Abstract

This paper proposes to add to the standard library an interface for two algorithms carrying out random sampling. Such algorithms have long been part of the original (SGI) implementation of the Standard Template Library.

"Sampling is the first step if you are looking to move things forward." — Tom Pirkos

1 Proposal

In [N2569], Matt Austern proposed several additional algorithms (mostly taken from SGI’s original STL implementation) for the standard library. Among these were random_sample and random_sample_n, based respectively on the well-known algorithms S (“selection sampling technique”) and R (“reservoir sampling”) elucidated by Donald Knuth in [Knu97, §3.4.2]. Austern’s paper succinctly describes these algorithms as “two important versions of random sampling, one of which randomly chooses \( n \) elements from a range of \( N \) elements and the other of which randomly chooses \( n \) elements from an input range whose size is initially unknown...”

After WG21 consideration at the Sophia-Antipolis meeting, Austern updated the proposal, producing [N2666]. Among other changes, he withdrew the sampling algorithms because “The LWG was concerned that they might not be well enough understood for standardization... It may be appropriate to propose those algorithms for TR2.” LWG subsequently achieved a solid consensus (10-1, 2 abs.) in support of having these algorithms in a future Technical Report (now termed a Technical Specification).

Given WG21’s stated near-term intent to publish such documents, and thereafter to issue a revised standard, we believe it is an appropriate time to reconsider these algorithms for the C++ standard library. Unlike the SGI implementation on which Austern’s proposal was based, the present proposal features a unified (common) interface, sample, that selects between algorithms R and S based on the categories of the iterators supplied at the point of call.
2 Expository implementation

Common interface As an implementation detail, we name both sampling algorithms __sample. The proposed sample template then relies on overload resolution via tag dispatch to choose between those algorithms:

```cpp
template< class PopIter, class SampleIter, class Size, class URNG >
SampleIter
sample( PopIter first, PopIter last
    , SampleIter out
    , Size n, URNG&& g
)
{
    using pop_t = typename iterator_traits<PopIter>::iterator_category;
    using samp_t = typename iterator_traits<SampleIter>::iterator_category;

    return __sample( first, last, pop_t{}
                    , out, samp_t{}
                    , n, forward<URNG>(g)
                    );
}
```

Reservoir sampling Our proposed version of the reservoir sampling algorithm R requires only input iterators for access to the population being sampled, but needs a random access iterator to (the start of) the reservoir that will ultimately hold the resulting sample:

```cpp
template< class PopIter, class SampleIter, class Size, class URNG >
SampleIter
__sample( PopIter first, PopIter last, input_iterator_tag
    , SampleIter out, random_access_iterator_tag
    , Size n, URNG&& g
)
{
    using dist_t = uniform_int_distribution<Size>;
    using param_t = typename dist_t::param_type;
    dist_t d{};

    Size sample_sz{0};
    while( first != last && sample_sz != n )
        out[sample_sz++] = *first++;
    for( Size pop_sz=sample_sz; first != last; ++first, ++pop_sz )
        param_t const p{0, pop_sz};
        Size const k{ d(g, p) };
        if( k < n ) out[k] = *first;
    return out + sample_sz;
}
```

---

2 Beware of bugs in this code; I have only tried it, not proved it correct. [Apologies to Knuth. ©]

3 Knuth's original algorithm R guarantees stability, but at the cost of an extra level of indirection, an additional sorting step, etc. The SGI version, as proposed here and in Austern's earlier paper, sacrifices stability in the interest of performance, but retains all other characteristics, especially the all-important randomness of the resulting sample.
Selection sampling  Our proposed selection sampling algorithm $S$ needs forward iterators to access the population, but only an output iterator to the resulting sample:

```cpp
template< class PopIter, class SampleIter, class Size, class URNG >
SampleIter
__sample( PopIter first, PopIter last, forward_iterator_tag
, SampleIter out, output_iterator_tag
, Size n, URNG&& g )
{
    using dist_t = uniform_int_distribution<Size>;
    using param_t = typename dist_t::param_type;
    dist_t d{};
    Size unsampled_sz = distance(first, last);
    for( n = min(n, unsampled_sz); n != 0; ++first ) {
        param_t const p(0, --unsampled_sz);
        if( d(g, p) < n ) { *out++ = *first; --n; }
    }
    return out;
}
```

3 Proposed wording

Change the heading of [alg.random.shuffle] as shown:

25.3.12 Random shuffle Shuffling and sampling

Append the following text to the newly retitled [alg.random.shuffle], also incorporating the new declaration into <algorithm>'s synopsis at the beginning of [algorithms].

```cpp
template <class PopulationIterator, class SampleIterator,
class Distance, class UniformRandomNumberGenerator>
SampleIterator sample(PopulationIterator first, PopulationIterator last,
SampleIterator out, Distance n,
UniformRandomNumberGenerator&& g);
```

Requires:

- **PopulationIterator** shall meet the requirements of an InputIterator type.
- **SampleIterator** shall meet the requirements of an OutputIterator type.
- **SampleIterator** shall meet the additional requirements of a RandomAccessIterator type unless **PopulationIterator** meets the additional requirements of a ForwardIterator type.
- **PopulationIterator's** value type shall be writable to **out**.
- **Distance** shall be an integer type.
- **UniformRandomNumberGenerator** shall meet the requirements of a uniform random number generator type (rand.req.urng) whose return type is convertible to **Distance**.
- **out** shall not be in the range [first, last).

---

4All proposed additions and deletions are relative to the post-Chicago Working Draft [N3797]. Editorial notes are displayed against a gray background.
Effects: Copies \( \min(\text{last} - \text{first}, \ n) \) elements (the sample) from \([\text{first}, \text{last}]\) (the population) to \text{out} such that each possible sample has equal probability of appearance. [Note: Algorithms that obtain such effects include selection sampling and reservoir sampling. — end note]

Returns: The end of the resulting sample range.

Complexity: \( O(n) \).

Remarks:

- Stable if and only if \text{PopulationIterator} meets the requirements of a \text{ForwardIterator} type.
- To the extent that the implementation of this function makes use of random numbers, the object \( g \) shall serve as the implementation's source of randomness.

4 Feature-testing macro

For the purposes of SG10, we recommend the macro name \texttt{__cpp_lib_sample}.

5 Acknowledgments

Many thanks to the readers of early drafts of this paper for their thoughtful comments, and to Matt Austern for the original proposal of the sampling algorithms.
