1 Introduction and motivation

C++11’s shared_ptr and unique_ptr facilities, like C++98’s auto_ptr before them, provide considerable expressive power for handling memory resources. In addition to the technical benefits of such smart pointers, their names provide de facto vocabulary types\(^1\) for describing certain common coding idioms that encompass pointer-related policies such as pointee copying and lifetime management.

As another example, consider boost::optional,\(^2\) which provides a pointer-like interface to access underlying (possibly uninitialized) values. Dave Abrahams characterizes\(^3\) “the fundamental semantics of optional [as] identical to those of a (non-polymorphic) clone_ptr.” Thus optional provides vocabulary for another common coding idiom in which bare pointers have been historically used.

Code that predates or otherwise avoids such smart pointers generally relies on C++’s native pointers for its memory management and allied needs, and so makes little or no coding use of any kind of standard descriptive vocabulary. As a result, it has often proven to be very challenging and time-consuming for a programmer to inspect code in order to discern the use to which any specific bare pointer is put, even if that use has no management role at all. As Loïc A. Joly observed,\(^4\) “it is not easy to disambiguate a T* pointer that is only observing the data. . . . Even if it would just

---

\(^1\) Defined by Pablo Halperin in N1850 as “ubiquitous types used throughout the internal interfaces of a program.” He goes on to say, “The use of a well-defined set of vocabulary types . . . lends simplicity and clarity to a piece of code.”

\(^2\) http://www.boost.org/doc/libs/1_52_0/libs/optional/doc/html/index.html. This functionality was recently accepted for C++14 per N3672 by Fernando Cacciola and Andrzej Krzeminski. See [optional].

\(^3\) Reflector message c++std-lib-31692.

\(^4\) Reflector message c++std-lib-31595.
serve for documentation, having a dedicated type would have some value I think.” Our experience leads us to agree with this assessment.

## 2 Alternative approaches

Responding to Joly’s above-cited comment, Howard Hinnant presented\(^5\) the following (lightly reformatted, excerpted) C++11 code to demonstrate one candidate mechanism for achieving Joly’s objective:

```cpp
struct do_nothing
{
    template <class T>
    void operator ()(T*) {} // do nothing
};

template <class T>
using non_owning_ptr = unique_ptr<T, do_nothing>;
```

At first glance, this certainly seems a reasonable approach. However, on further reflection, the copy semantics of these `non_owning_ptr<>` types seem subtly wrong for non-owning pointers (i.e., for pointers that behave strictly as observers): while the aliased underlying `unique_ptr` is (movable but) not copyable, we believe that an observer should be freely copyable to another observer object of the same or compatible type. Joly appears to concur with this view, stating\(^6\) that “`non_owning_ptr` should be CopyConstructible and Assignable.”

Later in the same thread, Howard Hinnant shared\(^7\) his personal preference: “I use raw pointers for non-owning relationships. And I actually *like* them. And I don’t find them difficult or error prone.” While this assessment from an acknowledged expert (with concurrence from others\(^8\)) is tempting, it seems most applicable when developing new code. However, we have found that a bare pointer is at such a low level of abstraction\(^9\) that it can mean any one of quite a number of possibilities, especially when working with legacy code (e.g., when trying to divine its intent or trying to interoperate with it).

Consistent with Bjarne Stroustrup’s guideline\(^10\) to “avoid very general types in interfaces,” our coding standard has for some time strongly discouraged the use of bare pointers in most public interfaces.\(^11\) However, it seems clear that there is and will continue to be a role for non-owning, observe-only pointers.

As Ville Voutilainen reminded us,\(^12\) “we haven’t standardized every useful smart pointer yet.” We certainly agree: in our experience, it has proven helpful to have a standard vocabulary type with which to document the observe-only behavior via code that can also interoperate with bare

\(^6\) Reflector message c++std-lib-31725.

\(^7\) Reflector message c++std-lib-31734.

\(^8\) For example, Nevin Liber in c++std-lib-31729 expresses a related preference: “for non-owning situations use references where you can and pointers where you must . . . and only use smart pointers when dealing with ownership.” Other posters shared similar sentiments.

\(^9\) It has been said that bare pointers are to data structures as `goto` is to control structures.

\(^10\) See, for example, his keynote talk “C++11 Style” given 2012-02-02 during the GoingNative 2012 event held in Redmond, WA, USA. Video and slides at [http://channel9.msdn.com/Events/GoingNative/GoingNative-2012](http://channel9.msdn.com/Events/GoingNative/GoingNative-2012).

\(^11\) Constructor parameters are a notable exception.

