Changelog

Changes from R0

- Changed the name of the type being proposed from `array_view` to `span` following feedback from LEWG at the Kona meeting.
- Removed multidimensional aspects from the proposal. `span` is now always single-dimension and contiguous.
- Added details on potential interoperation with the multidimensional `view` type from P0009 [5].
- Removed functions to convert from `span<byte>` to `span<T>` as they are not compatible with type aliasing rules.
- Added section containing proposed wording for inclusion in the standard.
- Simplified `span` interface based on reviewer feedback.

Changes from R1

- Added `difference_type` typedef to `span` to better support use in template functions.
- Removed `const_iterator begin const()` and `const_iterator end const()` members of `span` based on LEWG feedback. For a view type like `span`, the constness of the view is immaterial to the constness of the element type, the iterator interface of `span` now reflects that.
- Removed the deletion of constructors that take rvalue-references based on LEWG feedback.
- Added support for construction from `const Container&`.

Changes from R2

- Wording cleanup: removed `const` on non-member functions and inappropriate `noexcept` specifiers. Improved wording to be clear that the `reverse_iterator` is not contiguous. Removed `constexpr` from `as_bytes()` and `as_writeable_bytes()` as it would be illegal. Tidied up effects of `last()` overloads and of `array/std::array` constructors for cases when the array is empty.
- Added back `cbegin()` and `cend()` and `const_iterator` type based on LEWG feedback in Oulu.
- Improved colors.

Introduction

This paper presents a design for a fundamental vocabulary type `span`.

The `span` type is an abstraction that provides a view over a contiguous sequence of objects, the storage of which is owned by some other object. The design for `span` presented here provides bounds-safety guarantees through a combination of compile-time and (configurable) run-time constraints.

The design of the `span` type discussed in this paper is related to the `span` previously proposed in N3851 [1] and also draws on ideas in the `array_ref` and `string_ref` classes proposed in N3334 [2]. `span` is closely related to the generalized, multidimensional memory-access abstraction `array_ref` described in P0009 [5]. The `span` proposed here is sufficiently compatible with `array_ref` that interoperability between the two types would be simple and well-defined.
While `array_ref` is proposed by P0009 [5] as a generalized and highly configurable view type that can address needs for specialized domains such as scientific computing, `span` is proposed as a simple solution to the common need for a single-dimensional view over contiguous storage.

Motivation and Scope
The evolution of the standard library has demonstrated that it is possible to design and implement abstractions in Standard C++ that improve the reliability of C++ programs without sacrificing either performance or portability. This proposal identifies a new “vocabulary type” for inclusion in the standard library that enables both high performance and bounds-safe access to contiguous sequences of elements. This type would also improve modularity, composability, and reuse by decoupling accesses to array data from the specific container types used to store that data.

These characteristics lead to higher quality programs. Some of the bounds and type safety constraints of `span` directly support “correct-by-construction” programming methodology – where errors simply do not compile. One of the major advantages of `span` over the common idiom of a “pointer plus length” pair of parameters is that it provides clearer semantics hints to analysis tools looking to help detect and prevent defects early in a software development cycle.

Impact on the Standard
This proposal is a pure library extension. It does not require any changes to standard classes, functions, or headers. It would be enhanced if could depends on the `byte` type and changes to type aliasing behavior proposed in P0257 [6].

However – if adopted – it may be useful to overload some standard library functions for this new type (an example would be `copy()`).

`span` has been implemented in standard C++ (C++11) and is being successfully used within a commercial static analysis tool for C++ code as well as commercial office productivity software. An open source, reference implementation is available at [https://github.com/Microsoft/GSL](https://github.com/Microsoft/GSL) [3].

Design Decisions

View not container

`span` is simply a view over another object’s contiguous storage – but unlike `array` or `vector` it does not “own” the elements that are accessible through its interface. An important observation arises from this: `span` never performs any free store allocations.

While `span` is a view, it is not an iterator. You cannot perform increment or decrement operations on it, nor dereference it.

No configurable view properties

In the related `array_ref` type described in P0009 [5], properties are used to control policies such as memory layout (column-major, row-major) and location (on heterogenous memory architectures) for specific specializations of `array_ref`. `span` does not require properties as it is always a simple view over contiguous storage. Its memory layout and access characteristics are equivalent to those of a built-in
array. This difference should not prevent conversions between `array_ref` and `span` instances, it merely constrains that they could only be available in cases where `array_ref` properties are compatible with the characteristics of `span`.

