<sup>3</sup>University Medical Center, Göttingen, Germany

**ISO TC1/SC22/WG14**

document number: **N3005**

document date: 2022-6-15

**ISO TC1/SC22/WG21 SG22**

document number: **P2318R2**

document date: 2022-6-15

## Changes:

**2020-10-4:** WG14 N2577, original version

**2021-3-24:** WG14 N2676

- Change in terminology. Instead of using the confusing “indeterminate value”, change to “invalid value” for pointer values and to “indeterminate state” to describe certain object representations. Synchronized with WG14 N2668.

**2022-6-15:** WG14 N3005, this version

- Integrate changes of documents that are agreed by WG14 for the new revision of ISO/IEC 9899:2023.  
**N2861** Indeterminate Values and Trap Representations  
**N2888** Exact-width Integer Type Interfaces
- As agreed by WG14, integrate N2889, “Pointers and integer types”, and adapt the proposed text to refer to **uintptr\_t** for abstract addresses.
- Numerous editorial improvements.

## Foreword

ISO (the International Organization for Standardization) and IEC (the International Electrotechnical Commission) form the specialized system for worldwide standardization. National bodies that are member of ISO or IEC participate in the development of International Standards through technical committees established by the respective organization to deal with particular fields of technical activity. ISO and IEC technical committees collaborate in fields of mutual interest. Other international organizations, governmental and non-governmental, in liaison with ISO and IEC, also take part in the work. In the field of information technology, ISO and IEC have established a joint technical committee, ISO/IEC JTC 1.

The procedures used to develop this document and those intended for its further maintenance are described in the ISO/IEC Directives, Part 1. In particular, the different approval criteria needed for the different types of document should be noted. This document was drafted in accordance with the editorial rules of the ISO/IEC Directives, Part 2 (see [www.iso.org/directives](http://www.iso.org/directives)).

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO and IEC shall not be held responsible for identifying any or all such patent rights. Details of any patent rights identified during the development of the document will be in the Introduction and/or on the ISO list of patent declarations received (see [www.iso.org/patents](http://www.iso.org/patents)).

Any trade name used in this document is information given for the convenience of users and does not constitute an endorsement.

For an explanation of the voluntary nature of standards, the meaning of ISO specific terms and expressions related to conformity assessment, as well as information about ISO's adherence to the World Trade Organization (WTO) principles in the Technical Barriers to Trade (TBT), see the following URL: [www.iso.org/iso/foreword.html](http://www.iso.org/iso/foreword.html).

This document was prepared for presentation to the Technical Committee ISO/IEC JTC 1, *Information technology*, Subcommittee SC 22, *Programming languages, their environments and system software interfaces*.

## 1 Introduction

In a committee discussion from 2004 concerning **DR260**, WG14 confirmed the concept of provenance of pointers, introduced as means to track and distinguish pointer values that represent storage instances with same address but non-overlapping lifetimes. Implementations started to use that concept, in optimisations relying on provenance-based alias analysis, without it ever being clearly or formally defined, and without it being integrated consistently with the rest of the C standard.

This Technical Specification provides a solution for this: a provenance-aware memory object model for C to put C programmers and implementers on a solid footing in this regard. This draft Technical Specification is based on, and incorporates the content of, three earlier WG14 documents:

- N2362 *Moving to a provenance-aware memory model for C: proposal for C2x* by the memory object model study group. Jens Gustedt, Peter Sewell, Kayvan Memarian, Victor B. F. Gomes, Martin Uecker. This introduced the proposal and gives the proposed change to the standard text, presented as change-highlighted pages of the standard. Here, as appropriate for a Technical Specification, we instead present the proposed changes with respect to ISO/IEC 9899:2018.
- N2363 *C provenance semantics: examples*. Peter Sewell, Kayvan Memarian, Victor B. F. Gomes, Jens Gustedt, Martin Uecker. This explains the proposal and its design choices with discussion of a series of examples.
- N2364 *C provenance semantics: detailed semantics*. Peter Sewell, Kayvan Memarian, Victor B. F. Gomes. This gives a detailed mathematical semantics for the proposal

In the first draft of this Technical Specification, the latter two parts have identical text to those earlier N-papers. Later, we integrated the following papers into the specification of this TS:

- N2861 *Indeterminate Values and Trap Representations*. Martin Uecker, Jens Gustedt. This paper has already been accepted by WG14 for ISO/IEC 9899:2023. It clarifies the previous contradictory terminology for what was then called “indeterminate values”, but that described a property of an object *representation*.
- N2888 *Exact-width Integer Type Interfaces*. Jens Gustedt. This paper has also been accepted by WG14 for ISO/IEC 9899:2023. It clarifies some issues about integer types and is the basis for the integration of the following paper.
- N2889 *Pointers and integer types*. Jens Gustedt. Although this paper has not been accepted for ISO/IEC 9899:2023, WG14 voted in favor to integrate it in this TS. It makes the type `uintptr_t` mandatory and thereby eases the specifications that are proposed here.

In addition:

- At <http://cerberus.cl.cam.ac.uk/cerberus> we provide an executable version of the semantics, with a web interface that allows one to explore and visualise the behaviour of small test programs. Following N2363, we include the results of this for the example programs and for some major compilers.

The proposal has been developed in discussion among the C memory object model study group, including the authors listed above, Hubert Tong, Martin Sebor, and Hal Finkel. It has been discussed with WG14 (in multiple meetings) and at the March 2019 Cologne meeting of WG21, in SG12 *UB & Vulnerabilities*. Both of these have approved the overall direction, subject to implementation experience. It has also been discussed with the Clang/LLVM and GCC communities, with presentations and informal conversations at EuroLLVM and the GNU Tools Cauldron in 2018.

To the best of our knowledge and ability, the proposal reconciles the various demands of existing implementations and the corpus of existing C code.

This Technical Specification does not address subobject provenance.

### 1.1 Previous related papers

The proposal is based on discussion in the following WG14 notes and several plenary meetings. With respect to these, the main changes are

1. a clear preference among the study group and the compiler communities we have spoken with for a model that does not track provenance via integers (coined PNVI (provenance not via integers) models rather than PVI (provenance via integers));

2. the enhancement to the specific address-exposed variants (PNVI-ae-\*), which introduce the concepts of *exposed storage instances* and *synthesized pointer values* and which for many seems to be more intuitive than PNVI-plain (though it is also more complex); and
3. the refinement to the PNVI-ae-udi (user disambiguation) variant that leaves the responsibility for disambiguation of the provenance of synthesized pointer values of certain corner cases to the user code. This allows pointer-integer-pointer roundtrip casts for one-past pointers.

The papers that supported these discussions are:

- N2012 Clarifying the C memory object model
- N2013 C Memory Object and Value Semantics: The Space of de facto and ISO Standards
- N2014 What is C in Practice? (Cerberus Survey v2): Analysis of Response
- N2015 What is C in practice? (Cerberus survey v2): Analysis of Responses - with Comments
- N2090: Clarifying Pointer Provenance (Draft Defect Report or Proposal for C2x)
- N2219: Clarifying Pointer Provenance (Q1-Q20) v3
- N2263: Clarifying Pointer Provenance v4
- N2294: C Memory Object Model Study Group: Progress Report
- N2311: Exploring C Semantics and Pointer Provenance<sup>1</sup>
- N2388: Introduce the term storage instance

## 1.2 The basic idea

This section follows the start of Section 2 of N2363.

C pointer values are typically represented at runtime as simple concrete numeric values, but mainstream compilers routinely exploit information about the *provenance* of pointers to reason that they cannot alias, and hence to justify optimisations. In this section we develop a provenance semantics for simple cases of the construction and use of pointers,

For example, consider the classic test [Fea04, KW12, Kre15, CMM<sup>+</sup>16, MML<sup>+</sup>16] below. Note that this and many of the examples below are edge-cases, exploring the boundaries of what different semantic choices allow, and sometimes what behaviour existing compilers exhibit; they are not all intended as desirable code idioms.

```

1 #include <stdio.h>
2 #include <string.h>
3 int y=2, x=1;
4 int main() {
5     int *p = &x + 1;
6     int *q = &y;
7     printf("Addresses: p=%p q=%p\n", (void*)p, (void*)q);
8     if (memcmp(&p, &q, sizeof(p)) == 0) {
9         *p = 11; // does this have undefined behaviour?
10        printf("x=%d y=%d *p=%d *q=%d\n", x, y, *p, *q);
11    }
12 }
```

Depending on the implementation, `x` and `y` might in some executions happen to be allocated in adjacent memory, in which case `&x+1` and `&y` will have bitwise-identical representation values, the `memcmp` will succeed, and `p` (derived from a pointer to `x`) will have the same representation value as a pointer to a different object, `y`, at the point of the update `*p=11`. This can occur in practice, e.g. with GCC 8.1 -O2 on some platforms. Its output of

```
x=1 y=2 *p=11 *q=2
```

suggests that the compiler is reasoning that `*p` does not alias with `y` or `*q`, and hence that the initial value of `y=2` can be propagated to the final `printf`. ICC, e.g. ICC 19 -O2, also optimises here (for a variant with `x` and `y` swapped), producing

```
x=1 y=2 *p=11 *q=11.
```

In contrast, Clang 6.0 -O2 just outputs the

<sup>1</sup>Identical text to the POPL 2019 paper of the same title.

```
x=1 y=11 *p=11 *q=11
```

that one might expect from a concrete semantics. Note that this example does not involve type-based alias analysis, and the outcome is not affected by GCC or ICC's `-fno-strict-aliasing` flag. Note also that the mere formation of the `&x+1` one-past pointer is explicitly permitted by the ISO standard, and, because the `*p=11` access is guarded by the `memcmp` conditional check on the representation bytes of the pointer, it will not be attempted (and hence flag UB) in executions in which the two storage instances are not adjacent.

These GCC and ICC outcomes would not be correct with respect to a concrete semantics, and so to make the existing compiler behaviour sound it is necessary for this program to be deemed to have undefined behaviour.

The current ISO standard text does not explicitly speak to this, but the 2004 ISO WG14 C standards committee response to Defect Report 260 (DR260 CR) [Fea04] hints at a notion of provenance associated to values that keeps track of their "origins":

*"Implementations are permitted to track the origins of a bit-pattern and [...]. They may also treat pointers based on different origins as distinct even though they are bitwise identical."*

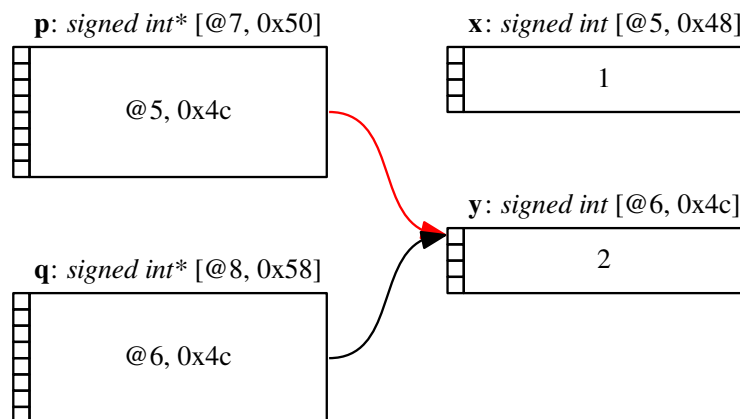

However, DR260 CR has never been incorporated in the standard text, and it gives no more detail. This leaves many specific questions unclear: it is ambiguous whether some programming idioms are allowed or not, and exactly what compiler alias analysis and optimisation are allowed to do.

**Basic provenance semantics for pointer values** For simple cases of the construction and use of pointers, capturing the basic intuition suggested by DR260 CR in a precise semantics is straightforward: we associate a *provenance* with every pointer value, identifying the original storage instance that the pointer is derived from. In more detail:

- We take abstract-machine pointer values to be pairs  $(\pi, a)$ , adding a *provenance*  $\pi$ , either  $@i$  where  $i$  is a storage instance ID, or the *empty* provenance  $@empty$ , to their concrete address  $a$ .
- On every creation of a storage instance (of objects with static, thread, automatic, and allocated storage duration), the abstract machine nondeterministically chooses a fresh storage instance ID  $i$  (unique across the entire execution), and the resulting pointer value carries that single storage instance ID as its provenance  $@i$ .
- Provenance is preserved by pointer arithmetic that adds or subtracts an integer to a pointer.
- At any access via a pointer value, its numeric address must be consistent with its provenance, with undefined behaviour otherwise. In particular:
  - access via a pointer value which has provenance a single storage instance ID  $@i$  must be within the memory footprint of the corresponding original storage instance, which must still be live.
  - all other accesses, including those via a pointer value with empty provenance, are undefined behaviour.

This undefined behaviour is what justifies optimisation based on provenance alias analysis.

Below is a provenance-semantics memory-state snapshot (from the Cerberus GUI) for `provenance_basic_global_yx.c`, just before the invalid access via `p`, showing how the provenance mismatch makes it UB: at the attempted access via `p`, its pointer-value address `0x4c` is not within the storage instance with the ID `@5` of the provenance of `p`.

All this is for the *C abstract machine* as defined in the standard: compilers might rely on provenance in their alias analysis and optimisation, but one would not expect normal implementations to record or manipulate provenance at runtime (though dynamic or static analysis tools might), as might non-standard or bug-finding-tool implementations. Provenances therefore do not have program-accessible runtime representations in the abstract machine.

Then there are many other ways to construct and manipulate pointer values: casts to and from integers, copying with `memcpy`, manipulation of their representation bytes, type punning, I/O, copying with `realloc`, and constructing pointer values that embody knowledge established from linking. N2363 discusses all these.

This technical specification follows the

**provenance not via integers  
exposed-address  
user-disambiguation**

model, abbreviated as **PNVI-ae-udi**. Here:

- **PNVI-plain** is a semantics that tracks provenance via pointer values but not via integers. Then, at integer-to-pointer cast points, it checks whether the given address points within a live storage instance and, if so, recreates the corresponding provenance.
- **PNVI-ae (PNVI exposed-address)** is a variant of PNVI that allows integer-to-pointer casts to recreate provenance only for storage instances that have previously been *exposed*. A storage instance is deemed *exposed* by a conversion of a pointer to it to an integer type, by a read (at non-pointer type) of the representation of the pointer, or by an output of the pointer using `"%p"`.
- **PNVI-ae-udi (PNVI exposed-address user-disambiguation)** is a further refinement of PNVI-ae that supports roundtrip casts, from pointer to integer and back, of pointers that are one-past a storage instance. This was the preferred option from WG14 and WG21 discussions and voted by WG14 to be used in this technical specification.

## 1.3 Newly introduced terms

### 1.3.1 Storage instance

An addressable *storage instance*<sup>2</sup> is the byte array that is created when either an object starts its lifetime (for static, automatic and thread storage duration) or an allocation function is called (`malloc`, `calloc` etc). Addressable storage instances are more than just an address, they have a unique ID throughout the whole execution. Once their lifetime ends, another storage instance may receive the same address, but never the same ID.

### 1.3.2 Provenance

The *provenance* of a valid pointer is the ID of the specific storage instance to which the pointer refers (or one-past). This ID is a genuine component of the pointer value in C's abstract machine, but does not necessarily take part in the object representation of the pointer; in general the provenance of a pointer is not observable.

Valid pointers keep provenance to the encapsulating storage instance of the referred object. When the storage instance dies (falls out of scope, the thread ends, `free` is called) the pointer value becomes invalid, and any stored representations of the pointer value becomes indeterminate.

### 1.3.3 Abstract address

The concept of *abstract address* lifts the implementation defined mapping required for pointer-to-integer conversions, up the level of the memory model.

- Each byte of a storage instance has an abstract address, which is a positive integer of type `uintptr_t` that is constant during the whole lifetime of the storage instance.
- Abstract addresses are increasing within a storage instance.
- Storage instances are strictly ordered by the induced order of their abstract addresses.
- Storage instances don't overlap.
- The set of all abstract addresses forms the *address space* of the execution.

<sup>2</sup>There are also storage instances that are not addressable, namely for `register` variables. But since provenance needs pointers, these play no role in the following and we don't discuss them, here.

- There are no other ordering constraints between any pair of storage instances. In particular, no syntactic features (declaration order) or runtime features (order of allocation) can give any hint about the relative position.

This concept is completely decorrelated from the object representation of pointers: it is up to any implementation to define the relation between the two in any way that suits best. In particular, the address offset between consecutive bytes does not need to be 1 (or any other constant). There can be bumps (corresponding to segments, for example) and strides, and address sharing on the boundary between the one-past pointer of one storage instance and the start address of the next.

Compared to C17, the type `uintptr_t` is made mandatory, here. On “usual” architectures where `uintptr_t` exists already, the abstract address of a pointer value `p` is just `(uintptr_t)p`. Architectures that do not yet have `uintptr_t` should be able to define an abstract address that is consistent with the other operations that they allow on pointers; the suggested changes now allow this type to be wider than `uintmax_t`.

### 1.3.4 Pointer exposure and synthesis

Tracking provenance for the sake of aliasing analysis will fail if pointers can acquire an abstract address with an arbitrary provenance of which the compiler could not be aware. With the above rules for abstract addresses this is only possible with a leak of information about a storage instance `A`:

- the abstract address of `A` has been made known,
- the object representation of a pointer to `A` is inspected.

In such a case we say that `A` has been *exposed*.

There are only very restricted contexts where a pointer value `p` can be constructed from scratch. In such a case we say that `p` has been *synthesized*. We require that a storage instance of such a synthesized pointer must have been exposed previously. By that we ensure that all storage instances that have *not* been exposed can be subject to a rigorous aliasing analysis, whereas pointers to potentially exposed storage instance acquire a clear “warning label” that tell the compiler to be cautious about them.

For the sake of sequencing and synchronization, exposure constitutes a side effect, even though it might not be directly observable.

## 1.4 Operations

### 1.4.1 Exposing and non-exposing operations

A storage instance is exposed once information from any valid pointer with this provenance has leaked into other parts of the program state. In C17 there are four different operations that can provide information about the address of a storage instance `A`.

- A pointer to `A` is converted to integer.
- `printf` (or similar) with `“%p”` is used to print the pointer value.
- A byte of the pointer representation is accessed directly.
- A byte of the pointer representation is written with `fwrite`.

All other C library functions (with the exception of `tss_set`) are guaranteed not to expose address information, unless they use a callback that does so (e.g `qsort` or `exit`). This guarantee has two different aspects:

- C library functions that receive pointers are not allowed to leak information about these pointers into global state.
- C library functions (such as `memcpy`, `realloc` or `atomic_compare_exchange_weak`) that copy bytes are supposed to know what they are doing. That is, if they copy the object representation of a pointer, they are supposed to transfer provenance information consistently.

### 1.4.2 Reconstructing operations

**Lvalue conversion** Lvalue conversion for a pointer object that has somehow been synthesized in memory, reads bytes of the object representation of the pointer and reinterprets them as a valid address with provenance. To be sure that we do not synthesize a pointer value for which the compiler has assumptions about non-aliasing, we must be sure that the provenance of that newly synthesized pointer value had been exposed before.

**Integer-to-pointer conversion** An integer-to-pointer conversion (cast) or IO (`scanf` with `"%p"`) is only defined if the corresponding storage instance had been exposed, and if the result is a pointer to a byte (or one-past) of the storage instance.

**Copies** Pointer values can be copied by the usual means that is: assignment, `memcpy`, `memmove` and byte-wise copy. The first three copy over provenance in addition to the representation and the effective type.

Byte-wise copy is special, here, because up to now there is no tool to hint a transfer of a pointer value including provenance to the compiler. Therefore this works only through exposure, that is a pointer value that is copied byte-wise is first exposed (because bytes are accessed) and then synthesized as before by lvalue conversion.

### 1.4.3 Pointer inquiry

**Pointer equality** With the tool of abstract addresses, the description of pointer equality becomes quite simple: pointers are equal if their abstract addresses are the same.

**Ordered comparison** Ordered comparisons (`<`, `>`, `>=`, `<=`) between pointers are only defined when the two pointers have the same provenance. They then can be defined by the relative position of the abstract addresses.

*A possible extension here would be to remove the constraint that the two pointers have to have the same provenance.*

### 1.4.4 Pointer arithmetic

**Pointer addition and subtraction** Pointer arithmetic (addition or subtraction of integers) preserves provenance. The resulting pointer value is invalid if the result not within (or one-past) the storage instance.

**Pointer difference** Pointer difference is only defined for pointers with the same provenance and within the same array. The latter is still necessary because pointer difference is not in byte but in number of elements of an array. The former is necessary because the one-past element of an array could be the first element of another storage instance that just happens to follow in the address space.

## 1.5 Ambiguous Provenance

With the above, there is one special case where a back-converted pointer (let's just assume integer-to-pointer) could have two different provenances. This can happen when:

- `p` is the end address (one past) pointer of a storage instance `A` and the start address of another storage instance `B`, and
- both storage instances `A` and `B` are exposed, that is at some point we did a pointer-to-integer conversion with two pointers `a == b`, `a` having provenance `A`, and `b` having provenance `B`.

In such a situation, both `A` and `B` could be valid choices for the provenance. Our solution in 6.2.5 p20 is to leave which of `A` or `B` is chosen to the programmer, allowing one or the other (but not both) to be used, so long as that is done consistently.

## **2 Scope**

This document specifies the form and establishes the interpretation of programs written in the C programming language. It is not a complete specification of that language but amends ISO/IEC 9899:2018 by providing a Technical Specification that constrains and clarifies the Memory Object Model implicit there.

### 3 Normative references

The following documents are referred to in the text in such a way that some or all of their content constitutes requirements of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

ISO/IEC 2382:2015, *Information technology – Vocabulary*. Available from the ISO online browsing platform at <http://www.iso.org/obp>.

ISO/IEC 9899:2018, *Programming languages – C*

ISO 80000–2, *Quantities and units — Part 2: Mathematical signs and symbols to be used in the natural sciences and technology*.

## 4 Terms and definitions

For the purposes of this document, the terms and definitions given in ISO/IEC 2382, ISO 80000-2, and the following apply.

ISO and IEC maintain terminological databases for use in standardization at the following addresses:

- ISO Online browsing platform: available at <https://www.iso.org/obp>
- IEC Electropedia: available at <http://www.electropedia.org/>

The following terms are explicitly defined in this document and are not to be presumed to refer implicitly to similar terms defined elsewhere. The clauses in the modified version of ISO/IEC 9899:2018 are 3.17 and 3.20, respectively.

### 4.1 pointer provenance

#### provenance

an entity that is associated to a pointer value in the abstract machine, which is either empty, or the identity of a storage instance

### 4.2 storage instance

the inclusion-maximal region of data storage in the execution environment that is created when either an object definition or an allocation is encountered

## **5 Specifications**

The normative specification is given in its entirety by modifications to ISO/IEC 9899:2018. These are provided by normative Annex C.

Prior to that, two informative annexes provide examples (Annex A) and detailed semantics (Annex B) for the different variants of the memory model that have been discussed in the introduction.

## A Examples (informative)

This annex discusses the design of provenance semantics for C, looking at a series of examples. We consider the three variants of the provenance-not-via-integer (PNVI) model: PNVI plain, PNVI address-exposed (PNVI-ae) and PNVI address-exposed user-disambiguation (PNVI-ae-udi), and also the provenance-via-integers (PVI) model. The examples include those of *Exploring C Semantics and Pointer Provenance* [POPL 2019] (also available as ISO WG14 N2311 <http://www.open-std.org/jtc1/sc22/wg14/www/docs/n2311.pdf>), with several additions.

### A.1 Introduction

The new material for PNVI-address-exposed and PNVI address-exposed user-disambiguation models starts in §A.3, but first we introduce the problem in general and describe the basic pointer provenance semantics.

The semantics of pointers and memory objects in C has been a vexed question for many years. A priori, one might imagine two language-design extremes: a concrete model that exposes the memory semantics of the underlying hardware, with memory being simply a finite partial map from machine-word addresses to bytes and pointers that are simply machine words, and an abstract model in which the language types enforce hard distinctions, e.g. between numeric types that support arithmetic and pointer types that support dereferencing. C is neither of these. Its values are not abstract: the language intentionally permits manipulation of their underlying representations, via casts between pointer and integer types, `char*` pointers to access representation bytes, and so on, to support low-level systems programming. But C values also cannot be considered to be simple concrete values: at runtime a C pointer will typically just be a machine word, but compiler analysis reasons about abstract notions of the provenance of pointers, and compiler optimisations rely on assumptions about these for soundness. Particularly relevant here, some compiler optimisations rely on alias analysis to deduce that two pointer values do not refer to the same object, which in turn relies on assumptions that the program only constructs pointer values in “reasonable” ways (with other programs regarded as having undefined behaviour, UB). The committee response to Defect Report DR260 [Fea04] states that implementations can track the origins (or “provenance”) of pointer values, “*the implementation is entitled to take account of the provenance of a pointer value when determining what actions are and are not defined*”, but exactly what this “provenance” means is left undefined, and it has never been incorporated into the standard text. Even what a memory object is is not completely clear in the standard, especially for aggregate types and for objects within heap regions.

Second, in some respects there are significant discrepancies between the ISO standard and the de facto standards, of C as it is implemented and used in practice. Major C codebases typically rely on particular compiler flags, e.g. `-fno-strict-aliasing` or `-fwrapv`, that substantially affect the semantics but which standard does not attempt to describe, and some idioms are UB in ISO C but relied on in practice, e.g. comparing against a pointer value after the lifetime-end of the object it pointed to. There is also not a unique de facto standard: in reality, one has to consider the expectations of expert C programmers and compiler writers, the behaviours of specific compilers, and the assumptions about the language implementations that the global C codebase relies upon to work correctly (in so far as it does). Our recent surveys [MML<sup>+</sup>16, MS16b] of the first revealed many discrepancies, with widely conflicting responses to specific questions.

Third, the ISO standard is a prose document, as is typical for industry standards. The lack of mathematical precision, while also typical for industry standards, has surely contributed to the accumulated confusion about C, but, perhaps more importantly, the prose standard is not *executable as a test oracle*. One would like, given small test programs, to be able to automatically compute the sets of their allowed behaviours (including whether they have UB). Instead, one has to do painstaking argument with respect to the text and concepts of the standard, a time-consuming and error-prone task that requires great expertise, and which will sometimes run up against the areas where the standard is unclear or differs with practice. One also cannot use conventional implementations to find the sets of all allowed behaviours, as (a) the standard is a loose specification, while particular compilations will resolve many nondeterministic choices, and (b) conventional implementations cannot detect all sources of undefined behaviour (that is the main point of UB in the standard, to let implementations assume that source programs do not exhibit UB, together with supporting implementation variation beyond the UB boundary). Sanitisers and other tools can detect some UB cases, but not all, and each tool builds in its own more-or-less ad hoc C semantics.

This is not just an academic problem: disagreements over exactly what is or should be permitted in C have caused considerable tensions, e.g. between OS kernel and compiler developers, as increasingly aggressive optimisations can break code that worked on earlier compiler implementations.

This note continues an exploration of the design space and two candidate semantics for pointers and memory objects in C, taking both ISO and de facto C into account. We earlier [MML<sup>+</sup>16, CMM<sup>+</sup>16] identified many design questions. We focus here on the questions concerning pointer provenance, which we revise and extend. We develop two main coherent proposals that reconcile many design concerns; both are broadly consistent with the provenance intuitions of practitioners and ISO DR260, while still reasonably simple. We highlight their pros and cons and various outstanding open questions. These proposals cover many of the interactions between abstract and concrete views in C: casts between pointers and integers, access to the byte representations of values, etc.

## A.2 Basic pointer provenance

C pointer values are typically represented at runtime as simple concrete numeric values, but mainstream compilers routinely exploit information about the *provenance* of pointers to reason that they cannot alias, and hence to justify optimisations. In this section we develop a provenance semantics for simple cases of the construction and use of pointers,

For example, consider the classic test [Fea04, KW12, Kre15, CMM<sup>+</sup>16, MML<sup>+</sup>16] on the right (note that this and many of the examples below are edge-cases, exploring the boundaries of what different semantic choices allow, and sometimes what behaviour existing compilers exhibit; they are not all intended as desirable code idioms).

Depending on the implementation, `x` and `y` might in some executions happen to be allocated in adjacent memory, in which case `&x+1` and `&y` will have bitwise-identical representation values, the `memcmp` will succeed, and `p` (derived from a pointer to `x`) will have the same representation value as a

pointer to a different object, `y`, at the point of the update `*p=11`. This can occur in practice, e.g. with GCC 8.1 -O2 on some platforms. Its output of `x=1 y=2 *p=11 *q=2` suggests that the compiler is reasoning that `*p` does not alias with `y` or `*q`, and hence that the initial value of `y=2` can be propagated to the final `printf`. ICC, e.g. ICC 19 -O2, also optimises here (for a variant with `x` and `y` swapped), producing `x=1 y=2 *p=11 *q=11`. In contrast, Clang 6.0 -O2 just outputs the `x=1 y=11 *p=11 *q=11` that one might expect from a concrete semantics. Note that this example does not involve type-based alias analysis, and the outcome is not affected by GCC or ICC's `-fno-strict-aliasing` flag. Note also that the mere formation of the `&x+1` one-past pointer is explicitly permitted by the ISO standard, and, because the `*p=11` access is guarded by the `memcmp` conditional check on the representation bytes of the pointer, it will not be attempted (and hence flag UB) in executions in which the two storage instances are not adjacent.

These GCC and ICC outcomes would not be correct with respect to a concrete semantics, and so to make the existing compiler behaviour sound it is necessary for this program to be deemed to have undefined behaviour.

The current ISO standard text does not explicitly speak to this, but the 2004 ISO WG14 C standards committee response to Defect Report 260 (DR260 CR) [Fea04] hints at a notion of provenance associated to values that keeps track of their "origins":

*"Implementations are permitted to track the origins of a bit-pattern and [...]. They may also treat pointers based on different origins as distinct even though they are bitwise identical."*

However, DR260 CR has never been incorporated in the standard text, and it gives no more detail. This leaves many specific questions unclear: it is ambiguous whether some programming idioms are allowed or not, and exactly what compiler alias analysis and optimisation are allowed to do.

**Basic provenance semantics for pointer values** For simple cases of the construction and use of pointers, capturing the basic intuition suggested by DR260 CR in a precise semantics is straightforward: we associate a *provenance* with every pointer value, identifying the original storage instance the pointer is derived from. In more detail:

- We take abstract-machine pointer values to be pairs  $(\pi, a)$ , adding a *provenance*  $\pi$ , either  $@i$  where  $i$  is a storage instance ID, or the *empty* provenance `@empty`, to their concrete address  $a$ .
- On every storage instance (of objects with static, thread, automatic, and allocated storage duration), the abstract machine nondeterministically chooses a fresh storage instance ID  $i$  (unique across the entire execution), and the resulting pointer value carries that single storage instance ID as its provenance  $@i$ .
- Provenance is preserved by pointer arithmetic that adds or subtracts an integer to a pointer.
- At any access via a pointer value, its numeric address must be consistent with its provenance, with undefined behaviour otherwise. In particular:
  - access via a pointer value which has provenance a single storage instance ID  $@i$  must be within the memory footprint of the corresponding original storage instance, which must still be live.
  - all other accesses, including those via a pointer value with empty provenance, are undefined behaviour.

Regarding such accesses as undefined behaviour is necessary to make optimisation based on provenance alias analysis sound: if the standard did define behaviour for programs that make provenance-violating accesses,

```

1 // provenance_basic_global_yx.c (and an xy variant)
2 #include <stdio.h>
3 #include <string.h>
4 int y=2, x=1;
5 int main() {
6     int *p = &x + 1;
7     int *q = &y;
8     printf("Addresses: p=%p q=%p\n", (void*)p, (void*)q);
9     if (memcmp(&p, &q, sizeof(p)) == 0) {
10         *p = 11; // does this have undefined behaviour?
11         printf("x=%d y=%d *p=%d *q=%d\n", x, y, *p, *q);
12     }
13 }

```

e.g. by adopting a concrete semantics, optimisation based on provenance-aware alias analysis would not be sound.

On the right is a provenance-semantics memory-state snapshot (from the Cerberus GUI) for `provenance_basic_global_xy.c`, just before the invalid access via `p`, showing how the provenance mismatch makes it UB: at the attempted access via `p`, its pointer-value address `0x4c` is not within the storage instance with the ID `@5` of the provenance of `p`.

All this is for the *C abstract machine* as defined in the standard: compilers might rely on provenance in their alias analysis and optimisation, but one would not expect normal implementations to record or manipulate provenance at runtime (though dynamic or static analysis tools might, as might non-standard implementations such as CHERI C). Provenances therefore do not have program-accessible runtime representations in the abstract machine.

Even for the basic provenance semantics, there are some open design questions, which we now discuss.

### Can one construct out-of-bounds (by more than one) pointer values by pointer arithmetic?

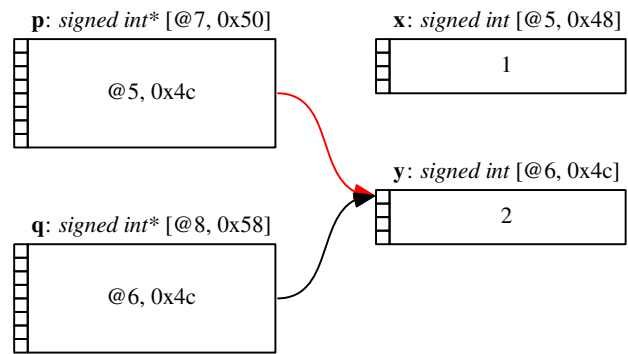

Consider the example below, where `q` is transiently (more than one-past) out of bounds but brought back into bounds before being used for access. In ISO C, constructing such a pointer value is clearly stated to be undefined behaviour [c1818, 6.5.6p8]. This can be captured using the provenance of the pointer value to determine the relevant bounds.

There are cases where such pointer arithmetic would go wrong on some platforms (some now exotic), e.g. where pointer arithmetic subtraction overflows, or if the transient value is not aligned and only aligned values are representable at the particular pointer type, or for hardware that does bounds checking, or where pointer arithmetic might wrap at values less than the obvious word size

(e.g. “near” or “huge” 8086 pointers). However, transiently out-of-bounds pointer construction seems to be common in practice. It may be desirable to make it implementation-defined whether such pointer construction is allowed. That would continue to permit implementations in which it would go wrong to forbid it, but give a clear way for other implementations to document that they do not exploit this UB in compiler optimisations that may be surprising to programmers.

**Inter-object pointer arithmetic** The first example in this section relied on guessing (and then checking) the offset between two storage instances. What if one instead calculates the offset, with pointer subtraction; should that let one move between objects, as below? In ISO C18, the `q-p` is UB (as it is a pointer subtraction between pointers to different objects, which in some abstract-machine executions are not one-past-related).

In a variant semantics that allows construction of more-than-one-past pointers (which allows the evaluation of `p + offset`), one would have to choose whether the `*r=11` access is UB or not. The basic provenance semantics will forbid it, because `r` will retain the provenance of the `x` storage instance, but its address is not in bounds for that. This is probably the most desirable semantics: we have found very few example idioms that intentionally use inter-object pointer arithmetic, and the freedom that forbidding it gives to alias analysis and optimisation seems significant.

```
// cheri_03_ii.c
```

```
1 int x[2];
2 int *p = &x[0];
3 int *q = p + 11; // defined behaviour?
4 q = q - 10;
5 *q = 1;
```

```
// pointer_offset_from_ptr_subtraction_global_xy.c
```

```
1 #include <stdio.h>
2 #include <string.h>
3 #include <stddef.h>
4 int x=1, y=2;
5 int main() {
6     int *p = &x;
7     int *q = &y;
8     ptrdiff_t offset = q - p;
9     int *r = p + offset;
10    if (memcmp(&r, &q, sizeof(r)) == 0) {
11        *r = 11; // is this free of UB?
12        printf("y=%d *q=%d *r=%d\n", y, *q, *r);
13    }
14 }
```

**Pointer equality comparison and provenance** A priori, pointer equality comparison (with == or !=) might be expected to just compare their numeric addresses, but we observe GCC 8.1 -O2 sometimes regarding two pointers with the same address but different provenance as nonequal. Unsurprisingly, this happens in some circumstances but not others, e.g. if the test is pulled into a simple separate function, but not if in a separate compilation unit. To be conservative w.r.t. current compiler behaviour, pointer equality in the semantics should give false if the addresses are not equal, but nondeterministically (at each runtime occurrence) either take provenance into account or not if the addresses are equal – this specification looseness accommodating implementation variation. Alternatively, one could require numeric comparisons, which would be a simpler semantics for programmers but force that GCC behaviour to be regarded as a bug. Cerberus supports both options. One might also imagine making it UB to compare pointers that are not strictly within their original storage instance [Kre15], but that would break loops that test against a one-past pointer, or requiring equality to *always* take provenance into account, but that would require implementations to track provenance at runtime.

```

1 // provenance_equality_global_xy.c
2 #include <stdio.h>
3 #include <string.h>
4 int x=1, y=2;
5 int main() {
6     int *p = &x + 1;
7     int *q = &y;
8     printf("Addresses: p=%p q=%p\n", (void*)p, (void*)q);
9     _Bool b = (p==q);
10    // can this be false even with identical addresses?
11    printf("(p==q) = %s\n", b?"true":"false");
12    return 0;
13 }

```

The current ISO C18 standard text is too strong here unless numeric comparison is required: 6.5.9p6 says “Two pointers compare equal **if and only if** both are [...] or one is a pointer to one past the end of one array object and the other is a pointer to the start of a different array object that happens to immediately follow the first array object in the address space”, which requires such pointers to compare equal – reasonable pre-DR260 CR, but debatable after it.

Pointer equality should not be confused with alias analysis: we could require == to return true for pointers with the same address but different provenance, while still permitting alias analysis to regard the two as distinct by making accesses via pointers with the wrong provenance UB.

**Pointer relational comparison and provenance** In ISO C (6.5.8p5), inter-object pointer relational comparison (with < etc.) is undefined behaviour. Just as for inter-object pointer subtraction, there are platforms where this would go wrong, but there are also substantial bodies of code that rely on it, e.g. for lock orderings

It may be desirable to make it implementation-defined whether such pointer construction is allowed.

### A.3 Refining the basic provenance model to support pointer construction via casts, representation accesses, etc.

To support low-level systems programming, C provides many other ways to construct and manipulate pointer values:

- casts of pointers to integer types and back, possibly with integer arithmetic, e.g. to force alignment, or to store information in unused bits of pointers;
- copying pointer values with `memcpy`;
- manipulation of the representation bytes of pointers, e.g. via user code that copies them via `char*` or `unsigned char*` accesses;
- type punning between pointer and integer values;
- I/O, using either `fprintf/fscanf` and the `%p` format, `fwrite/fread` on the pointer representation bytes, or pointer/integer casts and integer I/O;
- copying pointer values with `realloc`;
- constructing pointer values that embody knowledge established from linking, and from constants that represent the addresses of memory-mapped devices.

A satisfactory semantics has to address all these, together with the implications on optimisation. We define and explore several alternatives:

- **PNVI-plain**: a semantics that does not track provenance via integers, but instead, at integer-to-pointer cast points, checks whether the given address points within a live object and, if so, recreates the corresponding provenance. We explain in the next section why this is not as damaging to optimisation as it may sound.

- **PNVI-ae (PNVI exposed-address)**: a variant of PNVI that allows integer-to-pointer casts to recreate provenance only for storage instances that have previously been *exposed*. A storage instance is deemed exposed by a cast of a pointer to it to an integer type, by a read (at non-pointer type) of the representation of the pointer, or by an output of the pointer using `%p`.
- **PNVI-ae-udi (PNVI exposed-address user-disambiguation)**: a further refinement of PNVI-ae that supports roundtrip casts, from pointer to integer and back, of pointers that are one-past a storage instance. This is the currently preferred option in the C memory object model study group.
- **PVI**: a semantics that tracks provenance via integer computation, associating a provenance with all integer values (not just pointer values), preserving provenance through integer/pointer casts, and making some particular choices for the provenance results of integer and pointer +/- integer operations; or

We write PNVI-\* for PNVI-plain, PNVI-ae, and PNVI-ae-udi. The PNVI-plain and PVI semantics were described in the POPL 2019/N2311 paper. PNVI-ae and PNVI-ae-udi have emerged from discussions in the C memory object model study group.

We also mention other variants of PNVI that seem less desirable:

- **PNVI-address-taken**: an earlier variant of PNVI-ae that allowed integer-to-pointer casts to recreate provenance for objects whose address has been taken (irrespective of whether it has been exposed); and
- **PNVI-wildcard**: a variant that gives a “wildcard” provenance to the results of integer-to-pointer casts, delaying checks to access time.

The PVI semantics, originally developed informally in ISO WG14 working papers [MS16a, MGS18], was motivated in part by the GCC documentation [FSF18]:

*“When casting from pointer to integer and back again, the resulting pointer must reference the same object as the original pointer, otherwise the behavior is undefined. That is, one may not use integer arithmetic to avoid the undefined behavior of pointer arithmetic as proscribed in C99 and C11 6.5.6/8.”*

which presumes there is an “original” pointer, and by experimental data for `uintptr_t` analogues of the first test of §A.2, which suggested that GCC and ICC sometimes track provenance via integers (see `xy` and `yx` variants). However, discussions at the 2018 GNU Tools Cauldron suggest instead that at least some key developers regard the result of casts from integer types as potentially broadly aliasing, at least in their GIMPLE IR, and such test results as long-standing bugs in the RTL backend.

## A.4 Refining the basic provenance model: phenomena and examples

**Pointer/integer casts** The ISO standard (6.3.2.3) leaves conversions between pointer and integer types almost entirely implementation-defined, except for conversion of integer constant `0` and null pointers, and for the optional `intptr_t` and `uintptr_t` types, for which it guarantees that any “valid pointer to void” can be converted and back, and that “the result will compare equal to the original pointer”. As we have seen, in a post-DR260 CR provenance-aware semantics, “compare equal” is not enough to guarantee the two are interchangeable, which was clearly the intent of that phrasing. All variants of PNVI-\* and PVI support this, by reconstructing or preserving the original provenance respectively.

```

1 // provenance_roundtrip_via_intptr_t.c
2 #include <stdio.h>
3 #include <inttypes.h>
4 int x=1;
5 int main() {
6     int *p = &x;
7     intptr_t i = (intptr_t)p;
8     int *q = (int *)i;
9     *q = 11; // is this free of undefined behaviour?
10    printf("*p=%d *q=%d\n", *p, *q);
11 }

```

**Inter-object integer arithmetic** Below is a `uintptr_t` analogue of the §A.2 example `pointer_offset_from_ptr_subtraction_global_xy.c`, attempting to move between objects with `uintptr_t` arithmetic. In PNVI-\*, this has defined behaviour. For PNVI-plain: the integer values are pure integers, and at the `int*` cast the value of `ux+offset` matches the address of `y` (live and of the right type), so the resulting pointer value takes on the provenance of the `y` storage instance. For PNVI-ae and PNVI-ae-udi, the storage instance for `y` is marked as *exposed* at the cast of `&y` to an integer, and so the above is likewise permitted there.

In PVI, this is UB. First, the integer values of `ux` and `uy` have the provenances of the storage instances of `x` and `y` respectively. Then `offset` is a subtraction of two integer values with non-equal single provenances; we define the result of such to have the empty provenance. Adding that empty-provenance result to `ux` preserves the original `x`-storage instance provenance of the latter, as does the cast to `int*`. Then the final `*p=11` access is via a pointer value whose address is not consistent with its provenance. Similarly, PNVI-\* allows (contrary to current GCC/ICC O2) a `uintptr_t` analogue of the first test of §A.2, on the left below. PVI forbids this test.

```
// pointer_offset_from_int_subtraction_global_xy.c
```

```
1 #include <stdio.h>
2 #include <string.h>
3 #include <stdint.h>
4 #include <inttypes.h>
5 int x=1, y=2;
6 int main() {
7     uintptr_t ux = (uintptr_t)&x;
8     uintptr_t uy = (uintptr_t)&y;
9     uintptr_t offset = uy - ux;
10    printf("Addresses: &x=%"PRIuPTR" &y=%"PRIuPTR"\
11           " offset=%"PRIuPTR" \n", ux, uy, offset);
12    int *p = (int *) (ux + offset);
13    int *q = &y;
14    if (memcmp(&p, &q, sizeof(p)) == 0) {
15        *p = 11; // is this free of UB?
16        printf("x=%d y=%d *p=%d *q=%d\n", x, y, *p, *q);
17    }
18 }
```

```
// provenance_basic_using_uintptr_t_global_xy.c
```

```
1 #include <stdio.h>
2 #include <string.h>
3 #include <stdint.h>
4 #include <inttypes.h>
5 int x=1, y=2;
6 int main() {
7     uintptr_t ux = (uintptr_t)&x;
8     uintptr_t uy = (uintptr_t)&y;
9     uintptr_t offset = 4;
10    ux = ux + offset;
11    int *p = (int *)ux; // does this have UB?
12    int *q = &y;
13    printf("Addresses: &x=%p p=%p &y=%"PRIxPTR"\
14           "\n", (void*)&x, (void*)p, uy);
15    if (memcmp(&p, &q, sizeof(p)) == 0) {
16        *p = 11; // does this have undefined
17               behaviour?
18        printf("x=%d y=%d *p=%d *q=%d\n", x, y, *p, *
19               q);
20    }
21 }
```

```
// pointer_offset_xor_global.c
```

```
1 #include <stdio.h>
2 #include <inttypes.h>
3 int x=1;
4 int y=2;
5 int main() {
6     int *p = &x;
7     int *q = &y;
8     uintptr_t i = (uintptr_t) p;
9     uintptr_t j = (uintptr_t) q;
10    uintptr_t k = i ^ j;
11    uintptr_t l = k ^ i;
12    int *r = (int *)l;
13    // are r and q now equivalent?
14    *r = 11; // does this have defined
15            behaviour?
16    _Bool b = (r==q);
17    printf("x=%i y=%i *r=%i (r==p)=%s\n", x, y, *
18           r, b?"true":"false");
19 }
```

Both choices are defensible here: PVI will permit more aggressive alias analysis for pointers computed via integers (though those may be relatively uncommon), while PNVI-\* will allow not just this test, which as written is probably not idiomatic desirable C, but also the essentially identical XOR doubly linked list idiom, using only one pointer per node by storing the XOR of two, on the right above. Opinions differ as to whether that idiom matters for modern code.