\(^12\) Reflector message c++std-lib-31742.
pointers. The next section exhibits the essential aspects of \texttt{exempt\_ptr}, our candidate for the (facetious yet descriptive) title of “World’s Dumbest Smart Pointer.”

3 \textbf{A straw man implementation}

We present the following code as a preliminary specification of intent in order to serve as a basis for technical discussion. Designed as a pointer that takes no formal notice of its pointee’s lifetime, this not-very-smart pointer template is intended as a replacement for near-trivial uses of bare/native/raw/built-in/dumb C++ pointers, especially when used to communicate with (say) legacy code that traffics in such pointers. It is, by design, exempt (hence its working name) from any role in managing any pointee, and is thus freely copyable independent of and without regard for its pointee.

We have found that such a template provides us a standard vocabulary to denote non-owning pointers, with no need for further comment or other documentation to describe the near-vacuous semantics involved. As a small bonus, this template’s c’tors ensure that all instance variables are initialized.

```cpp
// ======================================================================
// exempt_ptr: a pointer that is nearly oblivious to its pointee
// ======================================================================

#include <cassert>        // nullptr_t, ptrdiff_t
#include <functional>     // less
#include <iterator>       // random_access_iterator_tag
#include <type_traits>    // add_pointer, enable_if, ...
#include <utility>        // swap

{ return x.get() - y.get(); }
4 Open questions

1. At the moment, exempt_ptr knows of no other smart pointer. Should exempt_ptr innately interoperate with any of the standard smart pointers? If so, with which one(s) and to what degree?

2. More generally, can LWG articulate a smart pointer interoperability policy or rationale in order to guide us in such decisions?

3. Alternative names\(^\text{13}\) (shown alphabetically) for bike-shed consideration:

5 Proposed wording\(^\text{14}\)

5.1 Synopsis

Append the following, in namespace std, to [memory.syn]:

```
// 20.8.x, class template exempt_ptr
template <class E> class exempt_ptr;
template <class E>
  void swap(const exempt_ptr<E>&, const exempt_ptr<E>&) noexcept;
template <class E>
  exempt_ptr<E> make_exempt(E*) noexcept;