**View length and measurement**

The general usage protocol of the `span` class template supports both static-size (fixed at compile time) and dynamic-size (provided at runtime) views. The `Extent` template parameter to `span` is used to provide the extent of the `span`.

```cpp
constexpr ptrdiff_t dynamic_extent = -1;
```

The default value for `Extent` is `dynamic_extent`: a unique value outside the normal range of lengths (0 to `PTRDIFF_MAX` inclusive) reserved to indicate that the length of the sequence is only known at runtime and must be stored within the `span`. A dynamic-size span is, conceptually, just a pointer and size field (this is not an implementation requirement, however).

```cpp
int* somePointer = new int[someLength];
// Declaring a dynamic-size span
// s will have a dynamic-size specified by someLength at construction
span<int> s = { somePointer, someLength };;
```

The type used for measuring and indexing into span is `ptrdiff_t`. Using a signed index type helps avoid common mistakes that come from implicit signed to unsigned integer conversions when users employ integer literals (which are nearly always signed). The use of `ptrdiff_t` is natural as it is the type used for pointer arithmetic and array indexing – two operations that `span` explicitly aims to replace but that an implementation of `span` would likely rely upon.

A fixed-size `span` provides a value for `Extent` that is between 0 and `PTRDIFF_MAX` (inclusive). A fixed-size `span` requires no storage size overhead beyond a single pointer – using the type system to carry the fixed-length information. This allows `span` to be an extremely efficient type to use for access to fixed-length buffers.

```cpp
int arr[10];
// deduction of size from arrays means that span size is always correct
span<int, 10> s2 = arr; // fixed-size span of 10 ints
span<int, 20> s3 = arr; // error: will fail compilation
span<int> s4 = arr; // dynamic-size span of 10 ints
```

**Value Type Semantics**

`span` is designed as a value type – it is expected to be cheap to construct, copy, move, and use. Users are encouraged to use it as a pass-by-value parameter type wherever they would have passed a pointer by value or a container type by reference, such as `array` or `vector`. 
Conceptually, *span* is simply a pointer to some storage and a count of the elements accessible via that pointer. Those two values within a span can only be set via construction or assignment (i.e. all member functions other than constructors and assignment operators are *const*). This property makes it easy for users to reason about the values of a span through the course of a function body.

These value type characteristics also help provide compiler implementations with considerable scope for optimizing the use of *span* within programs. For example, *span* has a trivial destructor, so common ABI conventions allow it to be passed in registers.

**Range-checking and bounds-safety**

All accesses to the data encapsulated by a span are conceptually range-checked to ensure they remain within the bounds of the *span*. What actually happens as the result of a failure to meet *span*’s bounds-safety constraints at runtime is undefined behavior. However, it should be considered effectively fatal to a program’s ability to continue reliable execution. This is a critical aspect of *span*’s design, and allows users to rely on the guarantee that as long as a sequence is accessed via a correctly initialized *span*, then its bounds cannot be overrun.

As an example, in the current reference implementation, violating a range-check results by default in a call to `terminate()` but can also be configured via build-time mechanisms to continue execution (albeit with undefined behavior from that point on).

Conversion between fixed-size and dynamic-size *span* objects is allowed, but with strict constraints that ensure bounds-safety is always preserved. At least two of these cases can be checked statically by leveraging the type system. In each case, the following rules assume the element types of the *span* objects are compatible for assignment.

1. A fixed-size *span* may be constructed or assigned from another fixed-size span of equal length.
2. A dynamic-size *span* may always be constructed or assigned from a fixed-size *span*.
3. A fixed-size *span* may always be constructed or assigned from a dynamic-size *span*. Undefined behavior will result if the construction or assignment is not bounds-safe. In the reference implementation, for example, this is achieved via a runtime check that results in `terminate()` on failure.

**Element types and conversions**

*span* must be configured with its element type via the template parameter `ValueType`, which is required to be a complete object type that is not an abstract class type. *span* supports either read-only or mutable access to the sequence it encapsulates. To access read-only data, the user can declare a `span<const T>`, and access to mutable data would use a `span<T>`.

Construction or assignment between *span* objects with different element types is allowed whenever it can be determined statically that the element types are exactly storage-size equivalent (so there is no difference in the extent of memory being accessed), and that the types can legally be aliased.