There are other real-world but rare cases of inter-object arithmetic, e.g. in the implementations of Linux and FreeBSD per-CPU variables, in fixing up pointers after a `realloc`, and in dynamic linking (though arguably some of these are not between C abstract-machine objects). These are rare enough that it seems reasonable to require additional source annotation, or some other mechanism, to prevent compilers implicitly assuming that uses of such pointers as undefined.

**Pointer provenance for pointer bit manipulations** It is a standard idiom in systems code to use otherwise unused bits of pointers: low-order bits for pointers known to be aligned, and/or high-order bits beyond the addressable range. The example on the right (which assumes `_Alignof(int)>= 4`) does this: casting a pointer to `uintptr_t` and back, using bitwise logical operations on the integer value to store some tag bits.

To allow this, we suggest that the set of unused bits for pointer types of each alignment should be made implementation-defined. In PNVI-\* the intermediate value of `q` will have empty provenance, but the value of `r` used for the access will re-acquire the correct provenance at cast time. In PVI we make the binary operations used here, combining an integer value that has some provenance ID with a pure integer, preserve that provenance.

(A separate question is the behaviour if the integer value with tag bits set is converted back to pointer type. In ISO the result is implementation-defined, per 6.3.2.3p{5,6} and 7.20.1.4.)

```
// provenance_tag_bits_via_uintptr_t_1.c
1 #include <stdio.h>
2 #include <stdint.h>
3 int x=1;
4 int main() {
5     int *p = &x;
6     // cast &x to an integer
7     uintptr_t i = (uintptr_t) p;
8     // set low-order bit
9     i = i | 1u;
10    // cast back to a pointer
11    int *q = (int *) i; // does this have UB?
12    // cast to integer and mask out low-order bits
13    uintptr_t j = ((uintptr_t)q) & ~((uintptr_t)3u);
14    // cast back to a pointer
15    int *r = (int *) j;
16    // are r and p now equivalent?
17    *r = 11; // does this have UB?
18    _Bool b = (r==p); // is this true?
19    printf("x=%i *r=%i (r==p)=%s\n",x,*r,b?"t":"f");
20 }
```

**Algebraic properties of integer operations** The PVI definitions of the provenance results of integer operations, chosen to make `pointer_offset_from_int_subtraction_global_xy.c` forbidden and `provenance_tag_bits_via_uintptr_t_1.c` allowed, has an unfortunate consequence: it makes those operations no longer associative. Compare the examples below:

```
// pointer_arith_algebraic_properties_2_global.c
1 #include <stdio.h>
2 #include <inttypes.h>
3 int y[2], x[2];
4 int main() {
5     int *p=(int*)((uintptr_t)&(x[0])) +
6         (((uintptr_t)&(y[1]))-((uintptr_t)&(y[0])));
7     *p = 11; // is this free of undefined behaviour?
8     printf("x[1]=%d *p=%d\n",x[1],*p);
9     return 0;
10 }
```

```
// pointer_arith_algebraic_properties_3_global.c
1 #include <stdio.h>
2 #include <inttypes.h>
3 int y[2], x[2];
4 int main() {
5     int *p=(int*)(
6         (((uintptr_t)&(x[0])) + ((uintptr_t)&(y[1]))
7         -((uintptr_t)&(y[0])) );
8     *p = 11; // is this free of undefined behaviour?
9     //(equivalent to the &x[0]+(&(y[1])-&(y[0])) version?)
10    printf("x[1]=%d *p=%d\n",x[1],*p);
11    return 0;
12 }
```

The latter is UB in PVI. It is unclear whether this would be acceptable in practice, either for C programmers or for compiler optimisation. One could conceivably switch to a PVI-multiple variant, allowing provenances to be finite sets of storage instance IDs. That would allow the `pointer_offset_from_int_subtraction_global_xy.c` example above, but perhaps too much else besides. The PNVI-\* models do not suffer from this problem.

**Copying pointer values with `memcpy()`** This clearly has to be allowed, and so, to make the results usable for accessing memory without UB, `memcpy()` and similar functions have to preserve the original provenance. The ISO C18 text does not explicitly address this (in a pre-provenance semantics, before DR260, it did not need to). One could do so by special-casing `memcpy()` and similar functions to preserve provenance, but the following questions suggest less ad hoc approaches, for PNVI-plain or PVI. For PNVI-ae and PNVI-ae-udi, the best approach is not yet clear.

```
// pointer_copy_memcpy.c
1 #include <stdio.h>
2 #include <string.h>
3 int x=1;
4 int main() {
5     int *p = &x;
6     int *q;
7     memcpy (&q, &p, sizeof p);
8     *q = 11; // is this free of undefined behaviour?
9     printf(" *p=%d *q=%d\n", *p, *q);
10 }
```

**Copying pointer values bitwise, with user-`memcpy`** One of the key aspects of C is that it supports manipulation of object representations, e.g. as in the following naive user implementation of a `memcpy`-like function, which constructs a pointer value from copied bytes. This too should be allowed. PNVI-plain makes it legal: the representation bytes have no provenance, but when reading a pointer value from the copied memory, the read will be from multiple representation-byte writes. We use essentially the same semantics for such reads as for integer-to-pointer casts: checking at read-time that the address is within a live object, and giving the result the corresponding provenance. For PNVI-ae and PNVI-ae-udi, the current proposal is to mark storage instances as exposed whenever representation bytes of pointers to them are read, and use the same semantics for reads of pointer values from representation-byte writes as for integer-to-pointer casts. This is attractively simple, but it does mean that integer-to-pointer casts become permitted for all storage instances for which a pointer has been copied via `user_memcpy`, which is arguably too liberal. It may be possible to add additional annotations for code like `user_memcpy` to indicate (to alias analysis) that (a) their target memory should have the same provenance as their source memory, and (b) the storage instances of any copied pointers should not be marked as exposed, despite the reads of their representation bytes. This machinery has not yet been designed.

```
// pointer_copy_user_dataflow_direct_bitwise.c
1 #include <stdio.h>
2 #include <string.h>
3 int x=1;
4 void user_memcpy(unsigned char* dest,
5                 unsigned char *src, size_t n) {
6     while (n > 0) {
7         *dest = *src;
8         src += 1; dest += 1; n -= 1;
9     }
10 }
11 int main() {
12     int *p = &x;
13     int *q;
14     user_memcpy((unsigned char*)&q,
15               (unsigned char*)&p, sizeof(int *));
16     *q = 11; // is this free of undefined behaviour?
17     printf(" *p=%d *q=%d\n", *p, *q);
18 }
```

One might instead think of recording symbolically in the semantics of integer values (e.g. for representation-byte values) whether they are of the form “byte  $n$  of pointer value  $v$ ”, or perhaps “byte  $n$  of pointer value of type  $t$ ”, and allow reads of pointer values from representation-byte writes only for such. This is more complex and rather ad hoc, arbitrarily restricting the integer computation that can be done on such bytes. If one wanted to allow (e.g.) bitwise operations on such bytes, as in `provenance_tag_bits_via_repr_byte_1.c`, one would essentially have to adopt a PVI model. However, note that to capture the 6.5p6 preservation of effective types by character-type array copy (“If a value is copied into an object having no declared type using `memcpy` or `memcpymove`, or is copied as an array of character type, then the effective type of the modified object for that access and for subsequent accesses that do not modify the value is the effective type of the object from which the value is copied, if it has one.”), we might need something like a very restricted version of PVI: some effective-type information attached to integer values of character type, to say “byte  $n$  of pointer value of type  $t$ ”, with all integer operations except character-type stores clearing that info.

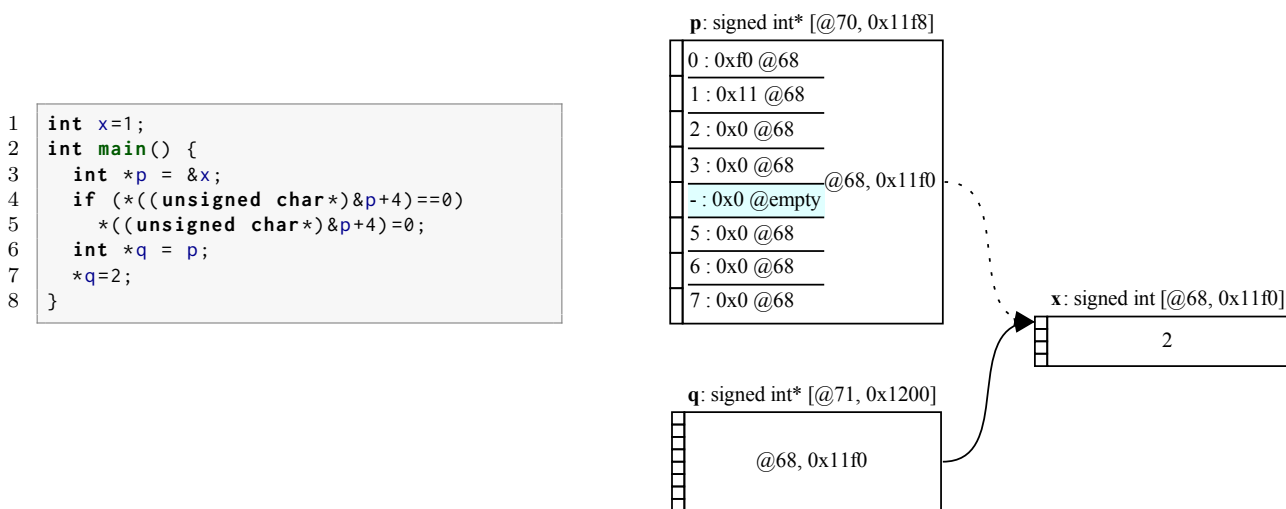

As Lee observes [private communication], to make it legal for compilers to replace `user_memcpy` by the library version, one might want the two to have exactly the same semantics. Though strictly speaking that is a question about the compiler intermediate language semantics, not C source semantics.

PVI makes `user_memcpy` legal by regarding each byte (as an integer value) as having the provenance of the original pointer, and the result pointer, being composed of representation bytes of which at least one has that provenance and none have a conflicting provenance, as having the same.

Real `memcpy()` implementations are more complex. The glibc `memcpy()`[gli18] involves copying byte-by-byte, as above, and also word-by-word and, using virtual memory manipulation, page-by-page. Word-by-word copying is not permitted by the ISO standard, as it violates the effective type rules, but we believe C2x should support it for suitably annotated code. Virtual memory manipulation is outside our scope at present.

**Reading pointer values from byte writes** In all these provenance semantics, pointer values carry their provenance unchanged, both while manipulated in expressions (e.g. with pointer arithmetic) and when stored or loaded as values of pointer type. In the detailed semantics, memory contains abstract bytes rather than general C language values, and so we record provenance in memory by attaching a provenance to each abstract byte. For pointer values stored by single writes, this will usually be identical in each abstract byte of the value.

However, we also have to define the result of reading a pointer value that has been partially or completely written by (integer) representation-byte writes. In PNVI-\*, we use the same semantics as for integer-to-pointer casts, reading the numeric address and reconstructing the associated provenance iff a live storage instance covering that address exists (and, for PNVI-ae and PNVI-ae-udi, if that instance has been exposed). To determine whether a pointer value read is from a single pointer value write (and thus should retain its original provenance when read), or from a combination of representation byte writes and perhaps also a pointer value write (and thus should use the integer-to-pointer cast semantics when read), we also record, in each abstract byte, an optional pointer-byte index (e.g. in 0..7 on an implementation with 8-byte pointer values). Pointer value writes will set these to the consecutive sequence 0, 1, ..., 7, while other writes will clear them. For example, the code on the left below sets the fourth byte of `p` to `0`. The memory state on the right, just after the `*q=2`, shows the pointer-byte indices of `p`, one of which has been cleared (shown as -). When the value of `p` is read (e.g. in the `q=p`), the fact that there is not a consecutive sequence 0, 1, ..., 7 means that PNVI-\* will apply the integer-to-pointer cast semantics, here successfully recovering the provenance `@68` of the storage instance `x`. Then the write of `q` will itself have a consecutive sequence (its pointer-byte indices are therefore suppressed in the diagram). Any non-pointer write overlapping the footprint of `p`, or any pointer write that overlaps that footprint but does not cover it all, would interrupt the consecutive sequence of indices.

In PNVI-plain a representation-byte copy of a pointer value thus is subtly different from a copy done at pointer type: the latter retains the original provenance, while the former, when it is loaded, will take on the provenance of whatever storage instance is live (and covers its address) *at load time*.

The conditional in the example is needed to avoid UB: the semantics does not constrain the allocation address of `x`, so there are executions in which byte 4 is not `0`, in which case the read of `p` would have a wild address and the empty provenance, and the write `*q=2` would flag UB.

**Pointer provenance for bitwise pointer representation manipulations** To examine the possible semantics for pointer representation bytes more closely, especially for PNVI-ae and PNVI-ae-udi, consider the following. As in `provenance_tag_bits_via_uintptr_t_1.c`, it manipulates the low-order bits of a pointer value, but now it does so by manipulating one of its representation bytes (as in `pointer_copy_user_dataflow_direct_bytewise.c`) instead of by casting to `uintptr_t`

and back. In PNVI-plain and PVI this will just work, respectively reconstructing the original provenance and tracking it through the (changed and unchanged) integer bytes.

In PNVI-ae and PNVI-ae-udi, we regard the storage instance of `x` as having been exposed by the read of a pointer value (with non-empty provenance in its abstract bytes in memory) at an integer (really, non-pointer) type. Then the last reads of the value of `p`, from a combination of the original `p=&x` write and later integer byte writes, use the same semantics as integer-to-pointer casts, and thus recreate the original provenance.

```
// provenance_tag_bits_via_repr_byte_1.c
1 #include <assert.h>
2 #include <stdio.h>
3 #include <stdint.h>
4 int x=1;
5 int main() {
6     int *p=&x, *q=&x;
7     // read low-order (little endian) representation byte of p
8     unsigned char i = *(unsigned char*)&p;
9     // check the bottom two bits of an int* are not used
10    assert(_Alignof(int) >= 4);
11    assert((i & 3u) == 0u);
12    // set the low-order bit of the byte
13    i = i | 1u;
14    // write the representation byte back
15    *(unsigned char*)&p = i;
16    // [p might be passed around or copied here]
17    // clear the low-order bits again
18    *(unsigned char*)&p = (*(unsigned char*)&p) & ~((unsigned char)3
19    u);
20    // are p and q now equivalent?
21    *p = 11; // does this have defined behaviour?
22    _Bool b = (p==q); // is this true?
23    printf("x=%i *p=%i (p==q)=%s\n", x, *p, b?"true":"false");
}
```

**Copying pointer values via encryption** To more clearly delimit what idioms our proposals do and do not allow, consider copying pointers via code that encrypts or compresses a block of multiple pointers together, decrypting or uncompressing later.

In PNVI-plain, it would just work, in the same way as `user_memcpy()`. In PNVI-ae and PNVI-ae-udi, it would work but leave storage instances pointed to by those pointers exposed (irrespective of whether the encryption is done via casts to integer types or by reads of representation bytes), similar to `user_memcpy` and `provenance_tag_bits_via_repr_byte_1.c`.

One might argue that pointer construction via `intptr_t` and back via any value-dependent identity function should be required to work. That would admit these, but defining that notion of “value-dependent” is exactly what is hard in the concurrency thin-air problem [BMN<sup>+</sup>15], and we do not believe that it is practical to make compilers respect dependencies in general.

In PVI, this case involves exactly the same combination of distinct-provenance values that (to prohibit inter-object arithmetic, and thereby enable alias analysis) we above regard as having empty-provenance results. As copying pointers in this way is a very rare idiom, one can argue that it is reasonable to require such code to have additional annotations.

**Copying pointer values via control flow** We also have to ask whether a usable pointer can be constructed via non-dataflow control-flow paths, e.g. if testing equality of an unprovenanced integer value against a valid pointer permits the integer to be used as if it had the same provenance as the pointer. We do not believe that this is relied on in practice. For example, consider exotic versions of `memcpy` that make a control-flow choice on the value of each bit or each byte, reconstructing each with constants in each control-flow branch

```
// pointer_copy_user_ctrlflow_bytewise_abbrev.c
1 #include <stdio.h>
2 #include <string.h>
3 #include <assert.h>
4 #include <limits.h>
5 int x=1;
6 unsigned char control_flow_copy(unsigned char
7     c) {
8     assert(UCHAR_MAX==255);
9     switch (c) {
10        case 0: return(0);
11        case 1: return(1);
12        case 2: return(2);
13        ...
14        case 255: return(255);
15    }
16 }
17 void user_memcpy2(unsigned char* dest,
18     unsigned char *src, size_t n
19     ) {
20     while (n > 0) {
21         *dest = control_flow_copy(*src);
22         src += 1;
23         dest += 1;
24         n -= 1;
25     }
26 }
27 int main() {
28     int *p = &x;
29     int *q;
30     user_memcpy2((unsigned char*)&q, (unsigned
31         char*)&p,
32         sizeof(p));
33     *q = 11; // does this have undefined
34             // behaviour?
35     printf(" *p=%d *q=%d\n", *p, *q);
36 }
```

```
// pointer_copy_user_ctrlflow_bitwise.c
1 #include <stdio.h>
2 #include <inttypes.h>
3 #include <limits.h>
4 int x=1;
5 int main() {
6     int *p = &x;
7     uintptr_t i = (uintptr_t)p;
8     int uintptr_t_width = sizeof(uintptr_t)
9         * CHAR_BIT;
10    uintptr_t bit, j;
11    int k;
12    j=0;
13    for (k=0; k<uintptr_t_width; k++) {
14        bit = (i & (((uintptr_t)1) << k)) >> k
15            ;
16        if (bit == 1)
17            j = j | ((uintptr_t)1 << k);
18        else
19            j = j;
20    }
21    int *q = (int *)j;
22    *q = 11; // is this free of undefined
23            // behaviour?
24    printf(" *p=%d *q=%d\n", *p, *q);
25 }
```

In PNVI-plain these would both work. In PNVI-ae and PNVI-ae-udi they would also work, as the first exposes the storage instance of the copied pointer value by representation-byte reads and the second by a pointer-to-integer cast. In PVI they would give empty-provenance pointer values and hence UB.

**Integer comparison and provenance** If integer values have associated provenance, as in PVI, one has to ask whether the result of an integer comparison should also be allowed to be provenance dependent (`provenance_equality_uintptr_t_global_xy.c`). GCC did do so at one point, but it was regarded as a bug and fixed (from 4.7.1 to 4.8). We propose that the numeric results of all operations on integers should be unaffected by the provenances of their arguments. For PNVI-\*, this question is moot, as there integer values have no provenance.

**Pointer provenance and union type punning** Pointer values can also be constructed in C by type punning, e.g. writing a pointer-type union member, reading it as a `uintptr_t` union member, and then casting back to a pointer type. (The example assumes that the object representation of the pointer and the object representation of the result of the cast to integer are identical. This property is not guaranteed by the C standard, but holds for many implementations.)

The ISO standard says “*the appropriate part of the object representation of the value is reinterpreted as an object representation in the new type*”, but says little about that reinterpretation. We propose that these reinterpretations be required to be implementation-defined, and, in PNVI-plain, that the usual integer-to-pointer cast semantics be used at such reads.

For PNVI-ae and PNVI-ae-udi, the same semantics as for representation-byte reads also permits this case: the storage instance is deemed to be exposed by the read of the provenanced representation bytes by the non-pointer-type read. The integer-to-pointer cast then recreates the provenance of `x`.

For PVI, we propose that it be implementation-defined whether the result preserves the original provenance (e.g. where they are the identity).

```

1 // provenance_union_punning_3_global.c
2 #include <stdio.h>
3 #include <string.h>
4 #include <inttypes.h>
5 int x=1;
6 typedef union { uintptr_t ui; int *up; } un;
7
8 int main() {
9     un u;
10    int *p = &x;
11    u.up = p;
12    uintptr_t i = u.ui;
13    int *q = (int*)i;
14    *q = 11; // does this have UB?
15    printf("x=%d *p=%d *q=%d\n", x, *p, *q);
16    return 0;
17 }

```

**Pointer provenance via IO** Consider now pointer provenance flowing via IO, e.g. writing the address of an object to a string, pipe or file and reading it back in. We have three versions: one using `fprintf/fscanf` and the `%p` format, one using `fwrite/fread` on the pointer representation bytes, and one converting the pointer to and from `uintptr_t` and using `fprintf/fscanf` on that value with the `PRIuPTR/SCNuPTR` formats (`provenance_via_io_percentp_global.c`, `provenance_via_io_bytewise_global.c`, and `provenance_via_io_uintptr_t_global.c`) The first gives a syntactic indication of a potentially escaping pointer value, while the others (after preprocessing) do not. Somewhat exotic though they are, these idioms are used in practice: in graphics code for serialisation/deserialisation (using `%p`), in xlib (using `SCNuPTR`), and in debuggers.

In the ISO standard, the text for `fprintf` and `scanf` for `%p` says that this should work: “*If the input item is a value converted earlier during the same program execution, the pointer that results shall compare equal to that value; otherwise the behavior of the %p conversion is undefined*” (again construing the pre-DR260 “compare equal” as implying the result should be usable for access), and the text for `uintptr_t` and the presence of `SCNuPTR` in `inttypes.h` weakly implies the same there.

But then what can compiler alias analyses assume about such a pointer read? In PNVI-plain, this is simple: at `scanf`-time, for the `%p` version, or when a pointer is read from memory written by the other two, we can do a runtime check and potential acquisition of provenance exactly like an integer-to-pointer cast.

In PNVI-ae and PNVI-ae-udi, for the `%p` case we mark the associated storage instance as exposed by the output, and use the same semantics as integer-to-pointer casts on the input. The `uintptr_t` case and representation-byte case also mark the storage instance as exposed, in the normal way for these models.

For PVI, there are several options, none of which seem ideal: we could use a PNVI-like semantics, but that would be stylistically inconsistent with the rest of PVI; or (only for the first) we could restrict that to provenances that have been output via `%p`, or we could require new programmer annotation, at output and/or input points, to constrain alias analysis.

**Pointers from device memory and linking** In practice, concrete memory addresses or relationships between them sometimes are determined and relied on by programmers, in implementation-specific ways. Sometimes these are simply concrete absolute addresses which will never alias C stack, heap, or program memory, e.g. those of particular memory-mapped devices in an embedded system. Others are absolute addresses and relative layout of program code and data, usually involving one or more *linking* steps. For example, platforms may lay out certain regions of memory so as to obey particular relationships, e.g. in a commodity operating system where high addresses are used for kernel mappings, initial stack lives immediately below the arguments passed from the operating system, and so on. The details of linking and of platform memory maps are outside the scope of ISO C, but real C code may embody knowledge of them. Such code might be as simple as casting a platform-specified address, represented as an integer literal, to a pointer. It might be more subtle, such as assuming that one object directly follows another in memory—the programmer having established this property at link time (perhaps by a custom linker script). It is necessary to preserve the legitimacy of such C code, so that compilers may not view such memory accesses as undefined behaviour, even with increasing link-time optimisation.

We leave the design of exactly what escape-hatch mechanisms are needed here as an open problem. For memory-mapped devices, one could simply posit implementation-defined ranges of such memory which are guaranteed not to alias C objects. The more general linkage case is more interesting, but well outside current ISO C. The tracking of provenance through embedded assembly is similar.

**Pointers from allocator libraries** Our semantics special-cases `malloc` and the related functions, by giving their results fresh provenances. This is stylistically consistent with the ISO text, which also special-cases them, but it would be better for C to support a general-purpose annotation, to let both `stdlib` implementations and other libraries return pointers that are treated as having fresh provenance outside (but not inside) their abstraction boundaries.

Compilers already have related annotations, e.g. GCC’s `malloc` attribute “tells the compiler that a function is *malloc-like*, i.e., that the pointer *P* returned by the function cannot alias any other pointer valid when the function returns, and moreover no pointers to valid objects occur in any storage addressed by *P*” (<https://gcc.gnu.org/onlinedocs/gcc/Common-Function-Attributes.html#Common-Function-Attributes>).

## A.5 Implications of provenance semantics for optimisations

In an ideal world, a memory object semantics for C would be consistent with all existing mainstream code usage and compiler behaviour. In practice, we suspect that (absent a precise standard) these have diverged too much for that, making some compromise required. As we have already seen, the PNVI semantics would make some currently observed GCC and ICC behaviour unsound, though at least some key GCC developers already regard that behaviour as a longstanding unfixed bug, due to the lack of integer/pointer type distinctions in RTL. We now consider some other important cases, by example.

**Optimisation based on equality tests** Both PNVI-\* and PVI let `p==q` hold in some cases where `p` and `q` are not interchangeable. As the authors of [LHJ<sup>+</sup>18] observe in the LLVM IR context, that may limit optimisations such as GVN (global value numbering) based on pointer equality tests. PVI suffers from the same problem also for integer comparisons, wherever the integers might have been cast from pointers and eventually be cast back. This may be more serious.

**Can a function argument alias local variables of the function?** In general one would like this to be forbidden, to let optimisation assume its absence. Consider first the example below, where

`main()` guesses the address of `f()`’s local variable, passing it in as a pointer, and `f()` checks it before using it for an access. Here we see, for example, GCC `-O0` optimising away the `if` and the write `*p=7`, even in executions where the `ADDRESS_PFI_1PG` constant is the same as the `printf`’d address of `j`. We believe that compiler behaviour should be permitted, and hence that this program should be deemed to have UB — or, in other words, that code should not normally be allowed to rely on implementation facts about the allocation addresses of C variables.

The PNVI-\* semantics deems this to be UB, because at the point of the `(int*)i` cast the `j` storage instance does not yet exist (let alone, for PNVI-ae and PNVI-ae-udi, having been exposed by having one of its addresses taken and cast to integer), so the cast gives a pointer with empty provenance; any execution that goes into the `if` would thus flag UB. The PVI semantics flags UB for the simple reason that `j` is created with the empty provenance, and hence `p` inherits that.

Varying to do the cast to `int*` in `f()` instead of `main()`, passing in an integer `i` instead of a pointer, this becomes defined in PNVI-plain, as `j` exists at the point when the abstract machine does the `(int*)i` cast. But in PNVI-ae and PNVI-ae-udi, the storage instance of `j` is not exposed, so the cast to `int*` gives a pointer with empty provenance and the access via it is UB. This example is also UB in PVI.

At present we do not see any strong reason why making this defined would not be acceptable — it amounts to requiring compilers to be conservative for the results of integer-to-pointer casts where they cannot see the source of the integer, which we imagine to be a rare case — but this does not match current `O2` or `O3` compilation for GCC, Clang, or ICC.

```
// pointer_from_integer_1pg.c
1 #include <stdio.h>
2 #include <stdint.h>
3 #include "charon_address_guesses.h"
4 void f(int *p) {
5     int j=5;
6     if (p==&j)
7         *p=7;
8     printf("j=%d &j=%p\n",j,(void*)&j);
9 }
10 int main() {
11     uintptr_t i = ADDRESS_PFI_1PG;
12     int *p = (int*)i;
13     f(p);
14 }
```

```
// pointer_from_integer_1ig.c
1 #include <stdio.h>
2 #include <stdint.h>
3 #include "charon_address_guesses.h"
4 void f(uintptr_t i) {
5     int j=5;
6     int *p = (int*)i;
7     if (p==&j)
8         *p=7;
9     printf("j=%d &j=%p\n",j,(void*)&j);
10 }
11 int main() {
12     uintptr_t j = ADDRESS_PFI_1IG;
13     f(j);
14 }
```

**Allocation-address nondeterminism** Note that both of the previous examples take the address of `j` to guard their `*p=7` accesses. Removing the conditional guards gives the left and middle tests below, that one would surely like to forbid:

<pre> 1 // pointer_from_integer_1p.c 2 #include &lt;stdio.h&gt; 3 #include &lt;stdint.h&gt; 4 #include " 5     charon_address_guesses.h" 6 void f(int *p) { 7     int j=5; 8     *p=7; 9     printf("j=%d\n",j); 10 } 11 int main() { 12     uintptr_t i = ADDRESS_PFI_1P 13     ; 14     int *p = (int*)i; 15     f(p); 16 } </pre>	<pre> 1 // pointer_from_integer_1i.c 2 #include &lt;stdio.h&gt; 3 #include &lt;stdint.h&gt; 4 #include " 5     charon_address_guesses.h" 6 void f(uintptr_t i) { 7     int j=5; 8     int *p = (int*)i; 9     *p=7; 10    printf("j=%d\n",j); 11 } 12 int main() { 13     uintptr_t j = 14     ADDRESS_PFI_1I; 15     f(j); 16 } </pre>	<pre> 1 // pointer_from_integer_1ie.c 2 #include &lt;stdio.h&gt; 3 #include &lt;stdint.h&gt; 4 #include " 5     charon_address_guesses.h" 6 void f(uintptr_t i) { 7     int j=5; 8     uintptr_t k = (uintptr_t)&amp;j 9     ; 10    int *p = (int*)i; 11    *p=7; 12    printf("j=%d\n",j); 13 } 14 int main() { 15     uintptr_t j = 16     ADDRESS_PFI_1I; 17     f(j); 18 } </pre>
--	---	--

Both are forbidden in PVI for the same reason as before, and the first is forbidden in PNVI\*, again because `j` does not exist at the cast point.

But the second forces us to think about how much allocation-address nondeterminism should be quantified over in the basic definition of undefined behaviour. For evaluation-order and concurrency nondeterminism, one would normally say that if there exists any execution that flags UB, then the program as a whole has UB (for the moment ignoring UB that occurs only on some paths following I/O input, which is another important question that the current ISO text does not address).

This view of UB seems to be unfortunate but inescapable. If one looks just at a single execution, then (at least between input points) we cannot temporally bound the effects of an UB, because compilers can and do re-order code w.r.t. the C abstract machine's sequencing of computation. In other words, UB may be flagged at some specific point in an abstract-machine trace, but its consequences on the observed implementation behaviour might happen much earlier (in practice, perhaps not very much earlier, but we do not have any good way of bounding how much). But then if one execution might have UB, and hence exhibit (in an implementation) arbitrary observable behaviour, then anything the standard might say about any other execution is irrelevant, because it can always be masked by that arbitrary observable behaviour.

Accordingly, our semantics nondeterministically chooses an arbitrary address for each storage instance, subject only to alignment and no-overlap constraints (ultimately one would also need to build in constraints from programmer linking commands). This is equivalent to noting that the ISO standard does not constrain how implementations choose storage instance addresses in any way (subject to alignment and no-overlap), and hence that programmers of standard-conforming code cannot assume anything about those choices. Then in PNVI-plain, the `..._1i.c` example is UB because, even though there is one execution in which the guess is correct, there is another (in fact many others) in which it is not. In those, the cast to `int*` gives a pointer with empty provenance, so the access flags UB — hence the whole program is UB, as desired. In PNVI-ae and PNVI-ae-udi, the `..._1i.c` example is UB for a different reason: the storage instance of `j` is not exposed before the cast `(int*)i`, and so the result of that cast has empty provenance and the access `*p=7` flags UB, in every execution. However, if `j` is exposed, as in the example on the right, these models still make it UB, now for the same reason as PNVI-plain.

**Can a function access local variables of its parent?** This too should be forbidden in general. The example on the left below is forbidden by PVI, again for the simple reason that `p` has the empty provenance, and by

<pre> 1 // pointer_from_integer_2.c 2 #include &lt;stdio.h&gt; 3 #include &lt;stdint.h&gt; 4 #include "charon_address_guesses.h" 5 void f() { 6     uintptr_t i=ADDRESS_PFI_2; 7     int *p = (int*)i; 8     *p=7; 9 } 10 int main() { 11     int j=5; 12     f(); 13     printf("j=%d\n",j); 14 } </pre>	<pre> 1 // pointer_from_integer_2g.c 2 #include &lt;stdio.h&gt; 3 #include &lt;stdint.h&gt; 4 #include "charon_address_guesses.h" 5 void f() { 6     uintptr_t i=ADDRESS_PFI_2G; 7     int *p = (int*)i; 8     *p=7; 9 } 10 int main() { 11     int j=5; 12     if ((uintptr_t)&amp;j == ADDRESS_PFI_2G) 13         f(); 14     printf("j=%d &amp;j=%p\n",j,(void*)&amp;j); 15 } </pre>
---	---

PNVI-plain by allocation-address nondeterminism, as there exist abstract-machine executions in which the guessed address is wrong. One cannot guard the access within `f()`, as the address of `j` is not available there. Guarding the call to `f()` with `if ((uintptr_t)&j == ADDRESS_PFI_2)` (`pointer_from_integer_2g.c` on the right above) again makes the example well-defined in PNVI-plain, as the address is correct and `j` exists at the `int*` cast point, but notice again that the guard necessarily involves `&j`. This does not match current Clang at O2 or O3, which print `j=5`.

In PNVI-ae and PNVI-ae-udi, `pointer_from_integer_2.c` is forbidden simply because `j` is never exposed (and if it were, it would be forbidden for the same reason as in PNVI-plain). PNVI-ae and PNVI-ae-udi allow `pointer_from_integer_2g.c`, because the `j` storage instance is exposed by the `(uintptr_t)&j` cast.

**The PNVI-address-taken and PNVI-wildcard alternatives** A different obvious refinement to PNVI would be to restrict integer-to-pointer casts to recover the provenance only of objects that have had their address taken, recording that in the memory state. PNVI-address-exposed is based on PNVI-address-taken but with the tighter condition that the address must also have been cast to integer.

A rather different model is to make the results of integer-to-pointer casts have a “wildcard” provenance, deferring the check that the address matches a live object from cast-time to access-time. This would make `pointer_from_integer_1pg.c` defined, which is surely not desirable.

Perhaps surprisingly, the PNVI-ae and PNVI-ae-udi variants seem not to make much difference to the allowed tests, because the tests one might write tend to already be UB due to allocation-address nondeterminism, or to already take the address of an object to use it in a guard. These variants do have the conceptual advantage of identifying these UBs without requiring examination of multiple executions, but the disadvantage that whether an address has been taken is a fragile syntactic property, e.g. not preserved by dead code elimination.

**The problem with lost address-takens and escapes** Our PVI proposal allows computations that erase the numeric value (and hence a concrete view of the “semantic dependencies”) of a pointer, but retain provenance. This makes examples like that below [Richard Smith, personal communication], in which the code correctly guesses a storage instance address (which has the empty provenance) and adds that to a zero-valued quantity (with the correct provenance), allowed in PVI. We emphasise that we do not think it especially desirable to allow such examples; this is just a consequence of choosing a straightforward provenance-via-integer semantics that allows the bitwise copying and the bitwise manipulation of pointers above. In other words, it is not clear how it could be forbidden simply in PVI.

However, in implementations some algebraic optimisations may be done before alias analysis, and those optimisations might erase the `&x`, replacing it and all the calculation of `i3` by `0x0` (a similar example would have `i3 = i1-i1`). But then alias analysis would be unable to see that `*q` could access `x`, and so report that it could not, and hence enable subsequent optimisations that are unsound w.r.t. PVI for this case. The basic point is that whether a variable has its address taken or escaped in the source language is not preserved by optimisation.

```

1 // provenance_lost_escape_1.c
2 #include <stdio.h>
3 #include <string.h>
4 #include <stdint.h>
5 #include "charon_address_guesses.h"
6 int x=1; // assume allocation ID @1, at ADDR_PLE_1
7 int main() {
8     int *p = &x;
9     uintptr_t i1 = (intptr_t)p; // (@1, ADDR_PLE_1)
10    uintptr_t i2 = i1 & 0x00000000FFFFFFFF; //
11    uintptr_t i3 = i2 & 0xFFFFFFFF00000000; // (@1, 0x0)
12    uintptr_t i4 = i3 + ADDR_PLE_1; // (@1, ADDR_PLE_1)
13    int *q = (int *)i4;
14    printf("Addresses: p=%p\n", (void*)p);
15    if (memcmp(&i1, &i4, sizeof(i1)) == 0) {
16        *q = 11; // does this have defined behaviour?
17        printf("x=%d *p=%d *q=%d\n", x, *p, *q);
18    }
19 }

```

A possible solution, which would need some implementation work for

implementations that do track provenance through integers, but perhaps acceptably so, would be to require those initial optimisation passes to record the address-takens involved in computations they erase, so that that could be passed in explicitly to alias analysis. In contrast to the difficulties of preserving dependencies to avoid thin-air concurrency, this does not forbid optimisations that remove dependencies; it merely requires them to describe what they do.

In PNVI-plain, the example is also allowed, but for a simpler reason that is not affected by such integer optimisation: the object exists at the `int*` cast. Implementations that take a conservative view of all pointers formed from integers would automatically be sound w.r.t. this. At present ICC is not, at O2 or O3.

PNVI-ae and PNVI-ae-udi are more like PVI here: they allow the example, but only because the address of `p` is both taken and cast to an integer type. If these semantics were used for alias analysis in an intermediate language after such optimisation, this would likewise require the optimisation passes to record which addresses have been taken and cast to integer (or otherwise exposed) in eliminated code, to be explicitly passed in to alias analysis.

**Should PNVI allow one-past integer-to-pointer casts?** For PNVI\*, one has to choose whether an integer that is one-past a live object (and not strictly within another) can be cast to a pointer with valid provenance, or whether this should give an empty-provenance pointer value. Lee observes that the latter may be necessary to make some optimisation sound [personal communication], and we imagine that this is not a common idiom in practice, so for PNVI-plain and PNVI-ae we follow the stricter semantics.

PNVI-ae-udi, however, is designed to permit a cast of a one-past pointer to integer and back to recover the original provenance, replacing the integer-to-pointer semantic check that `x` is properly within the footprint of the storage instance by a check that it is properly within or one-past. That makes the following example allowed in PNVI-ae-udi, while it is forbidden in PNVI-ae and PNVI-plain.

```

// provenance_roundtrip_via_intptr_t_onepast.c
1 #include <stdio.h>
2 #include <inttypes.h>
3 int x=1;
4 int main() {
5     int *p = &x;
6     p=p+1;
7     intptr_t i = (intptr_t)p;
8     int *q = (int *)i;
9     q=q-1;
10    *q = 11; // is this free of undefined behaviour?
11    printf(" *p=%d *q=%d\n", *p, *q);
12 }

```

The downside of this is that one has to handle pointer-to-integer casts for integer values that are ambiguously both one-past one storage instance and at the start of the next. The PNVI-ae-udi approach to that is to leave the provenance of pointer values resulting from such casts unknown until the first operation (e.g. an access, pointer arithmetic, or pointer relational comparison) that disambiguates them. This makes the following two, each of which uses the result of the cast in one consistent way, well defined:

<pre> // pointer_from_int_disambiguation_1.c 1 #include &lt;stdio.h&gt; 2 #include &lt;string.h&gt; 3 #include &lt;stdint.h&gt; 4 #include &lt;inttypes.h&gt; 5 int y=2, x=1; 6 int main() { 7     int *p = &amp;x+1; 8     int *q = &amp;y; 9     uintptr_t i = (uintptr_t)p; 10    uintptr_t j = (uintptr_t)q; 11    if (memcmp(&amp;p, &amp;q, sizeof(p)) == 0) { 12        int *r = (int *)i; 13        *r=11; // is this free of UB? 14        printf("x=%d y=%d *p=%d *q=%d *r=%d\n", x, y, 15              *p, *q, *r); 16    } 17 } </pre>	<pre> // pointer_from_int_disambiguation_2.c 1 #include &lt;stdio.h&gt; 2 #include &lt;string.h&gt; 3 #include &lt;stdint.h&gt; 4 #include &lt;inttypes.h&gt; 5 int y=2, x=1; 6 int main() { 7     int *p = &amp;x+1; 8     int *q = &amp;y; 9     uintptr_t i = (uintptr_t)p; 10    uintptr_t j = (uintptr_t)q; 11    if (memcmp(&amp;p, &amp;q, sizeof(p)) == 0) { 12        int *r = (int *)i; 13        r=r-1; // is this free of UB? 14        *r=11; // and this? 15        printf("x=%d y=%d *p=%d *q=%d *r=%d\n" 16              , x, y, *p, *q, *r); 17    } 18 } </pre>
--	---

while making the following, which tries to use the result of the cast to access both objects, UB.

```
// pointer_from_int_disambiguation_3.c
1  #include <stdio.h>
2  #include <string.h>
3  #include <stdint.h>
4  #include <inttypes.h>
5  int y=2, x=1;
6  int main() {
7      int *p = &x+1;
8      int *q = &y;
9      uintptr_t i = (uintptr_t)p;
10     uintptr_t j = (uintptr_t)q;
11     if (memcmp(&p, &q, sizeof(p)) == 0) {
12         int *r = (int *)i;
13         *r=11;
14         r=r-1; // is this free of UB?
15         *r=12; // and this?
16         printf("x=%d y=%d *p=%d *q=%d *r=%d\n",x,y,*p
17                ,*q,*r);
18     }
```

In this, the `*r=11` will resolve the provenance of the value in one way, making the `r-1` UB.

### A.6 Testing the example behaviour in Cerberus

We have implemented executable versions of the PNVI-plain, PNVI-ae, and PNVI-ae-udi models in Cerberus [MGD<sup>+</sup>19, MML<sup>+</sup>16], closely following the detailed semantics of the accompanying note. This makes it possible to interactively or exhaustively explore the behaviour of the examples, confirming that they are allowed or not as intended.

 grey = Cerberus' allocator doesn't trigger the interesting behaviour

### A.7 Testing the example behaviour in mainstream C implementations

We have also run the examples in various existing C implementations, including GCC and Clang at various optimisation levels.

Our test cases are typically written to illustrate a particular semantic question as concisely as possible. Some are “natural” examples, of desirable C code that one might find in the wild, but many are intentionally pathological or are corner cases, to explore just where the defined/undefined-behaviour boundary is; we are not suggesting that all these should be supported.

Making the tests concise to illustrate semantic questions also means that most are not written to trigger interesting compiler behaviour, which might only occur in a larger context that permits some analysis or optimisation pass to take effect. Moreover, following the spirit of C, conventional implementations cannot and do not report all instances of undefined behaviour. Hence, only in some cases is there anything to be learned from the experimental compiler behaviour. For any executable semantics or analysis tool, on the other hand, all the tests should have instructive outcomes.

Some tests rely on address coincidences for the interesting execution; for these we sometimes include multiple variants, tuned to the allocation behaviour in the implementations we consider. Where this has not been done, some of the experimental data is not meaningful.

The detailed data is available at <https://www.cl.cam.ac.uk/~pes20/cerberus/supplementary-material-pnvi-star/generated.html.pnvi.star/>, and summarised in the table below.

## B Detailed semantics (informative)

This annex gives detailed mathematical semantics for four variants of C provenance semantics:

- **PNVI-plain**: a semantics that does not track provenance via integers, but instead, at integer-to-pointer cast points, checks whether the given address points within a live object and, if so, recreates the corresponding provenance.
- **PNVI-ae (PNVI exposed-address)**: a variant of PNVI that allows integer-to-pointer casts to recreate provenance only for storage instances that have previously been *exposed*. A storage instance is deemed exposed by a cast of a pointer to it to an integer type, by a read (at non-pointer type) of the representation of the pointer, or by an output of the pointer using `%p`.
- **PNVI-ae-udi (PNVI exposed-address user-disambiguation)**: a further refinement of PNVI-ae that supports roundtrip casts, from pointer to integer and back, of pointers that are one-past a storage instance. This is the currently preferred option in the C memory object model study group.
- **PVI**: a semantics that tracks provenance via integer computation, associating a provenance with all integer values (not just pointer values), preserving provenance through integer/pointer casts, and making some particular choices for the provenance results of integer and pointer +/- integer operations; or

We write PNVI-\* for PNVI-plain, PNVI-ae, and PNVI-ae-udi. The PNVI-plain and PVI semantics were described in the POPL 2019/N2311 paper [MGD<sup>+</sup>19]. PNVI-ae and PNVI-ae-udi have emerged from discussions in the C memory object model study group.

