corresponding function parameter type:

```cpp
template <class T> struct B { };
template <class T> struct D : public B<T> {}; struct D2 : public B<int> {}; template <class T> void f(B<T>&){} void t() {
    D<int> d; D2 d2; f(d); // calls f(B<int>&) f(d2); // calls f(B<int>&)
}
```

—end example—

A template type argument $T$, a template template argument $TT$ or a template non-type argument $i$ can be deduced if $P$ and $A$ have one of the following forms:

- $T$
- $cv$-list $T$
- $T$
- $T$
- $T$
- $T[integer-constant]
- $template-name<T>$ (where $template-name$ refers to a class template)
- $type(T)$
- $T()$
- $T(T)$
- $T type::*$
- $type T::*$
- $T T::*$
- $T (type::*())$
- $type (T::*())()$
- $type (type::*())(T)$
- $type (T::*())(T)$
- $T (type::*())(T)$
- $T (T::*())()$
- $T (T::*())(T)$
- $type[i]
- $template-name<i>$ (where $template-name$ refers to a class template)
- $TT<T>$
- $TT<i>$
- $TT<>$

where $(T)$ represents argument lists where at least one argument type contains a $T$, and $(\cdot)$ represents argument lists
where no parameter contains a \( T \). Similarly, \(<T>\) represents template argument lists where at least one argument contains a \( T \), \(<i>\) represents template argument lists where at least one argument contains an \( i \) and \(<>\) represents template argument lists where no argument contains a \( T \) or an \( i \).

These forms can be used in the same way as \( T \) is for further composition of types. [ Example: ]

\[
X<\text{int}> (*)\!(\text{char}\![6])
\]
is of the form

\[
\text{template-name}<T> (*)\!(\text{type}\![i])
\]

which is a variant of

\[
\text{type} (*)\!(T)
\]

where type is \( X<\text{int}> \) and \( T \) is \( \text{char}\![6] \). — end example 

Template arguments cannot be deduced from function arguments involving constructs other than the ones specified above.

A template type argument cannot be deduced from the type of a non-type \text{template-argument}.

[ Example: ]

\[
\text{template}<\text{class}\ T,\ T\ i> \text{ void } f(\text{double}\ a[10][i]);
\]

\[
\text{int } v[10][20];
\]

\[
f(v); \quad // \text{error: argument for template-parameter T cannot be deduced}
\]

— end example 

[ Note: except for reference and pointer types, a major array bound is not part of a function parameter type and cannot be deduced from an argument: ]

\[
\text{template}<\text{int}\ i> \text{ void } f1(\text{int}\ a[10][i]);
\]

\[
\text{template}<\text{int}\ i> \text{ void } f2(\text{int}\ a[i][20]);
\]

\[
\text{template}<\text{int}\ i> \text{ void } f3(\text{int}\ (& a)[i][20]);
\]

\[
\text{void } g()
\]

\[
\{\text{int } v[10][20];\text{\hspace{1cm}}// \text{OK: } i\text{ deduced to be } 20
\text{f1}(v);\text{\hspace{1cm}}// \text{OK}
\text{f1<20>}(v);\text{\hspace{1cm}}// \text{OK}
\text{f2}(v);\text{\hspace{1cm}}// \text{error: cannot deduce template-argument } i
\text{f2<10>}(v);\text{\hspace{1cm}}// \text{OK}
\text{f3}(v);\text{\hspace{1cm}}// \text{OK: } i\text{ deduced to be } 10
\}
\]

If, in the declaration of a function template with a non-type template parameter, the non-type template parameter is used in an expression in the function parameter list, the expression is a non-deduced context. [ Example: ]
template <int i> class A { /* ... */ };  

void g(A<i+1>); 

template <int i> void f(A<i>, A<i+1>); 

void k() { 
    A<1> a1; 
    A<2> a2; 
    g(a1);  // error: deduction fails for expression i+1 
    g<0>(a1);  // OK 
    f(a1, a2);  // OK 
} 

— end example — end note — end note ] [Note: template parameters do not participate in template argument deduction if they are used only in non-deduced contexts. For example,] 

template<int i, typename T>

T deduce(typename A<T>::X x,  // T is not deduced here
          T t,  // but T is deduced here
          typename B<i>::Y y);  // i is not deduced here 

A<int> a; 
B<77> b; 

int x = deduce<77>(a.xm, 62, y.ym);  // T is deduced to be int, a.xm must be convertible to
                                          // A<int>::X
                                          // i is explicitly specified to be 77, y.ym must be convertible
                                          // to B<77>::Y

— end note ]

If, in the declaration of a function template with a non-type template-parameter, the non-type template-parameter is used in an expression in the function parameter-list and, if the corresponding template-argument is deduced, the template-argument type shall match the type of the template-parameter exactly, except that a template-argument deduced from an array bound may be of any integral type. [137] [Example:]

template<int i> class A { /* ... */ };  

void k1() { 
    A<1> a; 
    f(a);  // error: deduction fails for conversion from int to short
    f<1>(a);  // OK 
} 

template<const short cs> class B { }; 

template<short s> void h(B<s>); 

void k2() { 
    B<1> b; 
    g(b);  // OK: cv-qualifiers are ignored on template parameter types 
} 

[137] Although the template-argument corresponding to a template-parameter of type bool may be deduced from an array bound, the resulting value will always be true because the array bound will be non-zero.

Draft
A template-argument can be deduced from a function, pointer to function, or pointer to member function type.

Example:

```cpp
template<class T> void f(void (*)(T, int));
template<class T> void foo(T, int);
void g(int, int);
void g(char, int);
void h(int, int, int);
void h(char, int);
int m()
{
    f(&g); // error: ambiguous
    f(&h); // OK: void h(char, int) is a unique match
    f(&foo); // error: type deduction fails because foo is a template
}
```

A template type-parameter cannot be deduced from the type of a function default argument. Example:

```cpp
template<class T> void f(T = 5, T = 7);
void g()
{
    f(1); // OK: call f<int>(1,7)
    f(); // error: cannot deduce T
    f<int>(); // OK: call f<int>(5,7)
}
```

The template-argument corresponding to a template template-parameter is deduced from the type of the template-argument of a class template specialization used in the argument list of a function call. Example:

```cpp
template<template<class T> class X> struct A { };
template<template<class T> class X> void f(A<X>); {}
template<class T> class X; void f(A<X>); {}
d template class T> struct B { };
A<B> ab;
f(ab); // calls f(A<B>)
```

Note: a default template-argument cannot be specified in a function template declaration or definition; therefore default template-arguments cannot be used to influence template argument deduction. — end note —

14.8.3 Overload resolution

A function template can be overloaded either by (non-template) functions of its name or by (other) function templates of the same name. When a call to that name is written (explicitly, or implicitly using the operator notation), template
argument deduction (14.8.2) and checking of any explicit template arguments (14.3) are performed for each function template to find the template argument values (if any) that can be used with that function template to instantiate a function template specialization that can be invoked with the call arguments. For each function template, if the argument deduction and checking succeeds, the template-arguments (deduced and/or explicit) are used to instantiate a single function template specialization which is added to the candidate functions set to be used in overload resolution. If, for a given function template, argument deduction fails, no such function is added to the set of candidate functions for that template. The complete set of candidate functions includes all the function templates instantiated in this way and all of the non-template overloaded functions of the same name. The function template specializations are treated like any other functions in the remainder of overload resolution, except as explicitly noted in 13.3.3.

[Example:

```cpp
template< class T > T max(T a, T b) { return a>b?a:b; }

void f(int a, int b, char c, char d)
{
    int m1 = max(a,b); // max(int a, int b)
    char m2 = max(c,d); // max(char a, char b)
    int m3 = max(a,c); // error: cannot generate max(int,char)
}
```

2 Adding the non-template function

```cpp
int max(int, int);
```

to the example above would resolve the third call, by providing a function that could be called for `max(a,c)` after using the standard conversion of `char` to `int` for `c`.

3 Here is an example involving conversions on a function argument involved in template-argument deduction:

```cpp
template< class T > struct B { /* ... */ };
-template< class T > struct D : public B<T> { /* ... */ };
-template< class T > void f(B<T>&);

void g(B<int>& bi , D<int>& di)
{
    f(bi); // f(bi)
    f(di); // f(B<int>&)di
}
```

4 Here is an example involving conversions on a function argument not involved in template-parameter deduction:

```cpp
template< class T > void f(T*, int); // #1
-template< class T > void f(T, char); // #2

void h(int* pi , int i , char c)
```

---

138) The parameters of function template specializations contain no template parameter types. The set of conversions allowed on deduced arguments is limited, because the argument deduction process produces function templates with parameters that either match the call arguments exactly or differ only in ways that can be bridged by the allowed limited conversions. Non-deduced arguments allow the full range of conversions. Note also that 13.3.3 specifies that a non-template function will be given preference over a template specialization if the two functions are otherwise equally good candidates for an overload match.
14.8 Function template specializations

{  
  f(pi,i); // #1: f<int>(pi,i)
  f(pi,c); // #2: f<int*>(pi,c)

  f(i,c); // #2: f<int>(i,c);
  f(i,i); // #2: f<int>(i,char(i))
}

— end example ]

5 Only the signature of a function template specialization is needed to enter the specialization in a set of candidate functions. Therefore only the function template declaration is needed to resolve a call for which a template specialization is a candidate. [ Example:

    template<class T> void f(T);  // declaration

    void g()
    {
      f("Annemarie"); // call of f<const char*>  
    }

6 The call of f is well-formed even if the template f is only declared and not defined at the point of the call. The program will be ill-formed unless a specialization for f<const char*>, either implicitly or explicitly generated, is present in some translation unit. — end example ]
Chapter 15  Exception handling

1 Exception handling provides a way of transferring control and information from a point in the execution of a program to an exception handler associated with a point previously passed by the execution. A handler will be invoked only by a throw-expression invoked in code executed in the handler’s try block or in functions called from the handler’s try block.

   try-block:
      try compound-statement handler-seq
   function-try-block:
      try ctor-initializer_opt function-body handler-seq
   handler-seq:
      handler handler-seq_opt
   handler:
      catch ( exception-declaration ) compound-statement
   exception-declaration:
      type-specifier-seq declarator
      type-specifier-seq abstract-declarator
      type-specifier-seq ...
   throw-expression:
      throw assignment-expression_opt

2 A try-block is a statement (clause 6). A throw-expression is of type void. Code that executes a throw-expression is said to “throw an exception;” code that subsequently gets control is called a “handler.” [Note: within this clause “try block” is taken to mean both try-block and function-try-block. — end note]

3 A goto or switch statement shall not be used to transfer control into a try block or into a handler. [Example:

   void f() {
      goto 11;       // Ill-formed
      goto 12;       // Ill-formed
      try {
         goto 11;     // OK
         goto 12;     // Ill-formed
      11: ;
      } catch (...) {
         12: ;
         goto 11;     // Ill-formed
         goto 12;     // OK
      }
15.1 Throwing an exception

A goto, break, return, or continue statement can be used to transfer control out of a try block or handler. When this happens, each variable declared in the try block will be destroyed in the context that directly contains its declaration. [Example:

```c
lab: try {
    T1 t1;
    try {
        T2 t2;
        if (condition)
            goto lab;
    } catch(...) { /* handler 2 */ }
} catch(...) { /* handler 1 */ }
```

Here, executing `goto lab;` will destroy first `t2`, then `t1`, assuming the `condition` does not declare a variable. Any exception raised while destroying `t2` will result in executing `handler 2`; any exception raised while destroying `t1` will result in executing `handler 1`. — end example]

4 A function-try-block associates a handler-seq with the ctor-initializer, if present, and the function-body. An exception thrown during the execution of the initializer expressions in the ctor-initializer or during the execution of the function-body transfers control to a handler in a function-try-block in the same way as an exception thrown during the execution of a try-block transfers control to other handlers. [Example:

```c
int f(int);
class C {
    int i;
    double d;
public:
    C(int , double);
};
C::C(int ii , double id)
try
    : i(f(ii)) , d(id)
{  // constructor function body
} catch(...) {
    // handles exceptions thrown from the ctor-initializer
    // and from the constructor function body
}
```

— end example]

15.1 Throwing an exception

Throwing an exception transfers control to a handler. An object is passed and the type of that object determines which handlers can catch it. [Example:
can be caught by a **handler** of `const char*` type:

```cpp
try {
    // ...
}
catch(const char* p) {
    // handle character string exceptions here
}
```

and

```cpp
class Overflow {
    // ...
public:
    Overflow(char, double, double);
};
void f(double x)
{
    // ...
    throw Overflow('+', x, 3.45e107);
}
```

can be caught by a handler for exceptions of type `Overflow`

```cpp
try {
    // ...
    f(1.2);
    // ...
}
catch(Overflow& oo) {
    // handle exceptions of type Overflow here
}
```

--- end example ---

2 When an exception is thrown, control is transferred to the nearest handler with a matching type (15.3); “nearest” means the handler for which the compound-statement, ctor-initializer, or function-body following the `try` keyword was most recently entered by the thread of control and not yet exited.

3 A **throw-expression** initializes a temporary object, called the **exception object**, the type of which is determined by removing any top-level `cv-qualifiers` from the static type of the operand of `throw` and adjusting the type from “array of T” or “function returning T” to “pointer to T” or “pointer to function returning T”, respectively. [Note: the temporary object created for a `throw-expression` that is a string literal is never of type `char*` or `wchar_t*`; that is, the special conversions for string literals from the types “array of const char” and “array of const wchar_t” to the types “pointer to char” and “pointer to wchar_t”, respectively (4.2), are never applied to a `throw-expression`. — end note ] The temporary is an lvalue and is used to initialize the variable named in the matching `handler` (15.3). The type of the `throw-expression` shall not be an incomplete type, or a pointer to an incomplete type other than (possibly `cv-qualified`) `void`. Except for...
these restrictions and the restrictions on type matching mentioned in 15.3, the operand of throw is treated exactly as a function argument in a call (5.2.2) or the operand of a return statement.

The memory for the temporary copy of the exception being thrown is allocated in an unspecified way, except as noted in 3.7.3.1. The temporary persists as long as there is a handler being executed for that exception. In particular, if a handler exits by executing a throw; statement, that passes control to another handler for the same exception, so the temporary remains. When the last remaining active handler for the exception exits by any means other than throw; the temporary object is destroyed and the implementation may dealloclote the memory for the temporary object; any such deallocation is done in an unspecified way. The destruction occurs immediately after the destruction of the object declared in the exception-declaration in the handler.

If the use of the temporary object can be eliminated without changing the meaning of the program except for the execution of constructors and destructors associated with the use of the temporary object (12.2), then the exception in the handler can be initialized directly with the argument of the throw expression. When the thrown object is a class object, and the copy constructor used to initialize the temporary copy is not accessible, the program is ill-formed (even when the temporary object could otherwise be eliminated). Similarly, if the destructor for that object is not accessible, the program is ill-formed (even when the temporary object could otherwise be eliminated).

An exception is considered caught when a handler for that exception becomes active (15.3). [Note: an exception can have active handlers and still be considered uncaught if it is rethrown. —end note]

A throw-expression with no operand rethrows the currently handled exception (15.3). The exception is reactivated with the existing temporary; no new temporary exception object is created. The exception is no longer considered to be caught; therefore, the value of std::uncaught_exception() will again be true. [Example: code that must be executed because of an exception yet cannot completely handle the exception can be written like this:

```cpp
try {
    // ...
}
catch (...) {
    // catch all exceptions
    // respond (partially) to exception
    throw;  // pass the exception to some
            // other handler
}
```

—end example]

If no exception is presently being handled, executing a throw-expression with no operand calls std::terminate() (15.5.1).

15.2 Constructors and destructors [exceptctor]

As control passes from a throw-expression to a handler, destructors are invoked for all automatic objects constructed since the try block was entered. The automatic objects are destroyed in the reverse order of the completion of their construction.

An object that is partially constructed or partially destroyed will have destructors executed for all of its fully constructed subobjects, that is, for subobjects for which the constructor has completed execution and the destructor has not yet begun execution. Should a constructor for an element of an automatic array throw an exception, only the constructed elements of that array will be destroyed. If the object or array was allocated in a new-expression, the matching deallocation function (3.7.3.2, 5.3.4, 12.5), if any, is called to free the storage occupied by the object.
The process of calling destructors for automatic objects constructed on the path from a try block to a throw-expression is called “stack unwinding.” [Note: If a destructor called during stack unwinding exits with an exception, std::terminate is called (15.5.1). So destructors should generally catch exceptions and not let them propagate out of the destructor. — end note]

15.3 Handling an exception [except.handle]

1 The exception-declaration in a handler describes the type(s) of exceptions that can cause that handler to be entered. The exception-declaration shall not denote an incomplete type. The exception-declaration shall not denote a pointer or reference to an incomplete type, other than void*, const void*, volatile void*, or const volatile void*. Types shall not be defined in an exception-declaration.

2 A handler of type “array of T” or “function returning T” is adjusted to be of type “pointer to T” or “pointer to function returning T”, respectively.

3 A handler is a match for an exception object of type E if

- The handler is of type cv T or cv T& and E and T are the same type (ignoring the top-level cv-qualifiers), or
- the handler is of type cv T or cv T& and T is an unambiguous public base class of E, or
- the handler is of type cv1 T* cv2 and E is a pointer type that can be converted to the type of the handler by either or both of
  - a standard pointer conversion (4.10) not involving conversions to pointers to private or protected or ambiguous classes
  - a qualification conversion

[Note: A throw-expression which is an integral constant expression of integer type that evaluates to zero does not match a handler of pointer type; that is, the null pointer constant conversions (4.10, 4.11) do not apply. — end note]

[Example:

```cpp
class Matherr { /* ... */ virtual vf(); }; 
class Overflow: public Matherr { /* ... */ }; 
class Underflow: public Matherr { /* ... */ }; 
class Zerodivide: public Matherr { /* ... */ }; 

void f()
{
  try {
    g();
  }
  catch (Overflow oo) {
    // ...
  }
  catch (Matherr mm) {
    // ...
  }
}
```
]
Here, the **Overflow** handler will catch exceptions of type **Overflow** and the **Matherr** handler will catch exceptions of type **Matherr** and of all types publicly derived from **Matherr** including exceptions of type **Underflow** and **Zerodivide**. — end example]

4 The handlers for a try block are tried in order of appearance. That makes it possible to write handlers that can never be executed, for example by placing a handler for a derived class after a handler for a corresponding base class.

5 A ... in a handler’s exception-declaration functions similarly to ... in a function parameter declaration; it specifies a match for any exception. If present, a ... handler shall be the last handler for its try block.

6 If no match is found among the handlers for a try block, the search for a matching handler continues in a dynamically surrounding try block.

7 A handler is considered active when initialization is complete for the formal parameter (if any) of the catch clause. [ Note: the stack will have been unwound at that point. — end note ] Also, an implicit handler is considered active when std::terminate() or std::unexpected() is entered due to a throw. A handler is no longer considered active when the catch clause exits or when std::unexpected() exits after being entered due to a throw.

8 The exception with the most recently activated handler that is still active is called the currently handled exception.

9 If no matching handler is found in a program, the function std::terminate() is called; whether or not the stack is unwound before this call to std::terminate() is implementation-defined (15.5.1).

10 Referring to any non-static member or base class of an object in the handler for a function-try-block of a constructor or destructor for that object results in undefined behavior.

11 The fully constructed base classes and members of an object shall be destroyed before entering the handler of a function-try-block of a constructor or destructor for that object.

12 The scope and lifetime of the parameters of a function or constructor extend into the handlers of a function-try-block.

13 Exceptions thrown in destructors of objects with static storage duration or in constructors of namespace-scope objects are not caught by a function-try-block on main().

14 If a return statement appears in a handler of the function-try-block of a constructor, the program is ill-formed.

15 The currently handled exception is rethrown if control reaches the end of a handler of the function-try-block of a constructor or destructor. Otherwise, a function returns when control reaches the end of a handler for the function-try-block (6.6.3). Flowing off the end of a function-try-block is equivalent to a return with no value; this results in undefined behavior in a value-returning function (6.6.3).

16 When the exception-declaration specifies a class type, a copy constructor is used to initialize either the object declared in the exception-declaration or, if the exception-declaration does not specify a name, a temporary object of that type. The object shall not have an abstract class type. The object is destroyed when the handler exits, after the destruction of any automatic objects initialized within the handler. The copy constructor and destructor shall be accessible in the context of the handler. If the copy constructor and destructor are implicitly declared (12.8), such a use in the handler causes these functions to be implicitly defined; otherwise, the program shall provide a definition for these functions.

17 If the use of a temporary object can be eliminated without changing the meaning of the program except for execution of constructors and destructors associated with the use of the temporary object, then the optional name
can be bound directly to the temporary object specified in a *throw-expression* causing the handler to be executed. The copy constructor and destructor associated with the object shall be accessible even when the temporary object is eliminated.

When the handler declares a non-constant object, any changes to that object will not affect the temporary object that was initialized by execution of the *throw-expression*. When the handler declares a reference to a non-constant object, any changes to the referenced object are changes to the temporary object initialized when the *throw-expression* was executed and will have effect should that object be rethrown.

15.4 Exception specifications

A function declaration lists exceptions that its function might directly or indirectly throw by using an *exception-specification* as a suffix of its declarator.

```
exception-specification:
   throw ( type-id-listopt )
```

```
type-id-list:
   type-id
   type-id-list , type-id
```

An *exception-specification* shall appear only on a function declarator for a function type, pointer to function type, reference to function type, or pointer to member function type that is the top-level type of a declaration or definition, or on such a type appearing as a parameter or return type in a function declarator. An *exception-specification* shall not appear in a typedef declaration. [Example:

```
void f() throw(int);          // OK
void (*fp)() throw (int);     // OK
void g(void pfa() throw (int)); // OK
typedef int (*pf)() throw(int); // ill-formed
```

— end example ] A type denoted in an *exception-specification* shall not denote a pointer or reference to an incomplete type, other than void*, const void*, volatile void*, or const volatile void*.

If any declaration of a function has an *exception-specification*, all declarations, including the definition and an explicit specialization, of that function shall have an *exception-specification* with the same set of *type-ids*. If any declaration of a pointer to function, reference to function, or pointer to member function has an *exception-specification*, all occurrences of that declaration shall have an *exception-specification* with the same set of *type-ids*. In an explicit instantiation directive an *exception-specification* may be specified, but is not required. If an *exception-specification* is specified in an explicit instantiation directive, it shall have the same set of *type-ids* as other declarations of that function. A diagnostic is required only if the sets of *type-ids* are different within a single translation unit.

If a virtual function has an *exception-specification*, all declarations, including the definition, of any function that overrides that virtual function in any derived class shall only allow exceptions that are allowed by the *exception-specification* of the base class virtual function. [Example:

```
struct B {
   virtual void f() throw (int, double);
   virtual void g();
};
```

Draft
The declaration of D::f is ill-formed because it allows all exceptions, whereas B::f allows only int and double.

--- end example ---

A similar restriction applies to assignment to and initialization of pointers to functions, pointers to member functions, and references to functions: the target entity shall allow at least the exceptions allowed by the source value in the assignment or initialization. [Example:

```cpp
class A { /* ... */ };  // no exception specification
void (*pf1)();
void (*pf2)() throw (A);

define f()
{
    pf1 = pf2;  // OK: pf1 is less restrictive
    pf2 = pf1;  // error: pf2 is more restrictive
}

--- end example ---
```

In such an assignment or initialization, exception-specifications on return types and parameter types shall match exactly. In other assignments or initializations, exception-specifications shall match exactly.

5 Types shall not be defined in exception-specifications.

6 An exception-specification can include the same type more than once and can include classes that are related by inheritance, even though doing so is redundant. An exception-specification can also include the class std::bad_exception (18.6.2.1).

7 A function is said to allow an exception of type E if its exception-specification contains a type T for which a handler of type T would be a match (15.3) for an exception of type E.

8 Whenever an exception is thrown and the search for a handler (15.3) encounters the outermost block of a function with an exception-specification, the function std::unexpected() is called (15.5.2) if the exception-specification does not allow the exception. [Example:

```cpp
class X { };  // OK
class Y { };  // also OK
class Z: public X { };  // will call std::unexpected()

class W { };  // will call std::unexpected()
void f() throw (X, Y)
{
    int n = 0;
    if (n) throw X();
    if (n) throw Z();
    throw W();
}
```

--- end example ---
The function `std::unexpected()` may throw an exception that will satisfy the `exception-specification` for which it was invoked, and in this case the search for another handler will continue at the call of the function with this `exception-specification` (see Clause 15.5.2), or it may call `std::terminate()`.

An implementation shall not reject an expression merely because when executed it throws or might throw an exception that the containing function does not allow. [Example:

```cpp
extern void f() throw(X, Y);

void g() throw(X)
{
    f();  // OK
}
```

the call to `f` is well-formed even though when called, `f` might throw exception `Y` that `g` does not allow. — end example]

A function with no `exception-specification` allows all exceptions. A function with an empty `exception-specification`, `throw()`, does not allow any exceptions.

An `exception-specification` is not considered part of a function’s type.

An implicitly declared special member function (Clause 12) shall have an `exception-specification`. If `f` is an implicitly declared default constructor, copy constructor, destructor, or copy assignment operator, its implicit `exception-specification` specifies the type-id `T` if and only if `T` is allowed by the `exception-specification` of a function directly invoked by `f`’s implicit definition; `f` shall allow all exceptions if any function it directly invokes allows all exceptions, and `f` shall allow no exceptions if every function it directly invokes allows no exceptions. [Example:

```cpp
struct A {
    A();
    A(const A&) throw();
    ~A() throw(X);
};
struct B {
    B() throw();
    B(const B&) throw();
    ~B() throw(Y);
};
struct D : public A, public B {
    // Implicit declaration of D::D();
    // Implicit declaration of D::D(const D&) throw();
    // Implicit declaration of D::~D() throw(X,Y);
};
```

Furthermore, if `A::~A()` or `B::~B()` were virtual, `D::~D()` would not be as restrictive as that of `A::~A`, and the program would be ill-formed since a function that overrides a virtual function from a base class shall have an `exception-specification` at least as restrictive as that in the base class. — end example]

15.5 Special functions [except.special]

The exception handling mechanism relies on two functions, `std::terminate()` and `std::unexpected()`, for coping
15.5 Special functions

with errors related to the exception handling mechanism itself (18.6).

15.5.1 The std::terminate() function

In the following situations exception handling must be abandoned for less subtle error handling techniques:

— when the exception handling mechanism, after completing evaluation of the expression to be thrown but before the exception is caught (15.1), calls a user function that exits via an uncaught exception,\(^{139}\)

— when the exception handling mechanism cannot find a handler for a thrown exception (15.3), or

— when the destruction of an object during stack unwinding (15.2) exits using an exception, or

— when construction or destruction of a non-local object with static storage duration exits using an exception (3.6.2), or

— when execution of a function registered with std::atexit exits using an exception (18.3), or

— when a throw-expression with no operand attempts to rethrow an exception and no exception is being handled (15.1), or

— when std::unexpected throws an exception which is not allowed by the previously violated exception-specification, and std::bad_exception is not included in that exception-specification (15.5.2), or

— when the implementation’s default unexpected exception handler is called (18.6.2.2)

In such cases, std::terminate() is called (18.6.3). In the situation where no matching handler is found, it is implementation-defined whether or not the stack is unwound before std::terminate() is called. In all other situations, the stack shall not be unwound before std::terminate() is called. An implementation is not permitted to finish stack unwinding prematurely based on a determination that the unwind process will eventually cause a call to std::terminate().

15.5.2 The std::unexpected() function

1 If a function with an exception-specification throws an exception that is not listed in the exception-specification, the function std::unexpected() is called (18.6.2) immediately after completing the stack unwinding for the former function.

2 The std::unexpected() function shall not return, but it can throw (or re-throw) an exception. If it throws a new exception which is allowed by the exception specification which previously was violated, then the search for another handler will continue at the call of the function whose exception specification was violated. If it throws or rethrows an exception that the exception-specification does not allow then the following happens: If the exception-specification does not include the class std::bad_exception (18.6.2.1) then the function std::terminate() is called, otherwise the thrown exception is replaced by an implementation-defined object of the type std::bad_exception and the search for another handler will continue at the call of the function whose exception-specification was violated.

3 Thus, an exception-specification guarantees that only the listed exceptions will be thrown. If the exception-specification includes the type std::bad_exception then any exception not on the list may be replaced by std::bad_exception.

\(^{139}\) For example, if the object being thrown is of a class with a copy constructor, std::terminate() will be called if that copy constructor exits with an exception during a throw.
within the function `std::unexpected()`.

15.5.3 The `std::uncaught_exception()` function

The function `std::uncaught_exception()` returns `true` after completing evaluation of the object to be thrown until completing the initialization of the `exception-declaration` in the matching handler (18.6.4). This includes stack unwinding. If the exception is rethrown (15.1), `std::uncaught_exception()` returns `true` from the point of rethrow until the rethrown exception is caught again.

15.6 Exceptions and access

If the `exception-declaration` in a catch clause has class type, and the function in which the catch clause occurs does not have access to the destructor of that class, the program is ill-formed.

An object can be thrown if it can be copied and destroyed in the context of the function in which the `throw-expression` occurs.
Chapter 16  Preprocessing directives

A preprocessing directive consists of a sequence of preprocessing tokens. The first token in the sequence is a \# preprocessing token that is either the first character in the source file (optionally after white space containing no new-line characters) or that follows white space containing at least one new-line character. The last token in the sequence is the first new-line character that follows the first token in the sequence.\textsuperscript{140)

```
preprocessing-file:
group\textsubscript{opt}

group:
group-part

group-part:
 pp-tokens\textsubscript{opt} new-line
 if-section
 control-line

if-section:
 if-group elif-groups\textsubscript{opt} else-group\textsubscript{opt} endif-line

if-group:
 # if constant-expression new-line group\textsubscript{opt}
 # ifdef identifier new-line group\textsubscript{opt}
 # ifndef identifier new-line group\textsubscript{opt}

elif-groups:
 elif-group
 elif-groups elif-group

elif-group:
 # elif constant-expression new-line group\textsubscript{opt}

else-group:
 # else new-line group\textsubscript{opt}

endif-line:
 # endif new-line
```

\textsuperscript{140}) Thus, preprocessing directives are commonly called “lines.” These “lines” have no other syntactic significance, as all white space is equivalent except in certain situations during preprocessing (see the \# character string literal creation operator in 16.3.2, for example).
16.1 Conditional inclusion

control-line:

# include    pp-tokens new-line
# define     identifier replacement-list new-line
# define     identifier lparen identifier-list opt ) replacement-list new-line
# undef      identifier new-line
# line       pp-tokens new-line
# error      pp-tokens opt new-line
# pragma     pp-tokens opt new-line
# new-line

lparen:
the left-parenthesis character without preceding white-space

identifier-list:
identifier
identifier-list , identifier

replacement-list:
pp-tokens opt

pp-tokens:
preprocessing-token
pp-tokens preprocessing-token

new-line:
the new-line character

2 The only white-space characters that shall appear between preprocessing tokens within a preprocessing directive (from just after the introducing # preprocessing token through just before the terminating new-line character) are space and horizontal-tab (including spaces that have replaced comments or possibly other white-space characters in translation phase 3).

3 The implementation can process and skip sections of source files conditionally, include other source files, and replace macros. These capabilities are called preprocessing, because conceptually they occur before translation of the resulting translation unit.

4 The preprocessing tokens within a preprocessing directive are not subject to macro expansion unless otherwise stated.

16.1 Conditional inclusion [cpp.cond]

1 The expression that controls conditional inclusion shall be an integral constant expression except that: it shall not contain a cast; identifiers (including those lexically identical to keywords) are interpreted as described below,\footnote{Because the controlling constant expression is evaluated during translation phase 4, all identifiers either are or are not macro names — there simply are no keywords, enumeration constants, and so on.} and it may contain unary operator expressions of the form

\[
\text{defined identifier} \quad \text{or} \quad \text{defined ( identifier )}
\]

which evaluate to 1 if the identifier is currently defined as a macro name (that is, if it is predefined or if it has been the subject of a \#define preprocessing directive without an intervening \#undef directive with the same subject identifier), zero if it is not.

2 Each preprocessing token that remains after all macro replacements have occurred shall be in the lexical form of a token (2.6).
Preprocessing directives of the forms

```plaintext
# if constant-expression new-line group_opt
# endif
# else
```

check whether the controlling constant expression evaluates to nonzero.

Prior to evaluation, macro invocations in the list of preprocessing tokens that will become the controlling constant expression are replaced (except for those macro names modified by the `defined` unary operator), just as in normal text. If the token `defined` is generated as a result of this replacement process or use of the `defined` unary operator does not match one of the two specified forms prior to macro replacement, the behavior is undefined. After all replacements due to macro expansion and the `defined` unary operator have been performed, all remaining identifiers and keywords, except for `true` and `false`, are replaced with the pp-number 0, and then each preprocessing token is converted into a token. The resulting tokens comprise the controlling constant expression which is evaluated according to the rules of 5.19 using arithmetic that has at least the ranges specified in 18.2, except that `int` and `unsigned int` act as if they have the same representation as, respectively, `long` and `unsigned long`. This includes interpreting character literals, which may involve converting escape sequences into execution character set members. Whether the numeric value for these character literals matches the value obtained when an identical character literal occurs in an expression (other than within a `#if` or `#elif` directive) is implementation-defined. Also, whether a single-character character literal may have a negative value is implementation-defined. Each subexpression with type `bool` is subjected to integral promotion before processing continues.

Preprocessing directives of the forms

```plaintext
# ifndef identifier new-line group_opt
# if defined identifier
# ifndef identifier new-line group_opt
# ifdef identifier new-line group_opt
```

check whether the identifier is or is not currently defined as a macro name. Their conditions are equivalent to `#if defined identifier` and `#if !defined identifier` respectively.

Each directive’s condition is checked in order. If it evaluates to false (zero), the group that it controls is skipped; directives are processed only through the name that determines the directive in order to keep track of the level of nested conditionals; the rest of the directives’ preprocessing tokens are ignored, as are the other preprocessing tokens in the group. Only the first group whose control condition evaluates to true (nonzero) is processed. If none of the conditions evaluates to true, and there is a `#else` directive, the group controlled by the `#else` is processed; lacking a `#else` directive, all the groups until the `#endif` are skipped.

### 16.2 Source file inclusion

A `#include` directive shall identify a header or source file that can be processed by the implementation.

A preprocessing directive of the form

```plaintext
# include <h-char-sequence> new-line
```

[cpp.include]

[142] An alternative token (2.5) is not an identifier, even when its spelling consists entirely of letters and underscores. Therefore it is not subject to this replacement.

[143] Thus, the constant expression in the following `#if` directive and `if` statement is not guaranteed to evaluate to the same value in these two contexts.

```plaintext
# if 'z' - 'a' == 25
if ('z' - 'a' == 25)
```

[144] As indicated by the syntax, a preprocessing token shall not follow a `#else` or `#endif` directive before the terminating new-line character. However, comments may appear anywhere in a source file, including within a preprocessing directive.
searches a sequence of implementation-defined places for a header identified uniquely by the specified sequence between the `<` and `>` delimiters, and causes the replacement of that directive by the entire contents of the header. How the places are specified or the header identified is implementation-defined.

3 A preprocessing directive of the form

```
#include "q-char-sequence" new-line
```

causes the replacement of that directive by the entire contents of the source file identified by the specified sequence between the `"` delimiters. The named source file is searched for in an implementation-defined manner. If this search is not supported, or if the search fails, the directive is reprocessed as if it read

```
#include <b-char-sequence> new-line
```

with the identical contained sequence (including `>` characters, if any) from the original directive.

4 A preprocessing directive of the form

```
#include pp-tokens new-line
```

(that does not match one of the two previous forms) is permitted. The preprocessing tokens after `include` in the directive are processed just as in normal text (each identifier currently defined as a macro name is replaced by its replacement list of preprocessing tokens). If the directive resulting after all replacements does not match one of the two previous forms, the behavior is undefined.\(^{145}\) The method by which a sequence of preprocessing tokens between a `<` and a `>` preprocessing token pair or a pair of `"` characters is combined into a single header name preprocessing token is implementation-defined.

5 The mapping between the delimited sequence and the external source file name is implementation-defined. The implementation provides unique mappings for sequences consisting of one or more `nondigit` (2.10) followed by a period (\.) and a single `nondigit`. The implementation may ignore the distinctions of alphabetical case.

6 A `#include` preprocessing directive may appear in a source file that has been read because of a `#include` directive in another file, up to an implementation-defined nesting limit.

[Example: The most common uses of `#include` preprocessing directives are as in the following:

```c
#include <stdio.h>
#include "myprog.h"
```

— end example ]

[Example: Here is a macro-replaced `#include` directive:

```c
#if VERSION == 1
  #define INCFILE "vers1.h"
#elif VERSION == 2
  #define INCFILE "vers2.h" /* and so on */
#else
  #define INCFILE "versN.h"
#endif
#include INCFILE
```

\(^{145}\) Note that adjacent string literals are not concatenated into a single string literal (see the translation phases in 2.1); thus, an expansion that results in two string literals is an invalid directive.

Draft
16.3 Macro replacement

Two replacement lists are identical if and only if the preprocessing tokens in both have the same number, ordering, spelling, and white-space separation, where all white-space separations are considered identical.

An identifier currently defined as a macro without use of lparen (an object-like macro) may be redefined by another #define preprocessing directive provided that the second definition is an object-like macro definition and the two replacement lists are identical, otherwise the program is ill-formed.

An identifier currently defined as a macro using lparen (a function-like macro) may be redefined by another #define preprocessing directive provided that the second definition is a function-like macro definition that has the same number and spelling of parameters, and the two replacement lists are identical, otherwise the program is ill-formed.

The number of arguments in an invocation of a function-like macro shall agree with the number of parameters in the macro definition, and there shall exist a ) preprocessing token that terminates the invocation.

A parameter identifier in a function-like macro shall be uniquely declared within its scope.

The identifier immediately following the define is called the macro name. There is one name space for macro names. Any white-space characters preceding or following the replacement list of preprocessing tokens are not considered part of the replacement list for either form of macro.

If a # preprocessing token, followed by an identifier, occurs lexically at the point at which a preprocessing directive could begin, the identifier is not subject to macro replacement.

A preprocessing directive of the form

```
#define identifier replacement-list new-line
```

defines an object-like macro that causes each subsequent instance of the macro name to be replaced by the replacement list of preprocessing tokens that constitute the remainder of the directive. The replacement list is then rescanned for more macro names as specified below.

A preprocessing directive of the form

```
#define identifier lparen identifier-list opt ) replacement-list new-line
```

defines a function-like macro with parameters, similar syntactically to a function call. The parameters are specified by the optional list of identifiers, whose scope extends from their declaration in the identifier list until the new-line character that terminates the #define preprocessing directive. Each subsequent instance of the function-like macro name followed by a ( as the next preprocessing token introduces the sequence of preprocessing tokens that is replaced by the replacement list in the definition (an invocation of the macro). The replaced sequence of preprocessing tokens is terminated by the matching ) preprocessing token, skipping intervening matched pairs of left and right parenthesis preprocessing tokens. Within the sequence of preprocessing tokens making up an invocation of a function-like macro, new-line is considered a normal white-space character.

---

146) Since, by macro-replacement time, all character literals and string literals are preprocessing tokens, not sequences possibly containing identifier-like subsequences (see 2.1.1.2, translation phases), they are never scanned for macro names or parameters.

147) An alternative token (2.5) is not an identifier, even when its spelling consists entirely of letters and underscores. Therefore it is not possible to define a macro whose name is the same as that of an alternative token.
16.3 Macro replacement

The sequence of preprocessing tokens bounded by the outside-most matching parentheses forms the list of arguments for the function-like macro. The individual arguments within the list are separated by comma preprocessing tokens, but comma preprocessing tokens between matching inner parentheses do not separate arguments. If (before argument substitution) any argument consists of no preprocessing tokens, the behavior is undefined. If there are sequences of preprocessing tokens within the list of arguments that would otherwise act as preprocessing directives, the behavior is undefined.

16.3.1 Argument substitution

After the arguments for the invocation of a function-like macro have been identified, argument substitution takes place. A parameter in the replacement list, unless preceded by a # or ## preprocessing token or followed by a ## preprocessing token (see below), is replaced by the corresponding argument after all macros contained therein have been expanded. Before being substituted, each argument’s preprocessing tokens are completely macro replaced as if they formed the rest of the translation unit; no other preprocessing tokens are available.

16.3.2 The # operator

Each # preprocessing token in the replacement list for a function-like macro shall be followed by a parameter as the next preprocessing token in the replacement list.

If, in the replacement list, a parameter is immediately preceded by a # preprocessing token, both are replaced by a single character string literal preprocessing token that contains the spelling of the preprocessing token sequence for the corresponding argument. Each occurrence of white space between the argument’s preprocessing tokens becomes a single space character in the character string literal. White space before the first preprocessing token and after the last preprocessing token comprising the argument is deleted. Otherwise, the original spelling of each preprocessing token in the argument is retained in the character string literal, except for special handling for producing the spelling of string literals and character literals: a \ character is inserted before each " and \ character of a character literal or string literal (including the delimiting " characters). If the replacement that results is not a valid character string literal, the behavior is undefined. The order of evaluation of # and ## operators is unspecified.

16.3.3 The ## operator

A ## preprocessing token shall not occur at the beginning or at the end of a replacement list for either form of macro definition.

If, in the replacement list, a parameter is immediately preceded or followed by a ## preprocessing token, the parameter is replaced by the corresponding argument’s preprocessing token sequence.

For both object-like and function-like macro invocations, before the replacement list is reexamined for more macro names to replace, each instance of a ## preprocessing token in the replacement list (not from an argument) is deleted and the preceding preprocessing token is concatenated with the following preprocessing token. If the result is not a valid preprocessing token, the behavior is undefined. The resulting token is available for further macro replacement. The order of evaluation of ## operators is unspecified.

16.3.4 Rescanning and further replacement

After all parameters in the replacement list have been substituted, the resulting preprocessing token sequence is rescanned with all subsequent preprocessing tokens of the source file for more macro names to replace.

If the name of the macro being replaced is found during this scan of the replacement list (not including the rest of the source file’s preprocessing tokens), it is not replaced. Further, if any nested replacements encounter the name of the
macro being replaced, it is not replaced. These nonreplaced macro name preprocessing tokens are no longer available for further replacement even if they are later (re)examined in contexts in which that macro name preprocessing token would otherwise have been replaced.

3 The resulting completely macro-replaced preprocessing token sequence is not processed as a preprocessing directive even if it resembles one.

16.3.5 Scope of macro definitions [cpp.scope]

A macro definition lasts (independent of block structure) until a corresponding \#undef directive is encountered or (if none is encountered) until the end of the translation unit.

A preprocessing directive of the form

\# undef identifier new-line

causes the specified identifier no longer to be defined as a macro name. It is ignored if the specified identifier is not currently defined as a macro name.

[Note: The simplest use of this facility is to define a “manifest constant,” as in

\#define TABSIZE 100
int table[TABSIZE];

The following defines a function-like macro whose value is the maximum of its arguments. It has the advantages of working for any compatible types of the arguments and of generating in-line code without the overhead of function calling. It has the disadvantages of evaluating one or the other of its arguments a second time (including side effects) and generating more code than a function if invoked several times. It also cannot have its address taken, as it has none.

\#define max(a, b) ((a) > (b) ? (a) : (b))

The parentheses ensure that the arguments and the resulting expression are bound properly.

To illustrate the rules for redefinition and reexamination, the sequence

\#define x 3
\#define f(a) f(x * (a))
\#undef x
\#define x 2
\#define g f
\#define z z[0]
\#define h g(~
\#define m(a) a(w)
\#define w 0,1
\#define t(a) a

f(y+1) + f(f(z)) % t(g(0) + t)(1);
g(x+(3,4)-w) | h 5) & m
(f) ^ m(m);

results in

f(2 * (y+1)) + f(2 * (f(2 * (z[0])))) % f(2 * (0)) + t(1);
f(2 * (2+(3,4)-0,1)) | f(2 * (~5)) & f(2 * (0,1)) ` m(0,1);
Draft
To illustrate the rules for creating character string literals and concatenating tokens, the sequence

```c
#define str(s) #s
#define xstr(s) str(s)
#define debug(s, t) printf("x" # s " = %d, x" # t " = %s", \ 
    x ## s, x ## t)
#define INCFILE(n) vers ## n /* from previous #include example */
#define glue(a, b) a ## b
#define xglue(a, b) glue(a, b)
#define HIGHLOW "hello"
#define LOW LOW " , world"

debug(1, 2);

fputs(str(strncmp(" abc\0d", " abc", '\4') == 0) str(@
    str(: @
    #include xstr(INCFILE(2).h)

    glue(HIGH, LOW);
    xglue(HIGH, LOW)

results in

    printf("x" "1" " = %d, x" "2" " = %s", x1, x2);
fputs("strncpy("abc\0d", "abc", '\4') == 0" : @
    str(: @
    #include "vers2.h" (after macro replacement, before file access)

    "hello";
    "hello", world"

or, after concatenation of the character string literals,

    printf("x1= %d, x2= %s", x1, x2);
fputs("strncpy("abc\0d", "abc", '\4') == 0" : @
    str(: @
    #include "vers2.h" (after macro replacement, before file access)

    "hello";
    "hello, world"

Space around the # and ## tokens in the macro definition is optional.

And finally, to demonstrate the redefinition rules, the following sequence is valid.

```c
#define OBJ_LIKE (1-1)
#define OBJ_LIKE /* white space */(1-1)/* other */
#define FTN_LIKE(a) ( a )
#define FTN_LIKE(a) /* note the white space */
    /* other stuff on this line */

9 But the following redefinitions are invalid:

```c
#define OBJ_LIKE (0) /* different token sequence */
#define OBJ_LIKE (1 - 1) /* different white space */
#define FTN_LIKE(b) ( a ) /* different parameter usage */
#define FTN_LIKE(b) ( b ) /* different parameter spelling */

Draft
16.4 Line control

The string literal of a `#line` directive, if present, shall be a character string literal.

The line number of the current source line is one greater than the number of new-line characters read or introduced in translation phase 1 (2.1) while processing the source file to the current token.

A preprocessing directive of the form

```
# line digit-sequence new-line
```

causes the implementation to behave as if the following sequence of source lines begins with a source line that has a line number as specified by the digit sequence (interpreted as a decimal integer). If the digit sequence specifies zero or a number greater than 32767, the behavior is undefined.

A preprocessing directive of the form

```
# line digit-sequence " s-char-sequence opt " new-line
```

sets the line number similarly and changes the presumed name of the source file to be the contents of the character string literal.

A preprocessing directive of the form

```
# line pp-tokens new-line
```

(that does not match one of the two previous forms) is permitted. The preprocessing tokens after `line` on the directive are processed just as in normal text (each identifier currently defined as a macro name is replaced by its replacement list of preprocessing tokens). If the directive resulting after all replacements does not match one of the two previous forms, the behavior is undefined; otherwise, the result is processed as appropriate.

16.5 Error directive

A preprocessing directive of the form

```
# error pp-tokens opt new-line
```

causes the implementation to produce a diagnostic message that includes the specified sequence of preprocessing tokens, and renders the program ill-formed.

16.6 Pragma directive

A preprocessing directive of the form

```
# pragma pp-tokens opt new-line
```

causes the implementation to behave in an implementation-defined manner. Any pragma that is not recognized by the implementation is ignored.

16.7 Null directive

A preprocessing directive of the form

```
# new-line
```
16.8 Predefined macro names

The following macro names shall be defined by the implementation:

- **_ _ LINE _ _**
  The line number of the current source line (a decimal constant).

- **_ _ FILE _ _**
  The presumed name of the source file (a character string literal).

- **_ _ DATE _ _**
  The date of translation of the source file (a character string literal of the form "Mmm dd yyyy", where the names of the months are the same as those generated by the `asctime` function, and the first character of `dd` is a space character if the value is less than 10). If the date of translation is not available, an implementation-defined valid date is supplied.

- **_ _ TIME _ _**
  The time of translation of the source file (a character string literal of the form "hh:mm:ss" as in the time generated by the `asctime` function). If the time of translation is not available, an implementation-defined valid time is supplied.

- **_ _ STDC _ _**
  Whether _ _ STDC _ _ is predefined and if so, what its value is, are implementation-defined.

- **_ _ cplusplus**
  The name _ _ cplusplus is defined to the value [tbd] when compiling a C++ translation unit.

The values of the predefined macros (except for _ _ LINE _ _ and _ _ FILE _ _) remain constant throughout the translation unit.

If any of the pre-defined macro names in this subclause, or the identifier `defined`, is the subject of a `#define` or a `#undef` preprocessing directive, the behavior is undefined.

---

168) It is intended that future versions of this standard will replace the value of this macro with a greater value. Non-conforming compilers should use a value with at most five decimal digits.

Draft
Chapter 17  Library introduction  [lib.library]

This clause describes the contents of the C++ Standard Library, how a well-formed C++ program makes use of the library, and how a conforming implementation may provide the entities in the library.

The C++ Standard Library provides an extensible framework, and contains components for: language support, diagnostics, general utilities, strings, locales, containers, iterators, algorithms, numerics, and input/output. The language support components are required by certain parts of the C++ language, such as memory allocation (5.3.4, 5.3.5) and exception processing (clause 15).

The general utilities include components used by other library elements, such as a predefined storage allocator for dynamic storage management (3.7.3). The diagnostics components provide a consistent framework for reporting errors in a C++ program, including predefined exception classes.

The strings components provide support for manipulating text represented as sequences of type char, sequences of type wchar_t, or sequences of any other “character-like” type. The localization components extend internationalization support for such text processing.

The containers, iterators, and algorithms provide a C++ program with access to a subset of the most widely used algorithms and data structures.

Numeric algorithms and the complex number components extend support for numeric processing. The valarray components provide support for n-at-a-time processing, potentially implemented as parallel operations on platforms that support such processing.

The iostreams components are the primary mechanism for C++ program input/output. They can be used with other elements of the library, particularly strings, locales, and iterators.

This library also makes available the facilities of the Standard C library, suitably adjusted to ensure static type safety.

The following subclauses describe the definitions (17.1), and method of description (17.3) for the library. Clause 17.4, and clauses 18 through 27, and Annex D specify the contents of the library, and library requirements and constraints on both well-formed C++ programs and conforming implementations.

17.1  Definitions  [lib.definitions]

17.1.1  arbitrary-positional stream  [defns.arbitrary.stream]

A stream (described in clause 27) that can seek to any integral position within the length of the stream. Every arbitrary-positional stream is also a repositionable stream (17.1.16).

17.1.2  character  [defns.character]

In clauses 21, 22, and 27, means any object which, when treated sequentially, can represent text. The term does not only
mean char and wchar_t objects, but any value that can be represented by a type that provides the definitions specified in these clauses.

17.1.3 character container type

[a defns.character.container]
a class or a type used to represent a character (17.1.2). It is used for one of the template parameters of the string and iostream class templates. A character container class shall be a POD (3.9) type.

17.1.4 comparison function

[a defns.comparison]
an operator function (13.5) for any of the equality (5.10) or relational (5.9) operators.

17.1.5 component

[a defns.component]
a group of library entities directly related as members, parameters, or return types. For example, the class template basic_string and the non-member function templates that operate on strings are referred to as the string component.

17.1.6 default behavior

[a defns.default.behavior]
a description of replacement function and handler function semantics. Any specific behavior provided by the implementation, within the scope of the required behavior.

17.1.7 handler function

[a defns.handler]
a non-reserved function whose definition may be provided by a C++ program. A C++ program may designate a handler function at various points in its execution, by supplying a pointer to the function when calling any of the library functions that install handler functions (clause 18).

17.1.8 iostream class templates

[a defns.iostream.templates]
templates, defined in clause 27, that take two template arguments: charT and traits. The argument charT is a character container class, and the argument traits is a structure which defines additional characteristics and functions of the character type represented by charT necessary to implement the iostream class templates.

17.1.9 modifier function

[a defns.modifier]
a class member function (9.3), other than constructors, assignment, or destructor, that alters the state of an object of the class.

17.1.10 object state

[a defns.obj.state]
the current value of all non-static class members of an object (9.2). The state of an object can be obtained by using one or more observer functions.

17.1.11 narrow-oriented iostream classes

[a defns.narrow.iostream]
the instantiations of the iostream class templates on the character container class char and the default value of the
traits parameter. The traditional iostream classes are regarded as the narrow-oriented iostream classes (27.3.1).

17.1.12 **NTCTS**

a sequence of values that have *character type*, that precede the terminating null character type value charT().

17.1.13 **observer function**

a class member function (9.3) that accesses the state of an object of the class, but does not alter that state. Observer functions are specified as const member functions (9.3.2).

17.1.14 **replacement function**

a *non-reserved function* whose definition is provided by a C++ program. Only one definition for such a function is in effect for the duration of the program’s execution, as the result of creating the program (2.1) and resolving the definitions of all translation units (3.5).

17.1.15 **required behavior**

a description of *replacement function* and *handler function* semantics, applicable to both the behavior provided by the implementation and the behavior that shall be provided by any function definition in the program. If a function defined in a C++ program fails to meet the required behavior when it executes, the behavior is undefined.

17.1.16 **repositionable stream**

a stream (described in clause 27) that can seek only to a position that was previously encountered.

17.1.17 **reserved function**

a function, specified as part of the C++ Standard Library, that must be defined by the implementation. If a C++ program provides a definition for any reserved function, the results are undefined.

17.1.18 **stable algorithm**

an algorithm that preserves, as appropriate to the particular algorithm, the order of elements.

— For the *sort* algorithms the relative order of equivalent elements is preserved.

— For the *remove* algorithms the relative order of the elements that are not removed is preserved.

— For the *merge* algorithms, for equivalent elements in the original two ranges, the elements from the first range precede the elements from the second range.

17.1.19 **traits class**

a class that encapsulates a set of types and functions necessary for class templates and function templates to manipulate objects of types for which they are instantiated. Traits classes defined in clauses 21, 22 and 27 are *character traits*, which provide the character handling support needed by the string and iostream classes.

17.1.20 **wide-oriented iostream classes**

the instantiations of the iostream class templates on the character container class wchar_t and the default value of the
traits parameter (27.3.2).

17.2 Additional definitions

defines additional terms used elsewhere in this International Standard.

17.3 Method of description (Informative)

describes the conventions used to describe the C++ Standard Library. It describes the structures of the normative clauses 18 through 27 (17.3.1), Annex D and other editorial conventions (17.3.2).

17.3.1 Structure of each subclause

provides a summary of the C++ Standard library’s contents. Other Library clauses provide detailed specifications for each of the components in the library, as shown in Table 10.

Each Library clause contains the following elements, as applicable: \(^{149}\)

— Summary
— Requirements
— Detailed specifications
— References to the Standard C library

17.3.1.1 Summary

The Summary provides a synopsis of the category, and introduces the first-level subclauses. Each subclause also provides a summary, listing the headers specified in the subclause and the library entities provided in each header.

Paragraphs labelled “Note(s):” or “Example(s):” are informative, other paragraphs are normative.

The summary and the detailed specifications are presented in the order:

\(^{149}\) To save space, items that do not apply to a clause are omitted. For example, if a clause does not specify any requirements, there will be no “Requirements” subclause.

Draft
— Macros
— Values
— Types
— Classes
— Functions
— Objects

### 17.3.1.2 Requirements

The library can be extended by a C++ program. Each clause, as applicable, describes the requirements that such extensions must meet. Such extensions are generally one of the following:

— Template arguments
— Derived classes
— Containers, iterators, and/or algorithms that meet an interface convention

The string and iostreams components use an explicit representation of operations required of template arguments. They use a class template `char_traits` to define these constraints.

Interface convention requirements are stated as generally as possible. Instead of stating “class X has to define a member function `operator++()`,” the interface requires “for any object `x` of class `X`, `++x` is defined.” That is, whether the operator is a member is unspecified.

Requirements are stated in terms of well-defined expressions, which define valid terms of the types that satisfy the requirements. For every set of requirements there is a table that specifies an initial set of the valid expressions and their semantics (20.1.6, 23.1, 24.1). Any generic algorithm (clause 25) that uses the requirements is described in terms of the valid expressions for its formal type parameters.

Template argument requirements are sometimes referenced by name. See 17.3.2.1.

In some cases the semantic requirements are presented as C++ code. Such code is intended as a specification of equivalence of a construct to another construct, not necessarily as the way the construct must be implemented.\(^{150}\)

### 17.3.1.3 Specifications

The detailed specifications each contain the following elements:\(^{151}\)

— Name and brief description
— Synopsis (class definition or function prototype, as appropriate)
— Restrictions on template arguments, if any
— Description of class invariants

\(^{150}\) Although in some cases the code given is unambiguously the optimum implementation.

\(^{151}\) The form of these specifications was designed to follow the conventions established by existing C++ library vendors.
17.3 Method of description (Informative)  

Library introduction 368

— Description of function semantics

2 Descriptions of class member functions follow the order (as appropriate):  

— Constructor(s) and destructor
— Copying & assignment functions
— Comparison functions
— Modifier functions
— Observer functions
— Operators and other non-member functions

3 Descriptions of function semantics contain the following elements (as appropriate):  

— Requires: the preconditions for calling the function
— Effects: the actions performed by the function
— Postconditions: the observable results established by the function
— Returns: a description of the value(s) returned by the function
— Throws: any exceptions thrown by the function, and the conditions that would cause the exception
— Complexity: the time and/or space complexity of the function

4 For non-reserved replacement and handler functions, clause 18 specifies two behaviors for the functions in question: their required and default behavior. The default behavior describes a function definition provided by the implementation. The required behavior describes the semantics of a function definition provided by either the implementation or a C++ program. Where no distinction is explicitly made in the description, the behavior described is the required behavior.

5 Complexity requirements specified in the library clauses are upper bounds, and implementations that provide better complexity guarantees satisfy the requirements.

17.3.1.4 C Library  

Paragraphs labelled “SEE ALSO:” contain cross-references to the relevant portions of this Standard and the ISO C standard, which is incorporated into this Standard by reference.

17.3.2 Other conventions  

This subclause describes several editorial conventions used to describe the contents of the C++ Standard Library. These

152) To save space, items that do not apply to a class are omitted. For example, if a class does not specify any comparison functions, there will be no “Comparison functions” subclause.

153) To save space, items that do not apply to a function are omitted. For example, if a function does not specify any further preconditions, there will be no “Requires” paragraph.
conventions are for describing implementation-defined types (17.3.2.1), and member functions (17.3.2.2).

17.3.2.1 Type descriptions

The Requirements subclauses may describe names that are used to specify constraints on template arguments. These names are used in clauses 20, 23, 25, and 26 to describe the types that may be supplied as arguments by a C++ program when instantiating template components from the library.

Certain types defined in clause 27 are used to describe implementation-defined types. They are based on other types, but with added constraints.

17.3.2.1.1 Enumerated types

Several types defined in clause 27 are enumerated types. Each enumerated type may be implemented as an enumeration or as a synonym for an enumeration.

The enumerated type enumerated can be written:

```cpp
enum enumerated { V0, V1, V2, V3, ....; }
static const enumerated C0 (V0);
static const enumerated C1 (V1);
static const enumerated C2 (V2);
static const enumerated C3 (V3);
.....
```

Here, the names C0, C1, etc. represent enumerated elements for this particular enumerated type. All such elements have distinct values.

17.3.2.1.2 Bitmask types

Several types defined in clauses 18 through 27 and Annex D are bitmask types. Each bitmask type can be implemented as an enumerated type that overloads certain operators, as an integer type, or as a bitset (23.3.5).

The bitmask type bitmask can be written:

```cpp
enum bitmask {
    V0 = 1 << 0, V1 = 1 << 1, V2 = 1 << 2, V3 = 1 << 3, ....;
};
static const bitmask C0(V0);
static const bitmask C1(V1);
static const bitmask C2(V2);
static const bitmask C3(V3);
.....
```

bitmask operator& (bitmask X, bitmask Y)
// For exposition only.
// int_type is an integral type capable of

154) Examples from 20.1 include: EqualityComparable, LessThanComparable, CopyConstructable, etc. Examples from 24.1 include: InputIterator, ForwardIterator, Function, Predicate, etc.
155) Such as an integer type, with constant integer values (3.9.1).
// representing all values of bitmask
{ return static_cast<bitmask>(
  static_cast<int_type>(X) &
  static_cast<int_type>(Y)); }

bitmask operator | (bitmask X, bitmask Y)
{ return static_cast<bitmask>(
  static_cast<int_type>(X) |
  static_cast<int_type>(Y)); }

bitmask operator ^ (bitmask X, bitmask Y)
{ return static_cast<bitmask>(
  static_cast<int_type>(X) ~
  static_cast<int_type>(Y)); }

bitmask operator ~(bitmask X)
{ return static_cast<bitmask>(~static_cast<int_type>(X)); }

bitmask& operator&=(bitmask& X, bitmask Y)
{ X = X&Y; return X; }

bitmask& operator|==(bitmask& X, bitmask Y)
{ X = X|Y; return X; }

bitmask& operator^=(bitmask& X, bitmask Y)
{ X = X^Y; return X; }

Here, the names $C_0$, $C_1$, etc. represent bitmask elements for this particular bitmask type. All such elements have distinct values such that, for any pair $C_i$ and $C_j$, $C_i \& C_j$ is nonzero and $C_i \& C_j$ is zero.

The following terms apply to objects and values of bitmask types:

— To set a value $Y$ in an object $X$ is to evaluate the expression $X |= Y$.

— To clear a value $Y$ in an object $X$ is to evaluate the expression $X &= ~Y$.

— The value $Y$ is set in the object $X$ if the expression $X \& Y$ is nonzero.

### 17.3.2.1.3 Character sequences

The Standard C library makes widespread use of characters and character sequences that follow a few uniform conventions:

— A letter is any of the 26 lowercase or 26 uppercase letters in the basic execution character set.\(^{156}\)

— The decimal-point character is the (single-byte) character used by functions that convert between a (single-byte) character sequence and a value of one of the floating-point types. It is used in the character sequence to denote the beginning of a fractional part. It is represented in clauses 18 through 27 and Annex D by a period, ‘.’, which is also its value in the "C" locale, but may change during program execution by a call to setlocale(int, const char*),\(^{157}\) or by a change to a locale object, as described in clauses 22.1 and 27.

\(^{156}\)Note that this definition differs from the definition in ISO C subclause 7.1.1.

\(^{157}\)declared in <locale> (22.3).
— A character sequence is an array object \((8.3.4)\) that can be declared as \(T A[N]\), where \(T\) is any of the types \(\text{char, unsigned char, or signed char (3.9.1)}\), optionally qualified by any combination of \(\text{const or volatile}\). The initial elements of the array have defined contents up to and including an element determined by some predicate. A character sequence can be designated by a pointer value \(S\) that points to its first element.

17.3.2.1.3.1 Byte strings [lib.byte.strings]

1 A null-terminated byte string, or NTBS, is a character sequence whose highest-addressed element with defined content has the value zero (the terminating null character).\(^{158}\)

2 The length of an NTBS is the number of elements that precede the terminating null character. An empty NTBS has a length of zero.

3 The value of an NTBS is the sequence of values of the elements up to and including the terminating null character.

4 A static NTBS is an NTBS with static storage duration.\(^{159}\)

17.3.2.1.3.2 Multibyte strings [lib.multibyte.strings]

1 A null-terminated multibyte string, or NTMBS, is an NTBS that constitutes a sequence of valid multibyte characters, beginning and ending in the initial shift state.\(^{160}\)

2 A static NTMBS is an NTMBS with static storage duration.

17.3.2.1.3.3 Wide-character sequences [lib.wide.characters]

1 A wide-character sequence is an array object \((8.3.4)\) that can be declared as \(T A[N]\), where \(T\) is type \(\text{wchar_t (3.9.1)}\), optionally qualified by any combination of \(\text{const or volatile}\). The initial elements of the array have defined contents up to and including an element determined by some predicate. A character sequence can be designated by a pointer value \(S\) that designates its first element.

2 A null-terminated wide-character string, or NTWCS, is a wide-character sequence whose highest-addressed element with defined content has the value zero.\(^{161}\)

3 The length of an NTWCS is the number of elements that precede the terminating null wide character. An empty NTWCS has a length of zero.

4 The value of an NTWCS is the sequence of values of the elements up to and including the terminating null character.

5 A static NTWCS is an NTWCS with static storage duration.\(^{162}\)

17.3.2.2 Functions within classes [lib.functions.within.classes]

1 For the sake of exposition, clauses \(\text{18 through 27 and Annex D do not describe copy constructors, assignment operators, or (non-virtual) destructors with the same apparent semantics as those that can be generated by default (12.1, 12.4, 12.8).}\)

\(^{158}\) Many of the objects manipulated by function signatures declared in <cstring> (21.4) are character sequences or NTBSs. The size of some of these character sequences is limited by a length value, maintained separately from the character sequence.

\(^{159}\) A string literal, such as \"abc\", is a static NTBS.

\(^{160}\) An NTBS that contains characters only from the basic execution character set is also an NTMBS. Each multibyte character then consists of a single byte.

\(^{161}\) Many of the objects manipulated by function signatures declared in <wchar> are wide-character sequences or NTWCSs.

\(^{162}\) A wide string literal, such as L\"abc\" is a static NTWCS.
2. It is unspecified whether the implementation provides explicit definitions for such member function signatures, or for virtual destructors that can be generated by default.

17.3.2.3 Private members

Clauses 18 through 27 and Annex D do not specify the representation of classes, and intentionally omit specification of class members (9.2). An implementation may define static or non-static class members, or both, as needed to implement the semantics of the member functions specified in clauses 18 through 27 and Annex D.

Objects of certain classes are sometimes required by the external specifications of their classes to store data, apparently in member objects. For the sake of exposition, some subclauses provide representative declarations, and semantic requirements, for private member objects of classes that meet the external specifications of the classes. The declarations for such member objects and the definitions of related member types are enclosed in a comment that ends with `exposition only`, as in:

```c
// streambuf* sb;
```

3. Any alternate implementation that provides equivalent external behavior is equally acceptable.

17.4 Library-wide requirements

This subclause specifies requirements that apply to the entire C++ Standard library. Clauses 18 through 27 and Annex D specify the requirements of individual entities within the library.

The following subclauses describe the library’s contents and organization (17.4.1), how well-formed C++ programs gain access to library entities (17.4.2), constraints on such programs (17.4.3), and constraints on conforming implementations (17.4.4).

17.4.1 Library contents and organization

This subclause provides a summary of the entities defined in the C++ Standard Library. In general, these entities are defined in library headers, which subclause 17.4.1.2 lists alphabetically.

17.4.1.1 Library contents

The C++ Standard Library provides definitions for the following types of entities: Macros, Values, Types, Templates, Classes, Functions, Objects.

All library entities except macros, `operator new` and `operator delete` are defined within the namespace `std` or namespaces nested within namespace `std`.

Whenever a name `x` defined in the standard library is mentioned, the name `x` is assumed to be fully qualified as `::std::x`, unless explicitly described otherwise. For example, if the Effects section for library function `F` is described as calling library function `G`, the function `::std::G` is meant.

17.4.1.2 Headers

The elements of the C++ Standard Library are declared or defined (as appropriate) in a `header`.163)
The C++ Standard Library provides 33 C++ headers, as shown in Table 11.

The facilities of the Standard C Library are provided in 18 additional headers, as shown in Table 12.

Except as noted in clauses 18 through 27 and Annex D the contents of each header `<name>` shall be the same as that of the corresponding header `<name>.h`, as specified in ISO/IEC 9899:1990 Programming Languages C (clause 7), or ISO/IEC:1990 Programming Languages — C AMENDMENT 1: C Integrity, (clause 7), as appropriate, as if by inclusion. In the C++ Standard Library, however, the declarations and definitions (except for names which are defined as macros in C) are within namespace scope (3.3.5) of the namespace `std`.

Names which are defined as macros in C shall be defined as macros in the C++ Standard Library, even if C grants license for implementation as functions. \[Note: the names defined as macros in C include the following: `assert`, `offsetof`, `setjmp`, `va_arg`, `va_end`, and `va_start`. \] — end note

Names that are defined as functions in C shall be defined as functions in the C++ Standard Library.\[164\]

D.5, Standard C library headers, describes the effects of using the `<name>.h` (C header) form in a C++ program.\[165\]

### Freestanding implementations \[lib.compliance\]

Two kinds of implementations are defined: hosted and freestanding (1.4). For a hosted implementation, this International Standard describes the set of available headers.

A freestanding implementation has an implementation-defined set of headers. This set shall include at least the following headers, as shown in Table 13.

The supplied version of the header `<cstdlib>` shall declare at least the functions `abort()`, `atexit()`, and `exit()`

---

\[163\] A header is not necessarily a source file, nor are the sequences delimited by `<``` and `>` in header names necessarily valid source file names (16.2).

\[164\] This disallows the practice, allowed in C, of providing a "masking macro" in addition to the function prototype. The only way to achieve equivalent "inline" behavior in C++ is to provide a definition as an extern inline function.

\[165\] The ", h" headers dump all their names into the global namespace, whereas the newer forms keep their names in namespace `std`. Therefore, the newer forms are the preferred forms for all uses except for C++ programs which are intended to be strictly compatible with C.
17.4 Library-wide requirements

17.4.2 Using the library

This subclause describes how a C++ program gains access to the facilities of the C++ Standard Library. 17.4.2.1 describes effects during translation phase 4, while 17.4.2.2 describes effects during phase 8 (2.1).

17.4.2.1 Headers

The entities in the C++ Standard Library are defined in headers, whose contents are made available to a translation unit when it contains the appropriate `#include` preprocessing directive (16.2).

A translation unit may include library headers in any order (clause 2). Each may be included more than once, with no effect different from being included exactly once, except that the effect of including either `<cassert>` or `<assert.h>` depends each time on the lexically current definition of `NDEBUG`.166)

A translation unit shall include a header only outside of any external declaration or definition, and shall include the header lexically before the first reference to any of the entities it declares in that translation unit.

17.4.2.2 Linkage

Entities in the C++ Standard Library have external linkage (3.5). Unless otherwise specified, objects and functions have the default `extern "C++"` linkage (7.5).

Whether a name from the Standard C library declared with external linkage has `extern "C"` or `extern "C++"` linkage is implementation-defined. It is recommended that an implementation use `extern "C++"` linkage for this purpose.167)

Objects and functions defined in the library and required by a C++ program are included in the program prior to program startup.

SEE ALSO: replacement functions (17.4.3.4), run-time changes (17.4.3.5).

17.4.3 Constraints on programs

This subclause describes restrictions on C++ programs that use the facilities of the C++ Standard Library. The following subclauses specify constraints on the program's namespace (17.4.3.1), its use of headers (17.4.3.2), classes derived from

166) This is the same as the Standard C library.
167) The only reliable way to declare an object or function signature from the Standard C library is by including the header that declares it, notwithstanding the latitude granted in subclause 7.1.7 of the C Standard.

Draft
standard library classes (17.4.3.3), definitions of replacement functions (17.4.3.4), and installation of handler functions during execution (17.4.3.5).

17.4.3.1 Reserved names

It is undefined for a C++ program to add declarations or definitions to namespace std or namespaces within namespace std unless otherwise specified. A program may add template specializations for any standard library template to namespace std. Such a specialization (complete or partial) of a standard library template results in undefined behavior unless the declaration depends on a user-defined type of external linkage and unless the specialization meets the standard library requirements for the original template. A program may explicitly instantiate any templates in the standard library only if the declaration depends on the name of a user-defined type of external linkage and the instantiation meets the standard library requirements for the original template.

The C++ Standard Library reserves the following kinds of names:

— Macros
— Global names
— Names with external linkage

If the program declares or defines a name in a context where it is reserved, other than as explicitly allowed by this clause, the behavior is undefined.

17.4.3.1.1 Macro names

Each name defined as a macro in a header is reserved to the implementation for any use if the translation unit includes the header. A translation unit that includes a header shall not contain any macros that define names declared or defined in that header. Nor shall such a translation unit define macros for names lexically identical to keywords.

17.4.3.1.2 Global names

Certain sets of names and function signatures are always reserved to the implementation:

— Each name that contains a double underscore _ _ or begins with an underscore followed by an uppercase letter (2.11) is reserved to the implementation for any use.
— Each name that begins with an underscore is reserved to the implementation for use as a name in the global namespace.

17.4.3.1.3 External linkage

Each name declared as an object with external linkage in a header is reserved to the implementation to designate that library object with external linkage, both in namespace std and in the global namespace.

---

168 Any library code that instantiates other library templates must be prepared to work adequately with any user-supplied specialization that meets the minimum requirements of the Standard.
169 It is not permissible to remove a library macro definition by using the #undef directive.
170 Such names are also reserved in namespace ::std (17.4.3.1).
171 The list of such reserved names includes errno, declared or defined in <cerrno>.
Each global function signature declared with external linkage in a header is reserved to the implementation to designate that function signature with external linkage.\(^{172}\)

Each name having two consecutive underscores (2.11) is reserved to the implementation for use as a name with both extern "C" and extern "C++" linkage.

Each name from the Standard C library declared with external linkage is reserved to the implementation for use as a name with extern "C" linkage, both in namespace std and in the global namespace.

Each function signature from the Standard C library declared with external linkage is reserved to the implementation for use as a function signature with both extern "C" and extern "C++" linkage,\(^{173}\) or as a name of namespace scope in the global namespace.

### 17.4.3.1.4 Types [lib.extern.types]

For each type \(T\) from the Standard C library,\(^{174}\) the types ::\(T\) and std::\(T\) are reserved to the implementation and, when defined, ::\(T\) shall be identical to std::\(T\).

### 17.4.3.2 Headers [lib.alt.headers]

If a file with a name equivalent to the derived file name for one of the C++ Standard Library headers is not provided as part of the implementation, and a file with that name is placed in any of the standard places for a source file to be included (16.2), the behavior is undefined.

### 17.4.3.3 Derived classes [lib.derived.classes]

Virtual member function signatures defined for a base class in the C++ Standard library may be overridden in a derived class defined in the program (10.3).

### 17.4.3.4 Replacement functions [lib.replacement.functions]

Clauses 18 through 27 and Annex D describe the behavior of numerous functions defined by the C++ Standard Library. Under some circumstances, however, certain of these function descriptions also apply to replacement functions defined in the program (17.1).

A C++ program may provide the definition for any of eight dynamic memory allocation function signatures declared in header `<new>` (3.7.3, clause 18):

- operator new(std::size_t)
- operator new(std::size_t, const std::nothrow_t&)
- operator new[](std::size_t)
- operator new[](std::size_t, const std::nothrow_t&)
- operator delete(void*)
- operator delete(void*, const std::nothrow_t&)

\(^{172}\) The list of such reserved function signatures with external linkage includes setjmp(jmp_buf), declared or defined in `<setjmp>`, and va_end(va_list), declared or defined in `<stdarg>`,

\(^{173}\) The function signatures declared in `<csetjmp>` and `<cstdarg>` are always reserved, notwithstanding the restrictions imposed in subclause 4.5.1 of Amendment 1 to the C Standard for these headers.

\(^{174}\) These types are clock_t, div_t, FILE, fpos_t, lconv, ldiv_t, mbstate_t, ptdiff_t, sig_atomic_t, size_t, time_t, tm, va_list, wctrans_t, wctype_t, and wint_t.
operator delete[](void*)
operator delete[](void*, const std::nothrow_t&)

The program’s definitions are used instead of the default versions supplied by the implementation (18.4). Such replacement occurs prior to program startup (3.2, 3.6). The program’s definitions shall not be specified as inline. No diagnostic is required.

17.4.3.5 Handler functions [lib.handler.functions]

The C++ Standard Library provides default versions of the following handler functions (clause 18):

— unexpected_handler
— terminate_handler

A C++ program may install different handler functions during execution, by supplying a pointer to a function defined in the program or the library as an argument to (respectively):

— set_new_handler
— set_unexpected
— set_terminate

See also: subclauses 18.4.2, Storage allocation errors, and 18.6, Exception handling.

17.4.3.6 Other functions [lib.res.on.functions]

In certain cases (replacement functions, handler functions, operations on types used to instantiate standard library template components), the C++ Standard Library depends on components supplied by a C++ program. If these components do not meet their requirements, the Standard places no requirements on the implementation.

In particular, the effects are undefined in the following cases:

— for replacement functions (18.4.1), if the installed replacement function does not implement the semantics of the applicable Required behavior: paragraph.

— for handler functions (18.4.2.2, 18.6.3.1, 18.6.2.2), if the installed handler function does not implement the semantics of the applicable Required behavior: paragraph

— for types used as template arguments when instantiating a template component, if the operations on the type do not implement the semantics of the applicable Requirements subclause (20.1.6, 23.1, 24.1, 26.1). Operations on such types can report a failure by throwing an exception unless otherwise specified.

— if any replacement function or handler function or destructor operation throws an exception, unless specifically allowed in the applicable Required behavior: paragraph.

— if an incomplete type (3.9) is used as a template argument when instantiating a template component.
17.4 Library-wide requirements

17.4.3.7 Function arguments

Each of the following statements applies to all arguments to functions defined in the C++ Standard Library, unless explicitly stated otherwise.

— If an argument to a function has an invalid value (such as a value outside the domain of the function, or a pointer invalid for its intended use), the behavior is undefined.

— If a function argument is described as being an array, the pointer actually passed to the function shall have a value such that all address computations and accesses to objects (that would be valid if the pointer did point to the first element of such an array) are in fact valid.

17.4.3.8 Required paragraph

Violation of the preconditions specified in a function’s Required behavior: paragraph results in undefined behavior unless the function’s Throws: paragraph specifies throwing an exception when the precondition is violated.

17.4.4 Conforming implementations

This subclause describes the constraints upon, and latitude of, implementations of the C++ Standard library. The following subclauses describe an implementation’s use of headers (17.4.4.1), macros (17.4.4.2), global functions (17.4.4.3), member functions (17.4.4.4), reentrancy (17.4.4.5), access specifiers (17.4.4.6), class derivation (17.4.4.7), and exceptions (17.4.4.8).

17.4.4.1 Headers

A C++ header may include other C++ headers.\(^{(175)}\)

2 Certain types and macros are defined in more than one header. For such an entity, a second or subsequent header that also defines it may be included after the header that provides its initial definition (3.2).

3 Header inclusion is limited as follows:

— The C headers ( .h form, described in Annex D, D.5) shall include only their corresponding C++ header, as described above (17.4.1.2).

17.4.4.2 Restrictions on macro definitions

The names or global function signatures described in 17.4.1.1 are reserved to the implementation.

2 All object-like macros defined by the Standard C library and described in this clause as expanding to integral constant expressions are also suitable for use in \#if preprocessing directives, unless explicitly stated otherwise.

17.4.4.3 Global or non-member functions

It is unspecified whether any global or non-member functions in the C++ Standard Library are defined as inline (7.1.2).\(^{(175)}\) C++ headers must include a C++ header that contains any needed definition (3.2).
A call to a global or non-member function signature described in clauses 18 through 27 and Annex D behaves the same as if the implementation declares no additional global or non-member function signatures.176)

A global or non-member function cannot be declared by the implementation as taking additional default arguments.

Unless otherwise specified, no global or non-member function in the standard library shall use a function from another namespace which is found through argument-dependent name lookup (3.4.2). [Note: The phrase “unless otherwise specified” is intended to allow argument-dependent lookup in cases like that of ostream_iterators: Effects:

```cpp
    *out_stream << value;
    if (delim != 0)
        *out_stream << delim;
    return (*this);
```

— end note ]

17.4.4.4 Member functions [lib.member.functions]

It is unspecified whether any member functions in the C++ Standard Library are defined as inline (7.1.2).

An implementation can declare additional non-virtual member function signatures within a class:

— by adding arguments with default values to a member function signature;177) The same latitude does not extend to the implementation of virtual or global or non-member functions, however.

— by replacing a member function signature with default values by two or more member function signatures with equivalent behavior;

— by adding a member function signature for a member function name.

A call to a member function signature described in the C++ Standard library behaves the same as if the implementation declares no additional member function signatures.178)

17.4.4.5 Reentrancy [lib.reentrancy]

Which of the functions in the C++ Standard Library are not reentrant subroutines is implementation-defined.

17.4.4.6 Protection within classes [lib.protection.within.classes]

It is unspecified whether a function signature or class described in clauses 18 through 27 and Annex D is a friend of another class in the C++ Standard Library.

17.4.4.7 Derived classes [lib.derivation]

It is unspecified whether a class in the C++ Standard Library is itself derived from other classes (with names reserved to the implementation).

Certain classes defined in the C++ Standard Library are derived from other classes in the C++ Standard Library:

176) A valid C++ program always calls the expected library global or non-member function. An implementation may also define additional global or non-member functions that would otherwise not be called by a valid C++ program.

177) Hence, taking the address of a member function has an unspecified type.

178) A valid C++ program always calls the expected library member function, or one with equivalent behavior. An implementation may also define additional member functions that would otherwise not be called by a valid C++ program.
— It is unspecified whether a class described in the C++ Standard Library as derived from another class is derived from that class directly, or through other classes (with names reserved to the implementation) that are derived from the specified base class.

In any case:

— A base class described as virtual is always virtual;
— A base class described as virtual "non-" is never virtual;
— Unless explicitly stated otherwise, types with distinct names are distinct types.\(^{179}\)

### 17.4.4.8 Restrictions on exception handling

Any of the functions defined in the C++ Standard Library can report a failure by throwing an exception of the type(s) described in their Throws: paragraph and/or their exception-specification (15.4). An implementation may strengthen the exception-specification for a non-virtual function by removing listed exceptions.\(^{180}\)

None of the functions from the Standard C library shall report an error by throwing an exception,\(^ {181}\) unless it calls a program-supplied function that throws an exception.\(^ {182}\)

No destructor operation defined in the C++ Standard Library will throw an exception. Any other functions defined in the C++ Standard Library that do not have an exception-specification may throw implementation-defined exceptions unless otherwise specified.\(^ {183}\) An implementation may strengthen this implicit exception-specification by adding an explicit one.\(^ {184}\)

\(^{179}\) An implicit exception to this rule are types described as synonyms for basic integral types, such as size_t (18.1) and streamoff (27.4.1).

\(^{180}\) That is, an implementation of the function will have an explicit exception-specification that lists fewer exceptions than those specified in this International Standard. It may not, however, change the types of exceptions listed in the exception-specification from those specified, nor add others.

\(^{181}\) That is, the C library functions all have a throw() exception-specification. This allows implementations to make performance optimizations based on the absence of exceptions at runtime.

\(^{182}\) The functions qsort() and bsearch() (25.4) meet this condition.

\(^{183}\) In particular, they can report a failure to allocate storage by throwing an exception of type bad_alloc, or a class derived from bad_alloc (18.4.2.1). Library implementations are encouraged (but not required) to report errors by throwing exceptions from (or derived from) the standard exception classes (18.4.2.1, 18.6, 19.1).

\(^{184}\) That is, an implementation may provide an explicit exception-specification that defines the subset of “any” exceptions thrown by that function. This implies that the implementation may list implementation-defined types in such an exception-specification.
Chapter 18  Language support library
[lib.language.support]

1 This clause describes the function signatures that are called implicitly, and the types of objects generated implicitly, during the execution of some C++ programs. It also describes the headers that declare these function signatures and define any related types.

2 The following subclauses describe common type definitions used throughout the library, characteristics of the predefined types, functions supporting start and termination of a C++ program, support for dynamic memory management, support for dynamic type identification, support for exception processing, and other runtime support, as summarized in Table 14.

Table 14: Language support library summary

18.1 Types  [lib.support.types]

1 Common definitions.

Header <cstdlib> (Table 15).

2 The contents are the same as the Standard C library header <stddef.h>, with the following changes:

3 The macro NULL is an implementation-defined C++ null pointer constant in this International Standard (4.10).\(^{185}\)

\(^{185}\) Possible definitions include 0 and 0L, but not (void*)0.
18.2 Implementation properties

The macro `offsetof` accepts a restricted set of type arguments in this International Standard. If `type` is not a POD structure or a POD union (clause 9) the results are undefined.\(^{186}\) The result of applying the `offsetof` macro to a field that is a static data member or a function member is undefined.

The macro `offsetof` if `type` is not a POD structure or a POD union (clause 9) the results are undefined.\(^{187}\)

SEE ALSO: subclause 5.3.3, `sizeof`, subclause 5.7, Additive operators, subclause 12.5, Free store, and ISO C subclause 7.1.6.

18.2 Implementation properties

The headers `<limits>`, `<climits>`, and `<cfloat>` supply characteristics of implementation-dependent fundamental types (3.9.1).

18.2.1 Numeric limits

The `numeric_limits` component provides a C++ program with information about various properties of the implementation’s representation of the fundamental types.

Specializations shall be provided for each fundamental type, both floating point and integer, including `bool`. The member `is_specialized` shall be `true` for all such specializations of `numeric_limits`.

For all members declared `static const` in the `numeric_limits` template, specializations shall define these values in such a way that they are usable as integral constant expressions.

Non-fundamental standard types, such as `complex<T>` (26.2.2), shall not have specializations.

Header `<limits>` synopsis

```cpp
namespace std {
    template<class T> class numeric_limits;
    enum float_round_style;
    enum float_denorm_style;

    template<> class numeric_limits<bool>;
    template<> class numeric_limits<char>;
    template<> class numeric_limits<signed char>;
    template<> class numeric_limits<unsigned char>;
    template<> class numeric_limits<wchar_t>;

    template<> class numeric_limits<short>;
    template<> class numeric_limits<int>;
}
```

\(^{186}\) Note that `offsetof` is required to work as specified even if unary `operator&` is overloaded for any of the types involved.

\(^{187}\) Note that `offsetof` is required to work as specified even if unary `operator&` is overloaded for any of the types involved.
template<> class numeric_limits<long>;
template<> class numeric_limits<unsigned short>;
template<> class numeric_limits<unsigned int>;
template<> class numeric_limits<unsigned long>;

template<> class numeric_limits<float>;
template<> class numeric_limits<double>;
template<> class numeric_limits<long double>;

namespace std {
    template<class T> class numeric_limits {
    public:
        static const bool is_specialized = false;
        static T min() throw();
        static T max() throw();

        static const int digits = 0;
        static const int digits10 = 0;
        static const bool is_signed = false;
        static const bool is_integer = false;
        static const bool is_exact = false;
        static const int radix = 0;
        static T epsilon() throw();
        static T round_error() throw();

        static const int min_exponent = 0;
        static const int min_exponent10 = 0;
        static const int max_exponent = 0;
        static const int max_exponent10 = 0;

        static const bool has_infinity = false;
        static const bool has_quiet_NaN = false;
        static const bool has_signaling_NaN = false;
        static const float_denorm_style has_denorm = denorm_absent;
        static const bool has_denorm_loss = false;
        static T infinity() throw();
        static T quiet_NaN() throw();
        static T signaling_NaN() throw();
        static T denorm_min() throw();

        static const bool is_iec559 = false;
        static const bool is_bounded = false;
        static const bool is_modulo = false;
        static const bool traps = false;
        static const bool tinyness_before = false;
        static const float_round_style round_style = round_toward_zero;
    } // class numeric_limits

18.2.1.1 Class template numeric_limits
The member `is_specialized` makes it possible to distinguish between fundamental types, which have specializations, and non-scalar types, which do not.

The default `numeric_limits<T>` template shall have all members, but with 0 or `false` values.

### 18.2.1.2 `numeric_limits` members

```cpp
static T min() throw();
```

Minimum finite value.\(^{188}\)

For floating types with denormalization, returns the minimum positive normalized value.

Meaningful for all specializations in which `is_bounded` \(!= \text{false}\), or `is_bounded` \(== \text{false} && \text{is_signed} == \text{false}\).

```cpp
static T max() throw();
```

Maximum finite value.\(^{189}\)

Meaningful for all specializations in which `is_bounded` \(!= \text{false}\).

```cpp
static const int digits;
```

Number of radix digits that can be represented without change.

For built-in integer types, the number of non-sign bits in the representation.

For floating point types, the number of radix digits in the mantissa.\(^{190}\)

```cpp
static const int digits10;
```

Number of base 10 digits that can be represented without change.\(^{191}\)

Meaningful for all specializations in which `is_bounded` \(!= \text{false}\).

```cpp
static const bool is_signed;
```

True if the type is signed.

Meaningful for all specializations.

```cpp
static const bool is_integer;
```

True if the type is integer.

Meaningful for all specializations.