As a result of these rules, it is always possible to convert from a `span<T>` to a `span<const T>`. It is not allowed to convert in the opposite direction, from `span<const T>` to `span<T>`. This property is extremely convenient for calling functions that take *span* parameters.
Element access and iteration

span’s interface for accessing elements is largely similar to that of array. It overloads operator[] for element access, and offers random access iterators, making it adoptable with a minimum of source changes in code that previously used an array, an array object, or a pointer to access more than one object. span also overloads operator() for element access, to provide compatibility with code written to operate against view.

span provides random-access iterators over its data, comparable to vector and array. All accesses to elements made through these iterators are range-checked (subject to configuration as previously described), just as if they had been performed via the subscript operator on span. There is no difference in the mutability of the iterators returned from a const or non-const span as the constness of the element type is already determined when the span is created. As is appropriate for a view, whether the span itself is const does not affect the element type, and this is reflected in the simplicity of the iterator model.

```cpp
// [span.elem], span element access
constexpr reference operator[](index_type idx) const;
constexpr reference operator()(index_type idx) const;
constexpr pointer data() const noexcept;

// [span.iter], span iterator support
iterator begin() const noexcept;
iterator end() const noexcept;
const_iterator cbegin() const noexcept;
const_iterator cend() const noexcept;

reverse_iterator rbegin() const noexcept;
reverse_iterator rend() const noexcept;
const_reverse_iterator crbegin() const noexcept;
const_reverse_iterator crend() const noexcept;
```

Construction

The span class is expected to become a frequently used vocabulary type in function interfaces (as a safer replacement of “(pointer, length)” idioms), as it specifies a minimal set of requirements for safely accessing a sequence of objects and decouples a function that needs to access a sequence from the details of the storage that holds such elements.

To simplify use of span as a simple parameter, span offers a number of constructors for common container types that store contiguous sequences of elements. A summarized extract from the specification illustrates this:

```cpp
// [span.cons], span constructors, copy, assignment, and destructor
constexpr span();
constexpr span(nullptr_t);
constexpr span(pointer ptr, index_type count);
constexpr span(pointer firstElem, pointer lastElem);
template <size_t N>
constexpr span(element_type (&arr)[N]);
template <size_t N>
  constexpr span(array<remove_const_t<element_type>, N>& arr);
template <size_t N>
  constexpr span(const array<remove_const_t<element_type>, N>& arr);
template <class Container>
  constexpr span(Container& cont);
template <class Container>
  constexpr span(const Container& cont);
constexpr span(const span& other) noexcept = default;
constexpr span(span&& other) noexcept = default;
template <class OtherElementType, ptrdiff_t OtherExtent>
  constexpr span(const span<OtherElementType, OtherExtent>& other);
template <class OtherElementType, ptrdiff_t OtherExtent>
  constexpr span(span<OtherElementType, OtherExtent>&& other);

It is allowed to construct a span from the null pointer, and this creates an object with .size() == 0. Any attempt to construct a span with a null pointer value and a non-zero length is considered a range-check error.

**Byte representations and conversions**

`span` depends upon a distinct “byte” type that represents a single addressable byte on any system, for object representation – in preference to common practice of using character types for this purpose. Such a type is defined in the standard library as:

```cpp
enum class byte : unsigned char {};
```

For more details on the proposed byte type please refer to P0257 [6].

A span of any element type that is a standard-layout type can be converted to a span<const byte> or a span<byte> via the free functions `as_bytes()` and `as_writeable_bytes()` respectively. These operations are considered useful for systems programming where byte-oriented access for serialization and data transmission is essential.

```cpp
// [span.objectrep], views of object representation
template <class ElementType, ptrdiff_t Extent>
  span<const byte, ((Extent == dynamic_extent) ? dynamic_extent :
  (sizeof(ElementType) * Extent))> as_bytes(span<ElementType, Extent> s) noexcept;

template <class ElementType, ptrdiff_t Extent>
  span<byte, ((Extent == dynamic_extent) ? dynamic_extent :
  (sizeof(ElementType) * Extent))> as_writeable_bytes(span<ElementType, Extent> ) noexcept;
```

These byte-representation conversions still preserve const-correctness, however. It is not possible to convert from a `span<const T>` be converted to a `span<byte>` (through SFINAE overload restriction).
Comparisons

`span` supports all the same comparison operations as a sequential standard library container: element-wise comparison and a total ordering by lexicographical comparison. This helps make it an effective replacement for existing uses of sequential contiguous container types like `array` or `vector`.