Changes for PNVI-ae from PNVI-plain are [highlighted](#). Additional changes for PNVI-ae-udi are [highlighted](#).

This should be read together with the two companion notes, one giving a series of examples (N2363), and another giving detailed diffs to the C standard text (N2362).

The PNVI-ae and PNVI-ae-udi variants of PNVI permit bitwise copy of a pointer to an initially unexposed object, but leaves it marked as exposed. Additional machinery may well be desirable for PNVI-ae and PNVI-ae-udi to give programmers more control of the provenance of the results of byte manipulations, and of what is left marked as exposed. The design of that machinery should ideally be based on the treatment of representation-byte-accessed pointer values by existing compiler alias analyses and optimisations.

### B.1 The PNVI-ae-udi, PNVI-ae, PNVI-plain, and PVI semantics

These semantic definitions are manually typeset mathematics simplified from the executable-as-test-oracle Cerberus source (expressed in the pure-functional Lem [MOG<sup>+</sup>14] definition language). We have removed most subobject details, function pointers, and some options. Neither the typeset models or the Lem source consider linking, or pointers constructed via I/O (e.g. via `%p` or representation-byte I/O).

The memory object semantics can be combined with a semantics for the thread-local semantics of the rest of C (expressed in Cerberus as a translation from C source to the *Core* intermediate language, together with an operational semantics for Core) to give a complete semantics for a large fragment of sequential C.

For simplicity, we assume that pointer representations are the two's complement representation of their addresses (and identical to the two's complement representations of their conversions to sufficiently wide integer types), assume NULL pointers have address (and representation) 0, and allow NULL pointers to be constructed from any empty-provenance integer zero, not just integer constant expressions.

At present, the mathematical model does not include the ISO semantics that makes all pointers to an object or region invalid at the end of its lifetime, and it permits equality comparison between pointers irrespective of whether the objects of their provenances are live, but it does permit pointer subtraction, relational comparison, array offset, member offset, and casts to integer only for pointers to live objects for which the address is within or one past the object footprint. These are all debatable choices. One could instead check only that the addresses are within or one past the original object footprint (and not check the object is live), or go further towards a concrete-address view of pointer values and not check that either. Sketching out some of the options:

- **ZOMBIE-POINTERS-BECOME-INDETERMINATE** For the current ISO semantics, at the end of every storage instance's lifetime any pointer value referring to it becomes invalid. After that, every memory footprint containing a pointer value with that provenance (result of the store of such a pointer value) has an indeterminate representation. With this, the live-object evaluations and checks for equality, relational comparison, subtraction, array offset member offset, and casts to integers all become moot.
- **ZOMBIE-POINTERS-ALLOW-EQUALITY-ONLY** This is what the maths below details.
- **ZOMBIE-POINTERS-ALLOW-ALL-IN-BOUNDS-ARITHMETIC** For this, we would retain metadata for the bounds of lifetime-ended pointers and check against that for non-load/store operations.

- **ZOMBIE-POINTERS-ALLOW-ALL-ARITHMETIC** For this, we would remove the lifetime and bounds checks for non-load/store operations.
- **ALL-POINTERS-ALLOW-ALL-ARITHMETIC** This would make all the non-load/store operations operate just on abstract addresses, ignoring provenance and storage instance metadata.

### B.1.1 The memory object model interface

In Cerberus, the memory object model is factored out from Core with a clean interface, roughly as in [MML<sup>+</sup>16, Fig. 2]. This provides functions for memory operations:

- `allocate_object` (for objects with automatic or static storage duration, i.e. global and local variables),
- `allocate_region` (for the results of `malloc`, `calloc`, and `realloc`, i.e. heap-allocated regions),
- `kill` (for lifetime end of both kinds of allocation),
- `load`, and
- `store`,

and for pointer/integer operations: arithmetic, casts, comparisons, offsetting pointers by struct-member offsets, etc. The interface involves types `pointer_value` ( $p$ ), `integer_value` ( $x$ ), `floating_value`, and `mem_value` ( $v$ ), which are abstract as far as Core is concerned. Distinguishing pointer and integer values gives more precise internal types.

In PNVI-ae, PNVI, and PVI, a provenance  $\pi$  is either `@i` where  $i$  is a storage-instance ID, or the *empty* provenance `@empty`. In PNVI-ae-udi a provenance can also be a symbolic storage instance ID  $\iota$  (iota), initially associated to two storage instance IDs and later resolved to one or the other.

A pointer value can either be `null` or a pair  $(\pi, a)$  of a provenance  $\pi$  and address  $a$ . In PNVI\*, an integer value is simply a mathematical integer (within the appropriate range for the relevant C type), while in PVI, an integer value is a pair  $(\pi, n)$  of a provenance  $\pi$  and a mathematical integer  $n$ .

Memory values are the storable entities, either a pointer, integer, floating-point, array, struct, or union value, or `unspec` for unspecified values, each together with their C type.

## B.2 The memory object model state

In both PVI and PNVI\*, a memory state is a pair  $(A, M)$ . The  $A$  is a partial map from storage-instance IDs to either `killed` or storage-instance metadata  $(n, \tau_{\text{opt}}, a, f, k, t)$ :

- size  $n$ ,
- optional C type  $\tau$  (or `none` for allocated regions),
- base address  $a$ ,
- permission flag  $f \in \{\text{readWrite}, \text{readOnly}\}$ ,
- kind  $k \in \{\text{object}, \text{region}\}$ , and
- for PNVI-ae and PNVI-ae-udi, a taint flag  $t \in \{\text{unexposed}, \text{exposed}\}$ .

In PNVI-ae-udi,  $A$  also maps all symbolic storage instance IDs  $\iota$ , to sets of either one or two (non-symbolic) storage instance IDs. One might also need to record a partial equivalence relation over symbolic storage instance IDs, to cope with the pointer subtraction and relational comparison cases where one learns that two provenances are equal but both remain ambiguous, but that is debatable and not spelt out in this document.

The  $M$  is a partial map from addresses to abstract bytes, which are triples of a provenance  $\pi$ , either a byte  $b$  or `unspec`, and an optional integer pointer-byte index  $j$  (or `none`). The last is used in PNVI\* to distinguish between loads of pointer values that were written as whole pointer writes vs those that were written byte-wise or in some other way.

### B.2.1 Mappings between abstract values and representation abstract-byte sequences

The  $M$  models the memory state in terms of low-level abstract bytes, but `store` and `load` take and return the higher-level memory values. We relate the two with functions `repr(v)`, mapping a memory value to a list of abstract bytes, and `abst( $\tau, bs$ )`, mapping a list of abstract bytes  $bs$  to its interpretation as a memory value with C type  $\tau$ .

The `repr(v)` function is defined by induction over the structure of its memory value parameter and returns a list of `sizeof( $\tau$ )` abstract bytes, where  $\tau$  is the C type of the parameter. The base cases are values with scalar types (integer, floating and pointers) and unspecified values. For an unspecified value of type  $\tau$ , it returns a list with

abstract bytes of the form (`@empty`, `unspec`, `none`). Non-null pointer values are represented with lists of abstract bytes that each have the provenance of the pointer value, the appropriate part of the two's complement encoding of the address, and the  $0..sizeof(\tau) - 1$  index of each byte. Null pointers are represented with lists of abstract bytes of the form (`@empty`, `0`, `none`). In PVI, integer values are represented similarly to pointer values except that the third component of each abstract byte is `none`. In PNVI\*, integer values are represented by lists of abstract bytes, with each of their first components always the empty provenance, and each of their third components again `none`. Floating-point values are similar, in all the models, except that the provenance of the abstract bytes is always empty. For array and struct/union values the function is inductively applied to each subvalue and the resulting byte-lists concatenated. The layout of structs and unions follow an implementation-defined ABI, with padding bytes like those of unspecified values.

The  $abst(\tau, bs)$  function is defined by induction over  $\tau$ . The base cases are again the scalar types. For these,  $sizeof(\tau)$  abstract bytes are consumed from  $bs$  and a scalar memory value is constructed from their second components: if any abstract byte has an `unspec` value, an unspecified value is constructed; otherwise, depending on  $\tau$ , a pointer, integer or floating-point value is constructed using the two's complement or floating-point encoding. For pointers with address 0, the provenance is empty. For non-0 pointer values and integer values, in PVI the provenance is constructed as follows: if at least one abstract byte has non-empty provenance and all others have either the same or empty provenance, that provenance is taken, otherwise the empty provenance is taken. In PNVI\*, when constructing a pointer value, if the third components of the bytes all carry the appropriate index, and all have the same provenance (which will be guaranteed if pointer types all have the same size), the provenance of the result is that provenance. Otherwise, the  $A$  part of the memory state is examined to find whether a live storage instance exists with a footprint containing the pointer value that is being constructed. If so, in PNVI-plain, its storage instance ID is used for the provenance of the pointer value, otherwise the empty provenance is used. In PNVI-ae and PNVI-ae-udi, when constructing a pointer value, if  $A$  has to be examined then, matching the relevant integer-to-pointer cast semantics below, the storage instance must have been exposed, otherwise the result have the empty provenance. In PNVI-ae-udi, if there are two such live storage instances, with IDs  $i_1$  and  $i_2$ , the resulting pointer value is given a fresh symbolic storage instance ID  $\iota$ , and  $A$  is updated to map  $\iota$  to  $\{i_1, i_2\}$ . This can only happen if the two storage instances are adjacent and the address is one-past the first and at the start of the second. For array/struct types,  $abst()$  recurses on the progressively shrinking list of abstract bytes.

### B.2.2 Memory operations

The successful semantics of memory operations is expressed as a transition relation between memory states, with transitions labelled by the operation (including its arguments) and return value:

$$(A, M) \xrightarrow{\text{LABEL}} (A', M')$$

For example, the transitions

$$(A, M) \xrightarrow{\text{load}(\tau, p)=v} (A', M')$$

describe the semantics of a  $\text{load}(\tau, p)$  in memory state  $(A, M)$ , returning value  $v$  and with resulting memory state  $(A', M')$ . The semantics also defines when each operation flags an out-of-memory (OOM) or undefined behaviour (UB) in a memory state  $(A, M)$ .

**Storage instance creation** When a new storage instance is created, either with `allocate_region` (for the results of `malloc`, `calloc`, and `realloc`, i.e. heap-allocated regions), or with `allocate_object` (for objects with automatic or static storage duration, i.e. global and local variables), in non-`const` and `const` variants: a fresh storage-instance ID  $i$  is chosen; an address  $a$  is chosen from  $\text{newAlloc}(A, al, n)$ , defined to be the set of addresses of blocks of size  $n$  aligned by  $al$  that do not overlap with 0 or any other allocation in  $A$ ; and the pointer value  $p = (@i, a)$  is returned. In all three cases the storage-instance metadata  $A$  is updated with a new record for  $i$ , and this is initially marked as `unexposed`. In the `allocate_object` case the size  $n$  of the allocation is the representation size of the C type  $\tau$ . In the `allocate_region(al,  $\tau$ , readOnly( $v$ ))` case, the last of the three rules, the memory  $M$  is updated to contain the

representation of  $v$  at the addresses  $a..a + \text{sizeof}(\tau) - 1$ .

$$\begin{array}{c}
\text{[LABEL: allocate\_region}(al, n) = p] \\
i \notin \text{dom}(A) \quad a \in \text{newAlloc}(A, al, n) \\
p = (@i, a) \\
\hline
A, M \rightarrow A[i \mapsto (n, \text{none}, a, \text{readWrite}, \text{region}, \text{unexposed})], M \\
\\
\text{[LABEL: allocate\_object}(al, \tau, \text{readWrite}) = p] \\
i \notin \text{dom}(A) \quad a \in \text{newAlloc}(A, al, n) \\
n = \text{sizeof}(\tau) \quad p = (@i, a) \\
\hline
A, M \rightarrow A(i \mapsto (n, \tau, a, \text{readWrite}, \text{object}, \text{unexposed})), M \\
\\
\text{[LABEL: allocate\_object}(al, \tau, \text{readOnly}(v)) = p] \\
i \notin \text{dom}(A) \quad a \in \text{newAlloc}(A, al, n) \\
n = \text{sizeof}(\tau) \quad p = (@i, a) \\
\hline
A, M \rightarrow A(i \mapsto (n, \tau, a, \text{readOnly}, \text{object}, \text{unexposed})), M([a..a + n - 1] \mapsto \text{repr}(v))
\end{array}$$

**Storage instance lifetime end** When the storage instance of a pointer value  $(@i, a)$  is killed, either by a `free()` for a heap-allocated region or at the end of lifetime of an object with automatic storage duration, the storage-instance metadata  $A$  of storage instance  $i$  is updated to record that  $i$  has been killed.

$$\begin{array}{c}
\text{[LABEL: kill}(p, k)] \\
p = (@i, a) \quad k = k' \\
A(i) = (n, -, a, f, k', -) \\
\hline
A, M \rightarrow A(i \mapsto \text{killed}), M
\end{array}$$

**Load** To load a value  $v$  of type  $\tau$  from a pointer value  $p = (@i, a)$ , there must be a live storage instance for  $i$  in  $A$ , the footprint of  $\tau$  at  $a$  must be within the footprint of that allocation, and the value  $v$  must be the abstract value obtained from the appropriate memory bytes from  $M$ .

$$\begin{array}{c}
\text{[LABEL: load}(\tau, p) = v] \\
p = (@i, a) \quad A(i) = (n, -, a', f, k, -) \\
[a..a + \text{sizeof}(\tau) - 1] \subseteq [a'..a' + n - 1] \\
v = \text{abst}(\tau, M[a..a + \text{sizeof}(\tau) - 1]) \\
\hline
A, M \rightarrow A, M
\end{array}$$

For PNVI-ae and PNVI-ae-udi, if the recursive-on- $\tau$  computation of  $\text{abst}(\tau, M[a..a + \text{sizeof}(\tau) - 1])$  involves a call of `abst` at any non-pointer scalar type for a region of  $M$  including an abstract byte with non-empty provenance, and the corresponding storage instance is live, it is marked as exposed. This applies e.g. for reads of pointer values via `char*` pointers, and for union type punning reads at `uintptr_t` of pointer values.

**Store** To store a value  $v$  of type  $\tau$  to a pointer value  $p = (@i, a)$ , there must be a live storage instance for  $i$  in  $A$ , which must be writable, and the footprint of  $\tau$  at  $a$  must be within the footprint of that allocation. The memory  $M$  is updated with the representation bytes of the value  $v$ .

$$\begin{array}{c}
\text{[LABEL: store}(\tau, p, v)] \\
p = (@i, a) \quad A(i) = (n, -, a', \text{readWrite}, k, -) \\
[a..a + \text{sizeof}(\tau) - 1] \subseteq [a'..a' + n - 1] \\
\hline
A, M \rightarrow A, M([a..a + \text{sizeof}(\tau) - 1] \mapsto \text{repr}(v))
\end{array}$$

For PNVI-ae-udi, the kill, load, and store rules above must be adapted. If  $p = (\iota, a)$  and  $A(\iota) = \{i\}$ , the other premises and conclusion of the appropriate above rule apply. If  $A(\iota) = \{i_1, i_2\}$  and the premises are satisfied for one of the two, say  $i_j$ , the rest of the rule applies except that in the final state  $A$  is additionally updated to map  $\iota$  to  $\{i_j\}$ .

The memory operations flag out-of-memory (OOM) and undefined behaviour (UB) as follows:

allocate_region( $al, n$ ) / allocate_object( $al, \tau, \text{readwrite}$ ) / allocate_object( $al, \tau, \text{readOnly}(v)$ ):	
OOM out of memory	if $\text{newAlloc}(A, al, n) = \{\}$ or $\text{newAlloc}(A, al, \text{sizeof}(\tau)) = \{\}$
load( $\tau, p$ ) / store( $\tau, p, v$ ) / kill( $p$ ):	
UB null pointer	if $p = \text{null}$
UB empty provenance	if $p = (@\text{empty}, a)$
UB killed provenance	if $p = (@i, a)$ and $A(i) = \text{killed}$
load( $\tau, p$ ) / store( $\tau, p, v$ ):	
UB out of bounds	if $p = (@i, a)$ , $A(i) = (n, -, a', f, k, -)$ , and $[a..a + \text{sizeof}(\tau) - 1] \not\subseteq [a'..a' + n - 1]$
store( $\tau, p, v$ ):	
UB read-only	if $p = (@i, a)$ and $A(i) = (n, -, a', \text{readOnly}, k, -)$
kill( $p$ ):	
UB non-alloc-address	if $p = (@i, a)$ , $A(i) = (n, -, a', f, k, -)$ , and $a \neq a'$

For PNVI-ae-udi, the rules above must be adapted. In the case where  $p = (\iota, a)$  and  $A(\iota) = \{i\}$ , the semantics is exactly as for  $p = (i, a)$ , while if  $A(\iota) = \{i_1, i_2\}$ , one has UB only if the conditions above apply to both  $i_1$  and  $i_2$ .

### B.2.3 Pointer / Integer operations

**Pointer subtraction** Pointers  $p = (@i, a)$  and  $p' = (@i', a')$  can be subtracted if they have the same provenance ( $i = i'$ ), there is a live storage instance for  $i$  in  $A$ , and both  $a$  and  $a'$  are within or one-past the footprint of that allocation (in ISO C the last will always hold, otherwise UB would have been flagged in earlier pointer arithmetic). Otherwise UB. The result is the numerical difference  $a - a'$  divided by  $\text{sizeof}(\text{dearray}(\tau))$ , where  $\text{dearray}(\tau)$  returns  $\tau$  if it is not an array type, and otherwise returns its element type. Note that this disallows subtraction for which one or both arguments are null pointers, which is the ISO semantics but may be a debatable choice.

This rule is stated for PNVI and PNVI-ae, returning pure integer. For PVI,  $\text{diff_ptrval}$  constructs the same integer but with  $@\text{empty}$  provenance. For PNVI-ae-udi, because subtraction of pointers with different provenance should be UB:

- if both the two pointers have either a provenance  $@i$  (resp.  $@i'$ ) or a symbolic storage instance ID  $\iota$  (resp.  $\iota'$ ) mapped by  $A$  to a singleton  $\{i\}$  (resp.  $\{i'\}$ ), then  $i = i'$ , otherwise UB.
- if one of the two pointers has a symbolic storage instance ID  $\iota$ , mapped by  $A$  to  $\{i_1, i_2\}$ , while the other either has a provenance  $@i'$  or an  $\iota'$  mapped to a singleton  $\{i'\}$ , then  $i'$  must be either  $i_1$  or  $i_2$ , and  $\iota$  is resolved to that in the  $A$  of the final state. Otherwise UB.
- If both pointers are ambiguous, say mapped to  $\{i_1, i_2\}$  and  $\{i'_1, i'_2\}$ , then if those two sets share exactly one element which satisfies the other rule preconditions, both symbolic storage instance IDs are resolved to that. Otherwise UB.
- If both pointers are ambiguous and those sets share two elements that satisfy the other conditions (which we believe can only happen if the addresses are equal), then subtraction is permitted but the symbolic storage instance IDs are left unresolved. Otherwise UB.

For example, suppose  $p$  and  $q$  have been produced by separate casts from an integer which is ambiguously one-past one allocation and at the start of another. Then after  $p - q$  or  $p < q$  we know they must have been the same provenance, but we still don't know which. (Alternatively, we could change the semantics to record an identity relation over symbolic storage instance IDs, and additional modifications to the rules below beyond what is in this draft, but that seems to be unwarranted complexity).

$$\frac{\begin{array}{l} \text{[LABEL: diff_ptrval}(\tau, p, p') = x] \\ p = (@i, a) \quad p' = (@i', a') \quad i = i' \quad A(i) = (n, -, \hat{a}, f, k, -) \\ x = (a - a') / \text{sizeof}(\text{dearray}(\tau)) \quad a \in [\hat{a}.. \hat{a} + n] \quad a' \in [\hat{a}.. \hat{a} + n] \end{array}}{A, M \rightarrow A, M}$$

**Pointer relational comparison** Pointers  $p = (@i, a)$  and  $p' = (@i', a')$  can be compared with a relational operator ( $<$ ,  $<=$ , etc.) if they have the same provenance ( $i = i'$ ). The result is the boolean result of the mathematical comparison of  $a$  and  $a'$ . To make this analogous to pointer subtraction, we also require (though this is debatable) that there is a live storage instance for  $i$  in  $A$ , and both  $a$  and  $a'$  are within or one-past the footprint of that allocation. Otherwise UB. Note that this disallows relational comparison against null pointers; a debatable choice. For PNVI-ae-udi, this has to be adapted in much the same way as the pointer subtraction rule above.

$$\frac{\begin{array}{l} \text{[LABEL: rel_op_ptrval}(p, p', op) = b] \\ p = (@i, a) \quad p' = (@i', a') \quad i = i' \quad A(i) = (n, -, \hat{a}, f, k, -) \\ b = op(a, a') \quad a \in [\hat{a}.. \hat{a} + n] \quad a' \in [\hat{a}.. \hat{a} + n] \quad op \in \{\leq, <, >, \geq\} \end{array}}{A, M \rightarrow A, M}$$

Relational comparison is used in practice between pointers to different objects. A variant which would allow that, which we call `ALLOW-INTER-OBJECT-RELATIONAL-OPERATORS TRUE`, removes the  $i = i'$  test above and (in the `ZOMBIE-POINTERS-BECOME-INDETERMINATE` and `ZOMBIE-POINTERS-ALLOW-EQUALITY-ONLY` variants) additionally checks that  $i'$  maps to a live object with in-range address.

**Pointer equality comparison** Pointers  $p$  and  $p'$  can always be compared with an equality operator ( $=$ ,  $!=$ ). The result is true if they are either both null or both non-null and have the same provenance and address; nondeterministically either  $a = a'$  or false if they are both non-null and have different provenances; and false otherwise. For PNVI-ae-udi, because equality comparison is permitted (without UB) irrespective of the provenances of the pointers, if the two pointers both have determined single provenances after looking up any symbolic IDs in  $A$ , this should give true, otherwise the middle (nondeterministic) clause should apply. The final  $A$  should not resolve any symbolic IDs.

$$\frac{[\text{LABEL: eq\_op\_ptrval}(p, p') = b] \begin{cases} b = \text{true} & \text{if } p = p' \\ b \in \{(a = a'), \text{false}\} & \text{if } p = (\pi, a), p' = (\pi', a'), \text{ and } \pi \neq \pi' \\ b = \text{false} & \text{otherwise} \end{cases}}{A, M \rightarrow A, M}$$

Note that the above nondeterminism appears to be necessary to admit the observable behaviour of current compilers, but a simpler provenance-oblivious semantics is arguably desirable:

$$\frac{[\text{LABEL: eq\_op\_ptrval}(p, p') = b] \begin{cases} b = \text{true} & \text{if } p = p' = \text{null} \\ b = \text{true} & \text{if } p = (\pi, a), p' = (\pi', a'), \text{ and } a = a' \\ b = \text{false} & \text{otherwise} \end{cases}}{A, M \rightarrow A, M}$$

We call these two options `POINTER-EQUALITY-PROVENANCE-NONDET TRUE` and `FALSE`.

**Pointer array offset** Given a pointer  $p$  at C type  $\tau$ , the result of offsetting  $p$  by integer  $x$  (either by array indexing or explicit pointer/integer addition) is as follows, where  $x = n$  in PNVI\*, or  $x = (\pi', n)$  in PVI. For the operation to succeed,  $p$  must be some non-null  $(@i, a)$ . Then there must be a live storage instance for  $i$ , and the numeric result of the addition of  $a + n * \text{sizeof}(\tau)$  must be within or one-past the footprint of that storage instance. Otherwise the operation flags UB. For PNVI-ae-udi, if  $p$  is ambiguous (i.e.,  $p = (\iota, a)$  and  $A(\iota) = \{i_1, i_2\}$  then if  $x$  is non-zero this should only be defined behaviour for (at most) one of the two, and then  $\iota$  should be resolved to that one in the final state. If  $x = 0$  it does not resolve the ambiguity.

$$\text{iso\_array\_offset\_ptrval}(A, p, \tau, x) = \begin{cases} (@i, a') & \begin{array}{l} \text{if } p = (@i, a) \text{ and} \\ a' = a + n * \text{sizeof}(\tau) \text{ and} \\ A(i) = (n'', -, a'', -, -, -) \text{ and} \\ a' \in [a''..a'' + n''] \end{array} \\ \text{UB: out of bounds} & \text{if all except the last conjunct} \\ & \text{above hold} \\ \text{UB: empty prov} & \text{if } p = (@\text{empty}, a) \\ \text{UB: killed prov} & \text{if } p = (@i, a) \text{ and } A(i) = \text{killed} \\ \text{UB: null pointer} & \text{if } p = \text{null} \end{cases}$$

**Pointer member offset** Given a non-null pointer  $p$  at C type  $\tau$ , which points to the start of a struct or union type object (ISO C suggests this has to exist, writing “The value is that of the named member of the object to which the first expression points”) with a member  $m$ , if  $p$  is  $(\pi, a)$ , the result of offsetting the pointer to member  $m$  has the same provenance  $\pi$  and the suitably offset  $a$ .

If  $p$  is null, the result is a pointer with empty provenance and the integer offset of  $m$  within  $\tau$ 's representation (this is de facto C behaviour, in the sense that the GCC torture tests rely on it; it does not exactly match ISO C).

For the first case,  $p$  should point to the start of an object of type  $\tau$ , with UB otherwise, but without a subobject-aware effective-type semantics, we cannot check that here. Instead, we just check that there is a live storage instance of  $p$ 's provenance such that the resulting address is within or one-past its a footprint. That makes

this analogous to pointer array offset.

$$\text{member\_offset\_ptrval}(p, \tau, m) = \begin{cases} (\pi, a'), & \begin{array}{l} \text{if } p = (@i, a) \text{ and} \\ a' = a + \text{offsetof\_ival}(\tau, m) \text{ and} \\ A(i) = (n'', -, a'', -, -, -) \text{ and} \\ a' \in [a''..a'' + n''] \end{array} \\ (@\text{empty}, \text{offsetof\_ival}(\tau, m)), & \text{if } p = \text{null}. \end{cases}$$

**Casts (PNVI-plain)** In PNVI-plain, a cast of a pointer value  $p$  to an integer value (at type  $\tau$ ) just converts null pointers to zero and non-null pointer values to the address  $a$  of the pointer, if that is representable in  $\tau$ , otherwise flagging UB. The provenance of the pointer is discarded. At present we require that the object is live and that its address is within bounds.

$$\text{cast\_ptrval\_to\_ival}(\tau, p) = \begin{cases} 0, & \text{if } p = \text{null}; \\ a, & \text{if } p = (@i, a) \text{ and} \\ & A(i) = (n'', -, a'', -, -, -) \text{ and} \\ & a \in [a''..a'' + n''] \text{ and } a \in \text{value\_range}(\tau) \\ \text{UB}, & \text{otherwise} \end{cases}$$

In PNVI-plain, an integer-to-pointer cast of 0 returns the null pointer. For a non-0 integer  $x$ , casting to a pointer to  $\tau$ , if there is a storage instance  $i$  in the current memory model state  $(A, M)$  for which the address of the pointer would be properly within the footprint of the storage instance, it returns a pointer  $(@i, x)$  with the provenance of that storage instance. (The “properly within” prevents the one-past ambiguous case.) If there is no such storage instance, it returns a pointer with empty provenance.

$$\text{cast\_ival\_to\_ptrval}(\tau, x) = \begin{cases} \text{null}, & \text{if } x = 0 \\ (@i, x), & \text{if } A(i) = (n, -, a, f, k, -) \text{ and } x \in [a..a + n - 1] \\ (@\text{empty}, x), & \text{if there is no such } i \end{cases}$$

**Casts (PNVI-ae)** In PNVI-ae, the result of a cast of a pointer value  $p$  to an integer value is exactly as in PNVI-plain. In addition, for a cast of pointer value  $p = (@i, a)$  with provenance  $@i$ , where  $A(i) = (n, \tau_{\text{opt}}, a, f, k, t)$  is the storage instance metadata for  $i$ , the memory state  $(A, M)$  is updated to  $(A(i \mapsto (n, \tau_{\text{opt}}, a, f, k, \text{exposed})), M)$  to mark the that storage instance as exposed.

In PNVI-ae, an integer-to-pointer cast of 0 returns the null pointer. For a non-0 integer  $x$ , casting to a pointer to  $\tau$ , if there is a storage instance  $i$  in the current memory model state  $(A, M)$  for which the address of the pointer would be properly within the footprint of the storage instance, and storage instance  $i$  is exposed, it returns a pointer  $(@i, x)$  with the provenance of that storage instance. If there is no such storage instance, it returns a pointer with empty provenance.

$$\text{cast\_ival\_to\_ptrval}(\tau, x) = \begin{cases} \text{null}, & \text{if } x = 0 \\ (@i, x), & \text{if } A(i) = (n, -, a, f, k, \text{exposed}) \text{ and } x \in [a..a + n - 1] \\ (@\text{empty}, x), & \text{if there is no such } i \end{cases}$$

**Casts (PNVI-ae-udi)** In PNVI-ae-udi, a cast of a pointer value  $p$  to an integer is just like PNVI-ae.

Unlike PNVI-ae, PNVI-ae-udi permits a cast of a one-past pointer to integer and back to recover the original provenance, replacing the integer-to-pointer check that  $x$  is properly within the footprint of the storage instance by a check that it is properly within or one-past:

$$\text{cast\_ival\_to\_ptrval}(\tau, x) = \begin{cases} \text{null}, & \text{if } x = 0 \\ (@i, x), & \text{if } A(i) = (n, -, a, f, k, \text{exposed}) \text{ and } x \in [a..a + n] \\ (@\text{empty}, x), & \text{if there is no such } i \end{cases}$$

But then a PNVI-ae-udi cast of an integer value to a pointer can create a pointer with ambiguous provenance (as in the definition of repr) : if it could be within or one-past two live storage instances, with IDs  $i_1$  and  $i_2$ , and both storage instances have been marked as exposed, the resulting pointer value is given a fresh symbolic storage instance ID  $\iota$ , and  $A$  is updated to map  $\iota$  to  $\{i_1, i_2\}$ . This can only happen if the two storage instances are adjacent and the address is one-past the first and at the start of the second.

## Casts (PVI)

$$\begin{aligned} \text{cast\_ival\_to\_ptrval}(\tau, x) &= \begin{cases} \text{null}, & \text{if } x = (\text{@empty}, 0) \\ (\pi, n), & \text{otherwise, where } x = (\pi, n) \end{cases} \\ \text{cast\_ptrval\_to\_ival}(\tau, p) &= \begin{cases} (\text{@empty}, 0), & \text{if } p = \text{null}; \\ (\pi, a), & \text{if } p = (\pi, a) \text{ and } a \in \text{value\_range}(\tau) \\ \text{UB}, & \text{otherwise} \end{cases} \end{aligned}$$

**Integer operations (PVI)** In PVI one also has to define the provenance results of all the other operations returning integer values. Below we do so for the basic operations, though this would also be needed for all the integer-returning library functions. Most would give integers with empty provenance. One might or might not also want to require that the objects of those provenances are live.

$$\begin{aligned} \pi \oplus \pi' &= \begin{cases} \pi, & \text{if } \pi = \pi' \text{ or } \pi' = \text{@empty}; \\ \pi', & \text{if } \pi = \text{@empty}; \\ \text{@empty}, & \text{otherwise.} \end{cases} \\ \text{op\_ival}(op, (\pi, n), (\pi', m)) &= (\pi \oplus \pi', op(n, m)), \text{ where } op \in \{+, *, /, \%, \&, |, \wedge\} \\ \text{op\_ival}(-, (\pi, n), (\pi', m)) &= \begin{cases} (\text{@empty}, n - m), & \text{if } \pi = \text{@}i \text{ and } \pi' = \text{@}i', \text{ whether } i = i' \text{ or not;} \\ (\text{@}i, n - m), & \text{if } \pi = \text{@}i \text{ and } \pi' = \text{@empty}; \\ (\text{@empty}, n - m), & \text{if } \pi = \text{@empty}. \end{cases} \\ \text{eq\_ival}((\pi, n), (\pi', m)) &= (n = m) \\ \text{lt\_ival}((\pi, n), (\pi', m)) &= (n < m) \\ \text{le\_ival}((\pi, n), (\pi', m)) &= (n \leq m) \end{aligned}$$

### B.2.4 No-expose annotation

For PNVI-ae and PNVI-ae-udi, to permit implementations, e.g. of `memcpy`-like functions, to operate on representation bytes but without needlessly leaving all the storage instances that were pointed to in those bytes exposed, we envisaged some “no-expose” annotation that users could apply to such code. But now it’s not so clear how that could work. We can turn off exposure during execution of annotated code easily enough (though Jens points out that this might not be the right thing for code which is passed a function pointer). But if the user-`memcpy` code copies bytes via a `char *` pointer, then the resulting abstract types in memory still have empty provenance (because we’re not tracking provenance via the intervening integer values), so when a pointer value is read (after the user-`memcpy`) from the copy, it will still get empty provenance.

### B.2.5 Provenance of other operations

In addition to the operations defined above, some operations are desugared/elaborated to simpler expressions by the Cerberus pipeline. Their PVI results have provenance as follows; their PNVI\* results are the same except that there integers have no provenance:

- the result of address-of (&) has the provenance of the object associated with the lvalue, for non-function-pointers, or empty for function pointers.
- prefix increment and decrement operators follow the corresponding pointer or integer arithmetic rules.
- the conditional operator has the provenance of the second or third operand as appropriate; simple assignment has the provenance of the expression; compound assignment follows the pointer or integer arithmetic rules; the comma operator has the provenance of the second operand.
- integer unary +, unary -, and ~ operators preserve the original provenance; logical negation ! has a value with empty provenance.
- `sizeof` and `_Alignof` operators give values with empty provenance.
- bitwise shifts has the provenance of their first operand.
- Jens Gustedt highlights that atomic operations have their own specific provenance properties, not yet discussed here, as do some library functions.

## C Modifications to ISO/IEC 9899:2018 (normative)

Implementations that conform to this technical specification, shall behave as if the modifications described in this annex were applied to ISO/IEC 9899:2018. This annex is organized as follows:

- If possible, numbers of clauses refer to the clauses of ISO/IEC 9899:2018.
- Two new sub-clauses are introduced in clause 3 with numbers 3.17 (“provenance”) and 3.20 (“storage instance”). The given context of ISO/IEC 9899:2018 and the numbering indicates the places of insertion.
- The subclause (now 3.21.2) “indeterminate value” is modified and renamed to “indeterminate representation”.
- The subclause (now 3.21.4) “trap representation” is modified and renamed to “non-value representation”.
- Clause 6.2.4 of ISO/IEC 9899:2018 is renamed from ”~~Storage durations of objects~~” to ”Storage durations and object lifetimes”.
- Clause 7.22.3 of ISO/IEC 9899:2018 is renamed from ”~~Memory management functions~~” to ”Storage management functions”.
- Page numbers in the footer correspond to an approximation of the page number in ISO/IEC 9899:2018.
- Page numbers in the top right corner correspond to the page numbering within this document, here.
- Additions to the text are marked as shown.
- Deletions of text are marked as ~~shown~~.

contains four separate memory locations: The member **a**, and bit-fields **d** and **e**. **ee** are each separate memory locations, and can be modified concurrently without interfering with each other. The bit-fields **b** and **c** together constitute the fourth memory location. The bit-fields **b** and **c** cannot be concurrently modified, but **b** and **a**, for example, can be.

### 3.15

#### 1 **object**

region of data storage in the execution environment, the contents of which can represent values

2 **Note 1 to entry:** When referenced, an object can be interpreted as having a particular type; see 6.3.2.1.

### 3.16

#### 1 **parameter**

formal parameter

DEPRECATED: formal argument

object declared as part of a function declaration or definition that acquires a value on entry to the function, or an identifier from the comma-separated list bounded by the parentheses immediately following the macro name in a function-like macro definition

### 3.17

#### 1 **pointer provenance**

provenance

an entity that is associated to a pointer value in the abstract machine, which is either empty, or the identity of a storage instance

### 3.18

#### 1 **recommended practice**

specification that is strongly recommended as being in keeping with the intent of the standard, but that might be impractical for some implementations

### 3.19

#### 1 **runtime-constraint**

requirement on a program when calling a library function

2 **Note 1 to entry:** Despite the similar terms, a runtime-constraint is not a kind of constraint as defined by 3.8, and need not be diagnosed at translation time.

3 **Note 2 to entry:** Implementations that support the extensions in Annex K are required to verify that the runtime-constraints for a library function are not violated by the program; see K.3.1.4.

4 **Note 3 to entry:** Implementations that support Annex L are permitted to invoke a runtime-constraint handler when they perform a trap.

### 3.20

#### 1 **storage instance**

the inclusion-maximal region of data storage in the execution environment that is created when either an object definition or an allocation is encountered

2 **Note 1 to entry:** Storage instances are created and destroyed when specific language constructs (6.2.4) are met during program execution, including program startup, or when specific library functions (7.22.3) are called.

3 **Note 2 to entry:** A given storage instance may or may not have a memory address, and may or may not be accessible from all threads of execution.

4 **Note 3 to entry:** Storage instances have identities which are unique across the program execution.

5 **Note 4 to entry:** A storage instance with a memory address occupies a region of zero or more bytes of contiguous data storage in the execution environment.

6 **Note 5 to entry:** One or more objects may be represented within the same storage instance, such as two subobjects within an object of structure type, two **const**-qualified compound literals with identical object representation, or two string literals where one is the terminal character sequence of the other.

### 3.21

#### 1 value

precise meaning of the contents of an object when interpreted as having a specific type

#### 3.21.1

#### 1 implementation-defined value

unspecified value where each implementation documents how the choice is made

#### 3.21.2

#### 1 indeterminate representation

~~either object representation that either represents~~ an unspecified value or ~~a trap is a non-value~~ representation

#### 3.21.3

#### 1 unspecified value

valid value of the relevant type where this document imposes no requirements on which value is chosen in any instance ~~An unspecified value cannot be a trap representation.~~

#### 3.21.4

#### 1 non-value representation

an object representation that ~~need~~does not represent a value of the object type

#### 3.21.5

#### 1 perform a trap

interrupt execution of the program such that no further operations are performed

2 **Note 1 to entry:** In this document, when the word “trap” is not immediately followed by “representation”, this is the intended usage.<sup>2)</sup>

3 **Note 2 to entry:** Implementations that support Annex L are permitted to invoke a runtime-constraint handler when they perform a trap.

### 3.22

#### 1 $\lceil x \rceil$

ceiling of  $x$

the least integer greater than or equal to  $x$

2 **EXAMPLE**  $\lceil 2.4 \rceil$  is 3,  $\lceil -2.4 \rceil$  is  $-2$ .

### 3.23

#### 1 $\lfloor x \rfloor$

floor of  $x$

the greatest integer less than or equal to  $x$

2 **EXAMPLE**  $\lfloor 2.4 \rfloor$  is 2,  $\lfloor -2.4 \rfloor$  is  $-3$ .

<sup>2)</sup>For example, “Trapping or stopping (if supported) is disabled ...” (F.8.2). Note that fetching a ~~trap non-value~~ representation might perform a trap but is not required to (see 6.2.6.1).

of those operations are all *side effects*,<sup>12)</sup> which are changes in the state of the execution environment. *Evaluation* of an expression in general includes both value computations and initiation of side effects. Value computation for an lvalue expression includes determining the identity of the designated object.

- 3 *Sequenced before* is an asymmetric, transitive, pair-wise relation between evaluations executed by a single thread, which induces a partial order among those evaluations. Given any two evaluations *A* and *B*, if *A* is sequenced before *B*, then the execution of *A* shall precede the execution of *B*. (Conversely, if *A* is sequenced before *B*, then *B* is *sequenced after A*.) If *A* is not sequenced before or after *B*, then *A* and *B* are *unsequenced*. Evaluations *A* and *B* are *indeterminately sequenced* when *A* is sequenced either before or after *B*, but it is unspecified which.<sup>13)</sup> The presence of a *sequence point* between the evaluation of expressions *A* and *B* implies that every value computation and side effect associated with *A* is sequenced before every value computation and side effect associated with *B*. (A summary of the sequence points is given in Annex C.)
- 4 In the abstract machine, all expressions are evaluated as specified by the semantics. An actual implementation need not evaluate part of an expression if it can deduce that its value is not used and that no needed side effects are produced (including any caused by calling a function or accessing a volatile object).
- 5 When the processing of the abstract machine is interrupted by receipt of a signal, the values of objects that are neither lock-free atomic objects nor of type `volatile sig_atomic_t` are unspecified, as is the state of the floating-point environment. The value representation of any object modified by the handler that is neither a lock-free atomic object nor of type `volatile sig_atomic_t` becomes indeterminate when the handler exits, as does the state of the floating-point environment if it is modified by the handler and not restored to its original state.
- 6 The least requirements on a conforming implementation are:
  - Accesses to volatile objects are evaluated strictly according to the rules of the abstract machine.
  - At program termination, all data written into files shall be identical to the result that execution of the program according to the abstract semantics would have produced.
  - The input and output dynamics of interactive devices shall take place as specified in 7.21.3. The intent of these requirements is that unbuffered or line-buffered output appear as soon as possible, to ensure that prompting messages actually appear prior to a program waiting for input.

This is the *observable behavior* of the program.

- 7 What constitutes an interactive device is implementation-defined.
- 8 More stringent correspondences between abstract and actual semantics may be defined by each implementation.
- 9 **EXAMPLE 1** An implementation might define a one-to-one correspondence between abstract and actual semantics: at every sequence point, the values of the actual objects would agree with those specified by the abstract semantics. The keyword `volatile` would then be redundant.
- 10 Alternatively, an implementation might perform various optimizations within each translation unit, such that the actual semantics would agree with the abstract semantics only when making function calls across translation unit boundaries. In such an implementation, at the time of each function entry and function return where the calling function and the called function are in different translation units, the values of all externally linked objects and of all objects accessible via pointers therein would agree with the abstract semantics. Furthermore, at the time of each such function entry the values of the parameters of the called function and of all objects accessible via pointers therein would agree with the abstract semantics. In this type of implementation, objects referred to by interrupt service routines activated by the `signal` function would require explicit specification of `volatile` storage, as well as other implementation-defined restrictions.

<sup>12)</sup>The IEC 60559 standard for binary floating-point arithmetic requires certain user-accessible status flags and control modes. Floating-point operations implicitly set the status flags; modes affect result values of floating-point operations. Implementations that support such floating-point state are required to regard changes to it as side effects — see Annex F for details. The floating-point environment library `<fenv.h>` provides a programming facility for indicating when these side effects matter, freeing the implementations in other cases.

<sup>13)</sup>The executions of unsequenced evaluations can interleave. Indeterminately sequenced evaluations cannot interleave, but can be executed in any order.

- 12 pointer, array, and function declarators (in any combinations) modifying an arithmetic, structure, union, or **void** type in a declaration
- 63 nesting levels of parenthesized declarators within a full declarator
- 63 nesting levels of parenthesized expressions within a full expression
- 63 significant initial characters in an internal identifier or a macro name (each universal character name or extended source character is considered a single character)
- 31 significant initial characters in an external identifier (each universal character name specifying a short identifier of 0000FFFF or less is considered 6 characters, each universal character name specifying a short identifier of 00010000 or more is considered 10 characters, and each extended source character is considered the same number of characters as the corresponding universal character name, if any)<sup>19)</sup>
- 4095 external identifiers in one translation unit
- 511 identifiers with block scope declared in one block
- 4095 macro identifiers simultaneously defined in one preprocessing translation unit
- 127 parameters in one function definition
- 127 arguments in one function call
- 127 parameters in one macro definition
- 127 arguments in one macro invocation
- 4095 characters in a logical source line
- 4095 characters in a string literal (after concatenation)
- 65535 bytes in an object (in a hosted environment only)
- 15 nesting levels for **#included** files
- 1023 **case** labels for a **switch** statement (excluding those for any nested **switch** statements)
- 1023 members in a single structure or union
- 1023 enumeration constants in a single enumeration
- 63 levels of nested structure or union definitions in a single struct-declaration-list

#### 5.2.4.2 Numerical limits

- 1 An implementation is required to document all the limits specified in this subclause, which are specified in the headers `<limits.h>` and `<float.h>`. Additional limits are specified in `<stdint.h>`.

**Forward references:** integer types `<stdint.h>` (7.20).

##### 5.2.4.2.1 Sizes of integer types `<limits.h>`

- 1 The values given below shall be replaced by constant expressions. [If the value and promoted type is in the range of the type `intmax\_t` \(for a signed type\) or `uintmax\_t` \(for an unsigned type\), see 7.20.1.5, the expression shall be](#) suitable for use in **#if** preprocessing directives.

