2.7	Exception Handling [except]	11

1 Introduction

This document provides proposed wording for variadic templates [3, 1]. Readers unfamiliar with variadic templates are encouraged to read the complete proposal [3]. This document provides only minor, editorial changes to the previous wording [2] for variadic templates.¹

2 Proposed Wording

2.1 Basic concepts [basic]

Modify paragraph 3 of [basic] as follows:

An *entity* is a value, object, subobject, base class subobject, array element, variable, function, instance of a function, enumerator, type, class member, template, ~~or~~ namespace, or parameter pack.

¹Thanks to Daniel Krügler for his detailed suggestions.

2.2 Expressions [expr]

In [expr.post] paragraph 1, modify the grammar production of *expression-list* as follows:

```
assignment-expression ... opt
expression-list , assignment-expression ... opt
```

Add the following paragraph to [expr.post]:

An *assignment-expression* followed by an ellipsis is a pack expansion [temp.variadic].

In [expr.unary] paragraph 1, modify the grammar production of *unary-expression* as follows:

```
unary-expression:
  postfix-expression
  ++ cast-expression
  -- cast-expression
  unary-operator cast-expression
  sizeof unary-expression
  sizeof ( type-id )
  sizeof ... ( identifier )
  new-expression
  delete-expression
```

Modify paragraph 6 of [expr.sizeof] as follows:

- 1 The result of [sizeof and sizeof...](#) is a constant of type `std::size_t`. [Note: `std::size_t` is defined in the standard header `<cstdint>` (18.1). – end note]

Add the following paragraph to [expr.sizeof] prior to the existing paragraph 6:

The identifier in a `sizeof...` expression shall name a parameter pack. The `sizeof ...` operator yields the number of arguments provided for the parameter pack *identifier*. The parameter pack is expanded [temp.variadic] by the `sizeof ...` operator.

Modify paragraph 1 of [expr.const] as follows:

In several places, C++ requires expressions that evaluate to an integral or enumeration constant: as array bounds (8.3.4, 5.3.4), as case expressions (6.4.2), as bit-field lengths (9.6), as enumerator initializers (7.2), as static member initializers (9.4.2), and as integral or enumeration non-type template arguments (14.3).

```
constant-expression:
  conditional-expression
```

An *integral constant-expression* shall involve only literals of arithmetic types (2.13, 3.9.1), enumerators, non-volatile `const` variables and static data members of integral and enumeration types initialized with constant expressions (8.5), non-type template parameters of integral and enumeration types, ~~and `sizeof` expressions, and `sizeof...` expressions.~~ Floating literals (2.13.3) shall appear only if they are cast to integral or enumeration types. Only type conversions to integral and enumeration types shall be used. In particular, except in `sizeof` expressions, functions, class objects, pointers, or references shall not be used, and assignment, increment, decrement, function call (including *new-expressions* and *delete-expressions*), comma operators, and *throw-expressions* shall not be used.

2.3 Declarators [dcl]

In [dcl.decl] paragraph 4, modify the grammar production of *declarator-id* as follows:

```

declarator-id:
    ... opt id-expression
    :: opt nested-name-specifier opt class-name

```

In [dcl.name], paragraph 1, modify the grammar production of *abstract-declarator* as follows:

```

abstract-declarator:
    ptr-operator abstract-declarator opt
    direct-abstract-declarator
    ...

```

Modify paragraph 2 of [dcl.fct] as follows:

The *parameter-declaration-clause* determines the arguments that can be specified, and their processing, when the function is called. [*Note*: the *parameter-declaration-clause* is used to convert the arguments specified on the function call; see 5.2.2. – *end note*] If the *parameter-declaration-clause* is empty, the function takes no arguments. The parameter list (void) is equivalent to the empty parameter list. Except for this special case, void shall not be a parameter type (though types derived from void, such as void*, can). If the *parameter-declaration-clause* terminates with an ellipsis [or a function parameter pack \[temp.variadic\]](#), the number of arguments shall be equal to or greater than the number of parameters that do not have a default argument [and are not function parameter packs](#). Where syntactically correct [and where “...” is not part of an abstract-declarator](#), “...” is synonymous with “...”. [*Example*: the declaration

```
int printf(const char*, ...);
```

declares a function that can be called with varying numbers and types of arguments.

```
printf("hello world");
printf("a=%d b=%d", a, b);
```