```cpp
// [span.comparison], span comparison operators
template <class ElementType, ptrdiff_t Extent>
  constexpr bool operator==(const span<ElementType, Extent>& l, const span<ElementType, Extent>& r);

template <class ElementType, ptrdiff_t Extent>
  constexpr bool operator!=(const span<ElementType, Extent>& l, const span<ElementType, Extent>& r);

template <class ElementType, ptrdiff_t Extent>
  constexpr bool operator<(const span<ElementType, Extent>& l, const span<ElementType, Extent>& r);

template <class ElementType, ptrdiff_t Extent>
  constexpr bool operator<=(const span<ElementType, Extent>& l, const span<ElementType, Extent>& r);

template <class ElementType, ptrdiff_t Extent>
  constexpr bool operator>(const span<ElementType, Extent>& l, const span<ElementType, Extent>& r);

template <class ElementType, ptrdiff_t Extent>
  constexpr bool operator>=(const span<ElementType, Extent>& l, const span<ElementType, Extent>& r);
```

Regardless of whether they contain a valid pointer or null pointer, zero-length `spans` are all considered equal. This is considered a useful property when writing library code. If users wish to distinguish between a zero-length `span` with a valid pointer value and a `span` containing the null pointer, then they can do so by calling the `data()` member function and examining the pointer value directly.

Creating sub-spans

`span` offers convenient member functions for generating a new `span` that is a reduced view over its sequence. In each case, the newly constructed `span` is returned by value from the member function. As the design requires bounds-safety, these member functions are guaranteed to either succeed and return a valid `span`, or fail with undefined behavior (e.g. calling `terminate()`) if the parameters were not within range.

```cpp
// [span.sub], span subviews
constexpr span<element_type, dynamic_extent> first(index_type count) const;
constexpr span<element_type, dynamic_extent> last(index_type count) const;
constexpr span<element_type, dynamic_extent> subspan(index_type offset, index_type count = dynamic_extent) const;
```

`first()` returns a new `span` that is limited to the first N elements of the original sequence. Conversely, `last()` returns a new `span` that is limited to the last N elements of the original sequence. `subspan()` allows an arbitrary sub-range within the sequence to be selected and returned as a new `span`. 
All three member functions are overloaded in forms that accept their parameters as template parameters, rather than function parameters. These overloads are helpful for creating fixed-size span objects from an original input span, whether fixed- or dynamic-size.

```cpp
template <ptrdiff_t Count>
external constexpr span<element_type, Count> first() const;
template <ptrdiff_t Count>
external constexpr span<element_type, Count> last() const;
template <ptrdiff_t Offset, ptrdiff_t Count = dynamic_extent>
external constexpr span<element_type, Count> subspan() const;
```

Multidimensional span

span as presented here only supports a single-dimension view of a sequence. This covers the most common usage of contiguous sequences in C++. span has convenience (such as iterators, first(), last(), and subspan()) and default behaviors that make most sense in a single-dimension.

Adding support for multidimensional and noncontiguous (strided) views of data is deferred to a separate type not described here. One such candidate would be the more general array_ref facility described in P0009 [5]. The interface of span is sufficiently compatible with that of array_ref, that users should not feel any significant discontinuity between the two. In fact, it is entirely possible to implement a span using array_ref.

Proposed Wording Changes

The following proposed wording changes against the working draft of the standard are relative to N4567 [7]. If byte type would be available in the working draft, as proposed in P0257 [6] then the functions in section [span.objectrep] would use “byte” for the placeholder byte.

17.6.1.2 Headers [headers]

2 The C++ standard library provides 5354 C++ library headers, as shown in Table 14.

| <algorithm> | <fstream> | <list> | <regex> | <thread> |
| <array> | <functional> | <locale> | <scoped_allocator> | <tuple> |
| <atomic> | <future> | <map> | <set> | <type_traits> |
| <bitset> | <initializer_list> | <memory> | <span> | <type_index> |
| <chrono> | <iomanip> | <mutex> | <sstream> | <typeinfo> |
| <codecvt> | <ios> | <new> | <stream> | <unordered_map> |
| <complex> | <iosfwd> | <numeric> | <streambuf> | <unordered_set> |
| <condition_variable> | <iostream> | <ostream> | <streambuf> | <utility> |
| <deque> | <ostream> | <queue> | <string> | <valarray> |
| <exception> | <sstream> | <random> | <stringstream> | <vector> |
| <forward_list> | <streambuf> | <ratio> | <system_error> | |

23 Containers library [containers]

23.1 General [containers.general]
2 The following subclauses describe container requirements, and components for sequence containers, associative containers, and views as summarized in Table 94.

Table 94 – Containers library summary

23.7 Views [views]

23.7.1 General [views.general]

1 The header `<span>` defines the view span. A span is a view over a contiguous sequence of objects, the storage of which is owned by some other object.

Header `<span>` synopsis

