1 Introduction

This document is a revision of the documents N1794=05-0054 and N1721=04-0161. The document N1721=04-0161 contained the suggested wording for new uses of keyword *auto*, which were unanimously approved by the evolution group meeting in Redmond, October 2004. Based on the discussions and straw-polls in the Lillehammer meeting in April 2005, wording for allowing the initialization (with *auto*) of more than one variables in a single statement was added; N1721=04-0161 allowed only one variable initialization per statement. The current document revises the wording of N1794=05-0054 based on technical comments from the core working group from the Lillehammer meeting and repeated reviews in the Mont-Tremblant meeting. Essentially only the suggested wording has changed from N1794=05-0054.

2 Proposed features

We suggest that the *auto* keyword would indicate that the type of a variable is to be deduced from its initializer expression. For example:

```
auto x = 3.14;  // x has type double
```

The *auto* keyword can occur as a simple type specifier (allow to be used with cv-qualifiers, *, and &) and the semantics of *auto* should follow exactly the rules of template argument deduction. Examples (the notation *x* : *T* in the comments is read as “*x* has type *T*”):

```
int foo();
auto x1 = foo();  // x1 : int
const auto& x2 = foo();  // x2 : const int&
auto& x3 = foo();  // x3 : int&: error, cannot bind a reference to a temporary

float& bar();
auto y1 = bar();  // y1 : float
const auto& y2 = bar();  // y2 : const float&
```
auto& y3 = bar();   // y3 : float

A* fii()
auto* z1 = fii();   // z1 : A*
auto z2 = fii();    // z2 : A*
auto* z3 = bar();   // error, bar does not return a pointer type

A major concern in discussions of auto-like features has been the potential difficulty in figuring out whether the declared variable will be of a reference type or not. Particularly, is unintentional aliasing or slicing of objects likely? For example

```cpp
class B { ... virtual void f(); }
class D : public B { ... void f(); }
B* d = new D();
...
auto b = *d;    // is this casting a reference to a base or slicing an object?
b.f();         // is polymorphic behavior preserved?
```

Basing auto on template argument deduction rules provides a natural way for a programmer to express his intention. Controlling copying and referencing is essentially the same as with variables whose types are declared explicitly. For example:

```cpp
A foo();
A& bar();
...
A x1 = foo();   // x1 : A
auto x1 = foo(); // x1 : A
A& x2 = foo();  // error, we cannot bind a non-const reference
auto& x2 = foo(); // error
A y1 = bar();   // y1 : A
auto y1 = bar(); // y1 : A
A& y2 = bar();  // y2 : A&
auto& y2 = bar(); // y2 : A&
```

Thus, as in the rest of the language, value semantics is the default, and reference semantics is provided through consistent use of &.

Multi-variable declarations

More than one variable can be declared in a single statement:

```cpp
int i;
auto a = 1, *b = &i;
```

In the case of two or more variables, both deductions must lead to the same type. Note that the declared variables can get different types, as is the case in the above example. The requirement on the type deductions to lead to the same type is best explained by translation to template argument deduction. The deductions in the above example correspond to the deductions of template parameter T below:

```cpp
template <class T>
void foo(T a, T* b);
...
foo(1, &i);
```
Here, $T$ must be deduced to be the same type based on both arguments; otherwise the code is ill-defined.

**Direct initialization syntax**

Direct initialization syntax is allowed and is equivalent to copy initialization. For example:

```c
auto x = 1;  // x : int
auto x(1);   // x : int
```

The semantics of a direct-initialization expression of the form $T \, v(x)$ with $T$ a type expression containing an occurrence of of `auto`, $v$ as a variable name, and $x$ an expression, is defined as a translation to the corresponding copy initialization expression $T \, v = x$. Examples:

```c
const auto& y(x) -> const auto& y = x;
```

It follows that the direct initialization syntax is allowed with `new` expressions as well:

```c
new auto(1);
```

The expression `auto(1)` has type `int`, and thus `new auto(1)` has type `int*`. Combining a `new` expression using `auto` with an `auto` variable declaration gives:

```c
auto* x = new auto(1);
```

Here, `new auto(1)` has type `int*`, which will be the type of $x$ too.

