Working Draft, Standard for Programming Language C++

Note: this is an early draft. It’s known to be incomplet and incorrekt, and it has lots of bad formatting.

### 4 General principles
- 4.1 Implementation compliance
- 4.2 Structure of this document
- 4.3 Syntax notation
- 4.4 The C++ memory model
- 4.5 The C++ object model
- 4.6 Program execution
- 4.7 Multi-threaded executions and data races
- 4.8 Acknowledgments

### 5 Lexical conventions
- 5.1 Separate translation
- 5.2 Phases of translation
- 5.3 Character sets
- 5.4 Preprocessing tokens
- 5.5 Alternative tokens
- 5.6 Tokens
- 5.7 Comments
- 5.8 Header names
- 5.9 Preprocessing numbers
- 5.10 Identifiers
- 5.11 Keywords
- 5.12 Operators and punctuators
- 5.13 Literals

## 27 Iterators library
- 27.1 General
- 27.2 Iterator requirements
- 27.3 Header `<iterator>` synopsis
- 27.4 Iterator primitives
- 27.5 Iterator adaptors
- 27.6 Stream iterators
- 27.7 Range access
- 27.8 Container access

## 28 Algorithms library
- 28.1 General
- 28.2 Header `<algorithm>` synopsis
- 28.3 Algorithms requirements
- 28.4 Parallel algorithms
- 28.5 Non-modifying sequence operations
- 28.6 Mutating sequence operations
- 28.7 Sorting and related operations
- 28.8 C library algorithms

## 29 Numerics library
- 29.1 General
- 29.2 Definitions
- 29.3 Numeric type requirements
- 29.4 The floating-point environment
- 29.5 Complex numbers
- 29.6 Random number generation
- 29.7 Numeric arrays
- 29.8 Generalized numeric operations
- 29.9 Mathematical functions for floating-point types

## 30 Input/output library
- 30.1 General
- 30.2 Iostreams requirements
- 30.3 Forward declarations
- 30.4 Standard iostream objects
- 30.5 Iostreams base classes
- 30.6 Stream buffers
- 30.7 Formatting and manipulators
- 30.8 String-based streams
- 30.9 File-based streams
- 30.10 File systems
- 30.11 C library files

## 31 Regular expressions library
- 31.1 General
- 31.2 Definitions
- 31.3 Requirements
- 31.4 Header `<regex>` synopsis
- 31.5 Namespace `std::regex_constants`
- 31.6 Class `regex_error`
31.7 Class template `regex_traits`  ................................................................. 1310
31.8 Class template `basic_regex` ................................................................. 1312
31.9 Class template `sub_match` ................................................................. 1318
31.10 Class template `match_results` ......................................................... 1323

1 Scope

This document specifies requirements for implementations of the C++ programming language. The first such requirement is that they implement the language, so this document also defines C++. Other requirements and relaxations of the first requirement appear at various places within this document.

C++ is a general purpose programming language based on the C programming language as described in ISO/IEC 9899:2011 Programming languages — C (hereinafter referred to as the C standard). In addition to the facilities provided by C, C++ provides additional data types, classes, templates, exceptions, namespaces, operator overloading, function name overloading, references, free store management operators, and additional library facilities.
2 Normative references

The following documents are referred to in the text in such a way that some or all of their content constitutes requirements of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

(1.2) — ISO/IEC 2382 (all parts), *Information technology — Vocabulary*
(1.3) — ISO/IEC 9899:2011, *Programming languages — C*
(1.4) — ISO/IEC 9899:2011/Cor.1:2012(E), *Programming languages — C, Technical Corrigendum 1*
(1.5) — ISO/IEC 9945:2003, *Information Technology — Portable Operating System Interface (POSIX)*
(1.7) — ISO/IEC 10967-1:2012, *Information technology — Language independent arithmetic — Part 1: Integer and floating point arithmetic*
(1.9) — ISO 80000-2:2009, *Quantities and units — Part 2: Mathematical signs and symbols to be used in the natural sciences and technology*

The library described in Clause 7 of ISO/IEC 9899:2011 is hereinafter called the *C standard library.*

The operating system interface described in ISO/IEC 9945:2003 is hereinafter called *POSIX.*

The ECMAScript Language Specification described in Standard Ecma-262 is hereinafter called *ECMA-262.*

The arithmetic specification described in ISO/IEC 10967-1:2012 is hereinafter called *LIA-1.*

---

1) With the qualifications noted in Clauses 21 through 33 and in C.5, the C standard library is a subset of the C++ standard library.
3 Terms and definitions

For the purposes of this document, the terms and definitions given in ISO/IEC 2382-1:1993, the terms, definitions, and symbols given in ISO 80000-2:2009, and the following apply.

ISO and IEC maintain terminological databases for use in standardization at the following addresses:

— ISO Online browsing platform: available at http://www.iso.org/obp

20.3 defines additional terms that are used only in Clauses 20 through 33 and Annex D.