```cpp
static const bool is_exact;
```

\(^{188}\) Equivalent to `CHAR_MIN, SHRT_MIN, FLT_MIN, DBL_MIN`, etc.

\(^{189}\) Equivalent to `CHAR_MAX, SHRT_MAX, FLT_MAX, DBL_MAX`, etc.

\(^{190}\) Equivalent to `FLT_MANT_DIG, DBL_MANT_DIG, LDBL_MANT_DIG`.

\(^{191}\) Equivalent to `FLT_DIG, DBL_DIG, LDBL_DIG`.

Draft
True if the type uses an exact representation. All integer types are exact, but not all exact types are integer. For
example, rational and fixed-exponent representations are exact but not integer.

Meaningful for all specializations.

static const int radix;

For floating types, specifies the base or radix of the exponent representation (often 2).<sup>192</sup>

For integer types, specifies the base of the representation.<sup>193</sup>

Meaningful for all specializations.

static T epsilon() throw();

Machine epsilon: the difference between 1 and the least value greater than 1 that is representable.<sup>194</sup>

Meaningful for all floating point types.

static T round_error() throw();

Measure of the maximum rounding error.<sup>195</sup>

static const int min_exponent;

Minimum negative integer such that \( \text{radix} \) raised to the power of one less than that integer is a normalized floating point number.<sup>196</sup>

Meaningful for all floating point types.

static const int min_exponent10;

Minimum negative integer such that 10 raised to that power is in the range of normalized floating point numbers.<sup>197</sup>

Meaningful for all floating point types.

static const int max_exponent;

Maximum positive integer such that \( \text{radix} \) raised to the power one less than that integer is a representable finite floating point number.<sup>198</sup>

Meaningful for all floating point types.

static const int max_exponent10;

<sup>192</sup> Equivalent to FLT_RADIX.
<sup>193</sup> Distinguishes types with bases other than 2 (e.g. BCD).
<sup>194</sup> Equivalent to FLT_EPSILON, DBL_EPSILON, LDBL_EPSILON.
<sup>195</sup> Rounding error is described in ISO/IEC 10967-1 Language independent arithmetic - Part 1 Section 5.2.8 and Annex A Rationale Section A.5.2.8 - Rounding constants.
<sup>196</sup> Equivalent to FLT_MIN_EXP, DBL_MIN_EXP, LDBL_MIN_EXP.
<sup>197</sup> Equivalent to FLT_MIN_10_EXP, DBL_MIN_10_EXP, LDBL_MIN_10_EXP.
<sup>198</sup> Equivalent to FLT_MAX_EXP, DBL_MAX_EXP, LDBL_MAX_EXP.
Maximum positive integer such that 10 raised to that power is in the range of representable finite floating point numbers.\(^{199}\)

Meaningful for all floating point types.

\[
\text{static const bool has\_infinity;}\]

True if the type has a representation for positive infinity.

Meaningful for all floating point types.

Shall be \text{true} for all specializations in which \text{is\_iec559} \neq \text{false}.

\[
\text{static const bool has\_quiet\_NaN;}\]

True if the type has a representation for a quiet (non-signaling) “Not a Number.”\(^{200}\)

Meaningful for all floating point types.

Shall be \text{true} for all specializations in which \text{is\_iec559} \neq \text{false}.

\[
\text{static const bool has\_signaling\_NaN;}\]

True if the type has a representation for a signaling “Not a Number.”\(^{201}\)

Meaningful for all floating point types.

Shall be \text{true} for all specializations in which \text{is\_iec559} \neq \text{false}.

\[
\text{static const float\_denorm\_style has\_denorm;}\]

denorm\_present if the type allows denormalized values (variable number of exponent bits)\(^{202}\),
denorm\_absent if the type does not allow denormalized values, and
denorm\_indeterminate if it is indeterminate at compile time
whether the type allows denormalized values.

Meaningful for all floating point types.

\[
\text{static const bool has\_denorm\_loss;}\]

True if loss of accuracy is detected as a denormalization loss, rather than as an inexact result.\(^{203}\)

\[
\text{static T infinity}() \text{ throw}();\]

Representation of positive infinity, if available.\(^{204}\)

Meaningful for all specializations for which has\_infinity \neq \text{false}. Required in specializations for which
\text{is\_iec559} \neq \text{false}.

\[
\text{static T quiet\_NaN}() \text{ throw}();\]

\(^{199}\) Equivalent to \text{FLT\_MAX\_10\_EXP}, \text{DBL\_MAX\_10\_EXP}, \text{LDBL\_MAX\_10\_EXP}.

\(^{200}\) Required by LIA-1.

\(^{201}\) Required by LIA-1.

\(^{202}\) Required by LIA-1.

\(^{203}\) See IEC 559.

\(^{204}\) Required by LIA-1.
45 Representation of a quiet “Not a Number,” if available.\textsuperscript{205)
46 Meaningful for all specializations for which has\_quiet\_NaN != false. Required in specializations for which is\_iec559 != false.

\texttt{static T signaling\_NaN () throw();}
47 Representation of a signaling “Not a Number,” if available.\textsuperscript{206)
48 Meaningful for all specializations for which has\_signaling\_NaN != false. Required in specializations for which is\_iec559 != false.

\texttt{static T denorm\_min () throw();}
49 Minimum positive denormalized value.\textsuperscript{207)
50 Meaningful for all floating point types.
51 In specializations for which has\_denorm == false, returns the minimum positive normalized value.

\texttt{static const bool is\_iec559;
52 True if and only if the type adheres to IEC 559 standard.\textsuperscript{208)
53 Meaningful for all floating point types.

\texttt{static const bool is\_bounded;
54 True if the set of values representable by the type is finite.\textsuperscript{209) All built-in types are bounded, this member would be false for arbitrary precision types.
55 Meaningful for all specializations.

\texttt{static const bool is\_modulo;
56 True if the type is modulo.\textsuperscript{210) A type is modulo if it is possible to add two positive numbers and have a result that wraps around to a third number that is less.
57 Generally, this is false for floating types, true for unsigned integers, and true for signed integers on most machines.
58 Meaningful for all specializations.

\texttt{static const bool traps;
59 true if trapping is implemented for the type.\textsuperscript{211)
60 Meaningful for all specializations.

\textsuperscript{205) Required by LIA-1.
206) Required by LIA-1.
207) Required by LIA-1.
208) International Electrotechnical Commission standard 559 is the same as IEEE 754.
209) Required by LIA-1.
210) Required by LIA-1.
211) Required by LIA-1.
static const bool tinyness_before;
true if tinyness is detected before rounding.\(^{212}\)

Meaningful for all floating point types.
static const float_round_style round_style;
The rounding style for the type.\(^{213}\)

Meaningful for all floating point types. Specializations for integer types shall return round_toward_zero.

18.2.1.3 Type float_round_style

namespace std {
  enum float_round_style {
    round_indeterminate = -1,
    round_toward_zero = 0,
    round_to_nearest = 1,
    round_toward_infinity = 2,
    round_toward_neg_infinity = 3
  };
}

The rounding mode for floating point arithmetic is characterized by the values:
— round_indeterminate if the rounding style is indeterminable
— round_toward_zero if the rounding style is toward zero
— round_to_nearest if the rounding style is to the nearest representable value
— round_toward_infinity if the rounding style is toward infinity
— round_toward_neg_infinity if the rounding style is toward negative infinity

18.2.1.4 Type float_denorm_style

namespace std {
  enum float_denorm_style {
    denorm_indeterminate = -1,
    denorm_absent = 0,
    denorm_present = 1
  };
}

The presence or absence of denormalization (variable number of exponent bits) is characterized by the values:
— denorm_indeterminate if it cannot be determined whether or not the type allows denormalized values

\(^{212}\) Refer to IEC 559. Required by LIA-1.
\(^{213}\) Equivalent to FLT_ROUNDS. Required by LIA-1.
— denorm_absent if the type does not allow denormalized values
— denorm_present if the type does allow denormalized values

18.2.1.5 numeric_limits specializations

All members shall be provided for all specializations. However, many values are only required to be meaningful under certain conditions (for example, epsilon() is only meaningful if is_integer is false). Any value that is not “meaningful” shall be set to 0 or false.

Example:

```cpp
namespace std {
    template<> class numeric_limits<float> {
        public:
            static const bool is_specialized = true;

            inline static float min() throw() { return 1.17549435E-38F; }
            inline static float max() throw() { return 3.40282347E+38F; }

            static const int digits = 24;
            static const int digits10 = 6;

            static const bool is_signed = true;
            static const bool is_integer = false;
            static const bool is_exact = false;

            static const int radix = 2;
            inline static float epsilon() throw() { return 1.19209290E-07F; }
            inline static float round_error() throw() { return 0.5F; }

            static const int min_exponent = -125;
            static const int min_exponent10 = -37;
            static const int max_exponent = +128;
            static const int max_exponent10 = +38;

            static const bool has_infinity = true;
            static const bool has_quiet_NaN = true;
            static const bool has_signaling_NaN = true;
            static const float_denorm_style has_denorm = denorm_absent;
            static const bool has_denorm_loss = false;

            inline static float infinity() throw() { return ...; }
            inline static float quiet_NaN() throw() { return ...; }
            inline static float signaling_NaN() throw() { return ...; }
            inline static float denorm_min() throw() { return min(); }

            static const bool is_iec559 = true;
            static const bool is_bounded = true;
            static const bool is_modulo = false;
    }
}
```

Draft
The specialization for `bool` shall be provided as follows:

```cpp
namespace std {
    template<> class numeric_limits< bool > {
        public:
            static const bool is_specialized = true;
            static bool min() throw() { return false; }
            static bool max() throw() { return true; }
        static const int digits = 1;
        static const int digits10 = 0;
        static const bool is_signed = false;
        static const bool is_integer = true;
        static const bool is_exact = true;
        static const int radix = 2;
        static bool epsilon() throw() { return 0; }
        static bool round_error() throw() { return 0; }
        static const int min_exponent = 0;
        static const int min_exponent10 = 0;
        static const int max_exponent = 0;
        static const int max_exponent10 = 0;
        static const bool has_infinity = false;
        static const bool has_quiet_NaN = false;
        static const bool has_signaling_NaN = false;
        static const float_denorm_style has_denorm = denorm_absent;
        static const bool has_denorm_loss = false;
        static bool infinity() throw() { return 0; }
        static bool quiet_NaN() throw() { return 0; }
        static bool signaling_NaN() throw() { return 0; }
        static bool denorm_min() throw() { return 0; }
        static const bool is_iec559 = false;
        static const bool is_bounded = true;
        static const bool is_modulo = false;
        static const bool traps = false;
        static const bool tinyness_before = false;
        static const float_round_style round_style = round_toward_zero;
    };
    };
```
18.2.2 C Library [lib.c.limits]

1 Header <climits> (Table 16)

<tr>
<td>DBL_MAX_10_EXP</td>
<td>FLT_MIN_EXP</td>
</tr>
</tbody>
</table>

4 The contents are the same as the Standard C library header <float.h>.

See also: ISO C subclause 7.1.5, 5.2.4.2.2, 5.2.4.2.1.

18.3 Start and termination [lib.support.start.term]

1 Header <cstdlib> (partial), Table 18:

<table>
<thead>
<tr>
<th>Type</th>
<th>Name(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Macros:</td>
<td>EXIT_FAILURE</td>
</tr>
<tr>
<td>Functions:</td>
<td>EXIT_SUCCESS</td>
</tr>
<tr>
<td></td>
<td>abort</td>
</tr>
<tr>
<td></td>
<td>atexit</td>
</tr>
<tr>
<td></td>
<td>exit</td>
</tr>
</tbody>
</table>

2 The contents are the same as the Standard C library header <stdlib.h>, with the following changes:

    abort(void)

3 The function abort() has additional behavior in this International Standard:
18.3 Start and termination

The program is terminated without executing destructors for objects of automatic or static storage duration and without calling the functions passed to atexit() (3.6.3).

```
extern "C" int atexit(void (*f)(void))
extern "C++" int atexit(void (*f)(void))
```

**Effects:** The atexit() functions register the function pointed to by f, to be called without arguments at normal program termination.

For the execution of a function registered with atexit(), if control leaves the function because it provides no handler for a thrown exception, terminate() is called (18.6.3.3).

**Implementation limits:** The implementation shall support the registration of at least 32 functions.

**Returns:** The atexit() function returns zero if the registration succeeds, nonzero if it fails.

```
exit(int status)
```

The function exit() has additional behavior in this International Standard:

— First, objects with static storage duration are destroyed and functions registered by calling atexit are called. Non-local objects with static storage duration are destroyed in the reverse order of the completion of their constructor. (Automatic objects are not destroyed as a result of calling exit().)\(^{214}\) Functions registered with atexit are called in the reverse order of their registration, except that a function is called after any previously registered functions that had already been called at the time it was registered.\(^{215}\) A function registered with atexit before a non-local object obj1 of static storage duration is initialized will not be called until obj1’s destruction has completed. A function registered with atexit after a non-local object obj2 of static storage duration is initialized will be called before obj2’s destruction starts. A local static object obj3 is destroyed at the same time it would be if a function calling the obj3 destructor were registered with atexit at the completion of the obj3 constructor.

— Next, all open C streams (as mediated by the function signatures declared in `<cstdio>`) with unwritten buffered data are flushed, all open C streams are closed, and all files created by calling tmpfile() are removed.\(^{216}\)

— Finally, control is returned to the host environment. If status is zero or EXIT_SUCCESS, an implementation-defined form of the status successful termination is returned. If status is EXIT_FAILURE, an implementation-defined form of the status unsuccessful termination is returned. Otherwise the status returned is implementation-defined.\(^{217}\)

The function exit() never returns to its caller.

See also: subclauses 3.6.3, 3.6.6, ISO C subclause 7.10.4.

---

\(^{214}\) Objects with automatic storage duration are all destroyed in a program whose function main() contains no automatic objects and executes the call to exit(). Control can be transferred directly to such a main() by throwing an exception that is caught in main().

\(^{215}\) A function is called for every time it is registered.

\(^{216}\) Any C streams associated with cin, cout, etc (27.3) are flushed and closed when static objects are destroyed in the previous phase. The function tmpfile() is declared in `<cstdio>`.

\(^{217}\) The macros EXIT_FAILURE and EXIT_SUCCESS are defined in `<cstdlib>`. 

Draft
18.4 Dynamic memory management

The header `<new>` defines several functions that manage the allocation of dynamic storage in a program. It also defines components for reporting storage management errors.

**Header `<new>` synopsis**

```cpp
namespace std {
    class bad_alloc;
    struct nothrow_t {
        extern const nothrow_t nothrow;
        typedef void (* new_handler )();
        new_handler set_new_handler(new_handler new_p) throw();
    }

    void* operator new (std::size_t size) throw(std::bad_alloc);
    void* operator new (std::size_t size, const std::nothrow_t&) throw();
    void operator delete(void* ptr) throw();
    void operator delete(void* ptr, const std::nothrow_t&) throw();
    void* operator new[](std::size_t size) throw(std::bad_alloc);
    void* operator new[](std::size_t size, const std::nothrow_t&) throw();
    void operator delete[](void* ptr) throw();
    void operator delete[](void* ptr, const std::nothrow_t&) throw();
}
```

**See also**: 1.7, 3.7.3, 5.3.4, 5.3.5, 12.5, 20.4.

18.4.1 Storage allocation and deallocation

Except where otherwise specified, the provisions of (3.7.3) apply to the library versions of `operator new` and `operator delete`.

18.4.1.1 Single-object forms

```cpp
void* operator new (std::size_t size) throw(std::bad_alloc);
```

**Effects**: The allocation function (3.7.3.1) called by a `new-expression` (5.3.4) to allocate `size` bytes of storage suitably aligned to represent any object of that size.

**Replaceable**: A C++ program may define a function with this function signature that displaces the default version defined by the C++ Standard library.

**Required behavior**: Return a non-null pointer to suitably aligned storage (3.7.3), or else throw a `bad_alloc` exception. This requirement is binding on a replacement version of this function.

**Default behavior**:

---

Executes a loop: Within the loop, the function first attempts to allocate the requested storage. Whether the attempt involves a call to the Standard C library function `malloc` is unspecified.
— Returns a pointer to the allocated storage if the attempt is successful. Otherwise, if the last argument to
set_new_handler() was a null pointer, throw bad_alloc.

— Otherwise, the function calls the current new_handler (18.4.2.2). If the called function returns, the loop
repeats.

— The loop terminates when an attempt to allocate the requested storage is successful or when a called new_-
handler function does not return.

```c
void* operator new (std::size_t size, const std::nothrow_t&) throw();
```

**Effects:** Same as above, except that it is called by a placement version of a new-expression when a C++ program
prefers a null pointer result as an error indication, instead of a bad_alloc exception.

**Replaceable:** a C++ program may define a function with this function signature that displaces the default version
defined by the C++ Standard library.

**Required behavior:** Return a non-null pointer to suitably aligned storage (3.7.3), or else return a null pointer.
This noexcept version of operator new returns a pointer obtained as if acquired from the ordinary version. This
requirement is binding on a replacement version of this function.

**Default behavior:**

— Executes a loop: Within the loop, the function first attempts to allocate the requested storage. Whether the
attempt involves a call to the Standard C library function malloc is unspecified.

— Returns a pointer to the allocated storage if the attempt is successful. Otherwise, if the last argument to
set_new_handler() was a null pointer, return a null pointer.

— Otherwise, the function calls the current new_handler (18.4.2.2). If the called function returns, the loop
repeats.

— The loop terminates when an attempt to allocate the requested storage is successful or when a called new_-
handler function does not return. If the called new_handler function terminates by throwing a bad_alloc
exception, the function returns a null pointer.

**Example:**

```c
T* p1 = new T;   // throws bad_alloc if it fails
T* p2 = new(nothrow) T;  // returns 0 if it fails
```

— end example ]

```c
void operator delete (void* ptr) throw();
void operator delete (void* ptr, const std::nothrow_t&) throw();
```

**Effects:** The deallocation function (3.7.3.2) called by a delete-expression to render the value of ptr invalid.

**Replaceable:** a C++ program may define a function with this function signature that displaces the default version
defined by the C++ Standard library.

**Requires:** the value of ptr is null or the value returned by an earlier call to the default operator new(std::size_t) or operator new(std::size_t, const std::nothrow_t&).

**Default behavior:**

Draft
— For a null value of \( \text{ptr} \), do nothing.
— Any other value of \( \text{ptr} \) shall be a value returned earlier by a call to the default operator new, which was not invalidated by an intervening call to operator delete(\*void*) (17.4.3.7). For such a non-null value of \( \text{ptr} \), reclaims storage allocated by the earlier call to the default operator new.

Remarks: It is unspecified under what conditions part or all of such reclaimed storage is allocated by a subsequent call to operator new or any of calloc, malloc, or realloc, declared in <cstdlib>.

### 18.4.1.2 Array forms

```cpp
void* operator new[](std::size_t size) throw(std::bad_alloc);
```

**Effects:** The allocation function (3.7.3.1) called by the array form of a new-expression (5.3.4) to allocate \( \text{size} \) bytes of storage suitably aligned to represent any array object of that size or smaller.\(^{218}\)

**Replaceable:** a C++ program can define a function with this function signature that displaces the default version defined by the C++ Standard library.

**Required behavior:** Same as for operator new(std::size_t). This requirement is binding on a replacement version of this function.

**Default behavior:** Returns operator new(size).

```cpp
void* operator new[](std::size_t size, const std::nothrow_t&) throw();
```

**Effects:** Same as above, except that it is called by a placement version of a new-expression when a C++ program prefers a null pointer result as an error indication, instead of a bad_alloc exception.

**Replaceable:** a C++ program can define a function with this function signature that displaces the default version defined by the C++ Standard library.

**Required behavior:** Same as for operator new(std::size_t, const std::nothrow_t&). This nothrow version of operator new[] returns a pointer obtained as if acquired from the ordinary version.

**Default behavior:** Returns operator new(size, nothrow).

```cpp
void operator delete[](void* ptr) throw();
void operator delete[](void* ptr, const std::nothrow_t&) throw();
```

**Effects:** The deallocation function (3.7.3.2) called by the array form of a delete-expression to render the value of \( \text{ptr} \) invalid.

**Replaceable:** a C++ program can define a function with this function signature that displaces the default version defined by the C++ Standard library.

**Requires:** the value of \( \text{ptr} \) is null or the value returned by an earlier call to operator new[](std::size_t) or operator new[](std::size_t, const std::nothrow_t&).

**Default behavior:** Calls operator delete(ptr) or operator delete(ptr, std::nothrow) respectively.

\(^{218}\) It is not the direct responsibility of operator new[](std::size_t) or operator delete[](void*) to note the repetition count or element size of the array. Those operations are performed elsewhere in the array new and delete expressions. The array new expression, may, however, increase the size argument to operator new[](std::size_t) to obtain space to store supplemental information.
18.4 Dynamic memory management

18.4.1.3 Placement forms

These functions are reserved, a C++ program may not define functions that displace the versions in the Standard C++ library (17.4.3). The provisions of (3.7.3) do not apply to these reserved placement forms of \texttt{operator new} and \texttt{operator delete}.

\begin{verbatim}
void* operator new (std::size_t size, void* ptr) throw();
\end{verbatim}

\textit{Returns:} \texttt{ptr}.

\textit{Remarks:} Intentionally performs no other action.

\begin{verbatim}
void* operator new[] (std::size_t size, void* ptr) throw();
\end{verbatim}

\textit{Returns:} \texttt{ptr}.

\textit{Remarks:} Intentionally performs no other action.

\begin{verbatim}
void operator delete (void* ptr, void*) throw();
\end{verbatim}

\textit{Effects:} Intentionally performs no action.

\textit{Remarks:} Default function called when any part of the initialization in a placement new expression that invokes the library's non-array placement operator new terminates by throwing an exception (5.3.4).

\begin{verbatim}
void operator delete[] (void* ptr, void*) throw();
\end{verbatim}

\textit{Effects:} Intentionally performs no action.

\textit{Remarks:} Default function called when any part of the initialization in a placement new expression that invokes the library's array placement operator new terminates by throwing an exception (5.3.4).

18.4.2 Storage allocation errors

18.4.2.1 Class \texttt{bad_alloc}

\begin{verbatim}
namespace std {
    class bad_alloc : public exception {
        public:
            bad_alloc () throw();
            bad_alloc (const bad_alloc&) throw();
            bad_alloc& operator= (const bad_alloc&) throw();
            virtual const char* what() const throw();
        }
    }
\end{verbatim}
The class `bad_alloc` defines the type of objects thrown as exceptions by the implementation to report a failure to allocate storage.

```cpp
bad_alloc() throw();
```

**Effects:** Constructs an object of class `bad_alloc`.

**Remarks:** The result of calling `what()` on the newly constructed object is implementation-defined.

```cpp
bad_alloc(const bad_alloc &) throw();
bad_alloc& operator=(const bad_alloc &) throw();
```

**Effects:**Copies an object of class `bad_alloc`.

```cpp
virtual const char* what() const throw();
```

**Returns:** An implementation-defined NTBS.

### 18.4.2.2 Type `new_handler`

```cpp
typedef void (*new_handler)();
```

The type of a *handler function* to be called by `operator new()` or `operator new[]( )` (18.4.1) when they cannot satisfy a request for additional storage.

**Required behavior:** A `new_handler` shall perform one of the following:

- make more storage available for allocation and then return;
- throw an exception of type `bad_alloc` or a class derived from `bad_alloc`;
- call either `abort()` or `exit()`;

### 18.4.2.3 set_new_handler

```cpp
new_handler set_new_handler(new_handler new_p) throw();
```

**Effects:** Establishes the function designated by `new_p` as the current `new_handler`.

**Returns:** 0 on the first call, the previous `new_handler` on subsequent calls.

### 18.5 Type identification

The header `<typeinfo>` defines a type associated with type information generated by the implementation. It also defines two types for reporting dynamic type identification errors.

**Header `<typeinfo>` synopsis**

```cpp
namespace std {
    class type_info;
    class bad_cast;
    class bad_typeid;
}
```

Draft
The class `type_info` describes type information generated by the implementation. Objects of this class effectively store a pointer to a name for the type, and an encoded value suitable for comparing two types for equality or collating order. The names, encoding rule, and collating sequence for types are all unspecified and may differ between programs.

```cpp
bool operator==(const type_info& rhs) const;
```

**Effects:** Compares the current object with `rhs`.

**Returns:** `true` if the two values describe the same type.

```cpp
bool operator!=(const type_info& rhs) const;
```

**Returns:** `!(this == rhs)`.

```cpp
bool before(const type_info& rhs) const;
```

**Effects:** Compares the current object with `rhs`.

**Returns:** `true` if `*this` precedes `rhs` in the implementation’s collation order.

```cpp
const char* name() const;
```

**Returns:** an implementation-defined NTBS.

**Remarks:** The message may be a null-terminated multibyte string (17.3.2.1.3.2), suitable for conversion and display as a wstring (21.2.22.2.1.4)

```cpp
type_info(const type_info& rhs);
type_info& operator=(const type_info& rhs);
```

**Effects:** Copies a `type_info` object.

**Remarks:** Since the copy constructor and assignment operator for `type_info` are private to the class, objects of this type cannot be copied.
18.5.2 Class bad_cast

namespace std {
    class bad_cast : public exception {
    public:
        bad_cast() throw();
        bad_cast(const bad_cast& ) throw();
        bad_cast& operator=(const bad_cast& ) throw();
        virtual const char* what() const throw();
    }
}

The class bad_cast defines the type of objects thrown as exceptions by the implementation to report the execution of an invalid dynamic-cast expression (5.2.7).

bad_cast() throw();

Effects: Constructs an object of class bad_cast.

Remarks: The result of calling what() on the newly constructed object is implementation-defined.

bad_cast(const bad_cast& ) throw();
bad_cast& operator=(const bad_cast& ) throw();

Effects: Copies an object of class bad_cast.

virtual const char* what() const throw();

Returns: An implementation-defined NTBS.

Remarks: The message may be a null-terminated multibyte string (17.3.1.3.2), suitable for conversion and display as a wstring (21.2, 22.2.1.4)

18.5.3 Class bad_typeid

namespace std {
    class bad_typeid : public exception {
    public:
        bad_typeid() throw();
        bad_typeid(const bad_typeid& ) throw();
        bad_typeid& operator=(const bad_typeid& ) throw();
        virtual const char* what() const throw();
    }
}

The class bad_typeid defines the type of objects thrown as exceptions by the implementation to report a null pointer in a typeid expression (5.2.8).

bad_typeid() throw();

Effects: Constructs an object of class bad_typeid.

Remarks: The result of calling what() on the newly constructed object is implementation-defined.
18.6 Exception handling

The header `<exception>` defines several types and functions related to the handling of exceptions in a C++ program.

Header `<exception>` synopsis

```cpp
namespace std {
    class exception;
    class bad_exception;

    typedef void (*unexpected_handler)();
    unexpected_handler set_unexpected(unexpected_handler f) throw();
    void unexpected();

    typedef void (*terminate_handler)();
    terminate_handler set_terminate(terminate_handler f) throw();
    void terminate();

    bool uncaught_exception() throw();
}
```

See also: 15.5.

18.6.1 Class exception

```cpp
namespace std {
    class exception {
    public:
        exception() throw();
        exception(const exception&) throw();
        exception& operator=(const exception&) throw();
        virtual ~exception() throw();
        virtual const char* what() const throw();
    };
}
```

The class `exception` defines the base class for the types of objects thrown as exceptions by C++ Standard library components, and certain expressions, to report errors detected during program execution.

```cpp
exception() throw();
```

Draft
Effects: Constructs an object of class exception.
Remarks: Does not throw any exceptions.

```cpp
exception(const exception&) throw();
exception& operator=(const exception&) throw();
```

Effects: Copies an exception object.
Remarks: The effects of calling what() after assignment are implementation-defined.

```cpp
virtual ~exception() throw();
```

Effects: Destroys an object of class exception.
Remarks: Does not throw any exceptions.

```cpp
virtual const char* what() const throw();
```

Returns: An implementation-defined NTBS.
Remarks: The message may be a null-terminated multibyte string (17.3.1.3.2), suitable for conversion and display as a wstring (21.2, 22.2.1.4). The return value remains valid until the exception object from which it is obtained is destroyed or a non-const member function of the exception object is called.

### 18.6.2 Violating exception-specifications

#### 18.6.2.1 Class bad_exception

```cpp
namespace std {
  class bad_exception : public exception {
    public:
      bad_exception() throw();
      bad_exception(const bad_exception&) throw();
      bad_exception& operator=(const bad_exception&) throw();
      virtual const char* what() const throw();
  };
}
```

The class bad_exception defines the type of objects thrown as described in (15.5.2).

```cpp
bad_exception() throw();
```

Effects: Constructs an object of class bad_exception.
Remarks: The result of calling what() on the newly constructed object is implementation-defined.

```cpp
bad_exception(const bad_exception&) throw();
bad_exception& operator=(const bad_exception&) throw();
```

Effects: Copies an object of class bad_exception.

```cpp
virtual const char* what() const throw();
```
Returns: An implementation-defined NTBS.

Remarks: The message may be a null-terminated multibyte string (17.3.2.1.3.2), suitable for conversion and display as a wstring (21.2, 22.2.1.4).

18.6.2.2 Type unexpected_handler

typedef void (*unexpected_handler)();

The type of a handler function to be called by unexpected() when a function attempts to throw an exception not listed in its exception-specification.

Required behavior: An unexpected_handler shall not return. See also 15.5.2.

Default behavior: The implementation’s default unexpected_handler calls terminate().

18.6.2.3 set_unexpected

unexpected_handler set_unexpected(unexpected_handler f) throw();

Effects: Establishes the function designated by f as the current unexpected_handler.

Requires: f shall not be a null pointer.

Returns: The previous unexpected_handler.

18.6.2.4 unexpected

void unexpected();

Called by the implementation when a function exits via an exception not allowed by its exception-specification (15.5.2). May also be called directly by the program.

Effects: Calls the unexpected_handler function in effect immediately after evaluating the throw-expression (18.6.2.2), if called by the implementation, or calls the current unexpected_handler, if called by the program.

18.6.3 Abnormal termination

18.6.3.1 Type terminate_handler

typedef void (*terminate_handler)();

The type of a handler function to be called by terminate() when terminating exception processing.

Required behavior: A terminate_handler shall terminate execution of the program without returning to the caller.

Default behavior: The implementation’s default terminate_handler calls abort().

Draft
18.6.3.2 set_terminate

`terminate_handler set_terminate(terminate_handler f) throw();`

*Effects:* Establishes the function designated by `f` as the current handler function for terminating exception processing.

*Requires:* `f` shall not be a null pointer.

*Returns:* The previous `terminate_handler`.

18.6.3.3 terminate

`void terminate();`

Called by the implementation when exception handling must be abandoned for any of several reasons (15.5.1). May also be called directly by the program.

*Effects:* Calls the `terminate_handler` function in effect immediately after evaluating the `throw-expression` (18.6.3.1), if called by the implementation, or calls the current `terminate_handler` function, if called by the program.

18.6.4 uncaught_exception

`bool uncaught_exception() throw();`

*Returns:* `true` after completing evaluation of a `throw-expression` until either completing initialization of the `exception-declaration` in the matching handler or entering `unexpected()` due to the throw; or after entering `terminate()` for any reason other than an explicit call to `terminate()`. [Note: This includes stack unwinding (15.2). — end note]

*Remarks:* When `uncaught_exception()` is `true`, throwing an exception can result in a call of `terminate()` (15.5.1).

18.7 Other runtime support

`<stdarg>` (variable arguments), `<setjmp>` (nonlocal jumps), `<time>` (system clock `clock()`, `time()`), `<signal>` (signal handling), and `<stdlib>` (runtime environment `getenv()`, `system()`).

Draft
The restrictions that ISO C places on the second parameter to the `va_start()` macro in header `<stdarg.h>` are different in this International Standard. The parameter `parmN` is the identifier of the rightmost parameter in the variable parameter list of the function definition (the one just before the `...`).\(^{219}\) If the parameter `parmN` is declared with a function, array, or reference type, or with a type that is not compatible with the type that results when passing an argument for which there is no parameter, the behavior is undefined.

**SEE ALSO**: ISO C subclause 4.8.1.1.

The function signature `longjmp(jmp_buf jbuf, int val)` has more restricted behavior in this International Standard. If any automatic objects would be destroyed by a thrown exception transferring control to another (destination) point in the program, then a call to `longjmp(jbuf, val)` at the throw point that transfers control to the same (destination) point has undefined behavior.

**SEE ALSO**: ISO C subclause 7.10.4, 7.8, 7.6, 7.12.

The common subset of the C and C++ languages consists of all declarations, definitions, and expressions that may appear in a well formed C++ program and also in a conforming C program. A POF (“plain old function”) is a function that uses only features from this common subset, and that does not directly or indirectly use any function that is not a POF. All signal handlers shall have C linkage. A POF that could be used as a signal handler in a conforming C program does not produce undefined behavior when used as a signal handler in a C++ program. The behavior of any other function used as a signal handler in a C++ program is implementation-defined.\(^ {220}\)

\(^{219}\) Note that `va_start` is required to work as specified even if unary `operator&` is overloaded for the type of `parmN`.

\(^{220}\) In particular, a signal handler using exception handling is very likely to have problems.
Chapter 19  Diagnostics library  [lib.diagnostics]

1. This clause describes components that C++ programs may use to detect and report error conditions.
2. The following subclauses describe components for reporting several kinds of exceptional conditions, documenting program assertions, and a global variable for error number codes, as summarized in Table 24.

Table 24: Diagnostics library summary

</tbody>
</table>

19.1 Exception classes  [lib.std.exceptions]

1. The Standard C++ library provides classes to be used to report certain errors (17.4.4.8) in C++ programs. In the error model reflected in these classes, errors are divided into two broad categories: logic errors and runtime errors.
2. The distinguishing characteristic of logic errors is that they are due to errors in the internal logic of the program. In theory, they are preventable.
3. By contrast, runtime errors are due to events beyond the scope of the program. They cannot be easily predicted in advance. The header <stdexcept> defines several types of predefined exceptions for reporting errors in a C++ program. These exceptions are related by inheritance.

**Header** <stdexcept> synopsis

```cpp
namespace std {
    class logic_error;
    class domain_error;
    class invalid_argument;
    class length_error;
    class out_of_range;
    class runtime_error;
    class range_error;
    class overflow_error;
    class underflow_error;
}
```

19.1.1 Class logic_error  [lib.logic.error]
The class \texttt{logic\_error} defines the type of objects thrown as exceptions to report errors presumably detectable before the program executes, such as violations of logical preconditions or class invariants.

\begin{verbatim}
logic\_error(const string& what_arg); 
\end{verbatim}

\textbf{Effects:} Constructs an object of class \texttt{logic\_error}.

\textbf{Postcondition:} \texttt{strcmp(what(), what\_arg.c\_str()) == 0}.

### 19.1.2 Class \texttt{domain\_error}

The class \texttt{domain\_error} defines the type of objects thrown as exceptions by the implementation to report domain errors.

\begin{verbatim}
domain\_error(const string& what_arg); 
\end{verbatim}

\textbf{Effects:} Constructs an object of class \texttt{domain\_error}.

\textbf{Postcondition:} \texttt{strcmp(what(), what\_arg.c\_str()) == 0}.

### 19.1.3 Class \texttt{invalid\_argument}

The class \texttt{invalid\_argument} defines the type of objects thrown as exceptions to report an invalid argument.

\begin{verbatim}
invalid\_argument(const string& what_arg); 
\end{verbatim}

\textbf{Effects:} Constructs an object of class \texttt{invalid\_argument}.

\textbf{Postcondition:} \texttt{strcmp(what(), what\_arg.c\_str()) == 0}.
19.1.4 Class length_error

namespace std {
    class length_error : public logic_error {
        public:
            explicit length_error(const string & what_arg);
    };
}

The class length_error defines the type of objects thrown as exceptions to report an attempt to produce an object whose length exceeds its maximum allowable size.

length_error(const string & what_arg);

Effects: Constructs an object of class length_error.

Postcondition: strcmp(what(), what_arg.c_str()) == 0.

19.1.5 Class out_of_range

namespace std {
    class out_of_range : public logic_error {
        public:
            explicit out_of_range(const string & what_arg);
    };
}

The class out_of_range defines the type of objects thrown as exceptions to report an argument value not in its expected range.

out_of_range(const string & what_arg);

Effects: Constructs an object of class out_of_range.

Postcondition: strcmp(what(), what_arg.c_str()) == 0.

19.1.6 Class runtime_error

namespace std {
    class runtime_error : public exception {
        public:
            explicit runtime_error(const string & what_arg);
    };
}

The class runtime_error defines the type of objects thrown as exceptions to report errors presumably detectable only when the program executes.

runtime_error(const string & what_arg);
19.1 Exception classes

**Effects:** Constructs an object of class `runtime_error`.

**Postcondition:** `strcmp(what(), what_arg.c_str()) == 0`.

### 19.1.7 Class `range_error` [lib.range.error]

```cpp
namespace std {
  class range_error : public runtime_error {
    public:
      explicit range_error(const string & what_arg);
    }
}
```

The class `range_error` defines the type of objects thrown as exceptions to report range errors in internal computations.

```cpp
range_error(const string & what_arg);
```

**Effects:** Constructs an object of class `range_error`.

**Postcondition:** `strcmp(what(), what_arg.c_str()) == 0`.

### 19.1.8 Class `overflow_error` [lib.overflow.error]

```cpp
namespace std {
  class overflow_error : public runtime_error {
    public:
      explicit overflow_error(const string & what_arg);
    }
}
```

The class `overflow_error` defines the type of objects thrown as exceptions to report an arithmetic overflow error.

```cpp
overflow_error(const string & what_arg);
```

**Effects:** Constructs an object of class `overflow_error`.

**Postcondition:** `strcmp(what(), what_arg.c_str()) == 0`.

### 19.1.9 Class `underflow_error` [lib.underflow.error]

```cpp
namespace std {
  class underflow_error : public runtime_error {
    public:
      explicit underflow_error(const string & what_arg);
    }
}
```

The class `underflow_error` defines the type of objects thrown as exceptions to report an arithmetic underflow error.

```cpp
underflow_error(const string & what_arg);
```
2  Effects: Constructs an object of class underflow_error.
3  Postcondition: strcmp(what(), what_arg.c_str()) == 0.

19.2 Assertions
[lib.assertions]

1  Provides macros for documenting C++ program assertions, and for disabling the assertion checks.

Header <cassert> (Table 25):

Table 25: Header <cassert> synopsis

<table>
<thead>
<tr>
<th>Type</th>
<th>Name(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Macro:</td>
<td>assert</td>
</tr>
</tbody>
</table>

2  The contents are the same as the Standard C library header <assert.h>.

SEE ALSO: ISO C subclause 7.2.

19.3 Error numbers
[lib.errno]

1  Header <cerrno> (Table 26):

Table 26: Header <cerrno> synopsis

<table>

<tr>
<th>Type</th>
<th>Name(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Macros:</td>
<td>EDOM EILSEQ ERANGE errno</td>
</tr>
</tbody>
</table>

2  The contents are the same as the Standard C library header <errno.h>, except that errno shall be defined as a macro.

SEE ALSO: ISO C subclause 7.1.4, 7.2, Amendment 1 subclause 4.3.

Draft
19.3 Error numbers
Chapter 20   General utilities library   [lib.utilities]

1 This clause describes components used by other elements of the Standard C++ library. These components may also be used by C++ programs.

2 The following clauses describe utility and allocator requirements, utility components, function objects, dynamic memory management utilities, and date/time utilities, as summarized in Table 27.

Table 27: General utilities library summary

<table>
<thead>
<tr>
<th>Subclause</th>
<th>Header(s)</th>

<td>&lt;cstdlib&gt;, &lt;cstring&gt;</td>
</tr>
<tr>
<td>20.5 Date and time</td>
<td>&lt;ctime&gt;</td>
</tr>
</tbody>
</table>

20.1 Requirements   [lib.utility.requirements]

1 20.1 describes requirements on template arguments. 20.1.1 through 20.1.4 describe requirements on types used to instantiate templates. 20.1.6 describes the requirements on storage allocators.

20.1.1 Equality comparison   [lib.equalitycomparable]

1 In Table 28, T is a type to be supplied by a C++ program instantiating a template, a, b and c are values of type const T.

<table>
<thead>
<tr>
<th>expression</th>
<th>return type</th>
<th>requirement</th>
</tr>
</thead>
<tbody>

<td>— If a == b, then b == a.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>— If a == b and b == c, then a == c.</td>
</tr>
</tbody>
</table>
20.1 Requirements

20.1.2 Less than comparison

In the following Table 29, T is a type to be supplied by a C++ program instantiating a template, a and b are values of type T.

<table>
<thead>
<tr>
<th>expression</th>
<th>return type</th>
<th>requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>a &lt; b</td>
<td>convertible to bool</td>
<td>&lt; is a strict weak ordering relation (25.3)</td>
</tr>
</tbody>
</table>

20.1.3 Copy construction

In the following Table 30, T is a type to be supplied by a C++ program instantiating a template, t is a value of type T, and u is a value of type const T.

<table>
<thead>
<tr>
<th>expression</th>
<th>return type</th>
<th>requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>T(t)</td>
<td>t</td>
<td>t is equivalent to T(t)</td>
</tr>
<tr>
<td>T(u)</td>
<td>u</td>
<td>u is equivalent to T(u)</td>
</tr>
<tr>
<td>t.~T()</td>
<td></td>
<td>t.~T() is equivalent to T(u)</td>
</tr>
<tr>
<td>&amp;t</td>
<td>T*</td>
<td>&amp;t denotes the address of t</td>
</tr>
<tr>
<td>&amp;u</td>
<td>const T*</td>
<td>&amp;u denotes the address of u</td>
</tr>
</tbody>
</table>

20.1.4 Swapping

In the following Table 31, T is a non-const type to be supplied by a C++ program instantiating a template, and t and u are values of type T.

<table>
<thead>
<tr>
<th>expression</th>
<th>return type</th>
<th>post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>swap(t,u)</td>
<td>void</td>
<td>t has the value originally held by u, and u has the value originally held by t</td>
</tr>
</tbody>
</table>

The Swappable requirement is met by satisfying one or more of the following conditions:

— T is Swappable if T satisfies the CopyConstructible requirements (20.1.3) and the Assignable requirements (23.1);
— T is Swappable if a namespace scope function named swap exists in the same namespace as the definition of T, such that the expression swap(t, u) is valid and has the semantics described in Table 31.
20.1.5 Default construction

The default constructor is not required. Certain container class member function signatures specify the default constructor as a default argument. `T()` shall be a well-defined expression (8.5) if one of those signatures is called using the default argument (8.3.6).

20.1.6 Allocator requirements

The library describes a standard set of requirements for allocators, which are objects that encapsulate the information about an allocation model. This information includes the knowledge of pointer types, the type of their difference, the type of the size of objects in this allocation model, as well as the memory allocation and deallocation primitives for it. All of the containers (clause 23) are parameterized in terms of allocators.

Table 32 describes the requirements on types manipulated through allocators. All the operations on the allocators are expected to be amortized constant time. Table 33 describes the requirements on allocator types.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>T, U</code></td>
<td>any non-const, non-reference type</td>
</tr>
<tr>
<td><code>X</code></td>
<td>an Allocator class for type <code>T</code></td>
</tr>
<tr>
<td><code>Y</code></td>
<td>the corresponding Allocator class for type <code>U</code></td>
</tr>
<tr>
<td><code>t</code></td>
<td>a value of type <code>const T</code></td>
</tr>
<tr>
<td><code>a, a1, a2</code></td>
<td>values of type <code>X</code></td>
</tr>
<tr>
<td><code>b</code></td>
<td>a value of type <code>Y</code></td>
</tr>
<tr>
<td><code>p</code></td>
<td>a value of type <code>X::pointer</code>, obtained by calling <code>a1.allocate</code>, where <code>a1 == a</code></td>
</tr>
<tr>
<td><code>q</code></td>
<td>a value of type <code>X::const_pointer</code> obtained by conversion from a value <code>p</code>.</td>
</tr>
<tr>
<td><code>r</code></td>
<td>a value of type <code>X::reference</code> obtained by the expression <code>*p</code>.</td>
</tr>
<tr>
<td><code>s</code></td>
<td>a value of type <code>X::const_reference</code> obtained by the expression <code>*q</code> or by conversion from a value <code>r</code>.</td>
</tr>
<tr>
<td><code>u</code></td>
<td>a value of type <code>Y::const_pointer</code> obtained by calling <code>Y::allocate</code>, or else 0.</td>
</tr>
<tr>
<td><code>n</code></td>
<td>a value of type <code>X::size_type</code>.</td>
</tr>
</tbody>
</table>
Table 33: Allocator requirements

<tr>
<td>a.destroy(p)</td>
<td>(not used)</td>
<td>Effect: ((T*)p)-&gt;~T()</td>
</tr>
</tbody>
</table>

³ The member class template `rebind` in the table above is effectively a typedef template: if the name Allocator is bound to SomeAllocator<T>, then Allocator::rebind<U>::other is the same type as SomeAllocator<U>.

⁴ Implementations of containers described in this International Standard are permitted to assume that their Allocator template parameter meets the following two additional requirements beyond those in Table 33.

²²¹ It is intended that a.allocate be an efficient means of allocating a single object of type T, even when sizeof(T) is small. That is, there is no need for a container to maintain its own “free list”.

Draft
All instances of a given allocator type are required to be interchangeable and always compare equal to each other.

The typedef members `pointer`, `const_pointer`, `size_type`, and `difference_type` are required to be `T*`, `T const*`, `std::size_t`, and `std::ptrdiff_t`, respectively.

Implementors are encouraged to supply libraries that can accept allocators that encapsulate more general memory models and that support non-equal instances. In such implementations, any requirements imposed on allocators by containers beyond those requirements that appear in Table 33, and the semantics of containers and algorithms when allocator instances compare non-equal, are implementation-defined.

## 20.2 Utility components

This subclause contains some basic function and class templates that are used throughout the rest of the library.

### Header `<utility>` synopsis

```cpp
namespace std {
    // 20.2.1, operators:
    namespace rel_ops {
        template < class T > bool operator!=(const T&, const T&);
        template < class T > bool operator>(const T&, const T&);
        template < class T > bool operator<=(const T&, const T&);
        template < class T > bool operator>=(const T&, const T&);
    }

    // 20.2.2, pairs:
    template < class T1, class T2 > struct pair;
    template < class T1, class T2 >
        bool operator==(const pair<T1,T2>&, const pair<T1,T2>&);
    template < class T1, class T2 >
        bool operator<(const pair<T1,T2>&, const pair<T1,T2>&);
    template < class T1, class T2 >
        bool operator!=(const pair<T1,T2>&, const pair<T1,T2>&);
    template < class T1, class T2 >
        bool operator>(const pair<T1,T2>&, const pair<T1,T2>&);
    template < class T1, class T2 >
        bool operator>=(const pair<T1,T2>&, const pair<T1,T2>&);
    template < class T1, class T2 >
        bool operator<=(const pair<T1,T2>&, const pair<T1,T2>&);
    template < class T1, class T2 >
        pair<T1,T2> make_pair(T1, T2);
}
```

### 20.2.1 Operators

To avoid redundant definitions of `operator!=` out of `operator==` and operators `>`, `<=`, and `>=` out of `operator<`, the library provides the following:

```cpp
template < class T > bool operator!=(const T& x, const T& y);
```

**Requires:** Type T is `EqualityComparable (20.1.1)`.  
**Returns:** !(x == y).
template <class T> bool operator > (const T& x, const T& y);

Requires: Type T is LessThanComparable (20.1.2).
Returns: y < x.

template <class T> bool operator <= (const T& x, const T& y);

Requires: Type T is LessThanComparable (20.1.2).
Returns: !(y < x).

template <class T> bool operator >= (const T& x, const T& y);

Requires: Type T is LessThanComparable (20.1.2).
Returns: !(x < y).

In this library, whenever a declaration is provided for an operator !=, operator >, operator >=, or operator <=, and requirements and semantics are not explicitly provided, the requirements and semantics are as specified in this clause.

20.2.2 Pairs

The library provides a template for heterogeneous pairs of values. The library also provides a matching function template to simplify their construction.

template <class T1, class T2>
struct pair {
    typedef T1 first_type;
    typedef T2 second_type;

    T1 first;
    T2 second;

    pair();
    pair(const T1& x, const T2& y);
    template <class U, class V> pair(const pair<U, V>& p);
};

pair();

Effects: Initializes its members as if implemented: pair(): first(), second() {}

pair(const T1& x, const T2& y);

Effects: The constructor initializes first with x and second with y.

template <class U, class V> pair(const pair<U, V>& p);

Effects: Initializes members from the corresponding members of the argument, performing implicit conversions as needed.

template <class T1, class T2>
bool operator == (const pair<T1, T2>& x, const pair<T1, T2>& y);
419 General utilities library

20.3 Function objects

5 Returns: \( x.\text{first} == y.\text{first} && x.\text{second} == y.\text{second} \).

template \( \text{class T1, class T2} \)
\[
\text{bool operator\langle (const pair\langle T1, T2\rangle & x, const pair\langle T1, T2\rangle & y)\rangle;}
\]

6 Returns: \( x.\text{first} < y.\text{first} || !(y.\text{first} < x.\text{first}) && x.\text{second} < y.\text{second} \).

template \( \text{class T1, class T2} \)
\[
\text{pair\langle T1, T2\rangle make_pair\langle T1 \& x, T2 \& y\rangle;}
\]

7 Returns: \( \text{pair\langle T1, T2\rangle (x, y)} \).

8 [Example: In place of:
\[
\text{return pair\langle \text{int, double}\rangle (5, 3.1415926); // explicit types}
\]

a C++ program may contain:
\[
\text{return make_pair\langle 5, 3.1415926\rangle; // types are deduced}
\]

— end example ]

20.3 Function objects [lib.function.objects]

1 Function objects are objects with an \( \text{operator()} \) defined. In the places where one would expect to pass a pointer to a function to an algorithmic template (clause 25), the interface is specified to accept an object with an \( \text{operator()} \) defined. This not only makes algorithmic templates work with pointers to functions, but also enables them to work with arbitrary function objects.

2 Header \texttt{<functional> synopsis}

namespace std {
   // 20.3.1, base:
   \text{template <\text{class Arg, class Result}> struct unary\_function;}
   \text{template <\text{class Arg1, class Arg2, class Result}> struct binary\_function;}

   // 20.3.2, arithmetic operations:
   \text{template <\text{class T}> struct plus;}
   \text{template <\text{class T}> struct minus;}
   \text{template <\text{class T}> struct multiplies;}
   \text{template <\text{class T}> struct divides;}
   \text{template <\text{class T}> struct modulus;}
   \text{template <\text{class T}> struct negate;}

   // 20.3.3, comparisons:
   \text{template <\text{class T}> struct equal\_to;}
   \text{template <\text{class T}> struct not\_equal\_to;}
   \text{template <\text{class T}> struct greater;}
   \text{template <\text{class T}> struct less;}
   \text{template <\text{class T}> struct greater\_equal;}

\text{222) According to (12.8), an implementation is permitted to not perform a copy of an argument, thus avoiding unnecessary copies.}

Draft
template <class T> struct less_equal;

// 20.3.4, logical operations:
template <class T> struct logical_and;
template <class T> struct logical_or;
template <class T> struct logical_not;

// 20.3.5, negators:
template <class Predicate> class unary_negate;
template <class Predicate>
    unary_negate<Predicate> not1(const Predicate&);
template <class Predicate> class binary_negate;
template <class Predicate>
    binary_negate<Predicate> not2(const Predicate&);

// 20.3.6, binders:
template <class Operation> class binder1st;
template <class Operation, class T>
    binder1st<Operation> bind1st(const Operation&, const T&);
template <class Operation> class binder2nd;
template <class Operation, class T>
    binder2nd<Operation> bind2nd(const Operation&, const T&);

// 20.3.7, adaptors:
template <class Arg, class Result> class pointer_to_unary_function;
template <class Arg, class Result>
    pointer_to_unary_function<Arg,Result> ptr_fun(Result (*)(Arg));
template <class Arg1, class Arg2, class Result>
    class pointer_to_binary_function;
template <class Arg1, class Arg2, class Result>
    pointer_to_binary_function<Arg1,Arg2,Result>
        ptr_fun(Result (*)(Arg1,Arg2));

// 20.3.8, adaptors:
template <class S, class T> class mem_fun_t;
template <class S, class T, class A> class mem_fun1_t;
template <class S, class T>
    mem_fun_t<S,T> mem_fun(S (T::*f)());
template <class S, class T, class A>
    mem_fun1_t<S,T,A> mem_fun(S (T::*f)(A));
template <class S, class T> class mem_fun_ref_t;
template <class S, class T, class A> class mem_fun1_ref_t;
template <class S, class T>
    mem_fun_ref_t<S,T> mem_fun_ref(S (T::*f)());
template <class S, class T, class A>
    mem_fun1_ref_t<S,T,A> mem_fun_ref(S (T::*f)(A));

template <class S, class T> class const_mem_fun_t;
template <class S, class T, class A> class const_mem_fun1_t;
template <class S, class T>
const_mem_fun_t<S,T> mem_fun (S (*f)() const);
template <class S, class T, class A>
const_mem_fun1_t<S,T,A> mem_fun (S (*f)(A) const);
template <class S, class T, class A> class const_mem_fun1_ref_t;
template <class S, class T> class const_mem_fun_ref_t;
template <class S, class T>
const_mem_fun_ref_t<S,T> mem_fun_ref (S (*f)() const);
template <class S, class T, class A>
const_mem_fun1_ref_t<S,T,A> mem_fun_ref (S (*f)(A) const);
}

Example: If a C++ program wants to have a by-element addition of two vectors a and b containing double and put the result into a, it can do:

transform(a.begin(), a.end(), b.begin(), a.begin(), plus<double>());

— end example

Example: To negate every element of a:

transform(a.begin(), a.end(), a.begin(), negate<double>());

— end example

To enable adaptors and other components to manipulate function objects that take one or two arguments it is required that the function objects correspondingly provide typedefs argument_type and result_type for function objects that take one argument and first_argument_type, second_argument_type, and result_type for function objects that take two arguments.

20.3.1 Base

The following classes are provided to simplify the typedefs of the argument and result types:

template <class Arg, class Result>
struct unary_function {
    typedef Arg argument_type;
    typedef Result result_type;
};

template <class Arg1, class Arg2, class Result>
struct binary_function {
    typedef Arg1 first_argument_type;
    typedef Arg2 second_argument_type;
    typedef Result result_type;
};

20.3.2 Arithmetic operations

The library provides basic function object classes for all of the arithmetic operators in the language (5.6, 5.7).

template <class T> struct plus : binary_function<T,T,T> {
    T operator()(const T& x, const T& y) const;
};

Draft
20.3 Function objects

20.3.3 Comparisons [lib.comparisons]

The library provides basic function object classes for all of the comparison operators in the language (5.9, 5.10).

```cpp
template <class T> struct equal_to : binary_function<T,T,bool> {
    bool operator()(const T& x, const T& y) const;
};
operator() returns x == y.
```

```cpp
template <class T> struct not_equal_to : binary_function<T,T,bool> {
    bool operator()(const T& x, const T& y) const;
};
operator() returns x != y.
```

```cpp
template <class T> struct greater : binary_function<T,T,bool> {
    bool operator()(const T& x, const T& y) const;
};
operator() returns x > y.
```
template <class T> struct less : binary_function<T,T,bool> {
    bool operator()(const T& x, const T& y) const;
};
operator() returns \( x < y \).

template <class T> struct greater_equal : binary_function<T,T,bool> {
    bool operator()(const T& x, const T& y) const;
};
operator() returns \( x \geq y \).

template <class T> struct less_equal : binary_function<T,T,bool> {
    bool operator()(const T& x, const T& y) const;
};
operator() returns \( x \leq y \).

For templates greater, less, greater_equal, and less_equal, the specializations for any pointer type yield a total order, even if the built-in operators \(<,\),\(\geq,\),\(\leq,\) do not.

### 20.3.4 Logical operations

The library provides basic function object classes for all of the logical operators in the language (5.14, 5.15, 5.3.1).

```
template <class T> struct logical_and : binary_function<T,T,bool> {
    bool operator()(const T& x, const T& y) const;
};
operator() returns \( x \&\& y \).
```

```
template <class T> struct logical_or : binary_function<T,T,bool> {
    bool operator()(const T& x, const T& y) const;
};
operator() returns \( x || y \).
```

```
template <class T> struct logical_not : unary_function<T,bool> {
    bool operator()(const T& x) const;
};
operator() returns \( \neg x \).
```

### 20.3.5 Negators

Negators \( \text{not1} \) and \( \text{not2} \) take a unary and a binary predicate, respectively, and return their complements (5.3.1).

```
template <class Predicate>
class unary_negate
    : public unary_function<typename Predicate::argument_type,bool> {
public:
    explicit unary_negate(const Predicate& pred);

Draft
20.3 Function objects

bool operator()(const typename Predicate::argument_type& x) const;
}

operator() returns !pred(x).

template <class Predicate>
unary_negate<Predicate> not1(const Predicate& pred);

Returns: unary_negate<Predicate>(pred).

template <class Predicate>
class binary_negate

: public binary_function<
    typename Predicate::first_argument_type,
    typename Predicate::second_argument_type, bool>
{
public:
    explicit binary_negate(const Predicate& pred);
    bool operator()(const typename Predicate::first_argument_type& x,
                    const typename Predicate::second_argument_type& y) const;
};

operator() returns !pred(x, y).

template <class Predicate>
binary_negate<Predicate> not2(const Predicate& pred);

Returns:

binary_negate<Predicate>(pred).

20.3.6 Binders

Binders bind1st and bind2nd take a function object f of two arguments and a value x and return a function object of one argument constructed out of f with the first or second argument correspondingly bound to x.

20.3.6.1 Class template binder1st

template <class Operation>
class binder1st

: public unary_function<
    typename Operation::second_argument_type,
    typename Operation::result_type>
{
protected:
    Operation op;
    typename Operation::first_argument_type value;
public:
    binder1st(const Operation& x,
              const typename Operation::first_argument_type& y);
    typename Operation::result_type
    operator()(const typename Operation::second_argument_type& x) const;
    typename Operation::result_type
    operator()(typename Operation::second_argument_type& x) const;
};
The constructor initializes \( op \) with \( x \) and \( value \) with \( y \).

**operator()** returns \( op(value, x) \).

### 20.3.6.2 bind1st

**template** <class Operation, class T>

\[ \text{bind1st<Operation> bind1st(const Operation& op, const T& \( x \));} \]

**Returns:** bind1st<Operation>(\( op \), typename Operation::first_argument_type\( (x) \)).

### 20.3.6.3 Class template binder2nd

**template** <class Operation>

\[ \text{class binder2nd} \]

\[ \text{class binder2nd} : \text{public unary_function<typename Operation::first_argument_type,}
\]

\[ \text{typename Operation::result_type}> \{ \]

**protected:**

\[ \text{Operation op;} \]

\[ \text{typename Operation::second_argument_type value;} \]

**public:**

\[ \text{binder2nd(const Operation& \( x \),}
\]

\[ \text{const typename Operation::second_argument_type& \( y \);} \]

\[ \text{typename Operation::result_type}
\]

\[ \text{operator()}(\text{const typename Operation::first_argument_type& \( z \)} \text{) const;}
\]

\[ \text{typename Operation::result_type}
\]

\[ \text{operator()}(\text{typename Operation::first_argument_type& \( z \)} \text{) const;}
\]

The constructor initializes \( op \) with \( x \) and \( value \) with \( y \).

**operator()** returns \( op(x, value) \).

### 20.3.6.4 bind2nd

**template** <class Operation, class T>

\[ \text{bind2nd<Operation> bind2nd(const Operation& op, const T& \( x \));} \]

**Returns:** bind2nd<Operation>(\( op \), typename Operation::second_argument_type\( (x) \)).

**Example:**

\[ \text{find_if(v.begin(), v.end(), bind2nd(greater<int>(), 5));} \]

finds the first integer in vector \( v \) greater than 5:

\[ \text{find_if(v.begin(), v.end(), bind1st(greater<int>(), 5));} \]

finds the first integer in \( v \) less than 5. — end example ]
20.3 Function objects

20.3.7 Adaptors for pointers to functions

To allow pointers to (unary and binary) functions to work with function adaptors the library provides:

\[
\text{template < class Arg , class Result >}
\text{class pointer_to_unary_function : public unary_function<Arg, Result> {}
\text{public:}
\text{    explicit pointer_to_unary_function(Result (*)(Arg));}
\text{    Result operator()(Arg x) const;}
\text{};}
\]

\(\text{operator}()\) returns \(f(x)\).

\[
\text{template < class Arg , class Result >}
\text{    pointer_to_unary_function<Arg, Result> ptr_fun(Result (*)(Arg));}
\]

\(\text{Returns: }\) pointer_to_unary_function<Arg, Result>(f).

\[
\text{template < class Arg1 , class Arg2 , class Result >}
\text{    class pointer_to_binary_function : public binary_function<Arg1,Arg2, Result> {}
\text{public:}
\text{    explicit pointer_to_binary_function(Result (*)(Arg1, Arg2));}
\text{    Result operator()(Arg1 x, Arg2 y) const;}
\text{};}
\]

\(\text{operator}()\) returns \(f(x, y)\).

\[
\text{template < class Arg1 , class Arg2 , class Result >}
\text{    pointer_to_binary_function<Arg1,Arg2,Result> ptr_fun(Result (*)(Arg1, Arg2));}
\]

\(\text{Returns: }\) pointer_to_binary_function<Arg1,Arg2,Result>(f).

\[
\text{[Example:}
\text{    int compare(const char*, const char*);}
\text{    replace_if(v.begin(), v.end(),}
\text{        not1(bind2nd(ptr_fun(compare), "abc")), "def");}
\text{    replaces each abc with def in sequence v.} \text{— end example]}\]

20.3.8 Adaptors for pointers to members

The purpose of the following is to provide the same facilities for pointer to members as those provided for pointers to functions in 20.3.7.

\[
\text{template < class S , class T > class mem_fun_t : public unary_function<T*, S> {}
\text{public:}
\text{    explicit mem_fun_t(S (T::*p)());}
\text{    S operator()(T* p) const;}
\text{};}
\]

Draft
mem_fun_t calls the member function it is initialized with given a pointer argument.

```cpp
template <class S, class T, class A> class mem_fun1_t
    : public binary_function<T*, A, S> {
public:
    explicit mem_fun1_t(S (T::*p)(A));
    S operator()(T* p, A x) const;
};
```

mem_fun1_t calls the member function it is initialized with given a pointer argument and an additional argument of the appropriate type.

```cpp
template<class S, class T> mem_fun_t<S,T>
    mem_fun(S (T::*f)());
template<class S, class T, class A> mem_fun1_t<S,T,A>
    mem_fun(S (T::*f)(A));
```

mem_fun(&X::f) returns an object through which X::f can be called given a pointer to an X followed by the argument required for f (if any).

```cpp
template <class S, class T> class mem_fun_ref_t
    : public unary_function<T, S> {
public:
    explicit mem_fun_ref_t(S (T::*p)());
    S operator()(T& p) const;
};
```

mem_fun_ref_t calls the member function it is initialized with given a reference argument.

```cpp
template <class S, class T, class A> class mem_fun1_ref_t
    : public binary_function<T, A, S> {
public:
    explicit mem_fun1_ref_t(S (T::*p)(A));
    S operator()(T& p, A x) const;
};
```

mem_fun1_ref_t calls the member function it is initialized with given a reference argument and an additional argument of the appropriate type.

```cpp
template<class S, class T> mem_fun_ref_t<S,T>
    mem_fun_ref(S (T::*f)());
template<class S, class T, class A> mem_fun1_ref_t<S,T,A>
    mem_fun_ref(S (T::*f)(A));
```

mem_fun_ref(&X::f) returns an object through which X::f can be called given a reference to an X followed by the argument required for f (if any).

```cpp
template <class S, class T> class const_mem_fun_t
    : public unary_function< const T*, S> {
public:
    explicit const_mem_fun_t(S (T::*p)() const);
};
```
20.3 Function objects

S operator() (const T* p) const;
};

const_mem_fun_t calls the member function it is initialized with given a pointer argument.

template <class S, class T, class A> class const_mem_fun1_t
: public binary_function<const T*, A, S> {
  public:
    explicit const_mem_fun1_t (S (T::*p)(A) const);
    S operator()(const T* p, A x) const;
};

const_mem_fun1_t calls the member function it is initialized with given a pointer argument and an additional argument of the appropriate type.

template <class S, class T> const_mem_fun_t <S,T>
mem_fun(S (T::*f)() const);

template <class S, class T, class A> const_mem_fun1_t <S,T,A>
mem_fun(S (T::*f)(A) const);

mem_fun(&X::f) returns an object through which X::f can be called given a pointer to an X followed by the argument required for f (if any).

template <class S, class T> const_mem_fun_ref_t
: public unary_function<T, S> {
  public:
    explicit const_mem_fun_ref_t (S (T::*p)() const);
    S operator()(const T& p) const;
};

const_mem_fun_ref_t calls the member function it is initialized with given a reference argument.

template <class S, class T, class A> class const_mem_fun1_ref_t
: public binary_function<T, A, S> {
  public:
    explicit const_mem_fun1_ref_t (S (T::*p)(A) const);
    S operator()(const T& p, A x) const;
};

const_mem_fun1_ref_t calls the member function it is initialized with given a reference argument and an additional argument of the appropriate type.

template <class S, class T> const_mem_fun1_ref_t <S,T>
mem_fun_ref(S (T::*f)() const);

template <class S, class T, class A> const_mem_fun1_ref_t <S,T,A>
mem_fun_ref(S (T::*f)(A) const);

mem_fun_ref(&X::f) returns an object through which X::f can be called given a reference to an X followed by the argument required for f (if any).
20.4 Memory

Header `<memory>` synopsis

```cpp
namespace std {
    // 20.4.1, the default allocator:
    template <class T> class allocator;
    template <> class allocator<void>;
    template <class T, class U>
        bool operator==(const allocator<T>&, const allocator<U>&) throw();
    template <class T, class U>
        bool operator!=(const allocator<T>&, const allocator<U>&) throw();

    // 20.4.2, raw storage iterator:
    template <class OutputIterator, class T> class raw_storage_iterator;

    // 20.4.3, temporary buffers:
    template <class T>
        pair<T*, ptrdiff_t> get_temporary_buffer(ptrdiff_t n);
    template <class T>
        void return_temporary_buffer(T* p);

    // 20.4.4, specialized algorithms:
    template <class InputIterator, class ForwardIterator>
        ForwardIterator uninitialized_copy(InputIterator first, InputIterator last,
            ForwardIterator result);
    template <class ForwardIterator, class T>
        void uninitialized_fill(ForwardIterator first, ForwardIterator last,
            const T& x);
    template <class ForwardIterator, class Size, class T>
        void uninitialized_fill_n(ForwardIterator first, Size n, const T& x);

    // 20.4.5, pointers:
    template <class X> class auto_ptr;
}
```

20.4.1 The default allocator

```cpp
namespace std {
    template <class T> class allocator;

    // specialize for void:
    template <> class allocator<void> {
        public:
            typedef void* pointer;
            typedef const void* const_pointer;
            // reference-to-void members are impossible.
            typedef void value_type;
            template <class U> struct rebind { typedef allocator<U> other; };}
};
```

Draft
template <class T> class allocator {
  public:
    typedef size_t size_type;
    typedef ptrdiff_t difference_type;
    typedef T* pointer;
    typedef const T* const_pointer;
    typedef T& reference;
    typedef const T& const_reference;
    typedef T value_type;
    template <class U> struct rebind { typedef allocator <U> other; }

    allocator () throw();
    allocator (const allocator &) throw();
    template <class U> allocator (const allocator <U> & ) throw();
    ~allocator () throw();

    pointer address (reference x) const;
    const_pointer address (const_reference x) const;

    pointer allocate (size_type n, allocator <void >::const_pointer hint = 0);
    void deallocate (pointer p, size_type n);
    size_type max_size () const throw();
    void construct (pointer p, const T& val);
    void destroy (pointer p);
};

20.4.1.1 allocator members

pointer address (reference x) const;

Returns: &x.

const_pointer address (const_reference x) const;

Returns: &x.

pointer allocate (size_type n, allocator <void >::const_pointer hint = 0);

Remarks: Uses ::operator new (std::size_t) (18.4.1).
Requires: hint either 0 or previously obtained from member allocate and not yet passed to member deallocate. The value hint may be used by an implementation to help improve performance.

Returns: a pointer to the initial element of an array of storage of size n * sizeof(T), aligned appropriately for objects of type T.

Remark: the storage is obtained by calling ::operator new (std::size_t), but it is unspecified when or how

Draft
often this function is called. The use of \texttt{hint} is unspecified, but intended as an aid to locality if an implementation so desires.

7 \textit{Throws:} \texttt{bad_alloc} if the storage cannot be obtained.

void deallocate(pointer \texttt{p}, size_type \texttt{n});

8 \textit{Requires:} \texttt{p} shall be a pointer value obtained from \texttt{allocate()}. \texttt{n} shall equal the value passed as the first argument to the invocation of allocate which returned \texttt{p}.

9 \textit{Effects:} Deallocates the storage referenced by \texttt{p}.

10 \textit{Remarks:} Uses ::\texttt{operator delete(void*)} (18.4.1), but it is unspecified when this function is called.

size_type max_size() const throw();

11 \textit{Returns:} the largest value \texttt{N} for which the call \texttt{allocate(N,0)} might succeed.

void construct(pointer \texttt{p}, const reference \texttt{val});

12 \textit{Effects:} ::\texttt{new(void*)} \texttt{p}) \texttt{T(val) }

void destroy(pointer \texttt{p});

13 \textit{Effects:} \texttt{p->\texttt{~T}}()

\subsection{20.4.1.2 allocator globals} [lib.allocator.globals]

template <class \texttt{T1}, class \texttt{T2}>
bool operator==(const allocator<\texttt{T1>>& , const allocator<\texttt{T2>>&) throw();

1 \textit{Returns:} \texttt{true}.

template <class \texttt{T1}, class \texttt{T2}>
bool operator!=(const allocator<\texttt{T1>>& , const allocator<\texttt{T2>>&) throw();

2 \textit{Returns:} \texttt{false}.

\subsection{20.4.2 Raw storage iterator} [lib.storage.iterator]

\texttt{raw\_storage\_iterator} is provided to enable algorithms to store their results into uninitialized memory. The formal template parameter \texttt{OutputIterator} is required to have its \texttt{operator*} return an object for which \texttt{operator&} is defined and returns a pointer to \texttt{T}, and is also required to satisfy the requirements of an output iterator (24.1.2).

namespace std {
    template <class \texttt{OutputIterator}, class \texttt{T}>
    class raw_storage_iterator
        : public iterator<output_iterator_tag,\texttt{void},\texttt{void},\texttt{void},\texttt{void}> { 
        public:
            explicit raw_storage_iterator(OutputIterator \texttt{x});

    raw_storage_iterator<OutputIterator,\texttt{T}>& operator*();

Draft
raw_storage_iterator<OutputIterator,T>& operator=(const T& element);
raw_storage_iterator<OutputIterator,T>& operator++();
raw_storage_iterator<OutputIterator,T> operator++(int);
}

raw_storage_iterator(OutputIterator x);

Effects: Initializes the iterator to point to the same value to which x points.

raw_storage_iterator<OutputIterator,T>& operator*();

Returns: *this

raw_storage_iterator<OutputIterator,T>& operator=(const T& element);

Effects: Constructs a value from element at the location to which the iterator points.

raw_storage_iterator<OutputIterator,T>& operator++();

Effects: Pre-increment: advances the iterator and returns a reference to the updated iterator.

raw_storage_iterator<OutputIterator,T> operator++(int);

Effects: Post-increment: advances the iterator and returns the old value of the iterator.

20.4.3 Temporary buffers

template <class T>
pair<T*, ptrdiff_t> get_temporary_buffer(pdevdiff_t n);

Effects: Obtains a pointer to storage sufficient to store up to n adjacent T objects.

Returns: A pair containing the buffer’s address and capacity (in the units of sizeof(T)), or a pair of 0 values if no storage can be obtained or if n <= 0.

template <class T> void return_temporary_buffer(T* p);

Effects: Deallocates the buffer to which p points.

Requires: The buffer shall have been previously allocated by get_temporary_buffer.

20.4.4 Specialized algorithms

All the iterators that are used as formal template parameters in the following algorithms are required to have their operator* return an object for which operator& is defined and returns a pointer to T. In the algorithm uninitialized_copy, the formal template parameter InputIterator is required to satisfy the requirements of an input iterator (24.1.1). In all of the following algorithms, the formal template parameter ForwardIterator is required to satisfy the requirements of a forward iterator (24.1.3) and also to satisfy the requirements of a mutable iterator (24.1), and is
required to have the property that no exceptions are thrown from increment, assignment, comparison, or dereference of
valid iterators. In the following algorithms, if an exception is thrown there are no effects.

### 20.4.4.1 uninitialized_copy

```
template <class InputIterator, class ForwardIterator>
ForwardIterator
    uninitialized_copy(InputIterator first, InputIterator last,
                      ForwardIterator result);
```

**Effects:**

```cpp
for (; first != last; ++result, ++first)
    new (static_cast<void*>(&*result))
        typename iterator_traits<ForwardIterator>::value_type(*first);
```

**Returns:** result

### 20.4.4.2 uninitialized_fill

```
template <class ForwardIterator, class T>
void uninitialized_fill(ForwardIterator first, ForwardIterator last,
                        const T & x);
```

**Effects:**

```cpp
for (; first != last; ++first)
    new (static_cast<void*>(&*first))
        typename iterator_traits<ForwardIterator>::value_type(x);
```

### 20.4.4.3 uninitialized_fill_n

```
template <class ForwardIterator, class Size, class T>
void uninitialized_fill_n(ForwardIterator first, Size n, const T & x);
```

**Effects:**

```cpp
for (; n--; ++first)
    new (static_cast<void*>(&*first))
        typename iterator_traits<ForwardIterator>::value_type(x);
```

### 20.4.5 Class template auto_ptr

Template `auto_ptr` stores a pointer to an object obtained via `new` and deletes that object when it itself is destroyed
(such as when leaving block scope 6.7).

Template `auto_ptr_ref` holds a reference to an `auto_ptr`. It is used by the `auto_ptr` conversions to allow `auto_ptr`
objects to be passed to and returned from functions.
namespace std {
  template <class Y> struct auto_ptr_ref {};

  template<class X> class auto_ptr {
    public:
      typedef X element_type;

      // 20.4.5.1 construct/copy/destroy:
      explicit auto_ptr(X* p = 0) throw();
      auto_ptr(auto_ptr&) throw();
      template<class Y> auto_ptr(auto_ptr<Y>&) throw();
      auto_ptr& operator=(auto_ptr&) throw();
      template<class Y> auto_ptr& operator=(auto_ptr<Y>&) throw();
      auto_ptr& operator=(auto_ptr_ref<X> r) throw();
      ~auto_ptr() throw();

      // 20.4.5.2 members:
      X& operator*() const throw();
      X* operator->() const throw();
      X* get() const throw();
      X* release() throw();
      void reset(X* p = 0) throw();

      // 20.4.5.3 conversions:
      auto_ptr(auto_ptr_ref<X>) throw();
      template<class Y> operator auto_ptr_ref<Y>() throw();
      template<class Y> operator auto_ptr<Y>() throw();
  };
}

The auto_ptr provides a semantics of strict ownership. An auto_ptr owns the object it holds a pointer to. Copying an auto_ptr copies the pointer and transfers ownership to the destination. If more than one auto_ptr owns the same object at the same time the behavior of the program is undefined. [Note: The uses of auto_ptr include providing temporary exception-safety for dynamically allocated memory, passing ownership of dynamically allocated memory to a function, and returning dynamically allocated memory from a function. auto_ptr does not meet the CopyConstructible and Assignable requirements for Standard Library container elements and thus instantiating a Standard Library container with an auto_ptr results in undefined behavior. —end note]

20.4.5.1 auto_ptr constructors

  explicit auto_ptr(X* p = 0) throw();

  Postconditions: *this holds the pointer p.

  auto_ptr(auto_ptr& a) throw();

  Effects: Calls a.Release().

  Postconditions: *this holds the pointer returned from a.Release().

  template<class Y> auto_ptr(auto_ptr<Y>& a) throw();

Draft
435  General utilities library  20.4  Memory

4  \textit{Requires}: \(Y\)\* can be implicitly converted to \(X\)\*.

5  \textit{Effects}: Calls \(a\.release()\).

6  \textit{Postconditions}: \(\ast \text{this} \) holds the pointer returned from \(a\.release()\).

\begin{verbatim}
auto_ptr& operator=(auto_ptr& a) throw();
\end{verbatim}

7  \textit{Requires}: The expression delete \(get()\) is well formed.

8  \textit{Effects}: \(\text{reset}(a\.release())\).

9  \textit{Returns}: \(\ast \text{this}\).

\begin{verbatim}
template<class Y> auto_ptr& operator=(auto_ptr&lt;Y)& a) throw();
\end{verbatim}

10  \textit{Requires}: \(Y\)\* can be implicitly converted to \(X\)\*. The expression delete \(get()\) is well formed.

11  \textit{Effects}: \(\text{reset}(a\.release())\).

12  \textit{Returns}: \(\ast \text{this}\).

\begin{verbatim}
~auto_ptr() throw();
\end{verbatim}

13  \textit{Requires}: The expression delete \(get()\) is well formed.

14  \textit{Effects}: delete \(get()\).

\textbf{20.4.5.2  \texttt{auto\_ptr} members} \hfill \texttt{[lib.auto.ptr.members]}

\begin{verbatim}
X& operator*() const throw();
\end{verbatim}

1  \textit{Requires}: \(get() \neq 0\)

2  \textit{Returns}: \(\ast get()\)

\begin{verbatim}
X* operator-() const throw();
\end{verbatim}

3  \textit{Returns}: \(get()\)

\begin{verbatim}
X* get() const throw();
\end{verbatim}

4  \textit{Returns}: The pointer \(\ast \text{this}\) holds.

\begin{verbatim}
X* release() throw();
\end{verbatim}

5  \textit{Returns}: \(get()\)

6  \textit{Postcondition}: \(\ast \text{this} \) holds the null pointer.

\begin{verbatim}
void reset(X* p=0) throw();
\end{verbatim}

7  \textit{Effects}: If \(get() \neq p\) then delete \(get()\).

8  \textit{Postconditions}: \(\ast \text{this} \) holds the pointer \(p\).

Draft
20.4.5.3 auto_ptr conversions

auto_ptr(auto_ptr_ref<X> r) throw();

Effects: Calls p.release() for the auto_ptr p that r holds.

Postconditions: *this holds the pointer returned from release().

template<class Y> operator auto_ptr_ref<Y>() throw();

Returns: An auto_ptr_ref<Y> that holds *this.

template<class Y> operator auto_ptr<Y>() throw();

Effects: Calls release().

Returns: An auto_ptr<Y> that holds the pointer returned from release().

auto_ptr& operator=(auto_ptr_ref<X> r) throw()

Effects: Calls reset(p.release()) for the auto_ptr p that r holds a reference to.

Returns: *this

20.4.6 C Library

Header <cstdlib> (Table 34):

<table>
<thead>
<tr>
<th>Type</th>
<th>Name(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Functions:</td>
<td>calloc</td>
</tr>
<tr>
<td></td>
<td>malloc</td>
</tr>
<tr>
<td></td>
<td>free</td>
</tr>
<tr>
<td></td>
<td>realloc</td>
</tr>
</tbody>
</table>

The contents are the same as the Standard C library header <stdlib.h>, with the following changes:

The functions calloc(), malloc(), and realloc() do not attempt to allocate storage by calling ::operator new() (18.4).

The function free() does not attempt to deallocate storage by calling ::operator delete().

See also: ISO C clause 7.11.2.

Header <cstring> (Table 35):

<table>

Chapter 21  Strings library  [lib.strings]

This clause describes components for manipulating sequences of “characters,” where characters may be of any POD (3.9) type. In this clause such types are called char-like types, and objects of char-like types are called char-like objects or simply “characters.”

The following subclauses describe a character traits class, a string class, and null-terminated sequence utilities, as summarized in Table 37:

<table>
<thead>
<tr>
<th>Subclause</th>
<th>Header(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>21.1 Character traits</td>
<td>&lt;string&gt;</td>
</tr>
<tr>
<td>21.2 String classes</td>
<td>&lt;string&gt;, &lt;cctype&gt;, &lt;cwctype&gt;</td>
</tr>
<tr>
<td>21.4 Null-terminated sequence utilities</td>
<td>&lt;cstring&gt;, &lt;cwchar&gt;, &lt;cstdlib&gt;</td>
</tr>
</tbody>
</table>

21.1 Character traits  [lib.char.traits]

This subclause defines requirements on classes representing character traits, and defines a class template char_traits<charT>, along with two specializations, char_traits<char> and char_traits<wchar_t>, that satisfy those requirements.

Most classes specified in clauses 21.2 and 27 need a set of related types and functions to complete the definition of their semantics. These types and functions are provided as a set of member typedefs and functions in the template parameter ‘traits’ used by each such template. This subclause defines the semantics guaranteed by these members.

To specialize those templates to generate a string or iostream class to handle a particular character container type CharT, that and its related character traits class Traits are passed as a pair of parameters to the string or iostream template as formal parameters charT and traits. Traits::char_type shall be the same as CharT.

This subclause specifies a struct template, char_traits<charT>, and two explicit specializations of it, char_traits<char> and char_traits<wchar_t>, all of which appear in the header <string> and satisfy the requirements below.

21.1.1 Character traits requirements  [lib.char.traits.require]

In Table 38, X denotes a Traits class defining types and functions for the character container type CharT; c and d denote...
values of type CharT; p and q denote values of type const CharT*; s denotes a value of type CharT*; n, i and j denote values of type std::size_t; e and f denote values of type X::int_type; pos denotes a value of type X::pos_type; state denotes a value of type X::state_type; and r denotes an lvalue of type CharT. Operations on Traits shall not throw exceptions.

### Table 38: Traits requirements

2 The struct template

```cpp
template<class charT> struct char_traits;
```

shall be provided in the header `<string>` as a basis for explicit specializations.

3 In the following subclauses, the token `charT` represents the parameter of the traits template.

#### traits typedefs [lib.char.traits.typedefs]

```cpp
typedef CHAR_T char_type;
```

1 The type `char_type` is used to refer to the character container type in the implementation of the library classes defined in 21.2 and clause 27.

```cpp
typedef INT_T int_type;
```
21.1 Character traits

Requires: For a certain character container type char_type, a related container type INT_T shall be a type or class which can represent all of the valid characters converted from the corresponding char_type values, as well as an end-of-file value, eof(). The type int_type represents a character container type which can hold end-of-file to be used as a return type of the iostream class member functions.\footnote{If eof() can be held in char_type then some iostreams operations may give surprising results.}

```cpp
typedef OFF_T off_type;
typedef POS_T pos_type;
```

Requires: Requirements for off_type and pos_type are described in 27.1.2.

```cpp
typedef STATE_T state_type;
```

Requires: state_type shall meet the requirements of Assignable (23.1), CopyConstructible (20.1.3), and DefaultConstructible (20.1.5) types.

21.1.3 char_traits specializations

namespace std {
    template <> struct char_traits<char>;
    template <> struct char_traits<wchar_t>;
}

The header <string> declares two structs that are specializations of the template struct char_traits.

The struct char_traits<char> is the char type specialization of the template struct char_traits, which contains all of the types and functions necessary to ensure the behavior of the classes in 21.2 and clause 27.

The types and static member functions are described in detail in 21.1.

21.1.3.1 struct char_traits<char>

namespace std {
    struct char_traits<char> {
        typedef char char_type;
        typedef int int_type;
        typedef streamoff off_type;
        typedef streampos pos_type;
        typedef mbstate_t state_type;

        static void assign(char_type& c1, const char_type& c2);
        static bool eq(const char_type& c1, const char_type& c2);
        static bool lt(const char_type& c1, const char_type& c2);
        static int compare(const char_type* s1, const char_type* s2, size_t n);
        static size_t length(const char_type* s);
        static const char_type* find(const char_type* s, size_t n,
                                      const char_type& a);
        static char_type* move(char_type* s1, const char_type* s2, size_t n);
    }
}

Draft
The header `<string>` declares a specialization of the template struct char_traits for char. It is for narrow-oriented iostream classes.

The defined types for int_type, pos_type, off_type, and state_type are int, streampos, streamoff, and mbstate_t respectively.

The type streampos is an implementation-defined type that satisfies the requirements for POS_T in §21.1.2.

The type streamoff is an implementation-defined type that satisfies the requirements for OFF_T in §21.1.2.

The type mbstate_t is defined in `<cwchar>` and can represent any of the conversion states possible to occur in an implementation-defined set of supported multibyte character encoding rules.

The two-argument members assign, eq, and lt are defined identically to the built-in operators =, ==, and < respectively.

The member eof() returns EOF.

### §21.1.3.2 struct char_traits<wchar_t> [lib.char.traits.specializations.wchar.t]

namespace std {
    template<>
    struct char_traits<wchar_t> {
        typedef wchar_t char_type;
        typedef wint_t int_type;
        typedef streamoff off_type;
        typedef wstreampos pos_type;
        typedef mbstate_t state_type;

        static void assign(char_type & c1, const char_type & c2);
        static bool eq(const char_type & c1, const char_type & c2);
        static bool lt(const char_type & c1, const char_type & c2);

        static int compare(const char_type* s1, const char_type* s2, size_t n);
        static size_t length(const char_type* s);
        static const char_type* find(const char_type* s, size_t n,
                                      const char_type& a);
        static char_type* move(char_type* s1, const char_type* s2, size_t n);
        static char_type* copy(char_type* s1, const char_type* s2, size_t n);
        static char_type* assign(char_type* s, size_t n, char_type a);

        static int_type not_eof(const int_type & c);
    };
}
The header `<string>` (21.2) declares a specialization of the template struct `char_traits` for `wchar_t`. It is for wide-oriented iostream classes.

The defined types for `int_type`, `pos_type`, and `state_type` are `wint_t`, `wstreampos`, and `mbstate_t` respectively.

The type `wstreampos` is an implementation-defined type that satisfies the requirements for `POS_T` in 21.1.2.

[Note: This paragraph is intentionally empty. — end note]

The type `mbstate_t` is defined in `<cwchar>` and can represent any of the conversion states possible to occur in an implementation-defined set of supported multibyte character encoding rules.

The two-argument members `assign`, `eq`, and `lt` are defined identically to the built-in operators `=`, `==`, and `<` respectively.

The member `eof()` returns `WEOF`.

21.2 String classes

The header `<string>` (21.2) defines a basic string class template and its traits that can handle all char-like (clause 21) template arguments with several function signatures for manipulating varying-length sequences of char-like objects.

The header `<string>` (21.2) also defines two specific template classes `string` and `wstring` and their special traits.

Header `<string>` synopsis

```c
namespace std {
  // 21.1, character traits:
  template< class charT >
    struct char_traits;
  template <> struct char_traits< char >;
  template <> struct char_traits< wchar_t >;

  // 21.3, basic_string:
  template< class charT, class traits = char_traits< charT >,
    class Allocator = allocator< charT > >
    class basic_string;

  template< class charT, class traits, class Allocator >
    basic_string< charT, traits, Allocator >
    operator+(const basic_string< charT, traits, Allocator >& lhs,
    const basic_string< charT, traits, Allocator >& rhs);
  template< class charT, class traits, class Allocator >
    basic_string< charT, traits, Allocator >
    operator+(const charT* lhs,
    const basic_string< charT, traits, Allocator >& rhs);
  template< class charT, class traits, class Allocator >
    basic_string< charT, traits, Allocator >
    operator+(const basic_string< charT, traits, Allocator >& lhs,
    const charT* rhs);
}
```
basic_string<
  charT, traits, Allocator>
operator+(charT lhs, const basic_string<
  charT, traits, Allocator>& rhs);

template<class charT, class traits, class Allocator>
basic_string<
  charT, traits, Allocator>
operator+(const basic_string<
  charT, traits, Allocator>& lhs,
  const charT* rhs);

template<class charT, class traits, class Allocator>
basic_string<
  charT, traits, Allocator>
operator+(const basic_string<
  charT, traits, Allocator>& lhs,
  const charT rhs);

bool operator==(const basic_string<
  charT, traits, Allocator>& lhs,
  const basic_string<
  charT, traits, Allocator>& rhs);

  const charT *
  rhs);

bool operator!=(const basic_string<
  charT, traits, Allocator>& lhs,
  const basic_string<
  charT, traits, Allocator>& rhs);

bool operator!=(const charT *
  lhs, const basic_string<
  charT, traits, Allocator>& rhs);

bool operator!=(const basic_string<
  charT, traits, Allocator>& lhs,
  const charT *
  rhs);

bool operator<(const basic_string<
  charT, traits, Allocator>& lhs,
  const basic_string<
  charT, traits, Allocator>& rhs);

bool operator<(const charT *
  lhs, const basic_string<
  charT, traits, Allocator>& rhs);

bool operator<(const basic_string<
  charT, traits, Allocator>& lhs,
  const charT *
  rhs);
21.3 Class template basic_string

For a char-like type charT, the class template basic_string describes objects that can store a sequence consisting of a varying number of arbitrary char-like objects (clause 21). The first element of the sequence is at position zero. Such a sequence is also called a “string” if the given char-like type is clear from context. In the rest of this clause, charT denotes such a given char-like type. Storage for the string is allocated and freed as necessary by the member functions.
of class basic_string, via the Allocator class passed as template parameter. Allocator::value_type shall be the same as charT.