```cpp
namespace std {

  // [views.constants], constants
  constexpr ptrdiff_t dynamic_extent = -1;

  // [span], class template span
  template <class ElementType, ptrdiff_t Extent = dynamic_extent>
  class span;

  // [span.comparison], span comparison operators
  template <class ElementType, ptrdiff_t Extent>
    constexpr bool operator==(const span<ElementType, Extent>& l, const span<ElementType, Extent>& r);

  template <class ElementType, ptrdiff_t Extent>
    constexpr bool operator!=(const span<ElementType, Extent>& l, const span<ElementType, Extent>& r);

  template <class ElementType, ptrdiff_t Extent>
    constexpr bool operator<(const span<ElementType, Extent>& l, const span<ElementType, Extent>& r);
```

23.7.2 Class template `span` [views.span]

1 A `span` is a view over a contiguous sequence of objects, the storage of which is owned by some other object.

2 `ElementType` is required to be a complete object type that is not an abstract class type.

3 The `iterator` type for `span` is a random access iterator and contiguous iterator. The `reverse_iterator` type is a random access iterator.
constexpr span() noexcept;
constexpr span(nullptr_t) noexcept;
constexpr span(pointer ptr, index_type count);
constexpr span(pointer firstElem, pointer lastElem);
template <size_t N>
  constexpr span(element_type (&arr)[N]);
template <size_t N>
  constexpr span(array<remove_const_t<element_type>, N>& arr);
template <size_t N>
  constexpr span(const array<remove_const_t<element_type>, N>& arr);
template <class Container>
  constexpr span(Container& cont);
template <class Container>
  span(const Container&);
constexpr span(const span& other) noexcept = default;
constexpr span(span&& other) noexcept = default;
template <class OtherElementType, ptrdiff_t OtherExtent>
  constexpr span(const span<OtherElementType, OtherExtent>& other);
template <class OtherElementType, ptrdiff_t OtherExtent>
  constexpr span(span<OtherElementType, OtherExtent>&& other);
~span() noexcept = default;
constexpr span& operator=(const span& other) noexcept = default;
constexpr span& operator=(span&& other) noexcept = default;

// [span.sub], span subviews
template <ptrdiff_t Count>
  constexpr span<element_type, Count> first() const;
template <ptrdiff_t Count>
  constexpr span<element_type, Count> last() const;

// [span.obs], span observers
constexpr index_type length() const noexcept;
constexpr index_type size() const noexcept;
constexpr index_type length_bytes() const noexcept;
constexpr index_type size_bytes() const noexcept;
constexpr bool empty() const noexcept;

// [span.elem], span element access
constexpr reference operator[](index_type idx) const;
constexpr reference operator() (index_type idx) const;
constexpr pointer data() const noexcept;

// [span.iter], span iterator support
iterator begin() const noexcept;
iterator end() const noexcept;
const_iterator cbegin() const noexcept;
const_iterator cend() const noexcept;

reverse_iterator rbegin() const noexcept;
reverse_iterator rend() const noexcept;

const_reverse_iterator crbegin() const noexcept;
const_reverse_iterator crend() const noexcept;

private:
pointer data_;     // exposition only
index_type size_;  // exposition only

};

// [span.comparison], span comparison operators
template <class ElementType, ptrdiff_t Extent>
constexpr bool operator==(const span<ElementType, Extent>& l, const span<ElementType, Extent>& r);

template <class ElementType, ptrdiff_t Extent>
constexpr bool operator!=(const span<ElementType, Extent>& l, const span<ElementType, Extent>& r);

template <class ElementType, ptrdiff_t Extent>
constexpr bool operator<(const span<ElementType, Extent>& l, const span<ElementType, Extent>& r);

template <class ElementType, ptrdiff_t Extent>
constexpr bool operator<=(const span<ElementType, Extent>& l, const span<ElementType, Extent>& r);

template <class ElementType, ptrdiff_t Extent>
constexpr bool operator>(const span<ElementType, Extent>& l, const span<ElementType, Extent>& r);

template <class ElementType, ptrdiff_t Extent>
