1. Introduction
This proposal introduces a ring to the standard library operating on a span, named ring_span. The ring_span offers similar facilities to std::queue with the additional feature of storing the elements in contiguous memory and being of a fixed size. It is an update to P0059R1 to provide the addition of a concurrent ring span. The authors seek feedback on the design of the ring before submitting wording for the standard.

2. Motivation
Queues are widely used containers for collecting data prior to processing in order of entry to the queue (first in, first out). The std::queue container adaptor acts as a wrapper to an underlying container, typically std::deque or std::list. These containers are non-contiguous, which means that each item that is added to a std::queue may prompt an allocation, which will lead to memory fragmentation. The ring_span operates on elements in contiguous non-owned memory, so memory allocation is eliminated. The most common uses for the ring_span would be:
   ● Storing the last n events for later recovery
   ● Communicating between threads in an allocation-constrained environment
The latter use case requires a concurrent ring_span, so this paper proposes both a synchronous ring and a concurrent ring. Both of these use cases demand a single producer and a single consumer of elements.
3. Impact on the standard
This proposal is a pure library extension. It does not require changes to any standard classes, functions or headers.

4. Design decisions

Naming
In an earlier version of this paper the name ring_buffer was proposed, but given the new implementation the proposed name is ring_span. The name ring still remains the preferred choice of the authors.

Look like std::queue
There is already an object that offers FIFO support: the std::queue container. The queue grows to accommodate new entries, allocating new memory as necessary. The ring interface can therefore be similar to that of the queue with the addition of try_push, try_emplace and try_pop functions: these must now fail if they are called when the ring is full (or empty in the case of try_pop), and should therefore signal that condition by returning a success/fail value.

push_back and pop_front
Pushing items is a simple matter of assigning to a pre-existing element. The user can decide what to do on filling up the ring: for the synchronous ring it is possible to overwrite unpopped items, which would be desirable for the use case of storing the last n events for later recovery.

The concurrent implementation may not overwrite unpopped objects, since the consume thread may be popping while the push is happening. If the push were to overwrite an object while it was being popped, the object would be in an undefined state. Push must therefore not be called on a full concurrent_ring_span object.

Popping items is a more complicated matter than in other containers. If an item is popped from a std::queue it is destroyed and the memory is released. In the case of a ring_span however, it does not own the memory so a different strategy must be pursued. There are four things that could happen when an object is popped from a ring_span, besides the usual container housekeeping:

1. The object is destroyed via the class destructor and the memory is left in an undefined state.
2. The object is replaced with a default-constructed object.
3. The object is replaced with a copy of a user-specified object.
4. The object is not replaced at all.

This is a choice that will depend on the type being contained. For example, if the type is not default-constructible, option 2 is unavailable. If the type is not assignable, options 2 and 3 are unavailable. There is no single solution that covers all these situations, so as part of the definition of ring_span a number of pop strategy objects are defined. A strategy can be chosen at the point of declaration of an instance of a ring_span as a template parameter.
Although pop could theoretically safely be called on an empty ring with the implementation supplied below, it should yield undefined behaviour.

5. Header <ring_span> synopsis

This section contains the header declarations. Example definitions are also provided for clarity and to aid specification of the definitions.

```cpp
class ring_iterator;

template<typename T, class Popper = default_popper<T>>
class ring_span
{
public:
    using type = ring_span<T, Popper>;
    using size_type = std::size_t;
    using value_type = T;
    using pointer = T*;
    using reference = T&;
    using const_reference = const T&;
    using iterator = ring_iterator<type, false>;
    using const_iterator = ring_iterator<type, true>;

    friend class ring_iterator<type, false>;
    friend class ring_iterator<type, true>;

    template <class ContiguousIterator>
    ring_span(ContiguousIterator begin, ContiguousIterator end,
              Popper p = Popper()) noexcept;
```
template <class ContiguousIterator>
ring_span(ContiguousIterator begin, ContiguousIterator end,
         ContiguousIterator first, size_type size,
         Popper p = Popper()) noexcept;

    Ring* m_rv;
};
5.1. Function specifications: *popper

The **null_popper** object does nothing to the item being popped from the ring.

```cpp
template <typename T>
void null_popper::operator()(T&) {}
```

The **default_popper** object moves the item being popped from the ring into the return value.

```cpp
template <typename T>
T default_popper::operator()(T& t)
{
    return std::move(t);
}
```