2 The class template basic_string conforms to the requirements of a Sequence, as specified in (23.1.1). Additionally, because the iterators supported by basic_string are random access iterators (24.1.5), basic_string conforms to the requirements of a Reversible Container, as specified in (23.1).

3 In all cases, size() <= capacity().

4 The functions described in this clause can report two kinds of errors, each associated with a distinct exception:
   — a length error is associated with exceptions of type length_error (19.1.4);
   — an out-of-range error is associated with exceptions of type out_of_range (19.1.5).

5 For any string operation, if as a result of the operation, size() would exceed max_size() then the operation throws length_error.

6 References, pointers, and iterators referring to the elements of a basic_string sequence may be invalidated by the following uses of that basic_string object:
   — As an argument to non-member functions swap() (21.3.7.8), operator>>() (21.3.7.9), and getline() (21.3.7.9).
   — As an argument to basic_string::swap().
   — Calling data() and c_str() member functions.
   — Calling non-const member functions, except operator[], at, begin, rbegin, end, and rend.
   — Following construction or any of the above uses, except the forms of insert and erase that return iterators, the first call to non-const member functions operator[], at, begin, rbegin, end, or rend.

[ Note: These rules are formulated to allow, but not require, a reference counted implementation. A reference counted implementation must have the same semantics as a non-reference counted implementation. [Example:

```cpp
string s1("abc");
string::iterator i = s1.begin();
string s2 = s1;
*i = 'a'; // Must modify only s1
```

— end example ] — end note ]

namespace std {
    template<class charT, class traits = char_traits<charT>,
             class Allocator = allocator<charT> >

}}}
21.3 Class template basic_string

Strings library 452

basic_string(const basic_string<charT, traits, Allocator>& str);

basic_string(const basic_string<charT, traits, Allocator>& str,
             size_type pos, size_type n = npos,
             const Allocator& a = Allocator());

3 Requires: pos <= str.size()

4 Throws: out_of_range if pos > str.size().

5 Effects: Constructs an object of class basic_string and determines the effective length rlen of the initial string value as the smaller of n and str.size() - pos, as indicated in Table 40. In the first form, the Allocator value used is copied from str.get_allocator().

Table 40: basic_string(basic_string, size_type, size_type, const Allocator&) effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>data()</td>
<td>points at the first element of an allocated copy of rlen</td>
</tr>
<tr>
<td></td>
<td>consecutive elements of the string controlled by str</td>
</tr>
<tr>
<td></td>
<td>beginning at position pos</td>
</tr>
<tr>
<td>size()</td>
<td>rlen</td>
</tr>
<tr>
<td>capacity()</td>
<td>a value at least as large as size()</td>
</tr>
</tbody>
</table>

basic_string(const charT* s, size_type n,
             const Allocator& a = Allocator());

6 Requires: s shall not be a null pointer and n < npos.

7 [Note: This paragraph is intentionally empty. —end note ]

8 Effects: Constructs an object of class basic_string and determines its initial string value from the array of charT of length n whose first element is designated by s, as indicated in Table 41.

Table 41: basic_string(const charT*, size_type, const Allocator&) effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>data()</td>
<td>points at the first element of an allocated copy of the array whose first element is pointed at by s</td>
</tr>
<tr>
<td>size()</td>
<td>n</td>
</tr>
<tr>
<td>capacity()</td>
<td>a value at least as large as size()</td>
</tr>
</tbody>
</table>

basic_string(const charT* s, const Allocator& a = Allocator());

9 Requires: s shall not be a null pointer.

10 Effects: Constructs an object of class basic_string and determines its initial string value from the array of charT of length traits::length(s) whose first element is designated by s, as indicated in Table 42.

11 Remarks: Uses traits::length().

Draft
Table 42: basic_string(const charT*, const Allocator&) effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>data()</td>
<td>points at the first element of an allocated copy of the array whose first element is pointed at by s</td>
</tr>
<tr>
<td>size()</td>
<td>traits::length(s)</td>
</tr>
<tr>
<td>capacity()</td>
<td>a value at least as large as size()</td>
</tr>
</tbody>
</table>

\[
\text{basic_string(size_type } n, \text{ charT } c, \text{ const Allocator& } a = \text{ Allocator()});
\]

**Requires:** \( n < \text{npos} \)

[Note: This paragraph is intentionally empty. — end note]

**Effects:** Constructs an object of class basic_string and determines its initial string value by repeating the char-like object \( c \) for all \( n \) elements, as indicated in Table 43:

Table 43: basic_string(size_t, charT, const Allocator&) effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>data()</td>
<td>points at the first element of an allocated array of ( n ) elements, each storing the initial value ( c )</td>
</tr>
<tr>
<td>size()</td>
<td>( n )</td>
</tr>
<tr>
<td>capacity()</td>
<td>a value at least as large as size()</td>
</tr>
</tbody>
</table>

\[
\text{template< class InputIterator >}
\]

\[
\text{basic_string(InputIterator } \text{ begin}, \text{ InputIterator } \text{ end}, \text{ const Allocator& } a = \text{ Allocator()});
\]

**Effects:** If \( \text{InputIterator} \) is an integral type, equivalent to

\[
\text{basic_string(static_cast<size_type>(begin), static_cast<value_type>(end), a)}
\]

Otherwise constructs a string from the values in the range \( [\text{begin}, \text{end}) \), as indicated in the Sequence Requirements table (see 23.1.1).

\[
\text{basic_string< charT, traits, Allocator & str>}
\]

**operator=(const basic_string< charT, traits, Allocator & str>);**

**Effects:** If \( *\text{this} \) and \( str \) are not the same object, modifies \( *\text{this} \) as shown in Table 44:

Table 44: operator=(const basic_string< charT, traits, Allocator &>) effects

<table>
<thead>
<tr>
<th>Element</th>

<tbody>
<tr>
<td>data()</td>
<td>points at the first element of an allocated copy of the array whose first element is pointed at by str.data()</td>
</tr>
<tr>
<td>size()</td>
<td>str.size()</td>
</tr>
<tr>
<td>capacity()</td>
<td>a value at least as large as size()</td>
</tr>
</tbody>
</table>
If \*this and \textit{str} are the same object, the member has no effect.

*Returns:* \*this

\texttt{basic\_string\langle charT, traits, Allocator \rangle \&
operator=(\texttt{const charT* s});}

*Returns:* \*this = \texttt{basic\_string\langle charT, traits, Allocator \rangle\texttt{(s)}).

*Remarks:* Uses traits::length().

\texttt{basic\_string\langle charT, traits, Allocator \rangle \&
operator=(\texttt{charT c});}

*Returns:* \*this = \texttt{basic\_string\langle charT, traits, Allocator \rangle\texttt{(1, c)}}.

\textbf{21.3.2 \texttt{basic\_string} iterator support} \[\text{lib.string.iterators}\]

\texttt{iterator begin();
const\_iterator begin() const;}

*Returns:* an iterator referring to the first character in the string.

\texttt{iterator end();
const\_iterator end() const;}

*Returns:* an iterator which is the past-the-end value.

\texttt{reverse\_iterator rbegin();
const\_reverse\_iterator rbegin() const;}

*Returns:* an iterator which is semantically equivalent to reverse\_iterator\texttt{(end())}.

\texttt{reverse\_iterator rend();
const\_reverse\_iterator rend() const;}

*Returns:* an iterator which is semantically equivalent to reverse\_iterator\texttt{(begin())}.

\textbf{21.3.3 \texttt{basic\_string} capacity} \[\text{lib.string.capacity}\]

\texttt{size\_type size() const;}

*Returns:* a count of the number of char-like objects currently in the string.

\texttt{size\_type length() const;}

*Returns:* size().

\texttt{size\_type max\_size() const;}

*Returns:* The maximum size of the string.

*Remark:* See Container requirements table (23.1).

\texttt{void resize(size\_type n, charT c);}
5  Requires: \( n \leq \text{max\_size}() \)
6  Throws: \text{length\_error} if \( n > \text{max\_size}() \).
7  Effects: Alters the length of the string designated by \*this as follows:
   — If \( n \leq \text{size}() \), the function replaces the string designated by \*this with a string of length \( n \) whose elements are a copy of the initial elements of the original string designated by \*this.
   — If \( n > \text{size}() \), the function replaces the string designated by \*this with a string of length \( n \) whose first \text{size}() elements are a copy of the original string designated by \*this, and whose remaining elements are all initialized to \( c \).

   \begin{verbatim}
   void resize(size_type n);
   \end{verbatim}
8  Effects: \text{resize}(n,\text{charT}())

   \begin{verbatim}
   size_type capacity() const;
   \end{verbatim}
9  Returns: the size of the allocated storage in the string.

   \begin{verbatim}
   void reserve(size_type res_arg=0);
   \end{verbatim}
10 The member function \text{reserve()} is a directive that informs a \text{basic\_string} object of a planned change in size, so that it can manage the storage allocation accordingly.
11  Effects: After \text{reserve()}, \text{capacity()} is greater or equal to the argument of \text{reserve}. [\text{Note}: Calling \text{reserve()} with a \text{res\_arg} argument less than \text{capacity()} is in effect a non-binding shrink request. A call with \text{res\_arg} \leq \text{size}() is in effect a non-binding shrink-to-fit request. — end note]
12  Throws: \text{length\_error} if \text{res\_arg} > \text{max\_size}().\footnote{\text{reserve()} uses \text{Allocator::allocate()} which may throw an appropriate exception.}

   \begin{verbatim}
   void clear();
   \end{verbatim}
13  Effects: Behaves as if the function calls:
   \begin{verbatim}
   erase(begin(), end());
   \end{verbatim}

   \begin{verbatim}
   bool empty() const;
   \end{verbatim}
14  Returns: \text{size}() == 0.

21.3.4 \text{basic\_string element access} [\text{lib\_string\_access}]

   \begin{verbatim}
   const_reference operator[](size_type pos) const;
   reference operator[](size_type pos);
   \end{verbatim}
1  Returns: If \( pos < \text{size}() \), returns \(*(\text{begin}() + pos)\). Otherwise, if \( pos = \text{size}() \), the const version returns \text{charT}(). Otherwise, the behavior is undefined.

   \begin{verbatim}
   const_reference at(size_type pos) const;
   reference at(size_type pos);
   \end{verbatim}
21.3 Class template basic_string

21.3.5 Basic_string modifiers

21.3.5.1 basic_string::operator+=

basic_string < charT , traits , Allocator >&
operator +=(const basic_string < charT , traits , Allocator >& str);

Returns: append(str).

Remarks: Uses traits::length().

Returns: *this += basic_string< charT , traits , Allocator > (s).

basic_string < charT , traits , Allocator >& operator +=(charT c);

Returns: *this += basic_string< charT , traits , Allocator > (1, c).

21.3.5.2 basic_string::append

basic_string < charT , traits , Allocator >&
append(const basic_string < charT , traits >& str);

Returns: append(str, 0, npos).

basic_string < charT , traits , Allocator >&
append(const basic_string < charT , traits >& str, size_type pos, size_type n);

Requires: pos <= str.size()

Throws: out_of_range if pos > str.size().

Effects: Determines the effective length rlen of the string to append as the smaller of n and str.size() - pos. The function then throws length_error if size() >= npos - rlen.

Otherwise, the function replaces the string controlled by *this with a string of length size() + rlen whose first size() elements are a copy of the original string controlled by *this and whose remaining elements are a copy of the initial elements of the string controlled by str beginning at position pos.

Returns: *this.

basic_string < charT , traits , Allocator >&
append(const charT* s, size_type n);

Returns: append(basic_string< charT , traits , Allocator > (s, n)).
basic_string<charT,traits,Allocator>& append(const charT* s);

    *Returns:* append(basic_string<charT,traits,Allocator>(s)).

    *Remarks:* Uses traits::length().

basic_string<charT,traits,Allocator>&
    append(size_type n, charT c);

    *Returns:* append(basic_string<charT,traits,Allocator>(n,c)).

template<class InputIterator>
basic_string& append(InputIterator first, InputIterator last);

    *Returns:* append(basic_string<charT,traits,Allocator>(first,last)).

void push_back(charT c)

    *Effects:* Equivalent to append(static_cast<size_type>(1), c).

21.3.5.3 basic_string::assign

basic_string<charT,traits,Allocator>&
    assign(const basic_string<charT,traits>& str);

    *Returns:* assign(str, 0, npos).

basic_string<charT,traits,Allocator>&
    assign(const basic_string<charT,traits>& str, size_type pos, size_type n);

    *Requires:* pos <= str.size()

    *Throws:* out_of_range if pos > str.size().

    *Effects:* Determines the effective length rlen of the string to assign as the smaller of n and str.size() - pos. The function then replaces the string controlled by *this with a string of length rlen whose elements are a copy of the string controlled by str beginning at position pos.

    *Returns:* *this.

basic_string<charT,traits,Allocator>&
    assign(const charT* s, size_type n);

    *Returns:* assign(basic_string<charT,traits,Allocator>(s,n)).

basic_string<charT,traits,Allocator>& assign(const charT* s);

    *Returns:* assign(basic_string<charT,traits,Allocator>(s)).

    *Remarks:* Uses traits::length().

basic_string<charT,traits,Allocator>&
    assign(size_type n, charT c);
9     \textit{Returns:} \texttt{assign(basic\_string<charT,traits,Allocator>(n,c))}.

template<class InputIterator>
    basic\_string\& assign(InputIterator \emph{first}, InputIterator \emph{last});

10    \textit{Returns:} \texttt{assign(basic\_string<charT,traits,Allocator>(first,last))}.

21.3.5.4 \texttt{basic\_string::insert} \quad \textbf{[lib.string::insert]}

\texttt{basic\_string<charT,traits,Allocator>\&}
    \texttt{insert(size\_type \emph{pos1},}
    \texttt{const basic\_string<charT,traits,Allocator>\& \emph{str});}

1     \textit{Returns:} \texttt{insert(pos1,\emph{str},0,npos)}.

\texttt{basic\_string<charT,traits,Allocator>\&}
    \texttt{insert(size\_type \emph{pos1},}
    \texttt{const basic\_string<charT,traits,Allocator>\& \emph{str},}
    \texttt{size\_type \emph{pos2}, size\_type \emph{n});}

2     \textit{Requires:} \texttt{pos1} <= \texttt{size()} and \texttt{pos2} <= \texttt{str.size()}

3     \textit{Throws:} \texttt{out\_of\_range} if \texttt{pos1} > \texttt{size()} or \texttt{pos2} > \texttt{str.size()}.

4     \textit{Effects:} Determines the effective length \texttt{rlen} of the string to insert as the smaller of \texttt{n} and \texttt{str.size()} - \texttt{pos2}. Then throws \texttt{length\_error} if \texttt{size()} >= \texttt{npos - rlen}.

      Otherwise, the function replaces the string controlled by \texttt{*this} with a string of length \texttt{size()} + \texttt{rlen} whose first \texttt{pos1} elements are a copy of the initial elements of the original string controlled by \texttt{*this}, whose next \texttt{rlen} elements are a copy of the elements of the string controlled by \texttt{str} beginning at position \texttt{pos2}, and whose remaining elements are a copy of the remaining elements of the original string controlled by \texttt{*this}.

5     \textit{Returns:} \texttt{*this}.

\texttt{basic\_string<charT,traits,Allocator>\&}
    \texttt{insert(size\_type \emph{pos}, const charT* \emph{s}, size\_type \emph{n});}

6     \textit{Returns:} \texttt{insert(pos,\emph{basic\_string<charT,traits,Allocator>}(\emph{s},\emph{n}))}.

\texttt{basic\_string<charT,traits,Allocator>\&}
    \texttt{insert(size\_type \emph{pos}, const charT* \emph{s});}

7     \textit{Returns:} \texttt{insert(pos,\emph{basic\_string<charT,traits,Allocator>}(\emph{s}))}.

8     \textit{Remarks:} Uses \texttt{traits::length()}.

\texttt{basic\_string<charT,traits,Allocator>\&}
    \texttt{insert(size\_type \emph{pos}, size\_type \emph{n}, charT \emph{c});}

9     \textit{Returns:} \texttt{insert(pos,\emph{basic\_string<charT,traits,Allocator>}(\emph{n},\emph{c}))}.

iterator insert(iterator \emph{p}, charT \emph{c});

```c++
void insert(iterator p, size_type n, charT c);
```

Requires: `p` is a valid iterator on `*this`.
Effects: inserts a copy of `c` before the character referred to by `p`.
Returns: an iterator which refers to the copy of the inserted character.

```c++
template < class InputIterator >
void insert(iterator p, InputIterator first, InputIterator last);
```

Requires: `p` is a valid iterator on `*this`. `[first, last)` is a valid range.
Effects: Equivalent to `insert(p - begin(), basic_string(first, last))`.

### 21.3.5.5 basic_string::erase

```c++
iterable erase(size_type pos = 0, size_type n = npos);
```

Requires: `pos` <= `size()` 
Throws: `out_of_range` if `pos` > `size()`.
Effects: Determines the effective length `xlen` of the string to be removed as the smaller of `n` and `size() - pos`.
The function then replaces the string controlled by `*this` with a string of length `size() - xlen` whose first `pos` elements are a copy of the initial elements of the original string controlled by `*this`, and whose remaining elements are a copy of the elements of the original string controlled by `*this` beginning at position `pos + xlen`.
Returns: `*this`.

```c++
iterator erase(iterator p);
```

Effects: removes the character referred to by `p`.
Returns: an iterator which points to the element immediately following `p` prior to the element being erased. If no such element exists, `end()` is returned.

```c++
iterator erase(iterator first, iterator last);
```

Requires: `first` and `last` are valid iterators on `*this`, defining a range `[first, last)`.
Effects: removes the characters in the range `[first, last)`.
Returns: an iterator which points to the element pointed to by `last` prior to the other elements being erased. If no such element exists, `end()` is returned.
21.3 Class template basic_string

21.3.5.6 basic_string::replace

basic_string< charT , traits , Allocator >&
replace(size_type pos1, size_type n1, const basic_string< charT , traits , Allocator >& str);

1 Returns: replace(pos1, n1, str, 0, npos).

basic_string< charT , traits , Allocator >&
replace(size_type pos1, size_type n1, const basic_string< charT , traits , Allocator >& str,
   size_type pos2, size_type n2);

2 Requires: pos1 <= size() && pos2 <= str.size().

3 Throws: out_of_range if pos1 > size() or pos2 > str.size(), or length_error if the length of the
resulting string would exceed max_size() (see below).

4 Effects: Determines the effective length xlen of the string to be removed as the smaller of n1 and size() -
pos1. Also determines the effective length rlen of the string to be inserted as the smaller of n2 and str.size() -
pos2. If size() - xlen >= max_size() - rlen, throws length_error. Otherwise, the function replaces
the string controlled by *this with a string of length size() - xlen + rlen whose first xlen elements are a copy
of the initial elements of the original string controlled by *this, whose next rlen elements are a copy of
the initial elements of the string controlled by str beginning at position pos2, and whose remaining
elements are a copy of the elements of the original string controlled by *this beginning at position pos1 +
xlen.

5 Returns: *this.

basic_string< charT , traits , Allocator >&
replace(size_type pos, size_type n1, const charT* s, size_type n2);

6 Returns: replace(pos, n1, basic_string< charT , traits , Allocator >(s, n2)).

basic_string< charT , traits , Allocator >&
replace(size_type pos, size_type n1, const charT* s);

7 Returns: replace(pos, n1, basic_string< charT , traits , Allocator >(s)).

Remarks: Uses traits::length().

basic_string< charT , traits , Allocator >&
replace(size_type pos, size_type n1, size_type n2, charT c);

8 Returns: replace(pos, n1, basic_string< charT , traits , Allocator >(n2, c)).

basic_string& replace(iterator i1, iterator i2, const basic_string& str);

9 Requires: The iterators i1 and i2 are valid iterators on *this, defining a range [i1, i2).

10 Effects: Replaces the string controlled by *this with a string of length size() - (i2 - i1) + str.size()
whose first begin() - i1 elements are a copy of the initial elements of the original string controlled by *this.
whose next \( str \).size() elements are a copy of the string controlled by \( str \), and whose remaining elements are a copy of the elements of the original string controlled by \(*\text{this}\) beginning at position \( i2 \).

12

\textit{Returns:} \(*\text{this}\).

13

\textit{Remarks:} After the call, the length of the string will be changed by: \( str \).size() - (\( i2 - i1 \)).

basic_string&
replace(iterator \( i1 \), iterator \( i2 \), const charT* \( s \), size_type \( n \));

14

\textit{Returns:} replace(\( i1, i2 \), basic_string(\( s, n \))).

15

\textit{Remarks:} Length change: \( n - (i2 - i1) \).

basic_string& replace(iterator \( i1 \), iterator \( i2 \), const charT* \( s \));

16

\textit{Returns:} replace(\( i1, i2 \), basic_string(\( s \))).

17

\textit{Remarks:} Length change: traits::length(\( s \)) - (\( i2 - i1 \)).

Uses traits::length().

basic_string& replace(iterator \( i1 \), iterator \( i2 \), size_type \( n \), charT \( c \));

18

\textit{Returns:} replace(\( i1, i2 \), basic_string(\( n, c \))).

19

\textit{Remarks:} Length change: \( n - (i2 - i1) \).

template<class InputIterator>
basic_string& replace(iterator \( i1 \), iterator \( i2 \),
InputIterator \( j1 \), InputIterator \( j2 \));

20

\textit{Returns:} replace(\( i1, i2 \), basic_string(\( j1, j2 \))).

21

\textit{Remarks:} Length change: \( j2 - j1 - (i2 - i1) \).

21.3.5.7 basic_string::copy

[lib.string::copy]

size_type copy(charT* \( s \), size_type \( n \), size_type \( pos \) = 0) const;

1

\textit{Requires:} \( pos \leq \text{size()} \)

2

\textit{Throws:} out_of_range if \( pos > \text{size()} \).

3

\textit{Effects:} Determines the effective length \( rlen \) of the string to copy as the smaller of \( n \) and \( \text{size()} - pos \). \( s \) shall designate an array of at least \( rlen \) elements.

The function then replaces the string designated by \( s \) with a string of length \( rlen \) whose elements are a copy of the string controlled by \(*\text{this}\) beginning at position \( pos \).

The function does not append a null object to the string designated by \( s \).

4

\textit{Returns:} \( rlen \).
21.3

21.3.5.8 basic_string::swap

```cpp
void swap(basic_string<CharT, Traits, Allocator>& s);
```

**Effects:** Swaps the contents of the two strings.

**Throws:** Nothing.

**Postcondition:** \*this contains the characters that were in \(s\), \(s\) contains the characters that were in \*this.

**Complexity:** constant time.

21.3.6 basic_string string operations

```cpp
const CharT* c_str() const;
```

**Returns:** A pointer to the initial element of an array of length `size()` + 1 whose first `size()` elements equal the corresponding elements of the string controlled by \*this and whose last element is a null character specified by CharT().

**Requires:** The program shall not alter any of the values stored in the array. Nor shall the program treat the returned value as a valid pointer value after any subsequent call to a non-const member function of the class basic_string that designates the same object as this.

```cpp
const CharT* data() const;
```

**Returns:** If `size()` is nonzero, the member returns a pointer to the initial element of an array whose first `size()` elements equal the corresponding elements of the string controlled by \*this. If `size()` is zero, the member returns a non-null pointer that is copyable and can have zero added to it.

**Requires:** The program shall not alter any of the values stored in the character array. Nor shall the program treat the returned value as a valid pointer value after any subsequent call to a non-const member function of basic_string that designates the same object as this.

```cpp
allocator_type get_allocator() const;
```

**Returns:** A copy of the Allocator object used to construct the string.

21.3.6.1 basic_string::find

```cpp
size_type find(const basic_string<CharT, Traits, Allocator>& str, size_type pos = 0) const;
```

**Effects:** Determines the lowest position `npos`, if possible, such that both of the following conditions obtain:

- `pos <= npos` and `npos + str.size() <= size()`;
- `traits::eq(at(npos+I), str.at(I))` for all elements \(I\) of the string controlled by \(str\).

**Returns:** `npos` if the function can determine such a value for `npos`. Otherwise, returns `npos`.

**Remarks:** Uses `traits::eq()`.
size_type find(const charT* s, size_type pos, size_type n) const;  
    Returns: find(basic_string<charT,traits,Allocator>(s,n),pos).

size_type find(const charT* s, size_type pos = 0) const;  
    Returns: find(basic_string<charT,traits,Allocator>(s),pos).

Remarks: Uses traits::length().

size_type find(charT c, size_type pos = 0) const;  
    Returns: find(basic_string<charT,traits,Allocator>(1,c),pos).

21.3.6.2 basic_string::rfind  

size_type rfind(const basic_string<charT,traits,Allocator>& str,  
    size_type pos = npos) const;  
    Effects: Determines the highest position xpos, if possible, such that both of the following conditions obtain:
        — xpos <= pos and xpos + str.size() <= size();
        — traits::eq(at(xpos+I), str.at(I)) for all elements I of the string controlled by str.
    Returns: xpos if the function can determine such a value for xpos. Otherwise, returns npos.

Remarks: Uses traits::eq().

size_type rfind(const charT* s, size_type pos, size_type n) const;  
    Returns: rfind(basic_string<charT,traits,Allocator>(s),pos).

size_type rfind(const charT* s, size_type pos = npos) const;  
    Returns: rfind(basic_string<charT,traits,Allocator>(s),pos).

Remarks: Uses traits::length().

size_type rfind(charT c, size_type pos = npos) const;  
    Returns: rfind(basic_string<charT,traits,Allocator>(1,c),pos).

21.3.6.3 basic_string::find_first_of  

size_type find_first_of(const basic_string<charT,traits,Allocator>& str,  
    size_type pos = 0) const;  
    Effects: Determines the lowest position xpos, if possible, such that both of the following conditions obtain:
        — pos <= xpos and xpos < size();
        — traits::eq(at(xpos), str.at(I)) for some element I of the string controlled by str.

Draft
21.3 Class template basic_string

Strings library 464

Returns: xpos if the function can determine such a value for xpos. Otherwise, returns npos.

Remarks: Uses traits::eq().

size_type
find_first_of(const charT* s, size_type pos, size_type n) const;

Returns: find_first_of(basic_string<charT,traits,Allocator>(s,n),pos).

size_type find_first_of(const charT* s, size_type pos = 0) const;

Returns: find_first_of(basic_string<charT,traits,Allocator>(s),pos).

Remarks: Uses traits::length().

size_type find_first_of(charT c, size_type pos = 0) const;

Returns: find_first_of(basic_string<charT,traits,Allocator>(1,c),pos).

21.3.6.4 basic_string::find_last_of

size_type
find_last_of(const basic_string<charT,traits,Allocator>& str, size_type pos = npos) const;

Effects: Determines the highest position xpos, if possible, such that both of the following conditions obtain:

— ypos <= pos and ypos < size();
— traits::eq(at(ypos), str.at(I)) for some element I of the string controlled by str.

Returns: xpos if the function can determine such a value for xpos. Otherwise, returns npos.

Remarks: Uses traits::eq().

size_type find_last_of(const charT* s, size_type pos, size_type n) const;

Returns: find_last_of(basic_string<charT,traits,Allocator>(s,n),pos).

size_type find_last_of(const charT* s, size_type pos = npos) const;

Returns: find_last_of(basic_string<charT,traits,Allocator>(s),pos).

Remarks: Uses traits::length().

size_type find_last_of(charT c, size_type pos = npos) const;

Returns: find_last_of(basic_string<charT,traits,Allocator>(1,c),pos).

21.3.6.5 basic_string::find_first_not_of

size_type
find_first_not_of(const basic_string<charT,traits,Allocator>& str, size_type pos = 0) const;

Draft
Effects: Determines the lowest position \(xpos\), if possible, such that both of the following conditions obtain:

- \( pos \leq xpos \) and \( xpos < \text{size()} \);
- \( \text{traits:}:\text{eq}(\text{at}(xpos), \text{str}.\text{at}(I)) \) for no element \( I \) of the string controlled by \( \text{str} \).

Returns: \( xpos \) if the function can determine such a value for \( xpos \). Otherwise, returns \( \text{npos} \).

Remarks: Uses \( \text{traits:}:\text{eq}() \).

\[
\text{size_type find_first_not_of(const charT* s, size_type pos, size_type n) const;}
\]

Returns: \( \text{find_first_not_of(basic_string<charT,traits,Allocator>(s,n),pos)} \).

\[
\text{size_type find_first_not_of(const charT* s, size_type pos = 0) const;}
\]

Returns: \( \text{find_first_not_of(basic_string<charT,traits,Allocator>(s),pos)} \).

Remarks: Uses \( \text{traits:}:\text{length}() \).

\[
\text{size_type find_first_not_of(charT c, size_type pos = 0) const;}
\]

Returns: \( \text{find_first_not_of(basic_string<charT,traits,Allocator>(1,c),pos)} \).

21.3.6.6 basic_string::find_last_not_of

\[
\text{size_type find_last_not_of(const basic_string<charT,traits,Allocator>& str, size_type pos = npos) const;}
\]

Effects: Determines the highest position \( xpos \), if possible, such that both of the following conditions obtain:

- \( xpos \leq pos \) and \( xpos < \text{size()} \);
- \( \text{traits:}:\text{eq}(\text{at}(xpos), \text{str}.\text{at}(I)) \) for no element \( I \) of the string controlled by \( \text{str} \).

Returns: \( xpos \) if the function can determine such a value for \( xpos \). Otherwise, returns \( \text{npos} \).

Remarks: Uses \( \text{traits:}:\text{eq}() \).

\[
\text{size_type find_last_not_of(const charT* s, size_type pos, size_type n) const;}
\]

Returns: \( \text{find_last_not_of(basic_string<charT,traits,Allocator>(s,n),pos)} \).

\[
\text{size_type find_last_not_of(const charT* s, size_type pos = npos) const;}
\]

Returns: \( \text{find_last_not_of(basic_string<charT,traits,Allocator>(s),pos)} \).

Remarks: Uses \( \text{traits:}:\text{length}() \).

\[
\text{size_type find_last_not_of(charT c, size_type pos = npos) const;}
\]

Returns: \( \text{find_last_not_of(basic_string<charT,traits,Allocator>(1,c),pos)} \).
21.3 Class template basic_string

21.3.6.7 basic_string::substr

```cpp
basic_string<charT,traits,Allocator>
    substr(size_type pos = 0, size_type n = npos) const;
```

1 Requires: pos <= size()
2 Throws: out_of_range if pos > size().
3 Effects: Determines the effective length rlen of the string to copy as the smaller of n and size() - pos.
4 Returns: basic_string<charT,traits,Allocator>(data() + pos, rlen).

21.3.6.8 basic_string::compare

```cpp
int compare(const basic_string<charT,traits,Allocator>& str) const
```

1 Effects: Determines the effective length rlen of the string to compare as the smaller of size() and str.size(). The function then compares the two strings by calling traits::compare(data(), str.data(), rlen).
2 Returns: the nonzero result if the result of the comparison is nonzero. Otherwise, returns a value as indicated in Table 45.

<table>
<thead>
<tr>
<th>Condition</th>
<th>Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>size() &lt; str.size()</td>
<td>&lt; 0</td>
</tr>
<tr>
<td>size() == str.size()</td>
<td>0</td>
</tr>
<tr>
<td>size() &gt; str.size()</td>
<td>&gt; 0</td>
</tr>
</tbody>
</table>

```cpp
int compare(size_type pos1, size_type n1,
    const basic_string<charT,traits,Allocator>& str) const;
```

3 Returns:

```cpp
    basic_string<charT,traits,Allocator>(*this, pos1, n1).compare(str);
```

```cpp
int compare(size_type pos1, size_type n1,
    const basic_string<charT,traits,Allocator>& str,
    size_type pos2, size_type n2 ) const;
```

4 Returns:

```cpp
    basic_string<charT,traits,Allocator>(*(this, pos1, n1)).compare(
        basic_string<charT,traits,Allocator>((str, pos2, n2)));
```

```cpp
int compare(const charT *s) const;
```

5 Returns: this->compare(basic_string<charT,traits,Allocator>(s)).
Returns:

\[
\text{basic\_string}\ <\ \text{charT, traits, Allocator}>(\text{*this, pos, n1}).\ \text{compare}(
\text{basic\_string}\ <\ \text{charT, traits, Allocator}>(s))
\]

int compare(size_type pos, size_type n1, const charT *s, size_type n2) const;

Returns:

\[
\text{basic\_string}\ <\ \text{charT, traits, Allocator}>(\text{*this, pos, n1}).\ \text{compare}(
\text{basic\_string}\ <\ \text{charT, traits, Allocator}>(s, n2))
\]

### 21.3.7 basic\_string non-member functions

#### 21.3.7.1 operator+

template<class charT, class traits, class Allocator>

basic\_string\ <\ charT, traits, Allocator>

operator+(const basic\_string\ <\ charT, traits, Allocator>& \text{lhs},
const basic\_string\ <\ charT, traits, Allocator>& \text{rhs});

Returns: basic\_string\ <\ charT, traits, Allocator>(\text{lhs}).append(\text{rhs})

Remarks: Uses traits::length().

template<class charT, class traits, class Allocator>

basic\_string\ <\ charT, traits, Allocator>

operator+(const charT* \text{lhs},
const basic\_string\ <\ charT, traits, Allocator>& \text{rhs});

Returns: basic\_string\ <\ charT, traits, Allocator>(\text{lhs} + \text{rhs}).

Remarks: Uses traits::length().

template<class charT, class traits, class Allocator>

basic\_string\ <\ charT, traits, Allocator>

operator+(const basic\_string\ <\ charT, traits, Allocator>& \text{lhs},
const charT* \text{rhs});

Returns: \text{lhs} + basic\_string\ <\ charT, traits, Allocator>(\text{rhs}).

Remarks: Uses traits::length().

Draft
21.3 Class template basic_string

Returns: \( \text{lhs} + \text{basic_string}<\text{charT}, \text{traits}, \text{Allocator}>(1, \text{rhs}) \).

21.3.7.2 operator==

\[
\text{template<class charT, class traits, class Allocator>}
\text{bool operator==}(\text{const basic_string}<\text{charT}, \text{traits}, \text{Allocator}>& \text{lhs},
\text{const basic_string}<\text{charT}, \text{traits}, \text{Allocator}>& \text{rhs});
\]

\( \text{Returns: } \text{lhs.compare(rhs)} == 0. \)

\[
\text{template<class charT, class traits, class Allocator>}
\text{bool operator==}(\text{const charT* } \text{lhs},
\text{const basic_string}<\text{charT}, \text{traits}, \text{Allocator}>& \text{rhs});
\]

\( \text{Returns: basic_string<charT,traits,Allocator>(lhs) == rhs.} \)

\[
\text{template<class charT, class traits, class Allocator>}
\text{bool operator==}(\text{const basic_string}<\text{charT}, \text{traits}, \text{Allocator}>& \text{lhs},
\text{const charT* } \text{rhs});
\]

\( \text{Returns: lhs == basic_string<charT,traits,Allocator>(rhs).} \)

Remarks: Uses traits::length().

21.3.7.3 operator!=

\[
\text{template<class charT, class traits, class Allocator>}
\text{bool operator!=}(\text{const basic_string}<\text{charT}, \text{traits}, \text{Allocator}>& \text{lhs},
\text{const basic_string}<\text{charT}, \text{traits}, \text{Allocator}>& \text{rhs});
\]

\( \text{Returns: !(lhs == rhs).} \)

\[
\text{template<class charT, class traits, class Allocator>}
\text{bool operator!=}(\text{const charT* } \text{lhs},
\text{const basic_string}<\text{charT}, \text{traits}, \text{Allocator}>& \text{rhs});
\]

\( \text{Returns: basic_string<charT,traits,Allocator>(lhs) != rhs.} \)

\[
\text{template<class charT, class traits, class Allocator>}
\text{bool operator!=}(\text{const basic_string}<\text{charT}, \text{traits}, \text{Allocator}>& \text{lhs},
\text{const charT* } \text{rhs});
\]

\( \text{Returns: lhs != basic_string<charT,traits,Allocator>(rhs).} \)

Remarks: Uses traits::length().

21.3.7.4 operator<

\[
\text{template<class charT, class traits, class Allocator>}
\text{bool operator<}(\text{const basic_string}<\text{charT}, \text{traits}, \text{Allocator}>& \text{lhs},
\text{const basic_string}<\text{charT}, \text{traits}, \text{Allocator}>& \text{rhs});
\]

Draft
1 Returns: \( \text{lhs} \text{. compare}(\text{rhs}) < 0 \).

template<class charT, class traits, class Allocator>
bool operator< (const charT* \text{lhs},
const basic_string<charT,traits,Allocator>& \text{rhs});

2 Returns: basic_string<charT,traits,Allocator>(\text{lhs}) < \text{rhs}.

template<class charT, class traits, class Allocator>
bool operator< (const basic_string<charT,traits,Allocator>& \text{lhs},
const charT* \text{rhs});

3 Returns: \text{lhs} < basic_string<charT,traits,Allocator>(\text{rhs}).

21.3.7.5 operator>

template<class charT, class traits, class Allocator>
bool operator> (const basic_string<charT,traits,Allocator>& \text{lhs},
const basic_string<charT,traits,Allocator>& \text{rhs});

1 Returns: \text{lhs} \text{. compare}(\text{rhs}) > 0.

template<class charT, class traits, class Allocator>
bool operator> (const charT* \text{lhs},
const basic_string<charT,traits,Allocator>& \text{rhs});

2 Returns: basic_string<charT,traits,Allocator>(\text{lhs}) > \text{rhs}.

template<class charT, class traits, class Allocator>
bool operator> (const basic_string<charT,traits,Allocator>& \text{lhs},
const charT* \text{rhs});

3 Returns: \text{lhs} > basic_string<charT,traits,Allocator>(\text{rhs}).

21.3.7.6 operator<=

template<class charT, class traits, class Allocator>
bool operator<=(const basic_string<charT,traits,Allocator>& \text{lhs},
const basic_string<charT,traits,Allocator>& \text{rhs});

1 Returns: \text{lhs} \text{. compare}(\text{rhs}) <= 0.

template<class charT, class traits, class Allocator>
bool operator<=(const charT* \text{lhs},
const basic_string<charT,traits,Allocator>& \text{rhs});

2 Returns: basic_string<charT,traits,Allocator>(\text{lhs}) <= \text{rhs}.

template<class charT, class traits, class Allocator>
bool operator<=(const basic_string<charT,traits,Allocator>& \text{lhs},
const charT* \text{rhs});
21.3 Class template basic_string

3 Returns: \( \text{lhs} \leq \text{basic_string<charT,traits,Allocator>(rhs)} \).

21.3.7.7 operator\(\geq\)

\begin{verbatim}
template<
    class charT,
    class traits,
    class Allocator>
bool operator\(\geq\)(
    const basic_string<charT,traits,Allocator>& \textit{lhs},
    const basic_string<charT,traits,Allocator>& \textit{rhs});
\end{verbatim}

1 Returns: \( \text{lhs.compare(rhs)} \geq 0 \).

\begin{verbatim}
template<
    class charT,
    class traits,
    class Allocator>
bool operator\(\geq\)(
    const charT* \textit{lhs},
    const basic_string<charT,traits,Allocator>& \textit{rhs});
\end{verbatim}

2 Returns: basic_string<charT,traits,Allocator>(lhs) \(\geq\) rhs.

\begin{verbatim}
template<
    class charT,
    class traits,
    class Allocator>
bool operator\(\geq\)(
    const basic_string<charT,traits,Allocator>& \textit{lhs},
    const charT* \textit{rhs});
\end{verbatim}

3 Returns: \( \text{lhs} \geq \text{basic_string<charT,traits,Allocator>(rhs)} \).

21.3.7.8 swap

\begin{verbatim}
template<
    class charT,
    class traits,
    class Allocator>
void swap(
    basic_string<charT,traits,Allocator>& \textit{lhs},
    basic_string<charT,traits,Allocator>& \textit{rhs});
\end{verbatim}

1 Effects: \( \text{lhs.swap(rhs)} \);

21.3.7.9 Inserters and extractors

\begin{verbatim}
template<
    class charT,
    class traits,
    class Allocator>
basic_istream<charT,traits>&
operator>>(
    basic_istream<charT,traits>& \textit{is},
    basic_string<charT,traits,Allocator>& \textit{str});
\end{verbatim}

1 Effects: Behaves as a formatted input function (27.6.1.2.1). After constructing a sentry object, if the sentry
converts to true, calls \( \text{str.erase()} \) and then extracts characters from \( \textit{is} \) and appends them to \( \textit{str} \) as if by calling
\( \text{str.append(1, c)} \). If \( \textit{is.width()} \) is greater than zero, the maximum number \( n \) of characters appended is
\( \text{is.width()} \); otherwise \( n \) is \( \text{str.max_size()} \). Characters are extracted and appended until any of the following
occurs:

- \( n \) characters are stored;
- end-of-file occurs on the input sequence;
- \( \text{isspace(c, is.getloc())} \) is true for the next available input character \( c \).
After the last character (if any) is extracted, \texttt{is.width(0)} is called and the sentry object \( k \) is destroyed.

If the function extracts no characters, it calls \texttt{is.setstate(ios::failbit)}, which may throw \texttt{ios_base::failure} (27.4.4.3).

Returns: \texttt{is}

```cpp
template<class charT, class traits, class Allocator>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os,
           const basic_string<charT, traits, Allocator>& str);
```

Effects: Begins by constructing a sentry object \( k \) as if \( k \) were constructed by \texttt{typename basic_ostream<charT, traits>::sentry\( k(os) \). If \texttt{bool(k)} is true, determines padding as described in 22.2.2.2, then inserts the resulting sequence of characters \( \texttt{seq} \) as if by calling \texttt{os.rdbuf()->sputn(seq, n)}, where \( n \) is the larger of \texttt{os.width()} and \texttt{str.size()}; then calls \texttt{os.width(0)}. If the call to \texttt{sputn} fails, calls \texttt{os.setstate(ios_base::failbit)}.

Returns: \texttt{os}

```cpp
template<class charT, class traits, class Allocator>
basic_istream<charT, traits>&
getline (basic_istream<charT, traits>& is,
         basic_string<charT, traits, Allocator>& str,
         charT delim);
```

Effects: Behaves as an unformatted input function (27.6.1.3), except that it does not affect the value returned by subsequent calls to \texttt{basic_istream\::gcount()}. After constructing a sentry object, if the sentry converts to true, calls \texttt{str.erase()} and then extracts characters from \texttt{is} and appends them to \texttt{str} as if by calling \texttt{str.append(1, c)} until any of the following occurs:

- end-of-file occurs on the input sequence (in which case, the \texttt{getline} function calls \texttt{is.setstate(ios_base::eofbit)}).
- traits::eq(c, delim) for the next available input character \( c \) (in which case, \( c \) is extracted but not appended) (27.4.4.3)
- \texttt{str.max_size()} characters are stored (in which case, the function calls \texttt{is.setstate(ios_base::failbit)}) (27.4.4.3)

The conditions are tested in the order shown. In any case, after the last character is extracted, the sentry object \( k \) is destroyed.

If the function extracts no characters, it calls \texttt{is.setstate(ios_base::failbit)} which may throw \texttt{ios_base::failure} (27.4.4.3).

Returns: \texttt{is}

```cpp
template<class charT, class traits, class Allocator>
basic_istream<charT, traits>&
getline (basic_istream<charT, traits>& is,
         basic_string<charT, traits, Allocator>& str)
```
11. Returns: getline(is, str, is.widen(‘\n’))

21.4 Null-terminated sequence utilities

Tables 46, 47, 48, and 50 describe headers <cctype>, <cwctype>, <cstring>, <cwchar>, and <cstdlib> (multi-byte conversions), respectively.

Table 46: Header <cctype> synopsis

<table>
<thead>
<tr>
<th>Type</th>
<th>Name(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Functions</td>

</table>

2. The contents of these headers are the same as the Standard C library headers <ctype.h>, <wctype.h>, <string.h>, <wchar.h> and <stdlib.h> respectively, with the following modifications:

3. None of the headers shall define the type wchar_t (2.11).

4. The function signature strchr(const char*, int) is replaced by the two declarations:

```c
const char* strchr(const char* s, int c);
char* strchr(const char* s, int c);
```
### Table 49: Header `<cwchar>` synopsis

<table>
<thead>
<tr>
<th>Type</th>
<th>Name(s)</th>

<tr>
<td></td>
<td>atoi</td>
</tr>
</tbody>
</table>
both of which have the same behavior as the original declaration.

5 The function signature \texttt{strpbrk(const char*, const char*)} is replaced by the two declarations:

\begin{verbatim}
const char* strpbrk(const char* s1, const char* s2);
char* strpbrk(    char* s1, const char* s2);
\end{verbatim}

both of which have the same behavior as the original declaration.

6 The function signature \texttt{strrchr(const char*, int)} is replaced by the two declarations:

\begin{verbatim}
const char* strrchr(const char* s, int c);
char* strrchr(    char* s, int c);
\end{verbatim}

both of which have the same behavior as the original declaration.

7 The function signature \texttt{strstr(const char*, const char*)} is replaced by the two declarations:

\begin{verbatim}
const char* strstr(const char* s1, const char* s2);
char* strstr(    char* s1, const char* s2);
\end{verbatim}

both of which have the same behavior as the original declaration.

8 The function signature \texttt{memchr(const void*, int, size_t)} is replaced by the two declarations:

\begin{verbatim}
const void* memchr(const void* s, int c, size_t n);
void* memchr( void* s, int c, size_t n);
\end{verbatim}

both of which have the same behavior as the original declaration.

9 The function signature \texttt{wcschr(const wchar_t*, wchar_t)} is replaced by the two declarations:

\begin{verbatim}
const wchar_t* wcschr(const wchar_t* s, wchar_t c);
wchar_t* wcschr( wchar_t* s, wchar_t c);
\end{verbatim}

both of which have the same behavior as the original declaration.

10 The function signature \texttt{wcspbrk(const wchar_t*, const wchar_t*)} is replaced by the two declarations:

\begin{verbatim}
const wchar_t* wcspbrk(const wchar_t* s1, const wchar_t* s2);
wchar_t* wcspbrk(    wchar_t* s1, const wchar_t* s2);
\end{verbatim}

both of which have the same behavior as the original declaration.

11 The function signature \texttt{wcsrchr(const wchar_t*, wchar_t)} is replaced by the two declarations:

\begin{verbatim}
const wchar_t* wcsrchr(const wchar_t* s, wchar_t c);
wchar_t* wcsrchr( wchar_t* s, wchar_t c);
\end{verbatim}

both of which have the same behavior as the original declaration.

12 The function signature \texttt{wcsstr(const wchar_t*, const wchar_t*)} is replaced by the two declarations:

\begin{verbatim}
const wchar_t* wcsstr(const wchar_t* s1, const wchar_t* s2);
wchar_t* wcsstr(    wchar_t* s1, const wchar_t* s2);
\end{verbatim}
both of which have the same behavior as the original declaration.

The function signature \texttt{wmemchr(const wchar\_t*, int, size\_t)} is replaced by the two declarations:

\begin{verbatim}
const wchar\_t* wmemchr(const wchar\_t* s, wchar\_t c, size\_t n);
wchar\_t* wmemchr(wchar\_t* s, wchar\_t c, size\_t n);
\end{verbatim}

both of which have the same behavior as the original declaration.

\textsc{See Also:} ISO C subclauses 7.3, 7.10.7, 7.10.8, and 7.11. Amendment 1 subclauses 4.4, 4.5, and 4.6.
Chapter 22 Localization library [lib.localization]

1 This clause describes components that C++ programs may use to encapsulate (and therefore be more portable when confronting) cultural differences. The locale facility includes internationalization support for character classification and string collation, numeric, monetary, and date/time formatting and parsing, and message retrieval.

2 The following subclauses describe components for locales themselves, the standard facets, and facilities from the ISO C library, as summarized in Table 51

Table 51: Localization library summary

template <class charT, class OutputIterator> class time_put;
template <class charT, class OutputIterator> class time_put_byname;

// 22.2.6, money:
class money_base;
template <class charT, class InputIterator> class money_get;
template <class charT, class OutputIterator> class money_put;
template <class charT, bool Intl> class moneypunct;
template <class charT, bool Intl> class moneypunct_byname;

// 22.2.7, message retrieval:
class messages_base;
template <class charT> class messages;
template <class charT> class messages_byname;
}

The header <locale> defines classes and declares functions that encapsulate and manipulate the information peculiar to a locale.\(^\text{226}\)

22.1.1 Class locale

\begin{verbatim}
namespace std {

```
Draft
\end{verbatim}
class locale {
    public:
    // types:
    class facet;
    class id;
    typedef int category;  // values assigned here are for exposition only
    static const category
        none = 0,
        collate = 0x010, ctype = 0x020,
        monetary = 0x040, numeric = 0x080,
        time = 0x100, messages = 0x200,
        all = collate | ctype | monetary | numeric | time | messages;

    // construct/copy/destroy:
    locale() throw();
    locale(const locale & other) throw();
    explicit locale(const char * std_name);
    locale(const locale & other, const char * std_name, category);
    template <class Facet> locale(const locale & other, Facet * f);
    locale(const locale & other, const locale & one, category);
    ~locale() throw();  // non-virtual
    const locale & operator=(const locale & other) throw();
    template <class Facet> locale combine(const locale & other) const;

    // locale operations:
    basic_string<char> name() const;

    bool operator==(const locale & other) const;
    bool operator!=(const locale & other) const;

    template <class charT, class Traits, class Allocator>
    bool operator()(const basic_string<charT,Traits,Allocator>& s1,
        const basic_string<charT,Traits,Allocator>& s2) const;

    // global locale objects:
    static locale global(const locale&);
    static const locale & classic();
};

1. Class locale implements a type-safe polymorphic set of facets, indexed by facet type. In other words, a facet has a dual role: in one sense, it’s just a class interface; at the same time, it’s an index into a locale’s set of facets.

2. Access to the facets of a locale is via two function templates, use_facet<> and has_facet<>.

3. [Example: An iostream operator<< might be implemented as:][227]

```cpp
template <class charT, class traits>
basic_ostream<charT,traits>&
```

[227] Notice that, in the call to put, the stream is implicitly converted to an ostreambuf_iterator<charT,traits>.
operator<<(basic_ostream<charT,traits>& s, Date d) {
    typename basic_ostream<charT,traits>::sentry cerberos(s);
    if (cerberos) {
        ios_base::iostate err = 0;
        tm tmbuf; d.extract(tmbuf);
        use_facet<time_put<charT,ostreambuf_iterator<charT,traits>>>(s.getloc()).put(s, s, s.fill(), err, &tmbuf, 'x');
        s.setstate(err);       // might throw
    }
    return s;
}

/* end example */

In the call to use_facet<Facet>(loc), the type argument chooses a facet, making available all members of the named type. If Facet is not present in a locale, it throws the standard exception bad_cast. A C++ program can check if a locale implements a particular facet with the function template has_facet<Facet>(). User-defined facets may be installed in a locale, and used identically as may standard facets (22.2.8).

[Note: All locale semantics are accessed via use_facet<> and has_facet<> except that:
   — A member operator template operator()(basic_string<C,T,A>&, basic_string<C,T,A>&) is provided so that a locale may be used as a predicate argument to the standard collections, to collate strings.
   — Convenient global interfaces are provided for traditional ctype functions such as isdigit() and isspace(), so that given a locale object loc a C++ program can call isspace(c,loc). (This eases upgrading existing extractors (27.6.1.2).) — end note]

Once a facet reference is obtained from a locale object by calling use_facet<> that reference remains usable, and the results from member functions of it may be cached and re-used, as long as some locale object refers to that facet.

In successive calls to a locale facet member function on a facet object installed in the same locale, the returned result shall be identical.

A locale constructed from a name string (such as "POSIX"), or from parts of two named locales, has a name; all others do not. Named locales may be compared for equality; an unnamed locale is equal only to (copies of) itself. For an unnamed locale, locale::name() returns the string 

22.1.1 locale types [lib.locale.types]

22.1.1.1 Type locale::category [lib.locale.category]

typedef int category;

Valid category values include the locale member bitmask elements collate, ctype, monetary, numeric, time, and messages, each of which represents a single locale category. In addition, locale member bitmask constant none is defined as zero and represents no category. And locale member bitmask constant all is defined such that the expression

(collate | ctype | monetary | numeric | time | messages | all) == all

Draft
is true, and represents the union of all categories. Further, the expression \( (X \mid Y) \), where \( X \) and \( Y \) each represent a single category, represents the union of the two categories.

locale member functions expecting a category argument require one of the category values defined above, or the union of two or more such values. Such a category value identifies a set of locale categories. Each locale category, in turn, identifies a set of locale facets, including at least those shown in Table 52:

<table>
<thead>
<tr>
<th>Category</th>
<th>Includes Facets</th>
</tr>
</thead>
<tbody>
<tr>
<td>collate</td>
<td>collate&lt;char&gt;, collate&lt;wchar_t&gt;</td>
</tr>
<tr>
<td>ctype</td>
<td>ctype&lt;char&gt;, ctype&lt;wchar_t&gt;</td>
</tr>
<tr>
<td></td>
<td>codecvt&lt;char, char, mbstate_t&gt;</td>
</tr>
<tr>
<td></td>
<td>codecvt&lt;wchar_t, char, mbstate_t&gt;</td>
</tr>
<tr>
<td>monetary</td>
<td>moneyupunct&lt;char&gt;, moneyupunct&lt;wchar_t&gt;</td>
</tr>
<tr>
<td></td>
<td>moneyupunct&lt;char, true&gt;, moneyupunct&lt;wchar_t, true&gt;</td>
</tr>
<tr>
<td></td>
<td>money_get&lt;char&gt;, money_get&lt;wchar_t&gt;</td>
</tr>
<tr>
<td></td>
<td>money_put&lt;char&gt;, money_put&lt;wchar_t&gt;</td>
</tr>
<tr>
<td>numeric</td>
<td>numpunct&lt;char&gt;, numpunct&lt;wchar_t&gt;</td>
</tr>
<tr>
<td></td>
<td>num_get&lt;char&gt;, num_get&lt;wchar_t&gt;</td>
</tr>
<tr>
<td></td>
<td>num_put&lt;char&gt;, num_put&lt;wchar_t&gt;</td>
</tr>
<tr>
<td>time</td>
<td>time_get&lt;char&gt;, time_get&lt;wchar_t&gt;</td>
</tr>
<tr>
<td></td>
<td>time_put&lt;char&gt;, time_put&lt;wchar_t&gt;</td>
</tr>
<tr>
<td>messages</td>
<td>messages&lt;char&gt;, messages&lt;wchar_t&gt;</td>
</tr>
</tbody>
</table>

For any locale \( \text{loc} \) either constructed, or returned by \( \text{locale::classic()} \), and any facet \( \text{Facet} \) shown in Table 52, \( \text{has_facet<Facet>(\text{loc})} \) is true. Each \( \text{locale} \) member function which takes a \( \text{locale::category} \) argument operates on the corresponding set of facets.

An implementation is required to provide those specializations for facet templates identified as members of a category, and for those shown in Table 53.

The provided implementation of members of facets \( \text{num_get<charT>} \) and \( \text{num_put<charT>} \) calls \( \text{use_facet<F>(l)} \) (1) only for facet \( F \) of types \( \text{numpunct<charT>} \) and \( \text{ctype<charT>} \), and for locale \( l \) the value obtained by calling member \( \text{getloc()} \) on the \( \text{ios_base}& \) argument to these functions.

In declarations of facets, a template formal parameter with name \( \text{InputIterator} \) or \( \text{OutputIterator} \) indicates the set of all possible specializations on parameters that satisfy the requirements of an Input Iterator or an Output Iterator, respectively (24.1). A template formal parameter with name \( C \) represents the set of all possible specializations on a parameter that satisfies the requirements for a character on which any of the iostream components can be instantiated. A template formal parameter with name \( \text{International} \) represents the set of all possible specializations on a bool parameter.

22.1.1.2 Class \( \text{locale::facet} \) [lib.locale.facet]

```cpp
namespace std {
    class locale::facet {
        protected:
```
Table 53: Required Specializations

<table>
<thead>
<tr>
<th>Category</th>
<th>Includes Facets</th>
</tr>
</thead>
<tbody>
<tr>
<td>collate</td>
<td>collate_byname&lt;char&gt;, collate_byname&lt;wchar_t&gt;</td>
</tr>
<tr>

</tr>
<tr>
<td>messages</td>
<td>messages_byname&lt;char&gt;, messages_byname&lt;wchar_t&gt;</td>
</tr>
</tbody>
</table>

```cpp
explicit facet(size_t refs = 0);
virtual ~facet();
private:
    facet(const facet&); // not defined
    void operator=(const facet&); // not defined
};
```

1. Template parameters in this clause which are required to be facets are those named Facet in declarations. A program that passes a type that is not a facet, or a type that refers to a volatile-qualified facet, as an (explicit or deduced) template parameter to a locale function expecting a facet, is ill-formed. A const-qualified facet is a valid template argument to any locale function that expects a Facet template parameter.

2. The `refs` argument to the constructor is used for lifetime management.
   - For `refs == 0`, the implementation performs `delete static_cast<locale::facet*>(f)` (where `f` is a pointer to the facet) when the last `locale` object containing the facet is destroyed; for `refs == 1`, the implementation never destroys the facet.

3. Constructors of all facets defined in this clause take such an argument and pass it along to their `facet` base class constructor. All one-argument constructors defined in this clause are `explicit`, preventing their participation in automatic conversions.

4. For some standard facets a standard “…_byname” class, derived from it, implements the virtual function semantics
equivalent to that facet of the locale constructed by \texttt{locale(const char*)} with the same name. Each such facet provides a constructor that takes a \texttt{const char*} argument, which names the locale, and a \texttt{refs} argument, which is passed to the base class constructor. If there is no “\_byname” version of a facet, the base class implements named locale semantics itself by reference to other facets.

22.1.1.3 Class \texttt{locale::id} [lib.locale.id]

```cpp
namespace std {
    class locale::id {
    public:
        id();
        void operator=(const id&); // not defined
        id(const id&); // not defined
    }
}
```

The class \texttt{locale::id} provides identification of a locale facet interface, used as an index for lookup and to encapsulate initialization.

2 [Note: Because facets are used by iostreams, potentially while static constructors are running, their initialization cannot depend on programmed static initialization. One initialization strategy is for \texttt{locale} to initialize each facet’s \texttt{id} member the first time an instance of the facet is installed into a locale. This depends only on static storage being zero before constructors run (3.6.2). — end note]

22.1.2 \texttt{locale} constructors and destructor [lib.locale.cons]

\texttt{locale()} throw();

Default constructor: a snapshot of the current global locale.  

2 \textit{Effects:} Constructs a copy of the argument last passed to \texttt{locale::global(locale&)}, if it has been called; else, the resulting facets have virtual function semantics identical to those of \texttt{locale::classic()}.  

[Note: This constructor is commonly used as the default value for arguments of functions that take a \texttt{const locale&} argument. — end note]

\texttt{locale(const locale& other)} throw();

\textit{Effects:} Constructs a locale which is a copy of \texttt{other}.

\texttt{const locale& operator=(const locale& other)} throw();

\textit{Effects:} Creates a copy of \texttt{other}, replacing the current value.

\textit{Returns:} *this

\texttt{explicit locale(const char* std_name);} 

\textit{Effects:} Constructs a locale using standard C locale names, e.g. "POSIX". The resulting locale implements semantics defined to be associated with that name.

\textit{Throws:} \texttt{runtime_error} if the argument is not valid, or is null.
22.1 Locales

Remarks: The set of valid string argument values is "C", "", and any implementation-defined values.

locale(const locale& other, const char* std_name, category);

Effects: Constructs a locale as a copy of other except for the facets identified by the category argument, which instead implement the same semantics as locale(std_name).

Throws: runtime_error if the argument is not valid, or is null.

Remarks: The locale has a name if and only if other has a name.

template <class Facet> locale(const locale& other, Facet* f);

Effects: Constructs a locale incorporating all facets from the first argument except that of type Facet, and installs the second argument as the remaining facet. If f is null, the resulting object is a copy of other.

Remarks: The resulting locale has no name.

locale(const locale& other, const locale& one, category cats);

Effects: Constructs a locale incorporating all facets from the first argument except those that implement cats, which are instead incorporated from the second argument.

Remarks: The resulting locale has a name if and only if the first two arguments have names.

~locale() throw();

A non-virtual destructor that throws no exceptions.

22.1.1.3 locale members

template <class Facet> locale combine(const locale& other) const;

Effects: Constructs a locale incorporating all facets from *this except for that one facet of other that is identified by Facet.

Returns: The newly created locale.

Throws: runtime_error if has_facet<Facet>(other) is false.

Remarks: The resulting locale has no name.

basic_string<char> name() const;

Returns: The name of *this, if it has one; otherwise, the string ".". If *this has a name, then locale(name().c_str()) is equivalent to *this. Details of the contents of the resulting string are otherwise implementation-defined.

22.1.4 locale operators

bool operator==(const locale& other) const;

Draft
Returns: true if both arguments are the same locale, or one is a copy of the other, or each has a name and the names are identical; false otherwise.

bool operator!=(const locale& other) const;

Returns: The result of the expression: !(\*this == other).

template <class charT, class Traits, class Allocator>
bool operator()(const basic_string<charT,Traits,Allocator>& s1,
                const basic_string<charT,Traits,Allocator>& s2) const;

Effects: Compares two strings according to the collate<charT> facet.

Remarks: This member operator template (and therefore locale itself) satisfies requirements for a comparator predicate template argument (clause 25) applied to strings.

Returns: The result of the following expression:

\[
\text{use_facet<collate<charT>>(\*this).compare}\(s1.\text{data}()\), s1.\text{data}() + s1.\text{size}()\), s2.\text{data}()\), s2.\text{data}() + s2.\text{size}()\) < 0;
\]

[Example: A vector of strings v can be collated according to collation rules in locale loc simply by (25.3.1, 23.2.4):

\[
\text{std::sort(v.begin(), v.end(), loc)};
\]

— end example]

22.1.1.5 locale static members [lib.locale.statics]

static locale global(const locale& loc);

Sets the global locale to its argument.

Effects: Causes future calls to the constructor locale() to return a copy of the argument. If the argument has a name, does

\[
\text{std::setlocale(LC_ALL, loc.name().c_str())};
\]
otherwise, the effect on the C locale, if any, is implementation-defined. No library function other than locale::global() shall affect the value returned by locale().

Returns: The previous value of locale().

static const locale& classic();

The "C" locale.

Returns: A locale that implements the classic "C" locale semantics, equivalent to the value locale("C").

Remarks: This locale, its facets, and their member functions, do not change with time.
22.1 Locales

22.1.2 locale globals

```
template <class Facet> const Facet& use_facet(const locale& loc);
```

1. **Requires:** Facet is a facet class whose definition contains the public static member id as defined in 22.1.1.1.2.
2. **Returns:** a reference to the corresponding facet of loc, if present.
3. **Throws:** bad_cast if has_facet<Facet>(loc) is false.
4. **Remarks:** The reference returned remains valid at least as long as any copy of loc exists.

```
template <class Facet> bool has_facet(const locale& loc) throw();
```

5. **Returns:** true if the facet requested is present in loc; otherwise false.

22.1.3 Convenience interfaces

22.1.3.1 Character classification

```
template <class charT> bool isspace (charT c, const locale& loc);
template <class charT> bool isprint (charT c, const locale& loc);
template <class charT> bool iscntrl (charT c, const locale& loc);
template <class charT> bool isupper (charT c, const locale& loc);
template <class charT> bool islower (charT c, const locale& loc);
```

6. Each of these functions isF returns the result of the expression:

```
use_facet<ctype<charT> >(loc).is(ctype_base::F, c)
```

where F is the ctype_base::mask value corresponding to that function (22.2.1).

```
template <class charT> bool isdigit (charT c, const locale& loc);
template <class charT> bool ispunct (charT c, const locale& loc);
template <class charT> bool isxdigit (charT c, const locale& loc);
template <class charT> bool isgraph (charT c, const locale& loc);
```

7. When used in a loop, it is faster to cache the ctype<> facet and use it directly, or use the vector form of ctype<>::is.

22.1.3.2 Character conversions

```
template <class charT> charT toupper (charT c, const locale& loc);
```

8. **Returns:** use_facet<ctype<charT> >(loc).toupper(c).

```
template <class charT> charT tolower (charT c, const locale& loc);
```

9. **Returns:** use_facet<ctype<charT> >(loc).tolower(c).

---

228) When used in a loop, it is faster to cache the ctype<> facet and use it directly, or use the vector form of ctype<>::is.
Each of the standard categories includes a family of facets. Some of these implement formatting or parsing of a datum, for use by standard or users’ iostream operators << and>>, as members put() and get(), respectively. Each such member function takes an `ios_base&` argument whose members flags(), precision(), and width(), specify the format of the corresponding datum. (27.4.2). Those functions which need to use other facets call its member getloc() to retrieve the locale imbued there. Formatting facets use the character argument *fill* to fill out the specified width where necessary.

The `put()` members make no provision for error reporting. (Any failures of the OutputIterator argument must be extracted from the returned iterator.) The `get()` members take an `ios_base::iostate&` argument whose value they ignore, but set to `ios_base::failbit` in case of a parse error.

### 22.2.1 The `ctype` category

```cpp
namespace std {
    class ctype_base {
        public:
            typedef T mask;

            // numeric values are for exposition only.
            static const mask space = 1 << 0;
            static const mask print = 1 << 1;
            static const mask cntrl = 1 << 2;
            static const mask upper = 1 << 3;
            static const mask lower = 1 << 4;
            static const mask alpha = 1 << 5;
            static const mask digit = 1 << 6;
            static const mask punct = 1 << 7;
            static const mask xdigit = 1 << 8;
            static const mask alnum = alpha | digit;
            static const mask graph = alnum | punct;
    };
}
```

The type `mask` is a bitmask type (17.3.2.1.2).

### 22.2.1.1 Class template `ctype`

```cpp
namespace std {
    template <class charT>
    class ctype : public locale::facet, public ctype_base {
        public:
            typedef charT char_type;
            explicit ctype(size_t refs = 0);

            bool is(mask m, charT c) const;
            const charT* is(const charT* low, const charT* high, mask* vec) const;
            const charT* scan_is(mask m, const charT* low, const charT* high) const;
            const charT* scan_not(mask m,
```

Draft
22.2 Standard locale categories

locale::id id;

protected:

"ctype();
// virtual
virtual bool is(mask m, charT c) const;
virtual const charT* is(const charT* low, const charT* high, mask* vec) const;
virtual const charT* do_scan_is(mask m, const charT* low, const charT* high, mask* vec) const;
virtual const charT* do_scan_not(mask m, const charT* low, const charT* high) const;
virtual charT do_toupper(charT) const;
virtual const charT* do_toupper(const charT* low, const charT* high) const;
virtual charT do_tolower(charT) const;
virtual const charT* do_tolower(const charT* low, const charT* high) const;
virtual charT do_widen(char) const;
virtual const charT* do_widen(const charT* low, const charT* high, charT* dest) const;
virtual char do_narrow(charT, char default) const;
virtual const charT* do_narrow(const charT* low, const charT* high, char default, char* dest) const;

1 Class ctype encapsulates the C library <cctype> features. istream members are required to use ctype<> for character classing during input parsing.

2 The specializations required in Table 52 (22.1.1.1.1), namely ctype<char> and ctype<wchar_t>, implement character classing appropriate to the implementation’s native character set.

### 22.2.1.1 ctype members

```
bool is(mask m, charT c) const;
const charT* is(const charT* low, const charT* high, mask* vec) const;
```

Returns: do_is(m,c) or do_is(low,high,vec)

const charT* scan_is(mask m,
const charT* low, const charT* high) const;

Returns: do_scan_is(m,low,high)

Returns: do_scan_not(m,low,high)

Returns: do_toupper(c) or do_toupper(low,high)

Returns: do_tolower(c) or do_tolower(low,high)

Returns: do_widen(c) or do_widen(low,high, to)

Returns: do_narrow(c,default) or do_narrow(low,high,default,to)

22.2.1.1.2 ctype virtual functions

bool do_is(mask m, char c) const;
const charT* do_is(const charT* low, const charT* high,
                    mask* vec) const;

Effects: Classifies a character or sequence of characters. For each argument character, identifies a value \( M \) of type \text{ctype_base}::\text{mask}. The second form identifies a value \( M \) of type \text{ctype_base}::\text{mask} for each \(*p\) where \((\text{low}\leq p \land p < \text{high})\), and places it into \( \text{vec}[p - \text{low}] \).

Returns: The first form returns the result of the expression \((M \& m) \neq 0\); i.e., true if the character has the characteristics specified. The second form returns \text{high}.

Returns: The smallest pointer \( p \) in the range \([\text{low}, \text{high})\) such that \( \text{is}(m,*p) \) would return true; otherwise, returns \text{high}.

Draft
Effects: Locates a character in a buffer that fails to conform to a classification $m$.

Returns: The smallest pointer $p$, if any, in the range $[\text{low}, \text{high})$ such that is($m, *p$) would return false; otherwise, returns high.

```cpp
charT do_toupper(charT c) const;
const charT* do_toupper(charT* low, const charT* high) const;
```

Effects: Converts a character or characters to upper case. The second form replaces each character $*p$ in the range $[\text{low}, \text{high})$ for which a corresponding upper-case character exists, with that character.

Returns: The first form returns the corresponding upper-case character if it is known to exist, or its argument if not. The second form returns high.

```cpp
charT do_tolower(charT c) const;
const charT* do_tolower(charT* low, const charT* high) const;
```

Effects: Converts a character or characters to lower case. The second form replaces each character $*p$ in the range $[\text{low}, \text{high})$ and for which a corresponding lower-case character exists, with that character.

Returns: The first form returns the corresponding lower-case character if it is known to exist, or its argument if not. The second form returns high.

```cpp
charT do_widen(char c) const;
const char* do_widen(const char* low, const char* high,
charT* dest) const;
```

Effects: Applies the simplest reasonable transformation from a char value or sequence of char values to the corresponding charT value or values. The only characters for which unique transformations are required are those in the basic source character set (2.2).

For any named ctype category with a ctype<char> facet $ctc$ and valid ctype_base::mask value $M$, $\text{is}(M, c) \text{ or } !\text{is}(M, \text{do_widen}(c))$ is true.

The second form transforms each character $*p$ in the range $[\text{low}, \text{high})$, placing the result in $\text{dest}[p-\text{low}]$.

Returns: The first form returns the transformed value. The second form returns high.

```cpp
char do_narrow(charT c, char dfault) const;
const charT* do_narrow(const charT* low, const charT* high,
char dfault, char* dest) const;
```

Effects: Applies the simplest reasonable transformation from a charT value or sequence of charT values to the corresponding char value or values.

For any character $c$ in the basic source character set (2.2) the transformation is such that

\[
\text{do_widen}(\text{do_narrow}(c, 0)) = c
\]

For any named ctype category with a ctype<char> facet $ctc$ however, and ctype_base::mask value $M$,

\[
\text{is}(M, c) \text{ or } !\text{ctc$.is}(M, \text{do_narrow}(c, \text{dfault})\text{)}
\]

229) The char argument of do_widen is intended to accept values derived from character literals for conversion to the locale’s encoding.

230) In other words, the transformed character is not a member of any character classification that $c$ is not also a member of.
is true (unless do_narrow returns default). In addition, for any digit character $c$, the expression $(\text{do_narrow}(c, \text{default}) - '0')$ evaluates to the digit value of the character. The second form transforms each character $*p$ in the range $[\text{low}, \text{high}]$, placing the result (or default if no simple transformation is readily available) in $\text{dest}[p-\text{low}]$.

Returns: The first form returns the transformed value; or default if no mapping is readily available. The second form returns high.

### 22.2.1.2 Class template ctype_byname

```cpp
namespace std {
    template <class charT>
    class ctype_byname : public ctype<charT> {
        public:
            typedef ctype<charT>::mask mask;
            explicit ctype_byname(const char*, size_t refs = 0);
        protected:
            ~ctype_byname(); // virtual
    };
}
```

### 22.2.1.3 ctype specializations

```cpp
namespace std {
    template <> class ctype<char> : public locale::facet, public ctype_base {
        public:
            typedef char char_type;
            explicit ctype(const mask* tab = 0, bool del = false, size_t refs = 0);

            bool is(mask m, char c) const;
            const char* is(const char* low, const char* high, mask* vec) const;
            const char* scan_is(mask m, const char* low, const char* high) const;
            const char* scan_not(mask m, const char* low, const char* high) const;

            char toupper(char c) const;
            const char* toupper(char* low, const char* high) const;
            char tolower(char c) const;
            const char* tolower(char* low, const char* high) const;

            char widen(char c) const;
            const char* widen(const char* low, const char* high, char* to) const;
            char narrow(char c, char default) const;
            const char* narrow(const char* low, const char* high, char default, char* to) const;
    };
}
```
static locale::id id;
static const size_t table_size = IMPLEMENTATION_DEFINED;

protected:
const mask* table() const throw();
static const mask* classic_table() throw();
~ctype();  // virtual
virtual char do_toupper(char c) const;
virtual const char* do_toupper(const char* low, const char* high) const;
virtual char do_tolower(char c) const;
virtual const char* do_tolower(const char* low, const char* high) const;

virtual char do_widen(char c) const;
virtual const char* do_widen(const char* low, const char* high, char* to) const;
virtual char do_narrow(char c, char default) const;
virtual const char* do_narrow(const char* low, const char* high, char default, char* to) const;
};

A specialization ctype<char> is provided so that the member functions on type char can be implemented inline. The implementation-defined value of member table_size is at least 256.

22.2.1.3.1 ctype<char> destructor
~ctype();

Effects: If the constructor's first argument was nonzero, and its second argument was true, does delete [] table().

22.2.1.3.2 ctype<char> members
explicit ctype(const mask* tbl = 0, bool del = false, size_t refs = 0);

Precondition: tbl either 0 or an array of at least table_size elements.

Effects: Passes its refs argument to its base class constructor.

231) Only the char (not unsigned char and signed char) form is provided. The specialization is specified in the standard, and not left as an implementation detail, because it affects the derivation interface for ctype<char>.
bool is(mask m, char c) const;
const char* is(const char* low, const char* high,
    mask* vec) const;

Effects: The second form, for all *p in the range [low, high], assigns into vec[p-low] the value table()[(unsigned char)*p].

Returns: The first form returns table()[(unsigned char)c] & m; the second form returns high.

const char* scan_is(mask m,
    const char* low, const char* high) const;

Returns: The smallest p in the range [low, high) such that
table()[(unsigned char)*p] & m
is true.

const char* scan_not(mask m,
    const char* low, const char* high) const;

Returns: The smallest p in the range [low, high) such that
table()[(unsigned char)*p] & m
is false.

char toupper(char c) const;
const char* toupper(char* low, const char* high) const;

Returns: do_toupper(c) or do_toupper(low, high), respectively.

char tolower(char c) const;
const char* tolower(char* low, const char* high) const;

Returns: do_tolower(c) or do_tolower(low, high), respectively.

char widen(char c) const;
const char* widen(const char* low, const char* high,
    char* to) const;

Returns: do_widen(c) or do_widen(low, high, to), respectively.

char narrow(char c, char default) const;
const char* narrow(const char* low, const char* high,
    char default, char* to) const;

Returns: do_narrow(c, default) or do_narrow(low, high, default, to), respectively.

const mask* table() const throw();

Returns: The first constructor argument, if it was non-zero, otherwise classic_table().
22.2.1.3.3 `ctype<char>` static members

```cpp
static const mask* classic_table() throw();
```

Returs: A pointer to the initial element of an array of size `table_size` which represents the classifications of characters in the "C" locale.

22.2.1.3.4 `ctype<char>` virtual functions

```cpp
virtual char do_toupper(char) const;
const char* do_toupper(char* low, const char* high) const;
char do_tolower(char) const;
const char* do_tolower(char* low, const char* high) const;
```

virtual `char do_widen(char c)` const;
```
virtual const char* do_widen(const char* low, const char* high, char* to) const;
```

virtual `char do_narrow(char c, char default)` const;
```
virtual const char* do_narrow(const char* low, const char* high, char default, char* to) const;
```

These functions are described identically as those members of the same name in the `ctype` class template (22.2.1.1).

22.2.1.4 Class template `codecvt`

```cpp
namespace std {
    class codecvt_base {
    public:
        enum result { ok, partial, error, noconv };
    };
    template <class internT, class externT, class stateT>
    class codecvt : public locale::facet, public codecvt_base {
    public:
        typedef internT intern_type;
        typedef externT extern_type;
        typedef stateT state_type;

        explicit codecvt(size_t refs = 0);

        result out(stateT& state,
            const internT* from, const internT* from_end, const internT*& from_next, 
            externT* to, externT* to_limit, externT*& to_next) const;
        result unshift(stateT& state,
            externT* to, externT* to_limit, externT*& to_next) const;
        result in(stateT& state,
            const externT* from, const externT* from_end, const externT*& from_next, 
            internT* to, internT* to_limit, internT*& to_next) const;
        int encoding() const throw();
    };
}
```
The class `codecvt<internT, externT, stateT>` is for use when converting from one codeset to another, such as from wide characters to multibyte characters or between wide character encodings such as Unicode and EUC.

The `stateT` argument selects the pair of codesets being mapped between.

The specializations required in Table 52 (22.1.1.1.1), namely `codecvt<wchar_t, char, mbstate_t>` and `codecvt<char, char, mbstate_t>`, convert the implementation-defined native character set. `codecvt<char, char, mbstate_t>` implements a degenerate conversion; it does not convert at all. `codecvt<wchar_t, char, mbstate_t>` converts between the native character sets for tiny and wide characters. Specializations on `mbstate_t` perform conversion between encodings known to the library implementor. Other encodings can be converted by specializing on a user-defined `stateT` type. The `stateT` object can contain any state that is useful to communicate to or from the specialized `do_in` or `do_out` members.

22.2.1.4.1 `codecvt` members

```cpp
result out(stateT& state,
    const internT* from, const internT* from_end, const internT*& from_next,
    externT* to, externT* to_limit, externT*& to_next) const;

Returns: do_out(state, from, from_end, from_next, to, to_limit, to_next)
```

```cpp
result unshift(stateT& state,
    externT* to, externT* to_limit, externT*& to_next) const;

Returns: do_unshift(state, to, to_limit, to_next)
```
result in(stateT& state,
        const externT* from, const externT* from_end, const externT*& from_next,
                internT* to, internT* to_limit, internT*& to_next) const;

Returns: do_in(state, from, from_end, from_next, to, to_limit, to_next)

int encoding() const throw();

Returns: do_encoding()

bool always_noconv() const throw();

Returns: do_always_noconv()

int length(stateT& state, const externT* from, const externT* from_end,
            size_t max) const;

Returns: do_length(state, from, from_end, max)

int max_length() const throw();

Returns: do_max_length()

22.2.1.4.2  codecvt virtual functions

result do_out(stateT& state,
        const internT* from, const internT* from_end, const internT*& from_next,
                externT* to, externT* to_limit, externT*& to_next) const;

result do_in(stateT& state,
        const externT* from, const externT* from_end, const externT*& from_next,
                internT* to, internT* to_limit, internT*& to_next) const;

Preconditions: (from<=from_end && to<=to_end) well-defined and true; state initialized, if at the be-
            ginning of a sequence, or else equal to the result of converting the preceding characters in the sequence.

Effects: Translates characters in the source range [from, from_end), placing the results in sequential positions
            starting at destination to. Converts no more than (from_end-from) source elements, and stores no more than
            (to_limit-to) destination elements.

Stops if it encounters a character it cannot convert. It always leaves the from_next and to_next pointers
pointing one beyond the last element successfully converted. If returns noconv, internT and externT are the
same type and the converted sequence is identical to the input sequence [from, from_next). to_next is set
equal to to, the value of state is unchanged, and there are no changes to the values in [to, to_limit).

A codecvt facet that is used by basic_filebuf (27.8) shall have the property that if

    do_out(state, from, from_end, from_next, to, to_limit, to_next)

would return ok, where from != from_end, then

    do_out(state, from, from + 1, from_next, to, to_end, to_next)
shall also return ok, and that if

\[
\text{do\_in}(\text{state}, \text{from}, \text{from\_end}, \text{from\_next}, \text{to}, \text{to\_limit}, \text{to\_next})
\]

would return ok, where \( \text{to} \neq \text{to\_end} \), then

\[
\text{do\_in}(\text{state}, \text{from}, \text{from\_end}, \text{from\_next}, \text{to}, \text{to} + 1, \text{to\_next})
\]

shall also return ok. 232)

4 Remarks: Its operations on \textit{state} are unspecified. [\textit{Note}: This argument can be used, for example, to maintain shift state, to specify conversion options (such as count only), or to identify a cache of seek offsets. —\textit{end note}] Returns: An enumeration value, as summarized in Table 54:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>\text{ok}</td>
<td>completed the conversion</td>
</tr>
<tr>
<td>\text{partial}</td>
<td>not all source characters converted</td>
</tr>
<tr>
<td>\text{error}</td>
<td>encountered a character in ([\text{from},\text{from_end})) that it could not convert</td>
</tr>
<tr>
<td>\text{noconv}</td>
<td>\text{internT} and \text{externT} are the same type, and input sequence is identical to converted sequence</td>
</tr>
</tbody>
</table>

A return value of \text{partial}, if \((\text{from\_next}=\text{from\_end})\), indicates that either the destination sequence has not absorbed all the available destination elements, or that additional source elements are needed before another destination element can be produced.

\[
\text{result do\_unshift}(\text{stateT} & \text{state}, \text{externT} * \text{to}, \text{externT} * \text{to\_limit}, \text{externT} *& \text{to\_next}) \text{ const;}
\]

6 Requires: \((\text{to} \leq \text{to\_end})\) well defined and true; state initialized, if at the beginning of a sequence, or else equal to the result of converting the preceding characters in the sequence.

7 Effects: Places characters starting at \text{to} that should be appended to terminate a sequence when the current \text{stateT} is given by \text{state}. 233) Stores no more than \((\text{to\_limit}-\text{to})\) destination elements, and leaves the \text{to\_next} pointer pointing one beyond the last element successfully stored. \text{codecvt<char, char, mbstate_t>} stores no characters.

8 Returns: An enumeration value, as summarized in Table 55:

\[
\text{codecvt<char, char, mbstate_t>}, \text{returns noconv.}
\]

\[
\text{int do\_encoding()} \text{ const throw();}
\]

232) Informally, this means that \textit{basic\_filebuf} assumes that the mappings from internal to external characters is 1 to N: a \text{codecvt} facet that is used by \textit{basic\_filebuf} must be able to translate characters one internal character at a time. 233) Typically these will be characters to return the state to \text{stateT}()
Table 55: do_unshift result values

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ok</td>
<td>completed the sequence</td>
</tr>
<tr>
<td>partial</td>
<td>space for more than to_limit-to destination elements was needed to terminate a sequence given the value of state</td>
</tr>
<tr>
<td>error</td>
<td>an unspecified error has occurred</td>
</tr>
<tr>
<td>noconv</td>
<td>no termination is needed for this state_type</td>
</tr>
</tbody>
</table>

9 Returns: -1 if the encoding of the externT sequence is state-dependent; else the constant number of externT characters needed to produce an internal character; or 0 if this number is not a constant\(^\text{234}\). 

bool do_always_noconv() const throw();
10 Returns: true if do_in() and do_out() return noconv for all valid argument values. codecvt<char, char, mbstate_t> returns true.

int do_length(stateT & state, const externT* from, const externT* from_end, size_t max) const;
11 Preconditions: (from\(\leq\)from_end) well-defined and true; state initialized, if at the beginning of a sequence, or else equal to the result of converting the preceding characters in the sequence.

Effects: The effect on the state argument is “as if” it called do_in(state, from, from_end, from, to, to+max, to) for to pointing to a buffer of at least max elements.

Returns: (from_next-from) where from_next is the largest value in the range [from, from_end] such that the sequence of values in the range [from, from_next) represents max or fewer valid complete characters of type internT. The specialization codecvt<char, char, mbstate_t>, returns the lesser of max and (from_end-from).

int do_max_length() const throw();
13 Returns: The maximum value that do_length(state, from, from_end, 1) can return for any valid range [from, from_end] and stateT value state. The specialization codecvt<char, char, mbstate_t>::do_max_length() returns 1.

22.2.1.5 Class template codecvtbyname

namespace std {
  template <class internT, class externT, class stateT>
  class codecvtbyname : public codecvt<internT, externT, stateT> {
    public:
      explicit codecvtbyname(const char*, size_t refs = 0);
      protected:
        ~codecvtbyname(); // virtual
    }
  }\(^\text{234}\) If encoding() yields -1, then more than max_length() externT elements may be consumed when producing a single internT character, and additional externT elements may appear at the end of a sequence after those that yield the final internT character.

Draft
22.2.2 The numeric category

The classes num_get<> and num_put<> handle numeric formatting and parsing. Virtual functions are provided for several numeric types. Implementations may (but are not required to) delegate extraction of smaller types to extractors for larger types.\[235\]

All specifications of member functions for num_put and num_get in the subclauses of 22.2.2 only apply to the specializations required in Tables 52 and 53 (22.1.1.1.1), namely num_get<char>, num_get<wchar_t>, num_get<C, InputIterator>, num_put<char>, num_put<wchar_t>, and num_put<C,OutputIterator>. These specializations refer to the ios_base& argument for formatting specifications (22.2), and to its imbed locale for the numpunct<> facet to identify all numeric punctuation preferences, and also for the ctype<> facet to perform character classification.

Extractor and inserter members of the standard iostreams use num_get<> and num_put<> member functions for formatting and parsing numeric values (27.6.1.2.1, 27.6.2.5.1).

### Class template num_get

```cpp
namespace std {
    template <class charT, class InputIterator = istreambuf_iterator<charT> >
    class num_get : public locale::facet {
    public:
        typedef charT char_type;
        typedef InputIterator iter_type;

        explicit num_get(size_t refs = 0);

        iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, bool & v) const;
        iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, long & v) const;
        iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, unsigned short & v) const;
        iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, unsigned int & v) const;
        iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, unsigned long & v) const;
        iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, float & v) const;
        iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, double & v) const;
        iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, long double & v) const;
        iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, void* & v) const;

        static locale::id id;

        protected:
            "num_get(); // virtual
```

\[235\] Parsing "-1" correctly into (e.g.) an unsigned short requires that the corresponding member get() at least extract the sign before delegating.
virtual iter_type do_get(iter_type, iter_type, ios_base&, 
    ios_base::iostate& err, bool& v) const;
virtual iter_type do_get(iter_type, iter_type, ios_base&, 
    ios_base::iostate& err, long& v) const;
virtual iter_type do_get(iter_type, iter_type, ios_base&, 
    ios_base::iostate& err, unsigned short& v) const;
virtual iter_type do_get(iter_type, iter_type, ios_base&, 
    ios_base::iostate& err, unsigned int& v) const;
virtual iter_type do_get(iter_type, iter_type, ios_base&, 
    ios_base::iostate& err, unsigned long& v) const;
virtual iter_type do_get(iter_type, iter_type, ios_base&, 
    ios_base::iostate& err, float& v) const;
virtual iter_type do_get(iter_type, iter_type, ios_base&, 
    ios_base::iostate& err, double& v) const;
virtual iter_type do_get(iter_type, iter_type, ios_base&, 
    ios_base::iostate& err, long double& v) const;
virtual iter_type do_get(iter_type, iter_type, ios_base&, 
    ios_base::iostate& err, void*& v) const;
};

The facet `num_get` is used to parse numeric values from an input sequence such as an istream.

### 22.2.2.1.1 num_get members

```cpp
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, bool& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, long& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, unsigned short& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, unsigned int& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, unsigned long& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, float& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, double& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, long double& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, void*& val) const;
```

Returns: `do_get(in, end, str, err, val)`.

### 22.2.2.1.2 num_get virtual functions

```cpp
iter_type do_get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, bool& v) const;
```
Effects: Reads characters from in, interpreting them according to str.flags(), use_facet<ctype<charT>>>(loc), and use_facet<numpunct<charT>>>(loc), where loc is str.getloc(). If an error occurs, val is unchanged; otherwise it is set to the resulting value.

The details of this operation occur in three stages:

— Stage 1: Determine a conversion specifier
— Stage 2: Extract characters from in and determine a corresponding char value for the format expected by the conversion specification determined in stage 1.
— Stage 3: Store results

The details of the stages are presented below.

**Stage 1**: The function initializes local variables via

\[
\text{fmtflags flags} = \text{str.flags()};
\]
\[
\text{fmtflags basefield} = (\text{flags} \& \text{ios_base::basefield});
\]
\[
\text{fmtflags uppercase} = (\text{flags} \& \text{ios_base::uppercase});
\]
\[
\text{fmtflags boolalpha} = (\text{flags} \& \text{ios_base::boolalpha});
\]

For conversion to an integral type, the function determines the integral conversion specifier as indicated in Table 56. The table is ordered. That is, the first line whose condition is true applies.

<table>
<thead>
<tr>
<th>State</th>
<th>stdio equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>basefield == oct</td>
<td>%o</td>
</tr>
<tr>
<td>basefield == hex</td>
<td>%X</td>
</tr>
<tr>
<td>basefield == 0</td>
<td>%d</td>
</tr>
<tr>
<td>signed integral type</td>
<td>%d</td>
</tr>
<tr>
<td>unsigned integral type</td>
<td>%u</td>
</tr>
</tbody>
</table>

For conversions to a floating type the specifier is %g.
For conversions to `void*` the specifier is `%p`.

A length modifier is added to the conversion specification, if needed, as indicated in Table 57.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length Modifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>short</td>
<td>h</td>
</tr>
<tr>
<td>unsigned short</td>
<td>h</td>
</tr>
<tr>
<td>long</td>
<td>l</td>
</tr>
<tr>
<td>unsigned long</td>
<td>l</td>
</tr>
<tr>
<td>double</td>
<td>l</td>
</tr>
<tr>
<td>long double</td>
<td>L</td>
</tr>
</tbody>
</table>

### Stage 2: If `in == end` then stage 2 terminates. Otherwise a `charT` is taken from `in` and local variables are initialized as if by

```c++
char_type ct = *in;
char c = src[find(atoms, atoms + sizeof(src) - 1, ct) - atoms];
if (ct == use_facet<numpunct<charT>>(loc).decimal_point())
    c = '.';
bool discard =
    (ct == use_facet<numpunct<charT>>(loc).thousands_sep() &&
     use_facet<numpunct<charT>>(loc).grouping().length() != 0);
```

where the values `src` and `atoms` are defined as if by:

```c++
static const char src[] = "0123456789abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ+-";
char_type atoms[sizeof(src)];
use_facet<ctype<charT>>(loc).widen(src, src + sizeof(src), atoms);
```

for this value of `loc`.

If `discard` is true, then if `.'` has not yet been accumulated, then the position of the character is remembered, but the character is otherwise ignored. Otherwise, if `.'` has already been accumulated, the character is discarded and Stage 2 terminates.

If the character is either discarded or accumulated then `in` is advanced by `++in` and processing returns to the beginning of stage 2.

### Stage 3: The result of stage 2 processing can be one of

- A sequence of `char`s has been accumulated in stage 2 that is converted (according to the rules of `scanf`) to a value of the type of `val`. This value is stored in `val` and `ios_base::goodbit` is stored in `err`.
- The sequence of `char`s accumulated in stage 2 would have caused `scanf` to report an input failure. `ios_base::failbit` is assigned to `err`.

Digit grouping is checked. That is, the positions of discarded separators is examined for consistency with `use_- facet<numpunct<charT>>(loc).grouping()`. If they are not consistent then `ios_base::failbit` is assigned to `err`.
In any case, if stage 2 processing was terminated by the test for `in == end` then `err |= ios_base::eofbit` is performed.