However, the first argument must be of a type that can be converted to a `const char*` – *end example*] [*Note*: the standard header `<stdarg.h>` contains a mechanism for accessing arguments passed using the ellipsis (see 5.2.2 and 18.8). – *end note*]

Add the following paragraphs to [dcl.fct]:

A *parameter-declaration* with an ellipsis in its *declarator-id* is a parameter pack [temp.variadic]. When the *parameter-declaration* is part of a *parameter-declaration-clause*, the parameter pack is a function parameter pack with type “pack expansion of T” [temp.variadic], where T is the type of its *declarator-id*. [*Note*: Otherwise, the parameter-declaration is part of a *template-parameter-list* and the parameter pack is a template parameter pack; see [temp.param]. – *end note*] A function parameter pack shall occur at the end of the *parameter-declaration-list*.

There is a syntactic ambiguity when an ellipsis occurs at the end of a *parameter-declaration-clause* without a preceeding comma. In this case, the ellipsis is parsed as part of the *abstract-declarator* if the type of the parameter names template parameter packs that have not been expanded; otherwise, it is parsed as part of the *parameter-declaration-clause*.²

Modify paragraph 3 of [dcl.fct.default] as follows:

A default argument expression shall be specified only in the *parameter-declaration-clause* of a function declaration or in a *template-parameter* (14.1). [It shall not be specified for a parameter pack](#). If it is specified in a *parameter-declaration-clause*, it shall not occur within a declarator or *abstract-declarator* of a *parameter-declaration*.

²[One can explicitly disambiguate the parse either by introducing a comma \(so the ellipsis will be parsed as part of the *parameter-declaration-clause*\) or introducing a name for the parameter \(so the ellipsis will be parsed as part of the *declarator-id*\).](#)

In [dcl.init], paragraph 1, modify the grammar production of *initializer-list* as follows:

```
initializer-list:
    initializer-clause ... opt
    initializer-list , initializer-clause ... opt
```

Add the following paragraph to [dcl.init]:

An *initializer-clause* followed by an ellipsis is a pack expansion [temp.variadic].

2.4 Derived classes [class.derived]

In [class.derived], paragraph 1, modify the grammar production of *base-specifier-list* as follows:

```
base-specifier-list:
    base-specifier ... opt
    base-specifier-list , base-specifier ... opt
```

Add the following paragraph to [class.derived]:

A *base-specifier* followed by an ellipsis is a pack expansion [temp.variadic].

2.5 Special member functions [special]

In [class.base.init], paragraph 1, modify the grammar production of *mem-initializer-list* as follows:

```
mem-initializer-list:
    mem-initializer ... opt
    mem-initializer ... opt , mem-initializer-list
```

Add the following paragraph to [class.base.init]:

A *mem-initializer* followed by an ellipsis is a pack expansion [temp.variadic] that initializes the base classes specified by a pack expansion in the *base-specifier-list* for the class. [Example:

```
template<typename... Mixins>
struct X
{
    X(const Mixins&... mixins) : Mixins(mixins)... { }
};

– end example ]
```

2.6 Templates [temp]

In [temp.param], paragraph 1, modify the grammar production of *type-parameter* as follows:

```
type-parameter:
    class ... opt identifier opt
    class identifier opt = type-id
    typename ... opt identifier opt
    typename identifier opt = type-id
    template < template-parameter-list > class ... opt identifier opt
    template < template-parameter-list > class identifier opt = id-expression
```

Modify paragraph 3 of [temp.param] as follows:

A *type-parameter* [whose identifier does not follow an ellipsis](#) defines its *identifier* to be a *typedef-name* (if declared with `class` or `typename`) or *template-name* (if declared with `template`) in the scope of the template declaration. [*Note:* because of the name lookup rules, a *template-parameter* that could be interpreted as either a non-type *template-parameter* or a *type-parameter* (because its *identifier* is the name of an already existing class) is taken as a *type-parameter*. For example,

```
class T { /* ... */ };
int i;

template<class T, T i> void f(T t)
{
    T t1 = i; // template-parameters T and i
    ::T t2 = ::i; // global namespace members T and i
}
```

Here, the template `f` has a *type-parameter* called `T`, rather than an unnamed non-type *template-parameter* of class `T`. – *end note*]

Modify paragraph 9 of [temp.param] as follows:

A *default template-argument* is a *template-argument* (14.3) specified after `=` in a *template-parameter*. A default *template-argument* may be specified for any kind of *template-parameter* (type, non-type, template) [that is not a template parameter pack](#). A default *template-argument* may be specified in a template declaration. A default *template-argument* shall not be specified in the *template-parameter-lists* of the definition of a member of a class template that appears outside of the member's class. A default *template-argument* shall not be specified in a friend class template declaration. If a friend function template declaration specifies a default *template-argument*, that declaration shall be a definition and shall be the only declaration of the function template in the translation unit.

Add the following paragraph to [temp.param]:

[If a template-parameter is a type-parameter with an ellipsis prior to its optional identifier or is a parameter-declaration that declares a parameter pack \[dcl.fct\], then the template-parameter is a template parameter pack \[temp.variadic\].](#)

```
template<class... Types> class Tuple; // Types is a template type parameter pack
template<class T, int... Dims> struct multi_array; // Dims is a non-type template parameter pack
```

Modify paragraph 11 of [temp.param] as follows:

If a *template-parameter* of a class template has a default *template-argument*, all subsequent *template-parameters* shall [either](#) have a default *template-argument* supplied [or be template parameter packs](#). [If a template-parameter of a class template is a template parameter pack, it must be the last template-parameter.](#) [*Note:* ~~This is not a requirement~~ [These are not requirements](#) for function templates because template arguments might be deduced (14.8.2). [Example:

```
template<class T1 = int, class T2> class B; // error
```

– *end example*] – *end note*]

In [temp.names], paragraph 1, modify the *template-argument-list* grammar production as follows:

```
template-argument-list:
    template-argument ... opt
    template-argument-list , template-argument ... opt
```

Add the following paragraph to [temp.arg]:

A *template-argument* followed by an ellipsis is a pack expansion [temp.variadic]. A *template-argument* pack expansion shall not occur in a *simple-template-id* whose *template-name* refers to a class template, unless the *template-parameter-list* of that class template declares a *template parameter pack*.

Modify paragraph 4 of [temp.arg] as follows:

When template parameter packs or default *template-arguments* are used, a *template-argument* list can be empty. In that case the empty <> brackets shall still be used as the *template-argument-list*. [*Example*:

```
template<class T = char> class String;
String<>* p; // OK: String<char>
String* q; // syntax error
template<typename ... Elements> class Tuple;
Tuple<>* t; // OK: Elements is empty
Tuple* u; // syntax error
```

– end example]

Add the following paragraph to [temp.arg.template]:

[*Example*:

```
template<class T> class A { /* ... */ };
template<class T, class U = T> class B { /* ... */ };
template<class... Types> class C { /* ... */ };

template<template<class> class P> class X { /* ... */ };
template<template<class...> class Q> class Y { /* ... */ };
```

```
X<A> xa; // okay
X<B> xb; // ill-formed: default arguments for the parameters of a template template argument are ignored
X<C> xc; // ill-formed: a template parameter pack does not match a template parameter
```

```
Y<A> ya; // ill-formed: a template parameter pack does not match a template parameter
Y<B> yb; // ill-formed: a template parameter pack does not match a template parameter
Y<C> yc; // okay
```

– end example]

Modify paragraph 3 of [temp.class] as follows:

When a member function, a member class, a static data member or a member template of a class template is defined outside of the class template definition, the member definition is defined as a template definition in which the *template-parameters* are those of the class template. The names of the template parameters used in the definition of the member may be different from the template parameter names used in the class template definition. The template argument list following the class template name in the member definition shall name the parameters in the same order as the one used in the template parameter list of the member. Template parameter packs shall be expanded with an ellipsis in the template argument list. [*Example*:

```
template<class T1, class T2> struct A {
    void f1();
    void f2();
};

template<class T2, class T1> void A<T2,T1>::f1() { } // OK
template<class T2, class T1> void A<T1,T2>::f2() { } // error
```

```

template<class... Types> struct B {
    void f3();
    void f4();
};

template<class... Types> void B<Types...>::f3() { } // OK
template<class... Types> void B<Types>::f4() { } // error

```

– end example]

In paragraph 9 of [temp.class.spec], add the following bullet:

– An argument shall not contain unexpanded parameter packs. If an argument is a pack expansion [temp.variadic], it shall be the last argument in the template argument list.

Modify paragraph 3 of [temp.func.order] as follows:

To produce the transformed template, for each type, non-type, or template template parameter (or template parameter pack) synthesize a unique type, value, or class template respectively and substitute it for each occurrence of that parameter in the function type of the template.

Modify the fourth bullet of paragraph 1 of [temp.dep.type] as follows:

- in the definition of a partial specialization, the name of the class template followed by the template argument list of the partial specialization enclosed in <>. If the *n*th template parameter is a parameter pack, the *n*th template argument shall be a pack expansion [temp.variadic] whose pattern is the name of the parameter pack.

Modify paragraph 2 of [temp.dep.type] as follows:

The template argument list of a primary template is a template argument list in which the *n*th template argument has the value of the *n*th template parameter of the class template. If the *n*th template parameter is a template parameter pack, the *n*th template argument shall be a pack expansion [temp.variadic] whose pattern is the name of the template parameter pack.

In paragraph 4 of [temp.dep.expr], add the following case:

`sizeof ... (identifier)`

In [temp.dep.constexpr], add the following paragraph:

Expressions of the following form are value-dependent:

- `sizeof ... (identifier)`

Modify paragraph 3 of [temp.arg.explicit] as follows:

Trailing template arguments that can be deduced (14.8.2) or obtained from default *template-arguments* may be omitted from the list of explicit *template-arguments*. Trailing template parameter packs not otherwise deduced will be deduced to an empty sequence of template arguments. If all of the template arguments can be deduced, they may all be omitted; in this case, the empty template argument list <> itself may also be omitted. In contexts where deduction is done and fails, or in contexts where deduction is not done, if a template argument list is specified and it, along with any default template arguments, identifies a single function template specialization, then the *template-id* is an lvalue for the function template specialization. [*Example:*

```

template<class X, class Y, class... Z> X f(Y);
void g()
{
    int i = f<int>(5.6); // Y is deduced to be double, Z is deduced to an empty sequence
    int j = f(5.6); // ill-formed: X cannot be deduced
    f<void>(f<int, bool>); // Y for outer f deduced to be
                          // int (*)(bool), Z is deduced to an empty sequence
    f<void>(f<int>); // ill-formed: f<int> does not denote a
                  // single function template specialization
}

```

– end example]

Modify paragraph 5 of [temp.arg.explicit] as follows:

Template arguments that are present shall be specified in the declaration order of their corresponding *template-parameters*. The template argument list shall not specify more *template-arguments* than there are corresponding *template-parameters* unless one of the *template-parameters* is a template parameter pack. [*Example*:

```

template<class X, class Y, class Z> X f(Y,Z);
template<class... Args> void f2();
void g()
{
    f<int,char*,double>("aa",3.0);
    f<int,char*>("aa",3.0); // Z is deduced to be double
    f<int>("aa",3.0); // Y is deduced to be const char*, and
                  // Z is deduced to be double
    f("aa",3.0); // error: X cannot be deduced
    f2<char, short, int, long>(); // okay
}