The **copy_popper** object replaces the item being popped from the ring with a copy of an item of the contained type, chosen at the declaration site.

```cpp
template <typename T>
copy_popper::copy_popper(T&& t) :
    copy(std::move(t)) {}
```

```cpp
template <typename T>
T copy_popper::operator()(T& t)
{
    T old = t;
    t = copy;
    return t;
}
```

5.2 Function specifications: ring_span

The first constructor takes a range delimited by two contiguous iterators and an instance of a popper. After this constructor is executed, the capacity of the ring is the distance between the two iterators and the size of the ring is its capacity. A typical implementation would be

```cpp
template<typename T, class Popper>
template<class ContiguousIterator>
ring_span<T, Popper>::ring_span(ContiguousIterator begin,
                                ContiguousIterator end, Popper p) noexcept
    :
        m_data(&*begin),
        m_size(0),
        m_capacity(end - begin),
        m_front_idx(0),
        m_popper(std::move(p)) {}
```

The second constructor creates a partially full ring. It takes a range delimited by two contiguous iterators, a third iterator which points to the oldest item of the ring, a size
parameter which indicates how many items are in the ring, and an instance of a popper. After this constructor is executed, the capacity of the ring is the distance between the first two iterators and the size of the ring is the size parameter. A typical implementation would be:

```cpp
template<typename T, class Popper>
template<class ContiguousIterator>
ring_span<T, Popper>::ring_span(ContiguousIterator begin, ContiguousIterator end, ContiguousIterator first, size_type size, Popper p = Popper()) noexcept
  : m_data(&*begin),
    m_size(size),
    m_capacity(end - begin),
    m_front_idx(first - begin),
    m_popper(std::move(p))
{
}
```

empty(), full(), size() and capacity() behave as expected. Typical implementations would be:

```cpp
template<typename T, class Popper>
bool ring_span<T, Popper>::empty() const noexcept
{ return m_size == 0; }
```

```cpp
template<typename T, class Popper>
bool ring_span<T, Popper>::full() const noexcept
{ return m_size == m_capacity; }
```

```cpp
template<typename T, class Popper>
ring_span<T, Popper>::size_type ring_span<T, Popper>::size() const noexcept
{ return m_size; }
```

```cpp
template<typename T, class Popper>
ring_span<T, Popper>::size_type ring_span<T, Popper>::capacity() const noexcept
{ return m_capacity; }
```

front() and back() return the oldest and newest items in the ring. Typical implementations would be:

```cpp
template<typename T, class Popper>
ring_span<T, Popper>::reference ring_span<T, Popper>::front() noexcept
{ return *begin(); }
```

```cpp
template<typename T, class Popper>
ring_span<T, Popper>::reference ring_span<T, Popper>::back() noexcept
{ return *(--end()); }
```

```cpp
template<typename T, class Popper>
ring_span<T, Popper>::const_reference ring_span<T, Popper>::front() const noexcept
{ return *begin(); }
```

```cpp
template<typename T, class Popper>
```
ring_span<T, Popper>::const_reference ring_span<T, Popper>::back() const noexcept
{ return *(--end()); }

begin(), cbegin(), end() and cend() return iterators to the oldest and one-past-the-newest items. Typical implementations would be:

```cpp
template<typename T, class Popper>
ring_span<T, Popper>::iterator ring_span<T, Popper>::begin() noexcept
{ return iterator(m_front_idx, this); }

template<typename T, class Popper>
ring_span<T, Popper>::iterator ring_span<T, Popper>::end() noexcept
{ return iterator(size() + m_front_idx, this); }

template<typename T, class Popper>
ring_span<T, Popper>::const_iterator ring_span<T, Popper>::begin() const noexcept
{ return const_iterator(m_front_idx, this); }

template<typename T, class Popper>
ring_span<T, Popper>::const_iterator ring_span<T, Popper>::cbegin() const noexcept
{ return const_iterator(m_front_idx, this); }

template<typename T, class Popper>
ring_span<T, Popper>::const_iterator ring_span<T, Popper>::end() const noexcept
{ return const_iterator(size() + m_front_idx, this); }

template<typename T, class Popper>
ring_span<T, Popper>::const_iterator ring_span<T, Popper>::cend() const noexcept
{ return const_iterator(size() + m_front_idx, this); }
```