```cpp
type do_get(iter_type in, iter_type end, ios_base & str,
            ios_base :: iostate & err, bool & val) const;
```

**Effects:** If `(str.flags() & ios_base::boolalpha) == 0` then input proceeds as it would for a `long` except that if a value is being stored into `val`, the value is determined according to the following: If the value to be stored is 0 then `false` is stored. If the value is 1 then `true` is stored. Otherwise `err |= ios_base::failbit` is performed and no value is stored.

Otherwise target sequences are determined “as if” by calling the members `falseName()` and `trueName()` of the facet obtained by `use_facet<numpunct<charT>>(str.getloc())`. Successive characters in the range `[in, end)` (see 23.1.1) are obtained and matched against corresponding positions in the target sequences only as necessary to identify a unique match. The input iterator `in` is compared to `end` only when necessary to obtain a character. If and only if a target sequence is uniquely matched, `val` is set to the corresponding value.

The `in` iterator is always left pointing one position beyond the last character successfully matched. If `val` is set, then `err` is set to `str.goodbit`; or to `str.eofbit` if, when seeking another character to match, it is found that `(in == end)`. If `val` is not set, then `err` is set to `str.failbit` or to `(str.failbit | str.eofbit)` if the reason for the failure was that `(in == end)`. [Example: For targets `true`: "a" and false: "abb", the input sequence "a" yields `val == true` and `err == str.eofbit`; the input sequence "abc" yields `err == str.failbit`, with `in` ending at the 'c' element. For targets `true`: "1" and false: "0", the input sequence "1" yields `val == true` and `err == str.goodbit`. For empty targets (""), any input sequence yields `err == str.failbit`. — end example]

**Returns:** `in`.

### 22.2.2.2 Class template `num_put`

```cpp
namespace std {
    template <class charT, class OutputIterator = ostreambuf_iterator<charT> >
    class num_put : public locale::facet {
    public:
        typedef charT char_type;
        typedef OutputIterator iter_type;

        explicit num_put(size_t refs = 0);

        iter_type put(iter_type s, ios_base& f, char_type fill, bool v) const;
        iter_type put(iter_type s, ios_base& f, char_type fill, long v) const;
        iter_type put(iter_type s, ios_base& f, char_type fill,
                      unsigned long v) const;
        iter_type put(iter_type s, ios_base& f, char_type fill,
                      double v) const;
        iter_type put(iter_type s, ios_base& f, char_type fill,
                      long double v) const;
        iter_type put(iter_type s, ios_base& f, char_type fill,
                      const void* v) const;
    }
}
static locale::id id;

protected:

    "num_put();
    // virtual
    virtual iter_type do_put(iter_type, ios_base&, char_type fill, bool v) const;
    virtual iter_type do_put(iter_type, ios_base&, char_type fill, long v) const;
    virtual iter_type do_put(iter_type, ios_base&, char_type fill, unsigned long) const;
    virtual iter_type do_put(iter_type, ios_base&, char_type fill, double v) const;
    virtual iter_type do_put(iter_type, ios_base&, char_type fill, long double v) const;
    virtual iter_type do_put(iter_type, ios_base&, char_type fill, const void* v) const;
};

The facet num_put is used to format numeric values to a character sequence such as an ostream.

22.2.2.2.1 num_put members

iter_type put(iter_type out, ios_base& str, char_type fill, bool val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, unsigned long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, double val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, long double val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, const void* val) const;

Returns: do_put(out, str, fill, val).

22.2.2.2 num_put virtual functions

iter_type do_put(iter_type out, ios_base& str, char_type fill, long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, unsigned long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, double val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, long double val) const;

Draft
iter_type do_put(iter_type out, ios_base& str, char_type fill, 
const void* val) const;

Effects: Writes characters to the sequence out, formatting val as desired. In the following description, a local
variable initialized with

locale loc = str.getloc();

The details of this operation occur in several stages:

— Stage 1: Determine a printf conversion specifier spec and determining the characters that would be printed
by printf(27.8.2) given this conversion specifier for

printf(spec, val)

assuming that the current locale is the "C" locale.

— Stage 2: Adjust the representation by converting each char determined by stage 1 to a charT using a
conversion and values returned by members of use_facet< numpunct<charT> >(str.getloc())

— Stage 3: Determine where padding is required.

— Stage 4: Insert the sequence into the out.

Detailed descriptions of each stage follow.

Returns: out.

Stage 1: The first action of stage 1 is to determine a conversion specifier. The tables that describe this determi-
nation use the following local variables

fmtflags flags = str.flags();
fmtflags basefield = (flags & (ios_base::basefield));
fmtflags uppercase = (flags & (ios_base::uppercase));
fmtflags floatfield = (flags & (ios_base::floatfield));
fmtflags showpos = (flags & (ios_base::showpos));
fmtflags showbase = (flags & (ios_base::showbase));

All tables used in describing stage 1 are ordered. That is, the first line whose condition is true applies. A
line without a condition is the default behavior when none of the earlier lines apply.

For conversion from an integral type other than a character type, the function determines the integral con-
version specifier as indicated in Table 58.

For conversion from a floating-point type, the function determines the floating-point conversion specifier as
indicated in Table 59:

For conversions from an integral or floating type a length modifier is added to the conversion specifier as
indicated in Table 60

The conversion specifier has the following optional additional qualifiers prepended as indicated in Table 61

For conversion from a floating-point type, str.precision() is specified in the conversion specification.
Table 58: Integer Conversions

<table>
<thead>
<tr>
<th>State</th>
<th>stdio equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>basefield == ios_base::oct</td>
<td>%o</td>
</tr>
<tr>
<td>(basefield == ios_base::hex) &amp;&amp; !uppercase</td>
<td>%x</td>
</tr>
<tr>
<td>(basefield == ios_base::hex)</td>
<td>%X</td>
</tr>
<tr>
<td>for a signed integral type</td>
<td>%d</td>
</tr>
<tr>
<td>for an unsigned integral type</td>
<td>%u</td>
</tr>
</tbody>
</table>

Table 59: Floating-point Conversions

<table>

<td>none</td>
</tr>
</tbody>
</table>

Table 61: Numeric conversions

<table>
<thead>
<tr>
<th>Type(s)</th>
<th>State</th>
<th>stdio equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>an integral type</td>
<td>flags &amp; showpos</td>
<td>+</td>
</tr>
<tr>
<td></td>
<td>flags &amp; showbase</td>
<td>#</td>
</tr>
<tr>
<td>a floating-point type</td>
<td>flags &amp; showpos</td>
<td>+</td>
</tr>
<tr>
<td></td>
<td>flags &amp; showpoint</td>
<td>#</td>
</tr>
</tbody>
</table>
For conversion from void* the specifier is %p.

The representations at the end of stage 1 consists of the char’s that would be printed by a call of printf(s, val) where s is the conversion specifier determined above.

**Stage 2:** Any character c other than a decimal point(.) is converted to a charT via use_facet<ctype<charT>>(loc).widen( c )

A local variable punct is initialized via

\[ \text{numpunct<charT> punct} = \text{use_facet<numpunct<charT>}(str.getloc())} \]

For arithmetic types, punct.thousands_sep() characters are inserted into the sequence as determined by the value returned by punct.do_grouping() using the method described in 22.2.3.1.2

Decimal point characters(.) are replaced by punct.decimal_point()

**Stage 3:** A local variable is initialized as

\[ \text{fmtflags adjustfield} = (\text{flags} \& \text{ios_base::adjustfield}); \]

The location of any padding\(^{236}\) is determined according to Table 62

<table>
<thead>
<tr>
<th>State</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>adjustfield == ios_base::left</td>
<td>pad after</td>
</tr>
<tr>
<td>adjustfield == ios_base::right</td>
<td>pad before</td>
</tr>
<tr>
<td>adjustfield == internal and a sign occurs in the representation</td>
<td>pad after the sign</td>
</tr>
<tr>
<td>adjustfield == internal and representation after stage 1 began with 0x of 0X</td>
<td>pad after x or X</td>
</tr>
<tr>
<td>otherwise</td>
<td>pad before</td>
</tr>
</tbody>
</table>

If str.width() is nonzero and the number of charT’s in the sequence after stage 2 is less than str.width(), then enough fill characters are added to the sequence at the position indicated for padding to bring the length of the sequence to str.width().

str.width(0) is called.

**Stage 4:** The sequence of charT’s at the end of stage 3 are output via

\[ \ast out ++ = c \]

\[
\text{iter_type do_put(iter_type out, ios_base& str, char_type fill, bool val) const;}
\]

*Returns:* If str.flags() & ios_base::boolalpha == 0 returns do_put(out, str, fill, (int)val), otherwise obtains a string s as if by

\(^{236}\) The conversion specification #o generates a leading 0 which is not a padding character.
\begin{verbatim}
string_type s =
    val ? use_facet<ctype<charT>>(loc).truename() : use_facet<ctype<charT>>(loc).falsename();

and then inserts each character c of s into out via *out++ = c and returns out.
\end{verbatim}

22.2.3 The numeric punctuation facet

22.2.3.1 Class template numpunct

\begin{verbatim}
namespace std {
    template <class charT>
    class numpunct : public locale::facet {
public:
        typedef charT char_type;
        typedef basic_string<charT> string_type;

        explicit numpunct(size_t refs = 0);

        char_type decimal_point() const;
        char_type thousands_sep() const;
        string grouping() const;
        string_type truename() const;
        string_type falsename() const;

        static locale::id id;

    protected:
        "numpunct"();  // virtual
        virtual char_type do_decimal_point() const;
        virtual char_type do_thousands_sep() const;
        virtual string do_grouping() const;
        virtual string_type do_truename() const;  // for bool
        virtual string_type do_falsename() const;  // for bool
    }
}
\end{verbatim}

1 numpunct<> specifies numeric punctuation. The specializations required in Table 52 (22.1.1.1.1), namely numpunct<wchar_t> and numpunct<char>, provide classic "C" numeric formats, i.e. they contain information equivalent to that contained in the "C" locale or their wide character counterparts as if obtained by a call to widen.

2 The syntax for number formats is as follows, where digit represents the radix set specified by the fmtflags argument value, and thousands-sep and decimal-point are the results of corresponding numpunct<charT> members. Integer values have the format:

\begin{verbatim}
integer ::= [sign] units
sign ::= plusminus
plusminus ::= '+' | '-'
units ::= digits [thousands-sep units]
digits ::= digit [digits]
\end{verbatim}

Draft
and floating-point values have:

\[
\text{floatval ::= [sign] units [decimal-point [digits]] [e [sign] digits] | [sign] decimal-point digits [e [sign] digits]} \]
\[
e ::= 'e' | 'E'
\]

where the number of digits between thousands-seps is as specified by do_grouping(). For parsing, if the digits portion contains no thousands-separators, no grouping constraint is applied.

### 22.2.3.1.1 numpunct members

```cpp
char_type decimal_point() const;

char_type thousands_sep() const;

string grouping() const;

string_type truename() const;
string_type falsename() const;
```

1. **Returns:** do_decimal_point()
2. **Returns:** do_thousands_sep()
3. **Returns:** do_grouping()
4. **Returns:** do_truename() or do_falsename(), respectively.

### 22.2.3.1.2 numpunct virtual functions

```cpp
char_type do_decimal_point() const;

char_type do_thousands_sep() const;

string do_grouping() const;

string_type do_truename() const;
string_type do_falsename() const;
```

1. **Returns:** A character for use as the decimal radix separator. The required specializations return ‘.’ or L’.’.
2. **Returns:** A character for use as the digit group separator. The required specializations return ‘,’ or L’.’,’.
3. **Returns:** A basic_string<char> vec used as a vector of integer values, in which each element vec[i] represents the number of digits \(^{237}\) in the group at position i, starting with position 0 as the rightmost group. If vec.size() <= i, the number is the same as group \(i-1\); if \(i < 0\) || vec[i] <= 0 || vec[i]==CHAR_MAX), the size of the digit group is unlimited. The required specializations return the empty string, indicating no grouping.
4. **Returns:**

\(^{237}\) Thus, the string "\003" specifies groups of 3 digits each, and "3" probably indicates groups of 51 (!) digits each, because 51 is the ASCII value of "3".
5 Returns: A string representing the name of the boolean value true or false, respectively.
6 In the base class implementation these names are "true" and "false", or L"true" and L"false".

22.2.3.2 Class template numpunct_byname [lib.locale.numpunctbyname]

namespace std {
    template <class charT>
    class numpunct_byname : public numpunct<charT> {
        // this class is specialized for char and wchar_t.
        public:
            typedef charT char_type;
            typedef basic_string<charT> string_type;
            explicit numpunct_byname(const char*, size_t refs = 0);
        protected:
            "numpunct_byname(); // virtual
    };
}

22.2.4 The collate category [lib.category.collate]

22.2.4.1 Class template collate [lib.locale.collate]

namespace std {
    template <class charT>
    class collate : public locale::facet {
        typedef charT char_type;
        typedef basic_string<charT> string_type;

        explicit collate(size_t refs = 0);

        int compare(const charT* low1, const charT* high1,
                    const charT* low2, const charT* high2) const;
        string_type transform(const charT* low, const charT* high) const;
        long hash(const charT* low, const charT* high) const;

        static locale::id id;

    protected:
        "collate(); // virtual
        virtual int do_compare(const charT* low1, const charT* high1,
                                const charT* low2, const charT* high2) const;
        virtual string_type do_transform
                        (const charT* low, const charT* high) const;
        virtual long do_hash (const charT* low, const charT* high) const;
    };
}

Draft
The class `collate<charT>` provides features for use in the collation (comparison) and hashing of strings. A locale member function template, `operator()`, uses the collate facet to allow a locale to act directly as the predicate argument for standard algorithms (clause 25) and containers operating on strings. The specializations required in Table 52 (22.1.1.1.1), namely `collate<char>` and `collate<wchar_t>`, apply lexicographic ordering (25.3.8).

Each function compares a string of characters `*p` in the range `[low, high)`.

### 22.2.4.1.1 `collate` members

**`int compare(const charT* low1, const charT* high1, const charT* low2, const charT* high2) const;`**

Returns: `do_compare(low1, high1, low2, high2)`

**`string_type transform(const charT* low, const charT* high) const;`**

Returns: `do_transform(low, high)`

**`long hash(const charT* low, const charT* high) const;`**

Returns: `do_hash(low, high)`

### 22.2.4.1.2 `collate` virtual functions

**`int do_compare(const charT* low1, const charT* high1, const charT* low2, const charT* high2) const;`**

Returns: 1 if the first string is greater than the second, -1 if less, zero otherwise. The specializations required in Table 52 (22.1.1.1.1), namely `collate<char>` and `collate<wchar_t>`, implement a lexicographical comparison (25.3.8).

**`string_type do_transform(const charT* low, const charT* high) const;`**

Returns: A `basic_string<charT>` value that, compared lexicographically with the result of calling `transform()` on another string, yields the same result as calling `do_compare()` on the same two strings.\(^{238}\)

**`long do_hash(const charT* low, const charT* high) const;`**

Returns: An integer value equal to the result of calling `hash()` on any other string for which `do_compare()` returns 0 (equal) when passed the two strings. \(\text{[Note: The probability that the result equals that for another string which does not compare equal should be very small, approaching } (1.0/\text{numeric\_limits<unsigned long>::max}())\). \text{— end note}}\)

### 22.2.4.2 Class template `collate_byname`

```
namespace std {
    template <class charT>
    class collate_byname : public collate<charT> {
        public:

        // This function is useful when one string is being compared to many other strings.
    }
}
```

\(^{238}\) This function is useful when one string is being compared to many other strings.

```cpp
typedef basic_string<charT> string_type;
explicit collate_byname(const char*, size_t refs = 0);
protected:
    ~collate_byname();    // virtual
};
```

### 22.2.5 The time category

[lib.category.time]

Templates `time_get<charT, InputIterator>` and `time_put<charT, OutputIterator>` provide date and time formatting and parsing. All specifications of member functions for `time_put` and `time_get` in the subclauses of 22.2.5 only apply to the specializations required in Tables 52 and 53 (22.1.1.1.1). Their members use their `ios_base&`, `ios_base::iostate&`, and `fill` arguments as described in (22.2), and the `ctype<>` facet, to determine formatting details.

#### 22.2.5.1 Class template `time_get`

[lib.locale.time.get]

```cpp
namespace std {
    class time_base {
        public:
            enum dateorder { no_order, dmy, mdy, ymd, ydm };
        
        template < class charT , class InputIterator = istreambuf_iterator<charT> >
        class time_get : public locale::facet, public time_base {
            public:
                typedef charT char_type;
                typedef InputIterator iter_type;
                
                explicit time_get(size_t refs = 0);
                dateorder date_order() const { return do_date_order(); }
                iter_type get_time(iter_type s, iter_type end, ios_base & f,
                    ios_base::iostate & err, tm* t) const;
                iter_type get_date(iter_type s, iter_type end, ios_base & f,
                    ios_base::iostate & err, tm* t) const;
                iter_type get_weekday(iter_type s, iter_type end, ios_base & f,
                    ios_base::iostate & err, tm* t) const;
                iter_type get_monthname(iter_type s, iter_type end, ios_base & f,
                    ios_base::iostate & err, tm* t) const;
                iter_type get_year(iter_type s, iter_type end, ios_base & f,
                    ios_base::iostate & err, tm* t) const;
            
                static locale::id id;
            
            protected:
                ~time_get();    // virtual
                virtual dateorder do_date_order() const;
                virtual iter_type do_get_time(iter_type s, iter_type end, ios_base &,
                    ios_base::iostate & err, tm* t) const;
                virtual iter_type do_get_date(iter_type s, iter_type end, ios_base &,
                    ios_base::iostate & err, tm* t) const;
        }
    }
}
```
22.2.5.1.1 time_get members

```cpp
virtual iter_type do_get_weekday(iter_type s, iter_type end, ios_base&, ios_base::iostate& err, tm* t) const;
virtual iter_type do_get_monthname(iter_type s, iter_type end, ios_base&, ios_base::iostate& err, tm* t) const;
virtual iter_type do_get_year(iter_type s, iter_type end, ios_base&, ios_base::iostate& err, tm* t) const;
```

22.2.5.1.2 time_get virtual functions

```cpp
virtual dateorder do_date_order() const;
```

---

239) In other words, user confirmation is required for reliable parsing of user-entered dates and times, but machine-generated formats can be parsed reliably. This allows parsers to be aggressive about interpreting user variations on standard formats.
22.2 Standard locale categories

Returns: An enumeration value indicating the preferred order of components for those date formats that are composed of day, month, and year. Returns no_order if the date format specified by 'x' contains other variable components (e.g. Julian day, week number, week day).

```cpp
iter_type do_get_time(iter_type s, iter_type end, ios_base & str,
                      ios_base::iostate & err, tm * t) const;
```

Effects: Reads characters starting at s until it has extracted those struct tm members, and remaining format characters, used by time_put<>::put to produce the format specified by 'X', or until it encounters an error or end of sequence.

Returns: An iterator pointing immediately beyond the last character recognized as possibly part of a valid time.

```cpp
iter_type do_get_date(iter_type s, iter_type end, ios_base & str,
                      ios_base::iostate & err, tm * t) const;
```

Effects: Reads characters starting at s until it has extracted those struct tm members, and remaining format characters, used by time_put<>::put to produce the format specified by 'x', or until it encounters an error.

Returns: An iterator pointing immediately beyond the last character recognized as possibly part of a valid date.

```cpp
iter_type do_get_weekday(iter_type s, iter_type end, ios_base & str,
                         ios_base::iostate & err, tm * t) const;
iter_type do_get_monthname(iter_type s, iter_type end, ios_base & str,
                           ios_base::iostate & err, tm * t) const;
```

Effects: Reads characters starting at s until it has extracted the (perhaps abbreviated) name of a weekday or month. If it finds an abbreviation that is followed by characters that could match a full name, it continues reading until it matches the full name or fails. It sets the appropriate struct tm member accordingly.

Returns: An iterator pointing immediately beyond the last character recognized as part of a valid name.

```cpp
iter_type do_get_year(iter_type s, iter_type end, ios_base & str,
                      ios_base::iostate & err, tm * t) const;
```

Effects: Reads characters starting at s until it has extracted an unambiguous year identifier. It is implementation-defined whether two-digit year numbers are accepted, and (if so) what century they are assumed to lie in. Sets the t->tm_year member accordingly.

Returns: An iterator pointing immediately beyond the last character recognized as part of a valid year identifier.

---

22.2.5.2 Class template time_get_byname

```cpp
namespace std {
    template <class charT, class InputIterator = istreambuf_iterator<charT> >
    class time_get_byname : public time_get<charT, InputIterator> { 
        public:
            typedef time_base::dateorder dateorder;
            typedef InputIterator iter_type;
```
explicit time_get_byname(const char*, size_t refs = 0);
protected:
  ~time_get_byname();  // virtual
};

22.2.5.3 Class template time_put

namespace std {
  template <class charT, class OutputIterator = ostreambuf_iterator<charT>>
  class time_put : public locale::facet {
  public:
    typedef charT char_type;
    typedef OutputIterator iter_type;
    explicit time_put(size_t refs = 0);

    // the following is implemented in terms of other member functions.
    iter_type put(iter_type s, ios_base& f, char_type fill, const tm* tmb,
                  const charT* pattern, const charT* pat_end) const;
    iter_type put(iter_type s, ios_base& f, char_type fill,
                  const tm* tmb, char format, char modifier = 0) const;

    static locale::id id;

  protected:
    ~time_put();  // virtual
    virtual iter_type do_put(iter_type s, ios_base& str, char_type, const tm* t,
                             char format, char modifier) const;
  }
};

22.2.5.3.1 time_put members

iter_type put(iter_type s, ios_base& str, char_type fill, const tm* t,
             const charT* pattern, const charT* pat_end) const;
iter_type put(iter_type s, ios_base& str, char_type fill, const tm* t,
             char format, char modifier = 0) const;

Effects: The first form steps through the sequence from pattern to pat_end, identifying characters that are part of a format sequence. Each character that is not part of a format sequence is written to s immediately, and each format sequence, as it is identified, results in a call to do_put; thus, format elements and other characters are interleaved in the output in the order in which they appear in the pattern. Format sequences are identified by converting each character c to a char value as if by ct.narrow(c,0), where ct is a reference to ctype<charT> obtained from str.getloc(). The first character of each sequence is equal to '%', followed by an optional modifier character mod and a format specifier character spec as defined for the function strftime. If no modifier character is present, mod is zero. For each valid format sequence identified, calls do_put(s, str, fill, t, spec, mod).

241) Although the C programming language defines no modifiers, most vendors do.

Draft
The second form calls \texttt{do\_put(s, str, fill, t, format, modifier)}.

\textit{Note:} The \texttt{fill} argument may be used in the implementation-defined formats, or by derivations. A space character is a reasonable default for this argument. — end note

\textit{Returns:} An iterator pointing immediately after the last character produced.

\textbf{22.2.5.3.2 \texttt{time\_put} virtual functions} [lib.locale.time.put.virtuals]

\begin{verbatim}
iter_type do_put(iter_type s, ios_base & , char_type fill, const tm* t,
               char format, char modifier) const;
\end{verbatim}

\textit{Effects:} Formats the contents of the parameter \texttt{t} into characters placed on the output sequence \texttt{s}. Formatting is controlled by the parameters \texttt{format} and \texttt{modifier}, interpreted identically as the format specifiers in the string argument to the standard library function \texttt{strftime()}\footnote{Interpretation of the \texttt{modifier} argument is implementation-defined, but should follow POSIX conventions.} except that the sequence of characters produced for those specifiers that are described as depending on the C locale are instead implementation-defined.\footnote{Implementations are encouraged to refer to other standards (such as POSIX) for these definitions.}

\textit{Returns:} An iterator pointing immediately after the last character produced. \textit{Note:} The \texttt{fill} argument may be used in the implementation-defined formats, or by derivations. A space character is a reasonable default for this argument. — end note

\textbf{22.2.5.4 Class template \texttt{time\_put\_byname}} [lib.locale.time.putbyname]

\begin{verbatim}
namespace std {
  template < class charT, class OutputIterator = ostreambuf_iterator<charT> >
  class time_put_byname : public time_put<charT, OutputIterator>
  {
    public:
      typedef charT char_type;
      typedef OutputIterator iter_type;

      explicit time_put_byname(const char*, size_t refs = 0);
      protected:
        ~time_put_byname(); // virtual
    
  }
}
\end{verbatim}

\textbf{22.2.6 The monetary category} [lib.category.monetary]

These templates handle monetary formats. A template parameter indicates whether local or international monetary formats are to be used.

All specifications of member functions for \texttt{money\_put} and \texttt{money\_get} in the subclauses of 22.2.6 only apply to the specializations required in Tables 52 and 53 (22.1.1.1). Their members use their \texttt{ios\_base}, \texttt{ios\_base::iostate}, and \texttt{fill} arguments as described in (22.2), and the \texttt{moneypunct<>} and \texttt{ctype<>} facets, to determine formatting details.

\textbf{22.2.6.1 Class template \texttt{money\_get}} [lib.locale.money.get]
namespace std {
    template <class charT, 
             class InputIterator = istreambuf_iterator<charT> >
    class money_get : public locale::facet {
public:
    typedef charT char_type;
    typedef InputIterator iter_type;
    typedef basic_string<charT> string_type;
    
    explicit money_get(size_t refs = 0);

    iter_type get(iter_type s, iter_type end, bool intl,
            ios_base& f, ios_base::iostate& err,
            long double& units) const;
    iter_type get(iter_type s, iter_type end, bool intl,
            ios_base& f, ios_base::iostate& err,
            string_type& digits) const;

    static locale::id id;
    
    protected:
    ~money_get(); // virtual

    virtual iter_type do_get(iter_type, iter_type, bool, ios_base&,
            ios_base::iostate& err, long double& units) const;
    virtual iter_type do_get(iter_type, iter_type, bool, ios_base&,
            ios_base::iostate& err, string_type& digits) const;
    
};

22.2.6.1.1 money_get members

    iter_type get(iter_type s, iter_type end, bool intl,
            ios_base& f, ios_base::iostate& err,
            long double& units) const;
    iter_type get(s, iter_type end, bool intl, ios_base&f,
            ios_base::iostate& err, string_type& digits) const;

    Returns: do_get(s, end, intl, f, err, quant)

22.2.6.1.2 money_get virtual functions

    iter_type do_get(iter_type s, iter_type end, bool intl,
            ios_base& str, ios_base::iostate& err,
            long double& units) const;
    iter_type do_get(iter_type s, iter_type end, bool intl,
            ios_base& str, ios_base::iostate& err,
            string_type& digits) const;
Effects: Reads characters from \texttt{s} to parse and construct a monetary value according to the format specified by a \texttt{moneypunct<
charT, Intl>} facet reference \texttt{mp} and the character mapping specified by a \texttt{ctype<charT>} facet reference \texttt{ct} obtained from the locale returned by \texttt{str.getloc()}, and \texttt{str.flags()}. If a valid sequence is recognized, does not change \texttt{err}; otherwise, sets \texttt{err} to \texttt{(err | str.failbit)} or \texttt{(err | str.failbit | str.eofbit)} if no more characters are available, and does not change \texttt{units} or \texttt{digits}. Uses the pattern returned by \texttt{mp.neg_format()} to parse all values. The result is returned as an integral value stored in \texttt{units} or as a sequence of digits possibly preceded by a minus sign (as produced by \texttt{ct.widen(c)} where \texttt{c} is \texttt{'-'} or in the range from \texttt{'0'} through \texttt{'9'}, inclusive) stored in \texttt{digits}. [Example: The sequence \$1,056.23 in a common United States locale would yield, for \texttt{units}, 105623, or, for \texttt{digits}, "105623". — end example] If \texttt{mp.grouping()} indicates that no thousands separators are permitted, any such characters are not read, and parsing is terminated at the point where they first appear. Otherwise, thousands separators are optional; if present, they are checked for correct placement only after all format components have been read.

Where space or \texttt{none} appears in the format pattern, except at the end, optional white space (as recognized by \texttt{ct.in}) is consumed after any required space. If \texttt{(str.flags() & str.showbase)} is false, the currency symbol is optional and is consumed only if other characters are needed to complete the format; otherwise, the currency symbol is required.

If the first character (if any) in the string \texttt{pos} returned by \texttt{mp.positive_sign()} or the string \texttt{neg} returned by \texttt{mp.negative_sign()} is recognized in the position indicated by \texttt{sign} in the format pattern, it is consumed and any remaining characters in the string are required after all the other format components. [Example: If \texttt{showbase} is off, then for a \texttt{neg} value of \texttt{"()"} and a currency symbol of \texttt{"L"}, in \texttt{"(100 L)"} the \texttt{"L"} is consumed; but if \texttt{neg} is \texttt{"-"}, the \texttt{"L"} in \texttt{"-100 L"} is not consumed. — end example] If \texttt{pos} or \texttt{neg} is empty, the sign component is optional, and if no sign is detected, the result is given the sign that corresponds to the source of the empty string. Otherwise, the character in the indicated position must match the first character of \texttt{pos} or \texttt{neg}, and the result is given the corresponding sign. If the first character of \texttt{pos} or \texttt{neg} is equal to the first character of \texttt{neg}, or if both strings are empty, the result is given a positive sign.

Digits in the numeric monetary component are extracted and placed in \texttt{digits}, or into a character buffer \texttt{buf1} for conversion to produce a value for \texttt{units}, in the order in which they appear, preceded by a minus sign if and only if the result is negative. The value \texttt{units} is produced as if by

\begin{verbatim}
   for (int i = 0; i < n; ++i)
       buf2[i] = src[find(atoms, atoms+sizeof(src), buf1[i]) - atoms];
   buf2[n] = 0;
   sscanf(buf2, "%Lf", &units);
\end{verbatim}

where \texttt{n} is the number of characters placed in \texttt{buf1}, \texttt{buf2} is a character buffer, and the values \texttt{src} and \texttt{atoms} are defined as if by

\begin{verbatim}
   static const char src[] = "0123456789-";
   charT atoms[sizeof(src)];
   ct.widen(src, src + sizeof(src) - 1, atoms);
\end{verbatim}

Returns: An iterator pointing immediately beyond the last character recognized as part of a valid monetary quantity.

\footnote{The semantics here are different from \texttt{ct.narrow}.}
22.2.6.2 Class template money_put

```cpp
namespace std {
    template <class charT,
              class OutputIterator = ostreambuf_iterator<charT>>
    class money_put : public locale::facet {
public:
    typedef charT char_type;
    typedef OutputIterator iter_type;
    typedef basic_string<charT> string_type;

    explicit money_put(size_t refs = 0);

    iter_type put(iter_type s, bool intl, ios_base & f,
                  char_type fill, long double units) const;
    iter_type put(iter_type s, bool intl, ios_base & f,
                  char_type fill, const string_type & digits) const;

    static locale::id id;

protected:
    ~money_put(); // virtual
    virtual iter_type do_put(iter_type s, bool intl, ios_base & f,
                              char_type fill, long double units) const;
    virtual iter_type do_put(iter_type s, bool intl, ios_base & f,
                              char_type fill, const string_type & digits) const;
};
```

22.2.6.2.1 money_put members

```cpp
iter_type put(iter_type s, bool intl, ios_base & f,
              char_type fill, long double units) const;
iter_type put(iter_type s, bool intl, ios_base & f,
              char_type fill, const string_type & digits) const;
```

Returns: `do_put(s, intl, f, loc, quant)`

22.2.6.2.2 money_put virtual functions

```cpp
iter_type do_put(iter_type s, bool intl, ios_base & str,
                 char_type fill, long double units) const;
iter_type do_put(iter_type s, bool intl, ios_base & str,
                 char_type fill, const string_type & digits) const;
```

Effects: Writes characters to `s` according to the format specified by a moneypunct<charT, Intl> facet reference `mp` and the character mapping specified by a ctype<charT> facet reference `ct` obtained from the locale returned

Draft
by `str.getloc()`, and `str.flags()`. The argument `units` is transformed into a sequence of wide characters as if by

```cpp
ct.widen(buf1, buf1 + sprintf(buf1, "%.0Lf", units), buf2)
```
for character buffers `buf1` and `buf2`. If the first character in `digits` or `buf2` is equal to `ct.widen('-')`, then the pattern used for formatting is the result of `mp.neg_format()`; otherwise the pattern is the result of `mp.pos_format()`. Digit characters are written, interspersed with any thousands separators and decimal point specified by the format, in the order they appear (after the optional leading minus sign) in `digits` or `buf2`. In `digits`, only the optional leading minus sign and the immediately subsequent digit characters (as classified according to `ct`) are used; any trailing characters (including digits appearing after a non-digit character) are ignored. Calls `str.width(0)`.

Remarks: The currency symbol is generated if and only if `(str.flags() & str.showbase)` is nonzero. If the number of characters generated for the specified format is less than the value returned by `str.width()` on entry to the function, then copies of `fill` are inserted as necessary to pad to the specified width. For the value `af` equal to `(str.flags() & str.adjustfield), if (af == str.internal) is true, the fill characters are placed where none or space appears in the formatting pattern; otherwise if (af == str.left) is true, they are placed after the other characters; otherwise, they are placed before the other characters. [Note: It is possible, with some combinations of format patterns and flag values, to produce output that cannot be parsed using `num_get<>::get`. — end note]

Returns: An iterator pointing immediately after the last character produced.

### 22.2.6.3 Class template moneypunct

```cpp
class money_base {
public:
  enum part { none, space, symbol, sign, value };
  struct pattern { char field[4]; };
};

template <class charT, bool International = false>
class moneypunct : public locale::facet, public money_base {
public:
  typedef charT char_type;
  typedef basic_string<charT> string_type;
  explicit moneypunct(size_t refs = 0);

  charT decimal_point() const;
  charT thousands_sep() const;
  string grouping() const;
  string_type curr_symbol() const;
  string_type positive_sign() const;
  string_type negative_sign() const;
  int frac_digits() const;
  pattern pos_format() const;
};
```
The `moneypunct<>` facet defines monetary formatting parameters used by `money_get<>` and `money_put<>`. A monetary format is a sequence of four components, specified by a pattern value `p`, such that the part value `static_cast<part>(p.field[i])` determines the `i`th component of the format. In the `field` member of a `pattern` object, each value `symbol`, `sign`, `value`, and either `space` or `none` appears exactly once. The value `none`, if present, is not first; the value `space`, if present, is neither first nor last.

Where `none` or `space` appears, white space is permitted in the format, except where `none` appears at the end, in which case no white space is permitted. The value `space` indicates that at least one space is required at that position. Where `symbol` appears, the sequence of characters returned by `curr_symbol()` is permitted, and can be required. Where `sign` appears, the first (if any) of the sequence of characters returned by `positive_sign()` or `negative_sign()` (respectively as the monetary value is non-negative or negative) is required. Any remaining characters of the sign sequence are required after all other format components. Where `value` appears, the absolute numeric monetary value is required.

The format of the numeric monetary value is a decimal number:

```
value ::= units [ decimal-point [ digits ]]
          decimal-point digits
```

if `frac_digits()` returns a positive value, or

```
value ::= units
```

otherwise. The symbol `decimal-point` indicates the character returned by `decimal_point()`. The other symbols are defined as follows:

```
units ::= digits [ thousands-sep units ]
digits ::= adigit [ digits ]
```

An array of `char`, rather than an array of `part`, is specified for `pattern::field` purely for efficiency.
22.2 Standard locale categories

Localization library 522

In the syntax specification, the symbol `digit` is any of the values `ct.widen(c)` for `c` in the range `'0'` through `'9'`, inclusive, and `ct` is a reference of type `const ctype<charT>&` obtained as described in the definitions of `money_get<>` and `money_put<>`. The symbol `thousands-sep` is the character returned by `thousands_sep()`. The space character used is the value `ct.widen(' ')`. White space characters are those characters `c` for which `ci.is(space,c)` returns true. The number of digits required after the decimal point (if any) is exactly the value returned by `frac_digits()`. The placement of thousands-separator characters (if any) is determined by the value returned by `grouping()`, defined identically as the member `numpunct<>::do_grouping()`.

22.2.6.3.1 moneypunct members

```
charT decimal_point() const;
charT thousands_sep() const;
string grouping() const;
string_type curr_symbol() const;
string_type positive_sign() const;
string_type negative_sign() const;
int frac_digits() const;
pattern pos_format() const;
pattern neg_format() const;
```

Each of these functions `F` returns the result of calling the corresponding virtual member function `do_F()`.

22.2.6.3.2 moneypunct virtual functions

```
charT do_decimal_point() const;

Returns: The radix separator to use in case `do_frac_digits()` is greater than zero.\(^{246}\)

charT do_thousands_sep() const;

Returns: The digit group separator to use in case `do_grouping()` specifies a digit grouping pattern.\(^{247}\)

string do_grouping() const;

Returns: A pattern defined identically as, but not necessarily equal to, the result of `numpunct<>::do_-

string_type do_curr_symbol() const;

Returns: A string to use as the currency identifier symbol.\(^{249}\)

string_type do_positive_sign() const;
string_type do_negative_sign() const;

Returns: `do_positive_sign()` returns the string to use to indicate a positive monetary value;\(^{250}\) `do_negative_sign()` returns the string to use to indicate a negative value.
```

\(^{246}\) In common U.S. locales this is `.'.
\(^{247}\) In common U.S. locales this is `,',
\(^{248}\) To specify grouping by 3s, the value is `"\003 not *3")).
\(^{249}\) For international specializations (second template parameter `true`) this is always four characters long, usually three letters and a space.
\(^{250}\) This is usually the empty string.
int do_frac_digits() const;

6  Returns: The number of digits after the decimal radix separator, if any.\textsuperscript{251}

pattern do_pos_format() const;
pattern do_neg_format() const;

7  Returns: The specializations required in Table 53 (22.1.1.1.1), namely moneypunct<char>, moneypunct<wchar_t>, moneypunct<char,true>, and moneypunct<wchar_t,true>, return an object of type pattern initialized to \{ symbol, sign, none, value \}.\textsuperscript{252}

\section*{22.2.6.4 Class template moneypunct\_byname}

\begin{verbatim}
namespace std {
    template <class charT, bool Intl = false>
    class moneypunct\_byname : public moneypunct<charT, Intl> {
    public:
        typedef money_base::pattern pattern;
        typedef basic_string<charT> string_type;

        explicit moneypunct\_byname(const char*, size_t refs = 0);
    protected:
        "moneypunct\_byname"();    // virtual
    }
}
\end{verbatim}

\section*{22.2.7 The message retrieval category}

Class messages<charT> implements retrieval of strings from message catalogs.

\subsection*{22.2.7.1 Class template messages}

\begin{verbatim}
namespace std {
    class messages_base {
    public:
        typedef int catalog;
    };

    template <class charT>
    class messages : public locale::facet, public messages_base {
    public:
        typedef charT char_type;
        typedef basic_string<charT> string_type;

        explicit messages(size_t refs = 0);

        catalog open(const basic_string<char>& fn, const locale&) const;
        string_type get(catalog c, int set, int msgid, ...
\end{verbatim}

\textsuperscript{251} In common U.S. locales, this is 2.
\textsuperscript{252} Note that the international symbol returned by \texttt{do\_curr\_sym()} usually contains a space, itself; for example, "USD ".

Draft
22.2 Standard locale categories

Localization library

\begin{verbatim}
const string_type & dfault) const;
void close(catalog c) const;

static locale::id id;

protected:
    // virtual
    virtual catalog do_open(const basic_string<char>&, const locale&) const;
    virtual string_type do_get(catalog, int set, intmsgid,
                                const string_type& dfault) const;
    virtual void do_close(catalog) const;
};
\end{verbatim}

1 Values of type messages_base::catalog usable as arguments to members get and close can be obtained only by calling member open.

\subsection*{22.2.7.1.1 messages members \hfill [lib.locale.messages.members]}

\begin{verbatim}
catalog open(const basic_string<char>& name, const locale& loc) const;
\end{verbatim}

1 \textit{Returns:} do_open\((\text{name, loc})\).

\begin{verbatim}
string_type get(catalog cat, int set, intmsgid,
                const string_type& dfault) const;
\end{verbatim}

2 \textit{Returns:} do_get\((\text{cat, set,msgid, dfault})\).

\begin{verbatim}
void close(catalog cat) const;
\end{verbatim}

3 \textit{Effects:} Calls do_close\((\text{cat})\).

\subsection*{22.2.7.1.2 messages virtual functions \hfill [lib.locale.messages.virtuals]}

\begin{verbatim}
catalog do_open(const basic_string<char>& name, const locale& loc) const;
\end{verbatim}

1 \textit{Returns:} A value that may be passed to get\((\cdot)\) to retrieve a message, from the message catalog identified by the string name according to an implementation-defined mapping. The result can be used until it is passed to close\((\cdot)\).

2 Returns a value less than 0 if no such catalog can be opened.

3 \textit{Remarks:} The locale argument loc is used for character set code conversion when retrieving messages, if needed.

\begin{verbatim}
string_type do_get(catalog cat, int set, intmsgid,
                   const string_type& dfault) const;
\end{verbatim}

4 \textit{Requires:} A catalog cat obtained from open\((\cdot)\) and not yet closed.

5 \textit{Returns:} A message identified by arguments set,msgid, and dfault, according to an implementation-defined mapping. If no such message can be found, returns dfault.

Draft
void do_close(catalog cat) const;

Requires: A catalog *cat* obtained from open() and not yet closed.

Effects: Releases unspecified resources associated with *cat*.

Remarks: The limit on such resources, if any, is implementation-defined.

22.2.7.2 Class template messages_byname

namespace std {
    template <class charT>
    class messages_byname : public messages<charT> {
    public:
        typedef messages_base::catalog catalog;
        typedef basic_string<charT> string_type;

        explicit messages_byname(const char*, size_t refs = 0);
    protected:
        messages_byname(); // virtual
    }
} [lib.locale.messagesbyname]

22.2.8 Program-defined facets

A C++ program may define facets to be added to a locale and used identically as the built-in facets. To create a new facet interface, C++ programs simply derive from `locale::facet` a class containing a static member: `static locale::id id`.

[Note: The locale member function templates verify its type and storage class. — end note]

[Note: This paragraph is intentionally empty. — end note]

[Example: Traditional global localization is still easy:

```cpp
#include <iostream>
#include <locale>
int main(int argc, char** argv) {
    using namespace std;
    locale::global(locale("")); // set the global locale
    // imbue it on all the std streams
    cin.imbue(locale());
    cout.imbue(locale());
    cerr.imbue(locale());
    wcin.imbue(locale());
    wcout.imbue(locale());
    wcerr.imbue(locale());

    return MyObject(argc, argv).doit();
}
```]

Draft
22.2 Standard locale categories

Example: Greater flexibility is possible:

```cpp
#include <iostream>
#include <locale>

int main()
{
    using namespace std;
    cin.imbue(locale(""));    // the user’s preferred locale
    cout.imbue(locale::classic());
    double f;
    while (cin >> f) cout << f << endl;
    return (cin.fail() != 0);
}
```

In a European locale, with input 3.456,78, output is 3456.78. — end example ]

This can be important even for simple programs, which may need to write a data file in a fixed format, regardless of a user’s preference.

Example: Here is an example of the use of locales in a library interface.

```cpp
// file: Date.h
#include <iosfwd>
#include <string>
#include <locale>
...

class Date {
    ...
    public:
        Date(unsigned day, unsigned month, unsigned year);
        std::string asString(const std::locale& = std::locale());
    };
    istream& operator>>(istream& s, Date& d);
    ostream& operator<<(ostream& s, Date d);
...}
```

This example illustrates two architectural uses of class locale.

The first is as a default argument in Date::asString(), where the default is the global (presumably user-preferred) locale.

The second is in the operators << and >>, where a locale “hitchhikes” on another object, in this case a stream, to the point where it is needed.
A locale object may be extended with a new facet simply by constructing it with an instance of a class derived from `locale::facet`. The only member a C++ program must define is the static member `id`, which identifies your class interface as a new facet.

Example: Classifying Japanese characters:

```cpp
#include <locale>
namespace My {
    using namespace std;
    class JCtype : public locale::facet {
    public:
        static locale::id id; // required for use as a new locale facet
        bool is_kanji(wchar_t c) const;
        JCtype() {}
    protected:
        ~JCtype() {}
    }
}
```

```cpp
#include <iostream>
#include <locale>
#include "jctype" // above
std::locale::id My::JCtype::id; // the static JCtype member declared above.
```

```cpp
int main()
{
    using namespace std;
    typedef ctype<wchar_t> wctype;
    locale loc(locale(""), // the user's preferred locale ...
    Draft
```
new My::JCtype);    // and a new feature ...
wchar_t c = use_facet<wctype>(loc).widen('!');
if (!use_facet<My::JCtype>(loc).is_kanji(c))
    cout << "no it isn't!" << endl;
return 0;
}

The new facet is used exactly like the built-in facets. — end example ]

[ Example: Replacing an existing facet is even easier. Here we do not define a member id because we are reusing the numpunct<charT> facet interface:

// file: my_bool.C
#include <iostream>
#include <locale>
#include <string>
namespace My{
    using namespace std;
typedef numpunct_byname<char> cnumpunct;
class BoolNames : public cnumpunct {
    protected:
        string do_truename() const { return "Oui Oui!"; }
        string do_falsename() const { return "Mais Non!"; }
    BoolNames() {}}
    public:
        BoolNames(const char* name) : cnumpunct(name) {}}
}

int main(int argc, char** argv)
{
    using namespace std;
    // make the user's preferred locale, except for...
    locale loc(locale(""), new My::BoolNames(""));
    cout.imbue(loc);
    cout << boolalpha << "Any arguments today? " << (argc > 1) << endl;
    return 0;
}

— end example ]

22.3  C Library Locales

Header <locale> (Table 63):

The contents are the same as the Standard C library header <locale.h>.

23.1 Container requirements  [lib.container.requirements]

1  Containers are objects that store other objects. They control allocation and deallocation of these objects through constructors, destructors, insert and erase operations.
2  All of the complexity requirements in this clause are stated solely in terms of the number of operations on the contained objects. [Example: the copy constructor of type vector <vector<int> > has linear complexity, even though the complexity of copying each contained vector<int> is itself linear. —end example]
3  The type of objects stored in these components shall meet the requirements of CopyConstructible types (20.1.3).
4  Table 65 defines the Assignable requirement. Some containers require this property of the types to be stored in the container. T is the type used to instantiate the container, t is a value of T, and u is a value of (possibly const) T.

<table>
<thead>
<tr>
<th>expression</th>
<th>return type</th>
<th>post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>t == u</td>
<td>T&amp;</td>
<td>t is equivalent to u</td>
</tr>
</tbody>
</table>
In Tables 66 and 67, \( X \) denotes a container class containing objects of type \( T \), \( a \) and \( b \) denote values of type \( X \), \( u \) denotes an identifier and \( r \) denotes a value of \( X\& \).

<td></td>
<td>linear</td>
</tr>
<tr>
<td><code>a &gt;= b</code></td>
<td>convertible to bool</td>
<td><code>!(a &lt; b)</code></td>
<td></td>
<td>linear</td>
</tr>
</tbody>
</table>

Notes: the algorithms `swap()`, `equal()` and `lexicographical_compare()` are defined in clause 25. Those entries marked “(Note A)” should have constant complexity.

6 The member function `size()` returns the number of elements in the container. Its semantics is defined by the rules of constructors, inserts, and erases.

7 `begin()` returns an iterator referring to the first element in the container. `end()` returns an iterator which is the past-the-end value for the container. If the container is empty, then `begin() == end();`

8 In the expressions

   ```
   c == j
   c != j
   c < j
   c <= j
   c >= j
   c > j
   ```

Draft
i - j

where \( i \) and \( j \) denote objects of a container’s iterator type, either or both may be replaced by an object of the container’s const_iterator type referring to the same element with no change in semantics.

9 Copy constructors for all container types defined in this clause copy an allocator argument from their respective first parameters. All other constructors for these container types take an Allocator& argument (20.1.6), an allocator whose value type is the same as the container’s value type. A copy of this argument is used for any memory allocation performed, by these constructors and by all member functions, during the lifetime of each container object. In all container types defined in this clause, the member get_allocator() returns a copy of the Allocator object used to construct the container.253)

10 If the iterator type of a container belongs to the bidirectional or random access iterator categories (24.1), the container is called reversible and satisfies the additional requirements in Table 67.

Table 67: Reversible container requirements

<td>reverse_iterator(begin())</td>
<td>constant</td>
</tr>
</tbody>
</table>

11 Unless otherwise specified (see 23.2.1.3 and 23.2.4.3) all container types defined in this clause meet the following additional requirements:

— if an exception is thrown by an insert() function while inserting a single element, that function has no effects.

— if an exception is thrown by a push_back() or push_front() function, that function has no effects.

— no erase(), pop_back() or pop_front() function throws an exception.

— no copy constructor or assignment operator of a returned iterator throws an exception.

— no swap() function throws an exception unless that exception is thrown by the copy constructor or assignment operator of the container’s Compare object (if any; see 23.1.2).

— no swap() function invalidates any references, pointers, or iterators referring to the elements of the containers being swapped.

253) As specified in 20.1.6, paragraphs 4-5, the semantics described in this clause applies only to the case where allocators compare equal.
Unless otherwise specified (either explicitly or by defining a function in terms of other functions), invoking a container member function or passing a container as an argument to a library function shall not invalidate iterators to, or change the values of, objects within that container.

23.1.1 Sequences

A sequence is a kind of container that organizes a finite set of objects, all of the same type, into a strictly linear arrangement. The library provides three basic kinds of sequence containers: `vector`, `list`, and `deque`. It also provides container adaptors that make it easy to construct abstract data types, such as stacks or queues, out of the basic sequence kinds (or out of other kinds of sequences that the user might define).

`vector`, `list`, and `deque` offer the programmer different complexity trade-offs and should be used accordingly. `vector` is the type of sequence that should be used by default. `list` should be used when there are frequent insertions and deletions from the middle of the sequence. `deque` is the data structure of choice when most insertions and deletions take place at the beginning or at the end of the sequence.

In Tables 68 and 69, `X` denotes a sequence class, `a` denotes a value of `X`, `i` and `j` denote iterators satisfying input iterator requirements, `[i, j)` denotes a valid range, `n` denotes a value of `X::size_type`, `p` denotes a valid iterator to `a`, `q` denotes a valid dereferenceable iterator to `a`, `[q1, q2)` denotes a valid range in `a`, and `t` denotes a value of `X::value_type`.

The complexities of the expressions are sequence dependent.

<table>
<thead>
<tr>
<th>expression</th>
<th>return type</th>
<th>assertion/note</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>X(n, t)</code></td>
<td>iterator</td>
<td>pre: size() == n</td>
</tr>
<tr>
<td><code>X(a(n, t))</code></td>
<td>iterator</td>
<td>post: size() == n copies of t</td>
</tr>
<tr>
<td><code>X(i, j)</code></td>
<td>iterator</td>
<td>post: size() == distance between i and j</td>
</tr>
<tr>
<td><code>X(a(i, j))</code></td>
<td>iterator</td>
<td>constructs a sequence equal to the range [i, j]</td>
</tr>
<tr>
<td><code>a.insert(p,t)</code></td>
<td>iterator</td>
<td>inserts copy of t before p</td>
</tr>
<tr>
<td><code>a.insert(p,n,t)</code></td>
<td>void</td>
<td>inserts n copies of t before p</td>
</tr>
<tr>
<td><code>a.insert(p,i,j)</code></td>
<td>void</td>
<td>pre: i and j are not iterators into a. inserts copies of elements in [i, j] before p</td>
</tr>
<tr>
<td><code>a.erase(q)</code></td>
<td>iterator</td>
<td>erases the element pointed to by q</td>
</tr>
<tr>
<td><code>a.erase(q1,q2)</code></td>
<td>iterator</td>
<td>erases the elements in the range [q1, q2]</td>
</tr>
<tr>
<td><code>a.clear()</code></td>
<td>void</td>
<td>erase(begin(), end())</td>
</tr>
<tr>
<td><code>a.assign(i,j)</code></td>
<td>void</td>
<td>pre: i, j are not iterators into a. Replaces elements in a with a copy of [i, j].</td>
</tr>
<tr>
<td><code>a.assign(n,t)</code></td>
<td>void</td>
<td>pre: t is not a reference into a. Replaces elements in a with n copies of t.</td>
</tr>
</tbody>
</table>

5 iterator and const_iterator types for sequences shall be at least of the forward iterator category.
6 The iterator returned from `a.insert(p,t)` points to the copy of `t` inserted into `a`.

7 The iterator returned from `a.erase(q)` points to the element immediately following `q` prior to the element being erased. If no such element exists, `a.end()` is returned.

8 The iterator returned by `a.erase(q1,q2)` points to the element pointed to by `q2` prior to any elements being erased. If no such element exists, `a.end()` is returned.

9 For every sequence defined in this clause and in clause 21:
   - If the constructor
     
     ```
     template <class InputIterator>
     X(InputIterator first, InputIterator last,
        const allocator_type& alloc = allocator_type())
     ```

     is called with a type `InputIterator` that does not qualify as an input iterator, then the constructor will behave as if the overloaded constructor:
     
     ```
     X(size_type, const value_type& = value_type(),
        const allocator_type& = allocator_type())
     ```

     were called instead, with the arguments `static_cast<size_type>(first), last and alloc, respectively.
   - If the member functions of the forms:
     ```
     template <class InputIterator> // such as insert()
     rt fx1(iterator p, InputIterator first, InputIterator last);
     ```
     ```
     template <class InputIterator> // such as append(), assign()
     rt fx2(InputIterator first, InputIterator last);
     ```
     ```
     template <class InputIterator> // such as replace()
     rt fx3(iterator i1, iterator i2, InputIterator first, InputIterator last);
     ```

     are called with a type `InputIterator` that does not qualify as an input iterator, then these functions will behave as if the overloaded member functions:
     ```
     rt fx1(iterator, size_type, const value_type&);
     ```
     ```
     rt fx2(size_type, const value_type&);
     ```
     ```
     rt fx3(iterator, iterator, size_type, const value_type&);
     ```

     were called instead, with the same arguments.

10 In the previous paragraph the alternative binding will fail if `first` is not implicitly convertible to `X::size_type` or if `last` is not implicitly convertible to `X::value_type`.

11 The extent to which an implementation determines that a type cannot be an input iterator is unspecified, except that as a minimum integral types shall not qualify as input iterators.

Draft
Table 69 lists sequence operations that are provided for some types of sequential containers but not others. An implementation shall provide these operations for all container types shown in the “container” column, and shall implement them so as to take amortized constant time.

<table>
<thead>
<tr>
<th>expression</th>

</tbody>
</table>
| a.pop_back() | void | { iterator tmp = a.end(); 
- tmp; 
return *tmp; } | vector, list, deque |
| a[n]       | reference; const_reference | *(a.begin() + n) | vector, deque |
| a.at(n)    | reference; const_reference | for constant a | vector, deque |

The member function `at()` provides bounds-checked access to container elements. `at()` throws `out_of_range` if \( n \geq a.size() \).

### 23.1.2 Associative containers

Associative containers provide an ability for fast retrieval of data based on keys. The library provides four basic kinds of associative containers: `set`, `multiset`, `map` and `multimap`.

Each associative container is parameterized on `Key` and an ordering relation `Compare` that induces a strict weak ordering (25.3) on elements of `Key`. In addition, `map` and `multimap` associate an arbitrary type `T` with the `Key`. The object of type `Compare` is called the *comparison object* of a container. This comparison object may be a pointer to function or an object of a type with an appropriate function call operator.

The phrase “equivalence of keys” means the equivalence relation imposed by the comparison and *not* the operator== on keys. That is, two keys \( k_1 \) and \( k_2 \) are considered to be equivalent if for the comparison object \( \text{comp} \), \( \text{comp}(k_1, k_2) == \text{false} \) and \( \text{comp}(k_2, k_1) == \text{false} \). For any two keys \( k_1 \) and \( k_2 \) in the same container, calling \( \text{comp}(k_1, k_2) \) shall always return the same value.
4 An associative container supports *unique keys* if it may contain at most one element for each key. Otherwise, it supports *equivalent keys*. The *set* and *map* classes support unique keys; the *multiset* and *multimap* classes support equivalent keys.

5 For *set* and *multiset* the value type is the same as the key type. For *map* and *multimap* it is equal to `pair<const Key, T>`. Keys in an associative container are immutable.

6 *Iterator* of an associative container is of the bidirectional iterator category. For associative containers where the value type is the same as the key type, both *iterator* and *const_iterator* are constant iterators. It is unspecified whether or not *iterator* and *const_iterator* are the same type.

7 In Table 70, X is an associative container class, a is a value of X, a_uniq is a value of X when X supports unique keys, and a_eq is a value of X when X supports multiple keys, i and j satisfy input iterator requirements and refer to elements of `value_type`, [i, j) is a valid range, p is a valid iterator to a, q is a valid dereferenceable iterator to a, [q1, q2) is a valid range in a, t is a value of `value_type`, k is a value of `key_type` and c is a value of type `X::key_compare`.

8 The insert members shall not affect the validity of iterators and references to the container, and the erase members shall invalidate only iterators and references to the erased elements.

9 The fundamental property of iterators of associative containers is that they iterate through the containers in the non-descending order of keys where non-descending is defined by the comparison that was used to construct them. For any two dereferenceable iterators i and j such that distance from i to j is positive,

\[ \text{value_comp}(\ast j, \ast i) == \text{false} \]

10 For associative containers with unique keys the stronger condition holds,

\[ \text{value_comp}(\ast i, \ast j) != \text{false}. \]

11 When an associative container is constructed by passing a comparison object the container shall not store a pointer or reference to the passed object, even if that object is passed by reference. When an associative container is copied, either through a copy constructor or an assignment operator, the target container shall then use the comparison object from the container being copied, as if that comparison object had been passed to the target container in its constructor.

23.2.1 Class template deque

A deque is a kind of sequence that, like a vector (23.2.4), supports random access iterators. In addition, it supports constant time insert and erase operations at the beginning or the end; insert and erase in the middle take linear time. That is, a deque is especially optimized for pushing and popping elements at the beginning and end. As with vectors, storage management is handled automatically.
A deque satisfies all of the requirements of a container and of a reversible container (given in tables in 23.1) and of a sequence, including the optional sequence requirements (23.1.1). In addition to the requirements on the stored object described in 23.1, the stored object shall meet the requirements of Assignable. Descriptions are provided here only for operations on deque that are not described in one of these tables or for operations where there is additional semantic information.

namespace std {
    template <class T, class Allocator = allocator<T> >
    class deque {
        public:
            // types:
            typedef typename Allocator::reference reference;
            typedef typename Allocator::const_reference const_reference;
            typedef implementation-defined iterator;  // See 23.1
            typedef implementation-defined const_iterator;  // See 23.1
            typedef implementation-defined size_type;  // See 23.1
            typedef implementation-defined difference_type;  // See 23.1
            typedef T value_type;
            typedef Allocator allocator_type;
            typedef typename Allocator::pointer pointer;
            typedef typename Allocator::const_pointer const_pointer;
            typedef std::reverse_iterator<iterator> reverse_iterator;
            typedef std::reverse_iterator<const_iterator> const_reverse_iterator;

            // 23.2.1.1 construct/copy/destroy:
            explicit deque(const Allocator& = Allocator());
            explicit deque(size_type n, const T& value = T(),
                const Allocator& = Allocator());
            template <class InputIterator>
            deque(InputIterator first, InputIterator last,
                const Allocator& = Allocator());

                const deque<T, Allocator>& y);

template <class T, class Allocator>
bool operator>=(const deque<T, Allocator>& x,
                const deque<T, Allocator>& y);
bool operator<=(const deque<T,Allocator>& x,
    const deque<T,Allocator>& y);

// specialized algorithms:
    template <class T, class Allocator>
    void swap(deque<T,Allocator>& x, deque<T,Allocator>& y);
}

23.2.1.1 deque constructors, copy, and assignment [lib.deque.cons]

explicit deque(const Allocator& = Allocator());
   Effects: Constructs an empty deque, using the specified allocator.
   Complexity: Constant.

explicit deque(size_type n, const T& value = T(),
    const Allocator& = Allocator());
   Effects: Constructs a deque with n copies of value, using the specified allocator.
   Complexity: Linear in n.

template <class InputIterator>
    deque(InputIterator first, InputIterator last,
        const Allocator& = Allocator());
   Effects: Constructs a deque equal to the the range [first, last), using the specified allocator.
   Complexity: Makes distance(first, last) calls to the copy constructor of T. 2544

template <class InputIterator>
    void assign(InputIterator first, InputIterator last);
   Effects:
       erase(begin(), end());
       insert(begin(), first, last);

    void assign(size_type n, const T& t);
   Effects:
       erase(begin(), end());
       insert(begin(), n, t);

23.2.1.2 deque capacity [lib.deque.capacity]

void resize(size_type sz, T c = T());
   Effects:

2544) This footnote is intentionally empty.

Draft
if (sz > size())
    insert(end(), sz-size(), c);
else if (sz < size())
    erase(begin()+sz, end());
else
    // do nothing

23.2.1.3 deque modifiers

iterator insert(iterator position, const T& x);
void insert(iterator position, size_type n, const T& x);
template < class InputIterator>
    void insert(iterator position,
               InputIterator first, InputIterator last);

Effects: An insert in the middle of the deque invalidates all the iterators and references to elements of the deque. An insert at either end of the deque invalidates all the iterators to the deque, but has no effect on the validity of references to elements of the deque.

Remarks: If an exception is thrown other than by the copy constructor or assignment operator of T there are no effects.

Complexity: In the worst case, inserting a single element into a deque takes time linear in the minimum of the distance from the insertion point to the beginning of the deque and the distance from the insertion point to the end of the deque. Inserting a single element either at the beginning or end of a deque always takes constant time and causes a single call to the copy constructor of T.

iterator erase(iterator position);
iterator erase(iterator first, iterator last);

Effects: An erase in the middle of the deque invalidates all the iterators and references to elements of the deque. An erase at either end of the deque invalidates only the iterators and the references to the erased elements.

Complexity: The number of calls to the destructor is the same as the number of elements erased, but the number of the calls to the assignment operator is at most equal to the minimum of the number of elements before the erased elements and the number of elements after the erased elements.

Throws: Nothing unless an exception is thrown by the copy constructor or assignment operator of T.

23.2.1.4 deque specialized algorithms

template < class T, class Allocator>
    void swap(deque<T,Allocator>& x, deque<T,Allocator>& y);

Effects:
    x.swap(y);
23.2.2 Class template `list`  

A list is a kind of sequence that supports bidirectional iterators and allows constant time insert and erase operations anywhere within the sequence, with storage management handled automatically. Unlike vectors (23.2.4) and deques (23.2.1), fast random access to list elements is not supported, but many algorithms only need sequential access anyway.

A list satisfies all of the requirements of a container and of a reversible container (given in two tables in 23.1) and of a sequence, including most of the the optional sequence requirements (23.1.1). The exceptions are the operator[] and at member functions, which are not provided.\(^{255}\) list does not require the stored type \(T\) to be Assignable unless the following methods are instantiated:\(^{256}\)

```cpp
list<T,Allocator>& operator=(const list<T,Allocator>& x);
```

```cpp
template <class InputIterator>
void assign(InputIterator first, InputIterator last);
```

```cpp
void assign(size_type n, const T& t);
```

Descriptions are provided here only for operations on list that are not described in one of these tables or for operations where there is additional semantic information.

```cpp
namespace std {
    template <class T, class Allocator = allocator<T> >
    class list {
        public:
            // types:
            typedef typename Allocator::reference reference;
            typedef typename Allocator::const_reference const_reference;
            typedef implementation-defined iterator;       // See 23.1
            typedef implementation-defined const_iterator;  // See 23.1
            typedef implementation-defined size_type;       // See 23.1
            typedef implementation-defined difference_type; // See 23.1
            typedef T value_type;
            typedef Allocator allocator_type;
            typedef typename Allocator::pointer pointer;
            typedef typename Allocator::const_pointer const_pointer;
            typedef std::reverse_iterator<iterator> reverse_iterator;
            typedef std::reverse_iterator<const_iterator> const_reverse_iterator;

            // 23.2.2.1 construct/copy/destroy:
            explicit list(const Allocator& = Allocator());
            explicit list(size_type n, const T& value = T(),
                          const Allocator& = Allocator());
            template <class InputIterator>
            list(InputIterator first, InputIterator last,
                 const Allocator& = Allocator());
            list(const list<T,Allocator>& x);
            ~list();
            list<T,Allocator>& operator=(const list<T,Allocator>& x);

void assign(size_type n, const T& t);
\]
8 Effects: Replaces the contents of the list with \(n\) copies of \(t\).

23.2.2.2 list capacity

\[
void resize(size_type sz, T c = T());
\]
1 Effects:

\[
if (sz > size())
insert(end(), sz-size(), c);
else if (sz < size()) {
    iterator i = begin();
    advance(i, sz);
    erase(i, end());
}
else
    // do nothing
\]

23.2.2.3 list modifiers

\[
iterator insert(iterator position, const T& x);
void insert(iterator position, size_type n, const T& x);
template <class InputIterator>
void insert(iterator position, InputIterator first, InputIterator last);
\]

\[
void push_front(const T& x);
void push_back(const T& x);
\]
1 Remarks: Does not affect the validity of iterators and references. If an exception is thrown there are no effects.

2 Complexity: Insertion of a single element into a list takes constant time and exactly one call to the copy constructor of \(T\). Insertion of multiple elements into a list is linear in the number of elements inserted, and the number of calls to the copy constructor of \(T\) is exactly equal to the number of elements inserted.

\[
iterator erase(iterator position);
iterator erase(iterator first, iterator last);
void pop_front();
\]
23.2 Sequences

Containers library 552

void pop_back();
void clear();

Effects: Invalidates only the iterators and references to the erased elements.

Throws: Nothing.

Complexity: Erasing a single element is a constant time operation with a single call to the destructor of T. Erasing a range in a list is linear time in the size of the range and the number of calls to the destructor of type T is exactly equal to the size of the range.

23.2.2.4 list operations [lib.list.ops]

Since lists allow fast insertion and erasing from the middle of a list, certain operations are provided specifically for them.\(^{257}\)

list provides three splice operations that destructively move elements from one list to another.

void splice(iterator position, list<T, Allocator>& x);

Requires: &x ! = this.

Effects: Inserts the contents of x before position and x becomes empty. Pointers and references to the moved elements of x now refer to those same elements but as members of *this. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into *this, not into x.

Throws: Nothing

Complexity: Constant time.

void splice(iterator position, list<T, Allocator>& x, iterator i);

Requires: i is a valid dereferenceable iterator of x.

Complexity: Constant time.

void splice(iterator position, list<T, Allocator>& x, iterator first, iterator last);

Effects: Inserts elements in the range [first, last) before position and removes the elements from x.

Requires: [first, last) is a valid range in x. The result is undefined if position is an iterator in the range [first, last). Pointers and references to the moved elements of x now refer to those same elements but as members of *this. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into *this, not into x.

\(^{257}\)As specified in 20.1.6, the requirements in this clause apply only to lists whose allocators compare equal.
void remove(const T& value);

Effects: Erases all the elements in the list referred by a list iterator i for which the following conditions hold: \( *i == value \) or \( pred(*i) != false \).

Throws: Nothing unless an exception is thrown by \( *i == value \) or \( pred(*i) != false \).

Remarks: Stable.

Complexity: Exactly size() applications of the corresponding predicate.

void unique();

template <class BinaryPredicate> void unique(BinaryPredicate binary_pred);

Effects: Eliminates all but the first element from every consecutive group of equal elements referred to by the iterator i in the range \([first + 1, last)\) for which \( *i == *(i-1) \) (for the version of unique with no arguments) or \( pred(*i, *(i - 1)) \) (for the version of unique with a predicate argument) holds.

Throws: Nothing unless an exception in thrown by \( *i == *(i-1) \) or \( pred(*i, *(i - 1)) \)

Complexity: If the range \([first, last)\) is not empty, exactly \( (last - first) - 1 \) applications of the corresponding predicate, otherwise no applications of the predicate.

void merge(list<T,Allocator>& x);

template <class Compare> void merge(list<T,Allocator>& x, Compare comp);

Requires: \( comp \) defines a strict weak ordering (25.3), and the list and the argument list are both sorted according to this ordering.

Effects: If \( (&x == this) \) does nothing; otherwise, merges the two sorted ranges \([begin(), end())\) and \([x.\begin{comment}\text{begin}()\end{comment}, x.\text{end}())\). The result is a range in which the elements will be sorted in non-decreasing order according to the ordering defined by \( comp \); that is, for every iterator \( i \) in the range other than the first, the condition \( comp(*i, *(i - 1)) \) will be false.

Remarks: Stable. If \( (&x != this) \) the range \([x.\begin{comment}\text{begin}()\end{comment}, x.\text{end}())\) is empty after the merge.

Complexity: At most size() + x.size() - 1 applications of \( comp \) if \( (&x != this) \); otherwise, no applications of \( comp \) are performed. If an exception is thrown other than by a comparison there are no effects.

void reverse();

Effects: Reverses the order of the elements in the list.

Throws: Nothing.

Complexity: Linear time.

void sort();

template <class Compare> void sort(Compare comp);
Requires: \texttt{operator<} (for the first version) or \texttt{comp} (for the second version) defines a strict weak ordering (25.3).

Effects: Sorts the list according to the \texttt{operator<} or a \texttt{Compare} function object.

Remarks: Stable.

Complexity: Approximately $N \log(N)$ comparisons, where $N == \text{size()}$.

### 23.2.2.5 list specialized algorithms

```cpp
template <class T, class Allocator>
void swap(list<T,Allocator>& x, list<T,Allocator>& y);
```

Effects:

\hspace{1cm} $x$.\texttt{swap}(y);

### 23.2.3 Container adaptors

The container adaptors each take a Container template parameter, and each constructor takes a Container reference argument. This container is copied into the Container member of each adaptor.

#### 23.2.3.1 Class template \texttt{queue}

Any sequence supporting operations \texttt{front()}, \texttt{back()}, \texttt{push_back()} and \texttt{pop_front()} can be used to instantiate \texttt{queue}. In particular, \texttt{list} (23.2.2) and \texttt{deque} (23.2.1) can be used.

#### 23.2.3.1.1 queue definition

```cpp
namespace std {
    template <class T, class Container = deque<T>>
    class queue {
        public:
            typedef typename Container::value_type value_type;
            typedef typename Container::reference reference;
            typedef typename Container::const_reference const_reference;
            typedef typename Container::size_type size_type;
            typedef Container container_type;

            private:
                Container c;

            public:
                explicit queue(const Container& = Container());

                bool empty() const { return c.\texttt{empty}(); }
                size_type size() const { return c.\texttt{size}(); }
                reference front() const { return c.\texttt{front}(); }
                const_reference front() const { return c.\texttt{front}(); }
                reference back() const { return c.\texttt{back}(); }
                const_reference back() const { return c.\texttt{back}(); }
                void push(const value_type& x) { c.push_back(x); }

            private:
```

Draft
void pop() { c.pop_front(); }
);

template < class T, class Container >
  bool operator==(const queue<T, Container> & x,
                 const queue<T, Container> & y);

template < class T, class Container >
  bool operator!=(const queue<T, Container> & x,
                 const queue<T, Container> & y);

template < class T, class Container >
  bool operator<(const queue<T, Container> & x,
                const queue<T, Container> & y);

template < class T, class Container >
  bool operator>=(const queue<T, Container> & x,
                 const queue<T, Container> & y);

template < class T, class Container >
  bool operator<=(const queue<T, Container> & x,
                 const queue<T, Container> & y);

23.2.3.1.2 queue operators [lib.queue.ops]

template < class T, class Container >
  bool operator==(const queue<T, Container> & x,
                 const queue<T, Container> & y);

1 Returns: x.c == y.c.

template < class T, class Container >
  bool operator!=(const queue<T, Container> & x,
                 const queue<T, Container> & y);

2 Returns: x.c != y.c.

template < class T, class Container >
  bool operator<(const queue<T, Container> & x,
                const queue<T, Container> & y);

3 Returns: x.c < y.c.

template < class T, class Container >
  bool operator<=(const queue<T, Container> & x,
                 const queue<T, Container> & y);

4 Returns: x.c <= y.c.
23.2 Sequences

Returns: \( x.c > y.c \).

```cpp
template <class T, class Container>
bool operator>=(const queue<T, Container>& x,
              const queue<T, Container>& y);
```

Returns: \( x.c \geq y.c \).

23.2.3.2 Class template priority_queue

Any sequence with random access iterator and supporting operations `front()`, `push_back()` and `pop_back()` can be used to instantiate `priority_queue`. In particular, `vector (23.2.4)` and `deque (23.2.1)` can be used. Instantiating `priority_queue` also involves supplying a function or function object for making priority comparisons; the library assumes that the function or function object defines a strict weak ordering (25.3).

```cpp
namespace std {
    template <class T, class Container = vector<T>,
              class Compare = less<typename Container::value_type> >
    class priority_queue {
public:
    typedef typename Container::value_type value_type;
    typedef typename Container::reference reference;
    typedef typename Container::const_reference const_reference;
    typedef typename Container::size_type size_type;
    typedef Container container_type;

    protected:
    Container c;
    Compare comp;

    public:
    explicit priority_queue(const Compare & x = Compare(),
                            const Container & = Container());
    template <class InputIterator>
    priority_queue(InputIterator first, InputIterator last,
                    const Compare & x = Compare(),
                    const Container & = Container());

    bool empty() const { return c.empty(); }
    size_type size() const { return c.size(); }
    const_reference top() const { return c.front(); }
    void push(const value_type & x);
    void pop();
};
```

23.2.3.2.1 priority_queue constructors

```
priority_queue(const Compare & x = Compare(),
               const Container & y = Container());
```
Requires: \(x\) defines a strict weak ordering (25.3).

Effects: Initializes \(\text{comp}\) with \(x\) and \(\text{c}\) with \(y\); calls make_heap(c.begin(), c.end(), comp).

```cpp
template <class InputIterator>
priority_queue(InputIterator first, InputIterator last,
  const Compare & x = Compare(),
  const Container & y = Container());
```

Requires: \(x\) defines a strict weak ordering (25.3).

Effects: Initializes \(\text{c}\) with \(y\) and \(\text{comp}\) with \(x\); calls \(\text{c}.\text{insert}(\text{c}.\text{end()}, \text{first}, \text{last})\); and finally calls make_heap(c.begin(), c.end(), comp).

### 23.2.3.2.2 `priority_queue` members

#### void push(const value_type& x);

Effects:

- \(\text{c}.\text{push_back}(x)\);
- push_heap(c.begin(), c.end(), comp);

#### void pop();

Effects:

- pop_heap(c.begin(), c.end(), comp);
- c.pop_back();

### 23.2.3.3 Class template `stack`

Any sequence supporting operations `back()`, `push_back()` and `pop_back()` can be used to instantiate `stack`. In particular, `vector` (23.2.4), `list` (23.2.2) and `deque` (23.2.1) can be used.

#### 23.2.3.3.1 stack definition

```cpp
namespace std {
  template <class T, class Container = deque<T> >
  class stack {
  public:
    typedef typename Container::value_type value_type;
    typedef typename Container::reference reference;
    typedef typename Container::const_reference const_reference;
    typedef typename Container::size_type size_type;
    typedef Container container_type;

  protected:
    Container c;

  public:
    explicit stack(const Container& = Container());
  }
}
```
bool empty() const { return c.empty(); }
size_type size() const { return c.size(); }
reference top();
const_reference top() const { return c.back(); }
void push(const value_type& x) { c.push_back(x); }
void pop();

};

template<class T, class Container>
bool operator==(const stack<T, Container>& x, const stack<T, Container>& y);

template<class T, class Container>
bool operator<(const stack<T, Container>& x, const stack<T, Container>& y);

template<class T, class Container>
bool operator!=(const stack<T, Container>& x, const stack<T, Container>& y);

23.2.3.3.2 stack operators

Returns: x.c == y.c.

Returns: x.c != y.c.

Returns: x.c < y.c.

Returns: x.c <= y.c.
Returns: \( x.c \leq y.c \).

```
template <class T, class Container>
bool operator>(const stack<T, Container>& x,
             const stack<T, Container>& y);
```

Returns: \( x.c > y.c \).

```
template <class T, class Container>
bool operator>=(const stack<T, Container>& x,
               const stack<T, Container>& y);
```

Returns: \( x.c \geq y.c \).

### 23.2.4 Class template vector

A `vector` is a kind of sequence that supports random access iterators. In addition, it supports (amortized) constant time insert and erase operations at the end; insert and erase in the middle take linear time. Storage management is handled automatically, though hints can be given to improve efficiency. The elements of a vector are stored contiguously, meaning that if \( \text{v} \) is a `vector<T, Allocator>` where \( T \) is some type other than `bool`, then it obeys the identity \( \&\text{v}[n] = \&\text{v}[0] + n \) for all \( 0 \leq n < \text{v.size()} \).

A `vector` satisfies all of the requirements of a container and of a reversible container (given in two tables in 23.1) and of a sequence, including most of the optional sequence requirements (23.1.1). The exceptions are the `push_front` and `pop_front` member functions, which are not provided. In addition to the requirements on the stored object described in 23.1, the stored object shall meet the requirements of Assignable. Descriptions are provided here only for operations on `vector` that are not described in one of these tables or for operations where there is additional semantic information.

```cpp
namespace std {
    template <class T, class Allocator = allocator<T> >
    class vector {
        public:
            // types:
            typedef typename Allocator::reference reference;
            typedef typename Allocator::const_reference const_reference;
            typedef implementation-defined iterator;
            // See 23.1
            typedef implementation-defined const_iterator;
            // See 23.1
            typedef implementation-defined size_type;
            // See 23.1
            typedef implementation-defined difference_type; // See 23.1
            typedef T value_type;
            typedef Allocator allocator_type;
            typedef typename Allocator::pointer pointer;
            typedef typename Allocator::const_pointer const_pointer;
            typedef std::reverse_iterator<iterator> reverse_iterator;
            typedef std::reverse_iterator<const_iterator> const_reverse_iterator;

            // 23.2.4.1 construct/copy/destroy:
            explicit vector(const Allocator& = Allocator());
            explicit vector(size_type n, const T& value = T(),
```
const Allocator& = Allocator();

template <class InputIterator>
    vector(InputIterator first, InputIterator last,
       const Allocator& = Allocator());
vector(const vector<T,Allocator>& x);

vector<T,Allocator>& operator=(const vector<T,Allocator>& x);
template <class InputIterator>
    void assign(InputIterator first, InputIterator last);
    void assign(size_type n, const T& u);

allocator_type get_allocator() const;

// iterators:
iterator begin();
const_iterator begin() const;
iterator end();
const_iterator end() const;
reverse_iterator rbegin();
const_reverse_iterator rbegin() const;
reverse_iterator rend();
const_reverse_iterator rend() const;

// 23.2.4.2 capacity:
size_type size() const;
size_type max_size() const;
void resize(size_type sz, T c = T());
size_type capacity() const;
bool empty() const;
void reserve(size_type n);

// element access:
reference operator[](size_type n);
const_reference operator[](size_type n) const;
const_reference at(size_type n) const;
reference at(size_type n);
reference front();
const_reference front() const;
reference back();
const_reference back() const;

// 23.2.4.3 modifiers:
void push_back(const T& x);
void pop_back();

iterator insert(iterator position, const T& x);
void insert(iterator position, size_type n, const T& x);
template <class InputIterator>
    void insert(iterator position,
        InputIterator first, InputIterator last);

iterator erase(iterator position);
iterator erase(iterator first, iterator last);
void swap(vector<T, Allocator>&);
void clear();
};

template < class T, class Allocator >
bool operator==(const vector<T, Allocator>& x, const vector<T, Allocator>& y);

template < class T, class Allocator >
bool operator<(const vector<T, Allocator>& x, const vector<T, Allocator>& y);

template < class T, class Allocator >
bool operator!=(const vector<T, Allocator>& x, const vector<T, Allocator>& y);

template < class T, class Allocator >
bool operator>(const vector<T, Allocator>& x, const vector<T, Allocator>& y);

template < class T, class Allocator >
bool operator>=(const vector<T, Allocator>& x, const vector<T, Allocator>& y);

template < class T, class Allocator >
bool operator<=(const vector<T, Allocator>& x, const vector<T, Allocator>& y);

// specialized algorithms:
template < class T, class Allocator >
void swap(vector<T, Allocator>& x, vector<T, Allocator>& y);
}

23.2.4.1 vector constructors, copy, and assignment [lib.vector.cons]

vector(const Allocator& = Allocator());
explicit vector(size_type n, const T& value = T(),
const Allocator& = Allocator());
template < class InputIterator >
vector(InputIterator first, InputIterator last,
const Allocator& = Allocator());
vector(const vector<T, Allocator>& x);

1 Complexity: The constructor template < class InputIterator > vector(InputIterator first, InputIterator last) makes only $N$ calls to the copy constructor of $T$ (where $N$ is the distance between first and last) and no reallocations if iterators first and last are of forward, bidirectional, or random access categories. It makes order $N$ calls to the copy constructor of $T$ and order $\log(N)$ reallocations if they are just input iterators.

template < class InputIterator >
void assign(InputIterator first, InputIterator last);

2 Effects:
   
   erase(begin(), end());
   insert(begin(), first, last);

Draft
23.2 Sequences

```c++
void assign(size_type n, const T& t);

Effects:
    erase(begin(), end());
    insert(begin(), n, t);
```

### 23.2.4.2 vector capacity

```c++
size_type capacity() const;

Returns: The total number of elements that the vector can hold without requiring reallocation.
```

```c++
void reserve(size_type n);

Effects: A directive that informs a vector of a planned change in size, so that it can manage the storage allocation accordingly. After reserve(), capacity() is greater or equal to the argument of reserve if reallocation happens; and equal to the previous value of capacity() otherwise. Reallocation happens at this point if and only if the current capacity is less than the argument of reserve().

Complexity: It does not change the size of the sequence and takes at most linear time in the size of the sequence.

Throws: length_error if n > max_size().

Remarks: Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence. It is guaranteed that no reallocation takes place during insertions that happen after a call to reserve() until the time when an insertion would make the size of the vector greater than the value of capacity().
```

```c++
void swap(vector<T, Allocator>& x);

Effects: Exchanges the contents and capacity() of *this with that of x.

Complexity: Constant time.
```

```c++
void resize(size_type sz, T c = T());

Effects:
    if (sz > size())
        insert(end(), sz-size(), c);
    else if (sz < size())
        erase(begin()+sz, end());
    else
        // do nothing
```

### 23.2.4.3 vector modifiers

```c++
iterator insert(iterator position, const T& x);
void    insert(iterator position, size_type n, const T& x);
template <class InputIterator>
```

---

258) reserve() uses Allocator::allocate() which may throw an appropriate exception.
void insert(iterator position, InputIterator first, InputIterator last);

Remarks: Causes reallocation if the new size is greater than the old capacity. If no reallocation happens, all the iterators and references before the insertion point remain valid. If an exception is thrown other than by the copy constructor or assignment operator of T or by any InputIterator operation there are no effects.

Complexity: If first and last are forward iterators, bidirectional iterators, or random access iterators, the complexity is linear in the number of elements in the range [first, last) plus the distance to the end of the vector. If they are input iterators, the complexity is proportional to the number of elements in the range [first, last) times the distance to the end of the vector.

iterator erase(iterator position);
iterator erase(iterator first, iterator last);

Effects: Invalidates iterators and references at or after the point of the erase.

Complexity: The destructor of T is called the number of times equal to the number of the elements erased, but the assignment operator of T is called the number of times equal to the number of elements in the vector after the erased elements.

Throws: Nothing unless an exception is thrown by the copy constructor or assignment operator of T.

23.2.4.4 vector specialized algorithms

[lib.vector.special]

template <class T, class Allocator>
void swap(vector<T,Allocator>& x, vector<T,Allocator>& y);

Effects:

x.swap(y);

23.2.5 Class vector<bool>

[lib.vector.bool]

To optimize space allocation, a specialization of vector for bool elements is provided:

namespace std {
    template <class Allocator> class vector<bool, Allocator> {
        public:
            // types:
            typedef bool value_type;
            typedef Allocator allocator_type;
            typedef implementation-defined pointer;
            typedef implementation-defined const_pointer;
            typedef std::reverse_iterator<iterator> reverse_iterator;
            typedef std::reverse_iterator<const_iterator> const_reverse_iterator;

Draft
// bit reference:
class reference {
    friend class vector;
    reference();
public:
    ~reference();
    operator bool() const;
    reference& operator=(const bool x);
    reference& operator=(const reference& x);
    void flip(); // flips the bit
};

// construct/copy/destroy:
explicit vector(const Allocator& = Allocator());
explicit vector(size_type n, const bool& value = bool(),
    const Allocator& = Allocator());
template <class InputIterator>
    vector(InputIterator first, InputIterator last,
        const Allocator& = Allocator());
vector(const vector<bool, Allocator>& x);
    ~vector();
vector<bool, Allocator>& operator=(const vector<bool, Allocator>& x);
template <class InputIterator>
    void assign(InputIterator first, InputIterator last);
void assign(size_type n, const T& t);
allocator_type get_allocator() const;

// iterators:
iterator begin();
const_iterator begin() const;
iterator end();
const_iterator end() const;
reverse_iterator rbegin();
const_reverse_iterator rbegin() const;
reverse_iterator rend();
const_reverse_iterator rend() const;

// capacity:
size_type size() const;
size_type max_size() const;
void resize(size_type sz, bool c = false);
size_type capacity() const;
bool empty() const;
void reserve(size_type n);

// element access:
reference operator[](size_type n);
const_reference operator[](size_type n) const;
const_reference at(size_type n) const;
2 reference is a class that simulates the behavior of references of a single bit in vector<bool>.

### 23.3 Associative containers [lib.associative]

**Headers** `<map>` and `<set>`:

#### Header `<map>` synopsis

```cpp
namespace std {
    template <class Key, class T, class Compare = less<Key>,
              class Allocator = allocator<pair<const Key, T>>>
    class map;

template <class Key, class T, class Compare, class Allocator>
bool operator==(const map<Key,T,Compare,Allocator>& x,
               const map<Key,T,Compare,Allocator>& y);

template <class Key, class T, class Compare, class Allocator>
bool operator<(const map<Key,T,Compare,Allocator>& x,

23.3.1 Class template map

A map is a kind of associative container that supports unique keys (contains at most one of each key value) and provides for fast retrieval of values of another type T based on the keys. The map class supports bidirectional iterators.