constexpr bool operator>=(const span<ElementType, Extent>& l, const span<ElementType, Extent>& r);

// [span.objectrep], views of object representation
template <class ElementType, ptrdiff_t Extent>
constexpr span<const byte, ((Extent == dynamic_extent) ? dynamic_extent : (sizeof(ElementType) * Extent))> as_bytes(span<ElementType, Extent>& s);

template <class ElementType, ptrdiff_t Extent>
constexpr span<byte, ((Extent == dynamic_extent) ? dynamic_extent : (sizeof(ElementType) * Extent))> as_writeable_bytes(span<ElementType, Extent>& s);

} // namespace std

23.7.2.1 span constructors, copy, assignment, and destructor [span.cons]

constexpr span() noexcept;
constexpr span(nullptr_t) noexcept;

Remarks: if extent != dynamic_extent && extent != 0 then the program is ill-formed.

Effects: Constructs an empty span.

Postconditions: size() == 0 && data() == nullptr

Complexity: Constant.

castexpr span(pointer ptr, index_type count);

Requires: When ptr is null pointer then count shall be 0. When ptr is not null pointer, then it shall point to the beginning of a valid sequence of objects of at least count length. count shall always be >= 0. If extent is not dynamic_extent, then count shall be equal to extent.

Effects: Constructs a span that is a view over the sequence of objects pointed to by ptr. If ptr is null pointer or count is 0 then an empty span is constructed.

Postconditions: size() == count && data() == ptr

Complexity: Constant.

Throws: Nothing

castexpr span(pointer firstElem, pointer lastElem);

Requires: distance(firstElem, lastElem) >= 0. If extent is not equal to dynamic_extent, then distance(firstElem, lastElem) shall be equal to extent.

Effects: Constructs a span that is a view over the range [firstElem, lastElem). If distance(firstElem, lastElem) then an empty span is constructed.

Postconditions: size() == distance(firstElem, lastElem) && data() == firstElem

Complexity: Constant.

Throws: Nothing

template <size_t N>
castexpr span(element_type (&arr)[N]) noexcept;
template <size_t N>
castexpr span(array<element_type, N>& arr);
template <size_t N>
castexpr span(array<remove_const_t<element_type>, N>& arr);
constexpr span<const array<remove_const_t<element_type>, N>& arr>;

**Remarks:** If `extent != dynamic_extent` && `N != extent`, then the program is ill-formed.

The third constructor shall not participate in overload resolution unless `is_const<element_type>::value` is true.

**Effects:** Constructs a `span` that is a view over the supplied array.

**Postconditions:** `size() == N` && `data() == addressof(arr[0])`

**Complexity:** Constant

**Throws:** Nothing

template <class Container>
constexpr span(Container& cont);
template <class Container>
constexpr span(const Container& cont);

**Remarks:** The constructor shall not participate in overload resolution unless:

- `Container` meets the requirements of both a contiguous container (defined in 23.2.1/13) and a sequence container (defined in 23.2.3).
- `Container` implements the optional sequence container requirement of `operator[]` (defined in Table 100).
- `Container::value_type` is the same as `remove_const_t<element_type>`.

The constructor shall not participate in overload resolution if `Container` is a `span` or `array`.

The second constructor shall not participate in overload resolution unless `is_const<element_type>` == true.

**Requires:** If `extent` is not equal to `dynamic_extent`, then `cont.size()` shall be equal to `extent`.

**Effects:** Constructs a `span` that is a view over the sequence owned by `cont`.

**Postconditions:** `size() == cont.size()` && `data() == addressof(cont[0])`

**Complexity:** Constant.

**Throws:** Nothing

constexpr span(const span& other) noexcept = default;
constexpr span(span&& other) noexcept = default;

**Effects:** Constructs a `span` by copying the implementation data members of another `span`.
Postconditions: \( \text{other.size() == size()} \) \&\& \( \text{other.data() == data()} \)

**Complexity:** Constant.