Terms that are used only in a small portion of this document are defined where they are used and italicized where they are defined.

3.1 [defns.access]
access
 execution-time action to read or modify the value of an object

3.2 [defns.argument]
argument
 (function call expression) expression in the comma-separated list bounded by the parentheses (8.2.2)

3.3 [defns.argument.macro]
argument
 (function-like macro) sequence of preprocessing tokens in the comma-separated list bounded by the parentheses (19.3)

3.4 [defns.argument.throw]
argument
 (throw expression) the operand of throw (8.17)

3.5 [defns.argument.templ]
argument
 (template instantiation) constant-expression, type-id, or id-expression in the comma-separated list bounded by the angle brackets (17.3)

3.6 [defns.block]
block
 a thread of execution that blocks is waiting for some condition (other than for the implementation to execute its execution steps) to be satisfied before it can continue execution past the blocking operation

3.7 [defns.cond.supp]
conditionally-supported
 program construct that an implementation is not required to support
 [Note: Each implementation documents all conditionally-supported constructs that it does not support. — end note]

3.8 [defns.diagnostic]
diagnostic message
 message belonging to an implementation-defined subset of the implementation’s output messages
3.9 dynamic type
(type of the most derived object (4.5) to which the glvalue refers)

Example: If a pointer (11.3.1) p whose static type is “pointer to class B” is pointing to an object of class D, derived from B (Clause 13), the dynamic type of the expression *p is “D”. References (11.3.2) are treated similarly. —end example

3.10 dynamic type<br/prvalue>
(static type of the prvalue expression)

3.11 ill-formed program
(program that is not well-formed (3.29))

3.12 implementation-defined behavior
behavior, for a well-formed program construct and correct data, that depends on the implementation and that each implementation documents

3.13 implementation limits
restrictions imposed upon programs by the implementation

3.14 locale-specific behavior
behavior that depends on local conventions of nationality, culture, and language that each implementation documents

3.15 multibyte character
sequence of one or more bytes representing a member of the extended character set of either the source or the execution environment

Note: The extended character set is a superset of the basic character set (5.3). —end note

3.16 parameter
(object or reference declared as part of a function declaration or definition or in the catch clause of an exception handler that acquires a value on entry to the function or handler)

3.17 parameter
(identifier from the comma-separated list bounded by the parentheses immediately following the macro name)

3.18 parameter
(member of a template-parameter-list)

3.19 signature
(name, parameter type list (11.3.5), and enclosing namespace (if any)

Note: Signatures are used as a basis for name mangling and linking. —end note

§ 3.19
3.20  signature
⟨function template⟩ name, parameter type list (11.3.5), enclosing namespace (if any), return type, and template parameter list

3.21  signature
⟨function template specialization⟩ signature of the template of which it is a specialization and its template arguments (whether explicitly specified or deduced)

3.22  signature
⟨class member function⟩ name, parameter type list (11.3.5), class of which the function is a member, cv-qualifiers (if any), and ref-qualifier (if any)

3.23  signature
⟨class member function template⟩ name, parameter type list (11.3.5), class of which the function is a member, cv-qualifiers (if any), ref-qualifier (if any), return type (if any), and template parameter list

3.24  signature
⟨class member function template specialization⟩ signature of the member function template of which it is a specialization and its template arguments (whether explicitly specified or deduced)

3.25  static type
type of an expression (6.9) resulting from analysis of the program without considering execution semantics

3.26  unblock
satisfy a condition that one or more blocked threads of execution are waiting for

3.27  undefined behavior
behavior for which this International Standard imposes no requirements

3.28  unspecified behavior
behavior, for a well-formed program construct and correct data, that depends on the implementation

§ 3.28
3.29 well-formed program

C++ program constructed according to the syntax rules, diagnosable semantic rules, and the one-definition rule (6.2).
4 General principles

4.1 Implementation compliance

The set of diagnosable rules consists of all syntactic and semantic rules in this International Standard except for those rules containing an explicit notation that “no diagnostic is required” or which are described as resulting in “undefined behavior”.

Although this International Standard states only requirements on C++ implementations, those requirements are often easier to understand if they are phrased as requirements on programs, parts of programs, or execution of programs. Such requirements have the following meaning:

(2.1) — If a program contains no violations of the rules in this International Standard, a conforming implementation shall, within its resource limits, accept and correctly execute that program.

(2.2) — If a program contains a violation of any diagnosable rule or an occurrence of a construct described in this International Standard as “conditionally-supported” when the implementation does not support that construct, a conforming implementation shall issue at least one diagnostic message.

(2.3) — If a program contains a violation of a rule for which no diagnostic is required, this International Standard places no requirement on implementations with respect to that program.