The push_back() functions add an item after the most recently added item. The emplace_back() function creates an item after the most recently added item. If the size of the ring equals the capacity of the ring, then the oldest item is replaced. Otherwise, the size of the ring is increased by one. Typical implementations would be:

```cpp
template<typename T, class Popper>
template<bool b=true, typename=std::enable_if_t<b &&
std::is_copy_assignable<T>::value>>
void ring_span<T, Popper>::push_back(const T& value)
noexcept(std::is_nothrow_copy_assignable<T>::value)
{
    m_data[back_idx()] = value;
    increase_size();
}
```

```cpp
template<typename T, class Popper>
template<bool b=true, typename=std::enable_if_t<b &&
std::is_move_assignable<T>::value>>
```
void ring_span<T, Popper>::push_back(T&& value)
    noexcept(std::is_nothrow_move_assignable<T>::value)
{
    m_data[back_idx()] = std::move(value);
    increase_size();
}

template<typename T, class Popper>
template<class... FromType>
void ring_span<T, Popper>::emplace_back(FromType&&... from_value)
    noexcept(std::is_nothrow_constructible<T, FromType...>::value &&
        std::is_nothrow_move_assignable<T>::value);
{
    m_data[back_idx()] = T(std::forward<FromType>(from_value)...);
    increase_size();
}

The pop_front() function checks the size of the ring, asserting if it is zero. If it is non-zero, it
passes a reference to the oldest item to the Popper for transformation, reduces the size and
advances the front of the ring. By returning the item from pop, we are able to contain smart
pointers. A typical implementation might be:

```cpp
template<typename T, class Popper>
auto ring_span<T, Popper>::pop_front()
{
    assert(m_size != 0);
    auto old_front_idx = m_front_idx;
    m_front_idx = (m_front_idx + 1) % m_capacity;
    --m_size;
    return m_popper(m_data[old_front_idx]);
}
```

The swap() function is trivial. A typical implementation might be:

```cpp
template<typename T, class Popper>
void ring_span<T, Popper>::swap(ring_span<T, Popper>& rhs)
    noexcept(std::__is_nothrow_swappable<Popper>::value)
{
    using std::swap;
    swap(m_data, rhs.m_data);
    swap(m_size, rhs.m_size);
    swap(m_capacity, rhs.m_capacity);
    swap(m_front_idx, rhs.m_front_idx);
    swap(m_popper, rhs.m_popper);
}
```

For the sake of clarity, the private implementation used to describe these functions is as
follows:
template<typename T, class Popper>
ring_span<T, Popper>::reference ring_span<T, Popper>::at(size_type i) noexcept
{ return m_data[i % m_capacity]; }

template<typename T, class Popper>
ring_span<T, Popper>::const_reference ring_span<T, Popper>::at(size_type i) const noexcept
{ return m_data[i % m_capacity]; }

template<typename T, class Popper>
ring_span<T, Popper>::size_type ring_span<T, Popper>::back_idx() const noexcept
{ return (m_front_idx + m_size) % m_capacity; }

template<typename T, class Popper>
void ring_span<T, Popper>::increase_size() noexcept
{ if (++m_size > m_capacity) { m_size = m_capacity; } }

5.3 Function specifications: concurrent_ring_span

The concurrent_ring_span functions are identical except for those detailed below. The constructors initialise an additional data member, m_back_idx.

template<typename T, class Popper>
template <class ContiguousIterator>
sg14::concurrent_ring_span<T, Popper>::concurrent_ring_span(ContiguousIterator begin,
ContiguousIterator end, Popper p) noexcept
: m_data(&*begin)
, m_size(0)
, m_capacity(end - begin)
, m_front_idx(0)
, m_back_idx(0)
, m_popper(std::move(p))
{}

template<typename T, class Popper>
template<class ContiguousIterator>
sg14::concurrent_ring_span<T, Popper>::concurrent_ring_span(ContiguousIterator begin,
ContiguousIterator end, ContiguousIterator first, size_type size, Popper
p = Popper()) noexcept
: m_data(&*begin)
, m_size(size)
, m_capacity(end - begin)
, m_front_idx(first - begin)
, m_back_idx(m_front_idx + size - 1)
The push member functions must not overwrite unpopped data, since another thread may be attempting to pop that data.

```cpp
template<typename T, class Popper>
void sg14::concurrent_ring_span<T, Popper>::try_push_back(const T& value) noexcept(std::is_nothrow_copy_assignable<T>::value)
{
    if (m_size.load(std::memory_order_acquire) < m_capacity)
    {
        m_data[m_back_idx] = value;
        m_size.fetch_add(1, std::memory_order_release);
        m_back_idx = (m_back_idx + 1) % m_capacity;
        return true;
    }
    return false;
}
```

```cpp
template<typename T, class Popper>
bool sg14::concurrent_ring_span<T, Popper>::try_push_back(T&& value) noexcept(std::is_nothrow_move_assignable<T>::value)
{
    if (m_size.load(std::memory_order_acquire) < m_capacity)
    {
        m_data[m_back_idx] = value;
        m_size.fetch_add(1, std::memory_order_release);
        m_back_idx = (m_back_idx + 1) % m_capacity;
        return true;
    }
    return false;
}
```

```cpp
template<typename T, class Popper>
template<class... FromType>
bool sg14::concurrent_ring_span<T, Popper>::try_emplace_back(FromType&&... from_value)
noexcept(std::is_nothrow_constructible<T, FromType...>::value &&
         std::is_nothrow_move_assignable<T>::value)
{
    if (m_size.load(std::memory_order_acquire) < m_capacity)
    {
        // Implementation...
    }
```
m_data[m_back_idx] = T(std::forward<FromType>(from_value)...);
    m_size.fetch_add(1, std::memory_order_release);
    m_back_idx = (m_back_idx + 1) % m_capacity;
    return true;
}  
return false;