// (in)equality operators
template <class E1, class E2>
  bool operator==(const exempt_ptr<E1>&, const exempt_ptr<E2>&);
template <class E1, class E2>
```

\(^\text{13}\) Most of these names were suggested by readers of earlier drafts. While not all suggestions seem viable (e.g., some are clearly intended as humorous), we have opted to preserve all of them for the record.

\(^\text{14}\) All wording is relative to Working Draft N3691.
bool operator!=(const exempt_ptr<E1>&, const exempt_ptr<E2>&);

template <class E>
bool operator==(const exempt_ptr<E>&, nullptr_t) noexcept;
template <class E>
bool operator!=(const exempt_ptr<E>&, nullptr_t) noexcept;

template <class E>
bool operator==(nullptr_t, const exempt_ptr<E>&) noexcept;
template <class E>
bool operator!=(nullptr_t, const exempt_ptr<E>&) noexcept;

// ordering operators
template <class E1, class E2>
bool operator<(const exempt_ptr<E1>&, const exempt_ptr<E2>&);
template <class E1, class E2>
bool operator>(const exempt_ptr<E1>&, const exempt_ptr<E2>&);
template <class E1, class E2>
bool operator<=(const exempt_ptr<E1>&, const exempt_ptr<E2>&);
template <class E1, class E2>
bool operator>=(const exempt_ptr<E1>&, const exempt_ptr<E2>&);

// arithmetic operators
template <class E>
exempt_ptr<E> operator+(ptrdiff_t, const exempt_ptr<E>&);
template <class E>
ptrdiff_t operator-(const exempt_ptr<E>&, const exempt_ptr<E>&);

5.2 Class template, etc.

Create in [smartptr] a new subclause as follows:

20.8.x Non-owning pointers

1 A non-owning pointer, also known as an observer or watcher, is an object o that stores a pointer to a second object w. In this context, w is known as a watched object. [Note: There is no watched object when the stored pointer is nullptr. — end note] An observer takes no responsibility or ownership of any kind for the watched object, if any. In particular, there is no inherent relationship between the lifetimes of any observer and any watched objects.

2 Each type instantiated from the exempt_ptr template specified in this subclause shall meet the requirements of a CopyConstructible and CopyAssignable type. The template parameter E of exempt_ptr may be an incomplete type.

3 [Note: The uses of exempt_ptr include clarity of interface specification in new code, and interoperability with pointer-based legacy code. — end note]

Following the practice of C++11, another copy of the synopsis above is to be inserted here. However, comments are omitted from this copy.
20.8.x.1 Class template \texttt{exempt\_ptr} [exempt.ptr]

For the purposes of this subclause, a type \texttt{F} is said to be \textit{pointer-incompatible} with a type \texttt{E} if the expression \texttt{is\_convertible< add\_pointer\_t<F>, add\_pointer\_t<E> >::value} is \texttt{false}.

namespace std {
    template <class E> class exempt_ptr {
    public:
        // publish our template parameter and variations thereof
        using value_type = E;
        using pointer = add_pointer_t<E>;
        using const_pointer = add_pointer_t<const E>;
        using reference = add_lvalue_reference_t<E>;
        using const_reference = add_lvalue_reference_t<const E>;

        // enable use as a pointer-like iterator
        using difference_type = ptrdiff_t;
        using iterator_category = random_access_iterator_tag;

        // default c’tor
        constexpr exempt_ptr() noexcept;

        // pointer-accepting c’tors
        constexpr exempt_ptr(nullptr_t) noexcept;
        explicit exempt_ptr(pointer) noexcept;
        template <class E2> explicit exempt_ptr(E2*) noexcept;

        // copying c’tors (in addition to compiler-generated copy c’tor)
        template <class E2> exempt_ptr(const exempt_ptr<E2>&) noexcept;

        // pointer-accepting assignments
        exempt_ptr& operator=(nullptr_t) noexcept;
        template <class E2> exempt_ptr& operator=(E2* other) noexcept;

        // copying assignments (in addition to compiler-generated copy assignment)
        template <class E2> exempt_ptr& operator=(const exempt_ptr<E2>&) noexcept;

        // observers
        pointer get() const noexcept;
        reference operator*() const noexcept;
        pointer operator->() const noexcept;
        explicit operator bool() const noexcept;

        // conversions
        operator pointer() noexcept;
        operator const_pointer() const noexcept;

        // modifiers
        pointer release() noexcept;
        void reset(pointer t = nullptr) noexcept;
        void swap(exempt_ptr&) noexcept;

        // arithmetic
        exempt_ptr& operator++();
        exempt_ptr& operator--();
    }\}
exempt_ptr operator++(int);
exempt_ptr operator--(int);
exempt_ptr operator+(ptrdiff_t) const;
exempt_ptr operator-(ptrdiff_t) const;
value_type& operator[](ptrdiff_t);
const value_type& operator[](ptrdiff_t) const;
};  // exempt_ptr<>

20.8.x.1.1 exempt_ptr constructors
constexpr exempt_ptr() noexcept;
constexpr exempt_ptr(nullptr_t) noexcept;

1 Effects: Constructs an exempt_ptr object that has no corresponding watched object.
2 Postconditions: get() == nullptr.

explicit exempt_ptr(pointer other) noexcept;
3 Effects: Constructs an exempt_ptr object whose watched object is *other.

template <class E2> explicit exempt_ptr(E2* other) noexcept;
4 Effects: Constructs an exempt_ptr object whose watched object is *dynamic_cast<pointer>(other).
5 Remarks: This constructor shall not participate in overload resolution if E2 is pointer-incompatible with E.

template <class E2> exempt_ptr(const exempt_ptr<E2>& other) noexcept;
6 Effects: Constructs an exempt_ptr object whose watched object is *dynamic_cast<pointer>(other).
7 Remarks: This constructor shall not participate in overload resolution if E2 is pointer-incompatible with E.

20.8.x.1.2 exempt_ptr assignment
exempt_ptr& operator=(nullptr_t) noexcept;
1 Effects: Same as if calling reset(nullptr);
2 Returns: *this.

template <class E2> exempt_ptr& operator=(E2* other) noexcept;
3 Effects: Same as if calling reset(other);
4 Returns: *this.
5 Remarks: This operator shall not participate in overload resolution if E2 is pointer-incompatible with E.

template <class E2> exempt_ptr& operator=(const exempt_ptr<E2>& other) noexcept;
6 Effects: Same as if calling reset(other.get());
7 Returns: *this.
**Remarks:** This operator shall not participate in overload resolution if \( E_2 \) is pointer-incompatible with \( E \).

20.8.x.1.3 `exempt_ptr` observers

```cpp
pointer get() const noexcept;  // [exempt.ptr.obs]
```

1 **Returns:** The stored pointer.

```cpp
reference operator*() const noexcept;  // [exempt.ptr.obs]
```

2 **Requires:** `get() != nullptr`.