```cpp
template <class OtherElementType, ptrdiff_t OtherExtent>
    constexpr span(const span<OtherElementType, OtherExtent>& other);
```

```cpp
template <class OtherElementType, ptrdiff_t OtherExtent>
    constexpr span(span<OtherElementType, OtherExtent>&& other);
```

**Remarks:** These constructors shall not participate in overload resolution unless trying to access `OtherElementType` through an `ElementType*` would meet the rules for well-defined object access defined in 3.10/10.

**Requires:** If `extent` is not equal to `dynamic_extent`, then `other.size()` shall be equal to `extent`.

**Effects:** Constructs a `span` by copying the implementation data members of another `span`, performing suitable conversions.

**Postconditions:**

\[
\text{size()} == \text{other.size()} \&\& \\
\text{data()} == \text{reinterpret_cast<pointer>}(\text{other.data()})
\]

**Complexity:** Constant.

**Throws:** Nothing

```cpp
span& operator=(const span& other) noexcept = default;
span& operator=(span&& other) noexcept = default;
```

**Effects:** Assigns the implementation data of one `span` into another.

**Postconditions:**

\[
\text{size()} == \text{other.size()} \&\& \text{data()} == \text{other.data()}
\]

**Complexity:** Constant.

### 23.7.2.2 span subviews [span.sub]

```cpp
template <ptrdiff_t Count>
    constexpr span<element_type, Count> first() const;
```

**Requires:** `Count \geq 0` \&\& `Count \leq \text{size()}`

**Effects:** Returns a new `span` that is a view over the initial `Count` elements of the current `span`.

**Returns:** `span(data(), Count)`
template <ptrdiff_t Count>
constexpr span<element_type, Count> last() const;

Requires: Count >= 0 && Count <= size()

Effects: Returns a new span that is a view over the final Count elements of the current span.

Returns: span(data() + (size() – Count), Count)

Complexity: Constant.

template <ptrdiff_t Offset, ptrdiff_t Count = dynamic_extent>
constexpr span<element_type, Count> subspan() const;

Requires: (Offset == 0 || Offset > 0 && Offset < size()) && (Count == dynamic_extent || Count >= 0 && Offset + Count <= size())

Effects: Returns a new span that is a view over Count elements of the current span starting at element Offset. If Count is equal to dynamic_extent, then a span over all elements from Offset onwards is returned.

Returns: span(data() + Offset, Count == dynamic_extent ? size() – Offset : Count)

Complexity: Constant

constexpr span<element_type, dynamic_extent> first(index_type count) const;

Requires: count >= 0 && count <= size()

Effects: Returns a new span that is a view over the initial count elements of the current span.

Returns: span(data(), count);

Complexity: Constant.

constexpr span<element_type, dynamic_extent> last(index_type count) const;

Requires: count >= 0 && count <= size()
**Effects:** Returns a new `span` that is a view over the final `count` elements of the current `span`.

**Returns:** `span(data() + (size() – count), count)`

**Complexity:** Constant.

```cpp
constexpr span<element_type, dynamic_extent> subspan(index_type offset, index_type count = dynamic_extent) const;
```

**Requires:** `(offset == 0 || offset > 0 && offset < size()) && (count == dynamic_extent || count >= 0 && offset + count <= size())`

**Effects:** Returns a new `span` that is a view over `Count` elements of the current `span` starting at element `offset`. If `count` is equal to `dynamic_extent`, then a `span` over all elements from `offset` onwards is returned.

**Returns:** `span(data() + offset, count == dynamic_extent ? size() – offset : count)`

**Complexity:** Constant

### 23.7.2.2 span observers [span.obs]

```cpp
constexpr index_type length() const noexcept;
```

**Effects:** Equivalent to: `return size();`

```cpp
constexpr index_type size() const noexcept;
```

**Effects:** Returns the number of elements accessible through the `span`.

**Returns:** `>= 0`

**Complexity:** Constant

```cpp
constexpr index_type length_bytes() const noexcept;
```

**Effects:** Equivalent to: `return size_bytes();`

```cpp
constexpr index_type size_bytes() const noexcept;
```

**Effects:** Returns the number of bytes used for the object representation of all elements accessible through the `span`. 
Returns: \(\text{size() \times sizeof(element\_type)}\)

Complexity: Constant

```cpp
compexpr bool empty() const noexcept;
```

Effects: Equivalent to: \(\text{size() == 0}\);

Returns: \(\text{size() == 0}\)

Complexity: Constant

### 23.7.2.3 span element access [span.elem]