}  

template<typename T, class Popper>
std::pair<bool, T> sg14::concurrent_ring_span<T, Popper>::try_pop_front()
{
    auto not_empty = m_size.load(std::memory_order_acquire) > 0;
    auto value = std::make_pair(not_empty, m_data[m_front_idx]);
    if (not_empty)
    {
        m_size.fetch_sub(1, std::memory_order_release);
        m_front_idx = (m_front_idx + 1) % m_capacity;
    }
    return value;
}

template<typename T, class Popper>
void sg14::concurrent_ring_span<T, Popper>::swap(sg14::concurrent_ring_span<T, Popper>& rhs)
noexcept//(std::is_nothrow_swappable<Popper>::value)
{
    using std::swap;
    swap(m_data, rhs.m_data);
    swap(m_size, rhs.m_size);
    swap(m_capacity, rhs.m_capacity);
    swap(m_front_idx, rhs.m_front_idx);
    swap(m_back_idx, rhs.m_back_idx);
    swap(m_popper, rhs.m_popper);
}

5.4 Function specifications: ring_iterator
The equality and comparison operators use the index of the iterator to compare their order in
the ring. The iterators must be constructed from the same ring. They are equivalent if they
point to the same item. operator< will return true if the item pointed to by the member is
newer than the item pointed to by the parameter. Typical implementations might be:

    template <typename Ring, bool is_const>
    template<bool C>
    bool ring_iterator<Ring, is_const>::operator==(const ring_iterator<Ring, C>& rhs) const noexcept
The dereferencing operator and the pre- and post- increment operators are trivial. Typical implementations might be:

```cpp
template <typename Ring, bool is_const>
ring_iterator<Ring, is_const>::reference ring_iterator<Ring, is_const>::operator*() const noexcept
{ return m_rv->at(m_idx); }
```

```cpp
template <typename Ring, bool is_const>
ring_iterator<Ring, is_const>& ring_iterator<Ring, is_const>::operator++() noexcept
{ ++m_idx; return *this; }
```

```cpp
template <typename Ring, bool is_const>
ring_iterator<Ring, is_const>& ring_iterator<Ring, is_const>::operator++(int) noexcept
{ auto r(*this); ++*this; return r; }
```

```cpp
template <typename Ring, bool is_const>
ring_iterator<Ring, is_const>& ring_iterator<Ring, is_const>::operator--() noexcept
{ ++m_idx; return *this; }
```

```cpp
template <typename Ring, bool is_const>
ring_iterator<Ring, is_const>& ring_iterator<Ring, is_const>::operator--(int) noexcept
{ auto r(*this); ++*this; return r; }
```

Non-member operator+= and operator-= are also trivial. Typical implementations might be:

```cpp
template <typename Ring, bool is_const>
ring_iterator<Ring, is_const>& operator+=(ring_iterator<Ring, is_const>& it, int i) noexcept
{ it.m_idx += i; return it; }
```

```cpp
template <typename Ring, bool is_const>
ring_iterator<Ring, is_const>& operator-=(ring_iterator<Ring, is_const>& it, int i) noexcept
For the sake of clarity, a private constructor might be implemented like this:

```cpp
template <typename Ring, bool is_const>
ring_iterator<Ring, is_const>::ring_iterator(size_type idx, Ring* rv)
    noexcept
    : m_idx(idx), m_rv(rv) {}  
```

The modulo capacity normalises the index, as required for ordering and equality functions:

```cpp
template <typename Ring, bool is_const>
ring_iterator<Ring, is_const>::size_type ring_iterator<Ring, is_const>::modulo_capacity(size_type idx)
    {
        return idx % m_rv->capacity();
    }
```

### 6. Sample use