### 3 Proposed wording

**Section 7.1.1 Storage class specifiers**

Paragraph 1 should start:

The storage class specifiers are

```
storage-class-specifier:
    auto
    register
    static
    extern
    mutable
```

Paragraph 2 should be:

The **auto** and **register** specifiers shall be applied only to names of objects declared in a block (6.3) or to function parameters (8.4). They specify that the named object has automatic storage duration (3.7.2). An object declared without a `storage-class-specifier` at block scope or declared as a function parameter has automatic storage duration by default. [Note: hence, the **auto** specifier is almost always redundant and not often used; one use of **auto** is to distinguish a declaration statement from an expression statement (6.8) explicitly. —end note]

Paragraph 3 should be:

A **register** specifier has the same semantics as an **auto** specifier together with is a hint to the implementation that the object so declared will be heavily used. [Note: the hint can be ignored and in most implementations it will be ignored if the address of the object is taken. —end note]
Section 7.1.5 Type specifiers [dcl.type]

Paragraph 2 should read:

As a general rule, at most one type-specifier is allowed in the complete decl-specifier-seq of a declaration. The only exceptions to this rule are the following:

- `const` or `volatile` can be combined with any other type-specifier. However, redundant cv-qualifiers are prohibited except when introduced through the use of typedefs (7.1.3) or template type arguments (14.3), in which case the redundant cv-qualifiers are ignored.
- `signed` or `unsigned` can be combined with `char`, `long`, `short`, or `int`.
- `short` or `long` can be combined with `int`.
- `long` can be combined with `double`.

- `auto` can be combined with any other type specifier, except with itself.

Section 7.1.5.2 Simple type specifiers [dcl.type.simple]

In paragraph 1, add the following to the list of simple type specifiers:

- `auto`

To Table 7, add the line:

| auto  | placeholder for a type to be deduced |

Change paragraph 2 to read:

The `auto` specifier is a placeholder for a type to be deduced ([dcl.spec.auto] 7.1.5.4). The other simple-type-specifiers specify either a previously-declared user-defined type or one of the fundamental types (3.9.1). Table 7 summarizes the valid combinations of simple-type-specifiers and the types they specify.

New Section 7.1.5.4 auto specifier [dcl.spec.auto]

This would be a new section, even though `auto` is a simple type specifier.

Paragraph 1 should be:

The `auto` type-specifier has two meanings depending on the context of its use. In a decl-specifier-seq that contains at least one type-specifier (in addition to `auto`) that is not a cv-qualifier, the `auto` type-specifier specifies that the object named in the declaration has automatic storage duration. The decl-specifier-seq shall contain no storage-class-specifiers. This use of the `auto` specifier shall only be applied to names of objects declared in a block (6.3) or to function parameters (8.4).

Paragraph 2 should be:

Otherwise (`auto` appearing with no type specifiers other than cv-qualifiers), the `auto` type-specifier signifies that the type of an object being declared is to be deduced from its initializer. This use of `auto` is allowed when declaring objects in a block [stmt.block] (6.3), in namespace scope [basic.scope.namespace] (3.3.5), or in a for-init-statement [stmt.for] (6.5.3). The decl-specifier-seq shall be followed by one or more init-declarators, each of which shall have a non-empty initializer of either of the following two forms:
Paragraph 3 should be:

The `auto` type-specifier can also be used in declaring objects in the condition of a selection statement [stmt.select] (6.4) or of an iteration statement [stmt.iter] (6.5), and in the type-specifier-seq in new-type-id [expr.new] (5.3.4).

Paragraph 4 should be:

A program that uses `auto` in a context not explicitly allowed in this section is ill-formed.