```

– end example]

In [temp.arg.explicit], add the following paragraph:

Template argument deduction can extend the sequence of template arguments corresponding to a template parameter pack, even when the sequence contains explicitly-specified template arguments. [*Example*:

```

template<typename... Types> void f(Types... values);

void g()
{
    f<int*, float*>(0, 0, 0); // Types is deduced to the sequence int*, float*, int
}

```

– end example]

Modify the first bullet of paragraph 2 in [temp.deduct] as follows:

- The specified template arguments must match the template parameters in kind (i.e., type, non-type, template), ~~and there~~. There must not be more arguments than there are parameters unless at least one parameter is a template parameter pack; ~~otherwise~~ Otherwise, type deduction fails.

Modify paragraph 1 of [temp.deduct.call] as follows:

Template argument deduction is done by comparing each function template parameter type (call it P) with the type of the corresponding argument of the call (call it A) as described below. For each A_i corresponding to a pack expansion [temp.variadic] (that is, the type of a function parameter pack), P_i is the type that results from substituting the i th element of each expanded template parameter pack into the pattern of the expansion. [*Example:*

```

template<class...> struct Tuple { };

template<class... Types> void f(Types&...);
template<class... Types1, class... Types2> void g(Tuple<Types1...>, Tuple<Types2...>);

void h(int x, float& y)
{
    const int z = x;
    f(x, y, z); // Types is deduced to int, float, const int
    g(Tuple<short, int, long>(), Tuple<float, double>()); // Types1 is deduced to short, int, long
                                                    // Types2 is deduced to float, double
}

```

– *end example*]

In [temp.deduct.partial], add the following paragraph:

[*Note:* Partial ordering of function templates containing template parameter packs is independent of the number of deduced arguments for those template parameter packs. – *end note*] [*Example:*

```

template<typename...> struct Tuple { };
template<typename... Types> void g(Tuple<Types...>); // #1
template<typename T1, typename... Types> void g(Tuple<T1, Types...>); // #2
template<typename T1, typename... Types> void g(Tuple<T1, Types&...>); // #3

g(Tuple<>()); // calls #1
g(Tuple<int, float>()); // calls #2
g(Tuple<int, float&>()); // calls #3
g(Tuple<int>()); // calls #3

```

– *end example*]

Add the following paragraphs to [temp.deduct.type]:

For each A_i corresponding to a pack expansion [temp.variadic] (including the type of a function parameter pack), P_i is the type that results from substituting the i th element of each expanded template parameter pack into the pattern of the expansion. [*Example:*

```

template<class> struct X { };
template<class R, class... ArgTypes> struct X<R(int, ArgTypes...)> { };
template<class... Types> struct Y { };
template<class T, class... Types> struct Y<T, Types&...> { };

template <class... Types> int f (void (*)(Types...));
void g(int, float);

X<int> x1; // uses primary template
X<int(int, float, double)> x2; // uses partial specialization, ArgTypes contains float, double
X<int(float, int)> x3; // uses primary template
Y<> y1; // uses primary template, Types is empty
Y<int&, float&, double&> y2; // uses partial specialization. T is int&, Types contains float, double
Y<int, float, double> y3; // uses primary template, Types contains int, float, double
int fv = f(g); // okay, Types contains int, float

```

– *end example*]

If the original function parameter associated with A is a function parameter pack, and the function parameter associated with P is not a function parameter pack, then template argument deduction fails. [*Example*:

```

template<typename... Args> void f(Args... args); // #1
template<typename T1, typename... Args> void f(T1 a1, Args... args); // #2
template<typename T1, typename T2> void f(T1 a2, T2 a2); // #3

f(); // calls #1
f(1, 2, 3); // calls #2
f(1, 2); // calls #3; non-variadic template #3 is
        // more specialized than the variadic templates #1 and #2

```

– *end example*]

Add a new subsection to [temp.decls] that contains:

2.6.1 Variadic templates [temp.variadic]

- 1 A *template parameter pack* is a template parameter that accepts zero or more template arguments. [*Example*:

```

template<typename... Types> struct Tuple { };

Tuple<> t0; // Types contains no arguments
Tuple<int> t1; // Types contains one argument: int
Tuple<int, float> t2; // Types contains two arguments: int and float
Tuple<0> error; // Error: 0 is not a type

```

– *end example*]

- 2 A *function parameter pack* is a function parameter that accepts zero or more function arguments. [*Note*: The type of a function parameter pack is a pack expansion. – *end note*] [*Example*:

```

template<typename... Types>
void f(Types... args);

f(); // okay: args contains no arguments
f(1); // okay: args contains one int argument
f(2, 1.0); // okay: args contains two arguments, an int and a double

```

– *end example*]

- 3 A *parameter pack* is either a template parameter pack or a function parameter pack.
 4 A *pack expansion* is a sequence of tokens which names one or more parameter packs, followed by an ellipsis. The sequence of tokens is called the pattern of the expansion; its syntax depends on the context in which the expansion appears. Pack expansions can occur in the following contexts:

- In an *expression-list* [expr.post]; the pattern is an *assignment-expression*
- In an *initializer-list* [dcl.init]; the pattern is an *initializer-clause*
- In a *base-specifier-list* [class.derived]; the pattern is a *base-specifier*
- In a *mem-initializer-list* [class.base.init]; the pattern is a *mem-initializer*
- In a *template-argument-list* [temp.arg]; the pattern is a *template-argument*
- In an *exception-specification* [except.spec]; the pattern is a *type-id*

[*Example*:

```

template<typename... Types>
void f(Types... rest);

template<typename... Types>
void g(Types... rest) {
    f(&rest...); // "&rest..." is a pack expansion, "&rest" is its pattern
}

```

– end example]

- 5 A parameter pack whose name appears within the pattern of a pack expansion is expanded by that pack expansion. An appearance of the name of a parameter pack is only expanded by the innermost enclosing pack expansion. The pattern of a pack expansion shall name one or more parameter packs that are not expanded by a nested pack expansion. All of the parameter packs expanded by a pack expansion shall have the same number of arguments specified. An appearance of a name of a parameter pack that is not expanded is ill-formed. [*Example*:

```

template<typename...> struct Tuple {};
template<typename T1, typename T2> struct Pair {};

```

```

template<typename... Args1>
struct zip {
    template<typename... Args2>
    struct with {
        typedef Tuple<Pair<Args1, Args2>...> type;
    };
};

```

```

typedef zip<short, int>::with<unsigned short, unsigned>::type T1;
// T1 is Tuple<Pair<short, unsigned short>, Pair<int, unsigned> >

```

```

typedef zip<short>::with<unsigned short, unsigned>::type T2; // error: different number of arguments specified
// for Args1 and Args2

```

```

template<typename... Args> void g(Args... args)
{
    f(const_cast<const Args*>(&args)...); // okay: "Args" and "args" are expanded
    f(5 ...); // error: pattern does not contain any parameter packs
    f(args); // error: parameter pack "args" is not expanded
    f(h(args...) + args...); // okay: first "args" expanded within h, second "args" expanded within f.
}

```

– end example]

- 6 The instantiation of an expansion produces a comma-separated list E_1, E_2, \dots, E_N , where N is the number of elements in the pack expansion parameters. Each E_i is generated by instantiating the pattern and replacing each pack expansion parameter with its i th element. All of the E_i become elements in the enclosing list. [*Note*: The variety of list varies with context: *expression-list*, *base-specifier-list*, *template-argument-list*, etc. – end note]

2.7 Exception Handling [except]

In [except.spec], paragraph 1, modify the *type-id-list* grammar production as follows:

```

type-id-list:
    type-id ... opt
    type-id-list , type-id ... opt

```

Add the following paragraph to [except.spec]:

In an *exception-specification*, a *type-id* followed by an ellipsis is a pack expansion [temp.variadic].