[Note: During template argument deduction and substitution, certain constructs that in other contexts require a diagnostic are treated differently; see 17.8.2. — end note]

For classes and class templates, the library Clauses specify partial definitions. Private members (Clause 14) are not specified, but each implementation shall supply them to complete the definitions according to the description in the library Clauses.

For functions, function templates, objects, and values, the library Clauses specify declarations. Implementations shall supply definitions consistent with the descriptions in the library Clauses.

The names defined in the library have namespace scope (10.3). A C++ translation unit (5.2) obtains access to these names by including the appropriate standard library header (19.2).

The templates, classes, functions, and objects in the library have external linkage (6.5). The implementation provides definitions for standard library entities, as necessary, while combining translation units to form a complete C++ program (5.2).

Two kinds of implementations are defined: a hosted implementation and a freestanding implementation. For a hosted implementation, this International Standard defines the set of available libraries. A freestanding implementation is one in which execution may take place without the benefit of an operating system, and has an implementation-defined set of libraries that includes certain language-support libraries (20.5.1.3).

A conforming implementation may have extensions (including additional library functions), provided they do not alter the behavior of any well-formed program. Implementations are required to diagnose programs that use such extensions that are ill-formed according to this International Standard. Having done so, however, they can compile and execute such programs.

Each implementation shall include documentation that identifies all conditionally-supported constructs that it does not support and defines all locale-specific characteristics.

2) “Correct execution” can include undefined behavior, depending on the data being processed; see Clause 3 and 4.6.

3) This documentation also defines implementation-defined behavior; see 4.6.
4.2 Structure of this document

Clauses 5 through 19 describe the C++ programming language. That description includes detailed syntactic specifications in a form described in 4.3. For convenience, Annex A repeats all such syntactic specifications.

Clauses 21 through 33 and Annex D (the library clauses) describe the C++ standard library. That description includes detailed descriptions of the entities and macros that constitute the library, in a form described in Clause 20.

Annex B recommends lower bounds on the capacity of conforming implementations.

Annex C summarizes the evolution of C++ since its first published description, and explains in detail the differences between C++ and C. Certain features of C++ exist solely for compatibility purposes; Annex D describes those features.

Throughout this document, each example is introduced by “[Example: ” and terminated by “—end example]”.

Each note is introduced by “[Note: ” and terminated by “—end note]”. Examples and notes may be nested.

4.3 Syntax notation

In the syntax notation used in this document, syntactic categories are indicated by italic type, and literal words and characters in constant width type. Alternatives are listed on separate lines except in a few cases where a long set of alternatives is marked by the phrase “one of”. If the text of an alternative is too long to fit on a line, the text is continued on subsequent lines indented from the first one. An optional terminal or non-terminal symbol is indicated by the subscript “opt”, so

\{ expression_{opt} \}

indicates an optional expression enclosed in braces.

Names for syntactic categories have generally been chosen according to the following rules:

(2.1) — *X-name* is a use of an identifier in a context that determines its meaning (e.g., *class-name*, *typedef-name*).

(2.2) — *X-id* is an identifier with no context-dependent meaning (e.g., *qualified-id*).

(2.3) — *X-seq* is one or more *X*’s without intervening delimiters (e.g., *declaration-seq* is a sequence of declarations).

(2.4) — *X-list* is one or more *X*’s separated by intervening commas (e.g., *identifier-list* is a sequence of identifiers separated by commas).

4.4 The C++ memory model

The fundamental storage unit in the C++ memory model is the *byte*. A byte is at least large enough to contain any member of the basic execution character set (5.3) and the eight-bit code units of the Unicode UTF-8 encoding form and is composed of a contiguous sequence of bits,\(^4\) the number of which is implementation-defined. The least significant bit is called the *low-order bit*; the most significant bit is called the *high-order bit*. The memory available to a C++ program consists of one or more sequences of contiguous bytes. Every byte has a unique address.

\[ \text{Note: The representation of types is described in 6.9. — end note} \]

A memory location is either an object of scalar type or a maximal sequence of adjacent bit-fields all having nonzero width. \[ \text{Note: Various features of the language, such as references and virtual functions, might involve additional memory locations that are not accessible to programs but are managed by the implementation. — end note} \] Two or more threads of execution (4.7) can access separate memory locations without interfering with each other.

\[ \text{Note: Thus a bit-field and an adjacent non-bit-field are in separate memory locations, and therefore can be concurrently updated by two threads of execution without interference. The same applies to two bit-fields,} \]

\(^4\) The number of bits in a byte is reported by the macro \texttt{CHAR_BIT} in the header \texttt{<climits>}.
if one is declared inside a nested struct declaration and the other is not, or if the two are separated by a zero-length bit-field declaration, or if they are separated by a non-bit-field declaration. It is not safe to concurrently update two bit-fields in the same struct if all fields between them are also bit-fields of nonzero width. —end note