Moreover, except for **CHAR\_BIT** and **MB\_LEN\_MAX**, the following shall be replaced by expressions that have the same type as would an expression that is an object of the corresponding type converted according to the integer promotions. Their implementation-defined values shall be equal or greater in magnitude (absolute value) to those shown, with the same sign.

- number of bits for smallest object that is not a bit-field (byte)

<sup>19)</sup>See “future language directions” (6.11.3).

**Forward references:** enumeration specifiers (6.7.2.2), labeled statements (6.8.1), structure and union specifiers (6.7.2.1), structure and union members (6.5.2.3), tags (6.7.2.3), the **goto** statement (6.8.6.1).

~~An object has a that determines its lifetime. There are four storage durations: static, thread, automatic, and allocated. Allocated storage is described in ??.~~

## 6.2.4 Storage durations and object lifetimes

- 1 The *lifetime* of an object ~~is the portion of program execution during which storage is guaranteed has a start and an end, which both constitute side effects in the abstract state machine, and is the set of all evaluations that happen after the start and before the end. An object exists, has a storage instance that is guaranteed to be reserved for it.~~~~An object exists,~~<sup>33)</sup> has a constant address,<sup>34)</sup> ~~if any, and retains its last-stored value throughout its lifetime.~~<sup>35)</sup> ~~If~~
- 2 ~~The lifetime of~~ an object is ~~referred to outside of its lifetime, the behavior is undefined. The value of a pointer becomes indeterminate when the object it points to (or just past) reaches the end of its lifetime~~~~determined by its storage duration . There are four storage durations: static, thread, automatic, and allocated. Allocated storage and its duration are described in 7.22.3.~~
- 3 ~~An~~~~The storage instance of an~~ object whose identifier is declared without the storage-class specifier **\_Thread\_local**, and either with external or internal linkage or with the storage-class specifier **static**, has *static storage duration* ~~Its, as do storage instances for string literals and some compound literals.~~<sup>36)</sup> ~~The object's~~ lifetime is the entire execution of the program and its stored value is initialized only once, prior to program startup.
- 4 ~~An~~~~The storage instance of an~~ object whose identifier is declared with the storage-class specifier **\_Thread\_local** has *thread storage duration*. ~~Its~~~~The object's~~ lifetime is the entire execution of the thread for which it is created, and its stored value is initialized when the thread is started. There is a distinct ~~object instance of the object and distinct associated storage instance~~ per thread, and use of the declared name in an expression refers to the object associated with the thread evaluating the expression. The result of attempting to indirectly access an object with thread storage duration from a thread other than the one with which the object is associated is implementation-defined.
- 5 ~~An~~~~The storage instance of an~~ object whose identifier is declared with no linkage and without the storage-class specifier **static** has *automatic storage duration*, as do ~~storage instances of temporary objects and~~ some compound literals. The result of attempting to indirectly access an object with automatic storage duration from a thread other than the one with which the object is associated is implementation-defined.
- 6 For such an object that does not have a variable length array type, its lifetime extends from entry into the block with which it is associated until execution of that block ends in any way. (Entering an enclosed block or calling a function suspends, but does not end, execution of the current block.) If the block is entered recursively, a new instance of the object ~~and associated storage~~ is created each time. ~~The initial value~~~~The initial representation~~ of the object is indeterminate. If an initialization is specified for the object, it is performed each time the declaration or compound literal is reached in the execution of the block; otherwise, the ~~value~~~~representation of the object~~ becomes indeterminate each time the declaration is reached.
- 7 For such an object that does have a variable length array type, its lifetime extends from the declaration of the object until execution of the program leaves the scope of the declaration.<sup>37)</sup> If the scope is entered recursively, a new instance of the object ~~and associated storage~~ is created each time. ~~The initial value~~~~The initial representation~~ of the object is indeterminate.
- 8 A non-lvalue expression with structure or union type, where the structure or union contains a

<sup>33)</sup>~~String literals, compound literals or certain objects with temporary lifetime may share a storage instance with other such objects.~~

<sup>34)</sup>The term “constant address” means that two pointers to the object constructed at possibly different times will compare equal. The address can be different during two different executions of the same program.

<sup>35)</sup>In the case of a volatile object, the last store need not be explicit in the program.

<sup>36)</sup>~~Such are for example compound literals that are evaluated in file scope or that are **const** qualified and have only constant expressions as initializers.~~

<sup>37)</sup>Leaving the innermost block containing the declaration, or jumping to a point in that block or an embedded block prior to the declaration, leaves the scope of the declaration.

optionally specified name and possibly distinct type.

- A *function type* describes a function with specified return type. A function type is characterized by its return type and the number and types of its parameters. A function type is said to be derived from its return type, and if its return type is  $T$ , the function type is sometimes called “function returning  $T$ ”. The construction of a function type from a return type is called “function type derivation”.
- A *pointer type* may be derived from a function type or an object type, called the *referenced type*. A pointer type describes an object whose value provides a reference to an entity of the referenced type. If the type is an object type, the pointer also carries a provenance, typically identifying the storage instance holding the corresponding object, if any; its value is valid if and only if it has a non-empty provenance, there is a live storage instance for that provenance, and the address is either within or one-past the addresses of that storage instance. A pointer-to-function is valid if it refers to a valid function definition of the program. Pointers additionally may have a special value *null* that is different from the address of any storage instance and has no provenance (for object pointers),<sup>49)</sup> or from the address of any function of the program (for function pointers). If a pointer value is neither valid nor null, it is *invalid*. A pointer type derived from the referenced type  $T$  is sometimes called “pointer to  $T$ ”. The construction of a pointer type from a referenced type is called “pointer type derivation”. A pointer type is a complete object type.<sup>50)</sup> Under certain circumstances a pointer value can have an address that is the end address of one storage instance and the start address of another. It (and any pointer value derived from it by means of arithmetic operations) shall then not be used in ways that require (in different usages) more than one of these provenances
- An *atomic type* describes the type designated by the construct `_Atomic(type-name)`. (Atomic types are a conditional feature that implementations need not support; see 6.10.8.3.)

These methods of constructing derived types can be applied recursively.

- 21 Arithmetic types and pointer types are collectively called *scalar types*. Array and structure types are collectively called *aggregate types*.<sup>51)</sup>
- 22 An array type of unknown size is an incomplete type. It is completed, for an identifier of that type, by specifying the size in a later declaration (with internal or external linkage). A structure or union type of unknown content (as described in 6.7.2.3) is an incomplete type. It is completed, for all declarations of that type, by declaring the same structure or union tag with its defining content later in the same scope.
- 23 A type has *known constant size* if the type is not incomplete and is not a variable length array type.
- 24 Array, function, and pointer types are collectively called *derived declarator types*. A *declarator type derivation* from a type  $T$  is the construction of a derived declarator type from  $T$  by the application of an array-type, a function-type, or a pointer-type derivation to  $T$ .
- 25 A type is characterized by its *type category*, which is either the outermost derivation of a derived type (as noted above in the construction of derived types), or the type itself if the type consists of no derived types.
- 26 Any type so far mentioned is an *unqualified type*. Each unqualified type has several *qualified versions* of its type,<sup>52)</sup> corresponding to the combinations of one, two, or all three of the **const**, **volatile**,

<sup>49)</sup> A pointer object can be null by implicit or explicit initialization or assignment with a null pointer constant or by another null pointer value. A pointer value can be null if it is either a null pointer constant or the result of a lvalue conversion of a null pointer object. A null pointer will not appear as the result of an arithmetic operation.

<sup>50)</sup> The provenance of a pointer value and the property that such a pointer value is valid or not are generally not observable. In particular, in the course of the same program execution the same pointer object with the same representation bytes (6.2.6) may sometimes represent valid values but with different provenance (and thus refer to different objects). Sometimes the object representation may even be indeterminate, namely when the lifetime of the storage instance has ended and no new storage instance uses the same address.. Yet, this information is part of the abstract state machine and may restrict the set of operations that can be performed on the pointer.

<sup>51)</sup> Note that aggregate type does not include union type because an object with union type can only contain one member at a time.

<sup>52)</sup> See 6.7.3 regarding qualified array and function types.

and **restrict** qualifiers. The qualified or unqualified versions of a type are distinct types that belong to the same type category and have the same representation and alignment requirements.<sup>53)</sup> A derived type is not qualified by the qualifiers (if any) of the type from which it is derived.

27 Further, there is the **\_Atomic** qualifier. The presence of the **\_Atomic** qualifier designates an atomic type. The size, representation, and alignment of an atomic type need not be the same as those of the corresponding unqualified type. Therefore, this document explicitly uses the phrase “atomic, qualified or unqualified type” whenever the atomic version of a type is permitted along with the other qualified versions of a type. The phrase “qualified or unqualified type”, without specific mention of atomic, does not include the atomic types.

28 A pointer to **void** shall have the same representation and alignment requirements as a pointer to a character type.<sup>53)</sup> Similarly, pointers to qualified or unqualified versions of compatible types shall have the same representation and alignment requirements. All pointers to structure types shall have the same representation and alignment requirements as each other. All pointers to union types shall have the same representation and alignment requirements as each other. ~~Pointers to other types need not~~ It is implementation-defined whether other groups of pointer types have the same representation or alignment requirements.<sup>54)</sup>

29 **EXAMPLE 1** The type designated as “**float \***” has type “pointer to **float**”. Its type category is pointer, not a floating type. The const-qualified version of this type is designated as “**float \* const**” whereas the type designated as “**const float \***” is not a qualified type — its type is “pointer to const-qualified **float**” and is a pointer to a qualified type.

30 **EXAMPLE 2** The type designated as “**struct tag (\*[5])(float)**” has type “array of pointer to function returning **struct tag**”. The array has length five and the function has a single parameter of type **float**. Its type category is array.

**Forward references:** compatible type and composite type (6.2.7), declarations (6.7).

## 6.2.6 Representations of types

### 6.2.6.1 General

1 The representations of all types are unspecified except as stated in 6.2.5 and in this subclause. An object is represented (or held) by a storage instance (or part thereof) that is either created by an allocation (for allocated storage duration), at program startup (for static storage duration), at thread startup (for thread storage duration), or when the lifetime of the object starts (for automatic storage duration).

2 An addressable storage instance<sup>55)</sup> of size  $m$  provides access to a byte array of length  $m$ . Each byte of the array has an *abstract address*, which is a value of type **uintptr\_t** that is determined in an implementation-defined manner by pointer-to-integer conversion. The abstract addresses of the bytes are increasing with the ordering within the array, and they shall be unique and constant during the lifetime. The address of the first byte of the array is the *start address* of the storage instance, the address one element beyond the array at index  $m$  is its *end address*. The abstract addresses of the bytes of all storage instances of a program execution form its *address space*. A storage instance  $Y$  follows storage instance  $X$  if the start address of  $Y$  is greater or equal than the end address of  $X$ , and it follows *immediately* if they are equal. If the lifetime of any two distinct addressable storage instances  $X$  and  $Y$  overlaps, either  $Y$  follows  $X$  or  $X$  follows  $Y$  in the address space. This document imposes no other constraints about such relative position of addressable storage instances whenever they are created.<sup>56)</sup>

3 The object representation of a pointer object does not necessarily determine provenance of a pointer value; at different points of the program execution, identical object representations of pointer values may refer to distinct storage instances. Unless stated otherwise, a storage instance becomes *exposed* when a pointer value  $p$  of effective type  $T^*$  with this provenance is used in the following

<sup>53)</sup>The same representation and alignment requirements are meant to imply interchangeability as arguments to functions, return values from functions, and members of unions.

<sup>54)</sup>An implementation might represent all pointers the same and with the same alignment requirements.

<sup>55)</sup>All storage instances that do not originate from an object definition with **register** storage class are addressable by using the pointer value that was returned by their allocation (for allocated storage duration) or by applying the address-of operator & (6.5.3.2) to the object that gave rise to their definition (for other storage durations).

<sup>56)</sup>This means that no relative ordering between storage instances and the objects they represent can be deduced from syntactic properties of the program (such as declaration order or order inside a parameter list) or sequencing properties of the execution (such as one instantiation happening before another).

contexts:<sup>57)</sup>

- Any byte of the object representation of `p` is used in an expression.<sup>58)</sup>
- The byte array pointed-to by the first argument of a call to the `fwrite` library function intersects with an object representation of `p`.
- `p` is converted to an integer.
- `p` is used as an argument to a `%p` conversion specifier of the `printf` family of library functions.<sup>59)</sup>

Nevertheless, if the object representation of `p` is read through an lvalue of a pointer type `S*` that has the same representation and alignment requirements as `T*`, that lvalue has the same provenance as `p` and the provenance does not thereby become exposed.<sup>60)</sup> Exposure of a storage instance is irreversible and constitutes a side effect in the abstract state machine.

4 Unless stated otherwise, pointer value `p` is *synthesized* if it is constructed by one of the following:<sup>61)</sup>

- Any byte of the object representation of `p` is changed
  - by an explicit byte operation,
  - by type punning with a non-pointer object or with a pointer object that only partially overlaps,
  - or by a call to `memcpy` or similar function that does not write the entire pointer representation or where the source object does not have an effective pointer type.
- The object representation of `p` intersects with a byte array pointed-to by the first argument of a call to the `fread` library function.
- `p` is converted from an integer value.
- `p` is used as an argument to a `%p` conversion specifier of the `scanf` family of library functions.

Special provisions in the respective clauses clarify when such a synthesized pointer is a null, valid, or invalid.

- 5 Except for bit-fields, objects are composed of contiguous sequences of one or more bytes, the number, order, and encoding of which are either explicitly specified or implementation-defined.
- 6 Values stored in unsigned bit-fields and objects of type **unsigned char** shall be represented using a pure binary notation.<sup>62)</sup>
- 7 Values stored in non-bit-field objects of any other object type ~~consist of~~ are represented using  $n \times \text{CHAR\_BIT}$  bits, where  $n$  is the size of an object of that type, in bytes. The value may be copied into an object of type `char` or `void` yields a pointer into the byte array of the storage instance such that the values of the first  $n$  (e.g., by

<sup>57)</sup>Pointer values with exposed provenance may alias in ways that cannot be predicted by simple data flow analysis.

<sup>58)</sup>The exposure of bytes of the object representation can happen through a conversion of the address of a pointer object containing `p` to a character type and a subsequent access to the bytes, or by reading the representation of a pointer value `p` through a **union** with a type that is not a pointer type (for example an integer type) or with a pointer type that has a different object representation than the original pointer.

<sup>59)</sup>Passing a pointer value to a `%s` conversion, does not expose the storage instance.

<sup>60)</sup>This means that pointer members in a **union** can be used to reinterpret representations of different character and void pointers, different **struct** pointers, different **union** pointers or pointers with differently qualified target types.

<sup>61)</sup>Synthesized pointer values may alias in ways that cannot be predicted by simple data flow analysis.

<sup>62)</sup>A positional representation for integers that uses the binary digits 0 and 1, in which the values represented by successive bits are additive, begin with 1, and are multiplied by successive integral powers of 2, except perhaps the bit with the highest position. (Adapted from the *American National Dictionary for Information Processing Systems*.) A byte contains **CHAR\_BIT** bits, and the values of type **unsigned char** range from 0 to  $2^{\text{CHAR\_BIT}} - 1$ .

~~memcpy~~); the resulting set of bytes determine the value of the object; the position of the first byte of these in the byte array is the *byte offset* of the object in its storage instance, the converted address is called the *byte address* of the object, and the range of bytes within the byte array is called the *object representation* of the value. The object representation may be used to copy the value of the object into another object (e.g., by ~~memcpy~~). Values stored in bit-fields consist of  $m$  bits, where  $m$  is the size specified for the bit-field. The object representation is the *set-range* of  $m$  bits the bit-field comprises in the addressable storage unit holding it. Two values (other than NaNs) with the same object representation compare equal, but values that compare equal may have different object representations. The object representations of pointers and how they relate to the abstract addresses they represent are not further specified by this document.

- 8 Certain object representations need not represent a value of the object type. If ~~the stored value of an object has such a representation and is read by an lvalue expression that does not have character type, the behavior is undefined.~~ If such a representation is produced by a side effect that modifies all or any part of the object by an lvalue expression that does not have character type, the behavior is undefined.<sup>63</sup> Such a representation is called a ~~trap representation~~ *non-value representation*.
- 9 When a value is stored in an object of structure or union type, including in a member object, the bytes of the object representation that correspond to any padding bytes take unspecified values.<sup>64</sup> The *value object representation* of a structure or union object is never a ~~trap non-value~~ representation, even though the ~~value of byte range corresponding to~~ a member of the structure or union object may be a ~~trap representation~~ *non-value representation for that member*.
- 10 When a value is stored in a member of an object of union type, the bytes of the object representation that do not correspond to that member but do correspond to other members take unspecified values.
- 11 Where an operator is applied to a value that has more than one object representation, which object representation is used shall not affect the value of the result.<sup>65</sup> Where a value is stored in an object using a type that has more than one object representation for that value, it is unspecified which representation is used, but a ~~trap non-value~~ representation shall not be generated.
- 12 Loads and stores of objects with atomic types are done with `memory_order_seq_cst` semantics.

**Forward references:** declarations (6.7), expressions (6.5), [address and indirection operators \(6.5.3.2\)](#), lvalues, arrays, and function designators (6.3.2.1), order and consistency (7.17.3), [integer types capable of holding object pointers \(7.20.1.4\)](#), [input/output \(7.21\)](#).

### 6.2.6.2 Integer types

- 1 For unsigned integer types other than **unsigned char**, the bits of the object representation shall be divided into two groups: value bits and padding bits (there need not be any of the latter). If there are  $N$  value bits, each bit shall represent a different power of 2 between 1 and  $2^{N-1}$ , so that objects of that type shall be capable of representing values from 0 to  $2^N - 1$  using a pure binary representation; this shall be known as the *value representation*. The values of any padding bits are unspecified.<sup>66</sup>
- 2 For signed integer types, the bits of the object representation shall be divided into three groups: value bits, padding bits, and the sign bit. There need not be any padding bits; **signed char** shall not have any padding bits. There shall be exactly one sign bit. Each bit that is a value bit shall have the same value as the same bit in the object representation of the corresponding unsigned type (if there are  $M$  value bits in the signed type and  $N$  in the unsigned type, then  $M \leq N$ ). If the sign bit is zero, it shall not affect the resulting value. If the sign bit is one, the value shall be modified in one of the following ways:

<sup>63</sup>Thus, an automatic variable can be initialized to a trap representation without causing undefined behavior, but the value of the variable cannot be used until a proper value is stored in it.

<sup>64</sup>Thus, for example, structure assignment need not copy any padding bits.

<sup>65</sup>It is possible for objects  $x$  and  $y$  with the same effective type  $T$  to have the same value when they are accessed as objects of type  $T$ , but to have different values in other contexts. In particular, if `==` is defined for type  $T$ , then `x == y` does not imply that `memcmp(&x, &y, sizeof(T)) == 0`. Furthermore, `x == y` does not necessarily imply that  $x$  and  $y$  have the same value; other operations on values of type  $T$  might distinguish between them.

<sup>66</sup>Some combinations of padding bits might generate ~~trap non-value~~ representations, for example, if one padding bit is a parity bit. Regardless, no arithmetic operation on valid values can generate a ~~trap non-value~~ representation other than as part of an exceptional condition such as an overflow, and this cannot occur with unsigned types. All other combinations of padding bits are alternative object representations of the value specified by the value bits.

- the corresponding value with sign bit 0 is negated (*sign and magnitude*);
- the sign bit has the value  $-(2^M)$  (*two's complement*);
- the sign bit has the value  $-(2^M - 1)$  (*ones' complement*).

Which of these applies is implementation-defined, as is whether the value with sign bit 1 and all value bits zero (for the first two), or with sign bit and all value bits 1 (for ones' complement), is a [trap-non-value](#) representation or a normal value. In the case of sign and magnitude and ones' complement, if this representation is a normal value it is called a *negative zero*.

- 3 If the implementation supports negative zeros, they shall be generated only by:
  - the `&`, `|`, `^`, `~`, `<<`, and `>>` operators with operands that produce such a value;
  - the `+`, `-`, `*`, `/`, and `%` operators where one operand is a negative zero and the result is zero;
  - compound assignment operators based on the above cases.

It is unspecified whether these cases actually generate a negative zero or a normal zero, and whether a negative zero becomes a normal zero when stored in an object.

- 4 If the implementation does not support negative zeros, the behavior of the `&`, `|`, `^`, `~`, `<<`, and `>>` operators with operands that would produce such a value is undefined.
- 5 The values of any padding bits are unspecified.<sup>67)</sup> A valid (~~non-trap~~)-object representation of a signed integer type [that represents a value](#) where the sign bit is zero is a valid object representation of the corresponding unsigned type, and shall represent the same value. For any integer type, the object representation where all the bits are zero shall be a representation of the value zero in that type.
- 6 The *precision* of an integer type is the number of bits it uses to represent values, excluding any sign and padding bits. The *width* of an integer type is the same but including any sign bit; thus for unsigned integer types the two values are the same, while for signed integer types the width is one greater than the precision.

## 6.2.7 Compatible type and composite type

- 1 Two types have *compatible type* if their types are the same. Additional rules for determining whether two types are compatible are described in 6.7.2 for type specifiers, in 6.7.3 for type qualifiers, and in 6.7.6 for declarators.<sup>68)</sup> Moreover, two structure, union, or enumerated types declared in separate translation units are compatible if their tags and members satisfy the following requirements: If one is declared with a tag, the other shall be declared with the same tag. If both are completed anywhere within their respective translation units, then the following additional requirements apply: there shall be a one-to-one correspondence between their members such that each pair of corresponding members are declared with compatible types; if one member of the pair is declared with an alignment specifier, the other is declared with an equivalent alignment specifier; and if one member of the pair is declared with a name, the other is declared with the same name. For two structures, corresponding members shall be declared in the same order. For two structures or unions, corresponding bit-fields shall have the same widths. For two enumerations, corresponding members shall have the same values.
- 2 All declarations that refer to the same object or function shall have compatible type; otherwise, the behavior is undefined.
- 3 A *composite type* can be constructed from two types that are compatible; it is a type that is compatible with both of the two types and satisfies the following conditions:

<sup>67)</sup>Some combinations of padding bits might generate trap representations, for example, if one padding bit is a parity bit. Regardless, no arithmetic operation on valid values can generate a [trap-non-value](#) representation other than as part of an exceptional condition such as an overflow. All other combinations of padding bits are alternative object representations of the value specified by the value bits.

<sup>68)</sup>Two types need not be identical to be compatible.

Otherwise, if the type of the operand with signed integer type can represent all of the values of the type of the operand with unsigned integer type, then the operand with unsigned integer type is converted to the type of the operand with signed integer type.

Otherwise, both operands are converted to the unsigned integer type corresponding to the type of the operand with signed integer type.

- 2 The values of floating operands and of the results of floating expressions may be represented in greater range and precision than that required by the type; the types are not changed thereby.<sup>77)</sup>

## 6.3.2 Other operands

### 6.3.2.1 Lvalues, arrays, and function designators

- 1 An *lvalue* is an expression (with an object type other than **void**) that potentially designates an object;<sup>78)</sup> if an lvalue does not designate an object when it is evaluated, the behavior is undefined. When an object is said to have a particular type, the type is specified by the lvalue used to designate the object. A *modifiable lvalue* is an lvalue that does not have array type, does not have an incomplete type, does not have a const-qualified type, and if it is a structure or union, does not have any member (including, recursively, any member or element of all contained aggregates or unions) with a const-qualified type.
- 2 Except when it is the operand of the **sizeof** operator, the unary & operator, the ++ operator, the - - operator, or the left operand of the . operator or an assignment operator, an lvalue that does not have array type is converted to the value stored in the designated object (and is no longer an lvalue); this is called *lvalue conversion*. If the lvalue has qualified type, the value has the unqualified version of the type of the lvalue; additionally, if the lvalue has atomic type, the value has the non-atomic version of the type of the lvalue; otherwise, the value has the type of the lvalue. ~~If the behavior is undefined if the lvalue has an incomplete type and does not have array type, the behavior is undefined. If, if the object representation is a non-value representation for the type,<sup>79)</sup> or if the lvalue designates an object of automatic storage duration that could have been declared with the **register** storage class (never had its address taken), and that object is uninitialized (not declared with an initializer and no assignment to it has been performed prior to use), the .~~
- 3 Additionally, if the type is a pointer type T\*, a pointer value and an associated provenance, if any, is determined as follows:
  - If the object representation represents a null pointer the result is a null pointer.
  - If the last store to the representation array was with a pointer type S\* that has the same representation and alignment requirements as T\*, the result is the same address and provenance as the stored value.
  - Otherwise, the object representation of the lvalue shall represent a byte address within (or one-past) the object representation of an exposed storage instance, such that the exposure happened before this lvalue conversion, and the result has that address and provenance.<sup>80)</sup>

The behavior is undefined if the pointer object has an indeterminate representation, in particular if the lvalue conversion does not happen during the lifetime of the provenance that was associated to the stored pointer value, the represented address is not a valid address (or one-past) for the associated provenance, or the represented address is not correctly aligned for the type.

- 4 Except when it is the operand of the **sizeof** operator, or the unary & operator, or is a string literal used to initialize an array, an expression that has type “array of *type*” is converted to an expression

<sup>77)</sup>The cast and assignment operators are still required to remove extra range and precision.

<sup>78)</sup>The name “lvalue” comes originally from the assignment expression  $E1 = E2$ , in which the left operand  $E1$  is required to be a (modifiable) lvalue. It is perhaps better considered as representing an object “locator value”. What is sometimes called “rvalue” is in this document described as the “value of an expression”.

An obvious example of an lvalue is an identifier of an object. As a further example, if  $E$  is a unary expression that is a pointer to an object,  $*E$  is an lvalue that designates the object to which  $E$  points.

<sup>79)</sup>Character types have no non-value representation, thus reading representation bytes of an addressable live storage instance is always defined.

<sup>80)</sup>If the address corresponds to more than one provenance, only one of these shall be used in the sequel, see 6.2.5.

with type “pointer to *type*” that points to the initial element of the array object and is not an lvalue. If the array object has register storage class, the behavior is undefined.

- 5 A *function designator* is an expression that has function type. Except when it is the operand of the **sizeof** operator,<sup>81)</sup> or the unary & operator, a function designator with type “function returning *type*” is converted to an expression that has type “pointer to function returning *type*”.

**Forward references:** address and indirection operators (6.5.3.2), assignment operators (6.5.16), common definitions <stddef.h> (7.19), initialization (6.7.9), postfix increment and decrement operators (6.5.2.4), prefix increment and decrement operators (6.5.3.1), the **sizeof** and **\_Alignof** operators (6.5.3.4), structure and union members (6.5.2.3).

### 6.3.2.2 void

- 1 The (nonexistent) value of a *void expression* (an expression that has type **void**) shall not be used in any way, and implicit or explicit conversions (except to **void**) shall not be applied to such an expression. If an expression of any other type is evaluated as a void expression, its value or designator is discarded. (A void expression is evaluated for its side effects.)

### 6.3.2.3 Pointers

- 1 A pointer to **void** may be converted to or from a pointer to any object type. A pointer to any object type may be converted to a pointer to **void** and back again; the result shall compare equal to the original pointer.
- 2 For any qualifier *q*, a pointer to a non-*q*-qualified type may be converted to a pointer to the *q*-qualified version of the type; the values stored in the original and converted pointers shall compare equal.
- 3 An integer constant expression with the value 0, or such an expression cast to type **void \***, is called a *null pointer constant*.<sup>82)</sup> If a null pointer constant is converted to a pointer type, the resulting pointer, called a *null pointer*, is guaranteed to compare unequal to a pointer to any object or function.
- 4 Conversion of a null pointer to another pointer type yields a null pointer of that type. Any two null pointers shall compare equal.
- 5 An integer may be converted to any pointer type. If the source type is signed, the operand is first converted to the corresponding unsigned type. The result is then determined in the following order:
- The operand value could have been the result of the conversion of a null pointer value. The result is a null pointer.
  - The operand value is an abstract address within or one past a live and exposed storage instance, such that the exposure happened before this integer-to-pointer conversion. The conversion synthesizes a pointer value with that address, provenance and target type.<sup>83)</sup>
  - The pointer value is invalid.

Except as previously specified, the result is implementation-defined, might not be correctly aligned, might not point to an entity of the referenced type, ~~and might be a trap representation might be invalid, and might produce an indeterminate representation when stored into an object.~~ ~~The mapping functions for converting a pointer to an integer or an integer to a pointer are intended to be consistent with the addressing structure of the execution environment.~~

- 6 Any pointer type may be converted to an integer type. ~~Except as previously specified~~ For a null pointer, the result is chosen from a non-empty set of implementation-defined ~~—If the result cannot be represented in the integer type values.<sup>84)</sup>~~ If the pointer value is valid, its provenance is henceforth exposed. Except as previously specified, the result is the abstract address (which has

<sup>81)</sup>Because this conversion does not occur, the operand of the **sizeof** operator remains a function designator and violates the constraints in 6.5.3.4.

<sup>82)</sup>The macro **NULL** is defined in <stddef.h> (and other headers) as a null pointer constant; see 7.19.

<sup>83)</sup>If the address corresponds to more than one provenance, only one of these shall be used in the sequel, see 6.2.5.

<sup>84)</sup>It is recommended that 0 is a member of that set.

type `uintptr_t`) converted to the target type. If the target type has a width that is less than the width of `uintptr_t`, the behavior is undefined. ~~The result need not be in the range of values of any integer type~~ If the target type is a signed type and the abstract address is larger than the maximum value of that type the implementation-defined conversion from `uintptr_t` to the target type as specified in 6.3.1.3 is applied.<sup>85)</sup> If the pointer is null or valid, the integer result converted back to the pointer type shall compare equal to the original pointer.<sup>86)</sup> For two valid pointer values that compare equal, conversion to the same integer type yields identical values.

- 7 A pointer to an object type may be converted to a pointer to a different object type, retaining its provenance. If the resulting pointer is not correctly aligned<sup>87)</sup> for the referenced type, the behavior is undefined. Otherwise, when converted back again, the result shall compare equal to the original pointer. When a pointer to an object is converted to a pointer to a character type or void, the result ~~points to the lowest addressed byte of the object. Successive increments of the result, up to the size of the object, yield pointers to the remaining bytes~~ is the byte address of the object.
- 8 A pointer to a function of one type may be converted to a pointer to a function of another type and back again; the result shall compare equal to the original pointer. If a converted pointer is used to call a function whose type is not compatible with the referenced type, the behavior is undefined.

**Forward references:** cast operators (6.5.4), equality operators (6.5.9), integer types capable of holding object pointers (7.20.1.4), simple assignment (6.5.16.1).

- 9 **NOTE** If the result  $p$  of an lvalue conversion or integer-to-pointer conversion is the end address of an exposed storage instance  $A$  and the start address of another exposed storage instance  $B$  that happens to follow immediately in the address space, a conforming program must only use one of these provenances in any expressions that are derived from  $p$ , see 6.2.5. The following three cases determine if  $p$  is used with one of  $A$  or  $B$  and must hence not be used otherwise:

— Operations that constitute a use of  $p$  with either  $A$  or  $B$  and do not prohibit a use with the other:

- any relational operator or pointer subtraction where the other operand  $q$  may have both provenances, that is where  $q$  is also the result of a similar conversion and where  $p == q$ ;
- $q == p$  and  $q != p$  regardless of the provenance of  $q$ ;
- addition or subtraction of the value 0;
- conversion to integer.

For the latter,  $A$  and  $B$  must have been exposed before, and so any choice of provenance, that would otherwise have exposed one of the storage instances, is consistent with any other use.

— Operations that, if otherwise well defined, constitute a use of  $p$  with  $A$  and prohibit any use with  $B$ :

- Any relational operator or pointer subtraction where the other operand  $q$  has provenance  $A$  and cannot have provenance  $B$ .
- $p + n$  and  $p[n]$ , where  $n$  is an integer strictly less than 0.
- $p - n$ , where  $n$  is an integer strictly greater than 0.

— Operations that, if otherwise well defined, constitute a use of  $p$  with  $B$  and prohibit any use with  $A$ :

- Any relational operator or pointer subtraction where the other operand  $q$  has provenance  $B$  and cannot have provenance  $A$ .
- $p + n$  and  $p[n]$ , where  $n$  is an integer strictly greater than 0.
- $p - n$ , where  $n$  is an integer strictly less than 0.
- operations that access an object in  $B$ , that is indirection ( $*p$  or  $p[n]$  for  $n == 0$ ) and member access ( $p->member$ ).

<sup>85)</sup> Thus, the result is an implementation-defined value or an implementation-defined signal is raised.

<sup>86)</sup> Although such a round-trip conversion may be the identity for the pointer value, the side effect of exposing a storage instance still takes place.

<sup>87)</sup> In general, the concept “correctly aligned” is transitive: if a pointer to type  $A$  is correctly aligned for a pointer to type  $B$ , which in turn is correctly aligned for a pointer to type  $C$ , then a pointer to type  $A$  is correctly aligned for a pointer to type  $C$ .

values.<sup>98)</sup> If the program attempts to modify such an array, the behavior is undefined.

8 **EXAMPLE 1** This pair of adjacent character string literals

```
"\x12" "3"
```

produces a single character string literal containing the two characters whose values are '\x12' and '3', because escape sequences are converted into single members of the execution character set just prior to adjacent string literal concatenation.

9 **EXAMPLE 2** Each of the sequences of adjacent string literal tokens

```
"a" "b" L"c"
"a" L"b" "c"
L"a" "b" L"c"
L"a" L"b" L"c"
```

is equivalent to the string literal

```
L"abc"
```

Likewise, each of the sequences

```
"a" "b" u"c"
"a" u"b" "c"
u"a" "b" u"c"
u"a" u"b" u"c"
```

is equivalent to

```
u"abc"
```

**Forward references:** common definitions <stddef.h> (7.19), the **mbstowcs** function (7.22.8.1), Unicode utilities <uchar.h> (7.28).

## 6.4.6 Punctuators

### Syntax

1 *punctuator*: one of

```
[ ] ( ) { } . ->
++ -- & * + - ~ !
/ % << >> < > <= >= == != ^ | && ||
? : ; ...
= *= /= %= += -= <<= >>= &= ^= |=
, # ##
<: :> <% %> %: %:~:
```

### Semantics

2 A punctuator is a symbol that has independent syntactic and semantic significance. Depending on context, it may specify an operation to be performed (which in turn may yield a value or a function designator, produce a side effect, or some combination thereof) in which case it is known as an *operator* (other forms of operator also exist in some contexts). An *operand* is an entity on which an operator acts.

3 In all aspects of the language, the six tokens<sup>99)</sup>

```
<: :> <% %> %: %:~:
```

behave, respectively, the same as the six tokens

<sup>98)</sup>[This allows implementations to share storage instances for string literals and constant compound literals \(6.5.2.5\) with the same or overlapping representations.](#)

<sup>99)</sup>These tokens are sometimes called “digraphs”.

## 6.5 Expressions

- 1 An *expression* is a sequence of operators and operands that specifies computation of a value,<sup>104)</sup> or that designates an object or a function, or that generates side effects, or that performs a combination thereof. The value computations of the operands of an operator are sequenced before the value computation of the result of the operator.
- 2 If a side effect on a scalar object is unsequenced relative to either a different side effect on the same scalar object or a value computation using the value of the same scalar object, the behavior is undefined. If there are multiple allowable orderings of the subexpressions of an expression, the behavior is undefined if such an unsequenced side effect occurs in any of the orderings.<sup>105)</sup>
- 3 The grouping of operators and operands is indicated by the syntax.<sup>106)</sup> Except as specified later, side effects and value computations of subexpressions are unsequenced.<sup>107)</sup>
- 4 Some operators (the unary operator `~`, and the binary operators `<<`, `>>`, `&`, `^`, and `|`, collectively described as *bitwise operators*) are required to have operands that have integer type. These operators yield values that depend on the internal representations of integers, and have implementation-defined and undefined aspects for signed types.
- 5 If an *exceptional condition* occurs during the evaluation of an expression (that is, if the result is not mathematically defined or not in the range of representable values for its type), the behavior is undefined.
- 6 The *effective type* of an object for an access to its stored value is the declared type of the object, if any.<sup>108)</sup> If a value is stored into an object having no declared type through an lvalue having a type that is not a character type, then the type of the lvalue becomes the effective type of the object for that access and for subsequent accesses that do not modify the stored value. If a value is copied into an object having no declared type using `memcpy` or `memmove`, or is copied as an array of character type, then the effective type of the modified object for that access and for subsequent accesses that do not modify the value is the effective type of the object from which the value is copied, if it has one. For all other accesses to an object having no declared type, the effective type of the object is simply the type of the lvalue used for the access.
- 7 An object shall have its stored value accessed only by an lvalue expression that has one of the following types:<sup>109)</sup>
  - a type compatible with the effective type of the object,
  - a qualified version of a type compatible with the effective type of the object,

<sup>104)</sup>Annex H documents the extent to which the C language supports the ISO/IEC 10967–1 standard for language-independent arithmetic (LIA–1).

<sup>105)</sup>This paragraph renders undefined statement expressions such as

```
i = ++i + 1;
a[i++] = i;
```

while allowing

```
i = i + 1;
a[i] = i;
```

<sup>106)</sup>The syntax specifies the precedence of operators in the evaluation of an expression, which is the same as the order of the major subclauses of this subclause, highest precedence first. Thus, for example, the expressions allowed as the operands of the binary `+` operator (6.5.6) are those expressions defined in 6.5.1 through 6.5.6. The exceptions are cast expressions (6.5.4) as operands of unary operators (6.5.3), and an operand contained between any of the following pairs of operators: grouping parentheses `()` (6.5.1), subscripting brackets `[]` (6.5.2.1), function-call parentheses `()` (6.5.2.2), and the conditional operator `?:` (6.5.15).

Within each major subclause, the operators have the same precedence. Left- or right-associativity is indicated in each subclause by the syntax for the expressions discussed therein.

<sup>107)</sup>In an expression that is evaluated more than once during the execution of a program, unsequenced and indeterminately sequenced evaluations of its subexpressions need not be performed consistently in different evaluations.

<sup>108)</sup>~~Allocated objects have~~ An object with allocated storage duration has no declaration and thus no declared type.

<sup>109)</sup>The intent of this list is to specify those circumstances in which an object can or cannot be aliased.

of the arguments after promotion are not compatible with the types of the parameters, the behavior is undefined. If the function is defined with a type that does not include a prototype, and the types of the arguments after promotion are not compatible with those of the parameters after promotion, the behavior is undefined, except for the following cases:

- one promoted type is a signed integer type, the other promoted type is the corresponding unsigned integer type, and the value is representable in both types;
  - both types are pointers to qualified or unqualified versions of a character type or **void**.
- 7 If the expression that denotes the called function has a type that does include a prototype, the arguments are implicitly converted, as if by assignment, to the types of the corresponding parameters, taking the type of each parameter to be the unqualified version of its declared type. The ellipsis notation in a function prototype declarator causes argument type conversion to stop after the last declared parameter. The default argument promotions are performed on trailing arguments.
  - 8 No other conversions are performed implicitly; in particular, the number and types of arguments are not compared with those of the parameters in a function definition that does not include a function prototype declarator.
  - 9 If the function is defined with a type that is not compatible with the type (of the expression) pointed to by the expression that denotes the called function, the behavior is undefined.
  - 10 There is a sequence point after the evaluations of the function designator and the actual arguments but before the actual call. Every evaluation in the calling function (including other function calls) that is not otherwise specifically sequenced before or after the execution of the body of the called function is indeterminately sequenced with respect to the execution of the called function.<sup>116)</sup>
  - 11 Recursive function calls shall be permitted, both directly and indirectly through any chain of other functions.
  - 12 **EXAMPLE** In the function call

```
(*pf[f1()]) (f2(), f3() + f4())
```

the functions `f1`, `f2`, `f3`, and `f4` can be called in any order. All side effects have to be completed before the function pointed to by `pf[f1()]` is called.

**Forward references:** function declarators (including prototypes) (6.7.6.3), function definitions (6.9.1), the **return** statement (6.8.6.4), simple assignment (6.5.16.1).

### 6.5.2.3 Structure and union members

#### Constraints

- 1 The first operand of the `.` operator shall have an atomic, qualified, or unqualified structure or union type, and the second operand shall name a member of that type.
- 2 The first operand of the `->` operator shall have type “pointer to atomic, qualified, or unqualified structure” or “pointer to atomic, qualified, or unqualified union”, and the second operand shall name a member of the type pointed to.

#### Semantics

- 3 A postfix expression followed by the `.` operator and an identifier designates a member of a structure or union object. The value is that of the named member,<sup>117)</sup> and is an lvalue if the first expression is an lvalue. If the first expression has qualified type, the result has the so-qualified version of the type of the designated member.
- 4 A postfix expression followed by the `->` operator and an identifier designates a member of a structure or union object. The pointer value shall be valid, not be the end address of its provenance, and be

<sup>116)</sup>In other words, function executions do not “interleave” with each other.

<sup>117)</sup>If the member used to read the contents of a union object is not the same as the member last used to store a value in the object, the appropriate part of the object representation of the value is reinterpreted as an object representation in the new type as described in 6.2.6 (a process sometimes called “type punning”). This might be a trap-non-value representation.

correctly aligned for the structure or union type. The value is that of the named member of the object to which the first expression points, and is an lvalue.<sup>118)</sup> If the first expression is a pointer to a qualified type, the result has the so-qualified version of the type of the designated member.

- 5 Accessing a member of an atomic structure or union object results in undefined behavior.<sup>119)</sup>
- 6 One special guarantee is made in order to simplify the use of unions: if a union contains several structures that share a common initial sequence (see below), and if the union object currently contains one of these structures, it is permitted to inspect the common initial part of any of them anywhere that a declaration of the completed type of the union is visible. Two structures share a *common initial sequence* if corresponding members have compatible types (and, for bit-fields, the same widths) for a sequence of one or more initial members.
- 7 **EXAMPLE 1** If `f` is a function returning a structure or union, and `x` is a member of that structure or union, `f().x` is a valid postfix expression but is not an lvalue.
- 8 **EXAMPLE 2** In:

```
struct s { int i; const int ci; };
struct s s;
const struct s cs;
volatile struct s vs;
```

the various members have the types:

```
s.i    int
s.ci   const int
cs.i   const int
cs.ci  const int
vs.i   volatile int
vs.ci  volatile const int
```

- 9 **EXAMPLE 3** The following is a valid fragment:

```
union {
    struct {
        int    alltypes;
    } n;
    struct {
        int    type;
        int    intnode;
    } ni;
    struct {
        int    type;
        double doublenode;
    } nf;
} u;
u.nf.type = 1;
u.nf.doublenode = 3.14;
/* ... */
if (u.n.alltypes == 1)
    if (sin(u.nf.doublenode) == 0.0)
        /* ... */
```

The following is not a valid fragment (because the union type is not visible within function `f`):

```
struct t1 { int m; };
struct t2 { int m; };
int f(struct t1 *p1, struct t2 *p2)
{
    if (p1->m < 0)
```

<sup>118)</sup>If `&E` is a valid pointer expression (where `&` is the “address-of” operator, which generates a pointer to its operand), the expression `(&E) ->MOS` is the same as `E.MOS`.

<sup>119)</sup>For example, a data race would occur if access to the entire structure or union in one thread conflicts with access to a member from another thread, where at least one access is a modification. Members can be safely accessed using a non-atomic object which is assigned to or from the atomic object.

list.<sup>121)</sup>

- 4 If the type name specifies an array of unknown size, the size is determined by the initializer list as specified in 6.7.9, and the type of the compound literal is that of the completed array type. Otherwise (when the type name specifies an object type), the type of the compound literal is that specified by the type name. In either case, the result is an lvalue.
- 5 The value of the compound literal is that of an unnamed object initialized by the initializer list. If the compound literal occurs outside the body of a function, the object has static storage duration; otherwise, it has automatic storage duration associated with the enclosing block.
- 6 All the semantic rules for initializer lists in 6.7.9 also apply to compound literals.<sup>122)</sup>
- 7 String literals, and compound literals with const-qualified types, need not designate distinct objects. ~~This allows implementations to share storage for string literals and constant compound literals with the same or overlapping representations.~~<sup>123)</sup>
- 8 **EXAMPLE 1** The file scope definition

```
int *p = (int []){2, 4};
```

initializes `p` to point to the first element of an array of two ints, the first having the value two and the second, four. The expressions in this compound literal are required to be constant. The unnamed object has static storage duration.

- 9 **EXAMPLE 2** In contrast, in

```
void f(void)
{
    int *p;
    /*...*/
    p = (int [2]){*p};
    /*...*/
}
```

`p` is assigned the address of the first element of an array of two ints, the first having the value previously pointed to by `p` and the second, zero. The expressions in this compound literal need not be constant. The unnamed object has automatic storage duration.