A map satisfies all of the requirements of a container and of a reversible container (23.1) and of an associative container (23.1.2). A map also provides most operations described in (23.1.2) for unique keys. This means that a map supports the a_uniq operations in (23.1.2) but not the a_eq operations. For a map<Key,T> the key_type is Key and the value_type is pair<const Key,T>. Descriptions are provided here only for operations on map that are not described in one
of those tables or for operations where there is additional semantic information.

```cpp
namespace std {
    template <class Key, class T, class Compare = less<Key>,
              class Allocator = allocator<pair<const Key, T>>>>
    class map {
        public:
            // types:
            typedef Key key_type;
            typedef T mapped_type;
            typedef pair<const Key, T> value_type;
            typedef Compare key_compare;
            typedef Allocator allocator_type;
            typedef typename Allocator::reference reference;
            typedef typename Allocator::const_reference const_reference;
            typedef implementation-defined iterator;
            typedef implementation-defined const_iterator;
            typedef implementation-defined size_type;
            typedef implementation-defined difference_type;
            typedef typename Allocator::pointer pointer;
            typedef typename Allocator::const_pointer const_pointer;
            typedef std::reverse_iterator<iterator> reverse_iterator;
            typedef std::reverse_iterator<const_iterator> const_reverse_iterator;

            class value_compare
                : public binary_function<value_type, value_type, bool> {
            friend class map;
            protected:
                Compare comp;
                value_compare(Compare c) : comp(c) {}
            public:
                bool operator()(const value_type& x, const value_type& y) const {
                    return comp(x.first, y.first);
                }
        };

        // 23.3.1.1 construct/copy/destroy:
        explicit map(const Compare& comp = Compare(),
                     const Allocator& = Allocator());
        template <class InputIterator>
        map(InputIterator first, InputIterator last,
             const Compare& comp = Compare(), const Allocator& = Allocator());
        map(const map<Key, T, Compare, Allocator>& x);
        ~map();
        map<Key, T, Compare, Allocator>&
        operator=(const map<Key, T, Compare, Allocator>& x);
        allocator_type get_allocator() const;

        // iterators:
        iterator begin();
    }
}
```
template <class Key, class T, class Compare, class Allocator>
bool operator==(const map<Key,T,Compare,Allocator>& x,

const_iterator begin() const;
iterator end();
const_iterator end() const;
reverse_iterator rbegin();
const_reverse_iterator rbegin() const;
reverse_iterator rend();
const_reverse_iterator rend() const;

// capacity:
bool empty() const;
size_type size() const;
size_type max_size() const;

// 23.3.1.2 element access:
T& operator[](const key_type& x);

// modifiers:
pair<iterator, bool> insert(const value_type& x);
iterator insert(iterator position, const value_type& x);
template <class InputIterator>
void insert(InputIterator first, InputIterator last);

iterator erase(iterator position);
size_type erase(const key_type& x);
iterator erase(iterator first, iterator last);
void swap(map<Key,T,Compare,Allocator>&);
void clear();

// observers:
key_compare key_comp() const;
value_compare value_comp() const;

// 23.3.1.3 map operations:
iterator find(const key_type& x);
const_iterator find(const key_type& x) const;
size_type count(const key_type& x) const;

iterator lower_bound(const key_type& x);
const_iterator lower_bound(const key_type& x) const;
iterator upper_bound(const key_type& x);
const_iterator upper_bound(const key_type& x) const;

pair<iterator,iterator> 
equal_range(const key_type& x);
pair<const_iterator,const_iterator> 
equal_range(const key_type& x) const;

};
const map<Key,T,Compare,Allocator>& y);

template <class Key, class T, class Compare, class Allocator>
bool operator<( const map<Key,T,Compare,Allocator>& x,
const map<Key,T,Compare,Allocator>& y);

template <class Key, class T, class Compare, class Allocator>
bool operator!=(const map<Key,T,Compare,Allocator>& x,
const map<Key,T,Compare,Allocator>& y);

// specialized algorithms:

// / specialized algorithms:

template <class Key, class T, class Compare, class Allocator>
void swap(map<Key,T,Compare,Allocator>& x,
map<Key,T,Compare,Allocator>& y);

23.3.1.1 map constructors, copy, and assignment [lib.map.cons]

explicit map(const Compare& comp = Compare(),
const Allocator& = Allocator());

Effects: Constructs an empty map using the specified comparison object and allocator.

Complexity: Constant.

template <class InputIterator>
map(InputIterator first, InputIterator last,
    const Compare& comp = Compare(), const Allocator& = Allocator());

Effects: Constructs an empty map using the specified comparison object and allocator, and inserts elements from the range [first, last).

Complexity: Linear in N if the range [first, last) is already sorted using comp and otherwise N log N, where N is last - first.

23.3.1.2 map element access [lib.map.access]

T& operator[](const key_type& x);

Effects: If there is no key equivalent to x in the map, inserts value_type(x, T()) into the map.

Returns: A reference to the mapped_type corresponding to x in *this.

Complexity: logarithmic.
23.3.1.3 map operations

```cpp
iterator find(const key_type& x);  
const_iterator find(const key_type& x) const;

iterator lower_bound(const key_type& x);  
const_iterator lower_bound(const key_type& x) const;

iterator upper_bound(const key_type& x);  
const_iterator upper_bound(const key_type& x) const;

pair<iterator, iterator> equal_range(const key_type &x);  
pair<const_iterator, const_iterator> equal_range(const key_type & x) const;
```

The `find`, `lower_bound`, `upper_bound` and `equal_range` member functions each have two versions, one const and the other non-const. In each case the behavior of the two functions is identical except that the const version returns a `const_iterator` and the non-const version an `iterator` (23.1.2).

23.3.1.4 map specialized algorithms

```cpp
template <class Key, class T, class Compare, class Allocator>
void swap(map<Key,T,Compare,Allocator>& x,  
          map<Key,T,Compare,Allocator>& y);
```

Effects:

```cpp
x.swap(y);
```

23.3.2 Class template multimap

A multimap is a kind of associative container that supports equivalent keys (possibly containing multiple copies of the same key value) and provides for fast retrieval of values of another type `T` based on the keys. The multimap class supports bidirectional iterators.

A multimap satisfies all of the requirements of a container and of a reversible container (23.1) and of an associative container (23.1.2). A multimap also provides most operations described in (23.1.2) for equal keys. This means that a multimap supports the `a_eq` operations in (23.1.2) but not the `a_uniq` operations. For a `multimap<Key,T>` the `key_type` is `Key` and the `value_type` is `pair<const Key,T>`. Descriptions are provided here only for operations on `multimap` that are not described in one of those tables or for operations where there is additional semantic information.

```cpp
namespace std {
  template <class Key, class T, class Compare = less<Key>,  
            class Allocator = allocator<pair<const Key, T>>>
  class multimap {
    public:
      // types:
      typedef Key key_type;
```
typedef T mapped_type;
typedef pair<const Key,T> value_type;
typedef Compare key_compare;
typedef Allocator allocator_type;
typedef typename Allocator::reference reference;
typedef typename Allocator::const_reference const_reference;
typedef implementation-defined iterator; // See 23.1
typedef implementation-defined const_iterator; // See 23.1
typedef implementation-defined size_type; // See 23.1
typedef implementation-defined difference_type; // See 23.1
typedef typename Allocator::pointer pointer;
typedef typename Allocator::const_pointer const_pointer;
typedef std::reverse_iterator<iterator> reverse_iterator;
typedef std::reverse_iterator<const_iterator> const_reverse_iterator;

class value_compare
 : public binary_function<value_type,value_type,bool> {
friend class multimap;
protected:
  Compare comp;
  value_compare(Compare c) : comp(c) {} 
public:
  bool operator()(const value_type& x, const value_type& y) const {
    return comp(x.first, y.first);
  }
};

// construct/copy/destroy:
explicit multimap(const Compare& comp = Compare(),
                  const Allocator& = Allocator());
template <class InputIterator>
  multimap(InputIterator first, InputIterator last,
           const Compare& comp = Compare(),
           const Allocator& = Allocator());
  multimap(const multimap<Key,T,Compare,Allocator>& x);
  multimap();
  multimap<Key,T,Compare,Allocator>&
    operator=(const multimap<Key,T,Compare,Allocator>& x);
  allocator_type get_allocator() const;

// iterators:
iterator begin();
const_iterator begin() const;
iterator end();
const_iterator end() const;
reverse_iterator rbegin();
const_reverse_iterator rbegin() const;
reverse_iterator rend();
const_reverse_iterator rend() const;
// capacity:
bool empty() const;
size_type size() const;
size_type max_size() const;

// modifiers:
iterator insert(const value_type& x);
iterator insert(iterator position, const value_type& x);
template <class InputIterator>
    void insert(InputIterator first, InputIterator last);
iterator erase(iterator position);
size_type erase(const key_type& x);
iterator erase(iterator first, iterator last);
void swap(multimap<Key, T, Compare, Allocator>&);
void clear();

// observers:
key_compare key_comp() const;
value_compare value_comp() const;

// map operations:
iterator find(const key_type& x);
const_iterator find(const key_type& x) const;
size_type count(const key_type& x) const;
iterator lower_bound(const key_type& x);
const_iterator lower_bound(const key_type& x) const;
iterator upper_bound(const key_type& x);
const_iterator upper_bound(const key_type& x) const;
pair<iterator, iterator>
    equal_range(const key_type& x);
pair<const_iterator, const_iterator>
    equal_range(const key_type& x) const;

};

template <class Key, class T, class Compare, class Allocator>
bool operator==(const multimap<Key, T, Compare, Allocator>& x,
    const multimap<Key, T, Compare, Allocator>& y);
template <class Key, class T, class Compare, class Allocator>
bool operator<(const multimap<Key, T, Compare, Allocator>& x,
    const multimap<Key, T, Compare, Allocator>& y);
template <class Key, class T, class Compare, class Allocator>
bool operator!=(const multimap<Key, T, Compare, Allocator>& x,
    const multimap<Key, T, Compare, Allocator>& y);
template <class Key, class T, class Compare, class Allocator>
bool operator>(const multimap<Key, T, Compare, Allocator>& x,
    const multimap<Key, T, Compare, Allocator>& y);
template <class Key, class T, class Compare, class Allocator>
bool operator>=(const multimap<Key, T, Compare, Allocator>& x,
    const multimap<Key, T, Compare, Allocator>& y);
template <class Key, class T, class Compare, class Allocator>
bool operator<=(const multimap<Key, T, Compare, Allocator>& x,
    const multimap<Key, T, Compare, Allocator>& y);
bool operator >= (const multimap < Key , T , Compare , Allocator >& x,
            const multimap < Key , T , Compare , Allocator >& y);

template < class Key , class T , class Compare , class Allocator >
bool operator <= (const multimap < Key , T , Compare , Allocator >& x,
            const multimap < Key , T , Compare , Allocator >& y);

// specialized algorithms:
template < class Key , class T , class Compare , class Allocator >
void swap (multimap < Key , T , Compare , Allocator >& x,
           multimap < Key , T , Compare , Allocator >& y);
}

23.3.2.1 multimap constructors

explicit multimap (const Compare & comp = Compare (),
            const Allocator & = Allocator ());

1 Effects: Constructs an empty multimap using the specified comparison object and allocator.

2 Complexity: Constant.

template < class InputIterator >
multimap (InputIterator first, InputIterator last,
            const Compare & comp = Compare (),
            const Allocator & = Allocator ());

3 Effects: Constructs an empty multimap using the specified comparison object and allocator, and inserts elements from the range [first, last).

4 Complexity: Linear in N if the range [first, last) is already sorted using comp and otherwise N log N, where N is last - first.

23.3.2.2 multimap operations

iterator find (const key_type & x);
const_iterator find (const key_type& x) const;

iterator lower_bound (const key_type& x);
const_iterator lower_bound (const key_type& x) const;

pair<iterator , iterator>
equal_range (const key_type& x);
pair<const_iterator , const_iterator>
equal_range (const key_type& x) const;

1 The find, lower_bound, upper_bound, and equal_range member functions each have two versions, one const and one non-const. In each case the behavior of the two versions is identical except that the const version returns a const_iterator and the non-const version an iterator (23.1.2).
23.3.2.3 multimap specialized algorithms

```cpp
template <class Key, class T, class Compare, class Allocator>
void swap(multimap<Key,T,Compare,Allocator>& x,
          multimap<Key,T,Compare,Allocator>& y);
```

1. Effects:
   ```cpp
   x.swap(y);
   ```

23.3.3 Class template set

1. A `set` is a kind of associative container that supports unique keys (contains at most one of each key value) and provides for fast retrieval of the keys themselves. Class `set` supports bidirectional iterators.

2. A `set` satisfies all of the requirements of a container and of a reversible container (23.1), and of an associative container (23.1.2). A `set` also provides most operations described in (23.1.2) for unique keys. This means that a `set` supports the `a_uniq` operations in (23.1.2) but not the `a_eq` operations. For a `set<Key>` both the `key_type` and `value_type` are `Key`. Descriptions are provided here only for operations on `set` that are not described in one of these tables and for operations where there is additional semantic information.

```cpp
namespace std {
    template <class Key, class Compare = less<Key>,
              class Allocator = allocator<Key> >
    class set {
    public:
        // types:
        typedef Key key_type;
        typedef Key value_type;
        typedef Compare key_compare;
        typedef Compare value_compare;
        typedef Allocator allocator_type;
        typedef typename Allocator::reference reference;
        typedef typename Allocator::const_reference const_reference;
        typedef implementation-defined iterator;
        typedef implementation-defined const_iterator; // See 23.1
        typedef implementation-defined size_type; // See 23.1
        typedef implementation-defined difference_type; // See 23.1
        typedef typename Allocator::pointer pointer;
        typedef typename Allocator::const_pointer const_pointer;
        typedef std::reverse_iterator<iterator> reverse_iterator;
        typedef std::reverse_iterator<const_iterator> const_reverse_iterator;

        // 23.3.3.1 construct/copy/destroy:
        explicit set(const Compare& comp = Compare(),
                     const Allocator& = Allocator());
        template <class InputIterator>
        set(InputIterator first, InputIterator last,
            const Compare& comp = Compare(), const Allocator& = Allocator());
        set(const set<Key,Compare,Allocator>& x);
    }
}
```
```
~set();
set<Key,Compare,Allocator>& operator=(
(const set<Key,Compare,Allocator>& x);
allocator_type get_allocator() const;

// iterators:
iterator begin();
const_iterator begin() const;
iterator end();
const_iterator end() const;
reverse_iterator rbegin();
const_reverse_iterator rbegin() const;
reverse_iterator rend();
const_reverse_iterator rend() const;

// capacity:
bool empty() const;
size_type size() const;
size_type max_size() const;

// modifiers:
pair<iterator,bool> insert(const value_type& x);
iterator insert(iterator position, const value_type& x);
template <class InputIterator>
void insert(InputIterator first, InputIterator last);

iterator erase(iterator position);
size_type erase(const key_type& x);
iterator erase(iterator first, iterator last);
void swap(set<Key,Compare,Allocator>&);
void clear();

// observers:
key_compare key_comp() const;
value_compare value_comp() const;

// set operations:
iterator find(const key_type& x);
const_iterator find(const key_type& x) const;

size_type count(const key_type& x) const;

iterator lower_bound(const key_type& x);
const_iterator lower_bound(const key_type& x) const;

iterator upper_bound(const key_type& x);
const_iterator upper_bound(const key_type& x) const;

pair<iterator,iterator> equal_range(const key_type& x);
pair<const_iterator,const_iterator> equal_range(const key_type& x) const;
```
template <class Key, class Compare, class Allocator>
bool operator==(const set<Key, Compare, Allocator>& x,
              const set<Key, Compare, Allocator>& y);

template <class Key, class Compare, class Allocator>
bool operator<(const set<Key, Compare, Allocator>& x,
               const set<Key, Compare, Allocator>& y);

template <class Key, class Compare, class Allocator>
bool operator!=(const set<Key, Compare, Allocator>& x,
               const set<Key, Compare, Allocator>& y);

template <class Key, class Compare, class Allocator>
bool operator>(const set<Key, Compare, Allocator>& x,
               const set<Key, Compare, Allocator>& y);

template <class Key, class Compare, class Allocator>
bool operator>=(const set<Key, Compare, Allocator>& x,
                const set<Key, Compare, Allocator>& y);

template <class Key, class Compare, class Allocator>
bool operator<=(const set<Key, Compare, Allocator>& x,
                const set<Key, Compare, Allocator>& y);

// specialized algorithms:
template <class Key, class Compare, class Allocator>
void swap(set<Key, Compare, Allocator>& x,
          set<Key, Compare, Allocator>& y);

23.3.3.1 set constructors, copy, and assignment [lib.set.cons]

explicit set(const Compare& comp = Compare(),
             const Allocator& = Allocator());

Effects: Constructs an empty set using the specified comparison objects and allocator.

Complexity: Constant.

template <class InputIterator>
set(InputIterator first, InputIterator last,
    const Compare& comp = Compare(), const Allocator& = Allocator());

Effects: Constructs an empty set using the specified comparison object and allocator, and inserts elements from
the range [first, last).

Complexity: Linear in $N$ if the range $[first, last)$ is already sorted using $comp$ and otherwise $N \log N$, where
$N$ is $last - first$.

23.3.3.2 set specialized algorithms [lib.set.special]

template <class Key, class Compare, class Allocator>
void swap(set<Key, Compare, Allocator>& x,
Associative containers

set<Key,Compare,Allocator>& y);

Effects:

x.swap(y);

23.3.4 Class template multiset

A multiset is a kind of associative container that supports equivalent keys (possibly contains multiple copies of the same key value) and provides for fast retrieval of the keys themselves. Class multiset supports bidirectional iterators.

A multiset satisfies all of the requirements of a container and of a reversible container (23.1), and of an associative container (23.1.2). multiset also provides most operations described in (23.1.2) for duplicate keys. This means that a multiset supports the a_eq operations in (23.1.2) but not the a_uniq operations. For a multiset<Key> both the key_type and value_type are Key. Descriptions are provided here only for operations on multiset that are not described in one of these tables and for operations where there is additional semantic information.

namespace std {
    template <class Key, class Compare = less<Key>,
              class Allocator = allocator<Key> >
    class multiset {
        public:
            // types:
            typedef Key key_type;
            typedef Key value_type;

          multiset<Key,Compare,Allocator>& y);

23.3.4.1 multiset constructors

explicit multiset(const Compare& comp = Compare(),
                  const Allocator& = Allocator());

Effects: Constructs an empty set using the specified comparison object and allocator.

Complexity: Constant.

template <class InputIterator>
multiset(InputIterator first, last,
         const Compare& comp = Compare(), const Allocator& = Allocator());

Effects: Constructs an empty multiset using the specified comparison object and allocator, and inserts elements from the range [first, last).

Complexity: Linear in N if the range [first, last) is already sorted using comp and otherwise N log N, where N is last - first.

23.3.4.2 multiset specialized algorithms

template <class Key, class Compare, class Allocator>
void swap(multiset<Key,Compare,Allocator>& x,
          multiset<Key,Compare,Allocator>& y);

Effects:
The header `<bitset>` defines a class template and several related functions for representing and manipulating fixed-size sequences of bits.

```cpp
namespace std {
    template <size_t N> class bitset {
        public:
            // bit reference:
            class reference {
                friend class bitset;
                reference();
                public:
                    ~reference();
                    reference& operator=(bool x); // for b[i] = x;
                    reference& operator=(const reference&); // for b[i] = b[j];
                    bool operator~() const; // flips the bit
                    operator bool() const; // for x = b[i];
                    reference& flip(); // for b[i].flip();
            };
    } // 23.3.5.1 constructors:
```
The template class `bitset<N>` describes an object that can store a sequence consisting of a fixed number of bits, $N$. Each bit represents either the value zero (reset) or one (set). To toggle a bit is to change the value zero to one, or the value
one to zero. Each bit has a non-negative position \( pos \). When converting between an object of class \( \text{bitset}<N> \) and a value of some integral type, bit position \( pos \) corresponds to the bit value \( 1 << pos \). The integral value corresponding to two or more bits is the sum of their bit values.

The functions described in this subclause can report three kinds of errors, each associated with a distinct exception:

- an invalid-argument error is associated with exceptions of type \( \text{invalid_argument} \) (19.1.3);
- an out-of-range error is associated with exceptions of type \( \text{out_of_range} \) (19.1.5);
- an overflow error is associated with exceptions of type \( \text{overflow_error} \) (19.1.8).

### 23.3.5.2 bitset members

Draft
bitset\textless{}N\textgreater{}& operator\&=(\text{const} \ bitset\textless{}N\textgreater{}& \textit{rhs});

\textit{Effects:} Clears each bit in \textit{*this} for which the corresponding bit in \textit{rhs} is clear, and leaves all other bits unchanged.

\textit{Returns:} \textit{*this}.

bitset\textless{}N\textgreater{}& operator\|=\text{(const} \ bitset\textless{}N\textgreater{}& \textit{rhs});

\textit{Effects:} Sets each bit in \textit{*this} for which the corresponding bit in \textit{rhs} is set, and leaves all other bits unchanged.

\textit{Returns:} \textit{*this}.

bitset\textless{}N\textgreater{}& operator\^\text{=}(\text{const} \ bitset\textless{}N\textgreater{}& \textit{rhs});

\textit{Effects:} Toggles each bit in \textit{*this} for which the corresponding bit in \textit{rhs} is set, and leaves all other bits unchanged.

\textit{Returns:} \textit{*this}.

bitset\textless{}N\textgreater{}& operator\textless{}\textless{}=\text{(size}_t \ \textit{pos});

\textit{Effects:} Replaces each bit at position \textit{I} in \textit{*this} with a value determined as follows:
- If \textit{I} < \textit{pos}, the new value is zero;
- If \textit{I} >= \textit{pos}, the new value is the previous value of the bit at position \textit{I} - \textit{pos}.

\textit{Returns:} \textit{*this}.

bitset\textless{}N\textgreater{}& operator\geq\text{=(size}_t \ \textit{pos});

\textit{Effects:} Replaces each bit at position \textit{I} in \textit{*this} with a value determined as follows:
- If \textit{pos} >= \textit{N} - \textit{I}, the new value is zero;
- If \textit{pos} < \textit{N} - \textit{I}, the new value is the previous value of the bit at position \textit{I} + \textit{pos}.

\textit{Returns:} \textit{*this}.

bitset\textless{}N\textgreater{}& \textit{set}();

\textit{Effects:} Sets all bits in \textit{*this}.

\textit{Returns:} \textit{*this}.

bitset\textless{}N\textgreater{}& \textit{set(size}_t \ \textit{pos}, \ \textit{bool} \ \textit{val} = \text{true});

\textit{Requires:} \textit{pos} is valid

\textit{Throws:} \textit{out\_of\_range} if \textit{pos} does not correspond to a valid bit position.

\textit{Effects:} Stores a new value in the bit at position \textit{pos} in \textit{*this}. If \textit{val} is nonzero, the stored value is one, otherwise it is zero.

\textit{Returns:} \textit{*this}.

bitset\textless{}N\textgreater{}& \textit{reset}();

Draft
585  Containers library  23.3  Associative containers

Effects: Resets all bits in *this.

Returns: *this.

bitset<N>& reset(size_t pos);

Requires: pos is valid

Throws: out_of_range if pos does not correspond to a valid bit position.

Effects: Resets the bit at position pos in *this.

Returns: *this.

bitset<N> operator~() const;

Effects: Constructs an object \( x \) of class \( \text{bitset}<N> \) and initializes it with \*this.

Returns: \( x \).flip().

bitset<N>& flip();

Effects: Toggles all bits in *this.

Returns: *this.

bitset<N>& flip(size_t pos);

Requires: pos is valid

Throws: out_of_range if pos does not correspond to a valid bit position.

Effects: Toggles the bit at position pos in *this.

Returns: *this.

unsigned long to_ulong() const;

Throws: overflow_error if the integral value \( x \) corresponding to the bits in *this cannot be represented as type unsigned long.

Returns: \( x \).

template <class charT, class traits, class Allocator>
basic_string<charT, traits, Allocator> to_string() const;

Effects: Constructs a string object of the appropriate type and initializes it to a string of length \( N \) characters. Each character is determined by the value of its corresponding bit position in *this. Character position \( N - 1 \) corresponds to bit position zero. Subsequent decreasing character positions correspond to increasing bit positions. Bit value zero becomes the character 0, bit value one becomes the character 1.

Returns: The created object.

template <class charT, class traits>
basic_string<charT, traits, allocator<charT> > to_string() const;

Returns: to_string<charT, traits, allocator<charT> >().

Draft
template <class charT>
    basic_string<charT, char_traits<charT>, allocator<charT>> to_string() const;

Returns: to_string<charT, char_traits<charT>, allocator<charT>>().

basic_string<char, char_traits<char>, allocator<char>> to_string() const;

Returns: to_string<char, char_traits<char>, allocator<char>>().

size_t count() const;

Returns: A count of the number of bits set in *this.

size_t size() const;

Returns: N.

bool operator==(const bitset<N>& rhs) const;

Returns: A nonzero value if the value of each bit in *this equals the value of the corresponding bit in rhs.

bool operator!=(const bitset<N>& rhs) const;

Returns: A nonzero value if !(*this == rhs).

bool test(size_t pos) const;

Requires: pos is valid

Throws: out_of_range if pos does not correspond to a valid bit position.

Returns: true if the bit at position pos in *this has the value one.

bool any() const;

Returns: true if any bit in *this is one.

bool none() const;

Returns: true if no bit in *this is one.

bitset<N> operator<<(size_t pos) const;

Returns: bitset<N>(*this) <<= pos.

bitset<N> operator>>(size_t pos) const;

Returns: bitset<N>(*this) >>= pos.

bool operator[](size_t pos) const;

Requires: pos is valid.

Throws: nothing.

Returns: test(pos).

bitset<N>::reference operator[](size_t pos);
Requires: \( pos \) is valid.

Throws: nothing.

Returns: An object of type \( \text{bitset}\langle N\rangle::\text{reference} \) such that \((\ast\text{this})[pos] == \text{this}\rightarrow\text{test}(pos)\), and such that \((\ast\text{this})[pos] = \text{val} \) is equivalent to \( \text{this}\rightarrow\text{set}(pos, \text{val}) \).

\]
Chapter 24  Iterators library  [lib.iterators]

This clause describes components that C++ programs may use to perform iterations over containers (clause 23), streams (27.6), and stream buffers (27.5).

The following subclauses describe iterator requirements, and components for iterator primitives, predefined iterators, and stream iterators, as summarized in Table 71.

<table>
<thead>
<tr>
<th>Subclause</th>
<th>Header(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>24.1</td>
<td></td>
</tr>
<tr>
<td>24.3</td>
<td>&lt;iterator&gt;</td>
</tr>
<tr>
<td>24.4</td>
<td></td>
</tr>
<tr>
<td>24.5</td>
<td></td>
</tr>
</tbody>
</table>

### 24.1 Iterator requirements  [lib.iterator.requirements]

Iterators are a generalization of pointers that allow a C++ program to work with different data structures (containers) in a uniform manner. To be able to construct template algorithms that work correctly and efficiently on different types of data structures, the library formalizes not just the interfaces but also the semantics and complexity assumptions of iterators. All input iterators \( i \) support the expression \( *i \), resulting in a value of some class, enumeration, or built-in type \( T \), called the value type of the iterator. All output iterators support the expression \( *i = o \) where \( o \) is a value of some type that is in the set of types that are writable to the particular iterator type of \( i \). All iterators \( i \) for which the expression \( (*i).m \) is well-defined, support the expression \( i->m \) with the same semantics as \( (*i).m \). For every iterator type \( X \) for which equality is defined, there is a corresponding signed integral type called the difference type of the iterator.

Since iterators are an abstraction of pointers, their semantics is a generalization of most of the semantics of pointers in C++. This ensures that every function template that takes iterators works as well with regular pointers. This International Standard defines five categories of iterators, according to the operations defined on them: input iterators, output iterators, forward iterators, bidirectional iterators and random access iterators, as shown in Table 72.

<table>
<thead>
<tr>
<th>Random Access</th>
<th>Bidirectional</th>
<th>Forward</th>
<th>Input</th>
<th>Output</th>
</tr>
</thead>
</table>

Forward iterators satisfy all the requirements of the input and output iterators and can be used whenever either kind is specified; Bidirectional iterators also satisfy all the requirements of the forward iterators and can be used whenever a
forward iterator is specified; Random access iterators also satisfy all the requirements of bidirectional iterators and can be used whenever a bidirectional iterator is specified.

Besides its category, a forward, bidirectional, or random access iterator can also be mutable or constant depending on whether the result of the expression \( *i \) behaves as a reference or as a reference to a constant. Constant iterators do not satisfy the requirements for output iterators, and the result of the expression \( *i \) (for constant iterator \( i \)) cannot be used in an expression where an lvalue is required.

Just as a regular pointer to an array guarantees that there is a pointer value pointing past the last element of the array, so for any iterator type there is an iterator value that points past the last element of a corresponding container. These values are called past-the-end values. Values of an iterator \( i \) for which the expression \( *i \) is defined are called dereferenceable. The library never assumes that past-the-end values are dereferenceable. Iterators can also have singular values that are not associated with any container. [Example: After the declaration of an uninitialized pointer \( x \) (as with \( \text{int}^* \ x; \)), \( x \) must always be assumed to have a singular value of a pointer. — end example] Results of most expressions are undefined for singular values; the only exceptions are destroying an iterator that holds a singular value and the assignment of a non-singular value to an iterator that holds a singular value. In this case the singular value is overwritten the same way as any other value. Dereferenceable values are always non-singular.

An iterator \( j \) is called reachable from an iterator \( i \) if and only if there is a finite sequence of applications of the expression \( ++i \) that makes \( i == j \). If \( j \) is reachable from \( i \), they refer to the same container.

Most of the library’s algorithmic templates that operate on data structures have interfaces that use ranges. A range is a pair of iterators that designate the beginning and end of the computation. A range \( [i,i) \) is an empty range; in general, a range \( [i,j) \) refers to the elements in the data structure starting with the one pointed to by \( i \) and up to but not including the one pointed to by \( j \). Range \( [i,j) \) is valid if and only if \( j \) is reachable from \( i \). The result of the application of functions in the library to invalid ranges is undefined.

All the categories of iterators require only those functions that are realizable for a given category in constant time (amortized). Therefore, requirement tables for the iterators do not have a complexity column.

 Destruction of an iterator may invalidate pointers and references previously obtained from that iterator.

An invalid iterator is an iterator that may be singular. 259)

In the following sections, \( a \) and \( b \) denote values of type \( \text{const} \ X \), \( n \) denotes a value of the difference type \( \text{Distance} \), \( u \), \( \text{tmp} \), and \( m \) denote identifiers, \( x \) denotes a value of \( X^\& \), \( t \) denotes a value of value type \( T \), \( o \) denotes a value of some type that is writable to the output iterator.

24.1.1 Input iterators

A class or a built-in type \( X \) satisfies the requirements of an input iterator for the value type \( T \) if the following expressions are valid, where \( U \) is the type of any specified member of type \( T \), as shown in Table 73.

In Table 73, the term the domain of \( == \) is used in the ordinary mathematical sense to denote the set of values over which \( == \) is (required to be) defined. This set can change over time. Each algorithm places additional requirements on the domain of \( == \) for the iterator values it uses. These requirements can be inferred from the uses that algorithm makes of \( == \) and \(!==\). [Example: the call \( \text{find}(a,b,x) \) is defined only if the value of \( a \) has the property \( p \) defined as follows: \( b \) has property \( p \) and a value \( i \) has property \( p \) if \( *(i==x) \) or if \( *(i!=x \text{ and } ++i \text{ has property } p) \). — end example]

259) This definition applies to pointers, since pointers are iterators. The effect of dereferencing an iterator that has been invalidated is undefined.

Draft

</tr>
</tbody>
</table>

3 [Note: For input iterators, `a == b` does not imply `++a == ++b`. (Equality does not guarantee the substitution property or referential transparency.) Algorithms on input iterators should never attempt to pass through the same iterator twice. They should be single pass algorithms. Value type `T` is not required to be an Assignable type (23.1). These algorithms can be used with istreams as the source of the input data through the istream_iterator class. — end note]

24.1.2 Output iterators

A class or a built-in type `X` satisfies the requirements of an output iterator if `X` is a CopyConstructible (20.1.3) and Assignable type (23.1) and also the following expressions are valid, as shown in Table 74.

Table 74: Output iterator requirements

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return Type</th>
<th>Operational Semantics</th>
<th>Assertion/Note</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>X(a)</code></td>
<td></td>
<td><code>a = t</code> is equivalent to <code>X(a) = t</code>.</td>
<td>note: a destructor is assumed.</td>
</tr>
<tr>
<td><code>X u(a);</code></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>X u = a;</code></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>*r = o</code></td>
<td></td>
<td>result is not used</td>
<td></td>
</tr>
<tr>
<td><code>++r</code></td>
<td><code>X&amp;</code></td>
<td><code>kr == &amp;++r</code>.</td>
<td></td>
</tr>
</tbody>
</table>
### 24.1 Iterator requirements

<table>
<thead>
<tr>
<th>expression</th>
<th>return type</th>
<th>operational semantics</th>
<th>assertion/note</th>
</tr>
</thead>
<tbody>
<tr>
<td>r++</td>
<td>convertible to const X&amp;</td>
<td><code>{ X tmp = r; ++r; return tmp; }</code></td>
<td></td>
</tr>
<tr>
<td>*r++ = o</td>
<td>result is not used</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

2. [Note: The only valid use of an operator* is on the left side of the assignment statement. *Assignment through the same value of the iterator happens only once.* Algorithms on output iterators should never attempt to pass through the same iterator twice. They should be *single pass* algorithms. Equality and inequality might not be defined. Algorithms that take output iterators can be used with ostreems as the destination for placing data through the *ostream_iterator* class as well as with insert iterators and insert pointers. — end note ]

### 24.1.3 Forward iterators

A class or a built-in type *X* satisfies the requirements of a forward iterator if the following expressions are valid, as shown in Table 75.

**Table 75: Forward iterator requirements**

<table>
<thead>
<tr>
<th>expression</th>
<th>return type</th>
<th>operational semantics</th>
<th>assertion/note</th>
</tr>
</thead>
<tbody>
<tr>
<td>X u;</td>
<td>note: u might have a singular value. note: a destructor is assumed.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>X()</td>
<td>note: X() might be singular.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>X(a)</td>
<td>a == X(a)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>X u(a); X u = a;</td>
<td>X u; u = a; post: u == a.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>a == b</td>
<td>convertible to bool</td>
<td></td>
<td></td>
</tr>
<tr>
<td>a != b</td>
<td>convertible to bool</td>
<td></td>
<td></td>
</tr>
<tr>
<td>r = a</td>
<td>X&amp; post: r == a</td>
<td></td>
<td></td>
</tr>
<tr>
<td>*a</td>
<td>T if X is mutable, otherwise const T&amp;</td>
<td></td>
<td></td>
</tr>
<tr>
<td>a-&gt;m</td>
<td>U&amp; if X is mutable, otherwise const U&amp;</td>
<td></td>
<td></td>
</tr>
<tr>
<td>r-&gt;m</td>
<td>U&amp;</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Draft
### 24.1.4 Bidirectional iterators

A class or a built-in type \( X \) satisfies the requirements of a bidirectional iterator if, in addition to satisfying the requirements for forward iterators, the following expressions are valid as shown in Table 76.

Table 76: Bidirectional iterator requirements (in addition to forward iterator)

<table>
<thead>
<tr>
<th>expression</th>
<th>return type</th>
<th>operational semantics</th>
<th>assertion/note pre/post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>++r</td>
<td>( X &amp; )</td>
<td>pre: ( r ) is dereferenceable. post: ( r ) is dereferenceable or ( r ) is past-the-end. ( r == s ) and ( r ) is dereferenceable implies ( ++r == ++s ). ( kr == &amp;++r ).</td>
<td></td>
</tr>
<tr>
<td>r++</td>
<td>convertible to ( )</td>
<td>( { X ; \text{tmp} = r; ++r; \text{return tmp; } } )</td>
<td></td>
</tr>
<tr>
<td>*r++</td>
<td>( T &amp; ) if ( X ) is mutable, otherwise ( const ) ( T &amp; )</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

---

2 [Note: The condition that \( a == b \) implies \( ++a == ++b \) (which is not true for input and output iterators) and the removal of the restrictions on the number of the assignments through the iterator (which applies to output iterators) allows the use of multi-pass one-directional algorithms with forward iterators. — end note]
24.1.5 Random access iterators

A class or a built-in type \( X \) satisfies the requirements of a random access iterator if, in addition to satisfying the requirements for bidirectional iterators, the following expressions are valid as shown in Table 77.

Table 77: Random access iterator requirements (in addition to bidirectional iterator)

<table>
<thead>
<tr>
<th>expression</th>
<th>return type</th>
<th>operational semantics</th>
<th>assertion/note</th>
</tr>
</thead>
</table>
| \( r += n \) | \( X \& \) | \( \{ \text{Distance } m = n; \)

    class ostreambuf_iterator;
24.3 Iterator primitives

To simplify the task of defining iterators, the library provides several classes and functions:

24.3.1 Iterator traits

To implement algorithms only in terms of iterators, it is often necessary to determine the value and difference types that correspond to a particular iterator type. Accordingly, it is required that if `Iterator` is the type of an iterator, the types

\[
\begin{align*}
\text{iterator_traits}<\text{Iterator}>::\text{difference_type} \\
\text{iterator_traits}<\text{Iterator}>::\text{value_type} \\
\text{iterator_traits}<\text{Iterator}>::\text{iterator_category}
\end{align*}
\]

be defined as the iterator’s difference type, value type and iterator category, respectively. In addition, the types

\[
\begin{align*}
\text{iterator_traits}<\text{Iterator}>::\text{reference} \\
\text{iterator_traits}<\text{Iterator}>::\text{pointer}
\end{align*}
\]

shall be defined as the iterator’s reference and pointer types, that is, for an iterator object `a`, the same type as the type of `*a` and `a->`, respectively. In the case of an output iterator, the types

\[
\begin{align*}
\text{iterator_traits}<\text{Iterator}>::\text{difference_type} \\
\text{iterator_traits}<\text{Iterator}>::\text{value_type} \\
\text{iterator_traits}<\text{Iterator}>::\text{reference} \\
\text{iterator_traits}<\text{Iterator}>::\text{pointer}
\end{align*}
\]

may be defined as `void`.

The template `iterator_traits<Iterator>` is defined as

```cpp
namespace std {
    template<class Iterator> struct iterator_traits {
        typedef typename Iterator::difference_type difference_type;
        typedef typename Iterator::value_type value_type;
        typedef typename Iterator::pointer pointer;
        typedef typename Iterator::reference reference;
        typedef typename Iterator::iterator_category iterator_category;
    };
}
```

It is specialized for pointers as

```cpp
namespace std {
    template<class T> struct iterator_traits<T*> {
        typedef ptrdiff_t difference_type;
        typedef T value_type;
        typedef T* pointer;
        typedef T& reference;
        typedef random_access_iterator_tag iterator_category;
    };
}
```

and for pointers to const as

Draft
24.3 Iterator primitives

namespace std {
    template <class T> struct iterator_traits<const T*> {
        typedef ptrdiff_t difference_type;
        typedef T value_type;
        typedef const T* pointer;
        typedef const T& reference;
        typedef random_access_iterator_tag iterator_category;
    };
}

Note: If there is an additional pointer type __far such that the difference of two __far is of type long, an implementation may define

    template <class T> struct iterator_traits<T__far*> {
        typedef long difference_type;
        typedef T value_type;
        typedef T__far* pointer;
        typedef T__far& reference;
        typedef random_access_iterator_tag iterator_category;
    };

— end note ]

Example: To implement a generic reverse function, a C++ program can do the following:

    template <class BidirectionalIterator>
    void reverse(BidirectionalIterator first, BidirectionalIterator last) {
        typename iterator_traits<BidirectionalIterator>::difference_type n =
            distance(first, last);
        --n;
        while(n > 0) {
            typename iterator_traits<BidirectionalIterator>::value_type
                tmp = *first;
            *first++ = *--last;
            *last = tmp;
            n -= 2;
        }
    }

— end example ]

24.3.2 Basic iterator

The iterator template may be used as a base class to ease the definition of required types for new iterators.

namespace std {
    template <class Category, class T, class Distance = ptrdiff_t,
              class Pointer = T*, class Reference = T&>
    struct iterator {
        typedef T value_type;
        typedef Distance difference_type;
        typedef Pointer pointer;
    }
    Draft
It is often desirable for a function template specialization to find out what is the most specific category of its iterator argument, so that the function can select the most efficient algorithm at compile time. To facilitate this, the library introduces category tag classes which are used as compile time tags for algorithm selection. They are: `input_iterator_tag`, `output_iterator_tag`, `forward_iterator_tag`, `bidirectional_iterator_tag` and `random_access_iterator_tag`. For every iterator of type `Iterator`, `iterator_traits<Iterator>::iterator_category` shall be defined to be the most specific category tag that describes the iterator’s behavior.

```cpp
namespace std {
  struct input_iterator_tag {}
  struct output_iterator_tag {}
  struct forward_iterator_tag : public input_iterator_tag {}
  struct bidirectional_iterator_tag : public forward_iterator_tag {}
  struct random_access_iterator_tag : public bidirectional_iterator_tag {}
}
```

**Example:** For a program-defined iterator `BinaryTreeIterator`, it could be included into the bidirectional iterator category by specializing the `iterator_traits` template:

```cpp
template <class T> struct iterator_traits<BinaryTreeIterator<T>> {
  typedef std::ptrdiff_t difference_type;
  typedef T value_type;
  typedef T* pointer;
  typedef T& reference;
  typedef bidirectional_iterator_tag iterator_category;
};
```

Typically, however, it would be easier to derive `BinaryTreeIterator<T>` from `iterator<bidirectional_iterator_tag,T,ptrdiff_t,T*,T&>`. — end example]

**Example:** If `evolve()` is well defined for bidirectional iterators, but can be implemented more efficiently for random access iterators, then the implementation is as follows:

```cpp
template <class BidirectionalIterator>
inline void evolve(BidirectionalIterator first, BidirectionalIterator last) {
  evolve(first, last,
         typename iterator_traits<BidirectionalIterator>::iterator_category());
}

template <class BidirectionalIterator>
void evolve(BidirectionalIterator first, BidirectionalIterator last,
            bidirectional_iterator_tag) {
  // ... more generic, but less efficient algorithm
}
```

Draft
24.4 Predefined iterators

template <class RandomAccessIterator>
void evolve(RandomAccessIterator first, RandomAccessIterator last, 
            random_access_iterator_tag) {
    // ... more efficient, but less generic algorithm
}

— end example ]

[ Example: If a C++ program wants to define a bidirectional iterator for some data structure containing double and such that it works on a large memory model of the implementation, it can do so with:

class MyIterator :
    public iterator<bidirectional_iterator_tag, double, long, T*, T&> {
        // code implementing ++, etc.
    };

Then there is no need to specialize the iterator_traits template. — end example ]

24.3.4 Iterator operations

1 Since only random access iterators provide + and - operators, the library provides two function templates advance and distance. These function templates use + and - for random access iterators (and are, therefore, constant time for them); for input, forward and bidirectional iterators they use ++ to provide linear time implementations.

    template <class InputIterator, class Distance>
    void advance(InputIterator & i, Distance n);

2 Requires: n may be negative only for random access and bidirectional iterators.

3 Effects: Increments (or decrements for negative n) iterator reference i by n.

    template<class InputIterator>
    typename iterator_traits<InputIterator>::difference_type
    distance(InputIterator first, InputIterator last);

4 Effects: Returns the number of increments or decrements needed to get from first to last.

5 Requires: last shall be reachable from first.

24.4 Predefined iterators

24.4.1 Reverse iterators

1 Bidirectional and random access iterators have corresponding reverse iterator adaptors that iterate through the data structure in the opposite direction. They have the same signatures as the corresponding iterators. The fundamental relation between a reverse iterator and its corresponding iterator i is established by the identity: &*(reverse_iterator(i)) == &*(i - 1).

2 This mapping is dictated by the fact that while there is always a pointer past the end of an array, there might not be a valid pointer before the beginning of an array.

24.4.1.1 Class template reverse_iterator

Draft
namespace std {

template < class Iterator >
class reverse_iterator : public
    iterator<
        typename iterator_traits<Iterator>::iterator_category,
        typename iterator_traits<Iterator>::value_type,
        typename iterator_traits<Iterator>::difference_type,
        typename iterator_traits<Iterator>::pointer,
        typename iterator_traits<Iterator>::reference > {

protected:
    Iterator current;

public:
    typedef Iterator
        iterator_type;
    typedef typename iterator_traits<Iterator>::difference_type
        difference_type;
    typedef typename iterator_traits<Iterator>::reference
        reference;
    typedef typename iterator_traits<Iterator>::pointer
        pointer;

    reverse_iterator();
    explicit reverse_iterator(Iterator x);
    template < class U > reverse_iterator(const reverse_iterator<U>& u);

    Iterator base() const; // explicit
    reference operator*() const;
    pointer operator->() const;

    reverse_iterator& operator++();
    reverse_iterator operator++(int);
    reverse_iterator& operator--();
    reverse_iterator operator--(int);

    reverse_iterator operator+ (difference_type n) const;
    reverse_iterator& operator+=(difference_type n);
    reverse_iterator operator- (difference_type n) const;
    reverse_iterator& operator-=(difference_type n);
    unspecified operator[](difference_type n) const;
};

template < class Iterator >
bool operator==(
    const reverse_iterator<Iterator>& x,
    const reverse_iterator<Iterator>& y);

template < class Iterator >
bool operator<(
    const reverse_iterator<Iterator>& x,
    const reverse_iterator<Iterator>& y);

Draft
template <class Iterator>
bool operator !=(
    const reverse_iterator<Iterator>& x,
    const reverse_iterator<Iterator>& y);

template <class Iterator>
bool operator >(
    const reverse_iterator<Iterator>& x,
    const reverse_iterator<Iterator>& y);

template <class Iterator>
bool operator >=(
    const reverse_iterator<Iterator>& x,
    const reverse_iterator<Iterator>& y);

template <class Iterator>
bool operator <=(
    const reverse_iterator<Iterator>& x,
    const reverse_iterator<Iterator>& y);

template <class Iterator>
type_name reverse_iterator<Iterator>::difference_type operator -(
    const reverse_iterator<Iterator>& x,
    const reverse_iterator<Iterator>& y);

template <class Iterator>
reverse_iterator<Iterator> operator +( 
    typename reverse_iterator<Iterator>::difference_type n, 
    const reverse_iterator<Iterator>& x);

24.4.1.2 reverse_iterator requirements

1 The template parameter Iterator shall meet all the requirements of a Bidirectional Iterator (24.1.4).

2 Additionally, Iterator shall meet the requirements of a Random Access Iterator (24.1.5) if any of the members operator+ (24.4.1.3.7), operator- (24.4.1.3.9), operator+= (24.4.1.3.8), operator-= (24.4.1.3.10), operator [] (24.4.1.3.11), or the global operators operator< (24.4.1.3.13), operator> (24.4.1.3.15), operator <= (24.4.1.3.17), operator>= (24.4.1.3.16), operator~ (24.4.1.3.18) or operator+ (24.4.1.3.19). is referenced in a way that requires instantiation (14.7.1).

24.4.1.3 reverse_iterator operations

24.4.1.3.1 reverse_iterator constructor

reverse_iterator();

1 **Effects:** Default initializes current. Iterator operations applied to the resulting iterator have defined behavior if and only if the corresponding operations are defined on a default constructed iterator of type Iterator.

explicit reverse_iterator(Iterator x);
24.4.1.3.2 Conversion

**Iterator base() const;** // explicit

Returns: current.

24.4.1.3.3 operator*

**reference operator*() const;**

Effects:

```
  this->tmp = current;
  --this->tmp;
  return *this->tmp;
```

Note: This operation must use an auxiliary member variable, rather than a temporary variable, to avoid returning a reference that persists beyond the lifetime of its associated iterator. (See 24.1.) The name of this member variable is shown for exposition only. — end note]

24.4.1.3.4 operator->

**pointer operator->() const;**

Effects:

```
  return &(operator*());
```

24.4.1.3.5 operator++

**reverse_iterator& operator++();**

Effects: --current;

Returns: *this.

**reverse_iterator operator++(int);**

Effects:

```
  reverse_iterator tmp = *this;
  --current;
  return tmp;
```
24.4.1.3.6 operator--

reverse_iterator& operator--();

1   Effects: ++current
2   Returns: *this.

reverse_iterator operator--(int);

3   Effects:
    reverse_iterator tmp = *this;
    ++current;
    return tmp;

24.4.1.3.7 operator+

reverse_iterator
operator+(typename reverse_iterator<Iterator>::difference_type n) const;

1   Returns: reverse_iterator(current-n).

24.4.1.3.8 operator+=

reverse_iterator&
operator+=(typename reverse_iterator<Iterator>::difference_type n);

1   Effects: current -= n;
2   Returns: *this.

24.4.1.3.9 operator-

reverse_iterator
operator-(typename reverse_iterator<Iterator>::difference_type n) const;

1   Returns: reverse_iterator(current+n).

24.4.1.3.10 operator-=

reverse_iterator&
operator-=(typename reverse_iterator<Iterator>::difference_type n);

1   Effects: current += n;
2   Returns: *this.
24.4.1.3.11 operator[]

\textit{unspecified}

operator[](typename reverse_iterator<Iterator>::difference_type n) const;\nonumber

*Returns:* current[-n-1].

24.4.1.3.12 operator==

\textit{template <class Iterator>}

bool operator==(const reverse_iterator<Iterator>& x, const reverse_iterator<Iterator>& y);

*Returns:* x.current == y.current.

24.4.1.3.13 operator<

\textit{template <class Iterator>}

bool operator<(const reverse_iterator<Iterator>& x, const reverse_iterator<Iterator>& y);

*Returns:* x.current > y.current.

24.4.1.3.14 operator!=

\textit{template <class Iterator>}

bool operator!=(const reverse_iterator<Iterator>& x, const reverse_iterator<Iterator>& y);

*Returns:* x.current != y.current.

24.4.1.3.15 operator>

\textit{template <class Iterator>}

bool operator>(const reverse_iterator<Iterator>& x, const reverse_iterator<Iterator>& y);

*Returns:* x.current < y.current.

24.4.1.3.16 operator>=

\textit{template <class Iterator>}

bool operator>=(const reverse_iterator<Iterator>& x, const reverse_iterator<Iterator>& y);

*Returns:* x.current >= y.current.
template <class Iterator>
    bool operator>=(
        const reverse_iterator<Iterator>& x,
        const reverse_iterator<Iterator>& y);

Returns: x.current <= y.current.

24.4.1.3.17 operator<=

[lib.reverse.iter.op<=]

template <class Iterator>
    bool operator<=(
        const reverse_iterator<Iterator>& x,
        const reverse_iterator<Iterator>& y);

Returns: x.current >= y.current.

24.4.1.3.18 operator-

[lib.reverse.iter.opdiff]

template <class Iterator>
    typename reverse_iterator<Iterator>::difference_type operator-(
        const reverse_iterator<Iterator>& x,
        const reverse_iterator<Iterator>& y);

Returns: y.current - x.current.

24.4.1.3.19 operator+

[lib.reverse.iter.opsum]

template <class Iterator>
    reverse_iterator<Iterator> operator+(n,
            typename reverse_iterator<Iterator>::difference_type n,
            const reverse_iterator<Iterator>& x);

Returns: reverse_iterator<Iterator> (x.current - n).

24.4.2 Insert iterators

[lib.insert.iterators]

To make it possible to deal with insertion in the same way as writing into an array, a special kind of iterator adaptors, called insert iterators, are provided in the library. With regular iterator classes,

    while (first != last) *result++ = *first++;

causes a range [first, last) to be copied into a range starting with result. The same code with result being an insert iterator will insert corresponding elements into the container. This device allows all of the copying algorithms in the library to work in the insert mode instead of the regular overwrite mode.

An insert iterator is constructed from a container and possibly one of its iterators pointing to where insertion takes place if it is neither at the beginning nor at the end of the container. Insert iterators satisfy the requirements of output iterators.

Draft
allow writing into them, it inserts x right before where the insert iterator is pointing. In other words, an insert iterator is like a cursor pointing into the container where the insertion takes place. back_insert_iterator inserts elements at the end of a container, front_insert_iterator inserts elements at the beginning of a container, and insert_iterator inserts elements where the iterator points to in a container. back_inserter, front_inserter, and inserter are three functions making the insert iterators out of a container.

24.4.2.1 Class template back_insert_iterator

```cpp
namespace std {
    template < class Container >
    class back_insert_iterator :
        public iterator<output_iterator_tag,void,void,void,void> {

    private:
        Container* container;

    public:
        typedef Container container_type;
        explicit back_insert_iterator(Container& x);
        back_insert_iterator<Container>&
        operator=(typename Container::const_reference value);

        back_insert_iterator<Container>& operator*();
        back_insert_iterator<Container>& operator++();
        back_insert_iterator<Container>    operator++(int);
    }

    template < class Container >
    back_insert_iterator<Container> back_inserter(Container& x);
}
```

24.4.2.2 back_insert_iterator operations

24.4.2.2.1 back_insert_iterator constructor

```cpp
explicit back_insert_iterator(Container& x);
```

Effects: Initializes container with &x.

24.4.2.2.2 back_insert_iterator::operator=

```cpp
back_insert_iterator<Container>&
operator=(typename Container::const_reference value);
```

Effects: container->push_back(value);

Returns: *this.

24.4.2.2.3 back_insert_iterator::operator*

```cpp
back_insert_iterator<Container>& operator*();
```

Draft
24.4 Predefined iterators

24.4.2.2.4 back_insert_iterator::operator++

Back_insert_iterator & operator ++();
back_insert_iterator & operator ++(int);

Returns: *this.

24.4.2.2.5 back_inserter

template <class Container>
    back_insert_iterator<Container> back_inserter(Container & x);

Returns: back_insert_iterator<Container>(x).

24.4.2.3 Class template front_insert_iterator

namespace std {
    template <class Container>
    class front_insert_iterator:
        public iterator<output_iterator_tag,void,void,void,void> {
        protected:
            Container * container;

        public:
            typedef Container container_type;
            explicit front_insert_iterator(Container & x);
            front_insert_iterator &
                operator=(typename Container::const_reference value);
            front_insert_iterator & operator*();
            front_insert_iterator &
                operator++();
            front_insert_iterator &
                operator++(int);
        }

    template <class Container>
        front_insert_iterator<Container> front_inserter(Container & x);
}

24.4.2.4 front_insert_iterator operations

24.4.2.4.1 front_insert_iterator constructor

explicit front_insert_iterator(Container & x);

Effects: Initializes container with kx.
24.4.2.4.2  front_insert_iterator::operator=

front_insert_iterator<Container>&
operator=(typename Container::const_reference value);

Effects: container->push_front(value);

Returns: *this.

24.4.2.4.3  front_insert_iterator::operator*

front_insert_iterator<Container>& operator*();

Returns: *this.

24.4.2.4.4  front_insert_iterator::operator++

front_insert_iterator<Container>& operator++();
front_insert_iterator<Container> operator++(int);

Returns: *this.

24.4.2.4.5  front_inserter

template <class Container>
front_insert_iterator<Container> front_inserter(Container& x);

Returns: front_insert_iterator<Container>(x).

24.4.2.5  Class template insert_iterator

namespace std {
    template <class Container>
    class insert_iterator :
        public iterator<output_iterator_tag, void, void, void, void> {
            protected:
                Container* container;
                typename Container::iterator iter;

            public:
                typedef Container container_type;
                insert_iterator(Container& x, typename Container::iterator i);
                insert_iterator<Container>&
                    operator=(typename Container::const_reference value);

                insert_iterator<Container>& operator*();
                insert_iterator<Container>& operator++();
                insert_iterator<Container>& operator++(int);

        }
template <class Container, class Iterator>
    insert_iterator<Container> inserter(Container& x, Iterator i);

24.4.2.6 insert_iterator operations [lib.insert.iter.ops]

24.4.2.6.1 insert_iterator constructor [lib.insert.iter.cons]

    insert_iterator(Container& x, typename Container::iterator i);
    
    Effects: Initializes container with &x and iter with i.

24.4.2.6.2 insert_iterator::operator= [lib.insert.iter.op=]

    insert_iterator<Container>& operator=(typename Container::const_reference value);
    
    Effects:
    iter = container->insert(iter, value);
    ++iter;

    Returns: *this.

24.4.2.6.3 insert_iterator::operator* [lib.insert.iter.op*]

    insert_iterator<Container>& operator*();

    Returns: *this.

24.4.2.6.4 insert_iterator::operator++ [lib.insert.iter.op++]

    insert_iterator<Container>& operator++();
    insert_iterator<Container>& operator++(int);

    Returns: *this.

24.4.2.6.5 inserter [lib.inserter]

    template <class Container, class Inserter>
    insert_iterator<Container> inserter(Container& x, Inserter i);

    Returns: insert_iterator<Container>(x,typename Container::iterator(i)).
To make it possible for algorithmic templates to work directly with input/output streams, appropriate iterator-like class templates are provided.

Example:

```cpp
partial_sum_copy(istream_iterator<double, char>(cin),
                istream_iterator<double, char>(),
                ostream_iterator<double, char>(cout, "\n");
```

reads a file containing floating point numbers from `cin`, and prints the partial sums onto `cout`. — end example

24.5.1 Class template `istream_iterator`

`istream_iterator` reads (using `operator>>`) successive elements from the input stream for which it was constructed. After it is constructed, and every time `++` is used, the iterator reads and stores a value of `T`. If the end of stream is reached (`operator void*()` on the stream returns `false`), the iterator becomes equal to the `end-of-stream` iterator value. The constructor with no arguments `istream_iterator()` always constructs an end of stream input iterator object, which is the only legitimate iterator to be used for the end condition. The result of `operator*` on an end of stream is not defined. For any other iterator value a `const T*` is returned. The result of `operator->` on an end of stream is not defined. For any other iterator value a `const T*` is returned. It is impossible to store things into `istream iterators`. The main peculiarity of the `istream iterators` is the fact that `++` operators are not equality preserving, that is, `i == j` does not guarantee at all that `++i == ++j`. Every time `++` is used a new value is read.

The practical consequence of this fact is that `istream iterators` can be used only for one-pass algorithms, which actually makes perfect sense, since for multi-pass algorithms it is always more appropriate to use in-memory data structures.

Two end-of-stream iterators are always equal. An end-of-stream iterator is not equal to a non-end-of-stream iterator.

Two non-end-of-stream iterators are equal when they are constructed from the same stream.

```cpp
namespace std {
    template <class T, class charT = char, class traits = char_traits<charT>,
              class Distance = ptrdiff_t>
    class istream_iterator:
    public iterator<input_iterator_tag, T, Distance, const T*, const T&> {
    public:
        typedef charT char_type;
        typedef traits traits_type;
        typedef basic_istream<charT,traits> istream_type;
        istream_iterator();
        istream_iterator(istream_type& s);
        istream_iterator(const istream_iterator<T,charT,traits,Distance>& x);
        `istream_iterator();

        const T& operator*() const;
        const T* operator->() const;
        istream_iterator<T,charT,traits,Distance>& operator++();
        istream_iterator<T,charT,traits,Distance> operator++(int);
    private:
        // basic_istream<charT,traits>* in_stream;
    } // exposition only
    istream_iterator();
    istream_iterator(istream_type& s);
    istream_iterator(const istream_iterator<T,charT,traits,Distance>& x);
    `istream_iterator();
```

Draft

template <class T, class charT, class traits, class Distance>
bool operator==(const istream_iterator<T,charT,traits,Distance> &x,
const istream_iterator<T,charT,traits,Distance> &y);

Returns: \(x\.\text{in\_stream} == y\.\text{in\_stream}\).

Returns: \(!\left(x == y\right)\)

\section{Class template \texttt{ostream\_iterator}}

\texttt{ostream\_iterator} writes (using operator<<) successive elements onto the output stream from which it was constructed. If it was constructed with \texttt{char*} as a constructor argument, this string, called a \textit{delimiter string}, is written to the stream after every \(T\) is written. It is not possible to get a value out of the output iterator. Its only use is as an output iterator in situations like

\begin{verbatim}
while (first != last) *result ++ = *first ++;
\end{verbatim}

\texttt{ostream\_iterator} is defined as:

\begin{verbatim}
namespace std {
  template <class T, class charT = char, class traits = char_traits<charT> >
  class ostream_iterator;
  public:
    typedef charT char_type;
    typedef traits traits_type;
    typedef basic_ostream<charT,traits> ostream_type;
    ostream_iterator(ostream_type & s);
    ostream_iterator(ostream_type & s, const charT* delimiter);
    ostream_iterator(const ostream_iterator<T,charT,traits>& x);
    ~ostream_iterator();
    ostream_iterator<T,charT,traits>& operator=(const T& value);
    ostream_iterator<T,charT,traits>& operator*();
    ostream_iterator<T,charT,traits>& operator++();
    ostream_iterator<T,charT,traits>& operator++(int);
  private:
    // basic_ostream<charT,traits>* out_stream;
    // const charT* delim;
  };
}
\end{verbatim}

\subsection{ostream\_iterator constructors and destructor}

\texttt{ostream\_iterator(ostream\_type& s)};

\begin{verbatim}
Effects: Initializes out\_stream with \(s\) and delim with null.
\end{verbatim}

Draft
24.5 Stream iterators

The iterators library

24.5.2.2 ostream_iterator operations

\begin{verbatim}
ostream_iterator(ostream_type & s, const charT* delimiter);
\end{verbatim}

Effects: Initializes out_stream with \( s \) and delim with delimiter.

\begin{verbatim}
ostream_iterator(const ostream_iterator & z);
\end{verbatim}

Effects: Constructs a copy of \( z \).

\begin{verbatim}
~ostream_iterator();
\end{verbatim}

Effects: The iterator is destroyed.

\begin{verbatim}
ostream_iterator & operator=(const T& value);
\end{verbatim}

Effects:

\begin{verbatim}
  *out_stream << value;
  if(delim != 0) *out_stream << delim;
  return (*this);
\end{verbatim}

\begin{verbatim}
ostream_iterator & operator*();
\end{verbatim}

Returns: *this.

\begin{verbatim}
ostream_iterator & operator++();
ostream_iterator & operator++(int);
\end{verbatim}

Returns: *this.

24.5.3 Class template istreambuf_iterator

\begin{verbatim}
namespace std {
  template<class charT, class traits = char_traits<charT> >
  class istreambuf_iterator
    : public iterator<input_iterator_tag, charT, typename traits::off_type, charT*, charT> {
    public:
      typedef charT char_type;
      typedef traits traits_type;
      typedef typename traits::int_type int_type;
      typedef basic_streambuf<charT,traits> streambuf_type;
      typedef basic_istream<charT,traits> istream_type;

      class proxy; // exposition only

      public:
        istreambuf_iterator() throw();
        istreambuf_iterator(istream_type& s) throw();
        istreambuf_iterator(streambuf_type* s) throw();
    }
\end{verbatim}

Draft
The class template `istreambuf_iterator` reads successive `characters` from the streambuf for which it was constructed. `operator*` provides access to the current input character, if any. Each time `operator++` is evaluated, the iterator advances to the next input character. If the end of stream is reached (`streambuf_type::sgetc()` returns `traits::eof()`), the iterator becomes equal to the end of stream iterator value. The default constructor `istreambuf_iterator()` and the constructor `istreambuf_iterator(0)` both construct an end of stream iterator object suitable for use as an end-of-range.

The result of `operator*()` on an end of stream is undefined. For any other iterator value a `char_type` value is returned. It is impossible to assign a character via an input iterator.

Note that in the input iterators, `++` operators are not `equality preserving`, that is, `i == j` does not guarantee at all that `++i == ++j`. Every time `++` is evaluated a new value is used.

The practical consequence of this fact is that an `istreambuf_iterator` object can be used only for `one-pass algorithms`. Two end of stream iterators are always equal. An end of stream iterator is not equal to a non-end of stream iterator.

### 24.5.3.1 Class template `istreambuf_iterator::proxy`  

```cpp
namespace std {
    template <class charT, class traits = char_traits<charT> >
    class istreambuf_iterator< charT, traits >:: proxy {
        charT keep_; 
        basic_streambuf<charT, traits>* sbuf_; 
        proxy(charT c, 
            basic_streambuf<charT, traits>* sbuf) {
            keep_(c), sbuf_(sbuf) {}
        }
        public:
            charT operator*() { return keep_; } 
    }
}
```

Class `istreambuf_iterator< charT, traits >:: proxy` is for exposition only. An implementation is permitted to
provide equivalent functionality without providing a class with this name. Class istreambuf_iterator< charT, traits >::proxy provides a temporary placeholder as the return value of the post-increment operator (operator ++). It keeps the character pointed to by the previous value of the iterator for some possible future access to get the character.

### 24.5.3.2 istreambuf_iterator constructors

**istreambuf_iterator() throw();**

Effects: Constructs the end-of-stream iterator.

**istreambuf_iterator( basic_istream< charT, traits >& s ) throw();**

**istreambuf_iterator( basic_streambuf< charT, traits >* s ) throw();**

Effects: Constructs an istreambuf_iterator<> that uses the basic_streambuf<> object *(s.rdbuf()), or *s, respectively. Constructs an end-of-stream iterator if s.rdbuf() is null.

**istreambuf_iterator(const proxy& p) throw();**

Effects: Constructs a istreambuf_iterator<> that uses the basic_streambuf<> object pointed to by the proxy object’s constructor argument p.

### 24.5.3.3 istreambuf_iterator::operator* [[lib.istreambuf.iterator::op*]]

**charT operator*() const**

Returns: The character obtained via the streambuf member sbuf_->sgetc().

### 24.5.3.4 istreambuf_iterator::operator++ [[lib.istreambuf.iterator::op++]]

**istreambuf_iterator< charT, traits >& istreambuf_iterator< charT, traits >::operator++();**

Effects: sbuf_->sbumpc().

Returns: *this.

**proxy istreambuf_iterator< charT, traits >::operator++(int);**

Returns: proxy(sbuf_->sbumpc(), sbuf_).

### 24.5.3.5 istreambuf_iterator::equal [[lib.istreambuf.iterator::equal]]

**bool equal( istreambuf_iterator< charT, traits >& b ) const ;**

Returns: true if and only if both iterators are at end-of-stream, or neither is at end-of-stream, regardless of what streambuf object they use.
24.5.3.6 operator==

```cpp
template < class charT , class traits >
bool operator==( const istreambuf_iterator< charT , traits >& a,
                 const istreambuf_iterator< charT , traits >& b);
```

1. *Returns:* `a.equal(b)`.

24.5.3.7 operator!=

```cpp
template < class charT , class traits >
bool operator!=( const istreambuf_iterator< charT , traits >& a,
                 const istreambuf_iterator< charT , traits >& b);
```

1. *Returns:* `!a.equal(b)`.

24.5.4 Class template ostreambuf_iterator

```cpp
namespace std {
    template < class charT , class traits = char_traits< charT > >
    class ostreambuf_iterator:
        public iterator< output_iterator_tag , void , void , void , void > {
        public:
            typedef charT char_type;
            typedef traits traits_type;
            typedef basic_streambuf< charT , traits > streambuf_type;
            typedef basic_ostream< charT , traits > ostream_type;

            public:
                ostreambuf_iterator( ostream_type & s ) throw();
                ostreambuf_iterator( streambuf_type* s ) throw();
                ostreambuf_iterator& operator=( charT c );

                ostreambuf_iterator& operator*();
                ostreambuf_iterator& operator++();
                ostreambuf_iterator& operator++( int );
                bool failed() const throw();

            private:
                // streambuf_type* sbuf_; 
                exposition only
        }
    }
```

1. The class template `ostreambuf_iterator` writes successive *characters* onto the output stream from which it was constructed. It is not possible to get a character value out of the output iterator.

24.5.4.1 ostreambuf_iterator constructors

```
Draft
24.5 Stream iterators

`ostreambuf_iterator(ostream_type& s) throw();`

1. Requires: `s.rdbuf()` is not null.
2. Effects: `sbuf_(``s.rdbuf()``) {}.

`ostreambuf_iterator(streambuf_type* s) throw();`

3. Requires: `s` is not null.
4. Effects: `sbuf_(``s`) {}.

24.5.4.2 ostreambuf_iterator operations [lib.ostreambuf.iter.ops]

`ostreambuf_iterator<charT,traits>& operator=(charT c);`

1. Effects: If `failed()` yields false, calls `sbuf_->sputc(c)`; otherwise has no effect.
2. Returns: *this.

`ostreambuf_iterator<charT,traits>& operator*();`

3. Returns: *this.

`ostreambuf_iterator<charT,traits>& operator++();`

`ostreambuf_iterator<charT,traits>& operator++(int);`

4. Returns: *this.

`bool failed() const throw();`

5. Returns: true if in any prior use of member operator=, the call to `sbuf_->sputc()` returned traits::eof(); or false otherwise.
Chapter 25 Algorithms library [lib.algorithms]

1. This clause describes components that C++ programs may use to perform algorithmic operations on containers (clause 23) and other sequences.

2. The following subclauses describe components for non-modifying sequence operation, modifying sequence operations, sorting and related operations, and algorithms from the ISO C library, as summarized in Table 78.

<table>
<thead>
<tr>

All of the algorithms are separated from the particular implementations of data structures and are parameterized by iterator types. Because of this, they can work with program-defined data structures, as long as these data structures have iterator types satisfying the assumptions on the algorithms.

Throughout this clause, the names of template parameters are used to express type requirements. If an algorithm’s template parameter is InputIterator, InputIterator1, or InputIterator2, the actual template argument shall satisfy the requirements of an input iterator (24.1.1). If an algorithm’s template parameter is OutputIterator, OutputIterator1, or OutputIterator2, the actual template argument shall satisfy the requirements of an output iterator (24.1.2). If an algorithm’s template parameter is ForwardIterator, ForwardIterator1, or ForwardIterator2,
the actual template argument shall satisfy the requirements of a forward iterator (24.1.3). If an algorithm’s template parameter is `BidirectionalIterator`, `BidirectionalIterator1`, or `BidirectionalIterator2`, the actual template argument shall satisfy the requirements of a bidirectional iterator (24.1.4). If an algorithm’s template parameter is `RandomAccessIterator`, `RandomAccessIterator1`, or `RandomAccessIterator2`, the actual template argument shall satisfy the requirements of a random-access iterator (24.1.5).

If an algorithm’s **Effects** section says that a value pointed to by any iterator passed as an argument is modified, then that algorithm has an additional type requirement: The type of that argument shall satisfy the requirements of a mutable iterator (24.1). [Note: this requirement does not affect arguments that are declared as `OutputIterator`, `OutputIterator1`, or `OutputIterator2`, because output iterators must always be mutable. —end note]

Both in-place and copying versions are provided for certain algorithms. When such a version is provided for algorithm it is called `algorithm_copy`. Algorithms that take predicates end with the suffix `_if` (which follows the suffix `_copy`).

The `Predicate` parameter is used whenever an algorithm expects a function object that when applied to the result of dereferencing the corresponding iterator returns a value testable as `true`. In other words, if an algorithm takes `Predicate pred` as its argument and `first` as its iterator argument, it should work correctly in the construct `if (pred(*first)){{...}}`. The function object `pred` shall not apply any non-constant function through the dereferenced iterator. This function object may be a pointer to function, or an object of a type with an appropriate function call operator.

The `BinaryPredicate` parameter is used whenever an algorithm expects a function object that when applied to the result of dereferencing two corresponding iterators or to dereferencing an iterator and type `T` when `T` is part of the signature returns a value testable as `true`. In other words, if an algorithm takes `BinaryPredicate binary_pred` as its argument and `first1` and `first2` as its iterator arguments, it should work correctly in the construct `if (binary_pred(*first1, *first2)){{...}}`. `BinaryPredicate` always takes the first iterator type as its first argument, that is, in those cases when `T value` is part of the signature, it should work correctly in the context of if `(binary_pred(*first1, value)){{...}}`. `binary_pred` shall not apply any non-constant function through the dereferenced iterators.

[Note: Unless otherwise specified, algorithms that take function objects as arguments are permitted to copy those function objects freely. Programmers for whom object identity is important should consider using a wrapper class that points to a noncopied implementation object, or some equivalent solution. —end note]

When the description of an algorithm gives an expression such as `*first == value` for a condition, the expression shall evaluate to either true or false in boolean contexts.

In the description of the algorithms operators `+` and `-` are used for some of the iterator categories for which they do not have to be defined. In these cases the semantics of `a+n` is the same as that of

```c
{ X tmp = a;
    advance(tmp, n);
    return tmp;
}
```

and that of `b-a` is the same as of

260) The decision whether to include a copying version was usually based on complexity considerations. When the cost of doing the operation dominates the cost of copy, the copying version is not included. For example, `sort_copy` is not included because the cost of sorting is much more significant, and users might as well do `copy` followed by `sort`.

Draft
25.1 Non-modifying sequence operations

25.1.1 For each

```cpp
template< class InputIterator , class Function >
    Function for_each(InputIterator first, InputIterator last, Function f);
```

1. Effects: Applies \( f \) to the result of dereferencing every iterator in the range \([first, last)\), starting from \( first \) and proceeding to \( last - 1 \).
2. Returns: \( f \).
3. Complexity: Applies \( f \) exactly \( last - first \) times.
4. Remarks: If \( f \) returns a result, the result is ignored.

25.1.2 Find

```cpp
template< class InputIterator , class T>
    InputIterator find(InputIterator first, InputIterator last, const T& value);
```

```
template< class InputIterator , class Predicate >
    InputIterator find_if(InputIterator first, InputIterator last, Predicate pred);
```

1. Returns: The first iterator \( i \) in the range \([first, last)\) for which the following corresponding conditions hold: 
   \( *i == value \), \( pred(*i) != false \). Returns \( last \) if no such iterator is found.
2. Complexity: At most \( last - first \) applications of the corresponding predicate.

25.1.3 Find End

```cpp
template< class ForwardIterator1 , class ForwardIterator2 >
    ForwardIterator1 find_end(ForwardIterator1 first1, ForwardIterator1 last1,
        ForwardIterator2 first2, ForwardIterator2 last2);
```

```
template< class ForwardIterator1 , class ForwardIterator2 ,
    class BinaryPredicate >
    ForwardIterator1 find_end(ForwardIterator1 first1, ForwardIterator1 last1,
        ForwardIterator2 first2, ForwardIterator2 last2,
        BinaryPredicate pred);
```

1. Effects: Finds a subsequence of equal values in a sequence.
25.1 Non-modifying sequence operations

Returns: The last iterator \( i \) in the range \([first1, last1 - (last2 - first2))\) such that for any non-negative integer \( n < (last2 - first2) \), the following corresponding conditions hold: \( *(i + n) == *(first2 + n) \), \( \text{pred}(*(i + n), *(first2 + n)) != false \). Returns \( last1 \) if no such iterator is found.

Complexity: At most \((last2 - first2) * (last1 - first1 - (last2 - first2) + 1)\) applications of the corresponding predicate.

25.1.4 Find First

\[
\begin{align*}
\text{template} & \langle \text{class ForwardIterator1, class ForwardIterator2} \rangle \\
& \text{ForwardIterator1} \\
& \quad \text{find_first_of}(\text{ForwardIterator1} \ \text{first1}, \text{ForwardIterator1} \ \text{last1}, \\
& \quad \quad \text{ForwardIterator2} \ \text{first2}, \text{ForwardIterator2} \ \text{last2}); \\
\text{template} & \langle \text{class ForwardIterator1, class ForwardIterator2, class BinaryPredicate} \rangle \\
& \text{ForwardIterator1} \\
& \quad \text{find_first_of}(\text{ForwardIterator1} \ \text{first1}, \text{ForwardIterator1} \ \text{last1}, \\
& \quad \quad \text{ForwardIterator2} \ \text{first2}, \text{ForwardIterator2} \ \text{last2}, \\
& \quad \quad \text{BinaryPredicate} \ \text{pred}); \\
\end{align*}
\]

Effects: Finds an element that matches one of a set of values.

Returns: The first iterator \( i \) in the range \([first1, last1)\) such that for some iterator \( j \) in the range \([first2, last2)\) the following conditions hold: \( *i == *j \), \( \text{pred}(*i, *j) != false \). Returns \( last1 \) if no such iterator is found.

Complexity: At most \((last1 - first1) * (last2 - first2)\) applications of the corresponding predicate.

25.1.5 Adjacent find

\[
\begin{align*}
\text{template} & \langle \text{class ForwardIterator} \rangle \\
& \text{ForwardIterator} \ \text{adjacent_find}(\text{ForwardIterator} \ \text{first}, \text{ForwardIterator} \ \text{last}); \\
\text{template} & \langle \text{class ForwardIterator, class BinaryPredicate} \rangle \\
& \text{ForwardIterator} \ \text{adjacent_find}(\text{ForwardIterator} \ \text{first}, \text{ForwardIterator} \ \text{last}, \\
& \quad \quad \text{BinaryPredicate} \ \text{pred}); \\
\end{align*}
\]

Returns: The first iterator \( i \) such that both \( i \) and \( i + 1 \) are in the range \([first, last)\) for which the following corresponding conditions hold: \( *i == *(i + 1) \), \( \text{pred}(*i, *(i + 1)) != false \). Returns \( last \) if no such iterator is found.

Complexity: For a nonempty range, exactly \( \min((i - first) + 1, (last - first) - 1) \) applications of the corresponding predicate, where \( i \) is adjacent_find’s return value.

25.1.6 Count

\[
\text{template} \langle \text{class ForwardIterator} \rangle \\
\text{ForwardIterator} \ \text{count}(\text{ForwardIterator} \ \text{first}, \text{ForwardIterator} \ \text{last}); \\
\]
template<class InputIterator , class T>  
  typename iterator_traits<InputIterator>::difference_type  
  count ( InputIterator first , InputIterator last , const T& value );

template<class InputIterator , class Predicate >  
  typename iterator_traits<InputIterator>::difference_type  
  count_if ( InputIterator first , InputIterator last , Predicate pred );

Effects: Returns the number of iterators \( i \) in the range \([first, last)\) for which the following corresponding conditions hold: \( *i == value , pred(*i) != false \).

Complexity: Exactly \( last - first \) applications of the corresponding predicate.

25.1.7 Mismatch  

template<class InputIterator1 , class InputIterator2 >  
  pair<InputIterator1 , InputIterator2>  
  mismatch ( InputIterator1 first1 , InputIterator1 last1 ,  
            InputIterator2 first2 );

template<class InputIterator1 , class InputIterator2 ,  
         class BinaryPredicate >  
  pair<InputIterator1 , InputIterator2>  
  mismatch ( InputIterator1 first1 , InputIterator1 last1 ,  
            InputIterator2 first2 , BinaryPredicate pred );

1 Returns: A pair of iterators \( i \) and \( j \) such that \( j == first2 + (i - first1) \) and \( i \) is the first iterator in the range \([first1, last1)\) for which the following corresponding conditions hold:

\[
!(*i == *(first2 + (i - first1))) \quad \text{pred}(i , *(first2 + (i - first1))) == false
\]

Returns the pair \( last1 \) and \( first2 + (last1 - first1) \) if such an iterator \( i \) is not found.

Complexity: At most \( last1 - first1 \) applications of the corresponding predicate.

25.1.8 Equal  

template<class InputIterator1 , class InputIterator2 >  
  bool equal ( InputIterator1 first1 , InputIterator1 last1 ,  
               InputIterator2 first2 );

template<class InputIterator1 , class InputIterator2 ,  
         class BinaryPredicate >  
  bool equal ( InputIterator1 first1 , InputIterator1 last1 ,  
               InputIterator2 first2 , BinaryPredicate pred );

1 Returns: true if for every iterator \( i \) in the range \([first1, last1)\) the following corresponding conditions hold:

\[
*i == *(first2 + (i - first1)) , \text{pred(*i, *(first2 + (i - first1)))} != false.\]

Otherwise, returns false.

\[
\text{ForwardIterator1} \\
\text{search} (\text{ForwardIterator1 } \text{first1}, \text{ForwardIterator1 } \text{last1}, \\
\text{ForwardIterator2 } \text{first2}, \text{ForwardIterator2 } \text{last2});
\]

\[\text{template } \langle \text{class ForwardIterator1, class ForwardIterator2, class BinaryPredicate}\rangle\]
\[
\text{ForwardIterator1} \\
\text{search} (\text{ForwardIterator1 } \text{first1}, \text{ForwardIterator1 } \text{last1}, \\
\text{ForwardIterator2 } \text{first2}, \text{ForwardIterator2 } \text{last2}, \\
\text{BinaryPredicate } \text{pred});
\]

\[\text{Effects:}\] Finds a subsequence of equal values in a sequence.

Returns: The first iterator \(i\) in the range \([\text{first1}, \text{last1} - (\text{last2} - \text{first2}))\) such that for any non-negative integer \(n\) less than \(\text{last2} - \text{first2}\) the following corresponding conditions hold: \(* (i + n) == *(\text{first2} + n), \quad \text{pred}((i + n), *(\text{first2} + n)) != false.\) Returns \(\text{last1}\) if no such iterator is found.

Complexity: At most \((\text{last1} - \text{first1}) \ast (\text{last2} - \text{first2})\) applications of the corresponding predicate.

\[\text{template } \langle \text{class ForwardIterator, class Size, class T}\rangle\]
\[
\text{ForwardIterator} \\
\text{search}_n (\text{ForwardIterator } \text{first}, \text{ForwardIterator } \text{last}, \text{Size } \text{count}, \\
\text{const T& } \text{value});
\]

\[\text{template } \langle \text{class ForwardIterator, class Size, class T, class BinaryPredicate}\rangle\]
\[
\text{ForwardIterator} \\
\text{search}_n (\text{ForwardIterator } \text{first}, \text{ForwardIterator } \text{last}, \text{Size } \text{count}, \\
\text{const T& } \text{value}, \text{BinaryPredicate } \text{pred});
\]

Requires: The type \(\text{Size}\) is convertible to integral type (4.7, 12.3).

Effects: Finds a subsequence of equal values in a sequence.

Returns: The first iterator \(i\) in the range \([\text{first}, \text{last} - \text{count})\) such that for any non-negative integer \(n\) less than \(\text{count}\) the following corresponding conditions hold: \(* (i + n) == \text{value}, \quad \text{pred}(*(i + n), \text{value}) != false.\) Returns \(\text{last}\) if no such iterator is found.

Complexity: At most \((\text{last} - \text{first}) \ast \text{count}\) applications of the corresponding predicate if \(\text{count}\) is positive, or 0 otherwise.

25.2 Mutating sequence operations

25.2.1 Copy
template< class InputIterator , class OutputIterator >
OutputIterator copy ( InputIterator first , InputIterator last ,
OutputIterator result);

Effects: Copies elements in the range \([\text{first}, \text{last})\) into the range \([\text{result}, \text{result} + (\text{last} - \text{first}))\) starting from \text{first} and proceeding to \text{last}. For each non-negative integer \(n < (\text{last} - \text{first})\), performs \(* (\text{result} + n) = *(\text{first} + n)\).

Returns: \text{result} + (\text{last} - \text{first}).

Requires: \text{result} shall not be in the range \([\text{first}, \text{last})\).

Complexity: Exactly \(\text{last} - \text{first}\) assignments.

template< class BidirectionalIterator1 , class BidirectionalIterator2 >
BidirectionalIterator2 copy_backward ( BidirectionalIterator1 first ,
        BidirectionalIterator1 last ,
        BidirectionalIterator2 result);

Effects: Copies elements in the range \([\text{first}, \text{last})\) into the range \([\text{result} - (\text{last} - \text{first}), \text{result})\) starting from \text{last} - 1 and proceeding to \text{first}.\(^{261}\) For each positive integer \(n \leq (\text{last} - \text{first})\), performs \(* (\text{result} - n) = *(\text{last} - n)\).

Requires: \text{result} shall not be in the range \([\text{first}, \text{last})\).

Returns: \text{result} - (\text{last} - \text{first}).

Complexity: Exactly \(\text{last} - \text{first}\) assignments.

25.2.2 Swap \([\text{lib.alg.swap}]\)

template< class T > void swap ( T& a , T& b );

Requires: Type \(T\) is CopyConstructible (20.1.3) and Assignable (23.1).

Effects: Exchanges values stored in two locations.

template< class ForwardIterator1 , class ForwardIterator2 >
ForwardIterator2 swap_ranges ( ForwardIterator1 first1 , ForwardIterator1 last1 ,
        ForwardIterator2 first2 );

Effects: For each non-negative integer \(n < (\text{last1} - \text{first1})\) performs: \text{swap}(* (\text{first1} + n) , *(\text{first2} + n)).

Requires: The two ranges \([\text{first1}, \text{last1})\) and \([\text{first2}, \text{first2} + (\text{last1} - \text{first1}))\) shall not overlap. The type of \(\text{first1}\) shall be the same as the type of \(\text{first2}\) and that type shall satisfy the Swappable requirements (20.1.4).

Returns: \text{first2} + (\text{last1} - \text{first1}).

\(^{261}\) \text{copy_backward} should be used instead of \text{copy} when \text{last} is in the range \([\text{result} - (\text{last} - \text{first}), \text{result})\).
25.2 Mutating sequence operations

6  Complexity: Exactly last1 - first1 swaps.

   template<class ForwardIterator1, class ForwardIterator2>
   void iter_swap(ForwardIterator1 a, ForwardIterator2 b);

7  Effects: swap(*a, *b).

8  Requires: The type of *a shall be the same as the type of *b and that type shall satisfy the Swappable requirements (20.1.4).

25.2.3 Transform

   template<class InputIterator, class OutputIterator,
            class UnaryOperation>
   OutputIterator
   transform(InputIterator first, InputIterator last,
             OutputIterator result, UnaryOperation op);

   template<class InputIterator1, class InputIterator2,
            class OutputIterator, class BinaryOperation>
   OutputIterator
   transform(InputIterator1 first1, InputIterator1 last1,
             InputIterator2 first2, OutputIterator result,
             BinaryOperation binary_op);

1  Effects: Assigns through every iterator i in the range [result, result + (last1 - first1)) a new corresponding value equal to op(*(first1 + (i - result)) or binary_op(*(first1 + (i - result)),
                *(first2 + (i - result)))).

2  Requires: op and binary_op shall not invalidate iterators or subranges, or modify elements in the ranges [first1, last1],[first2,first2 + (last1 - first1)], and [result, result + (last1 - first1)].

3  Returns: result + (last1 - first1).

4  Complexity: Exactly last1 - first1 applications of op or binary_op.

5  Remarks: result may be equal to first in case of unary transform, or to first1 or first2 in case of binary transform.

25.2.4 Replace

   template<class ForwardIterator, class T>
   void replace(ForwardIterator first, ForwardIterator last,
                const T& old_value, const T& new_value);

   template<class ForwardIterator, class Predicate, class T>
   void replace_if(ForwardIterator first, ForwardIterator last,
                   Predicate pred, const T& new_value);

262) The use of fully closed ranges is intentional.
25.2 Mutating sequence operations

Requires: The expression \( \* \text{first} = \text{new\_value} \) must be valid.

Effects: Substitutes elements referred by the iterator \( \text{i} \) in the range \( [\text{first}, \text{last}) \) with \( \text{new\_value} \), when the following corresponding conditions hold: \( \* \text{i} == \text{old\_value}, \text{pred}(\* \text{i}) != \text{false} \).

Complexity: Exactly \( \text{last} - \text{first} \) applications of the corresponding predicate.