[Example: A structure declared as

```c
struct {
    char a;
    int b:5,
    c:11,
    :0,
    d:8;
    struct {int ee:8;} e;
}
```

contains four separate memory locations: The field `a` and bit-fields `d` and `e.ee` are each separate memory locations, and can be modified concurrently without interfering with each other. The bit-fields `b` and `c` together constitute the fourth memory location. The bit-fields `b` and `c` cannot be concurrently modified, but `b` and `a`, for example, can be. —end example]

4.5 The C++ object model [intro.object]

1 The constructs in a C++ program create, destroy, refer to, access, and manipulate objects. An object is created by a definition (6.1), by a new-expression (8.3.4), when implicitly changing the active member of a union (12.3), or when a temporary object is created (7.4, 15.2). An object occupies a region of storage in its period of construction (15.7), throughout its lifetime (6.8), and in its period of destruction (15.7). [Note: A function is not an object, regardless of whether or not it occupies storage in the way that objects do. —end note] The properties of an object are determined when the object is created. An object can have a name (Clause 6). An object has a storage duration (6.7) which influences its lifetime (6.8). An object has a type (6.9). Some objects are polymorphic (13.3); the implementation generates information associated with each such object that makes it possible to determine that object’s type during program execution. For other objects, the interpretation of the values found therein is determined by the type of the expressions (Clause 8) used to access them.

2 Objects can contain other objects, called subobjects. A subobject can be a member subobject (12.2), a base class subobject (Clause 13), or an array element. An object that is not a subobject of any other object is called a complete object. If an object is created in storage associated with a member subobject or array element `e` (which may or may not be within its lifetime), the created object is a subobject of `e`’s containing object if:

1. the lifetime of `e`’s containing object has begun and not ended, and
2. the storage for the new object exactly overlays the storage location associated with `e`, and
3. the new object is of the same type as `e` (ignoring cv-qualification).

[Note: If the subobject contains a reference member or a const subobject, the name of the original subobject cannot be used to access the new object (6.8). —end note] [Example:

```c
struct X { const int n; };
union U { X x; float f; };
void tong() {
    U u = {{ 1 }}; // OK, creates new subobject of u (12.3)
    u.f = 5.f;      // OK
    X *p = new (&u.x) X {2}; // OK, creates new subobject of u
    assert(p->n == 2); // OK
    assert(*std::launder(&u.x.n) == 2); // OK
    assert(u.x.n == 2); // undefined behavior, u.x does not name new subobject
```

§ 4.5
3 If a complete object is created (8.3.4) in storage associated with another object \( e \) of type “array of \( N \) unsigned char” or of type “array of \( N \) std::byte” (21.2.1), that array provides storage for the created object if:

(3.1) the lifetime of \( e \) has begun and not ended, and
(3.2) the storage for the new object fits entirely within \( e \), and
(3.3) there is no smaller array object that satisfies these constraints.

[Note: If that portion of the array previously provided storage for another object, the lifetime of that object ends because its storage was reused (6.8).] — end note

Example:

```cpp
template<typename ...T>
struct AlignedUnion {
    alignas(T...) unsigned char data[max(sizeof(T)...)];
};

int f() {
    AlignedUnion<int, char> au;
    int *p = new (au.data) int; // OK, au.data provides storage
    char *c = new (au.data) char(); // OK, ends lifetime of *p
    char *d = new (au.data + 1) char();
    return *c + *d; // OK
}
```

Note:

```cpp
struct A { unsigned char a[32];
};
struct B { unsigned char b[16];
};
A a;
B *b = new (a.a + 8) B; // a.a provides storage for *b
int *p = new (b->b + 4) int; // b->b provides storage for *p
// a.a does not provide storage for *p (directly),
// but *p is nested within a (see below)
```

— end example]

4 An object \( a \) is nested within another object \( b \) if:

(4.1) \( a \) is a subobject of \( b \), or
(4.2) \( b \) provides storage for \( a \), or
(4.3) there exists an object \( c \) where \( a \) is nested within \( c \), and \( c \) is nested within \( b \).

For every object \( x \), there is some object called the complete object of \( x \), determined as follows:

(5.1) If \( x \) is a complete object, then the complete object of \( x \) is itself.
(5.2) Otherwise, the complete object of \( x \) is the complete object of the (unique) object that contains \( x \).

6 If a complete object, a data member (12.2), or an array element is of class type, its type is considered the most derived class, to distinguish it from the class type of any base class subobject; an object of a most derived class type or of a non-class type is called a most derived object.

7 Unless it is a bit-field (12.2.4), a most derived object shall have a nonzero size and shall occupy one or more bytes of storage. Base class subobjects may have zero size. An object of trivially copyable or standard-layout type (6.9) shall occupy contiguous bytes of storage.