- 10 **EXAMPLE 3** Initializers with designations can be combined with compound literals. Structure objects created using compound literals can be passed to functions without depending on member order:

```
drawline((struct point){.x=1, .y=1},
        (struct point){.x=3, .y=4});
```

Or, if `drawline` instead expected pointers to `struct point`:

```
drawline(&(struct point){.x=1, .y=1},
        &(struct point){.x=3, .y=4});
```

- 11 **EXAMPLE 4** A read-only compound literal can be specified through constructions like:

```
(const float []){1e0, 1e1, 1e2, 1e3, 1e4, 1e5, 1e6}
```

- 12 **EXAMPLE 5** The following three expressions have different meanings:

```
"/tmp/fileXXXXXX"
(char []){"/tmp/fileXXXXXX"}
(const char []){"/tmp/fileXXXXXX"}
```

The first always has static storage duration and has type array of `char`, but need not be modifiable; the last two have automatic storage duration when they occur within the body of a function, and the first of these two is modifiable.

<sup>121)</sup>Note that this differs from a cast expression. For example, a cast specifies a conversion to scalar types or `void` only, and the result of a cast expression is not an lvalue.

<sup>122)</sup>For example, subobjects without explicit initializers are initialized to zero.

<sup>123)</sup>[This allows implementations to share storage instances for string literals and constant compound literals with the same or overlapping representations.](#)

- 13 **EXAMPLE 6** Like string literals, const-qualified compound literals can be placed into read-only memory and can even be shared. For example,

```
(const char []){"abc"} == "abc"
```

might yield 1 if the literals' storage [instance](#) is shared.

- 14 **EXAMPLE 7** Since compound literals are unnamed, a single compound literal cannot specify a circularly linked object. For example, there is no way to write a self-referential compound literal that could be used as the function argument in place of the named object `endless_zeros` below:

```
struct int_list { int car; struct int_list *cdr; };
struct int_list endless_zeros = {0, &endless_zeros};
eval(endless_zeros);
```

- 15 **EXAMPLE 8** Each compound literal creates only a single object in a given scope:

```
struct s { int i; };

int f (void)
{
    struct s *p = 0, *q;
    int j = 0;

    again:
    q = p, p = &((struct s){ j++ });
    if (j < 2) goto again;

    return p == q && q->i == 1;
}
```

The function `f()` always returns the value 1.

- 16 Note that if an iteration statement were used instead of an explicit `goto` and a labeled statement, the lifetime of the unnamed object would be the body of the loop only, and on entry next time around `p` would have an indeterminate [value, which would result in undefined behavior](#). [The behavior of the lvalue conversion of `p` in the assignment to `q` would then be undefined.](#)

**Forward references:** type names (6.7.7), initialization (6.7.9).

## 6.5.3 Unary operators

### Syntax

- 1 *unary-expression*:
- postfix-expression*
  - ++** *unary-expression*
  - *unary-expression*
  - unary-operator* *cast-expression*
  - sizeof** *unary-expression*
  - sizeof** ( *type-name* )
  - \_Alignof** ( *type-name* )

*unary-operator*: one of

**& \* + - ~ !**

### 6.5.3.1 Prefix increment and decrement operators

#### Constraints

- 1 The operand of the prefix increment or decrement operator shall have atomic, qualified, or unqualified real or pointer type, and shall be a modifiable lvalue.

**Semantics**

- 2 The value of the operand of the prefix ++ operator is incremented. The result is the new value of the operand after incrementation. The expression ++E is equivalent to (E+=1). See the discussions of additive operators and compound assignment for information on constraints, types, side effects, and conversions and the effects of operations on pointers.
- 3 The prefix - - operator is analogous to the prefix ++ operator, except that the value of the operand is decremented.

**Forward references:** additive operators (6.5.6), compound assignment (6.5.16.2).

**6.5.3.2 Address and indirection operators****Constraints**

- 1 The operand of the unary & operator shall be either a function designator, the result of a [ ] or unary \* operator, or an lvalue that designates an object that is not a bit-field and is not declared with the **register** storage-class specifier.
- 2 The operand of the unary \* operator shall have pointer type.

**Semantics**

- 3 The unary & operator yields the address of its operand. If the operand has type “type”, the result has type “pointer to type”. If the operand is the result of a unary \* operator, neither that operator nor the & operator is evaluated and the result is as if both were omitted, except that the constraints on the operators still apply and the result is not an lvalue. Similarly, if the operand is the result of a [ ] operator, neither the & operator nor the unary \* that is implied by the [ ] is evaluated and the result is as if the & operator were removed and the [ ] operator were changed to a + operator. Otherwise, the result is a pointer to the object or function designated by its operand.
- 4 The unary \* operator denotes indirection. If the operand points to a function, the result is a function designator; if it points to an object, the result is an lvalue designating the object. If the operand has type “pointer to type”, the result has type “type”. ~~If an invalid value has been assigned to the pointer, the behavior of the unary \* operator is undefined.~~ The pointer value shall be valid, not be the end address of its provenance, and be correctly aligned for “type”.<sup>124)</sup>

**Forward references:** storage-class specifiers (6.7.1), structure and union specifiers (6.7.2.1).

**6.5.3.3 Unary arithmetic operators****Constraints**

- 1 The operand of the unary + or - operator shall have arithmetic type; of the ~ operator, integer type; of the ! operator, scalar type.

**Semantics**

- 2 The result of the unary + operator is the value of its (promoted) operand. The integer promotions are performed on the operand, and the result has the promoted type.
- 3 The result of the unary - operator is the negative of its (promoted) operand. The integer promotions are performed on the operand, and the result has the promoted type.
- 4 The result of the ~ operator is the bitwise complement of its (promoted) operand (that is, each bit in the result is set if and only if the corresponding bit in the converted operand is not set). The integer promotions are performed on the operand, and the result has the promoted type. If the promoted type is an unsigned type, the expression ~E is equivalent to the maximum value representable in that type minus E.
- 5 The result of the logical negation operator ! is 0 if the value of its operand compares unequal to

<sup>124)</sup>Thus, &\*E is equivalent to E (even if E is a null pointer), and &(E1[E2]) to ((E1)+(E2)). It is always true that if E is a function designator or an lvalue that is a valid operand of the unary & operator, \*&E is a function designator or an lvalue equal to E. If \*P is an lvalue and T is the name of an object pointer type, \*(T)P is an lvalue that has a type compatible with that to which T points.

Among the invalid values for dereferencing a pointer by the unary \* operator are a null pointer, an address inappropriately aligned for the type of object pointed to, ~~and~~ the address of an object after the end of its lifetime, or any other invalid value.

## 6.5.6 Additive operators

### Syntax

- 1 *additive-expression*:
- multiplicative-expression*
  - additive-expression* + *multiplicative-expression*
  - additive-expression* - *multiplicative-expression*

### Constraints

- 2 For addition, either both operands shall have arithmetic type, or one operand shall be a pointer to a complete object type and the other shall have integer type. (Incrementing is equivalent to adding 1.)
- 3 For subtraction, one of the following shall hold:
- both operands have arithmetic type;
  - both operands are pointers to qualified or unqualified versions of compatible complete object types; or
  - the left operand is a pointer to a complete object type and the right operand has integer type.

(Decrementing is equivalent to subtracting 1.)

### Semantics

- 4 If both operands have arithmetic type, the usual arithmetic conversions are performed on them.
- 5 The result of the binary + operator is the sum of the operands.
- 6 The result of the binary - operator is the difference resulting from the subtraction of the second operand from the first.
- 7 For the purposes of these operators, a pointer to an object that is not an element of an array behaves the same as a pointer to the first element of an array of length one with the type of the object as its element type.
- 8 When an expression that has integer type is added to or subtracted from a pointer, the result has the type of the pointer operand. If the pointer operand points to an element of an array object, and the array is large enough, the result points to an element offset from the original element such that the difference of the subscripts of the resulting and original array elements equals the integer expression. ~~In other words, if the expression P points to the *i*-th element of an array object, the expressions (P)+N (equivalently, N+(P)) and (P)-N (where N has the value *n*) point to, respectively, the *i*+*n*-th and *i*-*n*-th elements of the array object, provided they exist. Moreover, if the expression P points to the last element of an array object, the expression (P)+1 points one past the last element of the array object, and if the expression Q points one past the last element of an array object, the expression (Q)-1 points to the last element of the array object.~~ If both the pointer operand and the result point to elements of the same array object, or one past the last element of the array object, the evaluation shall not produce an overflow; otherwise, the behavior is undefined. If the result points one past the last element of the array object, it shall not be used as the operand of a unary \* operator that is evaluated. The result pointer has the same provenance as the pointer operand.<sup>128)</sup>
- 9 When two pointers are subtracted, both shall be valid and point to elements of the same array object, or one past the last element of the array object;<sup>129)</sup> the result is the difference of the subscripts of the two array elements. The size of the result is implementation-defined, and its type (a signed integer type) is `ptrdiff_t` defined in the `<stddef.h>` header. If the result is not representable in an object of that type, the behavior is undefined. ~~In other words, if the~~

<sup>128)</sup> If the pointer operand P had been the result of an integer-to-pointer or `scanf` conversion that could have two possible provenances, and the integer value added or subtracted is not 0, the provenance S for the additive operation (and henceforth other operations with P) must be such that the result lies in S (or one beyond).

<sup>129)</sup> This implies that they also have the same provenance.

- 10 **NOTE 1** If the expression P points to the i-th element of an array object, the expressions (P)+N (equivalently, N+(P)) and (P)-N (where N has the value n) point to, respectively, the i+n-th and i-n-th elements of the array object, provided they exist. Moreover, if the expression P points to the last element of an array object, the expression (P)+1 points one past the last element of the array object, and if the expression Q points one past the last element of an array object, the expression (Q)-1 points to the last element of the array object.
- 11 **NOTE 2** If the expressions P and Q point to, respectively, the i-th and j-th elements of an array object, the expression (P)-(Q) has the value i-j provided the value fits in an object of type ptrdiff\_t. Moreover, if the expression P points either to an element of an array object or one past the last element of an array object, and the expression Q points to the last element of the same array object, the expression ((Q)+1)-(P) has the same value as ((Q)-(P))+1 and as -((P)-((Q)+1)), and has the value zero if the expression P points one past the last element of the array object, even though the expression (Q)+1 does not point to an element of the array object. ~~Another way to approach pointer arithmetic is first to convert the pointer(s) to character pointer(s): In this scheme the integer expression added to or subtracted from the converted pointer is first multiplied by the size of the object originally pointed to, and the resulting pointer is converted back to the original type. For pointer subtraction, the result of the difference between the character pointers is similarly divided by the size of the object originally pointed to. When viewed in this way, an implementation need only provide one extra byte (which can overlap another object in the program) just after the end of the object in order to satisfy the “one past the last element” requirements.~~
- 12 **NOTE 3** Another way to approach pointer arithmetic is first to convert the pointer(s) to character pointer(s): In this scheme the integer expression added to or subtracted from the converted pointer is first multiplied by the size of the object originally pointed to, and the resulting pointer is converted back to the original type. For pointer subtraction, the result of the difference between the character pointers is similarly divided by the size of the object originally pointed to.  
When viewed in this way, an implementation need only provide one extra byte (which can overlap another object in the program) just after the end of the object in order to satisfy the “one past the last element” requirements.
- 13 **EXAMPLE** Pointer arithmetic is well defined with pointers to variable length array types.

```

{
    int n = 4, m = 3;
    int a[n][m];
    int (*p)[m] = a; // p == &a[0]
    p += 1;         // p == &a[1]
    (*p)[2] = 99;   // a[1][2] == 99
    n = p - a;      // n == 1
}

```

- 14 If array `a` in the above example were declared to be an array of known constant size, and pointer `p` were declared to be a pointer to an array of the same known constant size (pointing to `a`), the results would be the same.

**Forward references:** array declarators (6.7.6.2), common definitions `<stddef.h>` (7.19).

## 6.5.7 Bitwise shift operators

### Syntax

- 1 *shift-expression:*
- ```

    additive-expression
    shift-expression << additive-expression
    shift-expression >> additive-expression

```

### Constraints

- 2 Each of the operands shall have integer type.

### Semantics

- 3 The integer promotions are performed on each of the operands. The type of the result is that of the promoted left operand. If the value of the right operand is negative or is greater than or equal to the width of the promoted left operand, the behavior is undefined.
- 4 The result of `E1 << E2` is `E1` left-shifted `E2` bit positions; vacated bits are filled with zeros. If `E1` has an unsigned type, the value of the result is  $E1 \times 2^{E2}$ , reduced modulo one more than the maximum value representable in the result type. If `E1` has a signed type and nonnegative value, and  $E1 \times 2^{E2}$  is representable in the result type, then that is the resulting value; otherwise, the behavior is undefined.
- 5 The result of `E1 >> E2` is `E1` right-shifted `E2` bit positions. If `E1` has an unsigned type or if `E1` has a signed type and a nonnegative value, the value of the result is the integral part of the quotient of

**E1/2<sup>E2</sup>**. If **E1** has a signed type and a negative value, the resulting value is implementation-defined.

## 6.5.8 Relational operators

### Syntax

- 1 *relational-expression*:
- shift-expression*
  - relational-expression* < *shift-expression*
  - relational-expression* > *shift-expression*
  - relational-expression* <= *shift-expression*
  - relational-expression* >= *shift-expression*

### Constraints

- 2 One of the following shall hold:
- both operands have real type; or
  - both operands are pointers to qualified or unqualified versions of compatible object types.

### Semantics

- 3 If both of the operands have arithmetic type, the usual arithmetic conversions are performed.
- 4 For the purposes of these operators, a pointer to an object that is not an element of an array behaves the same as a pointer to the first element of an array of length one with the type of the object as its element type.
- 5 When two pointers are compared, ~~the result depends on the relative locations in the address space of the objects pointed to. If two pointers to object types both point to the same object, or both point one past the last element of the same array object, they compare equal. If the objects pointed to are members of the same aggregate object, pointers to structure members declared later compare greater than pointers to members declared earlier in the structure, and pointers to array elements with larger subscript values compare greater than pointers to elements of the same array with lower subscript values. All pointers to members of the same union object compare equal. If the expression **P** points to an element of an array object and the expression **Q** points to the last element of the same array object, the pointer expression **Q+1** compares greater than **P**. In all other cases, the behavior is undefined~~ they shall both be valid and have the same provenance. The result depends on the relative ordering of their abstract addresses.
- 6 Each of the operators < (less than), > (greater than), <= (less than or equal to), and >= (greater than or equal to) shall yield 1 if the specified relation is true and 0 if it is false.<sup>130)</sup> The result has type **int**.

## 6.5.9 Equality operators

### Syntax

- 1 *equality-expression*:
- relational-expression*
  - equality-expression* == *relational-expression*
  - equality-expression* != *relational-expression*

### Constraints

- 2 One of the following shall hold:
- both operands have arithmetic type;
  - both operands are pointers to qualified or unqualified versions of compatible types;

<sup>130)</sup>The expression **a<b<c** is not interpreted as in ordinary mathematics. As the syntax indicates, it means (**a<b**)<**c**; in other words, “if **a** is less than **b**, compare 1 to **c**; otherwise, compare 0 to **c**”.

- one operand is a pointer to an object type and the other is a pointer to a qualified or unqualified version of **void**; or
- one operand is a pointer and the other is a null pointer constant.

### Semantics

- 3 The == (equal to) and != (not equal to) operators are analogous to the relational operators except for their lower precedence.<sup>131)</sup> None of the operands shall be an invalid pointer value. Each of the operators yields 1 if the specified relation is true and 0 if it is false. The result has type **int**. For any pair of operands, exactly one of the relations is true.
- 4 If both of the operands have arithmetic type, the usual arithmetic conversions are performed. Values of complex types are equal if and only if both their real parts are equal and also their imaginary parts are equal. Any two values of arithmetic types from different type domains are equal if and only if the results of their conversions to the (complex) result type determined by the usual arithmetic conversions are equal.
- 5 Otherwise, at least one operand is a pointer. If one operand is a pointer and the other is a null pointer constant, the null pointer constant is converted to the type of the pointer. If one operand is a pointer to an object type and the other is a pointer to a qualified or unqualified version of **void**, the former is converted to the type of the latter.
- 6 ~~Two pointers~~ If one operand is null they compare equal if and only if both are null pointers, both the other operand is null. Otherwise, if both operands are pointers to the same object (including a pointer to an object and a subobject at its beginning) or function, both function type they compare equal if and only if they refer to the same function. Otherwise, they are pointers to one past the last element of the same array object, or one is a pointer to one past the end of one array object and the other is a pointer to the start of a different array object that happens to immediately follow the first array object in the addressspace. Two objects can be adjacent in memory because they are adjacent elements of a larger array or adjacent members of a structure with no padding between them, or because the implementation chose to place them so, even though they are unrelated. If prior invalid pointer operations (such as accesses outside array bounds) produced undefined behavior, subsequent comparisons also produce undefined behavior. objects and compare equal if and only if they have the same abstract address.
- 7 For the purposes of these operators, a pointer to an object that is not an element of an array behaves the same as a pointer to the first element of an array of length one with the type of the object as its element type.

## 6.5.10 Bitwise AND operator

### Syntax

- 1 *AND-expression*:  

$$\text{equality-expression}$$

$$\text{AND-expression} \ \& \ \text{equality-expression}$$

### Constraints

- 2 Each of the operands shall have integer type.

### Semantics

- 3 The usual arithmetic conversions are performed on the operands.
- 4 The result of the binary & operator is the bitwise AND of the operands (that is, each bit in the result is set if and only if each of the corresponding bits in the converted operands is set).

<sup>131)</sup>Because of the precedences,  $a < b == c < d$  is 1 whenever  $a < b$  and  $c < d$  have the same truth-value.

```

const void *c_vp;
void *vp;
const int *c_ip;
volatile int *v_ip;
int *ip;
const char *c_cp;

```

the third column in the following table is the common type that is the result of a conditional expression in which the first two columns are the second and third operands (in either order):

|      |      |                      |
|------|------|----------------------|
| c_vp | c_ip | const void *         |
| v_ip | 0    | volatile int *       |
| c_ip | v_ip | const volatile int * |
| vp   | c_cp | const void *         |
| ip   | c_ip | const int *          |
| vp   | ip   | void *               |

## 6.5.16 Assignment operators

### Syntax

- 1 *assignment-expression*:
  - conditional-expression*
  - unary-expression assignment-operator assignment-expression*

*assignment-operator*: one of

= \*= /= %= += -= <<= >>= &= ^= |=

### Constraints

- 2 An assignment operator shall have a modifiable lvalue as its left operand.

### Semantics

- 3 An assignment operator stores a value in the object designated by the left operand. If a non-null pointer is stored by an assignment operator, either directly or within a structure or union object, the stored pointer object has the same provenance as the original. An assignment expression has the value of the left operand after the assignment,<sup>133)</sup> but is not an lvalue. The type of an assignment expression is the type the left operand would have after lvalue conversion. The side effect of updating the stored value of the left operand is sequenced after the value computations of the left and right operands. The evaluations of the operands are unsequenced.

#### 6.5.16.1 Simple assignment

##### Constraints

- 1 One of the following shall hold:<sup>134)</sup>
  - the left operand has atomic, qualified, or unqualified arithmetic type, and the right has arithmetic type;
  - the left operand has an atomic, qualified, or unqualified version of a structure or union type compatible with the type of the right;
  - the left operand has atomic, qualified, or unqualified pointer type, and (considering the type the left operand would have after lvalue conversion) both operands are pointers to qualified or unqualified versions of compatible types, and the type pointed to by the left has all the qualifiers of the type pointed to by the right;

<sup>133)</sup>The implementation is permitted to read the object to determine the value but is not required to, even when the object has volatile-qualified type.

<sup>134)</sup>The asymmetric appearance of these constraints with respect to type qualifiers is due to the conversion (specified in 6.3.2.1) that changes lvalues to “the value of the expression” and thus removes any type qualifiers that were applied to the type category of the expression (for example, it removes **const** but not **volatile** from the type **int volatile \* const**).

## 6.7 Declarations

### Syntax

- 1 *declaration*:
- declaration-specifiers* *init-declarator-list*<sub>opt</sub> ;  
*static\_assert-declaration*
- declaration-specifiers*:
- storage-class-specifier* *declaration-specifiers*<sub>opt</sub>  
*type-specifier* *declaration-specifiers*<sub>opt</sub>  
*type-qualifier* *declaration-specifiers*<sub>opt</sub>  
*function-specifier* *declaration-specifiers*<sub>opt</sub>  
*alignment-specifier* *declaration-specifiers*<sub>opt</sub>
- init-declarator-list*:
- init-declarator*  
*init-declarator-list* , *init-declarator*
- init-declarator*:
- declarator*  
*declarator* = *initializer*

### Constraints

- 2 A declaration other than a `static_assert` declaration shall declare at least a declarator (other than the parameters of a function or the members of a structure or union), a tag, or the members of an enumeration.
- 3 If an identifier has no linkage, there shall be no more than one declaration of the identifier (in a declarator or type specifier) with the same scope and in the same name space, except that:
- a typedef name may be redefined to denote the same type as it currently does, provided that type is not a variably modified type;
  - tags may be redeclared as specified in 6.7.2.3.
- 4 All declarations in the same scope that refer to the same object or function shall specify compatible types.

### Semantics

- 5 A declaration specifies the interpretation and attributes of a set of identifiers. A *definition* of an identifier is a declaration for that identifier that:
- for an object, causes **storage** a unique storage instance to be reserved for that object;
  - for a function, includes the function body;<sup>140)</sup>
  - for an enumeration constant, is the (only) declaration of the identifier;
  - for a typedef name, is the first (or only) declaration of the identifier.
- 6 The declaration specifiers consist of a sequence of specifiers that indicate the linkage, storage duration, and part of the type of the entities that the declarators denote. The *init-declarator-list* is a comma-separated sequence of declarators, each of which may have additional type information, or an initializer, or both. The declarators contain the identifiers (if any) being declared.
- 7 If an identifier for an object is declared with no linkage, the type for the object shall be complete by the end of its declarator, or by the end of its *init-declarator* if it has an initializer; in the case of function parameters (including in prototypes), it is the adjusted type (see 6.7.6.3) that is required to be complete.

**Forward references:** declarators (6.7.6), enumeration specifiers (6.7.2.2), initialization (6.7.9), type names (6.7.7), type qualifiers (6.7.3).

<sup>140)</sup>Function definitions have a different syntax, described in 6.9.1.

## 6.7.1 Storage-class specifiers

### Syntax

- 1 *storage-class-specifier*:
- typedef**
  - extern**
  - static**
  - \_Thread\_local**
  - auto**
  - register**

### Constraints

- 2 At most, one storage-class specifier may be given in the declaration specifiers in a declaration, except that **\_Thread\_local** may appear with **static** or **extern**.<sup>141)</sup>
- 3 In the declaration of an object with block scope, if the declaration specifiers include **\_Thread\_local**, they shall also include either **static** or **extern**. If **\_Thread\_local** appears in any declaration of an object, it shall be present in every declaration of that object.
- 4 **\_Thread\_local** shall not appear in the declaration specifiers of a function declaration.

### Semantics

- 5 The **typedef** specifier is called a “storage-class specifier” for syntactic convenience only; it is discussed in 6.7.8. The meanings of the various linkages and storage durations were discussed in 6.2.2 and 6.2.4 .
- 6 A declaration of an identifier for an object with storage-class specifier **register** suggests that access to the object be as fast as possible. The extent to which such suggestions are effective is implementation-defined.<sup>142)</sup>
- 7 The declaration of an identifier for a function that has block scope shall have no explicit storage-class specifier other than **extern**.
- 8 If an aggregate or union object is declared with a storage-class specifier other than **typedef**, the properties resulting from the storage-class specifier, except with respect to linkage, also apply to the members of the object, and so on recursively for any aggregate or union member objects.

**Forward references:** type definitions (6.7.8).

## 6.7.2 Type specifiers

### Syntax

- 1 *type-specifier*:
- void**
  - char**
  - short**
  - int**
  - long**
  - float**
  - double**
  - signed**
  - unsigned**
  - \_Bool**
  - \_Complex**
  - atomic-type-specifier*

<sup>141)</sup>See “future language directions” (6.11.5).

<sup>142)</sup>The implementation can treat any **register** declaration simply as an **auto** declaration. However, whether or not **addressable** a storage **instance that would otherwise be addressable** is actually used, the address of any part of an object declared with storage-class specifier **register** cannot be computed, either explicitly (by use of the unary & operator as discussed in 6.5.3.2) or implicitly (by converting an array name to a pointer as discussed in 6.3.2.1). Thus, the only operator that can be applied to an array declared with storage-class specifier **register** is **sizeof**.

incomplete until immediately after the } that terminates the list, and complete thereafter.

- 9 A member of a structure or union may have any complete object type other than a variably modified type.<sup>144)</sup> In addition, a member may be declared to consist of a specified number of bits (including a sign bit, if any). Such a member is called a *bit-field*;<sup>145)</sup> its width is preceded by a colon.
- 10 A bit-field is interpreted as having a signed or unsigned integer type consisting of the specified number of bits.<sup>146)</sup> If the value 0 or 1 is stored into a nonzero-width bit-field of type **\_Bool**, the value of the bit-field shall compare equal to the value stored; a **\_Bool** bit-field has the semantics of a **\_Bool**.
- 11 An implementation may allocate any addressable storage unit large enough to hold a bit-field. If enough space remains, a bit-field that immediately follows another bit-field in a structure shall be packed into adjacent bits of the same unit. If insufficient space remains, whether a bit-field that does not fit is put into the next unit or overlaps adjacent units is implementation-defined. The order of allocation of bit-fields within a unit (high-order to low-order or low-order to high-order) is implementation-defined. The alignment of the addressable storage unit is unspecified.
- 12 A bit-field declaration with no declarator, but only a colon and a width, indicates an unnamed bit-field.<sup>147)</sup> As a special case, a bit-field structure member with a width of 0 indicates that no further bit-field is to be packed into the unit in which the previous bit-field, if any, was placed.
- 13 An unnamed member whose type specifier is a structure specifier with no tag is called an *anonymous structure*; an unnamed member whose type specifier is a union specifier with no tag is called an *anonymous union*. The members of an anonymous structure or union are considered to be members of the containing structure or union. This applies recursively if the containing structure or union is also anonymous.
- 14 Each non-bit-field member of a structure or union object is aligned in an implementation-defined manner appropriate to its type.
- 15 Within a structure object, the non-bit-field members and the units in which bit-fields reside have addresses that increase in the order in which they are declared. A pointer to a structure object, suitably converted, points to its initial member (or if that member is a bit-field, then to the unit in which it resides), and vice versa. There may be unnamed padding within a structure object, but not at its beginning.
- 16 The size of a union is sufficient to contain the largest of its members. The value of at most one of the members can be stored in a union object at any time. A pointer to a union object, suitably converted, points to each of its members (or if a member is a bit-field, then to the unit in which it resides), and vice versa.
- 17 There may be unnamed padding at the end of a structure or union.
- 18 As a special case, the last member of a structure with more than one named member may have an incomplete array type; this is called a *flexible array member*. In most situations, the flexible array member is ignored. In particular, the size of the structure is as if the flexible array member were omitted except that it may have more trailing padding than the omission would imply. However, when a . (or ->) operator has a left operand that is (a pointer to) a structure with a flexible array member and the right operand names that member, it behaves as if that member were replaced with the longest array (with the same element type) that would not make the structure larger than the [object storage instance](#) being accessed; the offset of the array shall remain that of the flexible array member, even if this would differ from that of the replacement array. If this array would have no elements, it behaves as if it had one element but the behavior is undefined if any attempt is made to access that element or to generate a pointer one past it.

---

<sup>144)</sup>A structure or union cannot contain a member with a variably modified type because member names are not ordinary identifiers as defined in 6.2.3.

<sup>145)</sup>The unary & (address-of) operator cannot be applied to a bit-field object; thus, there are no pointers to or arrays of bit-field objects.

<sup>146)</sup>As specified in 6.7.2 above, if the actual type specifier used is **int** or a typedef-name defined as **int**, then it is implementation-defined whether the bit-field is signed or unsigned.

<sup>147)</sup>An unnamed bit-field structure member is useful for padding to conform to externally imposed layouts.

```
struct { int n; double d[8]; } *s1;
struct { int n; double d[5]; } *s2;
```

- 24 Following the further successful assignments:

```
s1 = malloc(sizeof (struct s) + 10);
s2 = malloc(sizeof (struct s) + 6);
```

they then behave as if the declarations were:

```
struct { int n; double d[1]; } *s1, *s2;
```

and:

```
double *dp;
dp = &(s1->d[0]); // valid
*dp = 42;         // valid
dp = &(s2->d[0]); // valid
*dp = 42;         // undefined behavior
```

- 25 The assignment:

```
*s1 = *s2;
```

only copies the member `n`; if any of the array elements are within the first `sizeof (struct s)` bytes of the structure, they ~~might be copied or simply overwritten with indeterminate values~~ are set to an indeterminate representation, that may or may not coincide with a copy of the representation of the elements of the source array.

- 26 **EXAMPLE 3** Because members of anonymous structures and unions are considered to be members of the containing structure or union, `struct s` in the following example has more than one named member and thus the use of a flexible array member is valid:

```
struct s {
    struct { int i; };
    int a[];
};
```

**Forward references:** declarators (6.7.6), tags (6.7.2.3).

### 6.7.2.2 Enumeration specifiers

#### Syntax

- 1 *enum-specifier*:
- ```
enum identifieropt { enumerator-list }
enum identifieropt { enumerator-list , }
enum identifier
```
- enumerator-list*:
- ```
enumerator
enumerator-list , enumerator
```
- enumerator*:
- ```
enumeration-constant
enumeration-constant = constant-expression
```

#### Constraints

- 2 The expression that defines the value of an enumeration constant shall be an integer constant expression that has a value representable as an `int`.

specify a pair of structures that contain pointers to each other. Note, however, that if `s2` were already declared as a tag in an enclosing scope, the declaration `D1` would refer to *it*, not to the tag `s2` declared in `D2`. To eliminate this context sensitivity, the declaration

```
struct s2;
```

can be inserted ahead of `D1`. This declares a new tag `s2` in the inner scope; the declaration `D2` then completes the specification of the new type.

**Forward references:** declarators (6.7.6), type definitions (6.7.8).

#### 6.7.2.4 Atomic type specifiers

##### Syntax

- 1 *atomic-type-specifier*:  
     **\_Atomic** ( *type-name* )

##### Constraints

- 2 Atomic type specifiers shall not be used if the implementation does not support atomic types (see 6.10.8.3).
- 3 The type name in an atomic type specifier shall not refer to an array type, a function type, an atomic type, or a qualified type.

##### Semantics

- 4 The properties associated with atomic types are meaningful only for expressions that are lvalues. If the **\_Atomic** keyword is immediately followed by a left parenthesis, it is interpreted as a type specifier (with a type name), not as a type qualifier.

### 6.7.3 Type qualifiers

##### Syntax

- 1 *type-qualifier*:  
     **const**  
     **restrict**  
     **volatile**  
     **\_Atomic**

##### Constraints

- 2 Types other than pointer types whose referenced type is an object type shall not be restrict-qualified.
- 3 The **\_Atomic** qualifier shall not be used if the implementation does not support atomic types (see 6.10.8.3).
- 4 The type modified by the **\_Atomic** qualifier shall not be an array type or a function type.

##### Semantics

- 5 The properties associated with qualified types are meaningful only for expressions that are lvalues.<sup>153)</sup>
- 6 If the same qualifier appears more than once in the same specifier-qualifier list or as declaration specifiers, either directly or via one or more **typedefs**, the behavior is the same as if it appeared only once. If other qualifiers appear along with the **\_Atomic** qualifier the resulting type is the so-qualified atomic type.
- 7 If an attempt is made to modify an object defined with a const-qualified type through use of an lvalue with non-const-qualified type, the behavior is undefined. If an attempt is made to refer to an

<sup>153)</sup>The implementation can place a **const** object that is not **volatile** in a read-only **region-of storage instance**. Moreover, ~~the implementation need not allocate a~~ storage **instance** for such an object **need not be addressable** if its address is never used.

operator and changing the value of the size expression would not affect the result of the operator, it is unspecified whether or not the size expression is evaluated.

- 6 For two array types to be compatible, both shall have compatible element types, and if both size specifiers are present, and are integer constant expressions, then both size specifiers shall have the same constant value. If the two array types are used in a context which requires them to be compatible, it is undefined behavior if the two size specifiers evaluate to unequal values.

7 **EXAMPLE 1**

```
float fa[11], *afp[17];
```

declares an array of **float** numbers and an array of pointers to **float** numbers.

- 8 **EXAMPLE 2** Note the distinction between the declarations

```
extern int *x;
extern int y[];
```

The first declares *x* to be a pointer to **int**; the second declares *y* to be an array of **int** of unspecified size (an incomplete type), the storage [instance](#) for which is defined elsewhere.

- 9 **EXAMPLE 3** The following declarations demonstrate the compatibility rules for variably modified types.

```
extern int n;
extern int m;

void fcompat(void)
{
    int a[n][6][m];
    int (*p)[4][n+1];
    int c[n][n][6][m];
    int (*r)[n][n][n+1];
    p = a;      // invalid: not compatible because 4 != 6
    r = c;      // compatible, but defined behavior only if
                // n == 6 and m == n+1
}
```

- 10 **EXAMPLE 4** All declarations of variably modified (VM) types have to be at either block scope or function prototype scope. Array objects declared with the **\_Thread\_local**, **static**, or **extern** storage-class specifier cannot have a variable length array (VLA) type. However, an object declared with the **static** storage-class specifier can have a VM type (that is, a pointer to a VLA type). Finally, all identifiers declared with a VM type have to be ordinary identifiers and cannot, therefore, be members of structures or unions.

```
extern int n;
int A[n];           // invalid: file scope VLA
extern int (*p2)[n]; // invalid: file scope VM
int B[100];         // valid: file scope but not VM

void fvla(int m, int C[m][m]); // valid: VLA with prototype scope

void fvla(int m, int C[m][m]) // valid: adjusted to auto pointer to VLA
{
    typedef int VLA[m][m];     // valid: block scope typedef VLA

    struct tag {
        int (*y)[n];          // invalid: y not ordinary identifier
        int z[n];             // invalid: z not ordinary identifier
    };
    int D[m];                 // valid: auto VLA
    static int E[m];          // invalid: static block scope VLA
    extern int F[m];          // invalid: F has linkage and is VLA
    int (*s)[m];              // valid: auto pointer to VLA
    extern int (*r)[m];       // invalid: r has linkage and points to VLA
    static int (*q)[m] = &B;  // valid: q is a static block pointer to VLA
```

- 3 The type of the entity to be initialized shall be an array of unknown size or a complete object type that is not a variable length array type.
- 4 All the expressions in an initializer for an object that has static or thread storage duration shall be constant expressions or string literals.
- 5 If the declaration of an identifier has block scope, and the identifier has external or internal linkage, the declaration shall have no initializer for the identifier.
- 6 If a designator has the form

[ *constant-expression* ]

then the current object (defined below) shall have array type and the expression shall be an integer constant expression. If the array is of unknown size, any nonnegative value is valid.

- 7 If a designator has the form

. *identifier*

then the current object (defined below) shall have structure or union type and the identifier shall be the name of a member of that type.

### Semantics

- 8 An initializer specifies the initial value stored in an object.
- 9 Except where explicitly stated otherwise, for the purposes of this subclause unnamed members of objects of structure and union type do not participate in initialization. Unnamed members of structure objects have indeterminate [value-representation](#) even after initialization.
- 10 If an object that has automatic storage duration is not initialized explicitly, its [value-representation](#) is indeterminate. If an object that has static or thread storage duration is not initialized explicitly, then:
- if it has pointer type, it is initialized to a null pointer;
  - if it has arithmetic type, it is initialized to (positive or unsigned) zero;
  - if it is an aggregate, every member is initialized (recursively) according to these rules, and any padding is initialized to zero bits;
  - if it is a union, the first named member is initialized (recursively) according to these rules, and any padding is initialized to zero bits;
- 11 The initializer for a scalar shall be a single expression, optionally enclosed in braces. The initial value of the object is that of the expression (after conversion); the same type constraints and conversions as for simple assignment apply, taking the type of the scalar to be the unqualified version of its declared type.
- 12 The rest of this subclause deals with initializers for objects that have aggregate or union type.
- 13 The initializer for a structure or union object that has automatic storage duration shall be either an initializer list as described below, or a single expression that has compatible structure or union type. In the latter case, the initial value of the object, including unnamed members, is that of the expression.
- 14 An array of character type may be initialized by a character string literal or UTF-8 string literal, optionally enclosed in braces. Successive bytes of the string literal (including the terminating null character if there is room or if the array is of unknown size) initialize the elements of the array.
- 15 An array with element type compatible with a qualified or unqualified version of `wchar_t`, `char16_t`, or `char32_t` may be initialized by a wide string literal with the corresponding encoding prefix (`L`, `u`, or `U`, respectively), optionally enclosed in braces. Successive wide characters of the wide string literal (including the terminating null wide character if there is room or if the array is of unknown size) initialize the elements of the array.
- 16 Otherwise, the initializer for an object that has aggregate or union type shall be a brace-enclosed list of initializers for the elements or named members.

## 6.8 Statements and blocks

### Syntax

- 1 *statement*:
- labeled-statement*
  - compound-statement*
  - expression-statement*
  - selection-statement*
  - iteration-statement*
  - jump-statement*

### Semantics

- 2 A *statement* specifies an action to be performed. Except as indicated, statements are executed in sequence.
- 3 A *block* allows a set of declarations and statements to be grouped into one syntactic unit. The initializers of objects that have automatic storage duration, and the variable length array declarators of ordinary identifiers with block scope, are evaluated and the values are stored in the objects (~~including storing an indeterminate value in the representation of~~ objects without an initializer becomes indeterminate) each time the declaration is reached in the order of execution, as if it were a statement, and within each declaration in the order that declarators appear.
- 4 A *full expression* is an expression that is not part of another expression, nor part of a declarator or abstract declarator. There is also an implicit full expression in which the non-constant size expressions for a variably modified type are evaluated; within that full expression, the evaluation of different size expressions are unsequenced with respect to one another. There is a sequence point between the evaluation of a full expression and the evaluation of the next full expression to be evaluated.
- 5 **NOTE** Each of the following is a full expression:
- a full declarator for a variably modified type,
  - an initializer that is not part of a compound literal,
  - the expression in an expression statement,
  - the controlling expression of a selection statement (**if** or **switch**),
  - the controlling expression of a **while** or **do** statement,
  - each of the (optional) expressions of a **for** statement,
  - the (optional) expression in a **return** statement.

While a constant expression satisfies the definition of a full expression, evaluating it does not depend on nor produce any side effects, so the sequencing implications of being a full expression are not relevant to a constant expression.

**Forward references:** expression and null statements (6.8.3), selection statements (6.8.4), iteration statements (6.8.5), the **return** statement (6.8.6.4).

### 6.8.1 Labeled statements

#### Syntax

- 1 *labeled-statement*:
- identifier* : *statement*
  - case** *constant-expression* : *statement*
  - default** : *statement*

#### Constraints

- 2 A **case** or **default** label shall appear only in a **switch** statement. Further constraints on such labels are discussed under the **switch** statement.
- 3 Label names shall be unique within a function.

7 EXAMPLE In the artificial program fragment

```
switch (expr)
{
    int i = 4;
    f(i);
    case 0:
        i = 17;
        /* falls through into default code */
    default:
        printf("%d\n", i);
}
```

the object whose identifier is `i` exists with automatic storage duration (within the block) but is never initialized, and thus if the controlling expression has a nonzero value, the call to the `printf` function will access an [indeterminate value object with an indeterminate representation](#). Similarly, the call to the function `f` cannot be reached.

## 6.8.5 Iteration statements

### Syntax

1 *iteration-statement*:

```
while ( expression ) statement
do statement while ( expression ) ;
for ( expressionopt ; expressionopt ; expressionopt ) statement
for ( declaration expressionopt ; expressionopt ) statement
```

### Constraints

- 2 The controlling expression of an iteration statement shall have scalar type.
- 3 The declaration part of a **for** statement shall only declare identifiers for objects having storage class **auto** or **register**.

### Semantics

- 4 An iteration statement causes a statement called the *loop body* to be executed repeatedly until the controlling expression compares equal to 0. The repetition occurs regardless of whether the loop body is entered from the iteration statement or by a jump.<sup>176)</sup>
- 5 An iteration statement is a block whose scope is a strict subset of the scope of its enclosing block. The loop body is also a block whose scope is a strict subset of the scope of the iteration statement.
- 6 An iteration statement may be assumed by the implementation to terminate if its controlling expression is not a constant expression,<sup>177)</sup> and none of the following operations are performed in its body, controlling expression or (in the case of a **for** statement) its *expression-3*:<sup>178)</sup>
  - input/output operations
  - accessing a volatile object
  - synchronization or atomic operations.

— input/output operations

— accessing a volatile object

— synchronization or atomic operations.

#### 6.8.5.1 The while statement

- 1 The evaluation of the controlling expression takes place before each execution of the loop body.

#### 6.8.5.2 The do statement

- 1 The evaluation of the controlling expression takes place after each execution of the loop body.

<sup>176)</sup>Code jumped over is not executed. In particular, the controlling expression of a **for** or **while** statement is not evaluated before entering the loop body, nor is *clause-1* of a **for** statement.

<sup>177)</sup>An omitted controlling expression is replaced by a nonzero constant, which is a constant expression.

<sup>178)</sup>This is intended to allow compiler transformations such as removal of empty loops even when termination cannot be proven.

## 6.9 External definitions

### Syntax

- 1 *translation-unit*:
- external-declaration*  
*translation-unit external-declaration*
- external-declaration*:
- function-definition*  
*declaration*

### Constraints

- 2 The storage-class specifiers **auto** and **register** shall not appear in the declaration specifiers in an external declaration.
- 3 There shall be no more than one external definition for each identifier declared with internal linkage in a translation unit. Moreover, if an identifier declared with internal linkage is used in an expression (other than as a part of the operand of a **sizeof** or **\_Alignof** operator whose result is an integer constant), there shall be exactly one external definition for the identifier in the translation unit.

### Semantics

- 4 As discussed in 5.1.1.1, the unit of program text after preprocessing is a translation unit, which consists of a sequence of external declarations. These are described as “external” because they appear outside any function (and hence have file scope). As discussed in 6.7, a declaration that also causes [storage a storage instance](#) to be reserved for an object or [provides the body of](#) a function named by the identifier is a definition.
- 5 An *external definition* is an external declaration that is also a definition of a function (other than an inline definition) or an object. If an identifier declared with external linkage is used in an expression (other than as part of the operand of a **sizeof** or **\_Alignof** operator whose result is an integer constant), somewhere in the entire program there shall be exactly one external definition for the identifier; otherwise, there shall be no more than one.<sup>182)</sup>

### 6.9.1 Function definitions

#### Syntax

- 1 *function-definition*:
- declaration-specifiers declarator declaration-list<sub>opt</sub> compound-statement*
- declaration-list*:
- declaration*  
*declaration-list declaration*

#### Constraints

- 2 The identifier declared in a function definition (which is the name of the function) shall have a function type, as specified by the declarator portion of the function definition.<sup>183)</sup>
- 3 The return type of a function shall be **void** or a complete object type other than array type.
- 4 The storage-class specifier, if any, in the declaration specifiers shall be either **extern** or **static**.
- 5 If the declarator includes a parameter type list, the declaration of each parameter shall include an identifier, except for the special case of a parameter list consisting of a single parameter of type **void**, in which case there shall not be an identifier. No declaration list shall follow.

<sup>182)</sup> Thus, if an identifier declared with external linkage is not used in an expression, there need be no external definition for it.

- 6 If the declarator includes an identifier list, each declaration in the declaration list shall have at least one declarator, those declarators shall declare only identifiers from the identifier list, and every identifier in the identifier list shall be declared. An identifier declared as a typedef name shall not be redeclared as a parameter. The declarations in the declaration list shall contain no storage-class specifier other than **register** and no initializations.

### Semantics

- 7 The declarator in a function definition specifies the name of the function being defined and the identifiers of its parameters. If the declarator includes a parameter type list, the list also specifies the types of all the parameters; such a declarator also serves as a function prototype for later calls to the same function in the same translation unit. If the declarator includes an identifier list,<sup>184)</sup> the types of the parameters shall be declared in a following declaration list. In either case, the type of each parameter is adjusted as described in 6.7.6.3 for a parameter type list; the resulting type shall be a complete object type.
- 8 If a function that accepts a variable number of arguments is defined without a parameter type list that ends with the ellipsis notation, the behavior is undefined.
- 9 Each parameter has automatic storage duration; its identifier is an lvalue. ~~A parameter identifier cannot be redeclared in the function body except in an enclosed block. The layout of the storage for parameters is unspecified.~~<sup>185)</sup>
- 10 On entry to the function, the size expressions of each variably modified parameter are evaluated and the value of each argument expression is converted to the type of the corresponding parameter as if by assignment. (Array expressions and function designators as arguments were converted to pointers before the call.)
- 11 After all parameters have been assigned, the compound statement that constitutes the body of the function definition is executed.
- 12 Unless otherwise specified, if the } that terminates a function is reached, and the value of the function call is used by the caller, the behavior is undefined.
- 13 **EXAMPLE 1** In the following:

```
extern int max(int a, int b)
{
    return a > b ? a : b;
}
```

**extern** is the storage-class specifier and **int** is the type specifier; **max(int a, int b)** is the function declarator; and

```
{ return a > b ? a : b; }
```

<sup>183)</sup>The intent is that the type category in a function definition cannot be inherited from a typedef:

```
typedef int F(void);           // type F is "function with no parameters
                              // returning int"
F f, g;                       // f and g both have type compatible with F
F f { /* ... */ }            // WRONG: syntax/constraint error
F g() { /* ... */ }          // WRONG: declares that g returns a function
int f(void) { /* ... */ }    // RIGHT: f has type compatible with F
int g() { /* ... */ }        // RIGHT: g has type compatible with F
F *e(void) { /* ... */ }     // e returns a pointer to a function
F *(e)(void) { /* ... */ }   // same: parentheses irrelevant
int (*fp)(void);             // fp points to a function that has type F
F *Fp;                       // Fp points to a function that has type F
```

<sup>184)</sup>See "future language directions" (6.11.7).