[Example:

```c
auto x = 5; // ok, x has type int
const auto *v = &x, u = 6; // ok, v has type int*, u has type int
static auto y = 0.0; // ok, y has type double
static auto int z; // ill-formed, auto and static conflict
auto int r; // ok, r has type int
```

— end example]

Paragraph 5 should be:

Once the type of a declarator-id has been determined according to [decl.meaning], the type of the declared variable using the declarator-id is determined from the type of its initializer using the rules for template argument deduction. Let \( T \) be the type that has been determined for a variable identifier \( d \). Obtain \( P \) from \( T \) by replacing the occurrence of `auto` with a new invented type template parameter \( U \). Let \( A \) be the type of the initializer expression for \( d \). The type deduced for the variable \( d \) is then the deduced type determined using the rules of template argument deduction from a function call ([temp.deduct.call]), where \( P \) is a function template parameter type and \( A \) the corresponding argument type. If the deduction fails, the declaration is ill-formed.

If the list of declarators contains more than one declarator, the type of each declared variable is determined as described above. If the type deduced for the template parameter \( U \) is not the same in each deduction, the program is ill-formed.

[Example:

```c
const auto &i = expr;
```

The type of \( i \) is the deduced type of the parameter \( u \) in the call \( f(exp) \) of the following invented function template:

```c
template <class U> void f(const U& u);
```

— end example]

Section 8.3.4 arrays [dcl.ptr]

In a declaration \( T \ D \) where \( D \) has the form

```c
D1 [constant-expression_opt]
```
and the type of the identifier in the declaration T D1 is “derived-declarator-type-list T,” then the type of the identifier of D is an array type; if the type of the identifier of D contains the auto type deduction type-specifier, the program is ill-formed.

Currently, the change is thus to ban the use of auto with arrays. This is due to arrays decaying to pointers automatically. For example:

```c
int x[5];
auto y[5] = x;
```

Here, expression x would decay to a pointer, and would not match the type “auto y[5]”. Note that depending on the work on initializers we may wish to revisit this part. For example, we may wish to enable

```c
auto x[] = {a, b, c};
```

Also, we can debate whether the following should be allowed:

```c
int x[5];
auto y[] = x; // would this be allowed and y: int *?
```

### Section 5.3.4 New [expr.new]

Add the following text after the paragraph 1

**If the auto type-specifier appears in the type-specifier-seq of a new-type-id or type-id of a new-expression, the type-specifier-seq shall contain no other type-specifiers except cv-qualifiers, and the new-expression shall contain a new-initializer of the form (assignment-expression).**

The allocated type is deduced from the new-initializer as follows: Let (e) be the new-initializer and T be the new-type-id or type-id of the new expression, then the allocated type is the type deduced for the variable x in the invented declaration ([dcl.spec.auto]):

```
T x = e;
```

**[Example:**

```c
new auto(1); // allocated type is int
auto x = new auto(‘a’); // allocated type is char, x is of type char*
```

—end example]

### 6.4. Selection statements [stmt.select]

Paragraph 2 should be:

The rules for conditions apply both to selection-statements and to the for and while statements (6.5). The declarator shall not specify a function or an array. The type-specifier-seq shall not contain typedef and shall not declare a new class or enumeration. **If the the auto type-specifier appears in the type-specifier-seq, the type-specifier-seq shall contain no other type-specifiers except cv-qualifiers, and the type of the identifier being declared is deduced from the assignment-expression as described in ([dcl.spec.auto]).**
4 Acknowledgments

We are grateful to Jeremy Siek, Douglas Gregor, Jeremiah Willcock, Gary Powell, Mat Marcus, Daveed Vandevoorde, David Abrahams, Andreas Hommel, Peter Dimov, and Paul Mensonides for their valuable input in preparing this proposal. Clearly, this proposal builds on input from members of the EWG as expressed in face-to-face meetings and reflector messages. The wording has been significantly improved as the result of careful, and repeated, reading by the members of the CWG.