```cpp
compexpr reference operator[](index\_type idx) const;
compexpr reference operator()(index\_type idx) const;
```

Requires: \(\text{idx} \geq 0 \&\& \text{idx} < \text{size()}\)

Effects: Returns a reference to the element at position \(\text{idx}\).

Returns: \(\ast(\text{data()} + \text{idx})\)

Complexity: Constant

```cpp
compexpr pointer data() const noexcept;
```

Effects: Returns either a pointer to the first element in the sequence accessible via the \text{span} or the null pointer if that was the value used to construct the \text{span}.

Returns: (for exposition) \text{data_}

Complexity: Constant

### 23.7.2.4 span iterator support [span.iterators]

```cpp
iterator begin() const noexcept;
```

Returns: An iterator referring to the first element in the \text{span}.

Complexity: Constant

```cpp
iterator end() const noexcept;
```
**Returns:** An iterator which is the past-the-end value.

**Complexity:** Constant

```cpp
reverse_iterator rbegin() const noexcept;
```

**Returns:** Equivalent to `reverse_iterator(end())`.

**Complexity:** Constant

```cpp
reverse_iterator rend() const noexcept;
```

**Returns:** Equivalent to: `return reverse_iterator(begin())`.

**Complexity:** Constant

### 23.7.2.5 span comparison operators [span.comparison]

```cpp
template <class ElementType, ptrdiff_t Extent>
    constexpr bool operator==(const span<ElementType, Extent>& l, const
    span<ElementType, Extent>& r);
```

**Effects:** Equivalent to: `return equal(l.begin(), l.end(), r.begin(), r.end());`

```cpp
template <class ElementType, ptrdiff_t Extent>
    constexpr bool operator!=(const span<ElementType, Extent>& l, const
    span<ElementType, Extent>& r);
```

**Effects:** Equivalent to: `return !(l == r);`

```cpp
template <class ElementType, ptrdiff_t Extent>
    constexpr bool operator<(const span<ElementType, Extent>& l, const
    span<ElementType, Extent>& r);
```

**Effects:** Equivalent to: `return lexicographical_compare(l.begin(), l.end(), r.begin(), r.end());`
constexpr bool operator<=(const span<ElementType, Extent>& l, const span<ElementType, Extent>& r);

Effects: Equivalent to: return !(l > r);

template <class ElementType, ptrdiff_t Extent>
constexpr bool operator>=(const span<ElementType, Extent>& l, const span<ElementType, Extent>& r);

Effects: Equivalent to: return !(l < r);

23.7.2.6 views of object representation [span.objectrep]

template <class ElementType, ptrdiff_t Extent>
span<const byte, ((Extent == dynamic_extent) ? dynamic_extent : (sizeof(ElementType) * Extent))> as_bytes(span<ElementType, Extent> s) noexcept;

Effects: Constructs a span over the object representation of the elements in s.

Returns: { reinterpret_cast<const byte*>(s.data()), sizeof(ElementType) * s.size() }

template <class ElementType, ptrdiff_t Extent>
span<byte, ((Extent == dynamic_extent) ? dynamic_extent : (sizeof(ElementType) * Extent))> as_writeable_bytes(span<ElementType, Extent>) noexcept;

Remarks: This function will not participate in overload resolution when is_const<ElementType>::value is true.

Effects: Constructs a span over the object representation of the elements in s.

Returns: { reinterpret_cast<byte*>(s.data()), sizeof(ElementType) * s.size() }
Acknowledgements

This work has been heavily informed by N3851 (an array_view proposal) and previous discussion amongst committee members regarding that proposal. Gabriel Dos Reis, Titus Winters and Stephan T. Lavavej provided valuable feedback on this document. Thanks to Casey Carter and Daniel Krügler for detailed feedback on the wording.

This version of span was designed to support the C++ Core Coding Guidelines [4] and as such, the current version reflects the input of Herb Sutter, Jim Springfield, Gabriel Dos Reis, Chris Hawblitzel, Gor Nishanov, and Dave Sielaff. Łukasz Mendakiewicz, Bjarne Stroustrup, Eric Niebler, and Artur Laksberg provided helpful review of this version of span during its development.

The authors of P0009 were invaluable in discussing how span and array_ref can be compatible and by doing so support a programming model that is safe and consistent as users move between a single dimension and multiple dimensions.