<sup>185)</sup>A parameter identifier cannot be redeclared in the function body except in an enclosed block. As any object with automatic storage duration, each parameter gives rise to a unique storage instance representing it. Thus the relative layout of parameters in the address space is unspecified.

- If an argument to a function has an invalid value (such as a value outside the domain of the function, or a pointer outside the address space of the program, or a null pointer, or a pointer to a non-modifiable storage [instance](#) when the corresponding parameter is not const-qualified) or a type (after default argument promotion) not expected by a function with a variable number of arguments, the behavior is undefined.
  - If a function argument is described as being an array, the pointer actually passed to the function shall have a value such that all address computations and accesses to objects (that would be valid if the pointer did point to the first element of such an array) are in fact valid.
  - Any function declared in a header may be additionally implemented as a function-like macro defined in the header, so if a library function is declared explicitly when its header is included, one of the techniques shown below can be used to ensure the declaration is not affected by such a macro. Any macro definition of a function can be suppressed locally by enclosing the name of the function in parentheses, because the name is then not followed by the left parenthesis that indicates expansion of a macro function name. For the same syntactic reason, it is permitted to take the address of a library function even if it is also defined as a macro.<sup>208)</sup> The use of **#undef** to remove any macro definition will also ensure that an actual function is referred to.
  - Any invocation of a library function that is implemented as a macro shall expand to code that evaluates each of its arguments exactly once, fully protected by parentheses where necessary, so it is generally safe to use arbitrary expressions as arguments.<sup>209)</sup>
  - Likewise, those function-like macros described in the following subclauses may be invoked in an expression anywhere a function with a compatible return type could be called.<sup>210)</sup>
  - All object-like macros listed as expanding to integer constant expressions shall additionally be suitable for use in **#if** preprocessing directives.
- 2 Provided that a library function can be declared without reference to any type defined in a header, it is also permissible to declare the function and use it without including its associated header.
  - 3 There is a sequence point immediately before a library function returns.
  - 4 The functions in the standard library are not guaranteed to be reentrant and may modify objects with static or thread storage duration.<sup>211)</sup>
  - 5 Unless explicitly stated otherwise in the detailed descriptions that follow, library functions shall prevent data races as follows: A library function shall not directly or indirectly access objects accessible by threads other than the current thread unless the objects are accessed directly or indirectly via the function's arguments. A library function shall not directly or indirectly modify objects accessible by threads other than the current thread unless the objects are accessed directly or indirectly via the function's non-const arguments.<sup>212)</sup> Implementations may share their own

<sup>208)</sup>This means that an implementation is required to provide an actual function for each library function, even if it also provides a macro for that function.

<sup>209)</sup>Such macros might not contain the sequence points that the corresponding function calls do.

<sup>210)</sup>Because external identifiers and some macro names beginning with an underscore are reserved, implementations can provide special semantics for such names. For example, the identifier `_BUILTIN_abs` could be used to indicate generation of in-line code for the `abs` function. Thus, the appropriate header could specify

```
#define abs(x) _BUILTIN_abs(x)
```

for a compiler whose code generator will accept it.

In this manner, a user desiring to guarantee that a given library function such as `abs` will be a genuine function can write

```
#undef abs
```

whether the implementation's header provides a macro implementation of `abs` or a built-in implementation. The prototype for the function, which precedes and is hidden by any macro definition, is thereby revealed also.

<sup>211)</sup>Thus, a signal handler cannot, in general, call standard library functions.

<sup>212)</sup>This means, for example, that an implementation is not permitted to use a `static` object for internal purposes without synchronization because it could cause a data race even in programs that do not explicitly share objects between threads.

internal objects between threads if the objects are not visible to users and are protected against data races.

- 6 Unless otherwise specified, library functions shall perform all operations solely within the current thread if those operations have effects that are visible to users.<sup>213)</sup>
- 7 Unless otherwise specified, library functions by themselves do not expose storage instances, but library functions that execute application specific callbacks<sup>214)</sup> may expose storage instances through calls into these callbacks.
- 8 **EXAMPLE** The function `atoi` can be used in any of several ways:

- by use of its associated header (possibly generating a macro expansion)

```
#include <stdlib.h>
const char *str;
/* ... */
i = atoi(str);
```

- by use of its associated header (assuredly generating a true function reference)

```
#include <stdlib.h>
#undef atoi
const char *str;
/* ... */
i = atoi(str);
```

or

```
#include <stdlib.h>
const char *str;
/* ... */
i = (atoi)(str);
```

- by explicit declaration

```
extern int atoi(const char *);
const char *str;
/* ... */
i = atoi(str);
```

Similarly, an implementation of `memcpy` is not permitted to copy bytes beyond the specified length of the destination object and then restore the original values because it could cause a data race if the program shared those bytes between threads.

<sup>213)</sup>This allows implementations to parallelize operations if there are no visible side effects.

<sup>214)</sup>The following library functions call application specific functions that they or related functions receive as arguments: `bsearch`, `call_once`, `exit` (for `atexit` handlers), `qsort`, `quick_exit` (for `at_quick_exit` handlers), and `thrd_exit` (for thread specific storage).

## 7.5 Errors <errno.h>

- 1 The header <errno.h> defines several macros, all relating to the reporting of error conditions.
- 2 The macros are

```
EDOM
EILSEQ
ERANGE
```

which expand to integer constant expressions with type **int**, distinct positive values, and which are suitable for use in **#if** preprocessing directives; and

```
errno
```

which expands to a modifiable lvalue<sup>225)</sup> that has type **int** and thread local storage duration, the value of which is set to a positive error number by several library functions. If a macro definition is suppressed in order to access an actual object, or a program defines an identifier with the name **errno**, the behavior is undefined.

- 3 The value of **errno** in the initial thread is zero at program startup (~~the initial value of **errno** in other threads is an indeterminate value~~initially representation of the object corresponding to **errno** in any other thread is indeterminate), but is never set to zero by any library function.<sup>226)</sup> The value of **errno** may be set to nonzero by a library function call whether or not there is an error, provided the use of **errno** is not documented in the description of the function in this document.
- 4 Additional macro definitions, beginning with **E** and a digit or **E** and an uppercase letter,<sup>227)</sup> may also be specified by the implementation.

<sup>225)</sup>The macro **errno** need not be the identifier of an object. It might expand to a modifiable lvalue resulting from a function call (for example, `*errno()`).

<sup>226)</sup>Thus, a program that uses **errno** for error checking would set it to zero before a library function call, then inspect it before a subsequent library function call. Of course, a library function can save the value of **errno** on entry and then set it to zero, as long as the original value is restored if **errno**'s value is still zero just before the return.

<sup>227)</sup>See "future library directions" (7.31.3).

## Description

- 2 The **longjmp** function restores the environment saved by the most recent invocation of the **setjmp** macro in the same invocation of the program with the corresponding **jmp\_buf** argument. If there has been no such invocation, or if the invocation was from another thread of execution, or if the function containing the invocation of the **setjmp** macro has terminated execution<sup>272)</sup> in the interim, or if the invocation of the **setjmp** macro was within the scope of an identifier with variably modified type and execution has left that scope in the interim, the behavior is undefined.
- 3 All accessible objects have values, and all other components of the abstract machine<sup>273)</sup> have state, as of the time the **longjmp** function was called, except that the values-representation of objects of automatic storage duration that are local to the function containing the invocation of the corresponding **setjmp** macro that do not have volatile-qualified type and have been changed between the **setjmp** invocation and **longjmp** call are-is indeterminate.

## Returns

- 4 After **longjmp** is completed, thread execution continues as if the corresponding invocation of the **setjmp** macro had just returned the value specified by **val**. The **longjmp** function cannot cause the **setjmp** macro to return the value 0; if **val** is 0, the **setjmp** macro returns the value 1.
- 5 **EXAMPLE** The **longjmp** function that returns control back to the point of the **setjmp** invocation might cause memory-the storage instance associated with a variable length array object to be squandered.

```
#include <setjmp.h>
jmp_buf buf;
void g(int n);
void h(int n);
int n = 6;

void f(void)
{
    int x[n];           // valid: f is not terminated
    setjmp(buf);
    g(n);
}

void g(int n)
{
    int a[n];          // a may remain allocated
    h(n);
}

void h(int n)
{
    int b[n];          // b may remain allocated
    longjmp(buf, 2);  // might cause memory loss
}
```

<sup>272)</sup>For example, by executing a **return** statement or because another **longjmp** call has caused a transfer to a **setjmp** invocation in a function earlier in the set of nested calls.

<sup>273)</sup>This includes, but is not limited to, the floating-point status flags and the state of open files.

- 3 When a signal occurs and `func` points to a function, it is implementation-defined whether the equivalent of `signal(sig, SIG_DFL)`; is executed or the implementation prevents some implementation-defined set of signals (at least including `sig`) from occurring until the current signal handling has completed; in the case of `SIGILL`, the implementation may alternatively define that no action is taken. Then the equivalent of `(*func)(sig)`; is executed. If and when the function returns, if the value of `sig` is `SIGFPE`, `SIGILL`, `SIGSEGV`, or any other implementation-defined value corresponding to a computational exception, the behavior is undefined; otherwise the program will resume execution at the point it was interrupted.
- 4 If the signal occurs as the result of calling the `abort` or `raise` function, the signal handler shall not call the `raise` function.
- 5 If the signal occurs other than as the result of calling the `abort` or `raise` function, the behavior is undefined if the signal handler refers to any object with static or thread storage duration that is not a lock-free atomic object other than by assigning a value to an object declared as `volatile sig_atomic_t`, or the signal handler calls any function in the standard library other than
- the `abort` function,
  - the `_Exit` function,
  - the `quick_exit` function,
  - the functions in `<stdatomic.h>` (except where explicitly stated otherwise) when the atomic arguments are lock-free,
  - the `atomic_is_lock_free` function with any atomic argument, or
  - the `signal` function with the first argument equal to the signal number corresponding to the signal that caused the invocation of the handler. Furthermore, if such a call to the `signal` function results in a `SIG_ERR` return, the value of object designated by `errno` is indeterminate has an indeterminate representation.<sup>276)</sup>
- 6 At program startup, the equivalent of

```
signal(sig, SIG_IGN);
```

may be executed for some signals selected in an implementation-defined manner; the equivalent of

```
signal(sig, SIG_DFL);
```

is executed for all other signals defined by the implementation.

- 7 Use of this function in a multi-threaded program results in undefined behavior. The implementation shall behave as if no library function calls the `signal` function.

### Returns

- 8 If the request can be honored, the `signal` function returns the value of `func` for the most recent successful call to `signal` for the specified signal `sig`. Otherwise, a value of `SIG_ERR` is returned and a positive value is stored in `errno`.

**Forward references:** the `abort` function (7.22.4.1), the `exit` function (7.22.4.4), the `_Exit` function (7.22.4.5), the `quick_exit` function (7.22.4.7).

## 7.14.2 Send signal

### 7.14.2.1 The `raise` function

#### Synopsis

```
1 #include <signal.h>
   int raise(int sig);
```

<sup>276)</sup>If any signal is generated by an asynchronous signal handler, the behavior is undefined.

## 7.16 Variable arguments <stdarg.h>

- 1 The header <stdarg.h> declares a type and defines four macros, for advancing through a list of arguments whose number and types are not known to the called function when it is translated.
- 2 A function may be called with a variable number of arguments of varying types. As described in 6.9.1, its parameter list contains one or more parameters. The rightmost parameter plays a special role in the access mechanism, and will be designated *parmN* in this description.
- 3 The type declared is

```
va_list
```

which is a complete object type suitable for holding information needed by the macros **va\_start**, **va\_arg**, **va\_end**, and **va\_copy**. If access to the varying arguments is desired, the called function shall declare an object (generally referred to as **ap** in this subclause) having type **va\_list**. The object **ap** may be passed as an argument to another function; if that function invokes the **va\_arg** macro with parameter **ap**, the value representation of **ap** in the calling function is indeterminate and shall be passed to the **va\_end** macro prior to any further reference to **ap**.<sup>277)</sup>

### 7.16.1 Variable argument list access macros

- 1 The **va\_start** and **va\_arg** macros described in this subclause shall be implemented as macros, not functions. It is unspecified whether **va\_copy** and **va\_end** are macros or identifiers declared with external linkage. If a macro definition is suppressed in order to access an actual function, or a program defines an external identifier with the same name, the behavior is undefined. Each invocation of the **va\_start** and **va\_copy** macros shall be matched by a corresponding invocation of the **va\_end** macro in the same function.

#### 7.16.1.1 The **va\_arg** macro

##### Synopsis

```
1 #include <stdarg.h>
   type va_arg(va_list ap, type);
```

##### Description

- 2 The **va\_arg** macro expands to an expression that has the specified type and the value of the next argument in the call. The parameter **ap** shall have been initialized by the **va\_start** or **va\_copy** macro (without an intervening invocation of the **va\_end** macro for the same **ap**). Each invocation of the **va\_arg** macro modifies **ap** so that the values of successive arguments are returned in turn. The parameter *type* shall be a type name specified such that the type of a pointer to an object that has the specified type can be obtained simply by postfixing a \* to *type*. If there is no actual next argument, or if *type* is not compatible with the type of the actual next argument (as promoted according to the default argument promotions), the behavior is undefined, except for the following cases:

- one type is a signed integer type, the other type is the corresponding unsigned integer type, and the value is representable in both types;
- one type is pointer to **void** and the other is a pointer to a character type.

##### Returns

- 3 The first invocation of the **va\_arg** macro after that of the **va\_start** macro returns the value of the argument after that specified by *parmN*. Successive invocations return the values of the remaining arguments in succession.

<sup>277)</sup>It is permitted to create a pointer to a **va\_list** and pass that pointer to another function, in which case the original function can make further use of the original list after the other function returns.

## 7.17.2 Initialization

### 7.17.2.1 The `ATOMIC_VAR_INIT` macro

#### Synopsis

```
1  #include <stdatomic.h>
   #define ATOMIC_VAR_INIT(C value)
```

#### Description

2 The `ATOMIC_VAR_INIT` macro expands to a token sequence suitable for initializing an atomic object of a type that is initialization-compatible with `value`. An atomic object with automatic storage duration that is not explicitly initialized ~~is initially in an indeterminate state~~ has initially an indeterminate representation; however, the default (zero) initialization for objects with static or thread-local storage duration is guaranteed to produce a valid state.<sup>279)</sup>

3 Concurrent access to the variable being initialized, even via an atomic operation, constitutes a data race.

#### EXAMPLE

```
atomic_int guide = ATOMIC_VAR_INIT(42);
```

### 7.17.2.2 The `atomic_init` generic function

#### Synopsis

```
1  #include <stdatomic.h>
   void atomic_init(volatile A *obj, C value);
```

#### Description

2 The `atomic_init` generic function initializes the atomic object pointed to by `obj` to the value `value`, while also initializing any additional state that the implementation might need to carry for the atomic object.

3 Although this function initializes an atomic object, it does not avoid data races; concurrent access to the variable being initialized, even via an atomic operation, constitutes a data race.

4 If a signal occurs other than as the result of calling the `abort` or `raise` functions, the behavior is undefined if the signal handler calls the `atomic_init` generic function.

#### Returns

5 The `atomic_init` generic function returns no value.

#### EXAMPLE

```
atomic_int guide;
atomic_init(&guide, 42);
```

## 7.17.3 Order and consistency

1 The enumerated type `memory_order` specifies the detailed regular (non-atomic) memory synchronization operations as defined in 5.1.2.4 and may provide for operation ordering. Its enumeration constants are as follows:<sup>280)</sup>

```
memory_order_relaxed
memory_order_consume
memory_order_acquire
memory_order_release
memory_order_acq_rel
memory_order_seq_cst
```

<sup>279)</sup>See “future library directions” (7.31.8).

<sup>280)</sup>See “future library directions” (7.31.8).

- 7 **EXAMPLE** A consequence of spurious failure is that nearly all uses of weak compare-and-exchange will be in a loop.

```

exp = atomic_load(&cur);
do {
    des = function(exp);
} while (!atomic_compare_exchange_weak(&cur, &exp, des));

```

When a compare-and-exchange is in a loop, the weak version will yield better performance on some platforms. When a weak compare-and-exchange would require a loop and a strong one would not, the strong one is preferable.

### Returns

- 8 The result of the comparison.

### 7.17.7.5 The `atomic_fetch` and modify generic functions

- 1 The following operations perform arithmetic and bitwise computations. All of these operations are applicable to an object of any atomic integer type. None of these operations is applicable to `atomic_bool`. The key, operator, and computation correspondence is:

key	op	computation
add	+	addition
sub	-	subtraction
or		bitwise inclusive or
xor	^	bitwise exclusive or
and	&	bitwise and

### Synopsis

```

#include <stdatomic.h>
C atomic_fetch_key(volatile A *object, M operand);
C atomic_fetch_key_explicit(volatile A *object,
    M operand, memory_order order);

```

### Description

- 3 Atomically replaces the value pointed to by `object` with the result of the computation applied to the value pointed to by `object` and the given operand. Memory is affected according to the value of `order`. These operations are atomic read-modify-write operations (5.1.2.4). For signed integer types, arithmetic is defined to use two's complement representation with silent wrap-around on overflow; there are no undefined results. For address types, the result may be an undefined address, but the operations otherwise have no undefined behavior.

### Returns

- 4 Atomically, the value pointed to by `object` immediately before the effects.
- 5 **NOTE** The operation of the `atomic_fetch` and modify generic functions are nearly equivalent to the operation of the corresponding `op=` compound assignment operators. The only differences are that the compound assignment operators are not guaranteed to operate atomically, and the value yielded by a compound assignment operator is the updated value of the object, whereas the value returned by the `atomic_fetch` and modify generic functions is the previous value of the atomic object.

## 7.17.8 Atomic flag type and operations

- 1 The `atomic_flag` type provides the classic test-and-set functionality. It has two states, set and clear.
- 2 Operations on an object of type `atomic_flag` shall be lock free.
- 3 **NOTE** Hence, as per 7.17.5, the operations should also be address-free. No other type requires lock-free operations, so the `atomic_flag` type is the minimum hardware-implemented type needed to conform to this document. The remaining types can be emulated with `atomic_flag`, though with less than ideal properties.
- 4 The macro `ATOMIC_FLAG_INIT` may be used to initialize an `atomic_flag` to the clear state. An `atomic_flag` that is not explicitly initialized with `ATOMIC_FLAG_INIT` ~~is initially in an indeterminate state~~ has initially an indeterminate representation.

## 7.20 Integer types <stdint.h>

- 1 The header <stdint.h> declares sets of integer types having specified widths, and defines corresponding sets of macros.<sup>285)</sup> It also defines macros that specify limits of integer types corresponding to types defined in other standard headers.
- 2 Types are defined in the following categories:
  - integer types having certain exact widths;
  - integer types having at least certain specified widths;
  - fastest integer types having at least certain specified widths;
  - integer types wide enough to hold pointers to objects;
  - integer types having greatest width.

(Some of these types may denote the same type.)

- 3 Corresponding macros specify limits of the declared types and construct suitable constants.
- 4 For each type described herein that the implementation provides,<sup>286)</sup> <stdint.h> shall declare that typedef name and define the associated macros. Conversely, for each type described herein that the implementation does not provide, <stdint.h> shall not declare that typedef name nor shall it define the associated macros. An implementation shall provide those types described as “required”, but need not provide any of the others (described as “optional”).

### 7.20.1 Integer types

- 1 When typedef names differing only in the absence or presence of the initial **u** are defined, they shall denote corresponding signed and unsigned types as described in 6.2.5; an implementation providing one of these corresponding types shall also provide the other.
- 2 In the following descriptions, the symbol *N* represents an unsigned decimal integer with no leading zeros (e.g., 8 or 24, but not 04 or 048).

#### 7.20.1.1 Exact-width integer types

- 1 The typedef name **intN\_t** designates a signed integer type with width *N*, no padding bits, and a two’s complement representation. Thus, **int8\_t** denotes such a signed integer type with a width of exactly 8 bits.
- 2 The typedef name **uintN\_t** designates an unsigned integer type with width *N* and no padding bits. Thus, **uint24\_t** denotes such an unsigned integer type with a width of exactly 24 bits.
- 3 ~~These types are optional. However, if~~ If an implementation provides standard or extended integer types with widths of 8, 16, 32, or 64 bits a particular width, no padding bits, and (for the signed types) that have a two’s complement representation, it shall define the corresponding typedef names.

#### 7.20.1.2 Minimum-width integer types

- 1 The typedef name **int\_leastN\_t** designates a signed integer type with a width of at least *N*, such that no signed integer type with lesser size has at least the specified width. Thus, **int\_least32\_t** denotes a signed integer type with a width of at least 32 bits.
- 2 The typedef name **uint\_leastN\_t** designates an unsigned integer type with a width of at least *N*, such that no unsigned integer type with lesser size has at least the specified width. Thus, **uint\_least16\_t** denotes an unsigned integer type with a width of at least 16 bits.
- 3 The following types are required:

<sup>285)</sup>See “future library directions” (7.31.10).

<sup>286)</sup>Some of these types might denote implementation-defined extended integer types.

<code>int_least8_t</code>	<code>uint_least8_t</code>
<code>int_least16_t</code>	<code>uint_least16_t</code>
<code>int_least32_t</code>	<code>uint_least32_t</code>
<code>int_least64_t</code>	<code>uint_least64_t</code>

All other types of this form are optional.

### 7.20.1.3 Fastest minimum-width integer types

- Each of the following types designates an integer type that is usually fastest<sup>287)</sup> to operate with among all integer types that have at least the specified width.
- The typedef name `int_fastN_t` designates the fastest signed integer type with a width of at least  $N$ . The typedef name `uint_fastN_t` designates the fastest unsigned integer type with a width of at least  $N$ .
- The following types are required:

<code>int_fast8_t</code>	<code>uint_fast8_t</code>
<code>int_fast16_t</code>	<code>uint_fast16_t</code>
<code>int_fast32_t</code>	<code>uint_fast32_t</code>
<code>int_fast64_t</code>	<code>uint_fast64_t</code>

All other types of this form are optional.

### 7.20.1.4 Integer types capable of holding object pointers

- The following type designates a signed integer type with the property that any valid pointer to `void` can be converted to this type, then converted back to pointer to `void`, and the result will compare equal to the original pointer:

`intptr_t`

The following type designates an the corresponding unsigned integer type with the property that any valid pointer to `void` can be converted to this type, then converted back to pointer to `void`, and the result will compare equal to the original pointer:

`uintptr_t`

These types are optional-~~required~~.

- NOTE 1 The types `intptr_t` and `uintptr_t` are possibly wider than the types `intmax_t` and `uintmax_t` (7.20.1.5). This exception is intended to accommodate implementations that otherwise would not be able to specify `intptr_t` and `uintptr_t` consistent with the rules for these types.
- NOTE 2 Although these integer types allow roundtrip conversions of values of type pointer to `void` and therefore guarantee that such conversions do not lose information, arithmetic on these types is not necessarily consistent with arithmetic on pointer to character types, nor can properties of pointer values such as alignment be portably deduced from the bit pattern of the integer result of a conversion.
- On the other hand, the rules for abstract addresses in 6.2.6.1, 6.5.8 and 6.5.9 impose that two values of type `uintptr_t` that originate from conversions of two pointers to the same storage instance compare the same for the relational and equality operators as the original pointer values. Also, the reconstruction of all the bits of a valid abstract address that has previously been exposed gives rise to an integer value that converts back to the corresponding byte address.

### 7.20.1.5 Greatest-width integer types

- The following type designates a signed integer type capable of representing any value of any signed integer type with the possible exception of signed extended integer types that are wider than `long long` and that are referred by the type definition for an exact width integer type or for `intptr_t`:

`intmax_t`

<sup>287)</sup>The designated type is not guaranteed to be fastest for all purposes; if the implementation has no clear grounds for choosing one type over another, it will simply pick some integer type satisfying the signedness and width requirements.

The following type designates ~~an unsigned integer type capable of representing any value of any the~~ unsigned integer type ~~that corresponds to `intmax_t`.~~<sup>288)</sup>

`uintmax_t`

These types are required.

## 7.20.2 Limits of specified-width integer types

- 1 The following object-like macros specify the minimum and maximum limits of the types declared in `<stdint.h>`. Each macro name corresponds to a similar type name in 7.20.1.
- 2 Each instance of any defined macro shall be replaced by a constant expression suitable for use in `#if` preprocessing directives, and this expression shall have the same type as would an expression that is an object of the corresponding type converted according to the integer promotions. Its implementation-defined value shall be equal to or greater in magnitude (absolute value) than the corresponding value given below, with the same sign, except where stated to be exactly the given value.

### 7.20.2.1 Limits of exact-width integer types

- 1 — minimum values of exact-width signed integer types

`INTN_MIN` exactly  $-(2^{N-1})$

- maximum values of exact-width signed integer types

`INTN_MAX` exactly  $2^{N-1} - 1$

- maximum values of exact-width unsigned integer types

`UINTN_MAX` exactly  $2^N - 1$

### 7.20.2.2 Limits of minimum-width integer types

- 1 — minimum values of minimum-width signed integer types

`INT_LEASTN_MIN`  $-(2^{N-1} - 1)$

- maximum values of minimum-width signed integer types

`INT_LEASTN_MAX`  $2^{N-1} - 1$

- maximum values of minimum-width unsigned integer types

`UINT_LEASTN_MAX`  $2^N - 1$

### 7.20.2.3 Limits of fastest minimum-width integer types

- 1 — minimum values of fastest minimum-width signed integer types

`INT_FASTN_MIN`  $-(2^{N-1} - 1)$

- maximum values of fastest minimum-width signed integer types

`INT_FASTN_MAX`  $2^{N-1} - 1$

<sup>288)</sup> Thus this type is capable of representing any value of any unsigned integer type with the possible exception of particular extended integer types that are wider than unsigned `long long`.

<b>SIZE_MAX</b>	65535
-----------------	-------

— limits of `wchar_t`

<b>WCHAR_MIN</b>	<i>see below</i>
<b>WCHAR_MAX</b>	<i>see below</i>

— limits of `wint_t`

<b>WINT_MIN</b>	<i>see below</i>
<b>WINT_MAX</b>	<i>see below</i>

- 3 If `sig_atomic_t` (see 7.14) is defined as a signed integer type, the value of **SIG\_ATOMIC\_MIN** shall be no greater than  $-127$  and the value of **SIG\_ATOMIC\_MAX** shall be no less than  $127$ ; otherwise, `sig_atomic_t` is defined as an unsigned integer type, and the value of **SIG\_ATOMIC\_MIN** shall be  $0$  and the value of **SIG\_ATOMIC\_MAX** shall be no less than  $255$ .
- 4 If `wchar_t` (see 7.19) is defined as a signed integer type, the value of **WCHAR\_MIN** shall be no greater than  $-127$  and the value of **WCHAR\_MAX** shall be no less than  $127$ ; otherwise, `wchar_t` is defined as an unsigned integer type, and the value of **WCHAR\_MIN** shall be  $0$  and the value of **WCHAR\_MAX** shall be no less than  $255$ .<sup>290)</sup>
- 5 If `wint_t` (see 7.29) is defined as a signed integer type, the value of **WINT\_MIN** shall be no greater than  $-32767$  and the value of **WINT\_MAX** shall be no less than  $32767$ ; otherwise, `wint_t` is defined as an unsigned integer type, and the value of **WINT\_MIN** shall be  $0$  and the value of **WINT\_MAX** shall be no less than  $65535$ .

## 7.20.4 Macros for integer constants

- 1 The following function-like macros expand to integer constants suitable for initializing objects that have integer types corresponding to types defined in `<stdint.h>`. Each macro name corresponds to a similar type name in 7.20.1.2 or 7.20.1.5.
- 2 The argument in any instance of these macros shall be an unsuffixed integer constant (as defined in 6.4.4.1) with a value that does not exceed the limits for the corresponding type.
- 3 Each invocation of one of these macros shall expand to an integer constant expression **suitable for use in `#if` preprocessing directives**. The type of the expression shall have the same type as would an expression of the corresponding type converted according to the integer promotions. The value of the expression shall be that of the argument. If the value and promoted type is in the range of the type `intmax_t` (for a signed type) or `uintmax_t` (for an unsigned type), see 7.20.1.5, the expression is suitable for use in `#if` preprocessing directives.

### 7.20.4.1 Macros for minimum-width integer constants

- 1 The macro **INTN\_C**(*value*) expands to an integer constant expression corresponding to the type **int\_leastN\_t**. The macro **UINTN\_C**(*value*) expands to an integer constant expression corresponding to the type **uint\_leastN\_t**. For example, if **uint\_least64\_t** is a name for the type **unsigned long long int**, then **UINT64\_C**( $0 \times 123$ ) might expand to the integer constant  $0 \times 123 \text{ULL}$ .

### 7.20.4.2 Macros for greatest-width integer constants

- 1 The following macro expands to an integer constant expression having the value specified by its argument and the type **intmax\_t**:

<b>INTMAX_C</b> ( <i>value</i> )
----------------------------------

The following macro expands to an integer constant expression having the value specified by its argument and the type **uintmax\_t**:

<sup>290)</sup>The values **WCHAR\_MIN** and **WCHAR\_MAX** do not necessarily correspond to members of the extended character set.

stream and those in the external representation. Data read in from a text stream will necessarily compare equal to the data that were earlier written out to that stream only if: the data consist only of printing characters and the control characters horizontal tab and new-line; no new-line character is immediately preceded by space characters; and the last character is a new-line character. Whether space characters that are written out immediately before a new-line character appear when read in is implementation-defined.

- 3 A binary stream is an ordered sequence of characters that can transparently record internal data. Data read in from a binary stream shall compare equal to the data that were earlier written out to that stream, under the same implementation. Such a stream may, however, have an implementation-defined number of null characters appended to the end of the stream.
- 4 Each stream has an *orientation*. After a stream is associated with an external file, but before any operations are performed on it, the stream is without orientation. Once a wide character input/output function has been applied to a stream without orientation, the stream becomes a *wide-oriented stream*. Similarly, once a byte input/output function has been applied to a stream without orientation, the stream becomes a *byte-oriented stream*. Only a call to the **freopen** function or the **fwide** function can otherwise alter the orientation of a stream. (A successful call to **freopen** removes any orientation.)<sup>293)</sup>
- 5 Byte input/output functions shall not be applied to a wide-oriented stream and wide character input/output functions shall not be applied to a byte-oriented stream. The remaining stream operations do not affect, and are not affected by, a stream's orientation, except for the following additional restrictions:
  - Binary wide-oriented streams have the file-positioning restrictions ascribed to both text and binary streams.
  - For wide-oriented streams, after a successful call to a file-positioning function that leaves the file position indicator prior to the end-of-file, a wide character output function can overwrite a partial multibyte character; any file contents beyond the byte(s) written **are henceforth indeterminate** may henceforth not consist of valid multibyte characters.
- 6 Each wide-oriented stream has an associated **mbstate\_t** object that stores the current parse state of the stream. A successful call to **fgetpos** stores a representation of the value of this **mbstate\_t** object as part of the value of the **fpos\_t** object. A later successful call to **fsetpos** using the same stored **fpos\_t** value restores the value of the associated **mbstate\_t** object as well as the position within the controlled stream.
- 7 Each stream has an associated lock that is used to prevent data races when multiple threads of execution access a stream, and to restrict the interleaving of stream operations performed by multiple threads. Only one thread may hold this lock at a time. The lock is reentrant: a single thread may hold the lock multiple times at a given time.
- 8 All functions that read, write, position, or query the position of a stream lock the stream before accessing it. They release the lock associated with the stream when the access is complete.

### Environmental limits

- 9 An implementation shall support text files with lines containing at least 254 characters, including the terminating new-line character. The value of the macro **BUFSIZ** shall be at least 256.

**Forward references:** the **freopen** function (7.21.5.4), the **fwide** function (7.29.3.5), **mbstate\_t** (7.29.1), the **fgetpos** function (7.21.9.1), the **fsetpos** function (7.21.9.3).

### 7.21.3 Files

- 1 A stream is associated with an external file (which may be a physical device) by *opening* a file, which may involve *creating* a new file. Creating an existing file causes its former contents to be discarded, if necessary. If a file can support positioning requests (such as a disk file, as opposed to a terminal), then a *file position indicator* associated with the stream is positioned at the start (character number

<sup>293)</sup>The three predefined streams **stdin**, **stdout**, and **stderr** are unoriented at program startup.

zero) of the file, unless the file is opened with append mode in which case it is implementation-defined whether the file position indicator is initially positioned at the beginning or the end of the file. The file position indicator is maintained by subsequent reads, writes, and positioning requests, to facilitate an orderly progression through the file.

- 2 Binary files are not truncated, except as defined in 7.21.5.3. Whether a write on a text stream causes the associated file to be truncated beyond that point is implementation-defined.
- 3 When a stream is *unbuffered*, characters are intended to appear from the source or at the destination as soon as possible. Otherwise characters may be accumulated and transmitted to or from the host environment as a block. When a stream is *fully buffered*, characters are intended to be transmitted to or from the host environment as a block when a buffer is filled. When a stream is *line buffered*, characters are intended to be transmitted to or from the host environment as a block when a new-line character is encountered. Furthermore, characters are intended to be transmitted as a block to the host environment when a buffer is filled, when input is requested on an unbuffered stream, or when input is requested on a line buffered stream that requires the transmission of characters from the host environment. Support for these characteristics is implementation-defined, and may be affected via the **setbuf** and **setvbuf** functions.
- 4 A file may be disassociated from a controlling stream by *closing* the file. Output streams are flushed (any unwritten buffer contents are transmitted to the host environment) before the stream is disassociated from the file. The **value of a pointer to a lifetime of a FILE object is indeterminate after ends when** the associated file is closed (including the standard text streams). Whether a file of zero length (on which no characters have been written by an output stream) actually exists is implementation-defined.
- 5 The file may be subsequently reopened, by the same or another program execution, and its contents reclaimed or modified (if it can be repositioned at its start). If the **main** function returns to its original caller, or if the **exit** function is called, all open files are closed (hence all output streams are flushed) before program termination. Other paths to program termination, such as calling the **abort** function, need not close all files properly.
- 6 The address of the **FILE** object used to control a stream may be significant; a copy of a **FILE** object need not serve in place of the original.
- 7 At program startup, three text streams are predefined and need not be opened explicitly — *standard input* (for reading conventional input), *standard output* (for writing conventional output), and *standard error* (for writing diagnostic output). As initially opened, the standard error stream is not fully buffered; the standard input and standard output streams are fully buffered if and only if the stream can be determined not to refer to an interactive device.
- 8 Functions that open additional (nontemporary) files require a *file name*, which is a string. The rules for composing valid file names are implementation-defined. Whether the same file can be simultaneously open multiple times is also implementation-defined.
- 9 Although both text and binary wide-oriented streams are conceptually sequences of wide characters, the external file associated with a wide-oriented stream is a sequence of multibyte characters, generalized as follows:
  - Multibyte encodings within files may contain embedded null bytes (unlike multibyte encodings valid for use internal to the program).
  - A file need not begin nor end in the initial shift state.<sup>294)</sup>
- 10 Moreover, the encodings used for multibyte characters may differ among files. Both the nature and choice of such encodings are implementation-defined.
- 11 The wide character input functions read multibyte characters from the stream and convert them to wide characters as if they were read by successive calls to the **fgetwc** function. Each conversion

<sup>294)</sup>Setting the file position indicator to end-of-file, as with **fseek(file, 0, SEEK\_END)**, has undefined behavior for a binary stream (because of possible trailing null characters) or for any stream with state-dependent encoding that does not assuredly end in the initial shift state.

### Returns

- 5 The **freopen** function returns a null pointer if the open operation fails. Otherwise, **freopen** returns the value of **stream**.

### 7.21.5.5 The **setbuf** function

#### Synopsis

```
1  #include <stdio.h>
    void setbuf(FILE * restrict stream,
               char * restrict buf);
```

#### Description

- 2 Except that it returns no value, the **setbuf** function is equivalent to the **setvbuf** function invoked with the values **\_IOFBF** for **mode** and **BUFSIZ** for **size**, or (if **buf** is a null pointer), with the value **\_IONBF** for **mode**.

#### Returns

- 3 The **setbuf** function returns no value.

Forward references: the **setvbuf** function (7.21.5.6).

### 7.21.5.6 The **setvbuf** function

#### Synopsis

```
1  #include <stdio.h>
    int setvbuf(FILE * restrict stream,
               char * restrict buf,
               int mode, size_t size);
```

#### Description

- 2 The **setvbuf** function may be used only after the stream pointed to by **stream** has been associated with an open file and before any other operation (other than an unsuccessful call to **setvbuf**) is performed on the stream. The argument **mode** determines how **stream** will be buffered, as follows:

**\_IOFBF** causes input/output to be fully buffered;

**\_IOLBF** causes input/output to be line buffered;

**\_IONBF** causes input/output to be unbuffered.

If **buf** is not a null pointer, the array it points to may be used instead of a buffer allocated by the **setvbuf** function<sup>299)</sup> and the argument **size** specifies the size of the array; otherwise, **size** may determine the size of a buffer allocated by the **setvbuf** function. The contents members of the array at any time are indeterminate have unspecified values.

#### Returns

- 3 The **setvbuf** function returns zero on success, or nonzero if an invalid value is given for **mode** or if the request cannot be honored.

### 7.21.6 Formatted input/output functions

- 1 The formatted input/output functions shall behave as if there is a sequence point after the actions associated with each specifier.<sup>300)</sup>

<sup>299)</sup>The buffer has to have a lifetime at least as great as the open stream, so not closing the stream before a buffer that has automatic storage duration is deallocated upon block exit results in undefined behavior.

<sup>300)</sup>The **printf** functions perform writes to memory for the **%n** specifier.

of 2, then the precision is sufficient to distinguish<sup>305)</sup> values of type **double**, except that trailing zeros may be omitted; if the precision is zero and the **#** flag is not specified, no decimal-point character appears. The letters **abcdef** are used for a conversion and the letters **ABCDEF** for A conversion. The A conversion specifier produces a number with **X** and **P** instead of **x** and **p**. The exponent always contains at least one digit, and only as many more digits as necessary to represent the decimal exponent of 2. If the value is zero, the exponent is zero.

A **double** argument representing an infinity or NaN is converted in the style of an **f** or **F** conversion specifier.

- c If no **l** length modifier is present, the **int** argument is converted to an **unsigned char**, and the resulting character is written.

If an **l** length modifier is present, the **wint\_t** argument is converted as if by an **ls** conversion specification with no precision and an argument that points to the initial element of a two-element array of **wchar\_t**, the first element containing the **wint\_t** argument to the **lc** conversion specification and the second a null wide character.

- s If no **l** length modifier is present, the argument shall be a pointer to the initial element of an array of character type.<sup>306)</sup> Characters from the array are written up to (but not including) the terminating null character. If the precision is specified, no more than that many bytes are written. If the precision is not specified or is greater than the size of the array, the array shall contain a null character.

If an **l** length modifier is present, the argument shall be a pointer to the initial element of an array of **wchar\_t** type. Wide characters from the array are converted to multibyte characters (each as if by a call to the **wcrtomb** function, with the conversion state described by an **mbstate\_t** object initialized to zero before the first wide character is converted) up to and including a terminating null wide character. The resulting multibyte characters are written up to (but not including) the terminating null character (byte). If no precision is specified, the array shall contain a null wide character. If a precision is specified, no more than that many bytes are written (including shift sequences, if any), and the array shall contain a null wide character if, to equal the multibyte character sequence length given by the precision, the function would need to access a wide character one past the end of the array. In no case is a partial multibyte character written.<sup>307)</sup>

- p The argument shall be a pointer to **void**. The value of the pointer shall be valid or null. It is converted to a sequence of printing characters, in an implementation-defined manner. If the value of the pointer is valid its provenance is henceforth exposed.

- n The argument shall be a pointer to signed integer into which is *written* the number of characters written to the output stream so far by this call to **fprintf**. No argument is converted, but one is consumed. If the conversion specification includes any flags, a field width, or a precision, the behavior is undefined.

- % A % character is written. No argument is converted. The complete conversion specification shall be %%.

- 9 If a conversion specification is invalid, the behavior is undefined.<sup>308)</sup> If any argument is not the correct type for the corresponding conversion specification, the behavior is undefined.

- 10 In no case does a nonexistent or small field width cause truncation of a field; if the result of a conversion is wider than the field width, the field is expanded to contain the conversion result.

- 11 For a and A conversions, if **FLT\_RADIX** is a power of 2, the value is correctly rounded to a hexadecimal floating number with the given precision.

<sup>305)</sup>The precision  $p$  is sufficient to distinguish values of the source type if  $16^{p-1} > b^n$  where  $b$  is **FLT\_RADIX** and  $n$  is the number of base- $b$  digits in the significand of the source type. A smaller  $p$  might suffice depending on the implementation's scheme for determining the digit to the left of the decimal-point character.

<sup>306)</sup>No special provisions are made for multibyte characters.

<sup>307)</sup>Redundant shift sequences can result if multibyte characters have a state-dependent encoding.

<sup>308)</sup>See "future library directions" (7.31.11).

- c Matches a sequence of characters of exactly the number specified by the field width (1 if no field width is present in the directive).<sup>312)</sup>
- If no `l` length modifier is present, the corresponding argument shall be a pointer to the initial element of a character array large enough to accept the sequence. No null character is added.
- If an `l` length modifier is present, the input shall be a sequence of multibyte characters that begins in the initial shift state. Each multibyte character in the sequence is converted to a wide character as if by a call to the `mbrtowc` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first multibyte character is converted. The corresponding argument shall be a pointer to the initial element of an array of `wchar_t` large enough to accept the resulting sequence of wide characters. No null wide character is added.
- s Matches a sequence of non-white-space characters.<sup>312)</sup>
- If no `l` length modifier is present, the corresponding argument shall be a pointer to the initial element of a character array large enough to accept the sequence and a terminating null character, which will be added automatically.
- If an `l` length modifier is present, the input shall be a sequence of multibyte characters that begins in the initial shift state. Each multibyte character is converted to a wide character as if by a call to the `mbrtowc` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first multibyte character is converted. The corresponding argument shall be a pointer to the initial element of an array of `wchar_t` large enough to accept the sequence and the terminating null wide character, which will be added automatically.
- [ Matches a nonempty sequence of characters from a set of expected characters (the *scanset*).<sup>312)</sup>
- If no `l` length modifier is present, the corresponding argument shall be a pointer to the initial element of a character array large enough to accept the sequence and a terminating null character, which will be added automatically.
- If an `l` length modifier is present, the input shall be a sequence of multibyte characters that begins in the initial shift state. Each multibyte character is converted to a wide character as if by a call to the `mbrtowc` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first multibyte character is converted. The corresponding argument shall be a pointer to the initial element of an array of `wchar_t` large enough to accept the sequence and the terminating null wide character, which will be added automatically.
- The conversion specifier includes all subsequent characters in the `format` string, up to and including the matching right bracket (`]`). The characters between the brackets (the *scanlist*) compose the scanset, unless the character after the left bracket is a circumflex (`^`), in which case the scanset contains all characters that do not appear in the scanlist between the circumflex and the right bracket. If the conversion specifier begins with `[]` or `[^]`, the right bracket character is in the scanlist and the next following right bracket character is the matching right bracket that ends the specification; otherwise the first following right bracket character is the one that ends the specification. If a `-` character is in the scanlist and is not the first, nor the second where the first character is a `^`, nor the last character, the behavior is implementation-defined.
- p Matches an-the-same implementation-defined set of sequences ~~,-which-should-be-the-same-as-the-set-of-sequences-of-characters~~ that may be produced by the `%p` conversion of the `fprintf` function. The corresponding argument ptr shall be a pointer to a pointer to `void`. ~~The input item is converted to a pointer value in an implementation-defined manner.~~

<sup>312)</sup>No special provisions are made for multibyte characters in the matching rules used by the `c`, `s`, and `[` conversion specifiers — the extent of the input field is determined on a byte-by-byte basis. The resulting field is nevertheless a sequence of multibyte characters that begins in the initial shift state.