8 Unless an object is a bit-field or a base class subobject of zero size, the address of that object is the address of the first byte it occupies. Two objects \( a \) and \( b \) with overlapping lifetimes that are not bit-fields may have the same address if one is nested within the other, or if at least one is a base class subobject of zero size and

§ 4.5
they are of different types; otherwise, they have distinct addresses.\footnote{Under the “as-if” rule an implementation is allowed to store two objects at the same machine address or not store an object at all if the program cannot observe the difference (4.6).}

\textbf{Example:}

\begin{verbatim}
static const char test1 = 'x';
static const char test2 = 'x';
const bool b = &test1 != &test2;  // always true
\end{verbatim}

\textit{— end example}\footnote{This provision is sometimes called the “as-if” rule, because an implementation is free to disregard any requirement of this International Standard as long as the result is as if the requirement had been obeyed, as far as can be determined from the observable behavior of the program. For instance, an actual implementation need not evaluate part of an expression if it can deduce that its value is not used and that no side effects affecting the observable behavior of the program are produced.}

\[ Note: \texttt{C++} provides a variety of fundamental types and several ways of composing new types from existing types (6.9). \textit{— end note} \]

\section{4.6 Program execution \[ intro.execution \]}

The semantic descriptions in this International Standard define a parameterized nondeterministic abstract machine. This International Standard places no requirement on the structure of conforming implementations. In particular, they need not copy or emulate the structure of the abstract machine. Rather, conforming implementations are required to emulate (only) the observable behavior of the abstract machine as explained below.\footnote{This documentation also includes conditionally-supported constructs and locale-specific behavior. See 4.1.}

Certain aspects and operations of the abstract machine are described in this International Standard as implementation-defined (for example, \texttt{sizeof(int)}). These constitute the parameters of the abstract machine. Each implementation shall include documentation describing its characteristics and behavior in these respects.\footnote{Under the “as-if” rule an implementation is allowed to store two objects at the same machine address or not store an object at all if the program cannot observe the difference (4.6).}

Certain other aspects and operations of the abstract machine are described in this International Standard as unspecified (for example, evaluation of expressions in a \texttt{new-initializer} if the allocation function fails to allocate memory (8.3.4)). Where possible, this International Standard defines a set of allowable behaviors. These define the nondeterministic aspects of the abstract machine. An instance of the abstract machine can thus have more than one possible execution for a given program and a given input.

Certain other operations are described in this International Standard as undefined (for example, the effect of attempting to modify a \texttt{const} object).\footnote{Under the “as-if” rule an implementation is allowed to store two objects at the same machine address or not store an object at all if the program cannot observe the difference (4.6).}

A conforming implementation executing a well-formed program shall produce the same observable behavior as one of the possible executions of the corresponding instance of the abstract machine with the same program and the same input. However, if any such execution contains an undefined operation, this International Standard places no requirement on the implementation executing that program with that input (not even with regard to operations preceding the first undefined operation).

An instance of each object with automatic storage duration (6.7.3) is associated with each entry into its block. Such an object exists and retains its last-stored value during the execution of the block and while the block is suspended (by a call of a function or receipt of a signal).

The least requirements on a conforming implementation are:

\begin{itemize}
  \item Accesses through volatile glvalues are evaluated strictly according to the rules of the abstract machine.\footnote{Under the “as-if” rule an implementation is allowed to store two objects at the same machine address or not store an object at all if the program cannot observe the difference (4.6).}
  \item At program termination, all data written into files shall be identical to one of the possible results that execution of the program according to the abstract semantics would have produced.
\end{itemize}
The input and output dynamics of interactive devices shall take place in such a fashion that prompting output is actually delivered before a program waits for input. What constitutes an interactive device is implementation-defined. These collectively are referred to as the observable behavior of the program. [Note: More stringent correspondences between abstract and actual semantics may be defined by each implementation. —end note]

8 [Note: Operators can be regrouped according to the usual mathematical rules only where the operators really are associative or commutative. For example, in the following fragment

```c
int a, b;
/* ... */
a = a + 32760 + b + 5;
```

the expression statement behaves exactly the same as

```c
a = (((a + 32760) + b) + 5);
```

due to the associativity and precedence of these operators. Thus, the result of the sum \((a + 32760)\) is next added to \(b\), and that result is then added to 5 which results in the value assigned to \(a\). On a machine in which overflows produce an exception and in which the range of values representable by an \(\text{int}\) is \([-32768, +32767]\), the implementation cannot rewrite this expression as

```c
a = ((a + b) + 32765);
```

since if the values for \(a\) and \(b\) were, respectively, -32754 and -15, the sum \(a + b\) would produce an exception while the original expression would not; nor can the expression be rewritten either as

```c
a = ((a + 32765) + b);
```
or

```c
a = (a + (b + 32765));
```

since the values for \(a\) and \(b\) might have been, respectively, 4 and -8 or -17 and 12. However on a machine in which overflows do not produce an exception and in which the results of overflows are reversible, the above expression statement can be rewritten by the implementation in any of the above ways because the same result will occur. —end note]

9 A constituent expression is defined as follows:

\[(9.1)\] — The constituent expression of an expression is that expression.

\[(9.2)\] — The constituent expressions of a \(\text{braced-init-list}\) or of a (possibly parenthesized) \(\text{expression-list}\) are the constituent expressions of the elements of the respective list.

\[(9.3)\] — The constituent expressions of a \(\text{brace-or-equal-initializer}\) of the form \(= \text{initializer-clause}\) are the constituent expressions of the \(\text{initializer-clause}\).