```cpp
template <class InputIterator, class OutputIterator, class T>
OutputIterator
replace_copy(InputIterator first, InputIterator last, OutputIterator result, const T& old_value, const T& new_value);
```

```cpp
template <class InputIterator, class OutputIterator, class Predicate, class T>
OutputIterator
replace_copy_if(InputIterator first, InputIterator last, OutputIterator result, Predicate pred, const T& new_value);
```

Requires: The results of the expressions \( \* \text{first} \) and \( \text{new\_value} \) shall be writable to the \( \text{result} \) output iterator. The ranges \( [\text{first}, \text{last}) \) and \( [\text{result}, \text{result} + (\text{last} - \text{first})) \) shall not overlap.

Effects: Assigns to every iterator \( \text{i} \) in the range \( [\text{result}, \text{result} + (\text{last} - \text{first})) \) either \( \text{new\_value} \) or \( \*(\text{first} + (\text{i} - \text{result})) \) depending on whether the following corresponding conditions hold:

\[
\* (\text{first} + (\text{i} - \text{result})) == \text{old\_value} \\
\text{pred}(\* (\text{first} + (\text{i} - \text{result}))) != \text{false}
\]

Returns: \( \text{result} + (\text{last} - \text{first}) \).

Complexity: Exactly \( \text{last} - \text{first} \) applications of the corresponding predicate.

### 25.2.5 Fill

```cpp
template <class ForwardIterator, class T>
void fill(ForwardIterator first, ForwardIterator last, const T& value);
```

```cpp
template <class OutputIterator, class Size, class T>
void fill_n(OutputIterator first, Size n, const T& value);
```

Requires: The expression \( \text{value} \) shall be writable to the output iterator. The type \( \text{Size} \) shall be convertible to an integral type (4.7, 12.3).

Effects: The first algorithm assigns \( \text{value} \) through all the iterators in the range \( [\text{first}, \text{last}) \). The second algorithm assigns \( \text{value} \) through all the iterators in the range \( [\text{first}, \text{first} + \text{n}) \) if \( \text{n} \) is positive, otherwise it does nothing.

Complexity: Exactly \( \text{last} - \text{first}, \text{n}, \) or 0 assignments, respectively.

### 25.2.6 Generate
25.2 Mutating sequence operations

**template< class ForwardIterator , class Generator >**
void generate (ForwardIterator first, ForwardIterator last, Generator gen);

**template< class OutputIterator , class Size , class Generator >**
void generate_n (OutputIterator first, Size n, Generator gen);

Effects: The first algorithm invokes the function object gen and assigns the return value of gen through all the iterators in the range \([first, last)\). The second algorithm invokes the function object gen and assigns the return value of gen through all the iterators in the range \([first, first + n)\) if \(n\) is positive, otherwise it does nothing.

Requires: gen takes no arguments, Size is convertible to an integral type (4.7, 12.3).

Complexity: Exactly \(last - first\), \(n\), or 0 invocations of gen and assignments, respectively.

25.2.7 Remove

**template< class ForwardIterator , class T >**
ForwardIterator remove (ForwardIterator first, ForwardIterator last, const T& value);

**template< class ForwardIterator , class Predicate >**
ForwardIterator remove_if (ForwardIterator first, ForwardIterator last, Predicate pred);

Requires: The type of \(*first\) shall satisfy the Assignable requirements (23.1).

Effects: Eliminates all the elements referred to by iterator \(i\) in the range \([first, last)\) for which the following corresponding conditions do not hold: \(*i == value, pred(*i) != false\).

Returns: The end of the resulting range.

Remarks: Stable.

Complexity: Exactly \(last - first\) applications of the corresponding predicate.

**template< class InputIterator , class OutputIterator , class T >**
OutputIterator remove_copy (InputIterator first, InputIterator last, OutputIterator result, const T& value);

**template< class InputIterator , class OutputIterator , class Predicate >**
OutputIterator remove_copy_if (InputIterator first, InputIterator last, OutputIterator result, Predicate pred);

Requires: Type \(T\) is EqualityComparable (20.1.1). The ranges \([first, last)\) and \([result, result + (last - first))\) shall not overlap.

Effects: Copies all the elements referred to by the iterator \(i\) in the range \([first, last)\) for which the following corresponding conditions do not hold: \(*i == value, pred(*i) != false\).

25.2.8 Unique

```cpp
template<class ForwardIterator>
ForwardIterator unique(ForwardIterator first, ForwardIterator last);
```

```cpp
template<class ForwardIterator, class BinaryPredicate>
ForwardIterator unique(ForwardIterator first, ForwardIterator last,
                       BinaryPredicate pred);
```

**Effects:** For a nonempty range, eliminates all but the first element from every consecutive group of equivalent elements referred to by the iterator \(i\) in the range \([first + 1, last)\) for which the following conditions hold:

\[ *(i - 1) == *i \text{ or } pred(*(i - 1), *i) != false. \]

**Requires:** The comparison function shall be an equivalence relation.

**Returns:** The end of the resulting range.

**Complexity:** For nonempty ranges, exactly \((last - first) - 1\) applications of the corresponding predicate.

```cpp
template<class InputIterator, class OutputIterator>
OutputIterator unique_copy(InputIterator first, InputIterator last,
                            OutputIterator result);
```

```cpp
template<class InputIterator, class OutputIterator, class BinaryPredicate>
OutputIterator unique_copy(InputIterator first, InputIterator last,
                            OutputIterator result, BinaryPredicate pred);
```

**Requires:** The ranges \([first, last)\) and \([result, result + (last - first))\) shall not overlap. The expression \(*result = *first\) shall be valid. If neither InputIterator nor OutputIterator meets the requirements of forward iterator then the value type of InputIterator shall be CopyConstructible (20.1.3). Otherwise CopyConstructible is not required.

**Effects:** Copies only the first element from every consecutive group of equal elements referred to by the iterator \(i\) in the range \([first, last)\) for which the following corresponding conditions hold: \(*i == *(i - 1)\) or \(pred(*i, *(i - 1)) != false.\)

**Returns:** The end of the resulting range.

**Complexity:** For nonempty ranges, exactly \((last - first) - 1\) applications of the corresponding predicate.

25.2.9 Reverse

```cpp
[lib.alg.reverse]
```
25.2 Mutating sequence operations

 template < class BidirectionalIterator >
 void reverse ( BidirectionalIterator first, BidirectionalIterator last );

 Effects: For each non-negative integer i <= (last - first)/2, applies iter_swap to all pairs of iterators first + i, (last - i) - 1.

 Requires: The type of *first shall satisfy the Swappable requirements (20.1.4).

 Complexity: Exactly (last - first)/2 swaps.

 template < class BidirectionalIterator, class OutputIterator >
 OutputIterator
 reverse_copy ( BidirectionalIterator first, BidirectionalIterator last, OutputIterator result );

 Effects: Copies the range [first, last) to the range [result, result+(last-first)) such that for any non-negative integer i < (last - first) the following assignment takes place: *(result + (last - first) - i) = *(first + i).

 Requires: The ranges [first, last) and [result, result+(last-first)) shall not overlap.

 Returns: result + (last - first).

 Complexity: Exactly last - first assignments.

25.2.10 Rotate

 template < class ForwardIterator >
 void rotate ( ForwardIterator first, ForwardIterator middle, ForwardIterator last );

 Effects: For each non-negative integer i < (last - first), places the element from the position first + i into position first + (i + (last - middle)) % (last - first).

 Remarks: This is a left rotate.

 Requires: [first, middle) and [middle, last) are valid ranges. The type of *first shall satisfy the Swappable requirements (20.1.4).

 Complexity: At most last - first swaps.

 template < class ForwardIterator, class OutputIterator >
 OutputIterator
 rotate_copy ( ForwardIterator first, ForwardIterator middle, ForwardIterator last, OutputIterator result );

 Effects: Copies the range [first, last) to the range [result, result + (last - first)) such that for each non-negative integer i < (last - first) the following assignment takes place: *(result + i) = *(first + (i + (middle - first)) % (last - first)).

 Returns: result + (last - first).

 Requires: The ranges [first, last) and [result, result + (last - first)) shall not overlap.
8     Complexity: Exactly last − first assignments.

25.2.11 Random shuffle [lib.alg.random.shuffle]

    template<class RandomAccessIterator>
    void random_shuffle(RandomAccessIterator first,
                        RandomAccessIterator last);

    template<class RandomAccessIterator, class RandomNumberGenerator>
    void random_shuffle(RandomAccessIterator first,
                        RandomAccessIterator last,
                        RandomNumberGenerator& rand);

1     Effects: Shuffles the elements in the range [first, last) with uniform distribution.

2     Requires: The type of *first shall satisfy the Swappable requirements (20.1.4).

3     Complexity: Exactly (last − first) − 1 swaps.

4     Remarks: The underlying source of random numbers for the first form of the function is implementation-defined. An implementation may use the rand function from the standard C library. The second form of the function takes a random number generating function object rand such that if n is an argument for rand, with a positive value, that has type iterator_traits RandomAccessIterator>::difference_type, then rand(n) returns a randomly chosen value, which lies in the interval [0, n), and which has a type that is convertible to iterator_traits RandomAccessIterator>::difference_type.

25.2.12 Partitions [lib.alg.partitions]

    template<class BidirectionalIterator, class Predicate>
    BidirectionalIterator
    partition(BidirectionalIterator first,
              BidirectionalIterator last, Predicate pred);

1     Effects: Places all the elements in the range [first, last) that satisfy pred before all the elements that do not satisfy it.

2     Returns: An iterator i such that for any iterator j in the range [first, i) pred(*j) != false, and for any iterator k in the range [i, last), pred(*k) == false.

3     Requires: The type of *first shall satisfy the Swappable requirements (20.1.4).

4     Complexity: At most (last − first)/2 swaps. Exactly last − first applications of the predicate are done.

    template<class BidirectionalIterator, class Predicate>
    BidirectionalIterator
    stable_partition(BidirectionalIterator first,
                    BidirectionalIterator last, Predicate pred);

Draft
25.3 Sorting and related operations

Effects: Places all the elements in the range \([\textit{first}, \textit{last})\) that satisfy \textit{pred} before all the elements that do not satisfy it.

Returns: An iterator \(i\) such that for any iterator \(j\) in the range \([\textit{first}, i)\), \(\textit{pred}(*j) \neq \textit{false}\), and for any iterator \(k\) in the range \([i, \textit{last})\), \(\textit{pred}(*k) == \textit{false}\). The relative order of the elements in both groups is preserved.

Requires: The type of \(*\textit{first}\) shall satisfy the Swappable requirements (20.1.4).

Complexity: At most \((\textit{last} - \textit{first}) \ast \log(\textit{last} - \textit{first}))\) swaps, but only linear number of swaps if there is enough extra memory. Exactly \(\textit{last} - \textit{first}\) applications of the predicate.

25.3 Sorting and related operations

All the operations in 25.3 have two versions: one that takes a function object of type \texttt{Compare} and one that uses an \texttt{operator<}.

\texttt{Compare} is used as a function object which returns \texttt{true} if the first argument is less than the second, and \texttt{false} otherwise. \texttt{Compare \texttt{comp}} is used throughout for algorithms assuming an ordering relation. It is assumed that \texttt{comp} will not apply any non-constant function through the dereferenced iterator.

For all algorithms that take \texttt{Compare}, there is a version that uses \texttt{operator<} instead. That is, \texttt{comp}(*i, *j) != \texttt{false} defaults to *i < *j != \texttt{false}. For algorithms other than those described in 25.3.3 to work correctly, \texttt{comp} has to induce a strict weak ordering on the values.

The term \texttt{strict} refers to the requirement of an irreflexive relation (\(!\texttt{comp}(x, \ x)\) for all x), and the term \texttt{weak} to requirements that are not as strong as those for a total ordering, but stronger than those for a partial ordering. If we define \texttt{equiv(a, \ b)} as \(!\texttt{comp}(a, \ b) \&\& !\texttt{comp}(b, \ a)\), then the requirements are that \texttt{comp} and \texttt{equiv} both be transitive relations:

- \texttt{comp(a, b) \&\& \texttt{comp}(b, c)} implies \texttt{comp(a, c)}

- \texttt{equiv(a, b) \&\& \texttt{equiv}(b, c)} implies \texttt{equiv(a, c)} [Note: Under these conditions, it can be shown that

- \texttt{equiv} is an equivalence relation

- \texttt{comp} induces a well-defined relation on the equivalence classes determined by \texttt{equiv}

- The induced relation is a strict total ordering. — end note]

A sequence is \texttt{sorted with respect to a comparator \texttt{comp}} if for any iterator \(i\) pointing to the sequence and any non-negative integer \(n\) such that \(i + n\) is a valid iterator pointing to an element of the sequence, \texttt{comp}(*i + n), *i) \(== \textit{false}\).

A sequence \([\texttt{start}, \texttt{finish})\) is \texttt{partitioned with respect to an expression \texttt{f(e)}} if there exists an integer \(n\) such that for all \(0 <= i < \text{distance}\texttt{start, finish), f(*(begin + i))}\) is true if and only if \(i < n\).

In the descriptions of the functions that deal with ordering relationships we frequently use a notion of equivalence to describe concepts such as stability. The equivalence to which we refer is not necessarily an \texttt{operator==}, but an equivalence relation induced by the strict weak ordering. That is, two elements \(a\) and \(b\) are considered equivalent if and only if \((a < b) \&\& !(b < a)\).

Draft
25.3.1 Sorting

25.3.1.1 sort

```cpp
template<class RandomAccessIterator>
void sort(RandomAccessIterator first, RandomAccessIterator last);
```

```cpp
template<class RandomAccessIterator, class Compare>
void sort(RandomAccessIterator first, RandomAccessIterator last, Compare comp);
```

1 Effects: Sorts the elements in the range \([first, last)\).
2 Requires: The type of *first shall satisfy the Swappable requirements (20.1.4).
3 Complexity: Approximately \(N \log(N)\) (where \(N \equiv last - first\)) comparisons on the average.\(^\text{263}\)

25.3.1.2 stable_sort

```cpp
template<class RandomAccessIterator>
void stable_sort(RandomAccessIterator first, RandomAccessIterator last);
```

```cpp
template<class RandomAccessIterator, class Compare>
void stable_sort(RandomAccessIterator first, RandomAccessIterator last, Compare comp);
```

1 Effects: Sorts the elements in the range \([first, last)\).
2 Requires: The type of *first shall satisfy the Swappable requirements (20.1.4).
3 Complexity: It does at most \(N \log^2(N)\) (where \(N \equiv last - first\)) comparisons; if enough extra memory is available, it is \(N \log(N)\).
4 Remarks: Stable.

25.3.1.3 partial_sort

```cpp
template<class RandomAccessIterator>
void partial_sort(RandomAccessIterator first, RandomAccessIterator middle, RandomAccessIterator last);
```

```cpp
template<class RandomAccessIterator, class Compare>
void partial_sort(RandomAccessIterator first, RandomAccessIterator middle, RandomAccessIterator last, Compare comp);
```

\(^{263}\) If the worst case behavior is important stable_sort() (25.3.1.2) or partial_sort() (25.3.1.3) should be used.
25.3 Sorting and related operations

Effects: Places the first \( \text{middle} - \text{first} \) sorted elements from the range \([\text{first}, \text{last})\) into the range \([\text{first}, \text{middle})\). The rest of the elements in the range \([\text{middle}, \text{last})\) are placed in an unspecified order.

Requires: The type of \*\text{first} shall satisfy the Swappable requirements (20.1.4).

Complexity: It takes approximately \((\text{last} - \text{first}) \times \log(\text{middle} - \text{first})\) comparisons.

25.3.1.4 partial_sort_copy

\[
\text{template}<\text{class } \text{InputIterator}, \text{class } \text{RandomAccessIterator}> \text{RandomAccessIterator} \partial_sort_copy(\text{InputIterator } \text{first}, \text{InputIterator } \text{last}, \text{RandomAccessIterator } \text{result_first}, \text{RandomAccessIterator } \text{result_last});
\]

\[
\text{template}<\text{class } \text{InputIterator}, \text{class } \text{RandomAccessIterator}, \text{class } \text{Compare}> \text{RandomAccessIterator} \partial_sort_copy(\text{InputIterator } \text{first}, \text{InputIterator } \text{last}, \text{RandomAccessIterator } \text{result_first}, \text{RandomAccessIterator } \text{result_last}, \text{Compare } \text{comp});
\]

Effects: Places the first \(\min(\text{last} - \text{first}, \text{result_last} - \text{result_first})\) sorted elements into the range \([\text{result_first}, \text{result_first} + \min(\text{last} - \text{first}, \text{result_last} - \text{result_first}))\).

Returns: The smaller of: \text{result_last} or \text{result_first} + (\text{last} - \text{first}).

Requires: The type of \*\text{result_last} or \*\text{result_first} shall satisfy the Swappable requirements (20.1.4).

Complexity: Approximately \((\text{last} - \text{first}) \times \log(\min(\text{last} - \text{first}, \text{result_last} - \text{result_first}))\) comparisons.

25.3.2 Nth element

\[
\text{template}<\text{class } \text{RandomAccessIterator}> \text{void } \text{nth_element}(\text{RandomAccessIterator } \text{first}, \text{RandomAccessIterator } \text{nth}, \text{RandomAccessIterator } \text{last});
\]

\[
\text{template}<\text{class } \text{RandomAccessIterator}, \text{class } \text{Compare}> \text{void } \text{nth_element}(\text{RandomAccessIterator } \text{first}, \text{RandomAccessIterator } \text{nth}, \text{RandomAccessIterator } \text{last}, \text{Compare } \text{comp});
\]

After \text{nth_element} the element in the position pointed to by \text{nth} is the element that would be in that position if the whole range were sorted. Also for any iterator \text{i} in the range \([\text{first}, \text{nth})\) and any iterator \text{j} in the range \([\text{nth}, \text{last})\) it holds that: \(!(*\text{i} > *\text{j}) \text{ or } \text{comp}(\*\text{j}, \*\text{i}) == \text{false}\).

Requires: The type of \*\text{first} shall satisfy the Swappable requirements (20.1.4).

Complexity: Linear on average.
25.3 Binary search

All of the algorithms in this section are versions of binary search and assume that the sequence being searched is partitioned with respect to an expression formed by binding the search key to an argument of the implied or explicit comparison function. They work on non-random access iterators minimizing the number of comparisons, which will be logarithmic for all types of iterators. They are especially appropriate for random access iterators, because these algorithms do a logarithmic number of steps through the data structure. For non-random access iterators they execute a linear number of steps.

25.3.3.1 lower_bound

```cpp
template<class ForwardIterator, class T>
ForwardIterator
lower_bound(ForwardIterator first, ForwardIterator last, const T& value);
```

```cpp
template<class ForwardIterator, class T, class Compare>
ForwardIterator
lower_bound(ForwardIterator first, ForwardIterator last, const T& value, Compare comp);
```

1 Requires: The elements e of [first, last) are partitioned with respect to the expression e < value or comp (e, value).

2 Returns: The furthermost iterator i in the range [first, last] such that for any iterator j in the range [first, i) the following corresponding conditions hold: *j < value or comp (*j, value) != false.

3 Complexity: At most log(last - first) + 1 comparisons.

25.3.3.2 upper_bound

```cpp
template<class ForwardIterator, class T>
ForwardIterator
upper_bound(ForwardIterator first, ForwardIterator last, const T& value);
```

```cpp
template<class ForwardIterator, class T, class Compare>
ForwardIterator
upper_bound(ForwardIterator first, ForwardIterator last, const T& value, Compare comp);
```

1 Requires: The elements e of [first, last) are partitioned with respect to the expression !(value < e) or !comp (value, e).

2 Returns: The furthermost iterator i in the range [first, last] such that for any iterator j in the range [first, i) the following corresponding conditions hold: !(value < *j) or comp (value, *j) == false.

3 Complexity: At most log(last - first) + 1 comparisons.
### 25.3.3.3 equal_range

template<class ForwardIterator , class T>
pair<ForwardIterator , ForwardIterator >
equal_range(ForwardIterator first, ForwardIterator last , const T& value);

template<class ForwardIterator , class T , class Compare >
pair<ForwardIterator , ForwardIterator >
equal_range(ForwardIterator first, ForwardIterator last, const T& value, Compare comp);

1 **Requires:** The elements $e$ of $[\text{first}, \text{last})$ are partitioned with respect to the expressions $e < \text{value}$ and !($\text{value} < e$) or $\text{comp}(e, \text{value})$ and !$\text{comp}(\text{value}, e)$. Also, for all elements $e$ of $[\text{first}, \text{last}), e < \text{value}$ implies !($\text{value} < e$) or $\text{comp}(e, \text{value})$ implies !$\text{comp}(\text{value}, e)$.

2 **Returns:**

   make_pair (lower_bound (first, last, value),
   upper_bound (first, last, value))

   or

   make_pair (lower_bound (first, last, value, comp),
   upper_bound (first, last, value, comp))

3 **Complexity:** At most $2 \times \log (\text{last} - \text{first}) + 1$ comparisons.

### 25.3.3.4 binary_search

template<class ForwardIterator , class T>
bool binary_search(ForwardIterator first, ForwardIterator last, const T& value);

template<class ForwardIterator , class T , class Compare >
bool binary_search(ForwardIterator first, ForwardIterator last, const T& value, Compare comp);

1 **Requires:** The elements $e$ of $[\text{first}, \text{last})$ are partitioned with respect to the expressions $e < \text{value}$ and !($\text{value} < e$) or $\text{comp}(e, \text{value})$ and !$\text{comp}(\text{value}, e)$. Also, for all elements $e$ of $[\text{first}, \text{last}), e < \text{value}$ implies !($\text{value} < e$) or $\text{comp}(e, \text{value})$ implies !$\text{comp}(\text{value}, e)$.

2 **Returns:** true if there is an iterator $i$ in the range $[\text{first}, \text{last})$ that satisfies the corresponding conditions: !(+$i < \text{value}$) $\&\&$ !(+$\text{value} < *i$) or $\text{comp}(*i, \text{value}) == \text{false} \&\& \text{comp} (\text{value}, *i) == \text{false}$.

3 **Complexity:** At most $\log (\text{last} - \text{first}) + 2$ comparisons.
### 25.3.4 Merge

**Template 1:***

```cpp
template < class InputIterator1 , class InputIterator2 ,
          class OutputIterator >
OutputIterator
merge ( InputIterator1 first1 , InputIterator1 last1 ,
         InputIterator2 first2 , InputIterator2 last2 ,
         OutputIterator result);
```

**Template 2:***

```cpp
template < class InputIterator1 , class InputIterator2 ,
          class OutputIterator , class Compare >
OutputIterator
merge ( InputIterator1 first1 , InputIterator1 last1 ,
         InputIterator2 first2 , InputIterator2 last2 ,
         OutputIterator result , Compare comp);
```

**Effects:** Merges two sorted ranges \([first1, last1)\) and \([first2, last2)\) into the range \([result, result + (last1 - first1) + (last2 - first2))\).

The resulting range shall not overlap with either of the original ranges. The list will be sorted in non-decreasing order according to the ordering defined by \(comp\); that is, for every iterator \(i\) in \([first, last)\) other than \(first\), the condition \(*i < *(i - 1)\) or \(comp(*i, *(i - 1))\) will be false.

**Returns:** \(result + (last1 - first1) + (last2 - first2)\).

**Complexity:** At most \((last1 - first1) + (last2 - first2) - 1\) comparisons.

**Remarks:** Stable.

**Template 3:***

```cpp
template < class BidirectionalIterator >
void inplace_merge ( BidirectionalIterator first ,
                    BidirectionalIterator middle ,
                    BidirectionalIterator last);
```

**Template 4:***

```cpp
template < class BidirectionalIterator , class Compare >
void inplace_merge ( BidirectionalIterator first ,
                    BidirectionalIterator middle ,
                    BidirectionalIterator last , Compare comp);
```

**Effects:** Merges two sorted consecutive ranges \([first, middle)\) and \([middle, last)\), putting the result of the merge into the range \([first, last)\). The resulting range will be in non-decreasing order; that is, for every iterator \(i\) in \([first, last)\) other than \(first\), the condition \(*i < *(i - 1)\) or, respectively, \(comp(*i, *(i - 1))\) will be false.

**Requires:** The type of \(*first\) shall satisfy the Swappable requirements (20.1.4).

**Complexity:** When enough additional memory is available, \((last - first) - 1\) comparisons. If no additional memory is available, an algorithm with complexity \(N \log(N)\) (where \(N\) is equal to \(last - first\)) may be used.

**Remarks:** Stable.
25.3 Sorting and related operations  

25.3.5 Set operations on sorted structures  

This section defines all the basic set operations on sorted structures. They also work with multisets (23.3.4) containing multiple copies of equivalent elements. The semantics of the set operations are generalized to multisets in a standard way by defining set_union() to contain the maximum number of occurrences of every element, set_intersection() to contain the minimum, and so on.

### 25.3.5.1 includes

```cpp
template< class InputIterator1 , class InputIterator2 >
bool includes ( InputIterator1 first1 , InputIterator1 last1 ,
               InputIterator2 first2 , InputIterator2 last2 );
```

Returns: true if every element in the range \([\text{first2}, \text{last2})\) is contained in the range \([\text{first1}, \text{last1})\). Returns false otherwise.

Complexity: At most \(2 \times ((\text{last1} - \text{first1}) + (\text{last2} - \text{first2})) - 1\) comparisons.

### 25.3.5.2 set_union

```cpp
template< class InputIterator1 , class InputIterator2 , class OutputIterator >
OutputIterator set_union ( InputIterator1 first1 , InputIterator1 last1 ,
                           InputIterator2 first2 , InputIterator2 last2 ,
                           OutputIterator result );
```

Effects: Constructs a sorted union of the elements from the two ranges; that is, the set of elements that are present in one or both of the ranges.

Requires: The resulting range shall not overlap with either of the original ranges.

Returns: The end of the constructed range.

Complexity: At most \(2 \times ((\text{last1} - \text{first1}) + (\text{last2} - \text{first2})) - 1\) comparisons.

Remarks: If \([\text{first1}, \text{last1})\) contains \(m\) elements that are equivalent to each other and \([\text{first2}, \text{last2})\) contains \(n\) elements that are equivalent to them, then all \(m\) elements from the first range shall be copied to the output range.
range, in order, and then \( \max(n - m, 0) \) elements from the second range shall be copied to the output range, in order.

25.3.5.3 set_intersection

```cpp
template< class InputIterator1 , class InputIterator2 ,
          class OutputIterator >
OutputIterator
  set_intersection(InputIterator1 first1, InputIterator1 last1,
                  InputIterator2 first2, InputIterator2 last2,
                  OutputIterator result);
```

```cpp
template< class InputIterator1 , class InputIterator2 ,
          class OutputIterator , class Compare >
OutputIterator
  set_intersection(InputIterator1 first1, InputIterator1 last1,
                  InputIterator2 first2, InputIterator2 last2,
                  OutputIterator result, Compare comp);
```

1. **Effects:** Constructs a sorted intersection of the elements from the two ranges; that is, the set of elements that are present in both of the ranges.

2. **Requires:** The resulting range shall not overlap with either of the original ranges.

3. **Returns:** The end of the constructed range.

4. **Complexity:** At most \( 2 \times ( (\text{last1} - \text{first1}) + (\text{last2} - \text{first2}) ) - 1 \) comparisons.

5. **Remarks:** If \([\text{first1},\text{last1})\) contains \( m \) elements that are equivalent to each other and \([\text{first2},\text{last2})\) contains \( n \) elements that are equivalent to them, the first \( \min(m,n) \) elements shall be copied from the first range to the output range, in order.

25.3.5.4 set_difference

```cpp
template< class InputIterator1 , class InputIterator2 ,
          class OutputIterator >
OutputIterator
  set_difference(InputIterator1 first1, InputIterator1 last1,
                 InputIterator2 first2, InputIterator2 last2,
                 OutputIterator result);
```

```cpp
template< class InputIterator1 , class InputIterator2 ,
          class OutputIterator , class Compare >
OutputIterator
  set_difference(InputIterator1 first1, InputIterator1 last1,
                 InputIterator2 first2, InputIterator2 last2,
                 OutputIterator result, Compare comp);
```

1. **Effects:** Copies the elements of the range \([\text{first1},\text{last1})\) which are not present in the range \([\text{first2},\text{last2})\) to the range beginning at result. The elements in the constructed range are sorted.
\section{Sorting and related operations \texttt{[lib.set.symmetric.difference]}}

\begin{verbatim}

\begin{verbatim}

template<class InputIterator1, class InputIterator2, class OutputIterator>
OutputIterator
set_symmetric_difference(InputIterator1 first1, InputIterator1 last1,
InputIterator2 first2, InputIterator2 last2,
OutputIterator result);

\end{verbatim}
\end{verbatim}

Effects: Copies the elements of the range \([first1, last1)\) which are not present in the range \([first2, last2)\), and the elements of the range \([first2, last2)\) which are not present in the range \([first1, last1)\) to the range beginning at result. The elements in the constructed range are sorted.

Requires: The resulting range shall not overlap with either of the original ranges.

Returns: The end of the constructed range.

Complexity: At most \(2 \times ((last1 - first1) + (last2 - first2)) - 1\) comparisons.

Remarks: If \([first1, last1)\) contains \(m\) elements that are equivalent to each other and \([first2, last2)\) contains \(n\) elements that are equivalent to them, then \(|m - n|\) of those elements shall be copied to the output range: the last \(m - n\) of these elements from \([first1, last1)\) if \(m > n\), and the last \(n - m\) of these elements from \([first2, last2)\) if \(m < n\).

\end{verbatim}

\section{Heap operations \texttt{[lib.alg.heap.operations]}}

A heap is a particular organization of elements in a range between two random access iterators \([a, b)\). Its two key properties are:

1. There is no element greater than \(*a\) in the range and
2. \(*a\) may be removed by \texttt{pop_heap()}, or a new element added by \texttt{push_heap()}, in \(\mathcal{O}(\log(N))\) time.
These properties make heaps useful as priority queues.

`make_heap()` converts a range into a heap and `sort_heap()` turns a heap into a sorted sequence.

### 25.3.6.1 `push_heap`

```cpp
template< class RandomAccessIterator >
void push_heap(RandomAccessIterator first, RandomAccessIterator last);
```

```cpp
template< class RandomAccessIterator, class Compare >
void push_heap(RandomAccessIterator first, RandomAccessIterator last, Compare comp);
```

**Effects:** Places the value in the location `last - 1` into the resulting heap `first, last`.

**Requires:** The range `first, last - 1` shall be a valid heap.

**Complexity:** At most \( \log(last - first) \) comparisons.

### 25.3.6.2 `pop_heap`

```cpp
template< class RandomAccessIterator >
void pop_heap(RandomAccessIterator first, RandomAccessIterator last);
```

```cpp
template< class RandomAccessIterator, class Compare >
void pop_heap(RandomAccessIterator first, RandomAccessIterator last, Compare comp);
```

**Effects:** Swaps the value in the location `first` with the value in the location `last - 1` and makes `first, last - 1` into a heap.

**Requires:** The range `first, last` shall be a valid heap. The type of `*first` shall satisfy the Swappable requirements (20.1.4).

**Complexity:** At most \( 2 \times \log(last - first) \) comparisons.

### 25.3.6.3 `make_heap`

```cpp
template< class RandomAccessIterator >
void make_heap(RandomAccessIterator first, RandomAccessIterator last);
```

```cpp
template< class RandomAccessIterator, class Compare >
void make_heap(RandomAccessIterator first, RandomAccessIterator last, Compare comp);
```

**Effects:** Constructs a heap out of the range `first, last`.

**Complexity:** At most \( 3 \times (last - first) \) comparisons.
25.3 Sorting and related operations

25.3.6.4 sort_heap

.template <class RandomAccessIterator>
  void sort_heap(RandomAccessIterator first, RandomAccessIterator last);

.template <class RandomAccessIterator, class Compare>
  void sort_heap(RandomAccessIterator first, RandomAccessIterator last, Compare comp);

Effects: Sorts elements in the heap [first, last).
Requires: The type of *first shall satisfy the Swappable requirements (20.1.4).
Complexity: At most Nlog(N) comparisons (where N == last - first).

25.3.7 Minimum and maximum

.template <class T> const T& min(const T& a, const T& b);
.template <class T, class Compare>
  const T& min(const T& a, const T& b, Compare comp);

Requires: Type T is LessThanComparable (20.1.2).
Returns: The smaller value.
Remarks: Returns the first argument when the arguments are equivalent.

.template <class T> const T& max(const T& a, const T& b);
.template <class T, class Compare>
  const T& max(const T& a, const T& b, Compare comp);

Requires: Type T is LessThanComparable (20.1.2).
Returns: The larger value.
Remarks: Returns the first argument when the arguments are equivalent.

.template <class ForwardIterator>
  ForwardIterator min_element(ForwardIterator first, ForwardIterator last);

.template <class ForwardIterator, class Compare>
  ForwardIterator min_element(ForwardIterator first, ForwardIterator last, Compare comp);

Returns: The first iterator i in the range [first, last) such that for any iterator j in the range [first, last)
the following corresponding conditions hold: !(j < i) or comp(*j, *i) == false. Returns last if first == last.
Complexity: Exactly max((last - first) - 1, 0) applications of the corresponding comparisons.

.template <class ForwardIterator>
  ForwardIterator max_element(ForwardIterator first, ForwardIterator last);
.template <class ForwardIterator, class Compare>

Draft
ForwardIterator max_element(ForwardIterator first, ForwardIterator last,
    Compare comp);

Returns: The first iterator \(i\) in the range \([first, last)\) such that for any iterator \(j\) in the range \([first, last)\) the following corresponding conditions hold: !(*i < *j) or comp(*i, *j) == false. Returns last if first == last.

Complexity: Exactly \(\max((last - first) - 1, 0)\) applications of the corresponding comparisons.

25.3.8 Lexicographical comparison

\[
\text{template<class InputIterator1, class InputIterator2>}
\text{bool lexicographical_compare(InputIterator1 first1, InputIterator1 last1,}
\text{ InputIterator2 first2, InputIterator2 last2);}\
\text{template<class InputIterator1, class InputIterator2, class Compare>}
\text{bool lexicographical_compare(InputIterator1 first1, InputIterator1 last1,}
\text{ InputIterator2 first2, InputIterator2 last2, Compare comp);}\
\]

Returns: true if the sequence of elements defined by the range \([first1, last1)\) is lexicographically less than the sequence of elements defined by the range \([first2, last2)\).

Returns false otherwise.

Complexity: At most \(2*\min((last1 - first1), (last2 - first2))\) applications of the corresponding comparison.

Remarks: If two sequences have the same number of elements and their corresponding elements are equivalent, then neither sequence is lexicographically less than the other. If one sequence is a prefix of the other, then the shorter sequence is lexicographically less than the longer sequence. Otherwise, the lexicographical comparison of the sequences yields the same result as the comparison of the first corresponding pair of elements that are not equivalent.

\[
\text{for ( ; first1 != last1 && first2 != last2 ; ++first1, ++first2) {}
\text{if (*first1 < *first2) return true;}
\text{if (*first2 < *first1) return false;}
\text{return first1 == last1 && first2 != last2;}
\]

25.3.9 Permutation generators

\[
\text{template<class BidirectionalIterator>}
\text{bool next_permutation(BidirectionalIterator first,}
\text{ BidirectionalIterator last);}\
\text{template<class BidirectionalIterator, class Compare>}
\]
bool next_permutation(BidirectionalIterator first,
                      BidirectionalIterator last, Compare comp);

Effects: Takes a sequence defined by the range \([first, last)\) and transforms it into the next permutation. The next permutation is found by assuming that the set of all permutations is lexicographically sorted with respect to \(\text{operator<}\) or \(\text{comp}\). If such a permutation exists, it returns \(\text{true}\). Otherwise, it transforms the sequence into the smallest permutation, that is, the ascendingly sorted one, and returns \(\text{false}\).

Requires: The type of \(*first\) shall satisfy the Swappable requirements (20.1.4).

Complexity: At most \((last - first)/2)\) swaps.

template<class BidirectionalIterator>
bool prev_permutation(BidirectionalIterator first,
                      BidirectionalIterator last);

template<class BidirectionalIterator, class Compare>
bool prev_permutation(BidirectionalIterator first,
                      BidirectionalIterator last, Compare comp);

Effects: Takes a sequence defined by the range \([first, last)\) and transforms it into the previous permutation. The previous permutation is found by assuming that the set of all permutations is lexicographically sorted with respect to \(\text{operator<}\) or \(\text{comp}\).

Returns: \(\text{true}\) if such a permutation exists. Otherwise, it transforms the sequence into the largest permutation, that is, the descendingly sorted one, and returns \(\text{false}\).

Requires: The type of \(*first\) shall satisfy the Swappable requirements (20.1.4).

Complexity: At most \((last - first)/2)\) swaps.

25.4 C library algorithms

Header \(<\text{cstdlib}>\) (partial, Table 79).

Table 79: Header \(<\text{cstdlib}>\) synopsis

<table>
<thead>
<tr>
<th>Type</th>
<th>Name(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type:</td>
<td>size_t</td>
</tr>
<tr>
<td>Functions:</td>
<td>bsearch qsort</td>
</tr>
</tbody>
</table>
int (*compar)(const void *, const void *));
extern "C++" void *bsearch(const void *key, const void *base,
  size_t nmemb, size_t size,
  int (*compar)(const void *, const void *));
both of which have the same behavior as the original declaration.

The function signature:

```c
qsort(void *, size_t, size_t,
  int (*)(const void *, const void *));
```

is replaced by the two declarations:

```c
extern "C" void qsort(void * base, size_t nmemb, size_t size,
  int (*compar)(const void *, const void *));
extern "C++" void qsort(void * base, size_t nmemb, size_t size,
  int (*compar)(const void *, const void *));
```
both of which have the same behavior as the original declaration. The behavior is undefined unless the objects in the array pointed to by base are of POD type.

[Note: Because the function argument compar() may throw an exception, bsearch() and qsort() are allowed to propagate the exception (17.4.4.8). — end note]

SEE ALSO: ISO C subclause 7.10.5.
Chapter 26  Numerics library

1 This clause describes components that C++ programs may use to perform seminumerical operations.

2 The following subclauses describe components for complex number types, numeric (n-at-a-time) arrays, generalized numeric algorithms, and facilities included from the ISO C library, as summarized in Table 80.

Table 80: Numerics library summary

</tr>
</tbody>
</table>

26.1 Numeric type requirements

1 The complex and valarray components are parameterized by the type of information they contain and manipulate. A C++ program shall instantiate these components only with a type T that satisfies the following requirements:

- T is not an abstract class (it has no pure virtual member functions);
- T is not a reference type;
- T is not cv-qualified;
- If T is a class, it has a public default constructor;
- If T is a class, it has a public copy constructor with the signature \( T::T(\text{const } T&) \);
- If T is a class, it has a public destructor;
- If T is a class, it has a public assignment operator whose signature is either \( T& \ T::\text{operator\=(}\text{const } T&) \) or \( T& \ T::\text{operator\=(}T \) ;
- If T is a class, its assignment operator, copy and default constructors, and destructor shall correspond to each other in the following sense: Initialization of raw storage using the default constructor, followed by assignment,

264] In other words, value types. These include built-in arithmetic types, pointers, the library class complex, and instantiations of valarray for value types.
is semantically equivalent to initialization of raw storage using the copy constructor. Destruction of an object, followed by initialization of its raw storage using the copy constructor, is semantically equivalent to assignment to the original object.

[Note: This rule states that there shall not be any subtle differences in the semantics of initialization versus assignment. This gives an implementation considerable flexibility in how arrays are initialized.

[Example: An implementation is allowed to initialize a valarray by allocating storage using the new operator (which implies a call to the default constructor for each element) and then assigning each element its value. Or the implementation can allocate raw storage and use the copy constructor to initialize each element. —end example]

If the distinction between initialization and assignment is important for a class, or if it fails to satisfy any of the other conditions listed above, the programmer should use vector (23.2.4) instead of valarray for that class; —end note]

— If T is a class, it does not overload unary operator&.

1 If any operation on T throws an exception the effects are undefined.

2 In addition, many member and related functions of valarray<T> can be successfully instantiated and will exhibit well-defined behavior if and only if T satisfies additional requirements specified for each such member or related function.

3 [Example: It is valid to instantiate valarray<complex>, but operator() will not be successfully instantiated for valarray<complex> operands, since complex does not have any ordering operators. —end example]

26.2 Complex numbers

The header <complex> defines a class template, and numerous functions for representing and manipulating complex numbers.

The effect of instantiating the template complex for any type other than float, double or long double is unspecified.

If the result of a function is not mathematically defined or not in the range of representable values for its type, the behavior is undefined.

26.2.1 Header <complex> synopsis

namespace std {
    template<class T> class complex;
    template<> class complex<float>;
    template<> class complex<double>;
    template<> class complex<long double>;

    // 26.2.6 operators:
    template<class T>
        complex<T> operator+(const complex<T>&, const complex<T>&);
    template<class T> complex<T> operator+(const complex<T>&, const T&);
    template<class T> complex<T> operator+(const T&, const complex<T>&);
    template<class T> complex<T> operator-(const complex<T>&, const complex<T>&);
    template<class T> complex<T> operator-(const complex<T>&, const T&);

    Draft
template<class T> complex<T> operator-(const T&, const complex<T>&);

template<class T> complex<T> operator*(
    (const complex<T>&, const complex<T>&);
template<class T> complex<T> operator*(const complex<T>&, const T&);

template<class T> complex<T> operator/(
    (const complex<T>&, const complex<T>&);

template<class T> complex<T> operator+=(const complex<T>&);

template<class T> complex<T> operator-=(const complex<T>&);
26.2 Complex numbers

template <class T> complex<T> pow(const complex<T>&, int);
template <class T> complex<T> pow(const complex<T>&, const T&);
template <class T> complex<T> pow(const complex<T>&, const complex<T>&);
template <class T> complex<T> pow(const T&, const complex<T>&);

template <class T> complex<T> sin (const complex<T>&); 
template <class T> complex<T> sinh (const complex<T>&); 
template <class T> complex<T> sqrt (const complex<T>&); 
template <class T> complex<T> tan (const complex<T>&); 
template <class T> complex<T> tanh (const complex<T>&);
}

26.2.2 Class template complex

namespace std {
template <class T>
class complex {
public:
  typedef T value_type;
  complex(const T& re = T(), const T& im = T());
  complex(const complex&);
  template <class X> complex(const complex<X>&);
  T real() const;
  T imag() const;
  complex<T>& operator=(const T&);
  complex<T>& operator+=(const T&);
  complex<T>& operator-=(const T&);
  complex<T>& operator*=(const T&);
  complex<T>& operator/=(const T&);
  complex& operator=(const complex&);
  template <class X> complex<T>& operator=(const complex<X>&);
  template <class X> complex<T>& operator+=(const complex<X>&);
  template <class X> complex<T>& operator-=(const complex<X>&);
  template <class X> complex<T>& operator*=(const complex<X>&);
  template <class X> complex<T>& operator/=(const complex<X>&);
};
}

The class complex describes an object that can store the Cartesian components, real() and imag(), of a complex number.

26.2.3 complex specializations

template <> class complex<float> {
public:
  typedef float value_type;
};

template<class X> complex<long double>& operator/=(const complex<X>&);
};

26.2.4 complex member functions

template<class T> complex(const T& re = T(), const T& im = T());

1 Effects: Constructs an object of class complex.
2 Postcondition: real() == re && imag() == im.

26.2.5 complex member operators

template<class T> complex<T>& operator+=(const T& rhs);
1 Effects: Adds the scalar value rhs to the real part of the complex value *this and stores the result in the real part of *this, leaving the imaginary part unchanged.
2 Returns: *this.

template<class T> complex<T>& operator-=(const T& rhs);
3 Effects: Subtracts the scalar value rhs from the real part of the complex value *this and stores the result in the real part of *this, leaving the imaginary part unchanged.
4 Returns: *this.

template<class T> complex<T>& operator*=(const T& rhs);
5 Effects: Multiplies the scalar value rhs by the complex value *this and stores the result in *this.
6 Returns: *this.

Draft
template <class T> complex<T>& operator/=(const T& rhs);

Effects: Divides the scalar value \(rhs\) into the complex value \(*this\) and stores the result in \(*this\).

Returns: \(*this\).

template <class T> complex<T>& operator+=(const complex<T>& rhs);

Effects: Adds the complex value \(rhs\) to the complex value \(*this\) and stores the sum in \(*this\).

Returns: \(*this\).

template <class T> complex<T>& operator-=(const complex<T>& rhs);

Effects: Subtracts the complex value \(rhs\) from the complex value \(*this\) and stores the difference in \(*this\).

Returns: \(*this\).

template <class T> complex<T>& operator*=(const complex<T>& rhs);

Effects: Multiplies the complex value \(rhs\) by the complex value \(*this\) and stores the product in \(*this\).

Returns: \(*this\).

template <class T> complex<T>& operator/=(const complex<T>& rhs);

Effects: Divides the complex value \(rhs\) into the complex value \(*this\) and stores the quotient in \(*this\).

Returns: \(*this\).

26.2.6 complex non-member operations

[lib.complex.ops]

template <class T> complex<T> operator+(const complex<T>& lhs);

Remarks: unary operator.

Returns: complex<T>(lhs).

template <class T>
complex<T> operator+(const complex<T>& lhs, const complex<T>& rhs);
template <class T> complex<T> operator+(const complex<T>& lhs, const T& rhs);
template <class T> complex<T> operator+(const T& lhs, const complex<T>& rhs);

Returns: complex<T>(lhs) += rhs.

template <class T> complex<T> operator-(const complex<T>& lhs);

Remarks: unary operator.

Returns: complex<T>(-lhs.real(), -lhs.imag()).

template <class T>
complex<T> operator-(const complex<T>& lhs, const complex<T>& rhs);
template <class T> complex<T> operator-(const complex<T>& lhs, const T& rhs);
template <class T> complex<T> operator-(const T& lhs, const complex<T>& rhs);
26.2 Complex numbers

Returns: `complex<T>(lhs) -= rhs`.

```cpp
template<typename T>
complex<T> operator-(const complex<T>& lhs, const complex<T>& rhs);
```

Returns: `complex<T>(lhs) *= rhs`.

```cpp
template<typename T>
complex<T> operator*(const complex<T>& lhs, const complex<T>& rhs);
```

Returns: `complex<T>(lhs) /= rhs`.

```cpp
template<typename T>
bool operator==(const complex<T>& lhs, const complex<T>& rhs);
```

Returns: `lhs.real() == rhs.real() && lhs.imag() == rhs.imag()`.

Remarks: The imaginary part is assumed to be `T()`, or 0.0, for the `T` arguments.

```cpp
template<typename T>
bool operator!=(const complex<T>& lhs, const complex<T>& rhs);
```

Returns: `rhs.real() != lhs.real() || rhs.imag() != lhs.imag()`.

```cpp
template<typename T, typename charT, typename traits>
basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& is, complex<T>& z);
```

Effects: Extracts a complex number `z` of the form: u, (u), or (u,v), where u is the real part and v is the imaginary part (27.6.1.2).

Requires: The input values be convertible to `T`.

If bad input is encountered, calls `is.setstate(ios::failbit)` (which may throw `ios::failure` (27.4.4.3).

Returns: `is`.

Remarks: This extraction is performed as a series of simpler extractions. Therefore, the skipping of whitespace is specified to be the same for each of the simpler extractions.

```cpp
template<typename T, typename charT, typename traits>
basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& o, const complex<T>& z);
```

Effects: inserts the complex number `z` onto the stream `o` as if it were implemented as follows:

```cpp
template<typename T, typename charT, typename traits>
Draft
```
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& o, const complex<T>& x)
{
    basic_ostream<CharT, Traits> s;
    s.flags(o.flags());
    s.imbue(o.getloc());
    s.precision(o.precision());
    s << '(' << x.real() << ',' << x.imag() << ')';
    return o << s.str();
}

26.2.7 complex value operations [lib.complex.value.ops]

    template<class T> T real(const complex<T>& z);
    Returns: z.real().

template<class T> T imag(const complex<T>& z);
    Returns: z.imag().

template<class T> T abs(const complex<T>& z);
    Returns: the magnitude of z.

template<class T> T arg(const complex<T>& z);
    Returns: the phase angle of z, or atan2(imag(z), real(z)).

template<class T> T norm(const complex<T>& z);
    Returns: the squared magnitude of z.

template<class T> complex<T> conj(const complex<T>& z);
    Returns: the complex conjugate of z.

template<class T> complex<T> polar(const T& rho, const T& theta = 0);
    Returns: the complex value corresponding to a complex number whose magnitude is rho and whose phase angle is theta.

26.2.8 complex transcendental [lib.complex.transcendentals]

    template<class T> complex<T> cos(const complex<T>& z);
    Returns: the complex cosine of z.

template<class T> complex<T> cosh(const complex<T>& z);
    Returns: the complex hyperbolic cosine of z.
template<class T> complex<T> exp(const complex<T>& x);

Returns: the complex base e exponential of \(x\).

template<class T> complex<T> log(const complex<T>& x);

Remarks: the branch cuts are along the negative real axis.

Returns: the complex natural (base e) logarithm of \(x\), in the range of a strip mathematically unbounded along the real axis and in the interval \([-i \times \pi, i \times \pi]\) along the imaginary axis. When \(x\) is a negative real number, \(\text{imag(log(x))}\) is \(\pi\).

template<class T> complex<T> log10(const complex<T>& x);

Remarks: the branch cuts are along the negative real axis.

Returns: the complex common (base 10) logarithm of \(x\), defined as \(\log(x)/\log(10)\).

template<class T> complex<T> pow(const complex<T>& x, int y);

template<class T>
  complex<T> pow(const complex<T>& x, const complex<T>& y);

template<class T> complex<T> pow(const complex<T>& x, const T& y);

template<class T> complex<T> pow(const T& x, const complex<T>& y);

Remarks: the branch cuts are along the negative real axis.

Returns: the complex power of base \(x\) raised to the \(y\)-th power, defined as \(\exp(y \times \log(x))\). The value returned for \(\text{pow}(0,0)\) is implementation-defined.

template<class T> complex<T> sin (const complex<T>& x);

Returns: the complex sine of \(x\).

template<class T> complex<T> sinh (const complex<T>& x);

Returns: the complex hyperbolic sine of \(x\).

template<class T> complex<T> sqrt (const complex<T>& x);

Remarks: the branch cuts are along the negative real axis.

Returns: the complex square root of \(x\), in the range of the right half-plane. If the argument is a negative real number, the value returned lies on the positive imaginary axis.

template<class T> complex<T> tan (const complex<T>& x);

Returns: the complex tangent of \(x\).

template<class T> complex<T> tanh (const complex<T>& x);

Returns: the complex hyperbolic tangent of \(x\).
namespace std {
    template<class T> class valarray; // An array of type T
    class slice; // A BLAS-like slice out of an array
    template<class T> class slice_array;

Draft
The header `<valarray>` defines five class templates (`valarray`, `slice_array`, `gslice_array`, `mask_array`, and `indirect_array`), two classes (`slice` and `gslice`), and a series of related function templates for representing and manipulating arrays of values.

The `valarray` array classes are defined to be free of certain forms of aliasing, thus allowing operations on these classes to be optimized.

Any function returning a `valarray<T>` is permitted to return an object of another type, provided all the const member functions of `valarray<T>` are also applicable to this type. This return type shall not add more than two levels of template nesting over the most deeply nested argument type.\(^{(265)}\)

Implementations introducing such replacement types shall provide additional functions and operators as follows:

- for every function taking a `const valarray<T>&`, identical functions taking the replacement types shall be added;
- for every function taking two `const valarray<T>&` arguments, identical functions taking every combination of `const valarray<T>&` and replacement types shall be added.

In particular, an implementation shall allow a `valarray<T>` to be constructed from such replacement types and shall allow assignments and computed assignments of such types to `valarray<T>`, `slice_array<T>`, `gslice_array<T>`, `mask_array<T>`, and `indirect_array<T>` objects.

These library functions are permitted to throw a `bad_alloc` (18.4.2.1) exception if there are not sufficient resources available to carry out the operation. Note that the exception is not mandated.

\(^{(265)}\) Clause B recommends a minimum number of recursively nested template instantiations. This requirement thus indirectly suggests a minimum allowable complexity for `valarray` expressions.
26.3 Numeric arrays

26.3.2 Class template valarray

namespace std {
    template<class T> class valarray {
public:
    typedef T value_type;

    // 26.3.2.1 construct/destroy:
    valarray();
    explicit valarray(size_t);
    valarray(const T&, size_t);
    valarray(const T*, size_t);
    valarray(const valarray&);
    valarray(const slice_array<T>&);
    valarray(const gslice_array<T>&);
    valarray(const mask_array<T>&);
    valarray(const indirect_array<T>&);
    ~valarray();

    // 26.3.2.2 assignment:
    valarray<T>& operator=(const valarray<T>&);
    valarray<T>& operator=(const T&);
    valarray<T>& operator=(const slice_array<T>&);
    valarray<T>& operator=(const gslice_array<T>&);
    valarray<T>& operator=(const mask_array<T>&);
    valarray<T>& operator=(const indirect_array<T>&);

    // 26.3.2.3 element access:
    const T& operator[](size_t) const;
    T& operator[](size_t);

    // 26.3.2.4 subset operations:
    valarray<T> operator[](slice) const;
    slice_array<T> operator[](slice);
    valarray<T> operator[](const gslice&) const;
    gslice_array<T> operator[](const gslice&);
    valarray<T> operator[](const mask-array<T>&) const;
    mask_array<T> operator[](const valarray<bool>&);
    valarray<T> operator[](const indirect_array<T>&) const;
    indirect_array<T> operator[](const valarray<size_t>&);

    // 26.3.2.5 unary operators:
    valarray<T> operator+() const;
    valarray<T> operator-() const;
    valarray<T> operator~() const;
    valarray<bool> operator!() const;

    // 26.3.2.6 computed assignment:
    valarray<T>& operator*= (const T&);
    valarray<T>& operator/=(const T&);

Draft
The class template `valarray<T>` is a one-dimensional smart array, with elements numbered sequentially from zero. It is a representation of the mathematical concept of an ordered set of values. The illusion of higher dimensionality may be produced by the familiar idiom of computed indices, together with the powerful subsetting capabilities provided by the generalized subscript operators.

An implementation is permitted to qualify any of the functions declared in `<valarray>` as `inline`.  

1. The intent is to specify an array template that has the minimum functionality necessary to address aliasing ambiguities and the proliferation of temporaries. Thus, the `valarray` template is neither a matrix class nor a field class. However, it is a very useful building block for designing such classes.

2. An implementation is permitted to qualify any of the functions declared in `<valarray>` as `inline`.  

```cpp
valarray<T>& operator %= (const T&);
valarray<T>& operator += (const T&);
valarray<T>& operator -= (const T&);
valarray<T>& operator ^= (const T&);
valarray<T>& operator &= (const T&);
valarray<T>& operator |= (const T&);
valarray<T>& operator <<= (const T&);
valarray<T>& operator >>= (const T&);

valarray<T>& operator *= (const valarray<T>&);
valarray<T>& operator /= (const valarray<T>&);
valarray<T>& operator %= (const valarray<T>&);
valarray<T>& operator += (const valarray<T>&);
valarray<T>& operator -= (const valarray<T>&);
valarray<T>& operator ^= (const valarray<T>&);
valarray<T>& operator |= (const valarray<T>&);
valarray<T>& operator <<= (const valarray<T>&);
valarray<T>& operator >>= (const valarray<T>&);

// 26.3.2.7 member functions:
size_t size() const;
T sum() const;
T min() const;
T max() const;

valarray<T> shift(int) const;
valarray<T> cshift(int) const;
valarray<T> apply(T func(T)) const;
valarray<T> apply(T func(const T&)) const;
void resize(size_t sz, T c = T());
```

26.3.2.1 `valarray` constructors  

```cpp
valarray();
```
26.3 Numeric arrays

Effects: Constructs an object of class `valarray<T>`\(^{267}\) which has zero length until it is passed into a library function as a modifiable lvalue or through a non-constant this pointer\(^{268}\).

```cpp
explicit valarray(size_t);
```

The array created by this constructor has a length equal to the value of the argument. The elements of the array are constructed using the default constructor for the instantiating type T.

```cpp
valarray(const T&, size_t);
```

The array created by this constructor has a length equal to the second argument. The elements of the array are initialized with the value of the first argument.

```cpp
valarray(const T*, size_t);
```

The array created by this constructor has a length equal to the second argument n. The values of the elements of the array are initialized with the first n values pointed to by the first argument.\(^{269}\) If the value of the second argument is greater than the number of values pointed to by the first argument, the behavior is undefined.

```cpp
valarray(const valarray<T>&);
```

The array created by this constructor has the same length as the argument array. The elements are initialized with the values of the corresponding elements of the argument array.\(^{270}\)

```cpp
valarray(const slice_array<T>&);
valarray(const gslice_array<T>&);
valarray(const mask_array<T>&);
valarray(const indirect_array<T>&);
```

These conversion constructors convert one of the four reference templates to a `valarray`.

```cpp
~valarray();
```

The destructor is applied to every element of *this; an implementation may return all allocated memory.

26.3.2.2 `valarray` assignment

```cpp
valarray<T>& operator=(const valarray<T>&);
```

Each element of the *this array is assigned the value of the corresponding element of the argument array. The resulting behavior is undefined if the length of the argument array is not equal to the length of the *this array.

```cpp
valarray<T>& operator=(const T&);
```

The scalar assignment operator causes each element of the *this array to be assigned the value of the argument.

\(^{267}\) For convenience, such objects are referred to as "arrays" throughout the remainder of 26.3.

\(^{268}\) This default constructor is essential, since arrays of `valarray` are likely to prove useful. There shall also be a way to change the size of an array after initialization; this is supplied by the semantics of the `resize` member function.

\(^{269}\) This constructor is the preferred method for converting a C array to a `valarray` object.

\(^{270}\) This copy constructor creates a distinct array rather than an alias. Implementations in which arrays share storage are permitted, but they shall implement a copy-on-reference mechanism to ensure that arrays are conceptually distinct.
valarray<T>& operator=(const slice_array<T>&);
valarray<T>& operator=(const gslice_array<T>&);
valarray<T>& operator=(const mask_array<T>&);
valarray<T>& operator=(const indirect_array<T>&);

These operators allow the results of a generalized subscripting operation to be assigned directly to a valarray.

If the value of an element in the left-hand side of a valarray assignment operator depends on the value of another element in that left-hand side, the resulting behavior is undefined.

26.3.2.3 valarray element access [lib.valarray.access]

const T& operator[](size_t) const;
T& operator[](size_t);

When applied to a constant array, the subscript operator returns the value of the corresponding element of the array. When applied to a non-constant array, the subscript operator returns a reference to the corresponding element of the array.

Thus, the expression (a[i] = q, a[i]) == q evaluates as true for any non-constant valarray<T> a, any T q, and for any size_t i such that the value of i is less than the length of a.

The expression &a[i+j] == &a[i] + j evaluates as true for all size_t i and size_t j such that i+j is less than the length of the non-constant array a.

Likewise, the expression &a[i] != &b[j] evaluates as true for any two non-constant arrays a and b and for any size_t i and size_t j such that i is less than the length of a and j is less than the length of b. This property indicates an absence of aliasing and may be used to advantage by optimizing compilers.\(^{271}\)

The reference returned by the subscript operator for a non-constant array is guaranteed to be valid until the member function resize(size_t, T) (26.3.2.7) is called for that array or until the lifetime of that array ends, whichever happens first.

If the subscript operator is invoked with a size_t argument whose value is not less than the length of the array, the behavior is undefined.

26.3.2.4 valarray subset operations [lib.valarray.sub]

valarray<T> operator[](slice) const;
slice_array<T> operator[](slice);
valarray<T> operator[](const gslice&) const;
gslice_array<T> operator[](const gslice&);
valarray<T> operator[](const valarray<bool>&) const;
mask_array<T> operator[](const valarray<bool>&);
valarray<T> operator[](const valarray<size_t>&) const;
indirect_array<T> operator[](const valarray<size_t>&);

\(^{271}\) Compilers may take advantage of inlining, constant propagation, loop fusion, tracking of pointers obtained from operator new, and other techniques to generate efficient valarrays.
Each of these operations returns a subset of the array. The \texttt{const\textemdash}qualified versions return this subset as a new \texttt{valarray}. The non-\texttt{const} versions return a class template object which has reference semantics to the original array.

### 26.3.2.5 \texttt{valarray} unary operators

\begin{verbatim}
valarray<T> operator+() const;
valarray<T> operator-() const;
valarray<T> operator~() const;
valarray<bool> operator!() const;
\end{verbatim}

Each of these operators may only be instantiated for a type \(T\) to which the indicated operator can be applied and for which the indicated operator returns a value which is of type \(T\) (\texttt{bool} for \texttt{operator!}) or which may be unambiguously converted to type \(T\) (\texttt{bool} for \texttt{operator!}).

Each of these operators returns an array whose length is equal to the length of the array. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding element of the array.

### 26.3.2.6 \texttt{valarray} computed assignment

\begin{verbatim}
valarray<T>& operator*=( const valarray<T>&);
valarray<T>& operator/=( const valarray<T>&);
valarray<T>& operator%=( const valarray<T>&);
valarray<T>& operator+= ( const valarray<T>&);
valarray<T>& operator-= ( const valarray<T>&);
valarray<T>& operator^=( const valarray<T>&);
valarray<T>& operator&=( const valarray<T>&);
valarray<T>& operator|=( const valarray<T>&);
valarray<T>& operator<<=( const valarray<T>&);
valarray<T>& operator>>=( const valarray<T>&);
\end{verbatim}

Each of these operators may only be instantiated for a type \(T\) to which the indicated operator can be applied. Each of these operators performs the indicated operation on each of its elements and the corresponding element of the argument array.

The array is then returned by reference.

If the array and the argument array do not have the same length, the behavior is undefined. The appearance of an array on the left-hand side of a computed assignment does \textit{not} invalidate references or pointers.

If the value of an element in the left-hand side of a \texttt{valarray} computed assignment operator depends on the value of another element in that left hand side, the resulting behavior is undefined.

\begin{verbatim}
valarray<T>& operator*=( const T&);
valarray<T>& operator/=( const T&);
valarray<T>& operator%=( const T&);
valarray<T>& operator+= ( const T&);
valarray<T>& operator-= ( const T&);
\end{verbatim}
valarray<T>& operator^= (const T&);
valarray<T>& operator&= (const T&);
valarray<T>& operator|= (const T&);
valarray<T>& operator<<= (const T&);
valarray<T>& operator>>= (const T&);

Each of these operators may only be instantiated for a type T to which the indicated operator can be applied.

Each of these operators applies the indicated operation to each element of the array and the non-array argument.
The array is then returned by reference.
The appearance of an array on the left-hand side of a computed assignment does not invalidate references or pointers to the elements of the array.

26.3.2.7 valarray member functions

size_t size() const;

This function returns the number of elements in the array.

T sum() const;

This function may only be instantiated for a type T to which operator+= can be applied. This function returns the sum of all the elements of the array.

If the array has length 0, the behavior is undefined. If the array has length 1, sum() returns the value of element 0. Otherwise, the returned value is calculated by applying operator+= to a copy of an element of the array and all other elements of the array in an unspecified order.

T min() const;

This function returns the minimum value contained in *this. The value returned for an array of length 0 is undefined. For an array of length 1, the value of element 0 is returned. For all other array lengths, the determination is made using operator<.

T max() const;

This function returns the maximum value contained in *this. The value returned for an array of length 0 is undefined. For an array of length 1, the value of element 0 is returned. For all other array lengths, the determination is made using operator<.

valarray<T> shift(int n) const;

This function returns an object of class valarray<T> of length size(), each of whose elements I is (*this)[I + n] if I + n is non-negative and less than size(), otherwise T(). Thus if element zero is taken as the leftmost element, a positive value of n shifts the elements left n places, with zero fill.

[Example: If the argument has the value -2, the first two elements of the result will be constructed using the default constructor; the third element of the result will be assigned the value of the first element of the argument; etc. — end example ]

valarray<T> cshift(int n) const;

Draft
This function returns an object of class `valarray<T>`, of length `size()`, each of whose elements \( I \) is \((\ast \text{this})[(I + n) \mod \text{size()}]\). Thus, if element zero is taken as the leftmost element, a positive value of \( n \) shifts the elements circularly left \( n \) places.

```cpp
valarray<T> apply(T func(T)) const;
valarray<T> apply(T func(const T&)) const;
```

These functions return an array whose length is equal to the array. Each element of the returned array is assigned the value returned by applying the argument function to the corresponding element of the array.

```cpp
void resize(size_t sz, T c = T());
```

This member function changes the length of the `\ast \text{this}` array to \( \text{sz} \) and then assigns to each element the value of the second argument. Resizing invalidates all pointers and references to elements in the array.

### 26.3.3 `valarray` non-member operations

#### 26.3.3.1 `valarray` binary operators

```cpp
template<class T> valarray<T> operator*(const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator/(const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator%(const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator+(const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator-(const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator^(const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator&(const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator|(const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator<<(const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> operator>>(const valarray<T>&, const valarray<T>&);
```

Each of these operators may only be instantiated for a type \( T \) to which the indicated operator can be applied and for which the indicated operator returns a value which is of type \( T \) or which can be unambiguously converted to type \( T \).

Each of these operators returns an array whose length is equal to the lengths of the argument arrays. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding elements of the argument arrays.

If the argument arrays do not have the same length, the behavior is undefined.

```cpp
template<class T> valarray<T> operator*(const valarray<T>&, const T&);
```
template<class T> valarray<T> operator* (const T&, const valarray<T>&);
template<class T> valarray<T> operator/ (const T&, const valarray<T>&);
template<class T> valarray<T> operator% (const T&, const valarray<T>&);
template<class T> valarray<T> operator% (const valarray<T>&, const T&);
template<class T> valarray<T> operator+ (const valarray<T>&, const T&);
template<class T> valarray<T> operator+ (const T& , const valarray<T>&);
template<class T> valarray<T> operator- (const valarray<T>&, const T&);
template<class T> valarray<T> operator- (const T& , const valarray<T>&);
template<class T> valarray<T> operator^ (const T& , const valarray<T>&);
template<class T> valarray<T> operator^ (const valarray<T>& , const T&);
template<class T> valarray<T> operator& (const valarray<T>&, const T&);
template<class T> valarray<T> operator& (const T& , const valarray<T>&);
template<class T> valarray<T> operator| (const valarray<T>&, const T&);
template<class T> valarray<T> operator| (const T& , const valarray<T>&);
template<class T> valarray<T> operator<<(const valarray<T>&, const T&);
template<class T> valarray<T> operator<<(const T& , const valarray<T>&);
template<class T> valarray<T> operator>>(const valarray<T>&, const T&);
template<class T> valarray<T> operator>>(const T& , const valarray<T>&);

Each of these operators may only be instantiated for a type \( T \) to which the indicated operator can be applied and for which the indicated operator returns a value which is of type \( T \) or which can be unambiguously converted to type \( T \).

Each of these operators returns an array whose length is equal to the length of the array argument. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding element of the array argument and the non-array argument.

### 26.3.3.2 valarray logical operators

[lib.valarray.comparison]

template<class T> valarray<bool> operator== (const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator!= (const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator< (const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator> (const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator<= (const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator>= (const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator&& (const valarray<T>&, const valarray<T>&);
template<class T> valarray<bool> operator|| (const valarray<T>&, const valarray<T>&);

Each of these operators may only be instantiated for a type \( T \) to which the indicated operator can be applied and for which the indicated operator returns a value which is of type \( bool \) or which can be unambiguously converted to \( bool \).
Each of these operators returns a *bool* array whose length is equal to the length of the array arguments. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding elements of the argument arrays.

If the two array arguments do not have the same length, the behavior is undefined.

template<typename T> valarray<bool> operator==(const valarray<T>&, const T&);
template<typename T> valarray<bool> operator==(const T&, const valarray<T>&);
template<typename T> valarray<bool> operator!=(const valarray<T>&, const T&);
template<typename T> valarray<bool> operator!=(const T&, const valarray<T>&);
template<typename T> valarray<bool> operator<(const valarray<T>&, const T&);
template<typename T> valarray<bool> operator<(const T&, const valarray<T>&);
template<typename T> valarray<bool> operator<=(const valarray<T>&, const T&);
template<typename T> valarray<bool> operator<=(const T&, const valarray<T>&);
template<typename T> valarray<bool> operator>(const valarray<T>&, const T&);
template<typename T> valarray<bool> operator>(const T&, const valarray<T>&);
template<typename T> valarray<bool> operator>=(const valarray<T>&, const T&);
template<typename T> valarray<bool> operator>=(const T&, const valarray<T>&);
template<typename T> valarray<bool> operator&&(const valarray<T>&, const T&);
template<typename T> valarray<bool> operator&&(const T&, const valarray<T>&);
template<typename T> valarray<bool> operator||(const valarray<T>&, const T&);
template<typename T> valarray<bool> operator||(const T&, const valarray<T>&);

Each of these operators may only be instantiated for a type *T* to which the indicated operator can be applied and for which the indicated operator returns a value which is of type *bool* or which can be unambiguously converted to type *bool*.

Each of these operators returns a *bool* array whose length is equal to the length of the array argument. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding element of the array and the non-array argument.

### 26.3.3.3 *valarray transcendental* [lib.valarray.transcend]

template<typename T> valarray<T> abs (const valarray<T>&);
template<typename T> valarray<T> acos (const valarray<T>&);
template<typename T> valarray<T> asin (const valarray<T>&);
template<typename T> valarray<T> atan (const valarray<T>&);
template<typename T> valarray<T> atan2 (const valarray<T>&, const valarray<T>&);
template<typename T> valarray<T> atan2(const valarray<T>&, const T&);
template<typename T> valarray<T> atan2(const T&, const valarray<T>&);
template<typename T> valarray<T> cos (const valarray<T>&);
template<typename T> valarray<T> cosh (const valarray<T>&);
template<typename T> valarray<T> exp (const valarray<T>&);
template<typename T> valarray<T> log (const valarray<T>&);
template<typename T> valarray<T> log10 (const valarray<T>&);
template<typename T> valarray<T> pow (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> pow (const valarray<T>&, const T&);
template<class T> valarray<T> pow (const T&, const valarray<T>&);
template<class T> valarray<T> sin (const valarray<T>&);
template<class T> valarray<T> sinh (const valarray<T>&);
template<class T> valarray<T> sqrt (const valarray<T>&);
template<class T> valarray<T> tan (const valarray<T>&);
template<class T> valarray<T> tanh (const valarray<T>&);

Each of these functions may only be instantiated for a type \( T \) to which a unique function with the indicated name can be applied (unqualified). This function shall return a value which is of type \( T \) or which can be unambiguously converted to type \( T \).

26.3.4 Class slice

namespace std {
    class slice {
        public:
            slice();
            slice(size_t, size_t, size_t);

            size_t start() const;
            size_t size() const;
            size_t stride() const;
    }
}

The slice class represents a BLAS-like slice from an array. Such a slice is specified by a starting index, a length, and a stride. \(^{272}\)

26.3.4.1 slice constructors

slice();
slice(size_t start, size_t length, size_t stride);
slice(const slice&);

The default constructor for slice creates a slice which specifies no elements. A default constructor is provided only to permit the declaration of arrays of slices. The constructor with arguments for a slice takes a start, length, and stride parameter.

[Example: slice(3, 8, 2) constructs a slice which selects elements 3, 5, 7, ... 17 from an array. — end example]

26.3.4.2 slice access functions

size_t start() const;
size_t size() const;

\(^{272}\) BLAS stands for Basic Linear Algebra Subprograms. C++ programs may instantiate this class. See, for example, Dongarra, Du Croz, Duff, and Hammerling: A set of Level 3 Basic Linear Algebra Subprograms; Technical Report MCS-P1-0888, Argonne National Laboratory (USA), Mathematics and Computer Science Division, August, 1988.
size_t stride() const;

These functions return the start, length, or stride specified by a slice object.

### 26.3.5 Class template slice_array

```cpp
namespace std {
    template < class T > class slice_array {
        public:
            typedef T value_type;
            void operator= (const valarray<T>&) const;
            void operator*= (const valarray<T>&) const;
            void operator/= (const valarray<T>&) const;
            void operator%= (const valarray<T>&) const;
            void operator+= (const valarray<T>&) const;
            void operator-= (const valarray<T>&) const;
            slice_array (const slice_array&);
            ~slice_array();
            slice_array& operator=(const slice_array&);
                void operator=(const T&) const;
        private:
            slice_array();
            }; // slice_array
    } // std
```

The `slice_array` template is a helper template used by the slice subscript operator

```cpp
slice_array<T> valarray<T>::operator[](slice);
```

It has reference semantics to a subset of an array specified by a slice object.

*Example:* The expression `a[slice(1, 5, 3)] = b;` has the effect of assigning the elements of `b` to a slice of the elements in `a`. For the slice shown, the elements selected from `a` are 1, 4, ..., 13. — *end example*

### 26.3.5.1 slice_array constructors

```cpp
slice_array();
```

This constructor is declared to be private. This constructor need not be defined.

### 26.3.5.2 slice_array assignment

```cpp
```

Draft
These assignment operators have reference semantics, assigning the values of the argument array elements to selected elements of the valarray\langle T\rangle object to which the slice_array object refers.

26.3.5.3 slice_array computed assignment

These computed assignments have reference semantics, applying the indicated operation to the elements of the argument array and selected elements of the valarray\langle T\rangle object to which the slice_array object refers.

26.3.5.4 slice_array fill function

This function has reference semantics, assigning the value of its argument to the elements of the valarray\langle T\rangle object to which the slice_array object refers.

26.3.6 The gslice class

This class represents a generalized slice out of an array. A gslice is defined by a starting offset (s), a set of lengths (l_j), and a set of strides (d_j). The number of lengths shall equal the number of strides.

A gslice represents a mapping from a set of indices (i_j), equal in number to the number of strides, to a single index k. It is useful for building multidimensional array classes using the valarray template, which is one-dimensional. The
set of one-dimensional index values specified by a \texttt{gslice} are

\[ k = s + \sum_{j} i_j d_j \]

where the multidimensional indices \( i_j \) range in value from 0 to \( l_{ij} - 1 \).

\[ \text{Example: The } \texttt{gslice} \text{ specification} \]

\begin{verbatim}
start = 3
length = \{2, 4, 3\}
stride = \{19, 4, 1\}
\end{verbatim}

yields the sequence of one-dimensional indices

\[ k = 3 + (0,1) \times 19 + (0,1,2,3) \times 4 + (0,1,2) \times 1 \]

which are ordered as shown in the following table:

\[
\begin{align*}
(i_0, & \quad i_1, \quad i_2, \quad k) = \\
(0, & \quad 0, \quad 0, \quad 3), \\
(0, & \quad 0, \quad 1, \quad 4), \\
(0, & \quad 0, \quad 2, \quad 5), \\
(0, & \quad 1, \quad 0, \quad 7), \\
(0, & \quad 1, \quad 1, \quad 8), \\
(0, & \quad 1, \quad 2, \quad 9), \\
(0, & \quad 2, \quad 0, \quad 11), \\
(0, & \quad 2, \quad 1, \quad 12), \\
(0, & \quad 2, \quad 2, \quad 13), \\
(0, & \quad 3, \quad 0, \quad 15), \\
(0, & \quad 3, \quad 1, \quad 16), \\
(0, & \quad 3, \quad 2, \quad 17), \\
(1, & \quad 0, \quad 0, \quad 22), \\
(1, & \quad 0, \quad 1, \quad 23), \\
\ldots & \\
(1, & \quad 3, \quad 2, \quad 36)
\end{align*}
\]

That is, the highest-ordered index turns fastest. \textit{— end example}]

It is possible to have degenerate generalized slices in which an address is repeated.

\[ \text{Example: If the stride parameters in the previous example are changed to } \{1, 1, 1\}, \text{ the first few elements of the resulting sequence of indices will be} \]

\[
\begin{align*}
(0, & \quad 0, \quad 0, \quad 3), \\
(0, & \quad 0, \quad 1, \quad 4), \\
(0, & \quad 0, \quad 2, \quad 5), \\
(0, & \quad 1, \quad 0, \quad 4), \\
(0, & \quad 1, \quad 1, \quad 5), \\
(0, & \quad 1, \quad 2, \quad 6), \\
\ldots &
\end{align*}
\]
If a degenerate slice is used as the argument to the non-const version of `operator[](const gslice&)`, the resulting behavior is undefined.

### 26.3.6.1 gslice constructors

```cpp
gslice();
gslice(size_t start, const valarray<size_t>& lengths,
       const valarray<size_t>& strides);
gslice(const gslice&);
```

The default constructor creates a `gslice` which specifies no elements. The constructor with arguments builds a `gslice` based on a specification of start, lengths, and strides, as explained in the previous section.

### 26.3.6.2 gslice access functions

```cpp
size_t start() const;
valarray<size_t> size() const;
valarray<size_t> stride() const;
```

These access functions return the representation of the start, lengths, or strides specified for the `gslice`.

### 26.3.7 Class template gslice_array

```cpp
namespace std {
    template <class T> class gslice_array {
        public:
            typedef T value_type;

            void operator=(const valarray<T>&) const;
            void operator*=(const valarray<T>&) const;
            void operator/=(const valarray<T>&) const;
            void operator%=(const valarray<T>&) const;
            void operator+=(const valarray<T>&) const;
            void operator-=(const valarray<T>&) const;
            void operator^=(const valarray<T>&) const;
            void operator&=(const valarray<T>&) const;
            void operator|=(const valarray<T>&) const;
            void operator<=(const valarray<T>&) const;
            void operator>=(const valarray<T>&) const;

            gslice_array(const gslice_array&);
            gslice_array();
            gslice_array& operator=(const gslice_array&);
            void operator=(const T&) const;
        private:
            gslice_array();
    }
}
```
This template is a helper template used by the \texttt{slice} subscript operator
\begin{verbatim}
gslice_array<T> valarray<T>::operator[](const gslice&);
\end{verbatim}
It has reference semantics to a subset of an array specified by a gslice object.
Thus, the expression \texttt{a[gslice(1, length, stride)] = b} has the effect of assigning the elements of \texttt{b} to a
generalized slice of the elements in \texttt{a}.

### 26.3.7.1 \texttt{gslice_array} constructors

\begin{verbatim}
gslice_array();
\end{verbatim}
This constructor is declared to be private. This constructor need not be defined.

### 26.3.7.2 \texttt{gslice_array} assignment

\begin{verbatim}
void operator=(const valarray<T>&) const;
gslice_array& operator=(const gslice_array&);
\end{verbatim}
These assignment operators have reference semantics, assigning the values of the argument array elements to
selected elements of the \texttt{valarray<T>} object to which the \texttt{gslice_array} object refers.

### 26.3.7.3 \texttt{gslice_array} computed assignments

\begin{verbatim}
void operator*=(const valarray<T>&) const;
void operator/=(const valarray<T>&) const;
void operator%=(const valarray<T>&) const;
void operator+=(const valarray<T>&) const;
void operator-=(const valarray<T>&) const;
void operator^=(const valarray<T>&) const;
void operator&=(const valarray<T>&) const;
void operator|=(const valarray<T>&) const;
void operator<=(const valarray<T>&) const;
void operator>=(const valarray<T>&) const;
\end{verbatim}
These computed assignments have reference semantics, applying the indicated operation to the elements of the
argument array and selected elements of the \texttt{valarray<T>} object to which the \texttt{gslice_array} object refers.

### 26.3.7.4 \texttt{gslice_array} fill function

\begin{verbatim}
void operator=(const T&) const;
\end{verbatim}
This function has reference semantics, assigning the value of its argument to the elements of the \texttt{valarray<T>}
object to which the \texttt{gslice_array} object refers.
26.3.8 Class template mask_array

namespace std {
    template <class T> class mask_array {
    public:
        typedef T value_type;
        void operator=(const valarray<T>&) const;
        void operator*=(const valarray<T>&) const;
        void operator/=(const valarray<T>&) const;
        void operator%=(const valarray<T>&) const;
        void operator+=(const valarray<T>&) const;
        void operator-=(const valarray<T>&) const;
        void operator^=(const valarray<T>&) const;
        void operator&=(const valarray<T>&) const;
        void operator|=(const valarray<T>&) const;
        void operator<<=(const valarray<T>&) const;
        void operator>>=(const valarray<T>&) const;

        mask_array(const mask_array&);
        ~mask_array();
        mask_array& operator=(const mask_array&);
        void operator=(const T&) const;
    private:
        mask_array();
    };
}

This template is a helper template used by the mask subscript operator:

\texttt{mask\_array<T>\ valarray<T>::operator[]()}(const valarray<bool>&).

It has reference semantics to a subset of an array specified by a boolean mask. Thus, the expression \texttt{a[mask] = b;} has the effect of assigning the elements of \texttt{b} to the masked elements in \texttt{a} (those for which the corresponding element in \texttt{mask} is true.)

26.3.8.1 mask_array constructors

\texttt{mask\_array()};

This constructor is declared to be private. This constructor need not be defined.

26.3.8.2 mask_array assignment

\texttt{void operator=(const valarray<T>&) const;}
\texttt{mask\_array\& operator=(const mask\_array\&);}.

These assignment operators have reference semantics, assigning the values of the argument array elements to selected elements of the \texttt{valarray<T> object to which it refers.}
26.3.8.3 mask_array computed assignment

```cpp
void operator**(const valarray<T>&) const;
void operator/=(const valarray<T>&) const;
void operator%=(const valarray<T>&) const;
void operator+=(const valarray<T>&) const;
void operator-=(const valarray<T>&) const;
void operator^=(const valarray<T>&) const;
void operator&=(const valarray<T>&) const;
void operator|=(const valarray<T>&) const;
void operator<=(const valarray<T>&) const;
void operator>=(const valarray<T>&) const;
```

These computed assignments have reference semantics, applying the indicated operation to the elements of the argument array and selected elements of the valarray<T> object to which the mask object refers.

26.3.8.4 mask_array fill function

```cpp
void operator=(const T&) const;
```

This function has reference semantics, assigning the value of its argument to the elements of the valarray<T> object to which the mask_array object refers.

26.3.9 Class template indirect_array

```cpp
namespace std {
    template<class T> class indirect_array {
        public:
            typedef T value_type;
            void operator=(const valarray<T>&) const;
            void operator**(const valarray<T>&) const;
            void operator/=(const valarray<T>&) const;
            void operator%=(const valarray<T>&) const;
            void operator+=(const valarray<T>&) const;
            void operator-=(const valarray<T>&) const;
            void operator^=(const valarray<T>&) const;
            void operator&=(const valarray<T>&) const;
            void operator|=(const valarray<T>&) const;
            void operator<=(const valarray<T>&) const;
            void operator>=(const valarray<T>&) const;

            indirect_array(const indirect_array&);
            indirect_array();
            indirect_array& operator=(const indirect_array&);
            void operator=(const T&) const;
        private:
            indirect_array();
    };
```

Draft
This template is a helper template used by the indirect subscript operator

\[
\text{indirect\_array<}T\text{> }\text{valarray<}T\text{>::operator[]}\text{(const valarray<}size\text{_t}\text{>&)}.\]

It has reference semantics to a subset of an array specified by an indirect\_array. Thus the expression \(a[\text{indirect}] = b\); has the effect of assigning the elements of \(b\) to the elements in \(a\) whose indices appear in indirect.

### 26.3.9.1 indirect\_array constructors

indirect\_array();

This constructor is declared to be private. This constructor need not be defined.

### 26.3.9.2 indirect\_array assignment

\[
\text{void operator=}\text{(const valarray<}T\text{>&) const;}\]

\[
\text{indirect\_array& operator=}\text{(const indirect\_array&);}\]

These assignment operators have reference semantics, assigning the values of the argument array elements to selected elements of the valarray\(T\) object to which it refers.

If the indirect\_array specifies an element in the valarray\(T\) object to which it refers more than once, the behavior is undefined.

[Example:

\[
\text{int addr[]} = \{2, 3, 1, 4, 4\};\]

\[
\text{valarray<}size\text{_t}> \text{indirect(addr, 5);}\]

\[
\text{valarray<}double\text{> a(0., 10), b(1., 5);}\]

\[
a[\text{indirect}] = b;\]

results in undefined behavior since element 4 is specified twice in the indirection. — end example]

### 26.3.9.3 indirect\_array computed assignment

\[
\text{void operator=}\text{(const valarray<}T\text{>&) const;}\]

\[
\text{void operator/= (const valarray<}T\text{>&) const;}\]

\[
\text{void operator%= (const valarray<}T\text{>&) const;}\]

\[
\text{void operator+= (const valarray<}T\text{>&) const;}\]

\[
\text{void operator-= (const valarray<}T\text{>&) const;}\]

\[
\text{void operator^= (const valarray<}T\text{>&) const;}\]

\[
\text{void operator&= (const valarray<}T\text{>&) const;}\]

\[
\text{void operator|= (const valarray<}T\text{>&) const;}\]

\[
\text{void operator<=(const valarray<}T\text{>&) const;}\]

\[
\text{void operator>==(const valarray<}T\text{>&) const;}\]

Draft
These computed assignments have reference semantics, applying the indicated operation to the elements of the argument array and selected elements of the \texttt{valarray<T>} object to which the \texttt{indirect_array} object refers.

If the \texttt{indirect_array} specifies an element in the \texttt{valarray<T>} object to which it refers more than once, the behavior is undefined.

### 26.3.9.4 \texttt{indirect_array} fill function

\begin{verbatim}
void operator=(const T&) const;
\end{verbatim}

This function has reference semantics, assigning the value of its argument to the elements of the \texttt{valarray<T>} object to which the \texttt{indirect_array} object refers.

### 26.4 Generalized numeric operations

Header \texttt{<numeric> synopsis}

\begin{verbatim}
namespace std {
    template <class InputIterator, class T>
    T accumulate(InputIterator first, InputIterator last, T init);
    template <class InputIterator, class T, class BinaryOperation>
    T accumulate(InputIterator first, InputIterator last, T init, BinaryOperation binary_op);

    template <class InputIterator1, class InputIterator2, class T>
    T inner_product(InputIterator1 first1, InputIterator1 last1, InputIterator2 first2, T init);
    template <class InputIterator1, class InputIterator2, class T, class BinaryOperation1, class BinaryOperation2>
    T inner_product(InputIterator1 first1, InputIterator1 last1, InputIterator2 first2, T init, BinaryOperation1 binary_op1, BinaryOperation2 binary_op2);

    template <class InputIterator, class OutputIterator>
    OutputIterator partial_sum(InputIterator first, InputIterator last, OutputIterator result);
    template <class InputIterator, class OutputIterator, class BinaryOperation>
    OutputIterator partial_sum(InputIterator first, InputIterator last, OutputIterator result, BinaryOperation binary_op);

    template <class InputIterator, class OutputIterator>
    OutputIterator adjacent_difference(InputIterator first, InputIterator last, OutputIterator result);
\end{verbatim}

Draft
template <class InputIterator , class OutputIterator ,
          class BinaryOperation >
    OutputIterator adjacent_difference ( InputIterator first ,
                                           InputIterator last ,
                                           OutputIterator result ,
                                           BinaryOperation binary_op );
}

The requirements on the types of algorithms’ arguments that are described in the introduction to clause 25 also apply to the following algorithms.

26.4.1 Accumulate

    template < class InputIterator , class T >
    T accumulate ( InputIterator first , InputIterator last , T init );
    template < class InputIterator , class T , class BinaryOperation >
    T accumulate ( InputIterator first , InputIterator last , T init ,
                   BinaryOperation binary_op );

    Effects: Computes its result by initializing the accumulator acc with the initial value init and then modifies it with acc = acc + *i or acc = binary_op(acc, *i) for every iterator i in the range [first,last) in order.273

    Requires: T shall meet the requirements of CopyConstructible (20.1.3) and Assignable (23.1) types. In the range [first,last], binary_op shall neither modify elements nor invalidate iterators or subranges.274

26.4.2 Inner product

    template < class InputIterator1 , class InputIterator2 , class T >
    T inner_product ( InputIterator1 first1 , InputIterator1 last1 ,
                      InputIterator2 first2 , T init );
    template < class InputIterator1 , class InputIterator2 , class T ,
               class BinaryOperation1 , class BinaryOperation2 >
    T inner_product ( InputIterator1 first1 , InputIterator1 last1 ,
                      InputIterator2 first2 , T init ,
                      BinaryOperation1 binary_op1 ,
                      BinaryOperation2 binary_op2 );

    Effects: Computes its result by initializing the accumulator acc with the initial value init and then modifying it with acc = acc + (*i1) * (*i2) or acc = binary_op1(acc, binary_op2(*i1, *i2)) for every iterator i1 in the range [first1,last1) and iterator i2 in the range [first2,first2 + (last2 - first2)) in order.

    Requires: T shall meet the requirements of CopyConstructible (20.1.3) and Assignable (23.1) types. In the ranges [first, last] and [first2, first2 + (last2 - first2)] binary_op1 and binary_op2 shall neither modify elements nor invalidate iterators or subranges.275

273) accumulate is similar to the APL reduction operator and Common Lisp reduce function, but it avoids the difficulty of defining the result of reduction on an empty sequence by always requiring an initial value.

274) The use of fully closed ranges is intentional.

275) The use of fully closed ranges is intentional.
26.4 Generalized numeric operations

26.4.3 Partial sum

```cpp
template < class InputIterator , class OutputIterator >
OutputIterator
partial_sum ( InputIterator first , InputIterator last ,
OutputIterator result );
```

```cpp
template < class InputIterator , class OutputIterator , class BinaryOperation >
OutputIterator
partial_sum ( InputIterator first , InputIterator last ,
OutputIterator result , BinaryOperation binary_op );
```

1 Effects: Assigns to every element referred to by iterator `i` in the range `[result, result + (last - first))` a value correspondingly equal to

\[ ((...(*first + *(first + 1)) + ...) + *(first + (i - result))) \]

or

\[ binary_op(binary_op(..., \quad binary_op(*first, *(first + 1)),...), *(first + (i - result))) \]

2 Returns: `result + (last - first)`.

3 Complexity: Exactly `(last - first) - 1` applications of `binary_op`.

4 Requires: In the ranges `[first, last]` and `[result, result + (last - first)]` `binary_op` shall neither modify elements nor invalidate iterators or subranges.\(^{276}\)

5 Remarks: `result` may be equal to `first`.

26.4.4 Adjacent difference

```cpp
template < class InputIterator , class OutputIterator >
OutputIterator
adjacent_difference ( InputIterator first , InputIterator last ,
OutputIterator result );
```

```cpp
template < class InputIterator , class OutputIterator , class BinaryOperation >
OutputIterator
adjacent_difference ( InputIterator first , InputIterator last ,
OutputIterator result , BinaryOperation binary_op );
```

1 Effects: Assigns to every element referred to by iterator `i` in the range `[result + 1, result + (last - first))` a value correspondingly equal to

\[ *(first + (i - result)) - *(first + (i - result) - 1) \]

or

\[ binary_op(binary_op(..., \quad binary_op(*first, *(first + 1)),...), *(first + (i - result))) \]

\(^{276}\)The use of fully closed ranges is intentional.
binary_op(*(first + (i - result)), *(first + (i - result) - 1)).

result gets the value of *first.

Requires: In the ranges [first,last] and [result,result + (last - first)], binary_op shall neither modify elements nor invalidate iterators or subranges.\textsuperscript{277)}

Remarks: result may be equal to first.

Returns: result + (last - first).

Complexity: Exactly (last - first) - 1 applications of binary_op.

26.5 C Library

Tables 81 and 82 describe headers <cmath> and <cstdlib>, respectively.

Table 81: Header <cmath> synopsis

<table>
<thead>
<tr>
<th>Type</th>
<th>Name(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Macro: HUGE_VAL</td>
<td></td>
</tr>
<tr>
<td>Functions:</td>
<td></td>
</tr>

<td>ldiv</td>
</tr>
</tbody>
</table>

2 The contents of these headers are the same as the Standard C library headers <math.h> and <stdlib.h> respectively, with the following changes:

3 The rand function has the semantics specified in the C standard, except that the implementation may specify that particular library functions may call rand.

4 In addition to the int versions of certain math functions in <cstdlib>, C++ adds long overloaded versions of these functions, with the same semantics.

5 The added signatures are:

\textsuperscript{277)}The use of fully closed ranges is intentional.
In addition to the `double` versions of the math functions in `<cmath>`, C++ adds `float` and `long double` overloaded versions of these functions, with the same semantics.

The added signatures are:

```c
float abs(float);
float acos(float);
float asin(float);
float atan(float);
float atan2(float, float);
float ceil(float);
float cos(float);
float cosh(float);
float exp(float);
float fabs(float);
float floor(float);
float fmod(float, float);
float frexp(float, int*);
float ldexp(float, int);
float log(float);
float log10(float);
float modf(float, float*);
float pow(float, float);
float pow(float, int);
float sin(float);
float sinh(float);
float sqrt(float);
float tan(float);
float tanh(float);

27.1 Iostreams requirements

27.1.1 Imbue Limitations

No function described in clause 27 except for ios_base::imbue causes any instance of basic_ios::imbue or basic_streambuf::imbue to be called. If any user function called from a function declared in clause 27 or as an overriding virtual function of any class declared in clause 27 calls imbue, the behavior is undefined.