- ~~If the input *item* is a value converted earlier during the same program execution, the pointer that results shall compare equal to that value; otherwise the behavior of the conversion is undefined.~~ sequence could have been printed from a null pointer value, a null pointer value is stored in *\*ptr*.
- Otherwise, if the input sequence could have been printed from a valid pointer *x* and if the address *x* currently refers to an exposed storage instance, a representation of a valid pointer with address *x* and the provenance of that storage instance is synthesized in *\*ptr*.<sup>313)</sup>
- Otherwise the representation of *\*ptr* becomes indeterminate.

- n No input is consumed. The corresponding argument shall be a pointer to signed integer into which is to be written the number of characters read from the input stream so far by this call to the **fscanf** function. Execution of a `%n` directive does not increment the assignment count returned at the completion of execution of the **fscanf** function. No argument is converted, but one is consumed. If the conversion specification includes an assignment-suppressing character or a field width, the behavior is undefined.
- % Matches a single `%` character; no conversion or assignment occurs. The complete conversion specification shall be `%`.

13 If a conversion specification is invalid, the behavior is undefined.<sup>314)</sup>

14 The conversion specifiers A, E, F, G, and X are also valid and behave the same as, respectively, a, e, f, g, and x.

15 Trailing white space (including new-line characters) is left unread unless matched by a directive. The success of literal matches and suppressed assignments is not directly determinable other than via the `%n` directive.

### Returns

16 The **fscanf** function returns the value of the macro **EOF** if an input failure occurs before the first conversion (if any) has completed. Otherwise, the function returns the number of input items assigned, which can be fewer than provided for, or even zero, in the event of an early matching failure.

17 **EXAMPLE 1** The call:

```
#include <stdio.h>
/* ... */
int n, i; float x; char name[50];
n = fscanf(stdin, "%d%f%s", &i, &x, name);
```

with the input line:

```
25 54.32E-1 thompson
```

will assign to `n` the value 3, to `i` the value 25, to `x` the value 5.432, and to `name` the sequence `thompson\0`.

18 **EXAMPLE 2** The call:

```
#include <stdio.h>
/* ... */
int i; float x; char name[50];
fscanf(stdin, "%2d%f*d %[0123456789]", &i, &x, name);
```

with input:

<sup>313)</sup> Thus, the constructed pointer value has a valid provenance. Nevertheless, because the original storage instance might be dead and a new storage instance might live at the same address, this provenance can be different from the provenance that gave rise to the print operation. If *x* can be an address with more than one provenance, only one of these shall be used in the sequel, see 6.2.5.

<sup>314)</sup> See “future library directions” (7.31.11).

### Returns

- 3 The **sscanf** function returns the value of the macro **EOF** if an input failure occurs before the first conversion (if any) has completed. Otherwise, the **sscanf** function returns the number of input items assigned, which can be fewer than provided for, or even zero, in the event of an early matching failure.

### 7.21.6.8 The **vfprintf** function

#### Synopsis

```
1  #include <stdarg.h>
   #include <stdio.h>
   int vfprintf(FILE * restrict stream,
               const char * restrict format,
               va_list arg);
```

#### Description

- 2 The **vfprintf** function is equivalent to **fprintf**, with the variable argument list replaced by **arg**, which shall have been initialized by the **va\_start** macro (and possibly subsequent **va\_arg** calls). The **vfprintf** function does not invoke the **va\_end** macro.<sup>315)</sup>

#### Returns

- 3 The **vfprintf** function returns the number of characters transmitted, or a negative value if an output or encoding error occurred.
- 4 **EXAMPLE** The following shows the use of the **vfprintf** function in a general error-reporting routine.

```
#include <stdarg.h>
#include <stdio.h>

void error(char *function_name, char *format, ...)
{
    va_list args;

    va_start(args, format);
    // print out name of function causing error
    fprintf(stderr, "ERROR in %s: ", function_name);
    // print out remainder of message
    vfprintf(stderr, format, args);
    va_end(args);
}
```

### 7.21.6.9 The **vfscanf** function

#### Synopsis

```
1  #include <stdarg.h>
   #include <stdio.h>
   int vfscanf(FILE * restrict stream,
               const char * restrict format,
               va_list arg);
```

#### Description

- 2 The **vfscanf** function is equivalent to **fscanf**, with the variable argument list replaced by **arg**, which shall have been initialized by the **va\_start** macro (and possibly subsequent **va\_arg** calls). The **vfscanf** function does not invoke the **va\_end** macro.<sup>315)</sup>

<sup>315)</sup>As the functions **vfprintf**, **vfscanf**, **vprintf**, **vsprintf**, **vsnprintf**, **vsprintf**, and **vsscanf** invoke the **va\_arg** macro, the value of **arg** after the return is [has an indeterminate representation](#).

**Returns**

- 3 If the end-of-file indicator for the stream is set, or if the stream is at end-of-file, the end-of-file indicator for the stream is set and the **fgetc** function returns **EOF**. Otherwise, the **fgetc** function returns the next character from the input stream pointed to by **stream**. If a read error occurs, the error indicator for the stream is set and the **fgetc** function returns **EOF**.<sup>316)</sup>

**7.21.7.2 The fgets function****Synopsis**

```
1  #include <stdio.h>
    char *fgets(char * restrict s, int n,
               FILE * restrict stream);
```

**Description**

- 2 The **fgets** function reads at most one less than the number of characters specified by **n** from the stream pointed to by **stream** into the array pointed to by **s**. No additional characters are read after a new-line character (which is retained) or after end-of-file. A null character is written immediately after the last character read into the array.

**Returns**

- 3 The **fgets** function returns **s** if successful. If end-of-file is encountered and no characters have been read into the array, the contents of the array remain unchanged and a null pointer is returned. If a read error occurs during the operation, the ~~array contents are indeterminate~~ members of the array have unspecified values and a null pointer is returned.

**7.21.7.3 The fputc function****Synopsis**

```
1  #include <stdio.h>
    int fputc(int c, FILE *stream);
```

**Description**

- 2 The **fputc** function writes the character specified by **c** (converted to an **unsigned char**) to the output stream pointed to by **stream**, at the position indicated by the associated file position indicator for the stream (if defined), and advances the indicator appropriately. If the file cannot support positioning requests, or if the stream was opened with append mode, the character is appended to the output stream.

**Returns**

- 3 The **fputc** function returns the character written. If a write error occurs, the error indicator for the stream is set and **fputc** returns **EOF**.

**7.21.7.4 The fputs function****Synopsis**

```
1  #include <stdio.h>
    int fputs(const char * restrict s,
               FILE * restrict stream);
```

**Description**

- 2 The **fputs** function writes the string pointed to by **s** to the stream pointed to by **stream**. The terminating null character is not written.

**Returns**

- 3 The **fputs** function returns **EOF** if a write error occurs; otherwise it returns a nonnegative value.

<sup>316)</sup>An end-of-file and a read error can be distinguished by use of the **feof** and **ferror** functions.

### 7.21.7.9 The `puts` function

#### Synopsis

```
1  #include <stdio.h>
    int puts(const char *s);
```

#### Description

2 The `puts` function writes the string pointed to by `s` to the stream pointed to by `stdout`, and appends a new-line character to the output. The terminating null character is not written.

#### Returns

3 The `puts` function returns `EOF` if a write error occurs; otherwise it returns a nonnegative value.

### 7.21.7.10 The `ungetc` function

#### Synopsis

```
1  #include <stdio.h>
    int ungetc(int c, FILE *stream);
```

#### Description

2 The `ungetc` function pushes the character specified by `c` (converted to an `unsigned char`) back onto the input stream pointed to by `stream`. Pushed-back characters will be returned by subsequent reads on that stream in the reverse order of their pushing. A successful intervening call (with the stream pointed to by `stream`) to a file positioning function (`fseek`, `fsetpos`, or `rewind`) discards any pushed-back characters for the stream. The external storage corresponding to the stream is unchanged.

3 One character of pushback is guaranteed. If the `ungetc` function is called too many times on the same stream without an intervening read or file positioning operation on that stream, the operation may fail.

4 If the value of `c` equals that of the macro `EOF`, the operation fails and the input stream is unchanged.

5 A successful call to the `ungetc` function clears the end-of-file indicator for the stream. The value of the file position indicator for the stream after reading or discarding all pushed-back characters shall be the same as it was before the characters were pushed back.<sup>317)</sup> For a text stream, the value of its file position indicator after a successful call to the `ungetc` function is unspecified until all pushed-back characters are read or discarded. For a binary stream, its file position indicator is decremented by each successful call to the `ungetc` function; if its value was zero before a call, it **is indeterminate** has an indeterminate representation after the call.<sup>318)</sup>

#### Returns

6 The `ungetc` function returns the character pushed back after conversion, or `EOF` if the operation fails.

Forward references: file positioning functions (7.21.9).

## 7.21.8 Direct input/output functions

### 7.21.8.1 The `fread` function

#### Synopsis

```
1  #include <stdio.h>
    size_t fread(void * restrict ptr,
                size_t size, size_t nmemb,
                FILE * restrict stream);
```

<sup>317)</sup>Note that a file positioning function could further modify the file position indicator after discarding any pushed-back characters.

<sup>318)</sup>See “future library directions” (7.31.11).

### Description

- The **fread** function reads, into the array pointed to by `ptr`, up to `nmemb` elements whose size is specified by `size`, from the stream pointed to by `stream`. For each object, `size` calls are made to the **fgetc** function and the results stored, in the order read, in an array of **unsigned char** exactly overlaying the object. The file position indicator for the stream (if defined) is advanced by the number of characters successfully read. If an error occurs, the resulting value-representation of the file position indicator for the stream is indeterminate. If a partial element is read, its value-representation is indeterminate.

### Returns

- The **fread** function returns the number of elements successfully read, which may be less than `nmemb` if a read error or end-of-file is encountered. If `size` or `nmemb` is zero, **fread** returns zero and the contents of the array and the state of the stream remain unchanged.

## 7.21.8.2 The **fwrite** function

### Synopsis

```
1  #include <stdio.h>
   size_t fwrite(const void * restrict ptr,
                size_t size, size_t nmemb,
                FILE * restrict stream);
```

### Description

- The **fwrite** function writes, from the array pointed to by `ptr`, up to `nmemb` elements whose size is specified by `size`, to the stream pointed to by `stream`. For each object, `size` calls are made to the **fputc** function, taking the values (in order) from an array of **unsigned char** exactly overlaying the object. The file position indicator for the stream (if defined) is advanced by the number of characters successfully written. If an error occurs, the resulting value-representation of the file position indicator for the stream is indeterminate.
- If the object (or part thereof) corresponding to the first `size*nmemb` bytes referred by `ptr` contains a valid pointer value with provenance `x`, the **fwrite** function exposes `x`.

### Returns

- The **fwrite** function returns the number of elements successfully written, which will be less than `nmemb` only if a write error is encountered. If `size` or `nmemb` is zero, **fwrite** returns zero and the state of the stream remains unchanged.

## 7.21.9 File positioning functions

### 7.21.9.1 The **fgetpos** function

#### Synopsis

```
1  #include <stdio.h>
   int fgetpos(FILE * restrict stream,
               fpos_t * restrict pos);
```

### Description

- The **fgetpos** function stores the current values of the parse state (if any) and file position indicator for the stream pointed to by `stream` in the object pointed to by `pos`. The values stored contain unspecified information usable by the **fsetpos** function for repositioning the stream to its position at the time of the call to the **fgetpos** function.

### Returns

- If successful, the **fgetpos** function returns zero; on failure, the **fgetpos** function returns nonzero and stores an implementation-defined positive value in **errno**.

**Forward references:** the **fsetpos** function (7.21.9.3).

```

static unsigned long int next = 1;

int rand(void) // RAND_MAX assumed to be 32767
{
    next = next * 1103515245 + 12345;
    return (unsigned int)(next/65536) % 32768;
}

void srand(unsigned int seed)
{
    next = seed;
}

```

### 7.22.3 Storage management functions

- 1 ~~The order and contiguity of storage allocated~~ If the allocation succeeds, the pointer to a storage instance returned by a call to ~~by successive calls to the~~ `aligned_alloc`, `calloc`, `malloc`, and/or `realloc` functions is unspecified. The pointer returned if the allocation succeeds is suitably aligned so that it may be assigned to a pointer to any type of object with a fundamental alignment requirement and ~~then size less than or equal to the size requested~~. It may then be used to access such an object or an array of such objects in the ~~space storage instance~~ allocated (until the ~~space storage instance~~ is explicitly deallocated). The lifetime of an allocated ~~object storage instance~~ extends from the allocation until the deallocation. Each such allocation shall yield a pointer to ~~an object a storage instance that is~~ disjoint from any other ~~object storage instance~~. The pointer returned points to the start (~~lowest byte address~~) address of the allocated ~~space storage instance~~. If the ~~space storage instance~~ cannot be allocated, a null pointer is returned. If the size of the ~~space storage instance~~ requested is zero, the behavior is implementation-defined: either a null pointer is returned to indicate an error, or the ~~behavior is as if the size were some nonzero value, except that~~ address of a storage instance of size zero is returned. For the latter, the returned pointer shall not be used to access an object.
- 2 For purposes of determining the existence of a data race, memory allocation functions behave as though they accessed only ~~memory locations storage instances~~ accessible through their arguments and not other static duration storage ~~instances~~. These functions may, however, visibly modify the storage instance that they allocate or deallocate. Calls to these functions that allocate or deallocate ~~storage instances in~~ a particular region of ~~memory the address space~~ shall occur in a single total order, and each such deallocation call shall synchronize with the next allocation (if any) in this order.<sup>323)</sup>

#### 7.22.3.1 The `aligned_alloc` function

##### Synopsis

```

1 #include <stdlib.h>
   void *aligned_alloc(size_t alignment, size_t size);

```

##### Description

- 2 The `aligned_alloc` function allocates ~~space for an object a storage instance~~ whose alignment is specified by `alignment`, whose size is specified by `size`, and whose ~~value representation~~ is indeterminate. If the value of `alignment` is not a valid alignment supported by the implementation the function shall fail by returning a null pointer.

##### Returns

- 3 The `aligned_alloc` function returns either a null pointer or a pointer to the allocated ~~space storage instance~~.

#### 7.22.3.2 The `calloc` function

<sup>323)</sup> This means that an implementation may only reuse a valid address that is computed from an allocated storage instance for a different allocated storage instance if the calls to allocate and deallocate the storage instances synchronize.

## Synopsis

```
1  #include <stdlib.h>
    void *calloc(size_t nmemb, size_t size);
```

## Description

2 The **calloc** function allocates space-a storage instance for an array of `nmemb` objects, each of whose size is `size`. The space-storage instance is initialized to all bits zero.<sup>324)</sup>

## Returns

3 The **calloc** function returns either a null pointer or a pointer to the allocated space-storage instance.

### 7.22.3.3 The **free** function

#### Synopsis

```
1  #include <stdlib.h>
    void free(void *ptr);
```

## Description

2 The **free** function causes the space-storage instance pointed to by `ptr` to be deallocated, that is, made available for further allocation-use.<sup>325)</sup> If `ptr` is a null pointer, no action occurs. Otherwise, if the argument does not match a pointer earlier returned by a memory-storage management function, or if the space-storage instance has been deallocated by a call to **free** or **realloc**, the behavior is undefined.

## Returns

3 The **free** function returns no value.

### 7.22.3.4 The **malloc** function

#### Synopsis

```
1  #include <stdlib.h>
    void *malloc(size_t size);
```

## Description

2 The **malloc** function allocates space-for-an-object-a storage instance whose size is specified by `size` and whose value-representation is indeterminate.

## Returns

3 The **malloc** function returns either a null pointer or a pointer to the allocated space-storage instance.

### 7.22.3.5 The **realloc** function

#### Synopsis

```
1  #include <stdlib.h>
    void *realloc(void *ptr, size_t size);
```

## Description

2 The **realloc** function deallocates the old object-storage instance pointed to by `ptr` and returns a pointer to a new object-storage instance that has the size specified by `size`. The contents-of-the new-object shall be the same as that bytes of the old object-prior-to-deallocation-storage instance

<sup>324)</sup>Note that this need not be the same as the representation of floating-point zero or a null pointer constant.

<sup>325)</sup>That means that the implementation may reuse the address range of the storage instance (determined by ptr and its size) for any storage instance whose instantiation synchronizes with the call.

up to the lesser of the new and old sizes ~~are copied as if by `memcpy` to the initial bytes of the new storage instance~~. Any bytes in the new ~~object storage instance~~ beyond the size of the old object have ~~indeterminate unspecified~~ values.

- 3 If `ptr` is a null pointer, the `realloc` function behaves like the `malloc` function for the specified size. Otherwise, if `ptr` does not match a pointer earlier returned by a ~~memory storage management function~~, or if the ~~space storage instance~~ has been deallocated by a call to the `free` or `realloc` function, the behavior is undefined. If `size` is nonzero and ~~memory for the new object is not no storage instance is~~ allocated, the old ~~object storage instance~~ is not deallocated. If `size` is zero and ~~memory for the new object is not no storage instance is~~ allocated, it is implementation-defined whether the old ~~object storage instance~~ is deallocated. If the old ~~object storage instance~~ is not deallocated, ~~its value it~~ shall be unchanged.

### Returns

- 4 The `realloc` function returns a pointer to the new ~~object storage instance~~ (which may have the same value as a pointer to the old ~~object storage instance~~), or a null pointer if ~~the new object has not no new storage instance has~~ been allocated.

- 5 **NOTE** If a call to `realloc` is successful, the initial part of the new storage instance represents objects with same value and effective type as the initial part of the old storage instance, if any. Nevertheless, the new storage instance has to be considered to be different from the old one:

- ~~Even if both storage instances have the same address, all pointers to the old storage instance (stored within or outside the storage instance) are invalid because that storage instance ceases to exist.~~
- ~~Copies of objects in the new storage instance that have hidden state and need explicit initialization (such as variable argument lists, atomic objects, mutexes, or condition variables) may have an indeterminate representation.~~
- ~~Resources reserved for the original objects in the old storage instance that have hidden state and need destruction (such as variable argument lists, mutexes or condition variables) may be squandered.~~

## 7.22.4 Communication with the environment

### 7.22.4.1 The `abort` function

#### Synopsis

```
1 #include <stdlib.h>
   _Noreturn void abort(void);
```

#### Description

- 2 The `abort` function causes abnormal program termination to occur, unless the signal `SIGABRT` is being caught and the signal handler does not return. Whether open streams with unwritten buffered data are flushed, open streams are closed, or temporary files are removed is implementation-defined. An implementation-defined form of the status *unsuccessful termination* is returned to the host environment by means of the function call `raise(SIGABRT)`.

#### Returns

- 3 The `abort` function does not return to its caller.

### 7.22.4.2 The `atexit` function

#### Synopsis

```
1 #include <stdlib.h>
   int atexit(void (*func)(void));
```

#### Description

- 2 The `atexit` function registers the function pointed to by `func`, to be called without arguments at normal program termination.<sup>326)</sup> It is unspecified whether a call to the `atexit` function that does not happen before the `exit` function is called will succeed.

<sup>326)</sup>The `atexit` function registrations are distinct from the `at_quick_exit` registrations, so applications might need to call both registration functions with the same argument.

### 7.22.7 Multibyte/wide character conversion functions

- 1 The behavior of the multibyte character functions is affected by the **LC\_CTYPE** category of the current locale. For a state-dependent encoding, each function is placed into its initial conversion state at program startup and can be returned to that state by a call for which its character pointer argument, *s*, is a null pointer. Subsequent calls with *s* as other than a null pointer cause the internal conversion state of the function to be altered as necessary. A call with *s* as a null pointer causes these functions to return a nonzero value if encodings have state dependency, and zero otherwise.<sup>334)</sup> Changing the **LC\_CTYPE** category causes the [internal object describing the conversion state of these functions to be indeterminate](#) [have an indeterminate representation](#).

#### 7.22.7.1 The **mblen** function

##### Synopsis

```
1 #include <stdlib.h>
   int mblen(const char *s, size_t n);
```

##### Description

- 2 If *s* is not a null pointer, the **mblen** function determines the number of bytes contained in the multibyte character pointed to by *s*. Except that the conversion state of the **mbtowc** function is not affected, it is equivalent to

```
mbtowc((wchar_t *)0, (const char *)0, 0);
mbtowc((wchar_t *)0, s, n);
```

- 3 The implementation shall behave as if no library function calls the **mblen** function.

##### Returns

- 4 If *s* is a null pointer, the **mblen** function returns a nonzero or zero value, if multibyte character encodings, respectively, do or do not have state-dependent encodings. If *s* is not a null pointer, the **mblen** function either returns 0 (if *s* points to the null character), or returns the number of bytes that are contained in the multibyte character (if the next *n* or fewer bytes form a valid multibyte character), or returns -1 (if they do not form a valid multibyte character).

**Forward references:** the **mbtowc** function (7.22.7.2).

#### 7.22.7.2 The **mbtowc** function

##### Synopsis

```
1 #include <stdlib.h>
   int mbtowc(wchar_t * restrict pwc,
             const char * restrict s,
             size_t n);
```

##### Description

- 2 If *s* is not a null pointer, the **mbtowc** function inspects at most *n* bytes beginning with the byte pointed to by *s* to determine the number of bytes needed to complete the next multibyte character (including any shift sequences). If the function determines that the next multibyte character is complete and valid, it determines the value of the corresponding wide character and then, if *pwc* is not a null pointer, stores that value in the object pointed to by *pwc*. If the corresponding wide character is the null wide character, the function is left in the initial conversion state.

- 3 The implementation shall behave as if no library function calls the **mbtowc** function.

##### Returns

- 4 If *s* is a null pointer, the **mbtowc** function returns a nonzero or zero value, if multibyte character encodings, respectively, do or do not have state-dependent encodings. If *s* is not a null pointer, the

<sup>334)</sup>If the locale employs special bytes to change the shift state, these bytes do not produce separate wide character codes, but are grouped with an adjacent multibyte character.

## 7.24 String handling <string.h>

### 7.24.1 String function conventions

- 1 The header <string.h> declares one type and several functions, and defines one macro useful for manipulating arrays of character type and other objects treated as arrays of character type.<sup>336)</sup> The type is `size_t` and the macro is `NULL` (both described in 7.19). Various methods are used for determining the lengths of the arrays, but in all cases a `char *` or `void *` argument points to the initial (lowest addressed) character of the array. If an array is accessed beyond the end of an object, the behavior is undefined.
- 2 Where an argument declared as `size_t n` specifies the length of the array for a function, `n` can have the value zero on a call to that function. Unless explicitly stated otherwise in the description of a particular function in this subclause, pointer arguments on such a call shall still have valid values, as described in 7.1.4. On such a call, a function that locates a character finds no occurrence, a function that compares two character sequences returns zero, and a function that copies characters copies zero characters.
- 3 For all functions in this subclause, each character shall be interpreted as if it had the type `unsigned char` (and therefore every possible object representation is valid and has a different value).

### 7.24.2 Copying functions

- 1 If the representation of a pointer object is copied by a copying function, either directly or within an aggregate or union object, the pointer copy has the same provenance as the original.

#### 7.24.2.1 The `memcpy` function

##### Synopsis

```
1  #include <string.h>
    void *memcpy(void * restrict s1,
                const void * restrict s2,
                size_t n);
```

##### Description

- 2 The `memcpy` function copies `n` characters from the object pointed to by `s2` into the object pointed to by `s1`. If copying takes place between objects that overlap, the behavior is undefined.

##### Returns

- 3 The `memcpy` function returns the value of `s1`.

#### 7.24.2.2 The `memmove` function

##### Synopsis

```
1  #include <string.h>
    void *memmove(void *s1, const void *s2, size_t n);
```

##### Description

- 2 The `memmove` function copies `n` characters from the object pointed to by `s2` into the object pointed to by `s1`. Copying takes place as if the `n` characters from the object pointed to by `s2` are first copied into a temporary array of `n` characters that does not overlap the objects pointed to by `s1` and `s2`, and then the `n` characters from the temporary array are copied into the object pointed to by `s1`.

##### Returns

- 3 The `memmove` function returns the value of `s1`.

#### 7.24.2.3 The `strcpy` function

##### Synopsis

---

1 <sup>336)</sup>See “future library directions” (7.31.13).

### Description

- 2 The **strncat** function appends not more than *n* characters (a null character and characters that follow it are not appended) from the array pointed to by *s2* to the end of the string pointed to by *s1*. The initial character of *s2* overwrites the null character at the end of *s1*. A terminating null character is always appended to the result.<sup>338)</sup> If copying takes place between objects that overlap, the behavior is undefined.

### Returns

- 3 The **strncat** function returns the value of *s1*.

**Forward references:** the **strlen** function (7.24.6.3).

## 7.24.4 Comparison functions

- 1 The sign of a nonzero value returned by the comparison functions **memcmp**, **strcmp**, and **strncmp** is determined by the sign of the difference between the values of the first pair of characters (both interpreted as **unsigned char**) that differ in the objects being compared.

### 7.24.4.1 The **memcmp** function

#### Synopsis

```
1 #include <string.h>
   int memcmp(const void *s1, const void *s2, size_t n);
```

#### Description

- 2 The **memcmp** function compares the first *n* characters of the object pointed to by *s1* to the first *n* characters of the object pointed to by *s2*.<sup>339)</sup>

#### Returns

- 3 The **memcmp** function returns an integer greater than, equal to, or less than zero, accordingly as the object pointed to by *s1* is greater than, equal to, or less than the object pointed to by *s2*.

### 7.24.4.2 The **strcmp** function

#### Synopsis

```
1 #include <string.h>
   int strcmp(const char *s1, const char *s2);
```

#### Description

- 2 The **strcmp** function compares the string pointed to by *s1* to the string pointed to by *s2*.

#### Returns

- 3 The **strcmp** function returns an integer greater than, equal to, or less than zero, accordingly as the string pointed to by *s1* is greater than, equal to, or less than the string pointed to by *s2*.

### 7.24.4.3 The **strcoll** function

#### Synopsis

```
1 #include <string.h>
   int strcoll(const char *s1, const char *s2);
```

#### Description

- 2 The **strcoll** function compares the string pointed to by *s1* to the string pointed to by *s2*, both interpreted as appropriate to the **LC\_COLLATE** category of the current locale.

<sup>338)</sup>Thus, the maximum number of characters that can end up in the array pointed to by *s1* is **strlen**(*s1*)+*n*+1.

<sup>339)</sup>The **contents-values** of “holes” bytes that are used as padding for purposes of alignment within structure objects are indeterminate take on unspecified values when a value is stored in the object (cf. 6.2.6.1). Strings shorter than their allocated space and unions can also cause problems in comparison.

**Returns**

- 3 The **strcoll** function returns an integer greater than, equal to, or less than zero, accordingly as the string pointed to by **s1** is greater than, equal to, or less than the string pointed to by **s2** when both are interpreted as appropriate to the current locale.

**7.24.4.4 The **strncmp** function****Synopsis**

```
1 #include <string.h>
   int strncmp(const char *s1, const char *s2, size_t n);
```

**Description**

- 2 The **strncmp** function compares not more than **n** characters (characters that follow a null character are not compared) from the array pointed to by **s1** to the array pointed to by **s2**.

**Returns**

- 3 The **strncmp** function returns an integer greater than, equal to, or less than zero, accordingly as the possibly null-terminated array pointed to by **s1** is greater than, equal to, or less than the possibly null-terminated array pointed to by **s2**.

**7.24.4.5 The **strxfrm** function****Synopsis**

```
1 #include <string.h>
   size_t strxfrm(char * restrict s1,
                 const char * restrict s2,
                 size_t n);
```

**Description**

- 2 The **strxfrm** function transforms the string pointed to by **s2** and places the resulting string into the array pointed to by **s1**. The transformation is such that if the **strcmp** function is applied to two transformed strings, it returns a value greater than, equal to, or less than zero, corresponding to the result of the **strcoll** function applied to the same two original strings. No more than **n** characters are placed into the resulting array pointed to by **s1**, including the terminating null character. If **n** is zero, **s1** is permitted to be a null pointer. If copying takes place between objects that overlap, the behavior is undefined.

**Returns**

- 3 The **strxfrm** function returns the length of the transformed string (not including the terminating null character). If the value returned is **n** or more, the contents of the members of the array pointed to by **s1** are indeterminate have an indeterminate representation.
- 4 **EXAMPLE** The value of the following expression is the size of the array needed to hold the transformation of the string pointed to by **s**.

```
1 + strxfrm(NULL, s, 0)
```

**7.24.5 Search functions****7.24.5.1 The **memchr** function****Synopsis**

```
1 #include <string.h>
   void *memchr(const void *s, int c, size_t n);
```

**Description**

- 2 The **memchr** function locates the first occurrence of **c** (converted to an **unsigned char**) in the initial **n** characters (each interpreted as **unsigned char**) of the object pointed to by **s**. The implementation

- 3 A null pointer value is associated with the newly created key in all existing threads. Upon subsequent thread creation, the value associated with all keys is initialized to a null pointer value in the new thread.
- 4 Destructors associated with thread-specific storage are not invoked at program termination.
- 5 The **tss\_create** function shall not be called from within a destructor.

#### Returns

- 6 If the **tss\_create** function is successful, it sets the thread-specific storage pointed to by **key** to a value that uniquely identifies the newly created pointer and returns **thrd\_success**; otherwise, **thrd\_error** is returned and the thread-specific storage pointed to by **key** is set to an indeterminate value representation.

#### 7.26.6.2 The **tss\_delete** function

##### Synopsis

```
1 #include <threads.h>
   void tss_delete(tss_t key);
```

##### Description

- 2 The **tss\_delete** function releases any resources used by the thread-specific storage identified by **key**. The **tss\_delete** function shall only be called with a value for **key** that was returned by a call to **tss\_create** before the thread commenced executing destructors.
- 3 If **tss\_delete** is called while another thread is executing destructors, whether this will affect the number of invocations of the destructor associated with **key** on that thread is unspecified.
- 4 Calling **tss\_delete** will not result in the invocation of any destructors.

##### Returns

- 5 The **tss\_delete** function returns no value.

#### 7.26.6.3 The **tss\_get** function

##### Synopsis

```
1 #include <threads.h>
   void *tss_get(tss_t key);
```

##### Description

- 2 The **tss\_get** function returns the value for the current thread held in the thread-specific storage identified by **key**. The **tss\_get** function shall only be called with a value for **key** that was returned by a call to **tss\_create** before the thread commenced executing destructors.

##### Returns

- 3 The **tss\_get** function returns the value for the current thread if successful, or zero if unsuccessful.

#### 7.26.6.4 The **tss\_set** function

##### Synopsis

```
1 #include <threads.h>
   int tss_set(tss_t key, void *val);
```

##### Description

- 2 The **tss\_set** function sets the value for the current thread held in the thread-specific storage identified by **key** to **val**. The **tss\_set** function shall only be called with a value for **key** that was returned by a call to **tss\_create** before the thread commenced executing destructors.
- 3 This action will not invoke the destructor associated with the key on the value being replaced.
- 4 If **val** is a valid pointer, its provenance is henceforth exposed.

%a	the first three characters of %A.
%A	one of “Sunday”, “Monday”, ..., “Saturday”.
%b	the first three characters of %B.
%B	one of “January”, “February”, ..., “December”.
%c	equivalent to “%a %b %e %T %Y”.
%p	one of “AM” or “PM”.
%r	equivalent to “%I:%M:%S %p”.
%x	equivalent to “%m/%d/%y”.
%X	equivalent to %T.
%Z	implementation-defined.

### Returns

- 8 If the total number of resulting characters including the terminating null character is not more than `maxsize`, the `strftime` function returns the number of characters placed into the array pointed to by `s` not including the terminating null character. Otherwise, zero is returned and the `contents members` of the array `are indeterminate` have an indeterminate representation.

for an exact representation of the value; if the precision is missing and **FLT\_RADIX** is not a power of 2, then the precision is sufficient to distinguish<sup>363)</sup> values of type **double**, except that trailing zeros may be omitted; if the precision is zero and the **#** flag is not specified, no decimal-point wide character appears. The letters **abcdef** are used for **a** conversion and the letters **ABCDEF** for **A** conversion. The **A** conversion specifier produces a number with **X** and **P** instead of **x** and **p**. The exponent always contains at least one digit, and only as many more digits as necessary to represent the decimal exponent of 2. If the value is zero, the exponent is zero.

A **double** argument representing an infinity or NaN is converted in the style of an **f** or **F** conversion specifier.

- c If no **l** length modifier is present, the **int** argument is converted to a wide character as if by calling **btowc** and the resulting wide character is written.  
If an **l** length modifier is present, the **wint\_t** argument is converted to **wchar\_t** and written.
- s If no **l** length modifier is present, the argument shall be a pointer to the initial element of a character array containing a multibyte character sequence beginning in the initial shift state. Characters from the array are converted as if by repeated calls to the **mbrtowc** function, with the conversion state described by an **mbstate\_t** object initialized to zero before the first multibyte character is converted, and written up to (but not including) the terminating null wide character. If the precision is specified, no more than that many wide characters are written. If the precision is not specified or is greater than the size of the converted array, the converted array shall contain a null wide character.  
If an **l** length modifier is present, the argument shall be a pointer to the initial element of an array of **wchar\_t** type. Wide characters from the array are written up to (but not including) a terminating null wide character. If the precision is specified, no more than that many wide characters are written. If the precision is not specified or is greater than the size of the array, the array shall contain a null wide character.
- p The argument shall be a pointer to **void**. The value of the pointer shall be valid or null. It is converted to a sequence of printing wide characters, in an implementation-defined manner. If the value of the pointer is valid its provenance is henceforth exposed.
- n The argument shall be a pointer to signed integer into which is *written* the number of wide characters written to the output stream so far by this call to **fwprintf**. No argument is converted, but one is consumed. If the conversion specification includes any flags, a field width, or a precision, the behavior is undefined.
- % A **%** wide character is written. No argument is converted. The complete conversion specification shall be **%%**.

9 If a conversion specification is invalid, the behavior is undefined.<sup>364)</sup> If any argument is not the correct type for the corresponding conversion specification, the behavior is undefined.

10 In no case does a nonexistent or small field width cause truncation of a field; if the result of a conversion is wider than the field width, the field is expanded to contain the conversion result.

11 For **a** and **A** conversions, if **FLT\_RADIX** is a power of 2, the value is correctly rounded to a hexadecimal floating number with the given precision.

**Recommended practice**

12 For **a** and **A** conversions, if **FLT\_RADIX** is not a power of 2 and the result is not exactly representable in the given precision, the result should be one of the two adjacent numbers in hexadecimal floating style with the given precision, with the extra stipulation that the error should have a correct sign for the current rounding direction.

<sup>363)</sup>The precision *p* is sufficient to distinguish values of the source type if  $16^{p-1} > b^n$  where *b* is **FLT\_RADIX** and *n* is the number of base-*b* digits in the significand of the source type. A smaller *p* might suffice depending on the implementation's scheme for determining the digit to the left of the decimal-point wide character.

<sup>364)</sup>See "future library directions" (7.31.16).

If no `l` length modifier is present, characters from the input field are converted as if by repeated calls to the `wcrtomb` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first wide character is converted. The corresponding argument shall be a pointer to the initial element of a character array large enough to accept the sequence and a terminating null character, which will be added automatically.

If an `l` length modifier is present, the corresponding argument shall be a pointer to the initial element of an array of `wchar_t` large enough to accept the sequence and the terminating null wide character, which will be added automatically.

The conversion specifier includes all subsequent wide characters in the `format` string, up to and including the matching right bracket (`]`). The wide characters between the brackets (the *scanlist*) compose the scanset, unless the wide character after the left bracket is a circumflex (`^`), in which case the scanset contains all wide characters that do not appear in the scanlist between the circumflex and the right bracket. If the conversion specifier begins with `[]` or `[^]`, the right bracket wide character is in the scanlist and the next following right bracket wide character is the matching right bracket that ends the specification; otherwise the first following right bracket wide character is the one that ends the specification. If a `-` wide character is in the scanlist and is not the first, nor the second where the first wide character is a `^`, nor the last character, the behavior is implementation-defined.

`p` Matches ~~an the same~~ implementation-defined set of sequences ~~, which should be the same as the set of sequences of wide characters~~ that may be produced by the `%p` conversion of the `fwprintf` function. The corresponding argument `ptr` shall be a pointer to a pointer to `void`. ~~The input item is converted to a pointer value in an implementation-defined manner.~~

- ~~~ If the input item is a value converted earlier during the same program execution, the pointer that results shall compare equal to that value; otherwise the behavior of the conversion is undefined.~~ sequence could have been printed from a null pointer value, a null pointer value is stored in \*ptr.
- ~~~ Otherwise, if the input sequence could have been printed from a valid pointer *x* and if the address *x* currently refers to an exposed storage instance, a representation of a valid pointer with address *x* and the provenance of that storage instance is synthesized in \*ptr.~~ <sup>368)</sup>
- ~~~ Otherwise the representation of \*ptr becomes indeterminate.~~

`n` No input is consumed. The corresponding argument shall be a pointer to signed integer into which is to be written the number of wide characters read from the input stream so far by this call to the `fwscanf` function. Execution of a `%n` directive does not increment the assignment count returned at the completion of execution of the `fwscanf` function. No argument is converted, but one is consumed. If the conversion specification includes an assignment-suppressing wide character or a field width, the behavior is undefined.

`%` Matches a single `%` wide character; no conversion or assignment occurs. The complete conversion specification shall be `%%`.

13 If a conversion specification is invalid, the behavior is undefined.<sup>369)</sup>

14 The conversion specifiers `A`, `E`, `F`, `G`, and `X` are also valid and behave the same as, respectively, `a`, `e`, `f`, `g`, and `x`.

15 Trailing white space (including new-line wide characters) is left unread unless matched by a directive. The success of literal matches and suppressed assignments is not directly determinable other than via the `%n` directive.

<sup>368)</sup> Thus, the constructed pointer value has a valid provenance. Nevertheless, because the original storage instance might be dead and a new storage instance might live at the same address, this provenance can be different from the provenance that gave rise to the print operation. If *x* can be an address with more than one provenance, only one of these shall be used in the sequel, see 6.2.5.

<sup>369)</sup> See "future library directions" (7.31.16).

### Returns

- 3 The **swscanf** function returns the value of the macro **EOF** if an input failure occurs before the first conversion (if any) has completed. Otherwise, the **swscanf** function returns the number of input items assigned, which can be fewer than provided for, or even zero, in the event of an early matching failure.

### 7.29.2.5 The **vfwprintf** function

#### Synopsis

```
1  #include <stdarg.h>
    #include <stdio.h>
    #include <wchar.h>
    int vfwprintf(FILE * restrict stream,
                 const wchar_t * restrict format,
                 va_list arg);
```

#### Description

- 2 The **vfwprintf** function is equivalent to **fwprintf**, with the variable argument list replaced by **arg**, which shall have been initialized by the **va\_start** macro (and possibly subsequent **va\_arg** calls). The **vfwprintf** function does not invoke the **va\_end** macro.<sup>370)</sup>

#### Returns

- 3 The **vfwprintf** function returns the number of wide characters transmitted, or a negative value if an output or encoding error occurred.
- 4 **EXAMPLE** The following shows the use of the **vfwprintf** function in a general error-reporting routine.

```
#include <stdarg.h>
#include <stdio.h>
#include <wchar.h>

void error(char *function_name, wchar_t *format, ...)
{
    va_list args;

    va_start(args, format);
    // print out name of function causing error
    fwprintf(stderr, L"ERROR in %s: ", function_name);
    // print out remainder of message
    vfwprintf(stderr, format, args);
    va_end(args);
}
```

### 7.29.2.6 The **vfwscanf** function

#### Synopsis

```
1  #include <stdarg.h>
    #include <stdio.h>
    #include <wchar.h>
    int vfwscanf(FILE * restrict stream,
                 const wchar_t * restrict format,
                 va_list arg);
```

#### Description

- 2 The **vfwscanf** function is equivalent to **fwscanf**, with the variable argument list replaced by **arg**, which shall have been initialized by the **va\_start** macro (and possibly subsequent **va\_arg** calls). The **vfwscanf** function does not invoke the **va\_end** macro.<sup>370)</sup>

<sup>370)</sup>As the functions **vfwprintf**, **vswprintf**, **vfwscanf**, **vwprintf**, **vwscanf**, and **vswscanf** invoke the **va\_arg** macro, the [value representation](#) of **arg** after the return is indeterminate.