```cpp
#include <ring_span>
#include <cassert>

using std::experimental::ring_span;

void ring_test()
{
    std::array<int, 5> A;
    std::array<int, 5> B;

    ring_span<int> Q(std::begin(A), std::end(A));

    Q.push_back(7);
    Q.push_back(3);
    assert(Q.size() == 2);
    assert(Q.front() == 7);
    Q.pop_front();
    assert(Q.size() == 1);
    Q.push_back(18);
    auto Q3 = std::move(Q);
    assert(Q3.front() == 3);
    assert(Q3.back() == 18);
    assert(Q3.size() == 2);

    sg14::ring_span<int> Q5(std::move(Q3));
    assert(Q5.front() == 3);
    assert(Q5.back() == 18);
    assert(Q5.size() == 2);
```
Q5.pop_front();
Q5.pop_front();
assert(Q5.empty());

sg14::ring_span<int> Q6(std::begin(B), std::end(B));
Q6.push_back(6);
Q6.push_back(7);
Q6.push_back(8);
Q6.push_back(9);
Q6.emplace_back(10);
Q6.swap(Q5);
assert(Q6.empty());
assert(Q5.size() == 5);
assert(Q5.front() == 6);
assert(Q5.back() == 10);

puts("Ring test completed.\n");
}

The most obvious use for the ring queue would be for communicating between threads:

void thread_communication_test()
{
    std::array<int, 5> A;
    sg14::concurrent_ring_span<int> buffer(std::begin(A), std::end(A));
    std::mutex m;
    std::condition_variable cv;

    puts("Enter some numbers; enter -1 to quit.\n");

    auto ci = std::async(std::launch::async, [&]() {
        int val = 0;
        do
        {
            std::cin >> val;
            { buffer.push_back(val);
            }
        } while (val != -1);
        });

    auto po = std::async(std::launch::async, [&]() {
        auto exit = false;
        do
```
if (!buffer.empty())
{
    auto res = buffer.pop_front();
    std::cout << res << std::endl;
    exit = (res == -1);
}
} while (!exit);
puts("Ring example completed.\n");
}

7. Future work
n3353 describes a proposal for a concurrent queue. The interface is quite different from ring. A concurrent ring could be adapted from the interface specified therein should n3353 be accepted into the standard.

The popper class templates are defined at an overly broad scope, rather than in the scope of the ring_span. However, no way of doing this is immediately apparent, beyond the obvious solution of creating a ring namespace and defining the poppers, the span, the iterator and the try_* functions inside it. Since this is somewhat counterintuitive in the context of the remainder of the standard library, the authors remain open to suggestions. If the popper class templates might have use in other container spans, then they could remain in the broader scope.

Requests have been made for a mechanism of notifying the consumer thread when an item has been pushed. This could be achieved by creating a pusher policy, analogous to the popper objects. If this is deemed valuable then this proposal can be modified accordingly.

Requests have been made for a multiple-producer/multiple-consumer ring. This carries with it a requirement for additional bookkeeping. Consider the case where three threads are writing consecutive elements and one thread is reading from the ring. Since there is no guarantee of which order the threads will complete their write, there needs to be an additional piece of data for each element to signal when it is available, typically a bool.

If the constructor is to remain a span of n elements, then only two solutions present themselves. Either the ring must allocate n flags to signify element readiness at construction, e.g. a vector<bool>, or the span must include these flags. In the latter case, the ring_span class template parameter for the contained type would have to be std::pair<T, bool> rather than simply T. If demand for such an object truly exists, named e.g. flagged_ring_span, then a separate proposal can be offered.

8. Acknowledgements
Thanks to Jonathan Wakely for sprucing up the first draft of the ring interface.
Thanks to the SG14 forum contributors: Nicolas Guillemot, John McFarlane, Scott Wardle, Chris Gascoyne, Matt Newport.
Thanks to the SG14 meeting contributors: Charles Beattie, Brittany Friedman, Billy Baker, Bob, Arthur O'Dwyer, Sean Middleditch, Ville Voutilainen.
Thanks to Michael McLaughlin for commentary on the draft of the text.
Thanks to Arthur O'Dwyer for unifying the interfaces of the original rings into a single span.
Thanks to Joe Best-Rotheray for offering a non-mutex solution to the two-thread model.
Thanks to Lawrence Crowl for pointing me to his paper on concurrent queues, n3353.
Special thanks also to Michael Wong for convening and shepherding SG14.