```cpp
pointer operator->() const noexcept;  // [exempt.ptr.obs]
```

4 **Requires:** `get() != nullptr`.

```cpp
explicit operator bool() const noexcept;  // [exempt.ptr.obs]
```

6 **Returns:** `get() != nullptr`.

20.8.x.1.4 `exempt_ptr` conversions

```cpp
operator pointer() noexcept;  // [exempt.ptr.conv]
```

1 **Returns:** `get()`.

```cpp
operator const_pointer() const noexcept;  // [exempt.ptr.conv]
```

2 **Returns:** `get()`.

20.8.x.1.5 `exempt_ptr` modifiers

```cpp
pointer release() noexcept;  // [exempt.ptr.mod]
```

1 **Postconditions:** `get() == nullptr`.

2 **Returns:** The value `get()` had at the start of the call to `release`.

```cpp
void reset(pointer p = nullptr) noexcept;  // [exempt.ptr.mod]
```

3 **Postconditions:** `get() == p`.

```cpp
void swap(exempt_ptr& other) noexcept;  // [exempt.ptr.mod]
```

4 **Effects:** Invokes `swap` on the stored pointers of `*this` and `other`.

20.8.x.1.6 `exempt_ptr` arithmetic

```cpp
exempt_ptr& operator++();  // [exempt.ptr.arith]
exempt_ptr& operator--();
```

1 **Effects:** Increments (or, in the second form, decrements) the stored pointer.

2 **Requires:** `get() != nullptr`.

```cpp
exempt_ptr operator++(int);  // [exempt.ptr.arith]
exempt_ptr operator--(int);
```
4 Effects: Increments (or, in the second form, decrements) the stored pointer.

5 Requires: get() != nullptr.

6 Returns: exempt_ptr(p++) or exempt_ptr(p--), respectively, where p denotes the original stored pointer.

exempt_ptr operator+() const;

7 Returns: *this.

exempt_ptr operator+(ptrdiff_t d) const;
exempt_ptr operator-(ptrdiff_t d) const;

8 Returns: exempt_ptr(p+d) or exempt_ptr(p-d), respectively, where p denotes the stored pointer.

value_type& operator[](ptrdiff_t k);
const value_type& operator[](ptrdiff_t k);

9 Returns: p[k], where p denotes the stored pointer.

20.8.x.1.7 exempt_ptr specialized algorithms [exempt.ptr.special]
template <class E>
    void swap(exempt_ptr<E> & p1, exempt_ptr<E> & p2) noexcept;

1 Effects: p1.swap(p2).

template <class E> exempt_ptr<E> make_exempt(E * p) noexcept;

2 Returns: exempt_ptr<E>{p}.

template <class E1, class E2>
    bool operator==(exempt_ptr<E1> const & p1, exempt_ptr<E2> const & p2);

3 Returns: equal_to<void>()(p1.get(), p2.get()).

template <class E1, class E2>
    bool operator!=(exempt_ptr<E1> const & p1, exempt_ptr<E2> const & p2);

4 Returns: not operator==(p1, p2).

template <class E>
    bool operator==(exempt_ptr<E> const & p, nullptr_t) noexcept;
template <class E>
    bool operator==(nullptr_t, exempt_ptr<E> const & p) noexcept;

5 Returns: not p.

template <class E>
    bool operator!=(exempt_ptr<E> const & p, nullptr_t) noexcept;
template <class E>
    bool operator!=(nullptr_t, exempt_ptr<E> const & p) noexcept;

6 Returns: (bool)p.

template <class E1, class E2>
    bool operator<(exempt_ptr<E1> const & p1, exempt_ptr<E2> const & p2);

7 Returns: less<void>()(x.get(), y.get());.
template <class E>
  bool operator>(exempt_ptr<E> const & p1, exempt_ptr<E> const & p2);

  8 Returns: p2 < p1.

template <class E>
  bool operator<=(exempt_ptr<E> const & p1, exempt_ptr<E> const & p2);

  9 Returns: not (p2 < p1).

template <class E>
  bool operator>=(exempt_ptr<E> const & p1, exempt_ptr<E> const & p2);

  10 Returns: not (p1 < p2).

template <class E>
exempt_ptr<E> operator+(ptrdiff_t d, exempt_ptr<E> const & p)

  11 Returns: (p + d).

template <class E>
ptrdiff_t operator-(const exempt_ptr<E>& p1, const exempt_ptr<E>& p2)

  12 Returns: p1.get() - p2.get()

6 Acknowledgments

Many thanks to the reviewers of early drafts of this paper for their helpful and constructive comments.

7 Revision history