27.1.2 Positioning Type Limitations

The classes of clause 27 with template arguments charT and traits behave as described if traits::pos_type and traits::off_type are streampos and streamoff respectively. Except as noted explicitly below, their behavior when traits::pos_type and traits::off_type are other types is implementation-defined.

27.2 Forward declarations

Header <iosfwd> synopsis
namespace std {

template<
class charT>
class char_traits;

template<>
class char_traits<char>;

template<>
class char_traits<wchar_t>;

typedef fpos<char_traits<char> ::state_type> streampos;
typedef fpos<char_traits<wchar_t> ::state_type> wstreampos;

1 Default template arguments are described as appearing both in <iosfwd> and in the synopsis of other headers but it is
well-formed to include both <iosfwd> and one or more of the other headers.278)

278 It is the implementation’s responsibility to implement headers so that including <iosfwd> and other headers does not violate the rules about
multiple occurrences of default arguments.

Draft
[Note: The class template specialization basic_ios<charT,traits> serves as a virtual base class for the class templates basic_istream, basic_ostream, and class templates derived from them. basic_iostream is a class template derived from both basic_istream<charT,traits> and basic_ostream<charT,traits>.

The class template specialization basic_streambuf<charT,traits> serves as a base class for template classes basic_stringbuf and basic_filebuf.

The class template specialization basic_istream<charT,traits> serves as a base class for template classes basic_stringstream and basic_ifstream.

The class template specialization basic_ostream<charT,traits> serves as a base class for template classes basic_stringstream and basic_ofstream.

The class template specialization basic_iostream<charT,traits> serves as a base class for template classes basic_stringstream and basic_fstream.

Other typedefs define instances of class templates specialized for char or wchar_t types.

Specializations of the class template fpos are used for specifying file position information.

The types streampos and wstreampos are used for positioning streams specialized on char and wchar_t respectively.

This synopsis suggests a circularity between streampos and char_traits<char>. An implementation can avoid this circularity by substituting equivalent types. One way to do this might be

```
template<class stateT> class fpos { ... }; // depends on nothing
typedef ... _STATE; // implementation private declaration of stateT
typedef fpos<_STATE> streampos;

template<> struct char_traits<char> {
  typedef streampos pos_type;
  // ...
};
```

— end note ]

27.3 Standard iostream objects

Header <iostream> synopsis

```
namespace std {
  extern istream cin;
  extern ostream cout;
  extern ostream cerr;
  extern ostream clog;

  extern wistream wcin;
  extern wostream wcout;
  extern wostream wcerr;
  extern wostream wclog;
}
```
The header `<iostream>` declares objects that associate objects with the standard C streams provided for by the functions declared in `<cstdio>` (27.8.2).

Mixing operations on corresponding wide- and narrow-character streams follows the same semantics as mixing such operations on FILEs, as specified in Amendment 1 of the ISO C standard. The objects are constructed, and the associations are established at some time prior to or during first time an object of class `ios_base::Init` is constructed, and in any case before the body of main begins execution. The objects are not destroyed during program execution.

### 27.3.1 Narrow stream objects

```c
istream cin;
```

The object `cin` controls input from a stream buffer associated with the object `stdin`, declared in `<cstdio>`.

After the object `cin` is initialized, `cin.tie()` returns `&cout`. Its state is otherwise the same as required for `basic_ios<char>::init` (27.4.4.1).

```c
ostream cout;
```

The object `cout` controls output to a stream buffer associated with the object `stdout`, declared in `<cstdio>` (27.8.2).

```c
ostream cerr;
```

The object `cerr` controls output to a stream buffer associated with the object `stderr`, declared in `<cstdio>` (27.8.2).

After the object `cerr` is initialized, `cerr.flags() & unitbuf` is nonzero and `cerr.tie()` returns `&cout`. Its state is otherwise the same as required for `basic_ios<char>::init` (27.4.4.1).

```c
ostream clog;
```

The object `clog` controls output to a stream buffer associated with the object `stderr`, declared in `<cstdio>` (27.8.2).

### 27.3.2 Wide stream objects

```c
wistream wcin;
```

The object `wcin` controls input from a stream buffer associated with the object `stdin`, declared in `<cstdio>`.

After the object `wcin` is initialized, `wcin.tie()` returns `&wcout`. Its state is otherwise the same as required for `basic_ios<wchar_t>::init` (27.4.4.1).

```c
wostream wcout;
```

The object `wcout` controls output to a stream buffer associated with the object `stdout`, declared in `<cstdio>` (27.8.2).

```c
wostream wcerr;
```

---

279) If it is possible for them to do so, implementations are encouraged to initialize the objects earlier than required.

280) Constructors and destructors for static objects can access these objects to read input from `stdin` or write output to `stdout` or `stderr`. 

Draft
The object \texttt{wcerr} controls output to a stream buffer associated with the object \texttt{stderr}, declared in \texttt{<cstdio> (27.8.2)}.

After the object \texttt{wcerr} is initialized, \texttt{wcerr.flags() & unitbuf} is nonzero and \texttt{wcerr.tie()} returns \texttt{&wcout}. Its state is otherwise the same as required for \texttt{basic_ios<wchar_t>::init (27.4.4.1)}.

\begin{verbatim}
wofstream wclog;
\end{verbatim}

The object \texttt{wclog} controls output to a stream buffer associated with the object \texttt{stderr}, declared in \texttt{<cstdio> (27.8.2)}.

### 27.4 Iostreams base classes

**Header** <ios> **synopsis**

```cpp
#include <iosfwd>
namespace std {
    typedef OFF_T streamoff;
    typedef SZ_T streamsize;
    template <class stateT> class fpos;

    class ios_base;
    template <class charT, class traits = char_traits<charT>>
        class basic_ios;

    // 27.4.5, manipulators:
    ios_base& boolalpha (ios_base& str);
    ios_base& noboolalpha (ios_base& str);
    ios_base& showbase (ios_base& str);
    ios_base& nobase (ios_base& str);
    ios_base& showpoint (ios_base& str);
    ios_base& noxpoint (ios_base& str);
    ios_base& showpos (ios_base& str);
    ios_base& nosh (ios_base& str);
    ios_base& skipws (ios_base& str);
    ios_base& noskipws (ios_base& str);
    ios_base& uppercase (ios_base& str);
    ios_base& nouppercase (ios_base& str);
    ios_base& unitbuf (ios_base& str);
    ios_base& nounitbuf (ios_base& str);

    // 27.4.5.2 adjustfield:
    ios_base& internal (ios_base& str);
```

Draft
typedef OFF_T streamoff;

1 The type streamoff is an implementation-defined type that satisfies the requirements of 27.4.3.2.

typedef SZ_T streamsize;

2 The type streamsize is a synonym for one of the signed basic integral types. It is used to represent the number of characters transferred in an I/O operation, or the size of I/O buffers.281)

27.4.2 Class ios_base

namespace std {
    class ios_base {
        public:
            class failure;

            typedef TI fmtflags;
            static const fmtflags boolalpha;
            static const fmtflags dec;
            static const fmtflags fixed;
            static const fmtflags hex;
            static const fmtflags internal;
            static const fmtflags left;
            static const fmtflags oct;
            static const fmtflags right;
            static const fmtflags scientific;
            static const fmtflags showbase;
            static const fmtflags showpoint;
            static const fmtflags showpos;
            static const fmtflags skipws;

281) streamsize is used in most places where ISO C would use size_t. Most of the uses of streamsize could use size_t, except for the strstreambuf constructors, which require negative values. It should probably be the signed type corresponding to size_t (which is what Posix.2 calls ssize_t).
static const fmtflags unitbuf;
static const fmtflags uppercase;
static const fmtflags adjustfield;
static const fmtflags basefield;
static const fmtflags floatfield;

typedef T2 iostate;
static const iostate badbit;
static const iostate eofbit;
static const iostate failbit;
static const iostate goodbit;

typedef T3 openmode;
static const openmode app;
static const openmode ate;
static const openmode binary;
static const openmode in;
static const openmode out;
static const openmode trunc;

typedef T4 seekdir;
static const seekdir beg;
static const seekdir cur;
static const seekdir end;

class Init;

// 27.4.2.2 fmtflags state:
fmtflags flags() const;
fmtflags flags(fmtflags fmtfl);
fmtflags setf(fmtflags fmtfl);
fmtflags setf(fmtflags fmtfl, fmtflags mask);
void unsetf(fmtflags mask);

streamsize precision() const;
streamsize precision(streamsize prec);
streamsize width() const;
streamsize width(streamsize wide);

// 27.4.2.3 locales:
locale imbue(const locale& loc);
locale getloc() const;

// 27.4.2.5 storage:
static int xalloc();
long& iword(int index);
void*& pword(int index);

// destructor
virtual ~ios_base();
// 27.4.2.6 callbacks:
enum event { erase_event, imbue_event, copyfmt_event };
typedef void (*event_callback)(event, ios_base&, int index);
void register_callback(event_callback fn, int index);

static bool sync_with_stdio(bool sync = true);

protected:
    ios_base();

private:
    // static int index;
    // long* iarray;
    // void** parray;
private:
    ios_base(const ios_base&);
    ios_base& operator=(const ios_base&);
};

1 ios_base defines several member types:
   — a class failure derived from exception;
   — a class Init;
   — three bitmask types, fmtflags, iostate, and openmode;
   — an enumerated type, seekdir.

2 It maintains several kinds of data:
   — state information that reflects the integrity of the stream buffer;
   — control information that influences how to interpret (format) input sequences and how to generate (format) output sequences;
   — additional information that is stored by the program for its private use.

[Note: For the sake of exposition, the maintained data is presented here as:
   — static int index, specifies the next available unique index for the integer or pointer arrays maintained for the private use of the program, initialized to an unspecified value;
   — long* iarray, points to the first element of an arbitrary-length long array maintained for the private use of the program;
   — void** parray, points to the first element of an arbitrary-length pointer array maintained for the private use of the program. — end note]
27.4 Iostreams base classes

27.4.2.1 Types

27.4.2.1.1 Class ios_base::failure

namespace std {
    class ios_base::failure : public exception {
        public:
            explicit failure(const string & msg);
            virtual const char* what() const throw();
    };
}

The class failure defines the base class for the types of all objects thrown as exceptions, by functions in the iostreams library, to report errors detected during stream buffer operations.

    explicit failure(const string & msg);

    Effects: Constructs an object of class failure.

    Postcondition: strcmp(what(), msg.c_str()) == 0

    const char* what() const;

    Returns: The message msg with which the exception was created.

27.4.2.1.2 Type ios_base::fmtflags

typedef T1 fmtflags;

The type fmtflags is a bitmask type (17.3.2.1.2). Setting its elements has the effects indicated in Table 84.

Type fmtflags also defines the constants indicated in Table 85.

27.4.2.1.3 Type ios_base::iostate

typedef T2 iostate;

The type iostate is a bitmask type (17.3.2.1.2) that contains the elements indicated in Table 86.

Type iostate also defines the constant:
    — goodbit, the value zero.

27.4.2.1.4 Type ios_base::openmode

typedef T3 openmode;

The type openmode is a bitmask type (17.3.2.1.2). It contains the elements indicated in Table 87.

Draft

27.4 Iostreams base classes

### 27.4.2.1.5 Type `ios_base::seekdir`

```cpp
typedef T4 seekdir;
```

The type `seekdir` is an enumerated type (17.3.2.1.1) that contains the elements indicated in Table 88.

<table>
<thead>
<tr>
<th>Element</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>beg</td>
<td>request a seek (for subsequent input or output) relative to the beginning of the stream</td>
</tr>
<tr>
<td>cur</td>
<td>request a seek relative to the current position within the sequence</td>
</tr>
<tr>
<td>end</td>
<td>request a seek relative to the current end of the sequence</td>
</tr>
</tbody>
</table>

### 27.4.2.1.6 Class `ios_base::Init`

```cpp
class ios_base::Init {
public:
    Init();
    ~Init();
private:
    // static int init_cnt;
};
```

The class `Init` describes an object whose construction ensures the construction of the eight objects declared in `<iostream>` (27.3) that associate file stream buffers with the standard C streams provided for by the functions declared in `<cstdio>` (27.8.2).

For the sake of exposition, the maintained data is presented here as:

- static int `init_cnt`, counts the number of constructor and destructor calls for class `Init`, initialized to zero.

`Init();`

**Effects:** Constructs an object of class `Init`. If `init_cnt` is zero, the function stores the value one in `init_cnt`, then constructs and initializes the objects `cin`, `cout`, `cerr`, `clog` (27.3.1), `wcin`, `wcout`, `wcerr`, and `wclog` (27.3.2). In any case, the function then adds one to the value stored in `init_cnt`.

`~Init();`

**Effects:** Destroys an object of class `Init`. The function subtracts one from the value stored in `init_cnt` and, if the resulting stored value is one, calls `cout.flush()`, `cerr.flush()`, `clog.flush()`, `wcout.flush()`, `wcerr.flush()`, `wclog.flush()`.

### 27.4.2.2 ios_base state functions

```cpp
fmtflags flags() const;
```
Returns: The format control information for both input and output.

```c++
fmtflags flags(fmtflags fmtfl);
```

Postcondition: `fmtfl == flags()`.

Returns: The previous value of `flags()`.

```c++
fmtflags setf(fmtflags fmtfl);
```

Effects: Sets `fmtfl` in `flags()`.

Returns: The previous value of `flags()`.

```c++
fmtflags setf(fmtflags fmtfl, fmtflags mask);
```

Effects: Clears `mask` in `flags()`, sets `fmtfl & mask` in `flags()`.

Returns: The previous value of `flags()`.

```c++
void unsetf(fmtflags mask);
```

Effects: Clears `mask` in `flags()`.

Returns: The previous value of `flags()`.

```c++
streamsize precision() const;
```

Returns: The precision to generate on certain output conversions.

```c++
streamsize precision(streamsize prec);
```

Postcondition: `prec == precision()`.

Returns: The previous value of `precision()`.

```c++
streamsize width() const;
```

Returns: The minimum field width (number of characters) to generate on certain output conversions.

```c++
streamsize width(streamsize wide);
```

Postcondition: `wide == width()`.

Returns: The previous value of `width()`.

### 27.4.2.3 ios_base functions

```c++
locale imbue(const locale& loc);
```

Effects: Calls each registered callback pair `(fn, index)` (27.4.2.6) as `(*(fn)(imbue_event,*this,index))` at such a time that a call to `ios_base::getloc()` from within `fn` returns the new locale value `loc`.

Returns: The previous value of `getloc()`.

Postcondition: `loc == getloc()`.

```c++
locale getloc() const;
```
Returns: If no locale has been imbued, a copy of the global C++ locale, `locale()`, in effect at the time of construction. Otherwise, returns the imbued locale, to be used to perform locale-dependent input and output operations.

27.4.2.4 **`ios_base` static members**

```cpp
bool sync_with_stdio(bool sync = true);
```

Returns: `true` if the previous state of the standard iostream objects (27.3) was synchronized and otherwise returns `false`. The first time it is called, the function returns `true`.

Effects: If any input or output operation has occurred using the standard streams prior to the call, the effect is implementation-defined. Otherwise, called with a false argument, it allows the standard streams to operate independently of the standard C streams.

When a standard iostream object `str` is synchronized with a standard stdio stream `f`, the effect of inserting a character `c` by

```cpp
fputc(f, c);
```

is the same as the effect of

```cpp
str.rdbuf()->sputc(c);
```

for any sequences of characters; the effect of extracting a character `c` by

```cpp
sgetc(f);
```

is the same as the effect of

```cpp
str.rdbuf()->sbumpc(c);
```

for any sequences of characters; and the effect of pushing back a character `c` by

```cpp
ungetc(c, f);
```

is the same as the effect of

```cpp
str.rdbuf()->sputbackc(c);
```

for any sequence of characters.\(^{282}\)

27.4.2.5 **`ios_base` storage functions**

```cpp
static int xalloc();
```

Returns: `index ++`.\(^{282}\)

\(^{282}\)This implies that operations on a standard iostream object can be mixed arbitrarily with operations on the corresponding stdio stream. In practical terms, synchronization usually means that a standard iostream object and a standard stio object share a buffer.
long & iword(int idx);

Effects: If iarray is a null pointer, allocates an array of long of unspecified size and stores a pointer to its first element in iarray. The function then extends the array pointed at by iarray as necessary to include the element iarray[idx]. Each newly allocated element of the array is initialized to zero. The reference returned is invalid after any other operations on the object. However, the value of the storage referred to is retained, so that until the next call to copyfmt, calling iword with the same index yields another reference to the same value. If the function fails and *this is a base subobject of a basic_ios<> object or subobject, the effect is equivalent to calling basic_ios<>::setstate(badbit) on the derived object (which may throw failure).

Returns: On success iarray[idx]. On failure, a valid long& initialized to 0.

void* & pword(int idx);

Effects: If parray is a null pointer, allocates an array of pointers to void of unspecified size and stores a pointer to its first element in parray. The function then extends the array pointed at by parray as necessary to include the element parray[idx]. Each newly allocated element of the array is initialized to a null pointer. The reference returned is invalid after any other operations on the object. However, the value of the storage referred to is retained, so that until the next call to copyfmt, calling pword with the same index yields another reference to the same value. If the function fails and *this is a base subobject of a basic_ios<> object or subobject, the effect is equivalent to calling basic_ios<>::setstate(badbit) on the derived object (which may throw failure).

Returns: On success parray[idx]. On failure a valid void*& initialized to 0.

Remarks: After a subsequent call to pword(int) for the same object, the earlier return value may no longer be valid.

27.4.2.6 ios_base callbacks

void register_callback(event_callback fn, int index);

Effects: Registers the pair (fn, index) such that during calls to imbue() (27.4.2.3), copyfmt(), or ~ios_base() (27.4.2.7), the function fn is called with argument index. Functions registered are called when an event occurs, in opposite order of registration. Functions registered while a callback function is active are not called until the next event.

Requires: The function fn shall not throw exceptions.

Remarks: Identical pairs are not merged. A function registered twice will be called twice.

27.4.2.7 ios_base constructors/destructors

ios_base();
27.4 Iostreams base classes

1. Effects: Each ios_base member has an indeterminate value after construction. These members shall be initialized by calling basic_ios::init. If an ios_base object is destroyed before these initializations have taken place, the behavior is undefined.

`~ios_base()`

2. Effects: Destroys an object of class ios_base. Calls each registered callback pair \((fn, index)\) (27.4.2.6) as \((*fn)(erase_event, *this, index)\) at such time that any ios_base member function called from within \(fn\) has well defined results.

27.4.3 Class template fpos

namespace std {
    template <class stateT>
    class fpos {
    public:
        // 27.4.3.1 Members
        stateT state() const;
        void state(stateT);
    private;
        // stateT st;
        exposition only
    };
}

27.4.3.1 fpos Members

void state(stateT s);

1. Effects: Assign \(s\) to \(st\).

stateT state() const;

2. Returns: Current value of \(st\).

27.4.3.2 fpos requirements

Operations specified in Table 89 are permitted. In that table,

- \(P\) refers to an instance of fpos,
- \(p\) and \(q\) refer to values of type \(P\),
- \(O\) refers to type streamoff,
- \(o\) refers to a value of type streamoff,
- \(sz\) refers to a value of type streamsize and
- \(i\) refers to a value of type int.
Table 89: Position type requirements

<table>

</tr>
<tr>
<td>0(sz)</td>
<td>OFF_T</td>
<td>converts</td>
<td>streamsize(O(sz)) == sz</td>
</tr>
</tbody>
</table>

[Note: Every implementation is required to supply overloaded operators on fpos objects to satisfy the requirements of 27.4.3.2. It is unspecified whether these operators are members of fpos, global operators, or provided in some other way. — end note]

Stream operations that return a value of type traits::pos_type return P(O(-1)) as an invalid value to signal an error. If this value is used as an argument to any istream, ostream, or streambuf member that accepts a value of type traits::pos_type then the behavior of that function is undefined.

27.4.4 Class template basic_ios

```cpp
namespace std {
    template <class charT, class traits = char_traits<charT> >
    class basic_ios : public ios_base {
        public:

        // Types:
        typedef charT char_type;
        typedef typename traits::int_type int_type;
        typedef typename traits::pos_type pos_type;
        typedef typename traits::off_type off_type;
        typedef traits traits_type;

        operator void*() const;
        bool operator!() const;
        iostate rdstate() const;
        void clear(iostate state = goodbit);
    }
}
```

Draft
void setstate(iostate state);
bool good() const;
bool eof() const;
bool fail() const;
bool bad() const;

iostate exceptions() const;
void exceptions(iostate except);

// 27.4.4.1 Constructor/destructor:
explicit basic_ios(basic_streambuf<charT,traits>* sb);
virtual ~basic_ios();

// 27.4.4.2 Members:
basic_ostream<charT,traits>* tie() const;
basic_ostream<charT,traits>* tie(basic_ostream<charT,traits>* tiestr);
basic_streambuf<charT,traits>* rdbuf() const;
basic_streambuf<charT,traits>* rdbuf(basic_streambuf<charT,traits>* sb);

basic_ios& copyfmt(const basic_ios& rhs);
char_type fill() const;
char_type fill(char_type ch);

// 27.4.2.3 locales:
locale imbue(const locale& loc);
char narrow(char_type c, char default) const;
char_type widen(char c) const;

protected:
basic_ios();
void init(basic_streambuf<charT,traits>* sb);

private:
basic_ios(const basic_ios& ); // not defined
basic_ios& operator=(const basic_ios& ); // not defined
};

27.4.4.1 basic_ios constructors

explicit basic_ios(basic_streambuf<charT,traits>* sb);

Effects: Constructs an object of class basic_ios, assigning initial values to its member objects by calling init(sb).

basic_ios();
Effects: Constructs an object of class basic_ios (27.4.2.7) leaving its member objects uninitialized. The object shall be initialized by calling its init member function. If it is destroyed before it has been initialized the behavior is undefined.

`~basic_ios();`

Remarks: The destructor does not destroy rdbuf().

`void init(basic_streambuf<charT,traits>* sb);`

Postconditions: The postconditions of this function are indicated in Table 90.

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>rdbuf()</td>
<td>sb</td>
</tr>
<tr>
<td>tie()</td>
<td>0</td>
</tr>
<tr>

<td>a null pointer</td>
</tr>
<tr>
<td>parray</td>
<td>a null pointer</td>
</tr>
</tbody>
</table>

27.4.4.2 Member functions

`basic_ostream<charT,traits>* tie() const;`

Returns: An output sequence that is tied to (synchronized with) the sequence controlled by the stream buffer.

`basic_ostream<charT,traits>* tie(basic_ostream<charT,traits>* tiestr);`

Postcondition: tiestr == tie().

Returns: The previous value of tie().

`basic_streambuf<charT,traits>* rdbuf() const;`

Returns: A pointer to the streambuf associated with the stream.

`basic_streambuf<charT,traits>* rdbuf(basic_streambuf<charT,traits>* sb);`

Postcondition: sb == rdbuf().

Effects: Calls clear().

Returns: The previous value of rdbuf().

Draft
27.4 Iostreams base classes

// 27.4.2.3 locales:
locale imbue(const locale& loc);

Effects: Calls ios_base::imbue(loc) (27.4.2.3) and if rdbuf() != 0 then rdbuf()->pubimbue(loc) (27.5.2.2.1).
Returns: The prior value of ios_base::imbue().

char narrow(char_type c, char default) const;

Returns: use_facet<ctype<char_type>>(getloc()).narrow(c, default)

char_type widen(char c) const;

Returns: use_facet<ctype<char_type>>(getloc()).widen(c)

char_type fill() const;
Returns: The character used to pad (fill) an output conversion to the specified field width.

char_type fill(char_type fillch);
Postcondition: traits::eq(fillch, fill())
Returns: The previous value of fill().

basic_iostream<basic_ios& copyfmt(const basic_ios& rhs);

Effects: If (this == &rhs) does nothing. Otherwise assigns to the member objects of *this the corresponding
member objects of rhs, except that:
— rdstate() and rdbuf() are left unchanged;
— exceptions() is altered last by calling exceptions(rhs.exceptions).
— The contents of arrays pointed at by pword and iword are copied not the pointers themselves.286)

If any newly stored pointer values in *this point at objects stored outside the object rhs, and those ob-
jects are destroyed when rhs is destroyed, the newly stored pointer values are altered to point at newly
constructed copies of the objects.

Before copying any parts of rhs, calls each registered callback pair (fn, index) as (*fn)(erase_event, *this, index). After all parts but exceptions() have been replaced, calls each callback pair
that was copied from rhs as (*fn)(copyfmt_event, *this, index).

Remarks: The second pass permits a copied pword value to be zeroed, or its referent deep copied or reference
counted or have other special action taken.

Returns: *this.

27.4.4.3 basic_ios flags functions

operator void*() const;

286) This suggests an infinite amount of copying, but the implementation can keep track of the maximum element of the arrays that is non-zero.
Returns: If fail() then a null pointer; otherwise some non-null pointer to indicate success.

```cpp
bool operator!() const;
```

Returns: fail().

```cpp
iostate rdstate() const;
```

Returns: The error state of the stream buffer.

```cpp
void clear(iostate state = goodbit);
```

Postcondition: If rdbuf() != 0 then state == rdstate(); otherwise rdstate() == (state | ios_base::badbit).

Effects: If ((state | (rdbuf() ? goodbit : badbit)) & exceptions()) == 0, returns. Otherwise, the function throws an object fail of class basic_ios::failure(27.4.2.1.1), constructed with implementation-defined argument values.

```cpp
void setstate(iostate state);
```

Effects: Calls clear(rdstate() | state) (which may throw basic_ios::failure(27.4.2.1.1)).

```cpp
bool good() const;
```

Returns: rdstate() == 0

```cpp
bool eof() const;
```

Returns: true if eofbit is set in rdstate().

```cpp
bool fail() const;
```

Returns: true if failbit or badbit is set in rdstate().

```cpp
bool bad() const;
```

Returns: true if badbit is set in rdstate().

```cpp
iostate exceptions() const;
```

Returns: A mask that determines what elements set in rdstate() cause exceptions to be thrown.

```cpp
void exceptions(iostate except);
```

Postcondition: except == exceptions().

Effects: Calls clear(rdstate()).

---

27.4.5  ios_base manipulators [lib.std.ios.manip]

27.4.5.1  fmtflags manipulators [lib.fmtflags.manip]

\(^{287}\) Checking badbit also for fail() is historical practice.
ios_base& boolalpha(ios_base& str);
  Effects: Calls str.setf(ios_base::boolalpha).
  Returns: str.

ios_base& noboolalpha(ios_base& str);
  Effects: Calls str.unsetf(ios_base::boolalpha).
  Returns: str.

ios_base& showbase(ios_base& str);
  Effects: Calls str.setf(ios_base::showbase).
  Returns: str.

ios_base& noshowbase(ios_base& str);
  Effects: Calls str.unsetf(ios_base::showbase).
  Returns: str.

ios_base& showpoint(ios_base& str);
  Effects: Calls str.setf(ios_base::showpoint).
  Returns: str.

ios_base& noshowpoint(ios_base& str);
  Effects: Calls str.unsetf(ios_base::showpoint).
  Returns: str.

ios_base& showpos(ios_base& str);
  Effects: Calls str.setf(ios_base::showpos).
  Returns: str.

ios_base& noshowpos(ios_base& str);
  Effects: Calls str.unsetf(ios_base::showpos).
  Returns: str.

ios_base& skipws(ios_base& str);
  Effects: Calls str.setf(ios_base::skipws).
  Returns: str.

ios_base& noskipws(ios_base& str);
  Effects: Calls str.unsetf(ios_base::skipws).
  Returns: str.
ios_base& uppercase( ios_base& str);
  Effects: Calls str.setf(ios_base::uppercase).
  Returns: str.

ios_base& nouppercase( ios_base& str);
  Effects: Calls str.unsetf(ios_base::uppercase).
  Returns: str.

ios_base& unitbuf( ios_base& str);
  Effects: Calls str.setf(ios_base::unitbuf).
  Returns: str.

ios_base& nounitbuf( ios_base& str);
  Effects: Calls str.unsetf(ios_base::unitbuf).
  Returns: str.

27.4.5.2 adjustfield manipulators

ios_base& internal( ios_base& str);
  Effects: Calls str.setf(ios_base::internal, ios_base::adjustfield).
  Returns: str.

ios_base& left( ios_base& str);
  Effects: Calls str.setf(ios_base::left, ios_base::adjustfield).
  Returns: str.

ios_base& right( ios_base& str);
  Effects: Calls str.setf(ios_base::right, ios_base::adjustfield).
  Returns: str.

27.4.5.3 basefield manipulators

ios_base& dec( ios_base& str);
  Effects: Calls str.setf(ios_base::dec, ios_base::basefield).
  Returns: str\(^{288}\).

\(^{288}\) The function signature `dec(ios_base&)` can be called by the function signature `basic_ostream& stream::operator<<(ios_base& (*)(ios_base&))` to permit expressions of the form `cout << dec` to change the format flags stored in `cout`.
27.5 Stream buffers

ios_base& hex(ios_base& str);
   Effects: Calls str.setf(ios_base::hex, ios_base::basefield).
   Returns: str.

ios_base& oct(ios_base& str);
   Effects: Calls str.setf(ios_base::oct, ios_base::basefield).
   Returns: str.

27.4.5.4 floatfield manipulators

ios_base& fixed(ios_base& str);
   Effects: Calls str.setf(ios_base::fixed, ios_base::floatfield).
   Returns: str.

ios_base& scientific(ios_base& str);
   Effects: Calls str.setf(ios_base::scientific, ios_base::floatfield).
   Returns: str.

27.5 Stream buffers

Header <streambuf> synopsis

namespace std {
   template <class charT, class traits = char_traits<charT> >
    class basic_streambuf;
   typedef basic_streambuf<char> streambuf;
   typedef basic_streambuff<wchar_t > wstreambuf;
}

The header <streambuf> defines types that control input from and output to character sequences.

27.5.1 Stream buffer requirements

Stream buffers can impose various constraints on the sequences they control. Some constraints are:

— The controlled input sequence can be not readable.
— The controlled output sequence can be not writable.
— The controlled sequences can be associated with the contents of other representations for character sequences, such as external files.
— The controlled sequences can support operations directly to or from associated sequences.
— The controlled sequences can impose limitations on how the program can read characters from a sequence, write characters to a sequence, put characters back into an input sequence, or alter the stream position.

Draft
Each sequence is characterized by three pointers which, if non-null, all point into the same `charT` array object. The array object represents, at any moment, a (sub)sequence of characters from the sequence. Operations performed on a sequence alter the values stored in these pointers, perform reads and writes directly to or from associated sequences, and alter “the stream position” and conversion state as needed to maintain this subsequence relationship. The three pointers are:

- the **beginning pointer**, or lowest element address in the array (called `xbeg` here);
- the **next pointer**, or next element address that is a current candidate for reading or writing (called `xnext` here);
- the **end pointer**, or first element address beyond the end of the array (called `xend` here).

The following semantic constraints shall always apply for any set of three pointers for a sequence, using the pointer names given immediately above:

- If `xnext` is not a null pointer, then `xbeg` and `xend` shall also be non-null pointers into the same `charT` array, as described above; otherwise, `xbeg` and `xend` shall also be null.
- If `xnext` is not a null pointer and `xnext < xend` for an output sequence, then a write position is available. In this case, `*xnext` shall be assignable as the next element to write (to put, or to store a character value, into the sequence).
- If `xnext` is not a null pointer and `xbeg < xnext` for an input sequence, then a putback position is available. In this case, `xnext[-1]` shall have a defined value and is the next (preceding) element to store a character that is put back into the input sequence.
- If `xnext` is not a null pointer and `xnext < xend` for an input sequence, then a read position is available. In this case, `*xnext` shall have a defined value and is the next element to read (to get, or to obtain a character value, from the sequence).

### 27.5.2 Class template `basic_streambuf< charT, traits >`

```cpp
namespace std {
    template < class charT, class traits >
    class basic_streambuf {
    public:

        // Types:
        typedef charT char_type;
        typedef typename traits::int_type int_type;
        typedef typename traits::pos_type pos_type;
        typedef typename traits::off_type off_type;
        typedef traits traits_type;

        virtual ~basic_streambuf();

        // 27.5.2.2.1 locales:
        locale pubimbue(const locale& loc);
        locale getloc() const;

        // 27.5.2.2.2 buffer and positioning:

    } // class basic_streambuf
} // namespace std
```
basic_streambuf<char_type, traits>*
    pubsetbuf(char_type* s, streamsize n);
pos_type pubseekoff(off_type off, ios_base::seekdir way,  
    ios_base::openmode which =  
    ios_base::in | ios_base::out);
pos_type pubseekpos(pos_type sp,  
    ios_base::openmode which =  
    ios_base::in | ios_base::out);
int pubsync();

// Get and put areas:
// 27.5.2.2.3 Get area:
streamsize in_avail();
int_type snextc();
int_type sbumpc();
int_type sgetc();
streamsize sgetn(char_type* s, streamsize n);

// 27.5.2.2.4 Putback:
int_type sputbackc(char_type c);
int_type sungetc();

// 27.5.2.2.5 Put area:
int_type sputc(char_type c);
streamsize sputn(const char_type* s, streamsize n);

protected:
    basic_streambuf<>;  

// 27.5.2.3.1 Get area:
char_type* eback() const;
char_type* gptr() const;
char_type* egptr() const;
void gbump(int n);
void setg(char_type*gbeg, char_type* gnext, char_type* gend);

// 27.5.2.3.2 Put area:
char_type* pbase() const;
char_type* pptr() const;
char_type* ppnext() const;
void pbump(int n);
void setp(char_type* pbeg, char_type* pend);

// 27.5.2.4 virtual functions:
// 27.5.2.4.1 Locales:
virtual void imbue(const locale& loc);

// 27.5.2.4.2 Buffer management and positioning:
virtual basic_streambuf<char_type, traits>*
    setbuf(char_type* s, streamsize n);
The class template `basic_streambuf<charT,traits>` serves as an abstract base class for deriving various stream buffers whose objects each control two character sequences:

— a character input sequence;
— a character output sequence.

[Note: This paragraph is intentionally empty. — end note]

[Note: This paragraph is intentionally empty. — end note]

### 27.5.2.1 basic_streambuf constructors

#### basic_streambuf() [lib.streambuf.cons]

```
basic_streambuf();
```

**Effects:** Constructs an object of class `basic_streambuf<charT,traits>` and initializes:

— all its pointer member objects to null pointers,
— the `getloc()` member to a copy the global locale, `locale()`, at the time of construction.

**Remarks:** Once the `getloc()` member is initialized, results of calling locale member functions, and of members of facets so obtained, can safely be cached until the next time the member `imbue` is called.

```c
~basic_streambuf();
```

**Effects:** None.

---

Note: This paragraph is intentionally empty. — end note

---

The default constructor is protected for class `basic_streambuf` to assure that only objects for classes derived from this class may be constructed.
27.5 Stream buffers

27.5.2.2 basic_streambuf public member functions

27.5.2.2.1 Locales

locale pubimbue(const locale& loc);

Postcondition: loc == getloc().
Effects: Calls imbue(loc).
Returns: Previous value of getloc().

locale getloc() const;
Returns: If pubimbue() has ever been called, then the last value of loc supplied, otherwise the current global locale, locale(), in effect at the time of construction. If called after pubimbue() has been called but before pubimbue has returned (i.e. from within the call of imbue()) then it returns the previous value.

27.5.2.2.2 Buffer management and positioning

basic_streambuf<char_type,traits>* pubsetbuf(char_type* s, streamsize n);
Returns: setbuf(s, n).

pos_type pubseekoff(off_type off, ios_base::seekdir way, ios_base::openmode which = ios_base::in | ios_base::out);
Returns: seekoff(off, way, which).

pos_type pubseekpos(pos_type sp, ios_base::openmode which = ios_base::in | ios_base::out);
Returns: seekpos(sp, which).

int pubsync();
Returns: sync().

27.5.2.2.3 Get area

streamsize in_avail();
Returns: If a read position is available, returns egptr() - gptr(). Otherwise returns showmanyc() (27.5.2.4.3).

int_type snextc();
Effects: Calls sbumpc().
Returns: if that function returns traits::eof(), returns traits::eof(). Otherwise, returns sgetc().

int_type sbumpc();
Returns: If the input sequence read position is not available, returns uflow(). Otherwise, returns traits::to_int_type(*gptr()) and increments the next pointer for the input sequence.

int_type sgetc();

Returns: If the input sequence read position is not available, returns underflow(). Otherwise, returns traits::to_int_type(*gptr()).

streamsize sgetn(char_type* s, streamsize n);

Returns: xsgetn(s, n).

27.5.2.2.4 Putback

int_type sputbackc(char_type c);

Returns: If the input sequence putback position is not available, or if traits::eq(c, gptr()[-1]) is false, returns pbackfail(traits::to_int_type(c)). Otherwise, decrements the next pointer for the input sequence and returns traits::to_int_type(*gptr()).

int_type sungetc();

Returns: If the input sequence putback position is not available, returns pbackfail(). Otherwise, decrements the next pointer for the input sequence and returns traits::to_int_type(*gptr()).

27.5.2.2.5 Put area

int_type sputc(char_type c);

Returns: If the output sequence write position is not available, returns overflow(traits::to_int_type(c)). Otherwise, stores c at the next pointer for the output sequence, increments the pointer, and returns traits::to_int_type(c).

streamsize sputn(const char_type* s, streamsize n);

Returns: xsputn(s, n).

27.5.2.3 basic_streambuf protected member functions

27.5.2.3.1 Get area access

cchar_type* eback() const;

Returns: The beginning pointer for the input sequence.

cchar_type* gptr() const;

Returns: The next pointer for the input sequence.

cchar_type* egptr() const;
3 *Returns:* The end pointer for the input sequence.

```c
void gbump(int n);
```

4 *Effects:* Adds \( n \) to the next pointer for the input sequence.

```c
void setg(char_type* gbeg, char_type* gnext, char_type* gend);
```

5 *Postconditions:* \( gbeg == 
back() \), \( gnext == gptr() \), and \( gend == egptr() \).

### 27.5.2.3.2 Put area access

[lib.streambuf.put.area]

```c
char_type* pbase() const;
```

1 *Returns:* The beginning pointer for the output sequence.

```c
char_type* pptr() const;
```

2 *Returns:* The next pointer for the output sequence.

```c
char_type* epptr() const;
```

3 *Returns:* The end pointer for the output sequence.

```c
void pbump(int n);
```

4 *Effects:* Adds \( n \) to the next pointer for the output sequence.

```c
void setp(char_type* pbeg, char_type* pend);
```

5 *Postconditions:* \( pbeg == pbase() \), \( pbeg == pptr() \), and \( pend == epptr() \).

### 27.5.2.4 basic_streambuf virtual functions

[lib.streambuf.virt.buffer]

### 27.5.2.4.1 Locales

[lib.streambuf.virtlocales]

```c
void imbue(const locale&);
```

1 *Effects:* Change any translations based on locale.

2 *Remarks:* Allows the derived class to be informed of changes in locale at the time they occur. Between invocations of this function a class derived from streambuf can safely cache results of calls to locale functions and to members of facets so obtained.

3 *Default behavior:* Does nothing.

### 27.5.2.4.2 Buffer management and positioning

[lib.streambuf.virt.buffer]

```c
basic_streambuf* setbuf(char_type* s, streamsize n);
```
Effects: Influences stream buffering in a way that is defined separately for each class derived from basic_streambuf in this clause (27.7.1.3, 27.8.1.4).

Default behavior: Does nothing. Returns this.

```c
pos_type seekoff(off_type off, ios_base::seekdir way,
                 ios_base::openmode which = ios_base::in | ios_base::out);
```

Effects: Alters the stream positions within one or more of the controlled sequences in a way that is defined separately for each class derived from basic_streambuf in this clause (27.7.1.3, 27.8.1.4).

Default behavior: Returns pos_type(off_type(-1)).

```c
pos_type seekpos(pos_type sp,
                 ios_base::openmode which = ios_base::in | ios_base::out);
```

Effects: Alters the stream positions within one or more of the controlled sequences in a way that is defined separately for each class derived from basic_streambuf in this clause (27.7.1.1, 27.8.1.1).

Default behavior: Returns pos_type(off_type(-1)).

```c
int sync();
```

Effects: Synchronizes the controlled sequences with the arrays. That is, if pbase() is non-null the characters between pbase() and pptr() are written to the controlled sequence. The pointers may then be reset as appropriate.

Returns: -1 on failure. What constitutes failure is determined by each derived class (27.8.1.4).

Default behavior: Returns zero.

### 27.5.2.4.3 Get area

```
streamsize showmanyc(); \[\text{lib.streambuf.virt.get}\]
```

Returns: an estimate of the number of characters available in the sequence, or -1. If it returns a positive value, then successive calls to underflow() will not return traits::eof() until at least that number of characters have been extracted from the stream. If showmanyc() returns -1, then calls to underflow() or uflow() will fail.

Default behavior: Returns zero.

Remarks: Uses traits::eof().

```c
streamsize xsgetn(char_type* s, streamsize n);
```

Effects: Assigns up to n characters to successive elements of the array whose first element is designated by s. The characters assigned are read from the input sequence as if by repeated calls to sbumpc(). Assigning stops when either n characters have been assigned or a call to sbumpc() would return traits::eof().

---

290) The morphemes of showmanyc are "es-how-many-see", not "show-manic".

291) underflow or uflow might fail by throwing an exception prematurely. The intention is not only that the calls will not return eof() but that they will return “immediately.”
Returns: The number of characters assigned.

Remarks: Uses traits::eof().

```cpp
int_type underflow();
```

Remarks: The public members of basic_streambuf call this virtual function only if gptr() is null or gptr() >= egptr().

Returns: traits::to_int_type(c), where c is the first character of the pending sequence, without moving the input sequence position past it. If the pending sequence is null then the function returns traits::eof() to indicate failure.

The pending sequence of characters is defined as the concatenation of:

a) If gptr() is non-NULL, then the egptr() - gptr() characters starting at gptr(), otherwise the empty sequence.

b) Some sequence (possibly empty) of characters read from the input sequence.

The result character is

a) If the pending sequence is non-empty, the first character of the sequence.

b) If the pending sequence is empty then the next character that would be read from the input sequence.

The backup sequence is defined as the concatenation of:

a) If eback() is null then empty.

b) Otherwise the gptr() - eback() characters beginning at eback().

Effects: The function sets up the gptr() and egptr() satisfying one of:

a) If the pending sequence is non-empty, egptr() is non-null and egptr() - gptr() characters starting at gptr() are the characters in the pending sequence.

b) If the pending sequence is empty, either gptr() is null or gptr() and egptr() are set to the same non-NULL pointer.

If eback() and gptr() are non-null then the function is not constrained as to their contents, but the “usual backup condition” is that either:

a) If the backup sequence contains at least gptr() - eback() characters, then the gptr() - eback() characters starting at eback() agree with the last gptr() - eback() characters of the backup sequence.

b) Or the n characters starting at gptr() - n agree with the backup sequence (where n is the length of the backup sequence).

Default behavior: Returns traits::eof().

```cpp
int_type uflow();
```
Required: The constraints are the same as for underflow(), except that the result character is transferred from the pending sequence to the backup sequence, and the pending sequence may not be empty before the transfer.

Default behavior: Calls underflow(). If underflow() returns traits::eof(), returns traits::eof(). Otherwise, returns the value of traits::to_int_type(*gptr()) and increment the value of the next pointer for the input sequence.

Returns: traits::eof() to indicate failure.

27.5.2.4.4 Putback [lib.streambuf.virt.pback]

int_type pbackfail(int_type c = traits::eof());

Remarks: The public functions of basic_streambuf call this virtual function only when gptr() is null, gptr() == eback(), or traits::eq(traits::to_char_type(c),gptr()[-1]) returns false. Other calls shall also satisfy that constraint.

The pending sequence is defined as for underflow(), with the modifications that

- If traits::eq_int_type(c,traits::eof()) returns true, then the input sequence is backed up one character before the pending sequence is determined.
- If traits::eq_int_type(c,traits::eof()) return false, then c is prepended. Whether the input sequence is backed up or modified in any other way is unspecified.

Postcondition: On return, the constraints of gptr(), eback(), and pptr() are the same as for underflow().

Returns: traits::eof() to indicate failure. Failure may occur because the input sequence could not be backed up, or if for some other reason the pointers could not be set consistent with the constraints. pbackfail() is called only when put back has really failed.

Returns some value other than traits::eof() to indicate success.

Default behavior: Returns traits::eof().

27.5.2.4.5 Put area [lib.streambuf.virt.put]

streamsize xsputn(const char_type* s, streamsize n);

Effects: Writes up to n characters to the output sequence as if by repeated calls to sputc(c). The characters written are obtained from successive elements of the array whose first element is designated by s. Writing stops when either n characters have been written or a call to sputc(c) would return traits::eof().

Returns: The number of characters written.

int_type overflow(int_type c = traits::eof());

Effects: Consumes some initial subsequence of the characters of the pending sequence. The pending sequence is defined as the concatenation of

  a) if pbase() is NULL then the empty sequence otherwise, pptr() - pbase() characters beginning at pbase().
b) if traits::eq_int_type(c,traits::eof()) returns true, then the empty sequence otherwise, the sequence consisting of c.

Remarks: The member functions sputc() and sputn() call this function in case that no room can be found in the put buffer enough to accomodate the argument character sequence.

Requires: Every overriding definition of this virtual function shall obey the following constraints:

1) The effect of consuming a character on the associated output sequence is specified\(^{293}\)

2) Let \( r \) be the number of characters in the pending sequence not consumed. If \( r \) is non-zero then pbase() and pptr() shall be set so that: \( pptr() - pbase() == r \) and the \( r \) characters starting at pbase() are the associated output stream. In case \( r \) is zero (all characters of the pending sequence have been consumed) then either pbase() is set to NULL, or pbase() and pptr() are both set to the same NULL non-value.

3) The function may fail if either appending some character to the associated output stream fails or if it is unable to establish pbase() and pptr() according to the above rules.

Returns: traits::eof() or throws an exception if the function fails.

Otherwise, returns some value other than traits::eof() to indicate success.\(^{294}\)

Default behavior: Returns traits::eof().

27.6 Formatting and manipulators [lib.io streams.format]

Header <istream> synopsis

namespace std {
    template <class charT, class traits = char_traits<charT> >
    class basic_istream;
    typedef basic_istream<char> istream;
    typedef basic_istream<wchar_t> wistream;

template <class charT, class traits = char_traits<charT> >
    class basic_ostream;
    typedef basic_ostream<char> ostream;
    typedef basic_ostream<wchar_t> wostream;

template <class charT, class traits>
    basic_istream<charT,traits>& ws(basic_istream<charT,traits>& is);
}

Header <ostream> synopsis

namespace std {
    template <class charT, class traits = char_traits<charT> >
    class basic_ostream;

\(^{293}\) That is, for each class derived from an instance of basic_streambuf in this clause (27.7.1, 27.8.1.1), a specification of how consuming a character effects the associated output sequence is given. There is no requirement on a program-defined class.

\(^{294}\) Typically, overflow returns c to indicate success, except when traits::eq_int_type(c,traits::eof()) returns true, in which case it returns traits::not_eof(c).
```cpp
typedef basic_ostream<char> ostream;
typedef basic_ostream<wchar_t> wostream;

template <class charT, class traits>
basic_ostream<charT, traits>& endl(basic_ostream<charT, traits>& os);
template <class charT, class traits>
basic_ostream<charT, traits>& ends(basic_ostream<charT, traits>& os);
template <class charT, class traits>
basic_ostream<charT, traits>& flush(basic_ostream<charT, traits>& os);
```

basic_istream<charT,traits>& seekg(pos_type);
basic_istream<charT,traits>& seekg(off_type, ios_base::seekdir);
}

// 27.6.1.3 Unformatted input:

Draft
The class `basic_istream` defines a number of member function signatures that assist in reading and interpreting input from sequences controlled by a stream buffer.

Two groups of member function signatures share common properties: the *formatted input functions* (or *extractors*) and the *unformatted input functions*. Both groups of input functions are documented as if they obtain (or *extract*) input characters by calling `rdbuf()->sbumpc()` or `rdbuf()->sgetc()`. They may use other public members of `istream`.

If `rdbuf()->sbumpc()` or `rdbuf()->sgetc()` returns `traits::eof()`, then the input function, except as explicitly noted otherwise, completes its actions and does `setstate(eofbit)`, which may throw `ios_base::failure` (27.4.4.3), before returning.

If one of these called functions throws an exception, then unless explicitly noted otherwise, the input function sets `badbit` in error state. If `badbit` is on in `exceptions()`, the input function rethrows the exception without completing its actions, otherwise it does not throw anything and proceeds as if the called function had returned a failure indication.

### 27.6.1.1 `basic_istream` constructors

`explicit basic_istream(basic_streambuf<charT,traits>* sb);`

*Effects:* Constructs an object of class `basic_istream`, assigning initial values to the base class by calling `basic_ios::init(sb)` (27.4.4.1).

*Postcondition:* `gcount() == 0`

*Remarks:* Does not perform any operations of `rdbuf()`.
27.6 Formatting and manipulators

27.6.1.1.2 Class basic_istream::sentry

namespace std {
    template <class charT, class traits = char_traits<charT> >
    class basic_istream<charT, traits>::sentry {
        typedef traits traits_type;
        // bool ok_; exposition only
    public:
        explicit sentry(basic_istream<charT, traits>& is, bool noskipws = false);
        ~sentry();
        operator bool() const { return ok_; }
    private:
        sentry(const sentry&);
        sentry& operator=(const sentry&); // not defined
    }
}

The class sentry defines a class that is responsible for doing exception safe prefix and suffix operations.

explicit sentry(basic_istream<charT, traits>& is, bool noskipws = false);

Effects: If is.good() is true, prepares for formatted or unformatted input. First, if is.tie() is not a null pointer, the function calls is.tie()->flush() to synchronize the output sequence with any associated external C stream. Except that this call can be suppressed if the put area of is.tie() is empty. Further an implementation is allowed to defer the call to flush until a call of is->rdbuf()->underflow occurs. If no such call occurs before the sentry object is destroyed, the call to flush may be eliminated entirely.

If noskipws is zero and is.flags() & ios_base::skipws is nonzero, the function extracts and discards each character as long as the next available input character c is a whitespace character. If is.rdbuf()->sbumpc() or is.rdbuf()->sgetc() returns traits::eof(), the function calls setstate(failbit | eofbit) (which may throw ios_base::failure).

Remarks: The constructor explicit sentry(basic_istream<charT, traits>& is, bool noskipws = false) uses the currently imbued locale in is, to determine whether the next input character is whitespace or not.

To decide if the character c is a whitespace character, the constructor performs “as if” it executes the following code fragment:

    const ctype<charT>& ctype = use_facet<ctype<charT> >(is.getloc());
    if (ctype.is(ctype.space, c)!=0)
        // c is a whitespace character.

If, after any preparation is completed, is.good() is true, ok_ != false otherwise, ok_ == false. During preparation, the constructor may call setstate(failbit) (which may throw ios_base::failure(27.4.4.3))

[Note: This paragraph is intentionally empty. — end note]

Effects: None.

---

295) This will be possible only in functions that are part of the library. The semantics of the constructor used in user code is as specified.
296) The sentry constructor and destructor can also perform additional implementation-dependent operations.
operator bool() const;

Effects: Returns ok_.

27.6.1.2 Formatted input functions

27.6.1.2.1 Common requirements

Each formatted input function begins execution by constructing an object of class sentry with the `noskipws` (second) argument `false`. If the sentry object returns true, when converted to a value of type `bool`, the function endeavors to obtain the requested input. If an exception is thrown during input then `ios::badbit` is turned on\(^\text{[297]}\) in \(\ast\)this’s error state. If `(exceptions()&badbit) !== 0` then the exception is rethrown. In any case, the formatted input function destroys the sentry object. If no exception has been thrown, it returns \(\ast\)this.

27.6.1.2.2 Arithmetic Extractors

As in the case of the inserters, these extractors depend on the locale’s `num_get<>` (22.2.2.1) object to perform parsing the input stream data. These extractors behave as formatted input functions (as described in 27.6.1.2.1). After a sentry object is constructed, the conversion occurs as if performed by the following code fragment:

```cpp
typedef num_get< charT, istreambuf_iterator< charT, traits > > numget;

iostate err = 0;
use_facet< numget >( loc ).get(* this, 0, * this, err , val);
setstate(err);
```

In the above fragment, `loc` stands for the private member of the `basic_ios` class. [Note: The first argument provides an object of the `istreambuf_iterator` class which is an iterator pointed to an input stream. It bypasses istreams and uses streambufs directly. — end note] Class `locale` relies on this type as its interface to `istream`, so that it does not need to depend directly on `istream`.

```cpp
operator>>(short& val);
```

The conversion occurs as if performed by the following code fragment (using the same notation as for the preceding code fragment):

```cpp
typedef num_get< charT, istreambuf_iterator< charT, traits > > numget;

iostate err = 0;
long lval;
use_facet< numget >( loc ).get(* this, 0, * this, err , lval);
```

\(^{297}\) This is done without causing an `ios::failure` to be thrown.
if (err == 0)  
  && (lval < numeric_limits<short>::min()  
    || numeric_limits<short>::max() < lval))  
  err = ios_base::failbit;  
setstate(err);  

operator>>(int & val);

The conversion occurs as if performed by the following code fragment (using the same notation as for the preceding code fragment):

typedef num_get<charT, istreambuf_iterator<charT,traits> > numget;
iostate err = 0;  
long lval;  
use_facet<numget>(loc).get(*this, 0, *this, err, lval);  
if (err == 0)  
  && (lval < numeric_limits<int>::min()  
    || numeric_limits<int>::max() < lval))  
  err = ios_base::failbit;  
setstate(err);

27.6.1.2.3 basic_istream::operator>>  
[lib.istream::extractors]

basic_istream<charT,traits>& operator>>(basic_istream<charT,traits>& (*pf)(basic_istream<charT,traits>&))  
Effects: None. This extractor does not behave as a formatted input function (as described in 27.6.1.2.1.)  
Returns: pf(*this).298

basic_istream<charT,traits>& operator>>(basic_ios<charT,traits>& (*pf)(basic_ios<charT,traits>&));  
Effects: Calls pf(*this). This extractor does not behave as a formatted input function (as described in 27.6.1.2.1).  
Returns: *this.

basic_istream<charT,traits>& operator>>(ios_base& (*pf)(ios_base&));  
Effects: Calls pf(*this).299 This extractor does not behave as a formatted input function (as described in 27.6.1.2.1).  
Returns: *this.

template<class charT, class traits>  
  basic_istream<charT,traits>& operator>>(basic_istream<charT,traits>& in,  
    charT* s);

template<class traits>

298 See, for example, the function signature ws(basic_istream&) (27.6.1.4).
299 See, for example, the function signature dec(ios_base&) (27.4.5.3).
Effects: Behaves like a formatted input member (as described in 27.6.1.2.1) of `in`. After a sentry object is constructed, `operator>>` extracts characters and stores them into successive locations of an array whose first element is designated by `s`. If `width()` is greater than zero, `n` is `width()`. Otherwise `n` is the number of elements of the largest array of `char_type` that can store a terminating `charT()`. `n` is the maximum number of characters stored.

Characters are extracted and stored until any of the following occurs:

- `n-1` characters are stored;
- end of file occurs on the input sequence;
- `ct.is(ct.space,c)` is true for the next available input character `c`, where `ct` is `use_facet<ctype<charT>>(in.getloc())`.

`operator>>` then stores a null byte (`charT()`) in the next position, which may be the first position if no characters were extracted. `operator>>` then calls `width(0)`.

If the function extracted no characters, it calls `setstate(failbit)`, which may throw `ios_base::failure` (27.4.4.3).

Returns: `in`.

Effects: Behaves like a formatted input member (as described in 27.6.1.2.1) of `in`. After a sentry object is constructed, a character is extracted from `in`, if one is available, and stored in `c`. Otherwise, the function calls `in.setstate(failbit)`.

Returns: `in`.

Effects: Behaves as a formatted input function (as described in 27.6.1.2.1). If `sb` is null, calls `setstate(failbit)`, which may throw `ios_base::failure` (27.4.4.3). After a sentry object is constructed, extracts characters from `*this` and inserts them in the output sequence controlled by `sb`. Characters are extracted and inserted until any of the following occurs:
— end-of-file occurs on the input sequence;
— inserting in the output sequence fails (in which case the character to be inserted is not extracted);
— an exception occurs (in which case the exception is caught).

If the function inserts no characters, it calls `setstate(failbit)`, which may throw `ios_base::failure`
(27.4.4.3). If it inserted no characters because it caught an exception thrown while extracting characters from
*this and failbit is on in `exceptions()` (27.4.4.3), then the caught exception is rethrown.

Returns: *this.

27.6.1.3 Unformatted input functions

Each unformatted input function begins execution by constructing an object of class `sentry` with the default argument
`noskipws` (second) argument `true`. If the `sentry` object returns `true`, when converted to a value of type `bool`, the
function endeavors to obtain the requested input. Otherwise, if the `sentry` constructor exits by throwing an exception or if
the `sentry` object returns `false`, when converted to a value of type `bool`, the function returns without attempting to obtain
any input. In either case the number of extracted characters is set to 0; unformatted input functions taking a character
array of non-zero size as an argument shall also store a null character (using `charT()`) in the first location of the array.
If an exception is thrown during input then `ios::badbit` is turned on in *this’s error state. (Exceptions thrown
from `basic_ios<>::clear()` are not caught or rethrown.) If `(exceptions()&badbit) != 0` then the exception is
rethrown. It also counts the number of characters extracted. If no exception has been thrown it ends by storing the count
in a member object and returning the value specified. In any event the `sentry` object is destroyed before leaving the
unformatted input function.

```cpp
streamsize gcount() const;
```

Effects: None. This member function does not behave as an unformatted input function (as described in 27.6.1.3,
paragraph 1).

Returns: The number of characters extracted by the last unformatted input member function called for the object.

```cpp
int_type get();
```

Effects: Behaves as an unformatted input function (as described in 27.6.1.3, paragraph 1). After constructing
a `sentry` object, extracts a character `c`, if one is available. Otherwise, the function calls `setstate(failbit)`,
which may throw `ios_base::failure` (27.4.4.3).

Returns: `c` if available, otherwise `traits::eof()`.

```cpp
basic_istream<charT,traits>& get(char_type& c);
```

Effects: Behaves as an unformatted input function (as described in 27.6.1.3, paragraph 1). After constructing
a `sentry` object, extracts a character, if one is available, and assigns it to `c`. Otherwise, the function calls
`setstate(failbit)` (which may throw `ios_base::failure` (27.4.4.3)).

Returns: *this.

---

Notes:

- (27.4.4.3) This is done without causing an `ios::failure` to be thrown.
- (27.4.4.3) Note that this function is not overloaded on types `signed char` and `unsigned char`.

Draft
basic_istream<charT,traits>& get(char_type* s, streamsize n, char_type delim);

Effects: Behaves as an unformatted input function (as described in Section 27.6.1.3, paragraph 1). After constructing a sentry object, extracts characters and stores them into successive locations of an array whose first element is designated by s.\[302\] Characters are extracted and stored until any of the following occurs:

- \( n - 1 \) characters are stored;
- end-of-file occurs on the input sequence (in which case the function calls `setstate(eofbit)`);
- `traits::eq(c, delim)` for the next available input character \( c \) (in which case \( c \) is not extracted).

If the function stores no characters, it calls `setstate(failbit)` (which may throw `ios_base::failure` (27.4.4.3)). In any case, it then stores a null character into the next successive location of the array.

Returns: \*this.

basic_istream<charT,traits>& get(char_type* s, streamsize n);

Effects: Calls `get(s, n, widen(‘\n’))`

Returns: Value returned by the call.

basic_istream<charT,traits>& get(basic_streambuf<char_type,traits>& sb, char_type delim);

Effects: Behaves as an unformatted input function (as described in Section 27.6.1.3, paragraph 1). After constructing a sentry object, extracts characters and inserts them in the output sequence controlled by \( sb \). Characters are extracted and inserted until any of the following occurs:

- end-of-file occurs on the input sequence;
- inserting in the output sequence fails (in which case the character to be inserted is not extracted);
- `traits::eq(c, delim)` for the next available input character \( c \) (in which case \( c \) is not extracted);
- an exception occurs (in which case, the exception is caught but not rethrown).

If the function inserts no characters, it calls `setstate(failbit)`, which may throw `ios_base::failure` (27.4.4.3).

Returns: \*this.

basic_istream<charT,traits>& get(basic_streambuf<char_type,traits>& sb);

Effects: Calls `get(sb, widen(‘\n’))`

Returns: Value returned by the call.

basic_istream<charT,traits>& getline(char_type* s, streamsize n, char_type delim);

\[302\] Note that this function is not overloaded on types `signed char` and `unsigned char`.

Draft
27.6 Formatting and manipulators

Effects: Behaves as an unformatted input function (as described in 27.6.1.3, paragraph 1). After constructing a sentry object, extracts characters and stores them into successive locations of an array whose first element is designated by $s$.\(^{303}\) Characters are extracted and stored until one of the following occurs:

1. end-of-file occurs on the input sequence (in which case the function calls `setstate(eofbit)`);
2. `traits::eq(c, delim)` for the next available input character $c$ (in which case the input character is extracted but not stored);\(^{304}\)
3. $n - 1$ characters are stored (in which case the function calls `setstate(failbit)`).

These conditions are tested in the order shown.\(^{305}\)

If the function extracts no characters, it calls `setstate(failbit)` (which may throw `ios_base::failure` (27.4.4.3)).\(^{306}\)

In any case, it then stores a null character (using `charT()`) into the next successive location of the array.

Returns: `*this`.

[Example:

```cpp
#include <iostream>

int main()
{
    using namespace std;
    const int line_buffer_size = 100;

    char buffer[line_buffer_size];
    int line_number = 0;
    while (cin.getline(buffer, line_buffer_size, '\n') || cin.gcount()) {
        int count = cin.gcount();
        if (cin.eof())
            cout << "Partial final line"; // cin.fail() is false
        else if (cin.fail()) {
            cout << "Partial long line";
            cin.clear(cin.rdstate() & ~ios::failbit);
        } else {
            count--; // Don't include newline in count
            cout << "Line " << ++line_number;
        }
        cout << " (" << count << " chars): " << buffer << endl;
    }
}

— end example]

\(^{303}\) Note that this function is not overloaded on types `signed char` and `unsigned char`.

\(^{304}\) Since the final input character is "extracted," it is counted in the `gcount()`, even though it is not stored.

\(^{305}\) This allows an input line which exactly fills the buffer, without setting `failbit`. This is different behavior than the historical AT&T implementation.

\(^{306}\) This implies an empty input line will not cause `failbit` to be set.
basic_istream<charT, traits>& getline(char_type* s, streamsize n);

Returns: getline(s, n, widen(‘\n’))

basic_istream<charT, traits>&
ignore(streamsize n = 1, int_type delim = traits::eof());

Effects: Behaves as an unformatted input function (as described in 27.6.1.3, paragraph 1). After constructing a
sentry object, extracts characters and discards them. Characters are extracted until any of the following occurs:
— if n != numeric_limits<streamsize>::max() (18.2.1), n characters are extracted
— end-of-file occurs on the input sequence (in which case the function calls setstate(eofbit), which may
throw ios_base::failure (27.4.4.3));
— traits::eq_int_type(traits::to_int_type(c), delim) for the next available input character c
(in which case c is extracted).

Remarks: The last condition will never occur if traits::eq_int_type(delim, traits::eof()).

Returns: *this.

int_type peek();

Effects: Behaves as an unformatted input function (as described in 27.6.1.3, paragraph 1). After constructing a
sentry object, reads but does not extract the current input character.

Returns: traits::eof() if good() is false. Otherwise, returns rdbuf()->sgetc().

basic_istream<charT, traits>& read(char_type* s, streamsize n);

Effects: Behaves as an unformatted input function (as described in 27.6.1.3, paragraph 1). After constructing
a sentry object, if !good() calls setstate(failbit) which may throw an exception, and return. Otherwise
extracts characters and stores them into successive locations of an array whose first element is designated by
s.\footnote{Note that this function is not overloaded on types signed char and unsigned char.} Characters are extracted and stored until either of the following occurs:
— n characters are stored;
— end-of-file occurs on the input sequence (in which case the function calls setstate(failbit|eofbit),
which may throw ios_base::failure (27.4.4.3)).

Returns: *this.

streamsize readsome(char_type* s, streamsize n);

Effects: Behaves as an unformatted input function (as described in 27.6.1.3, paragraph 1). After constructing
a sentry object, if !good() calls setstate(failbit) which may throw an exception, and return. Otherwise
extracts characters and stores them into successive locations of an array whose first element is designated by s. If
rdbuf()->in_avail() == -1, calls setstate(eofbit) (which may throw ios_base::failure (27.4.4.3)),
and extracts no characters;
— If rdbuf()->in_avail() == 0, extracts no characters

Draft
— If `rdbuf()->in_avail() > 0`, extracts \( \min(rdbuf()->in_avail(), n) \).

**Returns:** The number of characters extracted.

```cpp
basic_istream<charT, traits>& putback(char_type c);
```

**Effects:** Behaves as an unformatted input function (as described in 27.6.1.3, paragraph 1). After constructing a sentry object, if `!good()` calls `setstate(failbit)` which may throw an exception, and return. If `rdbuf()` is not null, calls `rdbuf()->sputbackc()`. If `rdbuf()` is null, or if `sputbackc()` returns `traits::eof()`, calls `setstate(badbit)` (which may throw `ios_base::failure` (27.4.4.3)). [Note: this function extracts no characters, so the value returned by the next call to `gcount()` is 0. — end note]

**Returns:** `*this`.

```cpp
basic_istream<charT, traits>& unget();
```

**Effects:** Behaves as an unformatted input function (as described in 27.6.1.3, paragraph 1). After constructing a sentry object, if `!good()` calls `setstate(failbit)` which may throw an exception, and return. If `rdbuf()` is null, calls `rdbuf()->sungetc()`. If `rdbuf()` is null, or if `sungetc()` returns `traits::eof()`, calls `setstate(badbit)` (which may throw `ios_base::failure` (27.4.4.3)). [Note: this function extracts no characters, so the value returned by the next call to `gcount()` is 0. — end note]

**Returns:** `*this`.

```cpp
int sync();
```

**Effects:** Behaves as an unformatted input function (as described in 27.6.1.3, paragraph 1), except that it does not count the number of characters extracted and does not affect the value returned by subsequent calls to `gcount()`. After constructing a sentry object, if `rdbuf()` is a null pointer, returns -1. Otherwise, calls `rdbuf()->pubsync()` and, if that function returns -1 calls `setstate(badbit)` (which may throw `ios_base::failure` (27.4.4.3)), and returns -1. Otherwise, returns zero.

```cpp
pos_type tellg();
```

**Effects:** Behaves as an unformatted input function (as described in 27.6.1.3, paragraph 1), except that it does not count the number of characters extracted and does not affect the value returned by subsequent calls to `gcount()`. After constructing a sentry object, if `fail() != false`, returns `pos_type(-1)` to indicate failure. Otherwise, returns `rdbuf()->pubseekoff(0, cur, in)`.

```cpp
basic_istream<charT, traits>& seekg(pos_type pos);
```

**Effects:** Behaves as an unformatted input function (as described in 27.6.1.3, paragraph 1), except that it does not count the number of characters extracted and does not affect the value returned by subsequent calls to `gcount()`. After constructing a sentry object, if `fail() != true`, executes `rdbuf()->pubseekpos(pos, ios_base::in)`. In case of failure, the function calls `setstate(failbit)` (which may throw `ios_base::failure`).

**Returns:** `*this`.

```cpp
basic_istream<charT, traits>& seekg(off_type& off, ios_base::seekdir dir);
```
**Effects:** Behaves as an unformatted input function (as described in 27.6.1.3, paragraph 1), except that it does not count the number of characters extracted and does not affect the value returned by subsequent calls to gcount(). After constructing a sentry object, if fail() != true, executes rdbuf()->pubseekoff(off, dir, ios_base::in).

**Returns:** *this.

### 27.6.1.4 Standard basic_istream manipulators

```cpp	namespace std {
    template <class charT, class traits>
    basic_istream<charT,traits>& ws(basic_istream<charT,traits>& is);
}
```

**Effects:** Behaves as an unformatted input function (as described in 27.6.1.3, paragraph 1), except that it does not count the number of characters extracted and does not affect the value returned by subsequent calls to is.gcount(). After constructing a sentry object extracts characters as long as the next available character c is whitespace or until there are no more characters in the sequence. Whitespace characters are distinguished with the same criterion as used by sentry::sentry (27.6.1.1.2). If ws stops extracting characters because there are no more available it sets eofbit, but not failbit.

**Returns:** is.

### 27.6.1.5 Class template basic_iostream

```cpp	namespace std {
    template <class charT, class traits = char_traits<charT> >
    class basic_iostream :
    public basic_istream<charT,traits>,
    public basic_ostream<charT,traits> {
    public:
        // types:
        typedef charT char_type;
        typedef typename traits::int_type int_type;
        typedef typename traits::pos_type pos_type;
        typedef typename traits::off_type off_type;
        typedef traits traits_type;

        explicit basic_iostream(basic_streambuf<charT,traits>* sb);
        virtual ~basic_iostream();
    }
}
```

The class basic_iostream inherits a number of functions that allow reading input and writing output to sequences controlled by a stream buffer.

### 27.6.1.5.1 basic_iostream constructors

Draft
explicit basic_iostream(basic_streambuf<charT,traits>* sb);

Effects: Constructs an object of class basic_iostream, assigning initial values to the base classes by calling basic_istream<charT,traits>(sb) (27.6.1.1) and basic_ostream<charT,traits>(sb) (27.6.2.1)

Postcondition: rdbuf()==sb and gcount()==0.

27.6.1.5.2 basic_iostream destructor [lib.iostream.dest]

virtual ~basic_iostream();

Effects: Destroys an object of class basic_iostream.

Remarks: Does not perform any operations on rdbuf().

27.6.2 Output streams [lib.output.streams]

The header <ostream> defines a type and several function signatures that control output to a stream buffer.

27.6.2.1 Class template basic_ostream [lib ostream]

namespace std {
    template < class charT, class traits = char_traits<charT> >
    class basic_ostream : virtual public basic_ios<charT,traits> {
public:
    // Types (inherited from basic_ios (27.4.4)):
    typedef charT char_type;
    typedef typename traits::int_type int_type;
    typedef typename traits::pos_type pos_type;
    typedef typename traits::off_type off_type;
    typedef traits traits_type;

    // 27.6.2.2 Constructor/destructor:
    explicit basic_ostream(basic_streambuf<char_type,traits>* sb);
    virtual ~basic_ostream();

    // 27.6.2.3 Prefix/suffix:
    class sentry;

    // 27.6.2.5 Formatted output:
    basic_ostream<charT,traits>& operator<<
        (basic_ostream<charT,traits>& (*pf)(basic_ostream<charT,traits>&));
    basic_ostream<charT,traits>& operator<<
        (basic_ios<charT,traits>& (*pf)(basic_ios<charT,traits>&));
    basic_ostream<charT,traits>& operator<<
        (ios_base& (*pf)(ios_base&));
    basic_ostream<charT,traits>& operator<<(bool n);
    basic_ostream<charT,traits>& operator<<(short n);
    basic_ostream<charT,traits>& operator<<(unsigned short n);

    Draft
basic_ostream<charT,traits>& operator<<(int n);
basic_ostream<charT,traits>& operator<<(unsigned int n);
basic_ostream<charT,traits>& operator<<(long n);
basic_ostream<charT,traits>& operator<<(unsigned long n);
basic_ostream<charT,traits>& operator<<(float f);
basic_ostream<charT,traits>& operator<<(double f);
basic_ostream<charT,traits>& operator<<(long double f);

basic_ostream<charT,traits>& operator<<(const void* p);
basic_ostream<charT,traits>& operator<<
(basic_streambuf<char_type,traits>* sb);

// 27.6.2.6 Unformatted output:
basic_ostream<charT,traits>& put(char_type c);
basic_ostream<charT,traits>& write(const char_type* s, streamsize n);

basic_ostream<charT,traits>& flush();

// 27.6.2.4 seeks:
pos_type tellp();
basic_ostream<charT,traits>& seekp(pos_type);
basic_ostream<charT,traits>& seekp(off_type, ios_base::seekdir);
};

// 27.6.2.5.4 character inserters
template<class charT, class traits>
basic_ostream<charT,traits>& operator<<(basic_ostream<charT,traits>&, charT);
template<class charT, class traits>
basic_ostream<charT,traits>& operator<<(basic_ostream<charT,traits>&, char);
template<class traits>
basic_ostream<char,traits>& operator<<(basic_ostream<char,traits>&, char);

// signed and unsigned
template<class traits>
basic_ostream<char,traits>& operator<<(basic_ostream<char,traits>&, signed char);
template<class traits>
basic_ostream<char,traits>& operator<<(basic_ostream<char,traits>&, unsigned char)

template<class charT, class traits>
basic_ostream<charT,traits>& operator<<(basic_ostream<charT,traits>&, const charT*);
template<class charT, class traits>
basic_ostream<charT,traits>& operator<<(basic_ostream<charT,traits>&, const char*);
template<class traits>
basic_ostream<char,traits>& operator<<(basic_ostream<char,traits>&, const char*);

Draft
27.6 Formatting and manipulators

const char*);

// signed and unsigned
template<class traits>
basic_ostream<char,traits>& operator<<(basic_ostream<char,traits>& ,
    const signed char*);

template<class traits>
basic_ostream<char,traits>& operator<<(basic_ostream<char,traits>& ,
    const unsigned char*);

}

1 The class basic_ostream defines a number of member function signatures that assist in formatting and writing output to output sequences controlled by a stream buffer.

2 Two groups of member function signatures share common properties: the formatted output functions (or inserters) and the unformatted output functions. Both groups of output functions generate (or insert) output characters by actions equivalent to calling rdbuf()->sputc(int_type). They may use other public members of basic_ostream except that they shall not invoke any virtual members of rdbuf() except overflow(), xsputn(), and sync().

3 If one of these called functions throws an exception, then unless explicitly noted otherwise the output function sets badbit in error state. If badbit is on in exceptions(), the output function rethrows the exception without completing its actions, otherwise it does not throw anything and treat as an error.

27.6.2.2 basic_ostream constructors

explicit basic_ostream(basic_streambuf<charT,traits>* sb);

1 Effects: Constructs an object of class basic_ostream, assigning initial values to the base class by calling basic_ios<charT,traits>::init(sb) (27.4.4.1).

2 Postcondition: rdbuf() == sb.

    virtual ~basic_ostream();

3 Effects: Destroys an object of class basic_ostream.

4 Remarks: Does not perform any operations on rdbuf().

27.6.2.3 Class basic_ostream::sentry

namespace std {
    template <class charT,class traits = char_traits<charT> >
class basic_ostream<charT,traits>::sentry {
        // bool ok_; exposition only

        public:
            explicit sentry(basic_ostream<charT,traits>& os);

            ~sentry();

            operator bool() const { return ok_; }

        private:
            sentry(const sentry&); // not defined

            sentry& operator=(const sentry&); // not defined

    }
The class **sentry** defines a class that is responsible for doing exception safe prefix and suffix operations.

```cpp
explicit sentry(basic_ostream<charT, traits>& os);
```

If `os.good()` is nonzero, prepares for formatted or unformatted output. If `os.tie()` is not a null pointer, calls `os.tie()->flush`.  

If, after any preparation is completed, `os.good()` is true, `ok_ = true` otherwise, `ok_ = false`. During preparation, the constructor may call `setstate(failbit)` (which may throw `ios_base::failure(27.4.4.3)`).  

```cpp
~sentry();
```

If `((os.flags() & ios_base::unitbuf) && !uncaught_exception())` is true, calls `os.flush()`.  

```cpp
operator bool() const;
```

**Effects:** Returns `ok_`.

### 27.6.2.4 basic_ostream seek members [lib.ostream.seeks]

```cpp
pos_type tellp();
```

**Returns:** if `fail() != false`, returns `pos_type(-1)` to indicate failure. Otherwise, returns `rdbuf()->pubseekoff(0, cur, out)`.  

```cpp
basic_ostream<charT, traits>& seekp(pos_type& pos);
```

**Effects:** If `fail() != true`, executes `rdbuf()->pubseekpos(pos, ios_base::out)`. In case of failure, the function calls `setstate(failbit)` (which may throw `ios_base::failure`).  

**Returns:** `*this`.

```cpp
basic_ostream<charT, traits>& seekp(off_type& off, ios_base::seekdir dir);
```

**Effects:** If `fail() != true`, executes `rdbuf()->pubseekoff(off, dir, ios_base::out)`.  

**Returns:** `*this`.

### 27.6.2.5 Formatted output functions [lib.ostream.formatted]

#### 27.6.2.5.1 Common requirements [lib.ostream.formatted.reqmts]

Each formatted output function begins execution by constructing an object of class **sentry**. If this object returns `true` when converted to a value of type `bool`, the function endeavors to generate the requested output. If the generation fails, then the formatted output function does `setstate(ios::failbit)`, which might throw an exception. If an exception is thrown during output, then `ios::badbit` is turned on in `*this`'s error state. If `(exceptions()&badbit) !=

---

308) The call `os.tie() -> flush()` does not necessarily occur if the function can determine that no synchronization is necessary.  
309) The **sentry** constructor and destructor can also perform additional implementation-dependent operations.  
310) Without causing an `ios::failure` to be thrown.
27.6 Formatting and manipulators

0 then the exception is rethrown. Whether or not an exception is thrown, the sentry object is destroyed before leaving the formatted output function. If no exception is thrown, the result of the formatted output function is \*this.

The descriptions of the individual formatted output operations describe how they perform output and do not mention the sentry object.

27.6.2.5.2 Arithmetic Inserters

\begin{verbatim}
operator<<(bool val);
operator<<(short val);
operator<<(unsigned short val);
operator<<(int val);
operator<<(unsigned int val);
operator<<(long val);
operator<<(unsigned long val);
operator<<(float val);
operator<<(double val);
operator<<(long double val);
operator<<(const void* val);
\end{verbatim}

Effects: The classes \texttt{num\_get\<\>} and \texttt{num\_put\<\>} handle locale-dependent numeric formatting and parsing. These inserter functions use the imbued \texttt{locale} value to perform numeric formatting. When \texttt{val} is of type \texttt{bool}, \texttt{long}, \texttt{unsigned long}, \texttt{double}, \texttt{long double}, or \texttt{const void*}, the formatting conversion occurs as if it performed the following code fragment:

\begin{verbatim}
bool failed = use_facet<
    num_put<charT,ostreambuf_iterator<charT,traits> >>(getloc()).put(*this,*this,fill(),val).failed();
\end{verbatim}

When \texttt{val} is of type \texttt{short} the formatting conversion occurs as if it performed the following code fragment:

\begin{verbatim}
ios_base::fmtflags baseflags = ios_base::flags() & ios_base::basefield;
bool failed = use_facet<
    num_put<charT,ostreambuf_iterator<charT,traits> >>(getloc()).put(*this,*this,fill(),
    baseflags == ios_base::oct || baseflags == ios_base::hex
    ? static_cast<long>(static_cast<unsigned short>(val))
    : static_cast<long>(val)).failed();
\end{verbatim}

When \texttt{val} is of type \texttt{int} the formatting conversion occurs as if it performed the following code fragment:

\begin{verbatim}
ios_base::fmtflags baseflags = ios_base::flags() & ios_base::basefield;
bool failed = use_facet<
    num_put<charT,ostreambuf_iterator<charT,traits> >>(getloc()).put(*this,*this,fill(),
    baseflags == ios_base::oct || baseflags == ios_base::hex
    ? static_cast<long>(static_cast<unsigned int>(val))
    : static_cast<long>(val)).failed();
\end{verbatim}

When \texttt{val} is of type \texttt{unsigned short} or \texttt{unsigned int} the formatting conversion occurs as if it performed the following code fragment:
bool failed = use_facet<
  num_put< charT, ostreambuf_iterator< charT, traits > > 
>(getloc()).put(*this, *this, fill(),
  static_cast<unsigned long>(val)).failed();

When \texttt{val} is of type \texttt{float} the formatting conversion occurs as if it performed the following code fragment:

\begin{verbatim}
bool failed = use_facet<
  num_put< charT, ostreambuf_iterator< charT, traits > > 
>(getloc()).put(*this, *this, fill(),
  static_cast<double>(val)).failed();
\end{verbatim}

The first argument provides an object of the \texttt{ostreambuf\_iterator<>} class which is an iterator for class \texttt{basic\_ostream<>}. It bypasses \texttt{ostream} and uses \texttt{streambufs} directly. Class locale relies on these types as its interface to \texttt{iostreams}, since for flexibility it has been abstracted away from direct dependence on \texttt{ostream}. The second parameter is a reference to the base subobject of type \texttt{ios\_base}. It provides formatting specifications such as field width, and a locale from which to obtain other facets. If \texttt{failed} is true then does \texttt{setstate(badbit)}, which may throw an exception, and returns.

\textit{Returns}: \texttt{*this}.

27.6.2.5.3  \texttt{basic\_ostream::operator<<} \hspace{1cm} \textit{[lib.ostream.inserters]}

\begin{verbatim}
basic\_ostream<charT, traits>& \& operator<<(
basic\_ostream<charT, traits>& (*pf)(basic\_ostream<charT, traits>&))
\end{verbatim}

1  \textit{Effects}: None. Does not behave as a formatted output function (as described in 27.6.2.5.1).
2  \textit{Returns}: \texttt{pf(*this).\hspace{1cm}311)}

\begin{verbatim}
basic\_ostream<charT, traits>& \& operator<<(
basic\_ios<charT, traits>& (*pf)(basic\_ios<charT, traits>&))
\end{verbatim}

3  \textit{Effects}: Calls \texttt{pf(*this)}. This inserter does not behave as a formatted output function (as described in 27.6.2.5.1).
4  \textit{Returns}: \texttt{*this}.\hspace{1cm}312)}

\begin{verbatim}
basic\_ostream<charT, traits>& \& operator<<(
  ios\_base& (*pf)(ios\_base&))
\end{verbatim}

5  \textit{Effects}: Calls \texttt{pf(*this)}. This inserter does not behave as a formatted output function (as described in 27.6.2.5.1).
6  \textit{Returns}: \texttt{*this}.

\begin{verbatim}
basic\_ostream<charT, traits>& \& operator<<(
  basic\_streambuf<charT, traits>\* sb);
\end{verbatim}

7  \textit{Effects}: Behaves as a formatted output function (as described in 27.6.2.5.1). After the sentry object is constructed, if \texttt{sb} is null calls \texttt{setstate(badbit)} (which may throw \texttt{ios\_base::failure}).

\footnotesize
\begin{itemize}
  \item[311)] See, for example, the function signature \texttt{endl(basic\_ostream\&)} (27.6.2.7).
  \item[312)] See, for example, the function signature \texttt{dec(ios\_base\&)} (27.4.5.3).
\end{itemize}

Draft
Gets characters from \( sb \) and inserts them in \(*this\). Characters are read from \( sb \) and inserted until any of the following occurs:

- end-of-file occurs on the input sequence;
- inserting in the output sequence fails (in which case the character to be inserted is not extracted);
- an exception occurs while getting a character from \( sb \).

If the function inserts no characters, it calls \texttt{setstate(failbit)} (which may throw \texttt{ios\_base::failure} (27.4.4.3)). If an exception was thrown while extracting a character, the function sets \texttt{failbit} in error state, and if \texttt{failbit} is on in \texttt{exceptions()} the caught exception is rethrown.

\textbf{Returns:} \(*this\).

### 27.6.2.5.4 Character inserter function templates [lib.ostream.inserters.character]

\begin{verbatim}

template< class charT, class traits >
    basic_ostream< charT, traits >& operator<<(basic_ostream<charT,traits>& out, charT c);

template< class charT, class traits >
    basic_ostream< charT, traits >& operator<<(basic_ostream<charT,traits>& out, char c);

    // specialization
    template< class traits >
        basic_ostream< char, traits >& operator<<(basic_ostream<char,traits>& out, char c);

    // signed and unsigned
    template< class traits >
        basic_ostream< char, traits >& operator<<(basic_ostream<char,traits>& out, signed char c);

    template< class traits >
        basic_ostream< char, traits >& operator<<(basic_ostream<char,traits>& out, unsigned char c);

\end{verbatim}

\textbf{Effects:} Behaves like a formatted inserter (as described in 27.6.2.5.1) of \( out \). After a \texttt{sentry} object is constructed it inserts characters. In case \( c \) has type \texttt{char} and the character type of the stream is not \texttt{char}, then the character to be inserted is \( out.widen(c) \); otherwise the character is \( c \)\(^{113}\). Padding is determined as described in 22.2.2.2.2. \texttt{width(0)} is called. The insertion character and any required padding are inserted into \( out \).

\textbf{Returns:} \( out \).

\begin{verbatim}

template< class charT, class traits >
    basic_ostream< charT, traits >& operator<<(basic_ostream<charT,traits>& out, const charT* s);

template< class charT, class traits >
    basic_ostream< charT, traits >& operator<<(basic_ostream<charT,traits>& out, const char* s);

\end{verbatim}

\(^{113}\) In case the insertion is into a \texttt{char} stream, \texttt{widen(c)} will usually be \( c \).
basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>& out, const char* s);

template<class traits>
basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>& out, const signed char* s);

template<class traits>
basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>& out, const unsigned char* s);

Requires: s is non-null.

Effects: Behaves like a formatted inserter (as described in 27.6.2.5.1) of out. After a sentry object is constructed it inserts n characters starting at s, where n is the number that would be computed as if by:

- traits::length(s) for the overload where the first argument is of type basic_ostream<charT, traits>& and the second is of type const charT*, and also for the overload where the first argument is of type basic_ostream<char, traits>& and the second is of type const char*.
- std::char_traits<char>::length(s) for the overload where the first argument is of type basic_ostream<charT, traits>& and the second is of type const charT*.
- traits::length(reinterpret_cast<const char*>(s)) for the other two overloads.

Padding is determined as described in 22.2.2.2. The n characters starting at s are widened using out.widen (27.4.4.2). The widened characters and any required padding are inserted into out. Calls width(0).

Returns: out.

27.6.2.6 Unformatted output functions

Each unformatted output function begins execution by constructing an object of class sentry. If this object returns true, while converting to a value of type bool, the function endeavors to generate the requested output. If an exception is thrown during output, then ios::badbit is turned on in *this's error state. If (exceptions() & badbit) != 0 then the exception is rethrown. In any case, the unformatted output function ends by destroying the sentry object, then, if no exception was thrown, returning the value specified for the unformatted output function.

basic_ostream<charT, traits>& put(char_type c);

Effects: Behaves as an unformatted output function (as described in 27.6.2.6, paragraph 1). After constructing a sentry object, inserts the character c, if possible.

Otherwise, calls setstate(badbit) (which may throw ios_base::failure (27.4.4.3)).

Returns: *this.

basic_ostream& write(const char_type* s, streamsize n);

314) without causing an ios::failure to be thrown.
315) Note that this function is not overloaded on types signed char and unsigned char.
5 Effects: Behaves as an unformatted output function (as described in 27.6.2.6, paragraph 1). After constructing a sentry object, obtains characters to insert from successive locations of an array whose first element is designated by \textit{s}.\footnote{Note that this function is not overloaded on types \texttt{signed char} and \texttt{unsigned char}.} Characters are inserted until either of the following occurs:

\begin{itemize}
  \item \textit{n} characters are inserted;
  \item inserting in the output sequence fails (in which case the function calls \texttt{setstate(badbit)}, which may throw \texttt{ios::base::failure (27.4.4.3)}).
\end{itemize}
6 Returns: \texttt{*this}.

\begin{verbatim}
basic_ostream& flush();
\end{verbatim}
7 If \texttt{rdbuf()} is not a null pointer, calls \texttt{rdbuf()->pubsync()}. If that function returns -1 calls \texttt{setstate(badbit)} (which may throw \texttt{ios::base::failure (27.4.4.3)}). Does not behave as an unformatted output function (as described in 27.6.2.6, paragraph 1).
8 Returns: \texttt{*this}.

27.6.2.7 Standard basic_ostream manipulators \[lib.ostream.manip\]

\begin{verbatim}
namespace std {
  template <class charT, class traits>
  basic_ostream<charT, traits>& endl(basic_ostream<charT, traits>& os);
}
\end{verbatim}
1 Effects: Calls \texttt{os.put(os.widen(\textbackslash n))}, then \texttt{os.flush()}.
2 Returns: \texttt{os}.

\begin{verbatim}
namespace std {
  template <class charT, class traits>
  basic_ostream<charT, traits>& ends(basic_ostream<charT, traits>& os);
}
\end{verbatim}
3 Effects: Inserts a null character into the output sequence: calls \texttt{os.put(charT())}.
4 Returns: \texttt{os}.

\begin{verbatim}
namespace std {
  template <class charT, class traits>
  basic_ostream<charT, traits>& flush(basic_ostream<charT, traits>& os);
}
\end{verbatim}
5 Effects: Calls \texttt{os.flush()}.
6 Returns: \texttt{os}.
The header `<iomanip>` defines a type and several related functions that use this type to provide extractors and inserters that alter information maintained by class `ios_base` and its derived classes.

The type designated `smanip` in each of the following function descriptions is implementation-defined and may be different for each function.