```
#include <stdio.h>
#include <wchar.h>
wint_t fgetwc(FILE *stream);
```

### Description

- If the end-of-file indicator for the input stream pointed to by `stream` is not set and a next wide character is present, the `fgetwc` function obtains that wide character as a `wchar_t` converted to a `wint_t` and advances the associated file position indicator for the stream (if defined).

### Returns

- If the end-of-file indicator for the stream is set, or if the stream is at end-of-file, the end-of-file indicator for the stream is set and the `fgetwc` function returns `WEOF`. Otherwise, the `fgetwc` function returns the next wide character from the input stream pointed to by `stream`. If a read error occurs, the error indicator for the stream is set and the `fgetwc` function returns `WEOF`. If an encoding error occurs (including too few bytes), the value of the macro `EILSEQ` is stored in `errno` and the `fgetwc` function returns `WEOF`.<sup>371)</sup>

### 7.29.3.2 The `fgetws` function

#### Synopsis

```
1 #include <stdio.h>
   #include <wchar.h>
   wchar_t *fgetws(wchar_t * restrict s,
                  int n, FILE * restrict stream);
```

### Description

- The `fgetws` function reads at most one less than the number of wide characters specified by `n` from the stream pointed to by `stream` into the array pointed to by `s`. No additional wide characters are read after a new-line wide character (which is retained) or after end-of-file. A null wide character is written immediately after the last wide character read into the array.

### Returns

- The `fgetws` function returns `s` if successful. If end-of-file is encountered and no characters have been read into the array, the contents of the array remain unchanged and a null pointer is returned. If a read or encoding error occurs during the operation, the array contents are indeterminate members have an indeterminate representation and a null pointer is returned.

### 7.29.3.3 The `fputwc` function

#### Synopsis

```
1 #include <stdio.h>
   #include <wchar.h>
   wint_t fputwc(wchar_t c, FILE *stream);
```

### Description

- The `fputwc` function writes the wide character specified by `c` to the output stream pointed to by `stream`, at the position indicated by the associated file position indicator for the stream (if defined), and advances the indicator appropriately. If the file cannot support positioning requests, or if the stream was opened with append mode, the character is appended to the output stream.

### Returns

- The `fputwc` function returns the wide character written. If a write error occurs, the error indicator for the stream is set and `fputwc` returns `WEOF`. If an encoding error occurs, the value of the macro `EILSEQ` is stored in `errno` and `fputwc` returns `WEOF`.

<sup>371)</sup>An end-of-file and a read error can be distinguished by use of the `feof` and `ferror` functions. Also, `errno` will be set to `EILSEQ` by input/output functions only if an encoding error occurs.

**Description**

- 2 The **wscmp** function compares the wide string pointed to by **s1** to the wide string pointed to by **s2**.

**Returns**

- 3 The **wscmp** function returns an integer greater than, equal to, or less than zero, accordingly as the wide string pointed to by **s1** is greater than, equal to, or less than the wide string pointed to by **s2**.

**7.29.4.4.2 The wscoll function****Synopsis**

```
1 #include <wchar.h>
   int wscoll(const wchar_t *s1, const wchar_t *s2);
```

**Description**

- 2 The **wscoll** function compares the wide string pointed to by **s1** to the wide string pointed to by **s2**, both interpreted as appropriate to the **LC\_COLLATE** category of the current locale.

**Returns**

- 3 The **wscoll** function returns an integer greater than, equal to, or less than zero, accordingly as the wide string pointed to by **s1** is greater than, equal to, or less than the wide string pointed to by **s2** when both are interpreted as appropriate to the current locale.

**7.29.4.4.3 The wcsncmp function****Synopsis**

```
1 #include <wchar.h>
   int wcsncmp(const wchar_t *s1, const wchar_t *s2,
              size_t n);
```

**Description**

- 2 The **wcsncmp** function compares not more than **n** wide characters (those that follow a null wide character are not compared) from the array pointed to by **s1** to the array pointed to by **s2**.

**Returns**

- 3 The **wcsncmp** function returns an integer greater than, equal to, or less than zero, accordingly as the possibly null-terminated array pointed to by **s1** is greater than, equal to, or less than the possibly null-terminated array pointed to by **s2**.

**7.29.4.4.4 The wcsxfrm function****Synopsis**

```
1 #include <wchar.h>
   size_t wcsxfrm(wchar_t * restrict s1,
                 const wchar_t * restrict s2,
                 size_t n);
```

**Description**

- 2 The **wcsxfrm** function transforms the wide string pointed to by **s2** and places the resulting wide string into the array pointed to by **s1**. The transformation is such that if the **wscmp** function is applied to two transformed wide strings, it returns a value greater than, equal to, or less than zero, corresponding to the result of the **wscoll** function applied to the same two original wide strings. No more than **n** wide characters are placed into the resulting array pointed to by **s1**, including the terminating null wide character. If **n** is zero, **s1** is permitted to be a null pointer.

**Returns**

- 3 The **wcsxfrm** function returns the length of the transformed wide string (not including the terminating null wide character). If the value returned is **n** or greater, the **contents-of-the-array-array**

elements pointed to by `s1` ~~are indeterminate~~ have an indeterminate representation.

- 4 **EXAMPLE** The value of the following expression is the length of the array needed to hold the transformation of the wide string pointed to by `s`:

```
1 + wcsxfrm(NULL, s, 0)
```

#### 7.29.4.4.5 The `wmemcmp` function

##### Synopsis

```
1 #include <wchar.h>
   int wmemcmp(const wchar_t *s1, const wchar_t *s2,
               size_t n);
```

##### Description

- 2 The `wmemcmp` function compares the first `n` wide characters of the object pointed to by `s1` to the first `n` wide characters of the object pointed to by `s2`.

##### Returns

- 3 The `wmemcmp` function returns an integer greater than, equal to, or less than zero, accordingly as the object pointed to by `s1` is greater than, equal to, or less than the object pointed to by `s2`.

#### 7.29.4.5 Wide string search functions

##### 7.29.4.5.1 The `wcschr` function

##### Synopsis

```
1 #include <wchar.h>
   wchar_t *wcschr(const wchar_t *s, wchar_t c);
```

##### Description

- 2 The `wcschr` function locates the first occurrence of `c` in the wide string pointed to by `s`. The terminating null wide character is considered to be part of the wide string.

##### Returns

- 3 The `wcschr` function returns a pointer to the located wide character, or a null pointer if the wide character does not occur in the wide string.

##### 7.29.4.5.2 The `wcscspn` function

##### Synopsis

```
1 #include <wchar.h>
   size_t wcscspn(const wchar_t *s1, const wchar_t *s2);
```

##### Description

- 2 The `wcscspn` function computes the length of the maximum initial segment of the wide string pointed to by `s1` which consists entirely of wide characters *not* from the wide string pointed to by `s2`.

##### Returns

- 3 The `wcscspn` function returns the length of the segment.

**Returns**

- 3 If the total number of resulting wide characters including the terminating null wide character is not more than `maxsize`, the `wcsftime` function returns the number of wide characters placed into the array pointed to by `s` not including the terminating null wide character. Otherwise, zero is returned and the `contents` `members` of the array `are indeterminate` `have an indeterminate representation`.

**7.29.6 Extended multibyte/wide character conversion utilities**

- 1 The header `<wchar.h>` declares an extended set of functions useful for conversion between multibyte characters and wide characters.
- 2 Most of the following functions — those that are listed as “restartable”, 7.29.6.3 and 7.29.6.4 — take as a last argument a pointer to an object of type `mbstate_t` that is used to describe the current *conversion state* from a particular multibyte character sequence to a wide character sequence (or the reverse) under the rules of a particular setting for the `LC_CTYPE` category of the current locale.
- 3 The initial conversion state corresponds, for a conversion in either direction, to the beginning of a new multibyte character in the initial shift state. A zero-valued `mbstate_t` object is (at least) one way to describe an initial conversion state. A zero-valued `mbstate_t` object can be used to initiate conversion involving any multibyte character sequence, in any `LC_CTYPE` category setting. If an `mbstate_t` object has been altered by any of the functions described in this subclause, and is then used with a different multibyte character sequence, or in the other conversion direction, or with a different `LC_CTYPE` category setting than on earlier function calls, the behavior is undefined.<sup>379)</sup>
- 4 On entry, each function takes the described conversion state (either internal or pointed to by an argument) as current. The conversion state described by the referenced object is altered as needed to track the shift state, and the position within a multibyte character, for the associated multibyte character sequence.

**7.29.6.1 Single-byte/wide character conversion functions****7.29.6.1.1 The `btowc` function****Synopsis**

```
1 #include <wchar.h>
   wint_t btowc(int c);
```

**Description**

- 2 The `btowc` function determines whether `c` constitutes a valid single-byte character in the initial shift state.

**Returns**

- 3 The `btowc` function returns `WEOF` if `c` has the value `EOF` or if `(unsigned char)c` does not constitute a valid single-byte character in the initial shift state. Otherwise, it returns the wide character representation of that character.

**7.29.6.1.2 The `wctob` function****Synopsis**

```
1 #include <wchar.h>
   int wctob(wint_t c);
```

**Description**

- 2 The `wctob` function determines whether `c` corresponds to a member of the extended character set whose multibyte character representation is a single byte when in the initial shift state.

**Returns**

- 3 The `wctob` function returns `EOF` if `c` does not correspond to a multibyte character with length one in the initial shift state. Otherwise, it returns the single-byte representation of that character as an `unsigned char` converted to an `int`.

<sup>379)</sup>Thus, a particular `mbstate_t` object can be used, for example, with both the `mbrtowc` and `mbsrtowcs` functions as long as they are used to step sequentially through the same multibyte character string.

## Annex J

(informative)

### Portability issues

1 This annex collects some information about portability that appears in this document.

#### J.1 Unspecified behavior

1 The following are unspecified:

- The manner and timing of static initialization (5.1.2).
- The termination status returned to the hosted environment if the return type of `main` is not compatible with `int` (5.1.2.2.3).
- The values of objects that are neither lock-free atomic objects nor of type `volatile sig_atomic_t` and the state of the floating-point environment, when the processing of the abstract machine is interrupted by receipt of a signal (5.1.2.3).
- The behavior of the display device if a printing character is written when the active position is at the final position of a line (5.2.2).
- The behavior of the display device if a backspace character is written when the active position is at the initial position of a line (5.2.2).
- The behavior of the display device if a horizontal tab character is written when the active position is at or past the last defined horizontal tabulation position (5.2.2).
- The behavior of the display device if a vertical tab character is written when the active position is at or past the last defined vertical tabulation position (5.2.2).
- How an extended source character that does not correspond to a universal character name counts toward the significant initial characters in an external identifier (5.2.4.1).
- Many aspects of the representations of types (6.2.6).
- The relative order of any two storage instances in the address space (6.2.6.1).
- The value of padding bytes when storing values in structures or unions (6.2.6.1).
- The values of bytes that correspond to union members other than the one last stored into (6.2.6.1).
- The representation used when storing a value in an object that has more than one object representation for that value (6.2.6.1).
- The values of any padding bits in integer representations (6.2.6.2).
- Whether certain operators can generate negative zeros and whether a negative zero becomes a normal zero when stored in an object (6.2.6.2).
- Whether two string literals result in distinct arrays (6.4.5).
- The order in which subexpressions are evaluated and the order in which side effects take place, except as specified for the function-call `()`, `&&`, `||`, `?:`, and comma operators (6.5).
- The order in which the function designator, arguments, and subexpressions within the arguments are evaluated in a function call (6.5.2.2).
- The order of side effects among compound literal initialization list expressions (6.5.2.5).
- The order in which the operands of an assignment operator are evaluated (6.5.16).
- The alignment of the addressable storage unit allocated to hold a bit-field (6.7.2.1).

- Whether a call to an inline function uses the inline definition or the external definition of the function (6.7.4).
- Whether or not a size expression is evaluated when it is part of the operand of a **sizeof** operator and changing the value of the size expression would not affect the result of the operator (6.7.6.2).
- The order in which any side effects occur among the initialization list expressions in an initializer (6.7.9).
- ~~The layout of storage for function parameters (6.9.1).~~ When a fully expanded macro replacement list contains a function-like macro name as its last preprocessing token and the next preprocessing token from the source file is a (, and the fully expanded replacement of that macro ends with the name of the first macro and the next preprocessing token from the source file is again a (, whether that is considered a nested replacement (6.10.3).
- The order in which **#** and **##** operations are evaluated during macro substitution (6.10.3.2, 6.10.3.3).
- The line number following a directive of the form **#line** **\_\_LINE\_\_** *new-line* (6.10.4).
- The state of the floating-point status flags when execution passes from a part of the program translated with **FENV\_ACCESS** “off” to a part translated with **FENV\_ACCESS** “on” (7.6.1).
- The order in which **feraiseexcept** raises floating-point exceptions, except as stated in F.8.6 (7.6.2.3).
- Whether **math\_errhandling** is a macro or an identifier with external linkage (7.12).
- The results of the **frexp** functions when the specified value is not a floating-point number (7.12.6.4).
- The numeric result of the **ilogb** functions when the correct value is outside the range of the return type (7.12.6.5, F.10.3.5).
- The result of rounding when the value is out of range (7.12.9.5, 7.12.9.7, F.10.6.5).
- The value stored by the **remquo** functions in the object pointed to by **quo** when **y** is zero (7.12.10.3).
- Whether a comparison macro argument that is represented in a format wider than its semantic type is converted to the semantic type (7.12.14).
- Whether **setjmp** is a macro or an identifier with external linkage (7.13).
- Whether **va\_copy** and **va\_end** are macros or identifiers with external linkage (7.16.1).
- The hexadecimal digit before the decimal point when a non-normalized floating-point number is printed with an **a** or **A** conversion specifier (7.21.6.1, 7.29.2.1).
- The value of the file position indicator after a successful call to the **ungetc** function for a text stream, or the **ungetwc** function for any stream, until all pushed-back characters are read or discarded (7.21.7.10, 7.29.3.10).
- The details of the value stored by the **fgetpos** function (7.21.9.1).
- The details of the value returned by the **ftell** function for a text stream (7.21.9.4).
- Whether the **strtod**, **strtof**, **strtold**, **wcstod**, **wcstof**, and **wcstold** functions convert a minus-signed sequence to a negative number directly or by negating the value resulting from converting the corresponding unsigned sequence (7.22.1.3, 7.29.4.1.1).

- ~~The order and contiguity of storage allocated by successive calls to the `calloc`, `malloc`, `realloc`, and `aligned_alloc` functions (??). The amount of storage allocated by a successful call to the `calloc`, `malloc`, `realloc`, or `aligned_alloc` function when requesting 0 bytes was requested (?? fails or returns a storage instance of size zero (7.22.3)).~~
- Whether a call to the `atexit` function that does not happen before the `exit` function is called will succeed (7.22.4.2).
- Whether a call to the `at_quick_exit` function that does not happen before the `quick_exit` function is called will succeed (7.22.4.3).
- Which of two elements that compare as equal is matched by the `bsearch` function (7.22.5.1).
- The order of two elements that compare as equal in an array sorted by the `qsort` function (7.22.5.2).
- The order in which destructors are invoked by `thrd_exit` (7.26.5.5).
- Whether calling `tss_delete` on a key while another thread is executing destructors affects the number of invocations of the destructors associated with the key on that thread (7.26.6.2).
- The encoding of the calendar time returned by the `time` function (7.27.2.4).
- The characters stored by the `strftime` or `wcsftime` function if any of the time values being converted is outside the normal range (7.27.3.5, 7.29.5.1).
- Whether an encoding error occurs if a `wchar_t` value that does not correspond to a member of the extended character set appears in the format string for a function in 7.29.2 or 7.29.5 and the specified semantics do not require that value to be processed by `wcrtomb` (7.29.1).
- The conversion state after an encoding error occurs (7.29.6.3.2, 7.29.6.3.3, 7.29.6.4.1, 7.29.6.4.2).
- The resulting value when the “invalid” floating-point exception is raised during IEC 60559 floating to integer conversion (F.4).
- Whether conversion of non-integer IEC 60559 floating values to integer raises the “inexact” floating-point exception (F.4).
- Whether or when library functions in `<math.h>` raise the “inexact” floating-point exception in an IEC 60559 conformant implementation (F.10).
- Whether or when library functions in `<math.h>` raise an undeserved “underflow” floating-point exception in an IEC 60559 conformant implementation (F.10).
- The exponent value stored by `frexp` for a NaN or infinity (F.10.3.4).
- The numeric result returned by the `lrint`, `llrint`, `lround`, and `llround` functions if the rounded value is outside the range of the return type (F.10.6.5, F.10.6.7).
- The sign of one part of the `complex` result of several math functions for certain special cases in IEC 60559 compatible implementations (G.6.1.1, G.6.2.2, G.6.2.3, G.6.2.4, G.6.2.5, G.6.2.6, G.6.3.1, G.6.4.2).

## J.2 Undefined behavior

- 1 The behavior is undefined in the following circumstances:
  - A “shall” or “shall not” requirement that appears outside of a constraint is violated (Clause 4).
  - A nonempty source file does not end in a new-line character which is not immediately preceded by a backslash character or ends in a partial preprocessing token or comment (5.1.1.2).
  - Token concatenation produces a character sequence matching the syntax of a universal character name (5.1.1.2).

- A program in a hosted environment does not define a function named `main` using one of the specified forms (5.1.2.2.1).
- The execution of a program contains a data race (5.1.2.4).
- A character not in the basic source character set is encountered in a source file, except in an identifier, a character constant, a string literal, a header name, a comment, or a preprocessing token that is never converted to a token (5.2.1).
- An identifier, comment, string literal, character constant, or header name contains an invalid multibyte character or does not begin and end in the initial shift state (5.2.1.2).
- The same identifier has both internal and external linkage in the same translation unit (6.2.2).
- An object is referred to outside of its lifetime (6.2.4).
- The value of a pointer to an object whose lifetime has ended is used (6.2.4).
- The value of an object with automatic storage duration is used while ~~it is indeterminate~~ the object has an indeterminate representation (6.2.4, 6.7.9, 6.8).
- A trap-non-value representation is read by an lvalue expression that does not have character type (6.2.6.1).
- A trap-non-value representation is produced by a side effect that modifies any part of the object using an lvalue expression that does not have character type (6.2.6.1).
- The operands to certain operators are such that they could produce a negative zero result, but the implementation does not support negative zeros (6.2.6.2).
- Two declarations of the same object or function specify types that are not compatible (6.2.7).
- A program requires the formation of a composite type from a variable length array type whose size is specified by an expression that is not evaluated (6.2.7).
- Conversion to or from an integer type produces a value outside the range that can be represented (6.3.1.4).
- Demotion of one real floating type to another produces a value outside the range that can be represented (6.3.1.5).
- An lvalue does not designate an object when evaluated (6.3.2.1).
- A non-array lvalue with an incomplete type is used in a context that requires the value of the designated object (6.3.2.1).
- An lvalue designating an object of automatic storage duration that could have been declared with the **register** storage class is used in a context that requires the value of the designated object, but the object is uninitialized. (6.3.2.1).
- An lvalue having array type is converted to a pointer to the initial element of the array, and the array object has register storage class (6.3.2.1).
- An attempt is made to use the value of a void expression, or an implicit or explicit conversion (except to **void**) is applied to a void expression (6.3.2.2).
- Conversion of a pointer to an integer type produces a value outside the range that can be represented (6.3.2.3).
- Conversion between two pointer types produces a result that is incorrectly aligned (6.3.2.3).
- A pointer is used to call a function whose type is not compatible with the referenced type (6.3.2.3).

- A `c`, `s`, or `l` conversion specifier is encountered by one of the formatted input functions, and the array pointed to by the corresponding argument is not large enough to accept the input sequence (and a null terminator if the conversion specifier is `s` or `l`) (7.21.6.2, 7.29.2.2).
- A `c`, `s`, or `l` conversion specifier with an `l` qualifier is encountered by one of the formatted input functions, but the input is not a valid multibyte character sequence that begins in the initial shift state (7.21.6.2, 7.29.2.2).
- The input item for a `%p` conversion by one of the formatted input functions is not a value converted earlier during the same program execution (7.21.6.2, 7.29.2.2).
- The `vfprintf`, `vfscanf`, `vprintf`, `vscanf`, `vsprintf`, `vscanf`, `vsscanf`, `vfwprintf`, `vfwscanf`, `vsprintf`, `vswscanf`, `vwprintf`, or `vwscanf` function is called with an improperly initialized `va_list` argument, or the argument is used (other than in an invocation of `va_end`) after the function returns (7.21.6.8, 7.21.6.9, 7.21.6.10, 7.21.6.11, 7.21.6.12, 7.21.6.13, 7.21.6.14, 7.29.2.5, 7.29.2.6, 7.29.2.7, 7.29.2.8, 7.29.2.9, 7.29.2.10).
- The contents of the array supplied in a call to the `fgets` or `fgetws` function are used after a read error occurred (7.21.7.2, 7.29.3.2).
- The file position indicator for a binary stream is used after a call to the `ungetc` function where its value was zero before the call (7.21.7.10).
- The file position indicator for a stream is used after an error occurred during a call to the `fread` or `fwrite` function (7.21.8.1, 7.21.8.2).
- A partial element read by a call to the `fread` function is used (7.21.8.1).
- The `fseek` function is called for a text stream with a nonzero offset and either the offset was not returned by a previous successful call to the `ftell` function on a stream associated with the same file or `whence` is not `SEEK_SET` (7.21.9.2).
- The `fsetpos` function is called to set a position that was not returned by a previous successful call to the `fgetpos` function on a stream associated with the same file (7.21.9.3).
- A non-null pointer returned by a call to the `calloc`, `malloc`, `realloc`, or `aligned_alloc` function with a zero requested size is used to access an object (7.22.3).
- The value of a pointer that refers to space-a storage instance deallocated by a call to the `free` or `realloc` function is used (7.22.3).
- The pointer argument to the `free` or `realloc` function does not match a pointer earlier returned by a memory-storage management function, or the space-storage instance has been deallocated by a call to `free` or `realloc` (7.22.3.3, 7.22.3.5).
- The value of the object allocated by the `malloc` function is used (7.22.3.4).
- The values of any bytes in a new object allocated by the `realloc` function beyond the size of the old object are used (7.22.3.5).
- The program calls the `exit` or `quick_exit` function more than once, or calls both functions (7.22.4.4, 7.22.4.7).
- During the call to a function registered with the `atexit` or `at_quick_exit` function, a call is made to the `longjmp` function that would terminate the call to the registered function (7.22.4.4, 7.22.4.7).
- The string set up by the `getenv` or `strerror` function is modified by the program (7.22.4.6, 7.24.6.2).
- A signal is raised while the `quick_exit` function is executing (7.22.4.7).
- A command is executed through the `system` function in a way that is documented as causing termination or some other form of undefined behavior (7.22.4.8).

- The mapping of members of the source character set (in character constants and string literals) to members of the execution character set (6.4.4.4, 5.1.1.2).
- The value of an integer character constant containing more than one character or containing a character or escape sequence that does not map to a single-byte execution character (6.4.4.4).
- The value of a wide character constant containing more than one multibyte character or a single multibyte character that maps to multiple members of the extended execution character set, or containing a multibyte character or escape sequence not represented in the extended execution character set (6.4.4.4).
- The current locale used to convert a wide character constant consisting of a single multibyte character that maps to a member of the extended execution character set into a corresponding wide character code (6.4.4.4).
- Whether differently-prefixed wide string literal tokens can be concatenated and, if so, the treatment of the resulting multibyte character sequence (6.4.5).
- The current locale used to convert a wide string literal into corresponding wide character codes (6.4.5).
- The value of a string literal containing a multibyte character or escape sequence not represented in the execution character set (6.4.5).
- The encoding of any of `wchar_t`, `char16_t`, and `char32_t` where the corresponding standard encoding macro (`__STDC_ISO_10646__`, `__STDC_UTF_16__`, or `__STDC_UTF_32__`) is not defined (6.10.8.2).

### J.3.5 Integers

- 1 — Any extended integer types that exist in the implementation (6.2.5).
  - Whether signed integer types are represented using sign and magnitude, two's complement, or ones' complement, and whether the extraordinary value is a `trap-non-value` representation or an ordinary value (6.2.6.2).
  - The rank of any extended integer type relative to another extended integer type with the same precision (6.3.1.1).
  - The result of, or the signal raised by, converting an integer to a signed integer type when the value cannot be represented in an object of that type (6.3.1.3).
  - The results of some bitwise operations on signed integers (6.5).

### J.3.6 Floating point

- 1 — The accuracy of the floating-point operations and of the library functions in `<math.h>` and `<complex.h>` that return floating-point results (5.2.4.2.2).
  - The accuracy of the conversions between floating-point internal representations and string representations performed by the library functions in `<stdio.h>`, `<stdlib.h>`, and `<wchar.h>` (5.2.4.2.2).
  - The rounding behaviors characterized by non-standard values of `FLT_ROUNDS` (5.2.4.2.2).
  - The evaluation methods characterized by non-standard negative values of `FLT_EVAL_METHOD` (5.2.4.2.2).
  - The direction of rounding when an integer is converted to a floating-point number that cannot exactly represent the original value (6.3.1.4).
  - The direction of rounding when a floating-point number is converted to a narrower floating-point number (6.3.1.5).

- Whether the last line of a text stream requires a terminating new-line character (7.21.2).
- Whether space characters that are written out to a text stream immediately before a new-line character appear when read in (7.21.2).
- The number of null characters that may be appended to data written to a binary stream (7.21.2).
- Whether the file position indicator of an append-mode stream is initially positioned at the beginning or end of the file (7.21.3).
- Whether a write on a text stream causes the associated file to be truncated beyond that point (7.21.3).
- The characteristics of file buffering (7.21.3).
- Whether a zero-length file actually exists (7.21.3).
- The rules for composing valid file names (7.21.3).
- Whether the same file can be simultaneously open multiple times (7.21.3).
- The nature and choice of encodings used for multibyte characters in files (7.21.3).
- The effect of the **remove** function on an open file (7.21.4.1).
- The effect if a file with the new name exists prior to a call to the **rename** function (7.21.4.2).
- Whether an open temporary file is removed upon abnormal program termination (7.21.4.3).
- Which changes of mode are permitted (if any), and under what circumstances (7.21.5.4).
- The style used to print an infinity or NaN, and the meaning of any n-char or n-wchar sequence printed for a NaN (7.21.6.1, 7.29.2.1).
- The output for %p conversion in the **fprintf** or **fwprintf** function (7.21.6.1, 7.29.2.1).
- The interpretation of a- character that is neither the first nor the last character, nor the second where a ^ character is the first, in the scanlist for %[ conversion in the **fscanf** or **fwscanf** function (7.21.6.2, 7.29.2.1).
- The set of sequences matched by a %p conversion and the interpretation of the corresponding input item in the **fscanf** or **fwscanf** function (7.21.6.2, 7.29.2.2).
- The value to which the macro **errno** is set by the **fgetpos**, **fsetpos**, or **ftell** functions on failure (7.21.9.1, 7.21.9.3, 7.21.9.4).
- The meaning of any n-char or n-wchar sequence in a string representing a NaN that is converted by the **strtod**, **strtof**, **strtold**, **wctod**, **wctof**, or **wctold** function (7.22.1.3, 7.29.4.1.1).
- Whether or not the **strtod**, **strtof**, **strtold**, **wctod**, **wctof**, or **wctold** function sets **errno** to **ERANGE** when underflow occurs (7.22.1.3, 7.29.4.1.1).
- Whether the **calloc**, **malloc**, **realloc**, and **aligned\_alloc** functions return a null pointer or a pointer to ~~an allocated object~~ a storage instance when the size requested is zero (7.22.3).
- Whether open streams with unwritten buffered data are flushed, open streams are closed, or temporary files are removed when the **abort** or **\_Exit** function is called (7.22.4.1, 7.22.4.5).
- The termination status returned to the host environment by the **abort**, **exit**, **\_Exit**, or **quick\_exit** function (7.22.4.1, 7.22.4.4, 7.22.4.5, 7.22.4.7).
- The value returned by the **system** function when its argument is not a null pointer (7.22.4.8).
- The range and precision of times representable in **clock\_t** and **time\_t** (7.27).

### K.3.5.3.9 The `vfscanf_s` function

#### Synopsis

```

1  #define __STDC_WANT_LIB_EXT1__ 1
    #include <stdarg.h>
    #include <stdio.h>
    int vfscanf_s(FILE * restrict stream,
                  const char * restrict format,
                  va_list arg);

```

#### Runtime-constraints

- 2 Neither `stream` nor `format` shall be a null pointer. Any argument indirected though in order to store converted input shall not be a null pointer.
- 3 If there is a runtime-constraint violation, the `vfscanf_s` function does not attempt to perform further input, and it is unspecified to what extent `vfscanf_s` performed input before discovering the runtime-constraint violation.

#### Description

- 4 The `vfscanf_s` function is equivalent to `fscanf_s`, with the variable argument list replaced by `arg`, which shall have been initialized by the `va_start` macro (and possibly subsequent `va_arg` calls). The `vfscanf_s` function does not invoke the `va_end` macro.<sup>429)</sup>

#### Returns

- 5 The `vfscanf_s` function returns the value of the macro `EOF` if an input failure occurs before any conversion or if there is a runtime-constraint violation. Otherwise, the `vfscanf_s` function returns the number of input items assigned, which can be fewer than provided for, or even zero, in the event of an early matching failure.

### K.3.5.3.10 The `vprintf_s` function

#### Synopsis

```

1  #define __STDC_WANT_LIB_EXT1__ 1
    #include <stdarg.h>
    #include <stdio.h>
    int vprintf_s(const char * restrict format,
                  va_list arg);

```

#### Runtime-constraints

- 2 `format` shall not be a null pointer. The `%n` specifier<sup>430)</sup> (modified or not by flags, field width, or precision) shall not appear in the string pointed to by `format`. Any argument to `vprintf_s` corresponding to a `%s` specifier shall not be a null pointer.
- 3 If there is a runtime-constraint violation, the `vprintf_s` function does not attempt to produce further output, and it is unspecified to what extent `vprintf_s` produced output before discovering the runtime-constraint violation.

#### Description

- 4 The `vprintf_s` function is equivalent to the `vprintf` function except for the explicit runtime-constraints listed above.

#### Returns

- 5 The `vprintf_s` function returns the number of characters transmitted, or a negative value if an output error, encoding error, or runtime-constraint violation occurred.

<sup>429)</sup>As the functions `vfprintf_s`, `vfscanf_s`, `vprintf_s`, `vscanf_s`, `vsnprintf_s`, `vsprintf_s`, and `vsscanf_s` invoke the `va_arg` macro, the [value-representation](#) of `arg` after the return is indeterminate.

<sup>430)</sup>It is not a runtime-constraint violation for the characters `%n` to appear in sequence in the string pointed at by `format` when those characters are not interpreted as a `%n` specifier. For example, if the entire format string was `%%n`.

### K.3.5.3.11 The `vscanf_s` function

#### Synopsis

```

1  #define __STDC_WANT_LIB_EXT1__ 1
    #include <stdarg.h>
    #include <stdio.h>
    int vscanf_s(const char * restrict format,
                va_list arg);

```

#### Runtime-constraints

- 2 `format` shall not be a null pointer. Any argument indirected though in order to store converted input shall not be a null pointer.
- 3 If there is a runtime-constraint violation, the `vscanf_s` function does not attempt to perform further input, and it is unspecified to what extent `vscanf_s` performed input before discovering the runtime-constraint violation.

#### Description

- 4 The `vscanf_s` function is equivalent to `scanf_s`, with the variable argument list replaced by `arg`, which shall have been initialized by the `va_start` macro (and possibly subsequent `va_arg` calls). The `vscanf_s` function does not invoke the `va_end` macro.<sup>431)</sup>

#### Returns

- 5 The `vscanf_s` function returns the value of the macro `EOF` if an input failure occurs before any conversion or if there is a runtime-constraint violation. Otherwise, the `vscanf_s` function returns the number of input items assigned, which can be fewer than provided for, or even zero, in the event of an early matching failure.

### K.3.5.3.12 The `vsprintf_s` function

#### Synopsis

```

1  #define __STDC_WANT_LIB_EXT1__ 1
    #include <stdarg.h>
    #include <stdio.h>
    int vsprintf_s(char * restrict s, rsize_t n,
                  const char * restrict format,
                  va_list arg);

```

#### Runtime-constraints

- 2 Neither `s` nor `format` shall be a null pointer. `n` shall neither equal zero nor be greater than `RSIZE_MAX`. The `%n` specifier<sup>432)</sup> (modified or not by flags, field width, or precision) shall not appear in the string pointed to by `format`. Any argument to `vsprintf_s` corresponding to a `%s` specifier shall not be a null pointer. No encoding error shall occur.
- 3 If there is a runtime-constraint violation, then if `s` is not a null pointer and `n` is greater than zero and not greater than `RSIZE_MAX`, then the `vsprintf_s` function sets `s[0]` to the null character.

#### Description

- 4 The `vsprintf_s` function is equivalent to the `vsprintf` function except for the explicit runtime-constraints listed above.
- 5 The `vsprintf_s` function, unlike `vsprintf_s`, will truncate the result to fit within the array pointed to by `s`.

<sup>431)</sup>As the functions `vfprintf_s`, `vfscanf_s`, `vprintf_s`, `vscanf_s`, `vsprintf_s`, `vsprintf_s`, and `vsscanf_s` invoke the `va_arg` macro, the [value-representation](#) of `arg` after the return is indeterminate.

<sup>432)</sup>It is not a runtime-constraint violation for the characters `%n` to appear in sequence in the string pointed at by `format` when those characters are not interpreted as a `%n` specifier. For example, if the entire format string was `%%n`.

### Description

- 4 The **vsscanf\_s** function is equivalent to **sscanf\_s**, with the variable argument list replaced by **arg**, which shall have been initialized by the **va\_start** macro (and possibly subsequent **va\_arg** calls). The **vsscanf\_s** function does not invoke the **va\_end** macro.<sup>434)</sup>

### Returns

- 5 The **vsscanf\_s** function returns the value of the macro **Eof** if an input failure occurs before any conversion or if there is a runtime-constraint violation. Otherwise, the **vscanf\_s** function returns the number of input items assigned, which can be fewer than provided for, or even zero, in the event of an early matching failure.

## K.3.5.4 Character input/output functions

### K.3.5.4.1 The **gets\_s** function

#### Synopsis

```
1  #define __STDC_WANT_LIB_EXT1__ 1
    #include <stdio.h>
    char *gets_s(char *s, rsize_t n);
```

#### Runtime-constraints

- 2 **s** shall not be a null pointer. **n** shall neither be equal to zero nor be greater than **RSIZE\_MAX**. A new-line character, end-of-file, or read error shall occur within reading **n**-1 characters from **stdin**.<sup>435)</sup>
- 3 If there is a runtime-constraint violation, characters are read and discarded from **stdin** until a new-line character is read, or end-of-file or a read error occurs, and if **s** is not a null pointer, **s[0]** is set to the null character.

#### Description

- 4 The **gets\_s** function reads at most one less than the number of characters specified by **n** from the stream pointed to by **stdin**, into the array pointed to by **s**. No additional characters are read after a new-line character (which is discarded) or after end-of-file. The discarded new-line character does not count towards number of characters read. A null character is written immediately after the last character read into the array.
- 5 If end-of-file is encountered and no characters have been read into the array, or if a read error occurs during the operation, then **s[0]** is set to the null character, and the other elements of **s** take unspecified values.

#### Recommended practice

- 6 The **fgets** function allows properly-written programs to safely process input lines too long to store in the result array. In general this requires that callers of **fgets** pay attention to the presence or absence of a new-line character in the result array. Consider using **fgets** (along with any needed processing based on new-line characters) instead of **gets\_s**.

#### Returns

- 7 The **gets\_s** function returns **s** if successful. If there was a runtime-constraint violation, or if end-of-file is encountered and no characters have been read into the array, or if a read error occurs during the operation, then a null pointer is returned.

<sup>434)</sup>As the functions **vfprintf\_s**, **vfprintf\_s**, **vprintf\_s**, **vscanf\_s**, **vsprintf\_s**, **vscanf\_s**, and **vsscanf\_s** invoke the **va\_arg** macro, the [value representation](#) of **arg** after the return is indeterminate.

<sup>435)</sup>The **gets\_s** function, unlike the historical **gets** function, makes it a runtime-constraint violation for a line of input to overflow the buffer to store it. Unlike the **fgets** function, **gets\_s** maintains a one-to-one relationship between input lines and successful calls to **gets\_s**. Programs that use **gets** expect such a relationship.

## Returns

- 7 The `qsort_s` function returns zero if there was no runtime-constraint violation. Otherwise, a nonzero value is returned.

### K.3.6.4 Multibyte/wide character conversion functions

- 1 The behavior of the multibyte character functions is affected by the `LC_CTYPE` category of the current locale. For a state-dependent encoding, each function is placed into its initial conversion state by a call for which its character pointer argument, `s`, is a null pointer. Subsequent calls with `s` as other than a null pointer cause the internal conversion state of the function to be altered as necessary. A call with `s` as a null pointer causes these functions to set the int pointed to by their `status` argument to a nonzero value if encodings have state dependency, and zero otherwise.<sup>444</sup> Changing the `LC_CTYPE` category causes the [internal object describing the conversion state of these functions to be indeterminate](#) [have an indeterminate representation](#).

#### K.3.6.4.1 The `wctomb_s` function

##### Synopsis

```
1  #define __STDC_WANT_LIB_EXT1__ 1
    #include <stdlib.h>
    errno_t wctomb_s(int * restrict status,
                    char * restrict s,
                    rsize_t smax,
                    wchar_t wc);
```

##### Runtime-constraints

- 2 Let  $n$  denote the number of bytes needed to represent the multibyte character corresponding to the wide character given by `wc` (including any shift sequences).
- 3 If `s` is not a null pointer, then `smax` shall not be less than  $n$ , and `smax` shall not be greater than `RSIZE_MAX`. If `s` is a null pointer, then `smax` shall equal zero.
- 4 If there is a runtime-constraint violation, `wctomb_s` does not modify the int pointed to by `status`, and if `s` is not a null pointer, no more than `smax` elements in the array pointed to by `s` will be accessed.

##### Description

- 5 The `wctomb_s` function determines  $n$  and stores the multibyte character representation of `wc` in the array whose first element is pointed to by `s` (if `s` is not a null pointer). The number of characters stored never exceeds `MB_CUR_MAX` or `smax`. If `wc` is a null wide character, a null byte is stored, preceded by any shift sequence needed to restore the initial shift state, and the function is left in the initial conversion state.
- 6 The implementation shall behave as if no library function calls the `wctomb_s` function.
- 7 If `s` is a null pointer, the `wctomb_s` function stores into the int pointed to by `status` a nonzero or zero value, if multibyte character encodings, respectively, do or do not have state-dependent encodings.
- 8 If `s` is not a null pointer, the `wctomb_s` function stores into the int pointed to by `status` either  $n$  or  $-1$  if `wc`, respectively, does or does not correspond to a valid multibyte character.
- 9 In no case will the int pointed to by `status` be set to a value greater than the `MB_CUR_MAX` macro.

##### Returns

- 10 The `wctomb_s` function returns zero if successful, and a nonzero value if there was a runtime-constraint violation or `wc` did not correspond to a valid multibyte character.

<sup>444</sup>If the locale employs special bytes to change the shift state, these bytes do not produce separate wide character codes, but are grouped with an adjacent multibyte character.

- 3 If there is a runtime-constraint violation, the `vfwprintf_s` function does not attempt to produce further output, and it is unspecified to what extent `vfwprintf_s` produced output before discovering the runtime-constraint violation.

### Description

- 4 The `vfwprintf_s` function is equivalent to the `vfwprintf` function except for the explicit runtime-constraints listed above.

### Returns

- 5 The `vfwprintf_s` function returns the number of wide characters transmitted, or a negative value if an output error, encoding error, or runtime-constraint violation occurred.

#### K.3.9.1.7 The `vfwscanf_s` function

##### Synopsis

```
1  #define __STDC_WANT_LIB_EXT1__ 1
    #include <stdarg.h>
    #include <stdio.h>
    #include <wchar.h>
    int vfwscanf_s(FILE * restrict stream,
                  const wchar_t * restrict format, va_list arg);
```

### Runtime-constraints

- 2 Neither `stream` nor `format` shall be a null pointer. Any argument indirected though in order to store converted input shall not be a null pointer.
- 3 If there is a runtime-constraint violation, the `vfwscanf_s` function does not attempt to perform further input, and it is unspecified to what extent `vfwscanf_s` performed input before discovering the runtime-constraint violation.

### Description

- 4 The `vfwscanf_s` function is equivalent to `fwscanf_s`, with the variable argument list replaced by `arg`, which shall have been initialized by the `va_start` macro (and possibly subsequent `va_arg` calls). The `vfwscanf_s` function does not invoke the `va_end` macro.<sup>466)</sup>

### Returns

- 5 The `vfwscanf_s` function returns the value of the macro `EOF` if an input failure occurs before any conversion or if there is a runtime-constraint violation. Otherwise, the `vfwscanf_s` function returns the number of input items assigned, which can be fewer than provided for, or even zero, in the event of an early matching failure.

#### K.3.9.1.8 The `vsnwprintf_s` function

##### Synopsis

```
1  #define __STDC_WANT_LIB_EXT1__ 1
    #include <stdarg.h>
    #include <wchar.h>
    int vsnwprintf_s(wchar_t * restrict s,
                    rsize_t n,
                    const wchar_t * restrict format,
                    va_list arg);
```

### Runtime-constraints

- 2 Neither `s` nor `format` shall be a null pointer. `n` shall neither equal zero nor be greater than `RSIZE_MAX/sizeof(wchar_t)`. The `%n` specifier<sup>467)</sup> (modified or not by flags, field width, or preci-

<sup>466)</sup>As the functions `vfwscanf_s`, `wscanf_s`, and `vswscanf_s` invoke the `va_arg` macro, the value-representation of `arg` after the return is indeterminate.

<sup>467)</sup>It is not a runtime-constraint violation for the wide characters `%n` to appear in sequence in the wide string pointed at by `format` when those wide characters are not interpreted as a `%n` specifier. For example, if the entire format string was

### K.3.9.1.10 The `vswscanf_s` function

#### Synopsis

```

1  #define __STDC_WANT_LIB_EXT1__ 1
    #include <stdarg.h>
    #include <wchar.h>
    int vswscanf_s(const wchar_t * restrict s,
                  const wchar_t * restrict format,
                  va_list arg);

```

#### Runtime-constraints

- 2 Neither `s` nor `format` shall be a null pointer. Any argument indirected though in order to store converted input shall not be a null pointer.
- 3 If there is a runtime-constraint violation, the `vswscanf_s` function does not attempt to perform further input, and it is unspecified to what extent `vswscanf_s` performed input before discovering the runtime-constraint violation.

#### Description

- 4 The `vswscanf_s` function is equivalent to `swscanf_s`, with the variable argument list replaced by `arg`, which shall have been initialized by the `va_start` macro (and possibly subsequent `va_arg` calls). The `vswscanf_s` function does not invoke the `va_end` macro.<sup>469)</sup>

#### Returns

- 5 The `vswscanf_s` function returns the value of the macro `EOF` if an input failure occurs before any conversion or if there is a runtime-constraint violation. Otherwise, the `vswscanf_s` function returns the number of input items assigned, which can be fewer than provided for, or even zero, in the event of an early matching failure.

### K.3.9.1.11 The `vwprintf_s` function

#### Synopsis

```

1  #define __STDC_WANT_LIB_EXT1__ 1
    #include <stdarg.h>
    #include <wchar.h>
    int vwprintf_s(const wchar_t * restrict format,
                  va_list arg);

```

#### Runtime-constraints

- 2 `format` shall not be a null pointer. The `%n` specifier<sup>470)</sup> (modified or not by flags, field width, or precision) shall not appear in the wide string pointed to by `format`. Any argument to `vwprintf_s` corresponding to a `%s` specifier shall not be a null pointer.
- 3 If there is a runtime-constraint violation, the `vwprintf_s` function does not attempt to produce further output, and it is unspecified to what extent `vwprintf_s` produced output before discovering the runtime-constraint violation.

#### Description

- 4 The `vwprintf_s` function is equivalent to the `vwprintf` function except for the explicit runtime-constraints listed above.

#### Returns

- 5 The `vwprintf_s` function returns the number of wide characters transmitted, or a negative value if an output error, encoding error, or runtime-constraint violation occurred.

<sup>469)</sup>As the functions `vfwscanf_s`, `wscanf_s`, and `vswscanf_s` invoke the `va_arg` macro, the [value-representation](#) of `arg` after the return is indeterminate.

<sup>470)</sup>It is not a runtime-constraint violation for the wide characters `%n` to appear in sequence in the wide string pointed at by `format` when those wide characters are not interpreted as a `%n` specifier. For example, if the entire format string was `L"%%n"`.

### K.3.9.1.12 The `wscanf_s` function

#### Synopsis

```

1  #define __STDC_WANT_LIB_EXT1__ 1
    #include <stdarg.h>
    #include <wchar.h>
    int wscanf_s(const wchar_t * restrict format,
                va_list arg);

```

#### Runtime-constraints

- 2 `format` shall not be a null pointer. Any argument indirected though in order to store converted input shall not be a null pointer.
- 3 If there is a runtime-constraint violation, the `wscanf_s` function does not attempt to perform further input, and it is unspecified to what extent `wscanf_s` performed input before discovering the runtime-constraint violation.

#### Description

- 4 The `wscanf_s` function is equivalent to `wscanf_s`, with the variable argument list replaced by `arg`, which shall have been initialized by the `va_start` macro (and possibly subsequent `va_arg` calls). The `wscanf_s` function does not invoke the `va_end` macro.<sup>471)</sup>

#### Returns

- 5 The `wscanf_s` function returns the value of the macro `EOF` if an input failure occurs before any conversion or if there is a runtime-constraint violation. Otherwise, the `wscanf_s` function returns the number of input items assigned, which can be fewer than provided for, or even zero, in the event of an early matching failure.

### K.3.9.1.13 The `wprintf_s` function

#### Synopsis

```

1  #define __STDC_WANT_LIB_EXT1__ 1
    #include <wchar.h>
    int wprintf_s(const wchar_t * restrict format, ...);

```

#### Runtime-constraints

- 2 `format` shall not be a null pointer. The `%n` specifier<sup>472)</sup> (modified or not by flags, field width, or precision) shall not appear in the wide string pointed to by `format`. Any argument to `wprintf_s` corresponding to a `%s` specifier shall not be a null pointer.
- 3 If there is a runtime-constraint violation, the `wprintf_s` function does not attempt to produce further output, and it is unspecified to what extent `wprintf_s` produced output before discovering the runtime-constraint violation.

#### Description

- 4 The `wprintf_s` function is equivalent to the `wprintf` function except for the explicit runtime-constraints listed above.

#### Returns

- 5 The `wprintf_s` function returns the number of wide characters transmitted, or a negative value if an output error, encoding error, or runtime-constraint violation occurred.

<sup>471)</sup>As the functions `vfwscanf_s`, `wscanf_s`, and `vsscanf_s` invoke the `va_arg` macro, the [value representation](#) of `arg` after the return is indeterminate.

<sup>472)</sup>It is not a runtime-constraint violation for the wide characters `%n` to appear in sequence in the wide string pointed at by `format` when those wide characters are not interpreted as a `%n` specifier. For example, if the entire format string was `L"%n"`.

# Annex L

(normative)

## Analyzability

### L.1 Scope

- 1 This annex specifies optional behavior that can aid in the analyzability of C programs.
- 2 An implementation that defines `__STDC_ANALYZABLE__` shall conform to the specifications in this annex.<sup>488)</sup>

### L.2 Definitions

#### L.2.1

##### 1 out-of-bounds store

an (attempted) access (3.1) that, at run time, for a given computational state, would modify (or, for an object declared **volatile**, fetch) one or more bytes that lie outside the bounds permitted by this document.

#### L.2.2

##### 1 bounded undefined behavior

undefined behavior (3.4.3) that does not perform an out-of-bounds store.

- 2 **Note 1 to entry:** The behavior might perform a trap.

- 3 **Note 2 to entry:** Any values produced or stored might be indeterminate values, unspecified values, and the representation of objects that are written to might become indeterminate.

#### L.2.3

##### 1 critical undefined behavior

undefined behavior that is not bounded undefined behavior.

- 2 **Note 1 to entry:** The behavior might perform an out-of-bounds store or perform a trap.

### L.3 Requirements

- 1 If the program performs a trap (3.21.5), the implementation is permitted to invoke a runtime-constraint handler. Any such semantics are implementation-defined.
- 2 All undefined behavior shall be limited to bounded undefined behavior, except for the following which are permitted to result in critical undefined behavior:
  - An object is referred to outside of its lifetime (6.2.4).
  - A store is performed to an object that has two incompatible declarations (6.2.7),
  - A pointer is used to call a function whose type is not compatible with the referenced type (6.2.7, 6.3.2.3, 6.5.2.2).
  - An lvalue does not designate an object when evaluated (6.3.2.1).
  - The program attempts to modify a string literal (6.4.5).
  - The operand of the unary `*` operator has an invalid value (6.5.3.2).
  - Addition or subtraction of a pointer into, or just beyond, an array object and an integer type produces a result that points just beyond the array object and is used as the operand of a unary `*` operator that is evaluated (6.5.6).
  - An attempt is made to modify an object defined with a const-qualified type through use of an lvalue with non-const-qualified type (6.7.3).

<sup>488)</sup>Implementations that do not define `__STDC_ANALYZABLE__` are not required to conform to these specifications.