[Example:

```c
struct A { int x; };
struct B { int y; struct A a; };
B b = { 5, { 1+1 } };
```

The constituent expressions of the \(\text{initializer}\) used for the initialization of \(b\) are 5 and 1+1. —end example]

10 The immediate subexpressions of an expression \(e\) are

\[(10.1)\] — the constituent expressions of \(e\)'s operands (Clause 8),

\[(10.2)\] — any function call that \(e\) implicitly invokes,

\[(10.3)\] — if \(e\) is a \(\text{lambda-expression}\) (8.1.5), the initialization of the entities captured by copy and the constituent

8) Overloaded operators are never assumed to be associative or commutative.
expressions of the *initializer* of the *init-captures*,

(10.4) — if \( e \) is a function call (8.2.2) or implicitly invokes a function, the constituent expressions of each default argument (11.3.6) used in the call, or

(10.5) — if \( e \) creates an aggregate object (11.6.1), the constituent expressions of each default member initializer (12.2) used in the initialization.

11 A *subexpression* of an expression \( e \) is an immediate subexpression of \( e \) or a subexpression of an immediate subexpression of \( e \). [*Note: Expressions appearing in the compound-statement of a lambda-expression are not subexpressions of the lambda-expression. — end note*]

12 A *full-expression* is

(12.1) — an unevaluated operand (Clause 8),
(12.2) — a *constant-expression* (8.20),
(12.3) — an *init-declarator* (Clause 11) or a *mem-initializer* (15.6.2), including the constituent expressions of the initializer,
(12.4) — an invocation of a destructor generated at the end of the lifetime of an object other than a temporary object (15.2), or
(12.5) — an expression that is not a subexpression of another expression and that is not otherwise part of a full-expression.

If a language construct is defined to produce an implicit call of a function, a use of the language construct is considered to be an expression for the purposes of this definition. Conversions applied to the result of an expression in order to satisfy the requirements of the language construct in which the expression appears are also considered to be part of the full-expression. For an initializer, performing the initialization of the entity (including evaluating default member initializers of an aggregate) is also considered part of the full-expression.

[Example:

```c
struct S {
    S(int i): I(i) { } // full-expression is initialization of I
    int& v() { return I; }
    ~S() noexcept(false) { }
private:
    int I;
};

S s1(1); // full-expression is call of S::S(int)
void f() {
    S s2 = 2; // full-expression is call of S::S(int)
    if (S(3).v()) // full-expression includes lvalue-to-rvalue and
        // int to bool conversions, performed before
        // temporary is deleted at end of full-expression
    {
    }
    bool b = noexcept(S()); // exception specification of destructor of S
    // considered for noexcept
    // full-expression is destruction of s2 at end of block
}
struct B {
    B(S = S(0));
};
B b[2] = { B(), B() }; // full-expression is the entire initialization
    // including the destruction of temporaries
}

§ 4.6
Reading an object designated by a `volatile` glvalue (6.10), modifying an object, calling a library I/O function, or calling a function that does any of those operations are all side effects, which are changes in the state of the execution environment. Evaluation of an expression (or a subexpression) in general includes both value computations (including determining the identity of an object for glvalue evaluation and fetching a value previously assigned to an object for prvalue evaluation) and initiation of side effects. When a call to a library I/O function returns or an access through a volatile glvalue is evaluated the side effect is considered complete, even though some external actions implied by the call (such as the I/O itself) or by the `volatile` access may not have completed yet.

Sequence before is an asymmetric, transitive, pair-wise relation between evaluations executed by a single thread (4.7), which induces a partial order among those evaluations. Given any two evaluations A and B, if A is sequenced before B (or, equivalently, B is sequenced after A), then the execution of A shall precede the execution of B. If A is not sequenced before B and B is not sequenced before A, then A and B are unsequenced. [Note: The execution of unsequenced evaluations can overlap. —end note] Evaluations A and B are indeterminately sequenced when either A is sequenced before B or B is sequenced before A, but it is unspecified which. [Note: Indeterminately sequenced evaluations cannot overlap, but either could be executed first. —end note] An expression X is said to be sequenced before an expression Y if every value computation and every side effect associated with the expression X is sequenced before every value computation and every side effect associated with the expression Y.

Every value computation and side effect associated with a full-expression is sequenced before every value computation and side effect associated with the next full-expression to be evaluated.9

Except where noted, evaluations of operands of individual operators and of subexpressions of individual expressions are unsequenced. [Note: In an expression that is evaluated more than once during the execution of a program, unsequenced and indeterminately sequenced evaluations of its subexpressions need not be performed consistently in different evaluations. —end note] The value computations of the operands of an operator are sequenced before the value computation of the result of the operator. If a side effect on a memory location (4.4) is unsequenced relative to either another side effect on the same memory location or a value computation using the value of any object in the same memory location, and they are not potentially concurrent (4.7), the behavior is undefined. [Note: The next section imposes similar, but more complex restrictions on potentially concurrent computations. —end note]

[Example:

```c
void g(int i) {
    i = 7, i++, i++;       // i becomes 9
    i = i++ + 1;            // the value of i is incremented
    i = i++ + i;            // the behavior is undefined
    i = i + 1;              // the value of i is incremented
}
```
—end example]

When calling a function (whether or not the function is inline), every value computation and side effect associated with any argument expression, or with the postfix expression designating the called function, is sequenced before execution of every expression or statement in the body of the called function. For each function invocation F, for every evaluation A that occurs within F and every evaluation B that does not

9) As specified in 15.2, after a full-expression is evaluated, a sequence of zero or more invocations of destructor functions for temporary objects takes place, usually in reverse order of the construction of each temporary object.
occur within \( F \) but is evaluated on the same thread and as part of the same signal handler (if any), either \( A \) is sequenced before \( B \) or \( B \) is sequenced before \( A \).\(^{10}\) \[ \text{Note: If } A \text{ and } B \text{ would not otherwise be sequenced then they are indeterminately sequenced.} \] Several contexts in C++ cause evaluation of a function call, even though no corresponding function call syntax appears in the translation unit. \[ \text{Example: Evaluation of a } \text{new-expression} \text{ invokes one or more allocation and constructor functions; see 8.3.4. For another example, invocation of a conversion function (15.3.2) can arise in contexts in which no function call syntax appears.} \] The sequencing constraints on the execution of the called function (as described above) are features of the function calls as evaluated, whatever the syntax of the expression that calls the function might be.

19 If a signal handler is executed as a result of a call to the `std::raise` function, then the execution of the handler is sequenced after the invocation of the `std::raise` function and before its return. \[ \text{[Note: When a signal is received for another reason, the execution of the signal handler is usually unsequenced with respect to the rest of the program.} \]}

4.7 Multi-threaded executions and data races [intro.multithread]

1 A thread of execution (also known as a thread) is a single flow of control within a program, including the initial invocation of a specific top-level function, and recursively including every function invocation subsequently executed by the thread. \[ \text{[Note: When one thread creates another, the initial call to the top-level function of the new thread is executed by the new thread, not by the creating thread.} \] Every thread in a program can potentially access every object and function in a program.\(^{11}\) Under a hosted implementation, a C++ program can have more than one thread running concurrently. The execution of each thread proceeds as defined by the remainder of this International Standard. The execution of the entire program consists of an execution of all of its threads. \[ \text{[Note: Usually the execution can be viewed as an interleaving of all its threads. However, some kinds of atomic operations, for example, allow executions inconsistent with a simple interleaving, as described below.} \] Under a freestanding implementation, it is implementation-defined whether a program can have more than one thread of execution.

2 For a signal handler that is not executed as a result of a call to the `std::raise` function, it is unspecified which thread of execution contains the signal handler invocation.

4.7.1 Data races [intro.races]

1 The value of an object visible to a thread \( T \) at a particular point is the initial value of the object, a value assigned to the object by \( T \), or a value assigned to the object by another thread, according to the rules below. \[ \text{[Note: In some cases, there may instead be undefined behavior. Much of this section is motivated by the desire to support atomic operations with explicit and detailed visibility constraints. However, it also implicitly supports a simpler view for more restricted programs.} \]

2 Two expression evaluations conflict if one of them modifies a memory location (4.4) and the other one reads or modifies the same memory location.

3 The library defines a number of atomic operations (Clause 32) and operations on mutexes (Clause 33) that are specially identified as synchronization operations. These operations play a special role in making assignments in one thread visible to another. A synchronization operation on one or more memory locations is either a consume operation, an acquire operation, a release operation, or both an acquire and release operation. A synchronization operation without an associated memory location is a fence and can be either an acquire fence, a release fence, or both an acquire and release fence. In addition, there are relaxed atomic operations, which are not synchronization operations, and atomic read-modify-write operations, which have special characteristics. \[ \text{[Note: For example, a call that acquires a mutex will perform an acquire operation on the locations comprising the mutex. Correspondingly, a call that releases the same mutex will perform a} \]

---

\(^{10}\) In other words, function executions do not interleave with each other.

\(^{11}\) An object with automatic or thread storage duration (6.7) is associated with one specific thread, and can be accessed by a different thread only indirectly through a pointer or reference (6.9.2).