```cpp
smanip resetiosflags(ios_base::fmtflags mask);
```

Returns: An object `s` of unspecified type such that if `out` is an instance of `basic_ostream<charT, traits>` then the expression `out<<s` behaves as if `f(s, mask)` were called, or if `in` is an instance of `basic_istream<charT, traits>` then the expression `in>>s` behaves as if `f(s, mask)` were called. The function `f` can be defined as:

```cpp
ios_base& f(ios_base& str, ios_base::fmtflags mask)
{
    // reset specified flags
    str.setf(ios_base::fmtflags(0), mask);
    return str;
}
```

The expression `out<<s` has type `basic_ostream<charT, traits>&` and value `out`. The expression `in>>s` has type `basic_istream<charT, traits>&` and value `in`.

```cpp
smanip setiosflags(ios_base::fmtflags mask);
```

Returns: An object `s` of unspecified type such that if `out` is an instance of `basic_ostream<charT, traits>` then the expression `out<<s` behaves as if `f(s, mask)` were called, or if `in` is an instance of `basic_istream<charT, traits>` then the expression `in>>s` behaves as if `f(s, mask)` were called. The function `f` can be defined as:

```cpp
ios_base& f(ios_base& str, ios_base::fmtflags mask)
{
    // set specified flags
    str.setf(mask);
    return str;
}
```

The expression `out<<s` has type `basic_ostream<charT, traits>&` and value `out`. The expression `in>>s` has type `basic_istream<charT, traits>&` and value `in`.

```cpp
smanip setbase(int base);
```

Returns: An object `s` of unspecified type such that if `out` is an instance of `basic_ostream<charT, traits>` then the expression `out<<s` behaves as if `f(s)` were called, or if `in` is an instance of `basic_istream<charT, traits>` then the expression `in>>s` behaves as if `f(s, base)` were called. The function `f` can be defined as:

```cpp
ios_base& f(ios_base& str, int base)
{
}
```

The expression `cin >> resetiosflags(ios_base::skipws)` clears `ios_base::skipws` in the format flags stored in the `basic_istream<charT, traits>` object `cin` (the same as `cin >> noskipws`), and the expression `cout << resetiosflags(ios_base::showbase)` clears `ios_base::showbase` in the format flags stored in the `basic_ostream<charT, traits>` object `cout` (the same as `cout << noshowbase`).
// set basefield
str.setf(base == 8 ? ios_base::oct :
    base == 10 ? ios_base::dec :
    base == 16 ? ios_base::hex :
    ios_base::fmtflags(0), ios_base::basefield);
return str;
}

The expression out<<s has type basic_ostream<charT, traits>& and value out. The expression in>>s has type basic_istream<charT, traits>& and value in.

smanip setfill(char_type c);

Returns: An object s of unspecified type such that if out is (or is derived from) basic_ostream<charT, traits> and c has type charT then the expression out<<s behaves as if f(s, c) were called. The function f can be defined as:

```
template<class charT, class traits>
basic_ios<charT, traits>& f(basic_ios<charT, traits>& str, charT c)
{
    // set fill character
    str.fill(c);
    return str;
}
```

The expression out<<s has type basic_ostream<charT, traits>& and value out.

smanip setprecision(int n);

Returns: An object s of unspecified type such that if out is an instance of basic_ostream<charT, traits> then the expression out<<s behaves as if f(s, n) were called, or if in is an instance of basic_istream<charT, traits> then the expression in>>s behaves as if f(s, n) were called. The function f can be defined as:

```
ios_base& f(ios_base& str, int n)
{
    // set precision
    str.precision(n);
    return str;
}
```

The expression out<<s has type basic_ostream<charT, traits>& and value out. The expression in>>s has type basic_istream<charT, traits>& and value in.

smanip setw(int n);

Returns: An object s of unspecified type such that if out is an (instance of) basic_ostream<charT, traits> then the expression out<<s behaves as if f(s, n) were called, or if in is an instance of basic_istream<charT, traits> then the expression in>>s behaves as if f(s, n) were called. The function f can be defined as:

```
ios_base& f(ios_base& str, int n)
{
    // set width
    Draft
The expression `out<<s` has type `basic_ostream<charT, traits>&` and value `out`. The expression `in>>s` has type `basic_istream<charT, traits>&` and value `in`.

### 27.7 String-based streams

The header `<sstream>` defines four class templates and eight types that associate stream buffers with objects of class `basic_string`, as described in 21.2.

#### Header `<sstream>` synopsis

```cpp
namespace std {
    template < class charT , class traits = char_traits<charT>,
             class Allocator = allocator<charT> >
    class basic_stringbuf;

typedef basic_stringbuf<char> stringbuf;
typedef basic_stringbuf<wchar_t> wstringbuf;

template < class charT , class traits = char_traits<charT>,
             class Allocator = allocator<charT> >
    class basic_istringstream;

typedef basic_istringstream<char> istringstream;
typedef basic_istringstream<wchar_t> wistringstream;

template < class charT , class traits = char_traits<charT>,
             class Allocator = allocator<charT> >
    class basic_ostringstream;

typedef basic_ostringstream<char> ostringstream;
typedef basic_ostringstream<wchar_t> wostringstream;

template < class charT , class traits = char_traits<charT>,
             class Allocator = allocator<charT> >
    class basic_stringstream;

typedef basic_stringstream<char> stringstream;
typedef basic_stringstream<wchar_t> wstringstream;
}
```

#### 27.7.1 Class template `basic_stringbuf`

```cpp
namespace std {
    template < class charT , class traits = char_traits<charT>,
             class Allocator = allocator<charT> >
    class basic_stringbuf : public basic_streambuf<charT,traits> {
        public:
            typedef charT char_type;

        Draft
```
27.7 String-based streams

The class `basic_stringbuf` is derived from `basic_streambuf` to associate possibly the input sequence and possibly the output sequence with a sequence of arbitrary characters. The sequence can be initialized from, or made available as, an object of class `basic_string`.

For the sake of exposition, the maintained data is presented here as:

- `ios_base::openmode mode`, has in set if the input sequence can be read, and out set if the output sequence can be written.

### 27.7.1.1 `basic_stringbuf` constructors

```c++
explicit basic_stringbuf (ios_base::openmode which = ios_base::in | ios_base::out);
explicit basic_stringbuf (const basic_string<CharT, traits, Allocator>& str,
                         ios_base::openmode which = ios_base::in | ios_base::out);
```

---

1. The class `basic_stringbuf` is derived from `basic_streambuf` to associate possibly the input sequence and possibly the output sequence with a sequence of arbitrary characters. The sequence can be initialized from, or made available as, an object of class `basic_string`.
2. For the sake of exposition, the maintained data is presented here as:
   - `ios_base::openmode mode`, has in set if the input sequence can be read, and out set if the output sequence can be written.

```c++
explicit basic_stringbuf (ios_base::openmode which =
```
Effects: Constructs an object of class basic_stringbuf, initializing the base class with basic_streambuf() (27.5.2.1), and initializing mode with which.

Postcondition: str() == "".

explicit basic_stringbuf(const basic_string< charT, traits, Allocator >& str, ios_base::openmode which = ios_base::in | ios_base::out);

Effects: Constructs an object of class basic_stringbuf, initializing the base class with basic_streambuf() (27.5.2.1), and initializing mode with which. Then copies the content of str into the basic_stringbuf underlying character sequence. If which & ios_base::out is true, initializes the output sequence such that pbase() points to the first underlying character, epptr() points one past the last underlying character, and pptr() is equal to epptr() if which & ios_base::ate is true, otherwise pptr() is equal to pbase(). If which & ios_base::in is true, initializes the input sequence such that eback() and gptr() point to the first underlying character and egptr() points one past the last underlying character.

27.7.1.2 Member functions

[lib.stringbuf.members]

basic_string< charT, traits, Allocator > str() const;

Returns: A basic_string object whose content is equal to the basic_stringbuf underlying character sequence. If the basic_stringbuf was created only in input mode, the resultant basic_string contains the character sequence in the range [eback(), egptr()). If the basic_stringbuf was created with which & ios_base::out being true then the resultant basic_string contains the character sequence in the range [pbase(), high_mark), where high_mark represents the position one past the highest initialized character in the buffer. Characters can be initialized by writing to the stream, by constructing the basic_stringbuf with a basic_string, or by calling the str(basic_string) member function. In the case of calling the str(basic_string) member function, all characters initialized prior to the call are now considered uninitialized (except for those characters re-initialized by the new basic_string). Otherwise the basic_stringbuf has been created in neither input nor output mode and a zero length basic_string is returned.

void str(const basic_string< charT, traits, Allocator >& s);

Effects: Copies the content of s into the basic_stringbuf underlying character sequence. If mode & ios_base::out is true, initializes the output sequence such that pbase() points to the first underlying character, epptr() points one past the last underlying character, and pptr() is equal to epptr() if mode & ios_base::in is true, otherwise pptr() is equal to pbase(). If mode & ios_base::in is true, initializes the input sequence such that eback() and gptr() point to the first underlying character and egptr() points one past the last underlying character.

27.7.1.3 Overridden virtual functions

[lib.stringbuf.virtuals]

int_type underflow();

Returns: If the input sequence has a read position available, returns traits::to_int_type(*gptr()). Otherwise, returns traits::eof(). Any character in the underlying buffer which has been initialized is considered to
be part of the input sequence.

```cpp
int_type pbackfail(int_type c = traits::eof());
```

**Effects:** Puts back the character designated by `c` to the input sequence, if possible, in one of three ways:

1. If `traits::eq_int_type(c, traits::eof())` returns `false` and if the input sequence has a putback position available, and if `traits::eq(to_char_type(c), gptr()[-1])` returns `true`, assigns `gptr() - 1` to `gptr()`.
   
   Returns: `c`.

2. If `traits::eq_int_type(c, traits::eof())` returns `true` and if the input sequence has a putback position available, assigns `gptr() - 1` to `gptr()`.
   
   Returns: `traits::not_eof(c)`.

3. Returns: `traits::eof()` to indicate failure.

**Remarks:** If the function can succeed in more than one of these ways, it is unspecified which way is chosen.

```cpp
int_type overflow(int_type c = traits::eof());
```

**Effects:** Appends the character designated by `c` to the output sequence, if possible, in one of two ways:

1. If `traits::eq_int_type(c, traits::eof())` returns `false` and if either the output sequence has a write position available or the function makes a write position available (as described below), the function calls `sputc(c)`.
   
   Signals success by returning `c`.

2. If `traits::eq_int_type(c, traits::eof())` returns `true`, there is no character to append.
   
   Signals success by returning a value other than `traits::eof()`.

**Remarks:** The function can alter the number of write positions available as a result of any call.

```cpp
pos_type seekoff(off_type off, ios_base::seekdir way,
                 ios_base::openmode which = ios_base::in | ios_base::out);
```

**Effects:** Alters the stream position within one of the controlled sequences, if possible, as indicated in Table 91.
Table 91: seekoff positioning

<table>
<thead>
<tr>
<th>Conditions</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>(which &amp; ios_base::in) != 0</td>
<td>positions the input sequence</td>
</tr>
<tr>
<td>(which &amp; ios_base::out) != 0</td>
<td>positions the output sequence</td>
</tr>
<tr>
<td>(which &amp; (ios_base::in</td>
<td>ios_base::out)) ==</td>
</tr>
<tr>
<td>(ios_base::in)</td>
<td></td>
</tr>
<tr>
<td>(ios_base::out))</td>
<td></td>
</tr>
<tr>
<td>and way == either</td>
<td></td>
</tr>
<tr>
<td>ios_base::beg or</td>
<td></td>
</tr>
<tr>
<td>ios_base::end</td>
<td></td>
</tr>
<tr>
<td>Otherwise</td>
<td>the positioning operation fails.</td>
</tr>
</tbody>
</table>

For a sequence to be positioned, if its next pointer (either gptr() or pptr()) is a null pointer and the new offset newoff is nonzero, the positioning operation fails. Otherwise, the function determines newoff as indicated in Table 92.

Table 92: newoff values

<table>
<thead>
<tr>
<th>Condition</th>
<th>newoff Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>way == ios_base::beg</td>
<td>0</td>
</tr>
<tr>
<td>way == ios_base::cur</td>
<td>the next pointer minus the beginning pointer (xnext - xbeg).</td>
</tr>
<tr>
<td>way == ios_base::end</td>
<td>the end pointer minus the beginning pointer (xend - xbeg).</td>
</tr>
</tbody>
</table>

If (newoff + off) < 0, or if newoff + off refers to an uninitialized character (as defined in 27.7.1.2 paragraph 1), the positioning operation fails. Otherwise, the function assigns xbeg + newoff + off to the next pointer xnext.

Returns: pos_type(newoff). constructed from the resultant offset newoff (of type off_type), that stores the resultant stream position, if possible. If the positioning operation fails, or if the constructed object cannot represent the resultant stream position, the return value is pos_type(off_type(-1)).

pos_type seekpos(pos_type sp, ios_base::openmode which
                 = ios_base::in | ios_base::out);

Effects: Alters the stream position within the controlled sequences, if possible, to correspond to the stream position stored in sp (as described below).

— If (which & ios_base::in) != 0, positions the input sequence.
— If (which & ios_base::out) != 0, positions the output sequence.
— If sp is an invalid stream position, or if the function positions neither sequence, the positioning operation fails. If sp has not been obtained by a previous successful call to one of the positioning functions (seekoff, seekpos, tellg, tellp) the effect is undefined.
Returns: \textit{sp} to indicate success, or pos\_type(\texttt{off\_type}(-1)) to indicate failure.

\begin{verbatim}
basic_stringbuf<charT, traits>* setbuf(charT* s, streamsize n);
\end{verbatim}

Effects: implementation-defined, except that setbuf(0,0) has no effect.

Returns: this.

### 27.7.2 Class template basic\_istringstream

```
namespace std {
    template <class charT, class traits = char_traits<charT>,
              class Allocator = allocator<charT> >
    class basic_istringstream : public basic_istream<charT, traits> { public:
        typedef charT char_type;
        typedef typename traits::int_type int_type;
        typedef typename traits::pos_type pos_type;
        typedef typename traits::off_type off_type;
        typedef traits traits_type;
        typedef Allocator allocator_type;

        // 27.7.2.1 Constructors:
        explicit basic_istringstream ( ios_base::openmode which = ios_base::in );
        explicit basic_istringstream ( const basic_string<charT, traits, Allocator>& str,
                                        ios_base::openmode which = ios_base::in );

        // 27.7.2.2 Members:
        basic_stringbuf<charT, traits, Allocator>* rdbuf () const;
        basic_string<charT, traits, Allocator> str () const;
        void str(const basic_string<charT, traits, Allocator>& s);
    private:
        // basic_stringbuf<charT,traits,Allocator> sb; // exposition only
    };
```

The class \texttt{basic\_istringstream\langle charT, traits, Allocator\rangle} supports reading objects of class \texttt{basic\_string\langle charT, traits, Allocator\rangle}. It uses a \texttt{basic\_stringbuf\langle charT, traits, Allocator\rangle} object to control the associated storage. For the sake of exposition, the maintained data is presented here as:

— \texttt{sb}, the stringbuf object.

#### 27.7.2.1 basic\_istringstream constructors

```
explicit basic_istringstream(ios_base::openmode which = ios_base::in);
```
Effects: Constructs an object of class basic_istringstream<charT, traits>, initializing the base class with basic_istream(&sb) and initializing sb with basic_stringbuf<charT, traits, Allocator>(which | ios_base::in)) (27.7.1.1).

explicit basic_istringstream(
    const basic_string<charT, traits, allocator>& str,
    ios_base::openmode which = ios_base::in);

Effects: Constructs an object of class basic_istringstream<charT, traits>, initializing the base class with basic_istream(&sb) and initializing sb with basic_stringbuf<charT, traits, Allocator>(str, which | ios_base::in)) (27.7.1.1).

27.7.2 Member functions

basic_stringbuf<charT, traits, Allocator>* rdbuf() const;
1
Returns: const_cast<basic_stringbuf<charT, traits, Allocator>*>(&sb).

basic_string<charT, traits, Allocator> str() const;
2
Returns: rdbuf()->str().

void str(const basic_string<charT, traits, Allocator>& s);
3
Effects: Calls rdbuf()->str(s).

27.7.3 Class basic_ostringstream

namespace std {
    template <class charT, class traits = char_traits<charT>,
              class Allocator = allocator<charT> >
    class basic_ostringstream : public basic_ostream<charT, traits> {
        public:

        // Types:
        typedef charT char_type;
        typedef typename traits::int_type int_type;
        typedef typename traits::pos_type pos_type;
        typedef typename traits::off_type off_type;
        typedef traits traits_type;
        typedef Allocator allocator_type;

        // 27.7.3.1 Constructors/destructor:
        explicit basic_ostringstream(ios_base::openmode which = ios_base::out);
        explicit basic_ostringstream(
            const basic_string<charT, traits, Allocator>& str,
            ios_base::openmode which = ios_base::out);

        // 27.7.3.2 Members:
        basic_stringbuf<charT, traits, Allocator>* rdbuf() const;
    }
}
The class `basic_ostringstream<charT, traits, Allocator>` supports writing objects of class `basic_string<charT, traits, Allocator>`. It uses a `basic_stringbuf` object to control the associated storage. For the sake of exposition, the maintained data is presented here as:

— `sb`, the stringbuf object.

### 27.7.3.1 Basic Ostringstream Constructors

#### Explicit Basic Ostringstream

```cpp
explicit basic_ostringstream( ios_base::openmode which = ios_base::out );
```

**Effects:** Constructs an object of class `basic_ostringstream`, initializing the base class with `basic_ostream(&sb)` and initializing `sb` with `basic_stringbuf<charT, traits, Allocator>(which | ios_base::out)` (27.7.1.1).

```cpp
explicit basic_ostringstream(  
    const basic_string<charT,traits,Allocator>& str,  
    ios_base::openmode which = ios_base::out );
```

**Effects:** Constructs an object of class `basic_ostringstream<charT, traits>`, initializing the base class with `basic_ostream(&sb)` and initializing `sb` with `basic_stringbuf<charT, traits, Allocator>(str, which | ios_base::out)` (27.7.1.1).

### 27.7.3.2 Member Functions

```cpp
basic_stringbuf<charT,traits,Allocator>* rdbuf() const;
```

**Returns:** `const_cast<basic_stringbuf<charT,traits,Allocator>*>(&sb)`.

```cpp
basic_string<charT,traits,Allocator> str() const;
```

**Returns:** `rdbuf()->str()`.

```cpp
void str(const basic_string<charT,traits,Allocator>& s);
```

**Effects:** Calls `rdbuf()->str(s)`.

### 27.7.4 Class Template Basic Stringstream

```cpp
namespace std {  
    template <class charT, class traits = char_traits<charT>,  
              class Allocator = allocator<charT> >
    
    Draft
The class template `basic_stringstream<charT, traits>` supports reading and writing from objects of class `basic_string<charT, traits, Allocator>`. It uses a `basic_stringbuf<charT, traits, Allocator>` object to control the associated sequence. For the sake of exposition, the maintained data is presented here as

— `sb`, the stringbuf object.

### 27.7.5 `basic_stringstream` constructors

```cpp
explicit basic_stringstream(
    ios_base::openmode which = ios_base::out|ios_base::in);
```

**Effects:** Constructs an object of class `basic_stringstream<charT, traits>`, initializing the base class with `basic_iostream(&sb)` and initializing `sb` with `basic_stringbuf<charT, traits, Allocator>(which)`.

```cpp
explicit basic_stringstream(
    const basic_string<charT, traits, Allocator>& str,
    ios_base::openmode which = ios_base::out|ios_base::in);
```

**Effects:** Constructs an object of class `basic_stringstream<charT, traits>`, initializing the base class with `basic_iostream(&sb)` and initializing `sb` with `basic_stringbuf<charT, traits, Allocator>(str, which)`. Draft
27.8 File-based streams

27.7.6 Member functions

\[\text{basic_stringbuf}\ <\ \text{charT, traits, Allocator}>\star\ rdbuf()\ \text{const};\]
\[\text{Returns:}\ \text{const}\_\text{cast}\langle\text{basic_stringbuf}\ <\ \text{charT, traits, Allocator}>&\rangle\text{\text{(}\&sb\text{)}}\]

\[\text{basic_string}\ <\ \text{charT, traits, Allocator}>\ \text{str()}\ \text{const};\]
\[\text{Returns:}\ \text{rdbuf()}\rightarrow\text{str()}.\]

\[\text{void str(const basic_string}\ <\ \text{charT, traits, Allocator}>&\text{ str});\]
\[\text{Effects: Calls rdbuf()}\rightarrow\text{str(str)}.\]

27.8 File-based streams

27.8.1 File streams

The header \texttt{<fstream>} defines four class templates and eight types that associate stream buffers with files and assist reading and writing files.

Header \texttt{<fstream> synopsis}

\[
\text{namespace std}\{
\text{template <class charT, class traits = char_traits<charT> >}
\text{class basic_filebuf;}
\text{typedef basic_filebuf<char> filebuf;}
\text{typedef basic_filebuf<wchar_t> wfilebuf;}
\text{template <class charT, class traits = char_traits<charT> >}
\text{class basic_ifstream;}
\text{typedef basic_ifstream<char> ifstream;}
\text{typedef basic_ifstream<wchar_t> wifstream;}
\text{template <class charT, class traits = char_traits<charT> >}
\text{class basic_ofstream;}
\text{typedef basic_ofstream<char> ofstream;}
\text{typedef basic_ofstream<wchar_t> wofstream;}
\text{template <class charT, class traits = char_traits<charT> >}
\text{class basic_fstream;}
\text{typedef basic_fstream<char> fstream;}
\text{typedef basic_fstream<wchar_t> wfstream;}
\}
\]

In this subclause, the type name \texttt{FILE} refers to the type \texttt{FILE} declared in \texttt{<cstdio>} (27.8.2).

\textbf{File} A File provides an external source/sink stream whose \textit{underlaid character type} is \texttt{char} (byte).\textsuperscript{319}

\textsuperscript{318} In C \texttt{FILE} must be a \texttt{typedef}. In C++ it may be a \texttt{typedef} or other type name.

\textsuperscript{319} A File is a sequence of multibyte characters. In order to provide the contents as a wide character sequence, \texttt{filebuf} should convert between wide character sequences and multibyte character sequences.
Multibyte character and Files  A File provides byte sequences. So the streambuf (or its derived classes) treats a file as the external source/sink byte sequence. In a large character set environment, multibyte character sequences are held in files. In order to provide the contents of a file as wide character sequences, wide-oriented filebuf, namely wfilebuf should convert wide character sequences.

27.8.1.1 Class template basic_filebuf

namespace std {

    template <class charT, class traits = char_traits<charT> >
    class basic_filebuf : public basic_streambuf<charT, traits> {

        public:
            typedef charT char_type;
            typedef typename traits::int_type int_type;
            typedef typename traits::pos_type pos_type;
            typedef typename traits::off_type off_type;
            typedef traits traits_type;

        // 27.8.1.2 Constructors/destructor:
        basic_filebuf();
        virtual ~basic_filebuf();

        // 27.8.1.3 Members:
        bool is_open() const;
        basic_filebuf<charT, traits> * open(const char * s,
            ios_base::openmode mode);
        basic_filebuf<charT, traits> * close();

        protected:
        // 27.8.1.4 Overridden virtual functions:
        virtual streamsize showmanyc();
        virtual int_type underflow();
        virtual int_type uflow();
        virtual int_type pbackfail(int_type c = traits::eof());
        virtual int_type overflow (int_type c = traits::eof());

        virtual basic_streambuf<charT, traits>*
            setbuf(char_type* s, streamsize n);
        virtual pos_type seekoff(off_type off, ios_base::seekdir way,
            ios_base::openmode which = ios_base::in | ios_base::out);
        virtual pos_type seekpos(pos_type sp,
            ios_base::openmode which = ios_base::in | ios_base::out);
        virtual int sync();
        virtual void imbue(const locale& loc);
    }
}

1 The class basic_filebuf<charT,traits> associates both the input sequence and the output sequence with a file.
2 The restrictions on reading and writing a sequence controlled by an object of class basic_filebuf<charT,traits>
are the same as for reading and writing with the Standard C library FILEs.

3 In particular:
   — If the file is not open for reading the input sequence cannot be read.
   — If the file is not open for writing the output sequence cannot be written.
   — A joint file position is maintained for both the input sequence and the output sequence.

4 An instance of basic_filebuf behaves as described in 27.8.1.1 provided traits::pos_type is fpos<traits::state_type>. Otherwise the behavior is undefined.

5 In order to support file I/O and multibyte/wide character conversion, conversions are performed using members of a facet, referred to as a_codecvt in following sections, obtained “as if” by

   codecvt<charT,char,typename traits::state_type> a_codecvt =
   use_facet<codecvt<charT,char,typename traits::state_type> >(getloc());

27.8.1.2 basic_filebuf constructors

    basic_filebuf();

1 Effects: Constructs an object of class basic_filebuf<charT,traits>, initializing the base class with basic_streambuf<charT,traits>() (27.5.2.1).

2 Postcondition: is_open() == false.

   virtual ~basic_filebuf();

3 Effects: Destroys an object of class basic_filebuf<charT,traits>. Calls close().

27.8.1.3 Member functions

    bool is_open() const;

1 Returns: true if a previous call to open succeeded (returned a non-null value) and there has been no intervening call to close.

   basic_filebuf<charT,traits>* open(const char* s,
   ios_base::openmode mode);

2 Effects: If is_open() != false, returns a null pointer. Otherwise, initializes the filebuf as required. It then opens a file, if possible, whose name is the NTBS s (“as if” by calling std::fopen(s,modstr)). The NTBS modstr is determined from mode & ~ios_base::ate as indicated in Table 93. If mode is not some combination of flags shown in the table then the open fails.

3 If the open operation succeeds and (mode & ios_base::ate) != 0, positions the file to the end (“as if” by calling std::fseek(file,0,SEEK_END)).

320 The macro SEEK_END is defined, and the function signatures fopen(const char*, const char*) and fseek(FILE*, long, int) are declared, in <cstdio> (27.8.2).
Table 93: File open modes

<table>
<thead>
<tr>
<th>ios_base Flag combination</th>
<th>stdio equivalent</th>

</tr>
<tr>
<td>+</td>
<td>&quot;wb&quot;</td>
</tr>
</tbody>
</table>

4 If the repositioning operation fails, calls close() and returns a null pointer to indicate failure.
5 Returns: this if successful, a null pointer otherwise.

    basic_filebuf<charT,traits>* close();
6 Effects: If is_open() == false, returns a null pointer. If a put area exists, calls overflow(traits::eof()) to flush characters. If the last virtual member function called on *this (between underflow, overflow, seekoff, and seekpos) was overflow then calls a_codecvt.unshift (possibly several times) to determine a termination sequence, inserts those characters and calls overflow(traits::eof()) again. Finally it closes the file (“as if” by calling std::fclose(file)).\(^{321}\) If any of the calls to overflow or std::fclose fails then close fails.
7 Returns: this on success, a null pointer otherwise.
8 Postcondition: is_open() == false.

27.8.1.4 Overridden virtual functions [lib.filebuf.virtuals]

    streamsize showmanyc();
1 Effects: Behaves the same as basic_streambuf::showmanyc() (27.5.2.4).
2 Remarks: An implementation might well provide an overriding definition for this function signature if it can determine that more characters can be read from the input sequence.

    int_type underflow();
321) The function signature fclose(FILE*) is declared in <stdio> (27.8.2).
Effects: Behaves according to the description of basic_streambuf<charT,traits>::underflow(), with the specialization that a sequence of characters is read from the input sequence “as if” by reading from the associated file into an internal buffer (extern_buf) and then “as if” doing

```cpp
char extern_buf[XSIZE];
char* extern_end;
charT intern_buf[ISIZE];
charT* intern_end;
codecvt_base::result r =
    a_codecvt.in(state, extern_buf, extern_buf+XSIZE, extern_end,
                 intern_buf, intern_buf+ISIZE, intern_end);
```

This shall be done in such a way that the class can recover the position (fpos_t) corresponding to each character between intern_buf and intern_end. If the value of r indicates that a_codecvt.in() ran out of space in intern_buf, retry with a larger intern_buf.

```cpp
int_type uflow();
```

Effects: Behaves according to the description of basic_streambuf<charT,traits>::uflow(), with the specialization that a sequence of characters is read from the input with the same method as used by underflow.

```cpp
int_type pbackfail(int_type c = traits::eof());
```

Effects: Puts back the character designated by c to the input sequence, if possible, in one of three ways:

- If traits::eq_int_type(c,traits::eof()) returns false and if the function makes a putback position available and if traits::eq(to_char_type(c),gptr()[0]) returns true, decrements the next pointer for the input sequence, gptr().
  
  Returns: c.

- If traits::eq_int_type(c,traits::eof()) returns false and if the function makes a putback position available and if the function is permitted to assign to the putback position, decrements the next pointer for the input sequence, and stores c there.
  
  Returns: c.

- If traits::eq_int_type(c,traits::eof()) returns true, and if either the input sequence has a putback position available or the function makes a putback position available, decrements the next pointer for the input sequence, gptr().
  
  Returns: traits::not_eof(c).

Returns: traits::eof() to indicate failure.

Remarks: If is_open() == false, the function always fails.

The function does not put back a character directly to the input sequence.

If the function can succeed in more than one of these ways, it is unspecified which way is chosen. The function can alter the number of putback positions available as a result of any call.

```cpp
int_type overflow(int_type c = traits::eof());
```
**Effects:** Behaves according to the description of `basic_streambuf<charT,traits>::overflow(c)`, except that the behavior of “consuming characters” is performed by first converting “as if” by:

```cpp
ccharT* b = pbase();
charT* p = pptr();
charT* end;
char xbuf[XSIZE];
char* xbuf_end;
codecvt_base::result r =
    a_codecvt.out(state, b, p, end, xbuf, xbuf+XSIZE, xbuf_end);
```

and then

- If `r == codecvt_base::error` then fail.
- If `r == codecvt_base::noconv` then output characters from `b` up to (and not including) `p`.
- If `r == codecvt_base::partial` then output to the file characters from `xbuf` up to `xbuf_end`, and repeat using characters from `end` to `p`. If output fails, fail (without repeating).
- Otherwise output from `xbuf` to `xbuf_end`, and fail if output fails. At this point if `b != p` and `b == end` (`xbuf` isn’t large enough) then increase `XSIZE` and repeat from the beginning.

**Returns:** `traits::not_eof(c)` to indicate success, and `traits::eof()` to indicate failure. If `is_open()` == false, the function always fails.

```cpp
basic_streambuf* setbuf(char_type* s, streamsize n);
```

**Effects:** If `setbuf(0,0)` is called on a stream before any I/O has occurred on that stream, the stream becomes unbuffered. Otherwise the results are implementation-defined. “Unbuffered” means that `pbase()` and `pptr()` always return null and output to the file should appear as soon as possible.

```cpp
pos_type seekoff(off_type off, ios_base::seekdir way,
    ios_base::openmode which = ios_base::in | ios_base::out);
```

**Effects:** Let `width` denote `a_codecvt.encoding()`. If `is_open() == false`, or `off != 0 && width <= 0`, then the positioning operation fails. Otherwise, if `way != basic_ios::cur` or `off != 0`, and if the last operation was output, then update the output sequence and write any unshift sequence. Next, seek to the new position: if `width > 0`, call `std::fseek(file, width * off, whence)`, otherwise call `std::fseek(file, 0, whence)`.

**Remarks:** “The last operation was output” means either the last virtual operation was overflow or the put buffer is non-empty. “Write any unshift sequence” means, if `width` if less than zero then call `a_codecvt.unshift(state, xbuf, xbuf+XSIZE, xbuf_end)` and output the resulting unshift sequence. The function determines one of three values for the argument `whence`, of type int, as indicated in Table 94.

**Returns:** a newly constructed `pos_type` object that stores the resultant stream position, if possible. If the positioning operation fails, or if the object cannot represent the resultant stream position, returns `pos_type(off_type(-1))`.

```cpp
pos_type seekpos(pos_type sp,
    ios_base::openmode which = ios_base::in | ios_base::out);
```
Alters the file position, if possible, to correspond to the position stored in \( sp \) (as described below). Altering the file position performs as follows:

1. if \(( om \& \ ios\_base::out) != 0\), then update the output sequence and write any unshift sequence;
2. set the file position to \( sp \);
3. if \(( om \& \ ios\_base::in) != 0\), then update the input sequence;

where \( om \) is the open mode passed to the last call to \( \text{open}() \). The operation fails if \( \text{is\_open}() \) returns false.

If \( sp \) is an invalid stream position, or if the function positions neither sequence, the positioning operation fails. If \( sp \) has not been obtained by a previous successful call to one of the positioning functions (\( \text{seekoff} \) or \( \text{seekpos} \)) on the same file the effects are undefined.

Returns: \( sp \) on success. Otherwise returns \( \text{pos\_type(off\_type(-1))} \).

\[ int \, \text{sync}(); \]

Effects: If a put area exists, calls \( \text{filebuf\_overflow} \) to write the characters to the file. If a get area exists, the effect is implementation-defined.

\[ \text{void imbue(const locale& loc);} \]

Precondition: If the file is not positioned at its beginning and the encoding of the current locale as determined by \( \text{a\_codecvt.encoding()} \) is state-dependent (22.2.1.4.2) then that facet is the same as the corresponding facet of \( \text{loc} \).

Effects: Causes characters inserted or extracted after this call to be converted according to \( \text{loc} \) until another call of \( \text{imbue} \).

Remark: This may require reconversion of previously converted characters. This in turn may require the implementation to be able to reconstruct the original contents of the file.

27.8.1.5 Class template \texttt{basic\_ifstream} 

namespace std {
    template <class charT, class traits = char_traits<charT> >
    class basic_ifstream : public basic_istream<charT,traits> {
        public:
            typedef charT char_type;
            typedef typename traits::int_type int_type;
            typedef typename traits::pos_type pos_type;
            typedef typename traits::off_type off_type;

Draft
The class `basic_ifstream<charT, traits>` supports reading from named files. It uses a `basic_filebuf<charT, traits>` object to control the associated sequence. For the sake of exposition, the maintained data is presented here as:

— `sb`, the filebuf object.

### 27.8.1.6 basic_ifstream constructors

```cpp
basic_ifstream();
```

Effects: Constructs an object of class `basic_ifstream<charT, traits>`, initializing the base class with `basic_istream(&sb)` and initializing `sb` with `basic_filebuf<charT, traits>()` (27.6.1.1.1, 27.8.1.2).

```cpp
explicit basic_ifstream(const char* s,
                        ios_base::openmode mode = ios_base::in);
```

Effects: Constructs an object of class `basic_ifstream`, initializing the base class with `basic_istream(&sb)` and initializing `sb` with `basic_filebuf<charT, traits>()` (27.6.1.1.1, 27.8.1.2), then calls `rdbuf()->open(s, mode | ios_base::in)`. If that function returns a null pointer, calls `setstate(failbit)`.

### 27.8.1.7 Member functions

```cpp
basic_filebuf<charT,traits>* rdbuf() const;
```

Returns: `const_cast<basic_filebuf<charT,traits>*>(&sb)`.

```cpp
bool is_open() const;
```

Returns: `rdbuf()->is_open()`.

```cpp
void open(const char* s, ios_base::openmode mode = ios_base::in);
```

Draft
Effects: Calls rdbuf()->open(s, mode | ios_base::in). If that function does not return a null pointer calls clear(), otherwise calls setstate(failbit) (which may throw ios_base::failure (27.4.4.3)).

```cpp
void close();
```

Effects: Calls rdbuf()->close() and, if that function returns false, calls setstate(failbit) (which may throw ios_base::failure (27.4.4.3)).

### 27.8.1.8 Class template basic_ofstream

```cpp
namespace std {
    template <class charT, class traits = char_traits<charT> >
    class basic_ofstream : public basic_ostream<charT, traits> {
    public:
        typedef charT char_type;
        typedef typename traits::int_type int_type;
        typedef typename traits::pos_type pos_type;
        typedef typename traits::off_type off_type;
        typedef traits traits_type;

        // 27.8.1.9 Constructors:
        basic_ofstream();
        explicit basic_ofstream(const char* s,
            ios_base::openmode mode = ios_base::out);

        // 27.8.1.10 Members:
        basic_filebuf<charT, traits>* rdbuf() const;

        bool is_open() const;
        void open(const char* s, ios_base::openmode mode = ios_base::out);
        void close();
    private:
        // basic_filebuf<charT, traits> sb; 
            exposition only
    }
}
```

The class basic_ofstream<charT, traits> supports writing to named files. It uses a basic_filebuf<charT, traits> object to control the associated sequence. For the sake of exposition, the maintained data is presented here as:

— sb, the filebuf object.

### 27.8.1.9 basic_ofstream constructors

```cpp
basic_ofstream();
```

Effects: Constructs an object of class basic_ofstream<charT, traits>, initializing the base class with basic_ostream(&sb) and initializing sb with basic_filebuf<charT, traits>(()) (27.6.2.2, 27.8.1.2).

[322] A successful open does not change the error state.
explicit basic_ofstream(const char* s,
    ios_base::openmode mode = ios_base::out);

Effects: Constructs an object of class basic_ofstream<charT,traits>, initializing the base class with basic_ostream(&sb) and initializing sb with basic_filebuf<charT,traits>() (27.6.2.2, 27.8.1.2), then calls rdbuf()->open(s, mode|ios_base::out). If that function returns a null pointer, calls setstate(failbit).

27.8.1.10 Member functions

basic_filebuf<charT,traits>* rdbuf() const;

Returns: const_cast<basic_filebuf<charT,traits>*>(&sb).

bool is_open() const;

Returns: rdbuf()->is_open().

void open(const char* s, ios_base::openmode mode = ios_base::out);

Effects: Calls rdbuf()->open(s, mode|ios_base::out). If that function does not return a null pointer calls clear(), otherwise calls setstate(failbit) (which may throw ios_base::failure (27.4.4.3)).

void close();

Effects: Calls rdbuf()->close() and, if that function fails (returns a null pointer), calls setstate(failbit) (which may throw ios_base::failure (27.4.4.3)).

27.8.1.11 Class template basic_fstream

namespace std {
    template <class charT, class traits=char_traits<charT> >
    class basic_fstream :
        public basic_iostream<charT,traits> {

        public:
            typedef charT char_type;
            typedef typename traits::int_type int_type;
            typedef typename traits::pos_type pos_type;
            typedef typename traits::off_type off_type;
            typedef traits traits_type;

            // constructors/destructor
            basic_fstream();
            explicit basic_fstream(const char* s,
                ios_base::openmode mode = ios_base::in|ios_base::out);

            // Members:

323) A successful open does not change the error state.
The class template `basic_fstream<charT, traits>` supports reading and writing from named files. It uses a `basic_filebuf<charT, traits>` object to control the associated sequences. For the sake of exposition, the maintained data is presented here as:

— `sb`, the `basic_filebuf` object.

### 27.8.1.12 basic_fstream constructors

#### basic_fstream();

*Effects:* Constructs an object of class `basic_fstream<charT, traits>`, initializing the base class with `basic_iosstream(&sb)` and initializing `sb` with `basic_filebuf<charT, traits>()`.

#### explicit basic_fstream(const char* s, ios_base::openmode mode = ios_base::in|ios_base::out);

*Effects:* Constructs an object of class `basic_fstream<charT, traits>`, initializing the base class with `basic_iosstream(&sb)` and initializing `sb` with `basic_filebuf<charT, traits>()`. Then calls `rdbuf() -> open(s, mode)`. If that function returns a null pointer, calls `setstate(failbit)`.

### 27.8.1.13 Member functions

#### basic_filebuf<charT, traits>* rdbuf() const;

*Returns:* `const_cast<basic_filebuf<charT, traits>*>(&sb)`.

#### bool is_open() const;

*Returns:* `rdbuf()->is_open()`.

#### void open(const char* s, ios_base::openmode mode = ios_base::in|ios_base::out);

*Effects:* Calls `rdbuf() -> open(s, mode)`. If that function does not return a null pointer calls `clear()`, otherwise calls `setstate(failbit)` (which may throw `ios_base::failure`)(27.4.4.3).

#### void close();

*Effects:* Calls `rdbuf() -> close()` and, if that function returns `false`, calls `setstate(failbit)`(27.4.4.3) (which may throw `ios_base::failure`).

| SEE ALSO: ISO C subclause 7.9, Amendment 1 subclause 4.6.2.
This summary of C++ syntax is intended to be an aid to comprehension. It is not an exact statement of the language. In particular, the grammar described here accepts a superset of valid C++ constructs. Disambiguation rules (6.8, 7.1, 10.2) must be applied to distinguish expressions from declarations. Further, access control, ambiguity, and type rules must be used to weed out syntactically valid but meaningless constructs.

### A.1 Keywords

New context-dependent keywords are introduced into a program by `typedef` (7.1.3), `namespace` (7.3.1), `class` (clause 9), `enumeration` (7.2), and `template` (clause 14) declarations.

```plaintext
typedef-name:        identifier
namespace-name:       identifier
                     original-namespace-name
                     namespace-alias
original-namespace-name:        identifier
namespace-alias:       identifier
class-name:           identifier
                     template-id
enum-name:            identifier
template-name:        identifier
```

Note that a `typedef-name` naming a class is also a `class-name` (9.1).

### A.2 Lexical conventions

```plaintext
hex-quad:             hexadecimal-digit hexadecimal-digit hexadecimal-digit hexadecimal-digit

Implementation quantities

Because computers are finite, C++ implementations are inevitably limited in the size of the programs they can successfully process. Every implementation shall document those limitations where known. This documentation may cite fixed limits where they exist, say how to compute variable limits as a function of available resources, or say that fixed limits do not exist or are unknown.

The limits may constrain quantities that include those described below or others. The bracketed number following each quantity is recommended as the minimum for that quantity. However, these quantities are only guidelines and do not determine compliance.

- Nesting levels of compound statements, iteration control structures, and selection control structures [256].
- Nesting levels of conditional inclusion [256].
- Pointer, array, and function declarators (in any combination) modifying an arithmetic, structure, union, or incomplete type in a declaration [256].
- Nesting levels of parenthesized expressions within a full expression [256].
- Number of characters in an internal identifier or macro name [1024].
- Number of characters in an external identifier [1024].
- External identifiers in one translation unit [65536].
- Identifiers with block scope declared in one block [1024].
- Macro identifiers simultaneously defined in one translation unit [65536].
- Parameters in one function definition [256].
- Arguments in one function call [256].
- Parameters in one macro definition [256].
- Arguments in one macro invocation [256].
- Characters in one logical source line [65536].
- Characters in a character string literal or wide string literal (after concatenation) [65536].
— Size of an object [262 144].
— Nesting levels for #include files [256].
— Case labels for a switch statement (excluding those for any nested switch statements) [16 384].
— Data members in a single class, structure, or union [16 384].
— Enumeration constants in a single enumeration [4 096].
— Levels of nested class, structure, or union definitions in a single struct-declaration-list [256].
— Functions registered by atexit() [32].
— Direct and indirect base classes [16 384].
— Direct base classes for a single class [1 024].
— Members declared in a single class [4 096].
— Final overriding virtual functions in a class, accessible or not [16 384].
— Direct and indirect virtual bases of a class [1 024].
— Static members of a class [1 024].
— Friend declarations in a class [4 096].
— Access control declarations in a class [4 096].
— Member initializers in a constructor definition [6 144].
— Scope qualifications of one identifier [256].
— Nested external specifications [1 024].
— Template arguments in a template declaration [1 024].
— Recursively nested template instantiations [17].
— Handlers per try block [256].
— Throw specifications on a single function declaration [256].
Appendix C
(informative)
Compatibility

C.1  C++ and ISO C

The subclauses of this subclause list the differences between C++ and ISO C, by the chapters of this document.

C.1.1  Clause 2: lexical conventions

2.3
Change: C++ style comments (//) are added
A pair of slashes now introduce a one-line comment.
Rationale: This style of comments is a useful addition to the language.
Effect on original feature: Change to semantics of well-defined feature. A valid ISO C expression containing a division operator followed immediately by a C-style comment will now be treated as a C++ style comment. For example:

```
{  
    int a = 4;
    int b = 8  // * divide by a*/ a;
    +a;
}
```

Difficulty of converting: Syntactic transformation. Just add white space after the division operator.
How widely used: The token sequence /* divides */ probably occurs very seldom.

2.11
Change: New Keywords New keywords are added to C++; see 2.11.
Rationale: These keywords were added in order to implement the new semantics of C++.
Effect on original feature: Change to semantics of well-defined feature. Any ISO C programs that used any of these keywords as identifiers are not valid C++ programs.
Difficulty of converting: Syntactic transformation. Converting one specific program is easy. Converting a large collection of related programs takes more work.
How widely used: Common.
2.13.2
Change: Type of character literal is changed from `int` to `char`.
Rationale: This is needed for improved overloaded function argument type matching. For example:

```c
int function( int i );
int function( char c );
function( 'x' );
```

It is preferable that this call match the second version of function rather than the first.

Effect on original feature: Change to semantics of well-defined feature. ISO C programs which depend on

```c
sizeof('x') == sizeof(int)
```

will not work the same as C++ programs.

Difficulty of converting: Simple.
How widely used: Programs which depend upon `sizeof('x')` are probably rare.

Subclause 2.13.4:
Change: String literals made `const` The type of a string literal is changed from “array of `char`” to “array of `const char`.” The type of a wide string literal is changed from “array of `wchar_t`” to “array of `const wchar_t`.”
Rationale: This avoids calling an inappropriate overloaded function, which might expect to be able to modify its argument.

Effect on original feature: Change to semantics of well-defined feature.

Difficulty of converting: Simple syntactic transformation, because string literals can be converted to `char*`; (4.2). The most common cases are handled by a new but deprecated standard conversion:

```c
char* p = "abc";  // valid in C, deprecated in C++
char* q = expr ? "abc" : "de";  // valid in C, invalid in C++
```

How widely used: Programs that have a legitimate reason to treat string literals as pointers to potentially modifiable memory are probably rare.

C.1.2 Clause 3: basic concepts

3.1
Change: C++ does not have “tentative definitions” as in C E.g., at file scope,

```c
int i;
```

is valid in C, invalid in C++. This makes it impossible to define mutually referential file-local static objects, if initializers are restricted to the syntactic forms of C. For example,

```c
struct X { int i; struct X *next; };
static struct X a;
static struct X b = { 0, &a };  
static struct X a = { 1, &b };  
```

Draft
Rationale: This avoids having different initialization rules for built-in types and user-defined types.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Semantic transformation.
Rationale: In C++, the initializer for one of a set of mutually-referential file-local static objects must invoke a function call to achieve the initialization.
How widely used: Seldom.

3.3
Change: A struct is a scope in C++, not in C
Rationale: Class scope is crucial to C++, and a struct is a class.
Effect on original feature: Change to semantics of well-defined feature.
Difficulty of converting: Semantic transformation.
How widely used: C programs use struct extremely frequently, but the change is only noticeable when struct, enumeration, or enumerator names are referred to outside the struct. The latter is probably rare.

3.5 [also 7.1.5]
Change: A name of file scope that is explicitly declared const, and not explicitly declared extern, has internal linkage, while in C it would have external linkage
Rationale: Because const objects can be used as compile-time values in C++, this feature urges programmers to provide explicit initializer values for each const. This feature allows the user to put const objects in header files that are included in many compilation units.
Effect on original feature: Change to semantics of well-defined feature.
Difficulty of converting: Semantic transformation
How widely used: Seldom

3.6
Change: Main cannot be called recursively and cannot have its address taken
Rationale: The main function may require special actions.
Effect on original feature: Deletion of semantically well-defined feature
Difficulty of converting: Trivial: create an intermediary function such as mymain(argc, argv.
How widely used: Seldom

3.9
Change: C allows “compatible types” in several places, C++ does not. For example, otherwise-identical struct types with different tag names are “compatible” in C but are distinctly different types in C++.
Rationale: Stricter type checking is essential for C++.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Semantic transformation. The “typesafe linkage” mechanism will find many, but not all, of such problems. Those problems not found by typesafe linkage will continue to function properly, according to the “layout compatibility rules” of this International Standard.
How widely used: Common.

4.10
Change: Converting void* to a pointer-to-object type requires casting

```c
char a[10];
void *b=a;
void foo() {
```

Draft
ISO C will accept this usage of pointer to void being assigned to a pointer to object type. C++ will not.

**Rationale:** C++ tries harder than C to enforce compile-time type safety.

**Effect on original feature:** Deletion of semantically well-defined feature.

**Difficulty of converting:** Could be automated. Violations will be diagnosed by the C++ translator. The fix is to add a cast. For example:

```c
char *c = (char *) b;
```

**How widely used:** This is fairly widely used but it is good programming practice to add the cast when assigning pointer-to-void to pointer-to-object. Some ISO C translators will give a warning if the cast is not used.

### 4.10

**Change:** Only pointers to non-const and non-volatile objects may be implicitly converted to `void*`.

**Rationale:** This improves type safety.

**Effect on original feature:** Deletion of semantically well-defined feature.

**Difficulty of converting:** Could be automated. A C program containing such an implicit conversion from (e.g.) pointer-to-const-object to `void*` will receive a diagnostic message. The correction is to add an explicit cast.

**How widely used:** Seldom.

### C.1.3 Clause 5: expressions

5.2.2

**Change:** Implicit declaration of functions is not allowed.

**Rationale:** The type-safe nature of C++.

**Effect on original feature:** Deletion of semantically well-defined feature. Note: the original feature was labeled as “obsolete” in ISO C.

**Difficulty of converting:** Syntactic transformation. Facilities for producing explicit function declarations are fairly widespread commercially.

**How widely used:** Common.

5.3.3, 5.4

**Change:** Types must be declared in declarations, not in expressions In C, a `sizeof` expression or cast expression may create a new type. For example,

```c
p = (void*)(struct x {int i;} *)0;
```

declares a new type, struct x .

**Rationale:** This prohibition helps to clarify the location of declarations in the source code.

**Effect on original feature:** Deletion of a semantically well-defined feature.

**Difficulty of converting:** Syntactic transformation.

**How widely used:** Seldom.

5.16, 5.17, 5.18

**Change:** The result of a conditional expression, an assignment expression, or a comma expression may be an lvalue.
**Rationale:** C++ is an object-oriented language, placing relatively more emphasis on lvalues. For example, functions may return lvalues.

**Effect on original feature:** Change to semantics of well-defined feature. Some C expressions that implicitly rely on lvalue-to-rvalue conversions will yield different results. For example,

```c
char arr[100];
sizeof(0, arr)
```

yields 100 in C++ and `sizeof(char*)` in C.

**Difficulty of converting:** Programs must add explicit casts to the appropriate rvalue.

**How widely used:** Rare.

---

**C.1.4 Clause 6: statements**

6.4.2, 6.6.4 (switch and goto statements)

**Change:** It is now invalid to jump past a declaration with explicit or implicit initializer (except across entire block not entered)

**Rationale:** Constructors used in initializers may allocate resources which need to be de-allocated upon leaving the block. Allowing jump past initializers would require complicated run-time determination of allocation. Furthermore, any use of the uninitialized object could be a disaster. With this simple compile-time rule, C++ assures that if an initialized variable is in scope, then it has assuredly been initialized.

**Effect on original feature:** Deletion of semantically well-defined feature.

**Difficulty of converting:** Semantic transformation.

**How widely used:** Seldom.

---

**C.1.5 Clause 7: declarations**

7.1.1

**Change:** In C++, the `static` or `extern` specifiers can only be applied to names of objects or functions Using these specifiers with type declarations is illegal in C++. In C, these specifiers are ignored when used on type declarations.

**Example:**

```c
static struct S { // valid C, invalid in C++
    int i;
    // ...
};
```

Draft
Rationale: Storage class specifiers don’t have any meaning when associated with a type. In C++, class members can be declared with the `static` storage class specifier. Allowing storage class specifiers on type declarations could render the code confusing for users.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Syntactic transformation.

How widely used: Seldom.

7.1.3

Change: A C++ typedef name must be different from any class type name declared in the same scope (except if the typedef is a synonym of the class name with the same name). In C, a typedef name and a struct tag name declared in the same scope can have the same name (because they have different name spaces)

Example:

```c
typedef struct name1 { /* ... */ } name1; // valid C and C++
struct name { /* ... */ };
typedef int name; // valid C, invalid C++
```

Rationale: For ease of use, C++ doesn’t require that a type name be prefixed with the keywords `class`, `struct` or `union` when used in object declarations or type casts.

Example:

```c
class name { /* ... */ };
name i; // i has type class name
```

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Semantic transformation. One of the 2 types has to be renamed.

How widely used: Seldom.

7.1.5 [see also 3.5]

Change: const objects must be initialized in C++ but can be left uninitialized in C

Rationale: A const object cannot be assigned to so it must be initialized to hold a useful value.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Semantic transformation.

How widely used: Seldom.

7.1.5 (type specifiers)

Change: Banning implicit int

In C++ a `decl-specifier-seq` must contain a `type-specifier`. In the following example, the left-hand column presents valid C; the right-hand column presents equivalent C++:

```c
void f(const parm); void f(const int parm);
const n = 3; const int n = 3;
main() int main()
    /* ... */ /* ... */
```

Draft
Rationale: In C++, implicit int creates several opportunities for ambiguity between expressions involving function-like casts and declarations. Explicit declaration is increasingly considered to be proper style. Liaison with WG14 (C) indicated support for (at least) deprecating implicit int in the next revision of C.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Syntactic transformation. Could be automated.

How widely used: Common.

7.2

Change: C++ objects of enumeration type can only be assigned values of the same enumeration type. In C, objects of enumeration type can be assigned values of any integral type

Example:

```c
enum color { red, blue, green };
color c = 1;                     // valid C, invalid C++
```

Rationale: The type-safe nature of C++.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Syntactic transformation. (The type error produced by the assignment can be automatically corrected by applying an explicit cast.)

How widely used: Common.

7.2

Change: In C++, the type of an enumerator is its enumeration. In C, the type of an enumerator is int.

Example:

```c
enum e { A };
sizeof(A) == sizeof(int)    // in C
sizeof(A) == sizeof(e)      // in C++
/* and sizeof(int) is not necessarily equal to sizeof(e) */
```

Rationale: In C++, an enumeration is a distinct type.

Effect on original feature: Change to semantics of well-defined feature.

Difficulty of converting: Semantic transformation.

How widely used: Seldom. The only time this affects existing C code is when the size of an enumerator is taken. Taking the size of an enumerator is not a common C coding practice.

C.1.6 Clause 8: declarators

8.3.5

Change: In C++, a function declared with an empty parameter list takes no arguments. In C, an empty parameter list means that the number and type of the function arguments are unknown

Example:

```c
int f();                        // means int f(void) in C++
                             // int f(unknown) in C
```

Draft
Rationale: This is to avoid erroneous function calls (i.e. function calls with the wrong number or type of arguments).

Effect on original feature: Change to semantics of well-defined feature. This feature was marked as “obsolescent” in C.

Difficulty of converting: Syntactic transformation. The function declarations using C incomplete declaration style must be completed to become full prototype declarations. A program may need to be updated further if different calls to the same (non-prototype) function have different numbers of arguments or if the type of corresponding arguments differed.

How widely used: Common.

8.3.5 [see 5.3.3]

Change: In C++, types may not be defined in return or parameter types. In C, these type definitions are allowed

Example:

```c
void f( struct S { int a; } arg ) {} // valid C, invalid C++
enum E { A, B, C } f() {} // valid C, invalid C++
```

Rationale: When comparing types in different compilation units, C++ relies on name equivalence when C relies on structural equivalence. Regarding parameter types: since the type defined in an parameter list would be in the scope of the function, the only legal calls in C++ would be from within the function itself.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Semantic transformation. The type definitions must be moved to file scope, or in header files.

How widely used: Seldom. This style of type definitions is seen as poor coding style.

8.4

Change: In C++, the syntax for function definition excludes the “old-style” C function. In C, “old-style” syntax is allowed, but deprecated as “obsolescent.”

Rationale: Prototypes are essential to type safety.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Syntactic transformation.

How widely used: Common in old programs, but already known to be obsolescent.

8.5.2

Change: In C++, when initializing an array of character with a string, the number of characters in the string (including the terminating ’\0’) must not exceed the number of elements in the array. In C, an array can be initialized with a string even if the array is not large enough to contain the string-terminating ’\0’

Example:

```c
char array[4] = "abcd"; // valid C, invalid C++
```

Rationale: When these non-terminated arrays are manipulated by standard string routines, there is potential for major catastrophe.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Semantic transformation. The arrays must be declared one element bigger to contain the string terminating ’\0’.
How widely used: Seldom. This style of array initialization is seen as poor coding style.

C.1.7 Clause 9: classes

9.1 [see also 7.1.3]
Change: In C++, a class declaration introduces the class name into the scope where it is declared and hides any object, function or other declaration of that name in an enclosing scope. In C, an inner scope declaration of a struct tag name never hides the name of an object or function in an outer scope.

Example:
```c
int x[99];
void f()
{
    struct x { int a; };
    sizeof(x); // size of the array in C */
    /* size of the struct in C++ */
}
```

Rationale: This is one of the few incompatibilities between C and C++ that can be attributed to the new C++ name space definition where a name can be declared as a type and as a non-type in a single scope causing the non-type name to hide the type name and requiring that the keywords `class`, `struct`, `union` or `enum` be used to refer to the type name. This new name space definition provides important notational conveniences to C++ programmers and helps making the use of the user-defined types as similar as possible to the use of built-in types. The advantages of the new name space definition were judged to outweigh by far the incompatibility with C described above.

Effect on original feature: Change to semantics of well-defined feature.

Difficulty of converting: Semantic transformation. If the hidden name that needs to be accessed is at global scope, the `::` C++ operator can be used. If the hidden name is at block scope, either the type or the struct tag has to be renamed.

How widely used: Seldom.

9.7
Change: In C++, the name of a nested class is local to its enclosing class. In C the name of the nested class belongs to the same scope as the name of the outermost enclosing class.

Example:
```c
struct X {
    struct Y { /* ... */ } y;
};
struct Y yy; // valid C, invalid C++
```

Rationale: C++ classes have member functions which require that classes establish scopes. The C rule would leave classes as an incomplete scope mechanism which would prevent C++ programmers from maintaining locality within a class. A coherent set of scope rules for C++ based on the C rule would be very complicated and C++ programmers would be unable to predict reliably the meanings of nontrivial examples involving nested or local functions.

Effect on original feature: Change of semantics of well-defined feature.

Difficulty of converting: Semantic transformation. To make the struct type name visible in the scope of the enclosing...
struct, the struct tag could be declared in the scope of the enclosing struct, before the enclosing struct is defined. Example:

```c
struct Y;                     // struct Y and struct X are at the same scope
struct X {
    struct Y { /* ... */ } y;
};
```

All the definitions of C struct types enclosed in other struct definitions and accessed outside the scope of the enclosing struct could be exported to the scope of the enclosing struct. Note: this is a consequence of the difference in scope rules, which is documented in 3.3.

How widely used: Seldom.

9.9

Change: In C++, a typedef name may not be redeclared in a class definition after being used in that definition

Example:

```c
typedef int I;
struct S {
    I i;
    int I;                          // valid C, invalid C++
};
```

Rationale: When classes become complicated, allowing such a redefinition after the type has been used can create confusion for C++ programmers as to what the meaning of ‘I’ really is.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Semantic transformation. Either the type or the struct member has to be renamed.

How widely used: Seldom.

C.1.8 Clause 12: special member functions

12.8 (copying class objects)

Change: Copying volatile objects

The implicitly-declared copy constructor and implicitly-declared copy assignment operator cannot make a copy of a volatile lvalue. For example, the following is valid in ISO C:

```c
struct X { int i; };
struct X x1, x2;
volatile struct X x3 = {0};
x1 = x3;                      // invalid C++
x2 = x3;                      // also invalid C++
```

Rationale: Several alternatives were debated at length. Changing the parameter to `volatile const X&` would greatly complicate the generation of efficient code for class objects. Discussion of providing two alternative signatures for these implicitly-defined operations raised unanswered concerns about creating ambiguities and complicating the rules that specify the formation of these operators according to the bases and members.

Effect on original feature: Deletion of semantically well-defined feature.
**Difficulty of converting:** Semantic transformation. If volatile semantics are required for the copy, a user-declared constructor or assignment must be provided. If non-volatile semantics are required, an explicit `const_cast` can be used.

**How widely used:** Seldom.

**C.1.9 Clause 16: preprocessing directives**

16.8 (predefined names)

**Change:** Whether `_STDC_` is defined and if so, what its value is, are implementation-defined

**Rationale:** C++ is not identical to ISO C. Mandating that `_STDC_` be defined would require that translators make an incorrect claim. Each implementation must choose the behavior that will be most useful to its marketplace.

**Effect on original feature:** Change to semantics of well-defined feature.

**Difficulty of converting:** Semantic transformation.

**How widely used:** Programs and headers that reference `_STDC_` are quite common.

**C.2 Standard C library**

This subclause summarizes the contents of the C++ Standard library included from the Standard C library. It also summarizes the explicit changes in definitions, declarations, or behavior from the ISO/IEC 9899:1990 and ISO/IEC 9899:1990/DAM 1 noted in other subclauses (17.4.1.2, 18.1, 21.4).

The C++ Standard library provides 54 standard macros from the C library, as shown in Table 96.

The header names (enclosed in `< and >`) indicate that the macro may be defined in more than one header. All such definitions are equivalent (3.2).

The C++ Standard library provides 45 standard values from the C library, as shown in Table 97.

The C++ Standard library provides 19 standard types from the C library, as shown in Table 98.

The C++ Standard library provides 2 standard structures from the C library, as shown in Table 99.

The C++ Standard library provides 209 standard functions from the C library, as shown in Table 100.

C.2 Standard C library

C.2.1 Modifications to headers

For compatibility with the Standard C library, the C++ Standard library provides the 18 C headers (D.5), but their use is deprecated in C++.

C.2.2 Modifications to definitions

C.2.2.1 Type wchar_t

wchar_t is a keyword in this International Standard (2.11). It does not appear as a type name defined in any of <cstddef>, <cstdlib>, or <wchar> (21.4).

C.2.2.2 Header <iso646.h>

The tokens and, and_eq, bitand, bitor, compl, not_eq, not, or, or_eq, xor, and xor_eq are keywords in this International Standard (2.11). They do not appear as macro names defined in <ciso646>.

C.2.2.3 Macro NULL

The macro NULL, defined in any of <locale>, <cstddef>, <stdio>, <stdlib>, <string>, <ctime>, or <wchar>, is an implementation-defined C++ null pointer constant in this International Standard (18.1).

C.2.3 Modifications to declarations

Header <cstring>: The following functions have different declarations:

- strchr
- strpbrk
- strrchr
- strstr
- memchr

21.4 describes the changes.

C.2.4 Modifications to behavior

Header <cstdlib>: The following functions have different behavior:

- atexit
- exit
- abort

18.3 describes the changes.

Header <csetjmp>: The following functions have different behavior:

- longjmp

18.7 describes the changes.
C.2.4.1 Macro offsetof(type,member-designator) [diff.offsetof]

The macro offsetof, defined in `<cstddef>`, accepts a restricted set of type arguments in this International Standard. 18.1 describes the change.

C.2.4.2 Memory allocation functions [diff.malloc]

The functions calloc, malloc, and realloc are restricted in this International Standard. 20.4.6 describes the changes.
Appendix D
(normative)
Compatibility features

1 This clause describes features of the C++ Standard that are specified for compatibility with existing implementations.

2 These are deprecated features, where deprecated is defined as: Normative for the current edition of the Standard, but not guaranteed to be part of the Standard in future revisions.

D.1 Increment operator with bool operand

1 The use of an operand of type bool with the ++ operator is deprecated (see 5.3.2 and 5.2.6).

D.2 static keyword

1 The use of the static keyword is deprecated when declaring objects in namespace scope (see 3.3.5).

D.3 Access declarations

1 Access declarations are deprecated (see 11.3).

D.4 Implicit conversion from const strings

1 The implicit conversion from const to non-const qualification for string literals (4.2) is deprecated.

D.5 Standard C library headers

1 For compatibility with the Standard C library, the C++ Standard library provides the 18 C headers, as shown in Table 101.

| <assert.h> | <iso646.h> | <setjmp.h> | <stdio.h> | <wchar.h> |
| <ctype.h> | <limits.h> | <signal.h> | <stdlib.h> | <wctype.h> |
| <errno.h> | <locale.h> | <stdarg.h> | <string.h> |
| <float.h> | <math.h> | <stddef.h> | <time.h> |

2 Every C header, each of which has a name of the form name.h, behaves as if each name placed in the Standard library namespace by the corresponding cname header is also placed within the namespace scope of the namespace std and is followed by an explicit using-declaration (7.3.3).
D.6 Old iostreams members

[Example: The header <cstdlib> provides its declarations and definitions within the namespace std. The header <stdlib.h> makes these available also in the global namespace, much as in the C Standard. — end example]

D.6 Old iostreams members

The following member names are in addition to names specified in clause 27:

```cpp
namespace std {
    class ios_base {
        public:
            typedef T1 io_state;
            typedef T2 open_mode;
            typedef T3 seek_dir;
            typedef OFF_T streamoff;
            typedef POS_T streampos;
            // remainder unchanged
    };
}
```

1 The type `io_state` is a synonym for an integer type (indicated here as `T1`) that permits certain member functions to overload others on parameters of type `iostate` and provide the same behavior.

2 The type `open_mode` is a synonym for an integer type (indicated here as `T2`) that permits certain member functions to overload others on parameters of type `openmode` and provide the same behavior.

3 The type `seek_dir` is a synonym for an integer type (indicated here as `T3`) that permits certain member functions to overload others on parameters of type `seekdir` and provide the same behavior.

4 The type `streamoff` is an implementation-defined type that satisfies the requirements of type `OFF_T (27.4.1)`.

5 The type `streampos` is an implementation-defined type that satisfies the requirements of type `POS_T (27.2)`.

6 An implementation may provide the following additional member function, which has the effect of calling `sbumpc()` (27.5.2.2.3):

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT> >
    class basic_streambuf {
        public:
            void stossc();
            // remainder unchanged
    };
}
```

7 An implementation may provide the following member functions that overload signatures specified in clause 27:

```cpp
namespace std {
    template<class charT, class Traits> class basic_ios {
        public:
            void clear(io_state state);
            void setstate(io_state state);
            void exceptions(io_state);
    };
}
```
The effects of these functions is to call the corresponding member function specified in clause 27.

D.7 char* streams

The header `<strstream>` defines three types that associate stream buffers with character array objects and assist reading and writing such objects.

D.7.1 Class strstreambuf
namespace std {
    class strstreambuf : public basic_streambuf<char> {
        public:
            explicit strstreambuf(streamsize alsize_arg = 0);
            strstreambuf(void* (*palloc_arg)(size_t), void (*pfree_arg)(void*));
            strstreambuf(char* gnext_arg, streamsize n, char* pbeg_arg = 0);
            strstreambuf(const char* gnext_arg, streamsize n);
            strstreambuf(const signed char* gnext_arg, streamsize n);
            strstreambuf(signed char* gnext_arg, streamsize n, signed char* pbeg_arg = 0);
            strstreambuf(const signed char* gnext_arg, streamsize n);
            strstreambuf(const unsigned char* gnext_arg, streamsize n);
            strstreambuf(unsigned char* gnext_arg, streamsize n, unsigned char* pbeg_arg = 0);
            strstreambuf(const unsigned char* gnext_arg, streamsize n);
            virtual ~strstreambuf();
            void freeze(bool freezefl = true);
            char* str();
            int pcount();
        protected:
            virtual int_type overflow(int_type c = EOF);
            virtual int_type pbackfail(int_type c = EOF);
            virtual int_type underflow();
            virtual pos_type seekoff(off_type off, ios_base::seekdir way,
                                       ios_base::openmode which = ios_base::in | ios_base::out);
            virtual pos_type seekpos(pos_type sp, ios_base::openmode which = ios_base::in | ios_base::out);
            virtual streambuf* setbuf(char* s, streamsize n);
        private:
            // typedef T1 strstate;          
            // static const strstate allocated; 
            // static const strstate constant; 
            // static const strstate dynamic; 
            // static const strstate frozen; 
            // strstate strmode; 
            // streamsize alsize; 
            // void* (*palloc)(size_t); 
            // void (*pfree)(void*); 
    };
}

The class strstreambuf associates the input sequence, and possibly the output sequence, with an object of some character array type, whose elements store arbitrary values. The array object has several attributes.

[Note: For the sake of exposition, these are represented as elements of a bitmask type (indicated here as T1) called strstate. The elements are:
813 Compatibility features

D.7 char* streams

--- allocated, set when a dynamic array object has been allocated, and hence should be freed by the destructor for the strstreambuf object;
--- constant, set when the array object has const elements, so the output sequence cannot be written;
--- dynamic, set when the array object is allocated (or reallocated) as necessary to hold a character sequence that can change in length;
--- frozen, set when the program has requested that the array object not be altered, reallocated, or freed.
--- end note ]

[ Note: For the sake of exposition, the maintained data is presented here as:
--- strstate strmode, the attributes of the array object associated with the strstreambuf object;
--- int alsize, the suggested minimum size for a dynamic array object;
--- void* palloc(size_t), points to the function to call to allocate a dynamic array object;
--- void(* pfree)(void*), points to the function to call to free a dynamic array object.
--- end note ]

Each object of class strstreambuf has a seekable area, delimited by the pointers seeklow and seekhigh. If gnext is a null pointer, the seekable area is undefined. Otherwise, seeklow equals gbeg and seekhigh is either pend, if pend is not a null pointer, or gend.

D.7.1.1 strstreambuf constructors

[depr.strstreambuf.cons]

explicit strstreambuf(streamsize alsize_arg = 0);

Effects: Constructs an object of class strstreambuf, initializing the base class with streambuf(). The postconditions of this function are indicated in Table 102.

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>strmode</td>
<td>dynamic</td>
</tr>
<tr>
<td>alsize</td>
<td>alsize_arg</td>

<td>a null pointer</td>
</tr>
<tr>
<td>pfree</td>
<td>a null pointer</td>
</tr>
</tbody>
</table>

strstreambuf(void* (*palloc_arg)(size_t), void (*pfree_arg)(void*));

Effects: Constructs an object of class strstreambuf, initializing the base class with streambuf(). The postconditions of this function are indicated in Table 103.

strstreambuf(char* gnext_arg, streamsize n, char *pbeg_arg = 0);
strstreambuf(signed char* gnext_arg, streamsize n,
            signed char *pbeg_arg = 0);
strstreambuf(unsigned char* gnext_arg, streamsize n,
            unsigned char *pbeg_arg = 0);

Draft
Table 103: `strstreambuf(void (*)(size_t), void (*)(void*))` effects

<td>a null pointer</td>
</tr>
</tbody>
</table>

`gnext_arg` shall point to the first element of an array object whose number of elements `N` is determined as follows:

- If `n > 0`, `N` is `n`.
- If `n == 0`, `N` is `std::strlen(gnext_arg)`.
- If `n < 0`, `N` is `INT_MAX`.\(^{324}\)

If `pbeg_arg` is a null pointer, the function executes:

```
setg(gnext_arg, gnext_arg, gnext_arg + N);
```

Otherwise, the function executes:

```
setg(gnext_arg, gnext_arg, pbeg_arg);
setp(pbeg_arg, pbeg_arg + N);
strstreambuf(const char* gnext_arg, streamsize n);
strstreambuf(const signed char* gnext_arg, streamsize n);
strstreambuf(const unsigned char* gnext_arg, streamsize n);
```

**Effects:** Behaves the same as `strstreambuf((char*)gnext_arg, n)`, except that the constructor also sets `constant` in `strmode`.

`virtual ~strstreambuf();`

\(^{324}\) The function signature `strlen(const char*)` is declared in `<cstring>` (21.4). The macro `INT_MAX` is defined in `<climits>` (18.2).
Effects: Destroys an object of class `strstreambuf`. The function frees the dynamically allocated array object only if `strmode & allocated` != 0 and `strmode & frozen` == 0. (D.7.1.3 describes how a dynamically allocated array object is freed.)

D.7.1.2 Member functions

```cpp
void freeze(bool freezefl = true);
```

Effects: If `strmode & dynamic` is non-zero, alters the freeze status of the dynamic array object as follows:

- If `freezefl` is true, the function sets `frozen` in `strmode`.
- Otherwise, it clears `frozen` in `strmode`.

```cpp
char* str();
```

Effects: Calls `freeze()`, then returns the beginning pointer for the input sequence, `gbeg`.

Remarks: The return value can be a null pointer.

```cpp
int pcount() const;
```

Effects: If the next pointer for the output sequence, `pnext`, is a null pointer, returns zero. Otherwise, returns the current effective length of the array object as the next pointer minus the beginning pointer for the output sequence, `pnext - pbeg`.

D.7.1.3 `strstreambuf` overridden virtual functions

```cpp
int_type overflow(int_type c = EOF);
```

Effects: Appends the character designated by `c` to the output sequence, if possible, in one of two ways:

- If `c` != `EOF` and if either the output sequence has a write position available or the function makes a write position available (as described below), assigns `c` to `*pnext++`.
  
  Returns `(unsigned char)c`.

- If `c` == `EOF`, there is no character to append.

  Returns a value other than `EOF`.

Returns `EOF` to indicate failure.

Remarks: The function can alter the number of write positions available as a result of any call.

To make a write position available, the function reallocates (or initially allocates) an array object with a sufficient number of elements `n` to hold the current array object (if any), plus at least one additional write position. How many additional write positions are made available is otherwise unspecified.\(^{325}\) If `palloc` is not a null pointer, the function calls `(*palloc)(n)` to allocate the new dynamic array object. Otherwise, it evaluates the expression `new charT[n]`. In either case, if the allocation fails, the function returns `EOF`. Otherwise, it sets `allocated` in `strmode`.

\(^{325}\) An implementation should consider `alsize` in making this decision.
To free a previously existing dynamic array object whose first element address is \( p \): If \( p \) is not a null pointer, the function calls \((*pfree)(p)\). Otherwise, it evaluates the expression \( \text{delete[]}\ p \).

If \( \text{strmode} \& \text{dynamic} == 0 \), or if \( \text{strmode} \& \text{frozen} != 0 \), the function cannot extend the array (reallocate it with greater length) to make a write position available.

```c
int_type pbackfail(int_type c = EOF);
```

Puts back the character designated by \( c \) to the input sequence, if possible, in one of three ways:

- If \( c \neq \text{EOF} \), if the input sequence has a putback position available, and if \( \langle \text{char}\rangle c == \text{gnext}[-1] \), assigns \( \text{gnext} - 1 \) to \( \text{gnext} \).
  
  Returns \( c \).

- If \( c \neq \text{EOF} \), if the input sequence has a putback position available, and if \( \text{strmode} \& \text{constant} \) is zero, assigns \( c \) to \( *-\text{gnext} \).
  
  Returns \( c \).

- If \( c == \text{EOF} \) and if the input sequence has a putback position available, assigns \( \text{gnext} - 1 \) to \( \text{gnext} \).
  
  Returns a value other than \( \text{EOF} \).

Returns \( \text{EOF} \) to indicate failure.

Remarks: If the function can succeed in more than one of these ways, it is unspecified which way is chosen. The function can alter the number of putback positions available as a result of any call.

```c
int_type underflow();
```

Effects: Reads a character from the input sequence, if possible, without moving the stream position past it, as follows:

- If the input sequence has a read position available, the function signals success by returning \((\text{unsigned char}*)\text{gnext} \).

- Otherwise, if the current write next pointer \( \text{pnext} \) is not a null pointer and is greater than the current read end pointer \( \text{gend} \), makes a read position available by assigning to \( \text{gend} \) a value greater than \( \text{gnext} \) and no greater than \( \text{pnext} \).

Returns \((\text{unsigned char}*)\text{gnext} \).

Returns \( \text{EOF} \) to indicate failure.

Remarks: The function can alter the number of read positions available as a result of any call.

```c
pos_type seekoff(off_type off, seekdir way, openmode which = in | out);
```

Effects: Alters the stream position within one of the controlled sequences, if possible, as indicated in Table 105.

For a sequence to be positioned, if its next pointer is a null pointer, the positioning operation fails. Otherwise, the function determines \( \text{newoff} \) as indicated in Table 106.

Otherwise, the function assigns \( \text{xbeg} + \text{newoff} + \text{off} \) to the next pointer \( \text{xnext} \).
Table 105: seekoff positioning

<table>
<thead>
<tr>
<th>Conditions</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>(which &amp; ios::in) != 0</td>
<td>positions the input sequence</td>
</tr>
<tr>
<td>(which &amp; ios::out) != 0</td>
<td>positions the output sequence</td>
</tr>
<tr>
<td>(which &amp; (ios::in</td>
<td>ios::out)) == (ios::in</td>
</tr>
<tr>
<td>Otherwise</td>
<td>the positioning operation fails.</td>
</tr>
</tbody>
</table>

Table 106: newoff values

<table>
<thead>
<tr>
<th>Condition</th>
<th>newoff Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>way == ios::beg</td>
<td>0</td>
</tr>
<tr>
<td>way == ios::cur</td>
<td>the next pointer minus the beginning pointer (xnext - xbeg).</td>
</tr>
<tr>
<td>way == ios::end</td>
<td>seekhigh minus the beginning pointer (seekhigh - xbeg).</td>
</tr>
<tr>
<td>If (newoff + off) &lt; (seeklow - xbeg), or (seekhigh - xbeg) &lt; (newoff + off)</td>
<td>the positioning operation fails</td>
</tr>
</tbody>
</table>
Returns: \texttt{pos\_type(newoff)}, constructed from the resultant offset \texttt{newoff} (of type \texttt{off\_type}), that stores the resultant stream position, if possible. If the positioning operation fails, or if the constructed object cannot represent the resultant stream position, the return value is \texttt{pos\_type(off\_type(-1))}.

\begin{verbatim}
pos_type seekpos(pos_type sp, ios_base::openmode which = ios_base::in | ios_base::out);
\end{verbatim}

Effects: Alters the stream position within one of the controlled sequences, if possible, to correspond to the stream position stored in \texttt{sp} (as described below).

\begin{itemize}
    \item If \texttt{(which \& ios::in) != 0}, positions the input sequence.
    \item If \texttt{(which \& ios::out) != 0}, positions the output sequence.
    \item If the function positions neither sequence, the positioning operation fails.
\end{itemize}

For a sequence to be positioned, if its next pointer is a null pointer, the positioning operation fails. Otherwise, the function determines \texttt{newoff} from \texttt{sp.offset()}: 

\begin{itemize}
    \item If \texttt{newoff} is an invalid stream position, has a negative value, or has a value greater than \texttt{(seekhigh - seeklow)}, the positioning operation fails
    \item Otherwise, the function adds \texttt{newoff} to the beginning pointer \texttt{xbeg} and stores the result in the next pointer \texttt{xnext}.
\end{itemize}

Returns: \texttt{pos\_type(newoff)}, constructed from the resultant offset \texttt{newoff} (of type \texttt{off\_type}), that stores the resultant stream position, if possible. If the positioning operation fails, or if the constructed object cannot represent the resultant stream position, the return value is \texttt{pos\_type(off\_type(-1))}.

\begin{verbatim}
streambuf<char>* setbuf(char* s, streamsize n);
\end{verbatim}

Effects: Implementation defined, except that \texttt{setbuf(0, 0)} has no effect.

### D.7.2 Class istrstream

[depr.istrstream]

\begin{verbatim}
namespace std {
    class istrstream : public basic_istream<char> {
        public:
            explicit istrstream(const char* s);
            explicit istrstream(char* s);
            istrstream(const char* s, streamsize n);
            istrstream(char* s, streamsize n);
            virtual ~istrstream();
            
            strstreambuf* rdbuf() const;
            char *str();
        
        private:
            // strstreambuf sb; \textit{exposition only}
    }
}
\end{verbatim}
The class `istrstream` supports the reading of objects of class `strstreambuf`. It supplies a `strstreambuf` object to control the associated array object. For the sake of exposition, the maintained data is presented here as:

— `sb`, the `strstreambuf` object.

### D.7.2.1 istrstream constructors

**explicit istrstream(const char* s);**

**explicit istrstream(char* s);**

1  
**Effects:** Constructs an object of class `istrstream`, initializing the base class with `istream(&sb)` and initializing `sb` with `strstreambuf(s,0)`. `s` shall designate the first element of an NTBS.

**istrstream(const char* s, streamsize n);**

2  
**Effects:** Constructs an object of class `istrstream`, initializing the base class with `istream(&sb)` and initializing `sb` with `strstreambuf(s,n)`.

### D.7.2.2 Member functions

**strstreambuf* rdbuf() const;**

1  
**Returns:** `const_cast<strstreambuf*>(&sb)`.

**char* str();**

2  
**Returns:** `rdbuf()->str()`.

### D.7.3 Class ostrstream

```cpp
namespace std {
    class ostrstream : public basic_ostream<char> {
        public:
            ostrstream();
            ostrstream(char* s, int n, ios_base::openmode mode = ios_base::out);
            virtual ~ostrstream();

            strstreambuf* rdbuf() const;
            void freeze(bool freezefl = true);
            char* str();
            int pcount() const;
        private:
            // strstreambuf sb;
            exposition only
        };
    };
}
```

The class `ostrstream` supports the writing of objects of class `strstreambuf`. It supplies a `strstreambuf` object to control the associated array object. For the sake of exposition, the maintained data is presented here as:
D.7 char* streams

— sb, the strstreambuf object.

D.7.3.1 ostrstream constructors [depr.ostrstream.cons]

ostrstream();

Effects: Constructs an object of class ostrstream, initializing the base class with ostream(&sb) and initializing sb with strstreambuf().

ostrstream(char* s, int n, ios_base::openmode mode = ios_base::out);

Effects: Constructs an object of class ostrstream, initializing the base class with ostream(&sb), and initializing sb with one of two constructors:

— If (mode & app) == 0, then s shall designate the first element of an array of n elements. The constructor is strstreambuf(s, n, s).

— If (mode & app) != 0, then s shall designate the first element of an array of n elements that contains an NTBS whose first element is designated by s. The constructor is strstreambuf(s, n, s + std::strlen(s)).

D.7.3.2 Member functions [depr.ostrstream.members]

strstreambuf* rdbuf() const;

Returns: (strstreambuf*)&sb.

void freeze(bool freezefl = true);

Effects: Calls rdbuf()->freeze(freezefl).

char* str();

Returns: rdbuf()->str().

int pcount() const;

Returns: rdbuf()->pcount().

D.7.4 Class strstream [depr.strstream]

namespace std {
class strstream
: public basic_iostream<char> {
public:
// Types
typedef char char_type;
typedef typename char_traits<char>::int_type int_type;

326 The function signature strlen(const char*) is declared in <cstring> (21.4).
The class `strstream` supports reading and writing from objects of class `strstreambuf`. It supplies a `strstreambuf` object to control the associated array object. For the sake of exposition, the maintained data is presented here as

— `sb`, the `strstreambuf` object.

### D.7.4.1 `strstream` constructors

**`strstream()`**

1. **Effects:** Constructs an object of class `strstream`, initializing the base class with `iostream(&sb)`.

**`strstream(char* s, int n,`**

1. **Effects:** Constructs an object of class `strstream`, initializing the base class with `iostream(&sb)` and initializing `sb` with one of the two constructors:

   — If `(mode & app) == 0`, then `s` shall designate the first element of an array of `n` elements. The constructor is `strstreambuf(s,n,s)`.

   — If `(mode & app) != 0`, then `s` shall designate the first element of an array of `n` elements that contains an NTBS whose first element is designated by `s`. The constructor is `strstreambuf(s,n,s + std::strlen(s))`.

### D.7.4.2 `strstream` destructor

**virtual `~strstream()`**

1. **Effects:** Destroys an object of class `strstream`. 
D.7 char* streams Compatibility features 822

D.7.4.3 strstream operations [depr.strstream.oper]

void freeze(bool freezefl = true);
Effects: Calls rdbuf()->freeze(freezefl).

char* str();
Returns: rdbuf()->str().

int pcount() const;
Returns: rdbuf()->pcount().

strstreambuf* rdbuf() const;
Returns: &sb.
Appendix E
(normative)
Universal-character-names

1. This clause lists the complete set of hexadecimal code values that are valid in universal-character-names in C++ identifiers (2.10).

2. This table is reproduced unchanged from ISO/IEC PDTR 10176, produced by ISO/IEC JTC1/SC22/WG20, except that the ranges 0041–005a and 0061–007a designate the upper and lower case English alphabets, which are part of the basic source character set, and are not repeated in the table below.