release operation on those same locations. Informally, performing a release operation on A forces prior side effects on other memory locations to become visible to other threads that later perform a consume or an acquire operation on A. “Relaxed” atomic operations are not synchronization operations even though, like synchronization operations, they cannot contribute to data races. — end note

4 All modifications to a particular atomic object M occur in some particular total order, called the modification order of M. [Note: There is a separate order for each atomic object. There is no requirement that these can be combined into a single total order for all objects. In general this will be impossible since different threads may observe modifications to different objects in inconsistent orders. — end note]

5 A release sequence headed by a release operation A on an atomic object M is a maximal contiguous subsequence of side effects in the modification order of M, where the first operation is A, and every subsequent operation

\( (5.1) \) — is performed by the same thread that performed A, or

\( (5.2) \) — is an atomic read-modify-write operation.

6 Certain library calls synchronize with other library calls performed by another thread. For example, an atomic store-release synchronizes with a load-acquire that takes its value from the store (32.4). [Note: Except in the specified cases, reading a later value does not necessarily ensure visibility as described below. Such a requirement would sometimes interfere with efficient implementation. — end note] [Note: The specifications of the synchronization operations define when one reads the value written by another. For atomic objects, the definition is clear. All operations on a given mutex occur in a single total order. Each mutex acquisition “reads the value written” by the last mutex release. — end note]

7 An evaluation A carries a dependency to an evaluation B if

\( (7.1) \) — the value of A is used as an operand of B, unless:

\( (7.1.1) \) — B is an invocation of any specialization of std::kill_dependency (32.4), or

\( (7.1.2) \) — A is the left operand of a built-in logical AND (&&, see 8.14) or logical OR (|, see 8.15) operator, or

\( (7.1.3) \) — A is the left operand of a conditional (?:, see 8.16) operator, or

\( (7.1.4) \) — A is the left operand of the built-in comma (, operator (8.19);

or

\( (7.2) \) — A writes a scalar object or bit-field M, B reads the value written by A from M, and A is sequenced before B, or

\( (7.3) \) — for some evaluation X, A carries a dependency to X, and X carries a dependency to B.

[Note: “Carries a dependency to” is a subset of “is sequenced before”, and is similarly strictly intra-thread. — end note]

8 An evaluation A is dependency-ordered before an evaluation B if

\( (8.1) \) — A performs a release operation on an atomic object M, and, in another thread, B performs a consume operation on M and reads a value written by any side effect in the release sequence headed by A, or

\( (8.2) \) — for some evaluation X, A is dependency-ordered before X and X carries a dependency to B.

[Note: The relation “is dependency-ordered before” is analogous to “synchronizes with”, but uses release/consume in place of release/acquire. — end note]

9 An evaluation A inter-thread happens before an evaluation B if

\( (9.1) \) — A synchronizes with B, or

\( (9.2) \) — A is dependency-ordered before B, or

§ 4.7.1
(9.3) — for some evaluation $X$

(9.3.1) — $A$ synchronizes with $X$ and $X$ is sequenced before $B$, or

(9.3.2) — $A$ is sequenced before $X$ and $X$ inter-thread happens before $B$, or

(9.3.3) — $A$ inter-thread happens before $X$ and $X$ inter-thread happens before $B$.

[Note: The “inter-thread happens before” relation describes arbitrary concatenations of “sequenced before”, “synchronizes with” and “dependency-ordered before” relationships, with two exceptions. The first exception is that a concatenation is not permitted to end with “dependency-ordered before” followed by “sequenced before”. The reason for this limitation is that a consume operation participating in a “dependency-ordered before” relationship provides ordering only with respect to operations to which this consume operation actually carries a dependency. The reason that this limitation applies only to the end of such a concatenation is that any subsequent release operation will provide the required ordering for a prior consume operation. The second exception is that a concatenation is not permitted to consist entirely of “sequenced before”. The reasons for this limitation are (1) to permit “inter-thread happens before” to be transitively closed and (2) the “happens before” relation, defined below, provides for relationships consisting entirely of “sequenced before”. — end note]

10 An evaluation $A$ happens before an evaluation $B$ (or, equivalently, $B$ happens after $A$) if:

(10.1) — $A$ is sequenced before $B$, or

(10.2) — $A$ inter-thread happens before $B$.

The implementation shall ensure that no program execution demonstrates a cycle in the “happens before” relation. [Note: This cycle would otherwise be possible only through the use of consume operations. — end note]

11 An evaluation $A$ strongly happens before an evaluation $B$ if either

(11.1) — $A$ is sequenced before $B$, or

(11.2) — $A$ synchronizes with $B$, or

(11.3) — $A$ strongly happens before $X$ and $X$ strongly happens before $B$.

[Note: In the absence of consume operations, the happens before and strongly happens before relations are identical. Strongly happens before essentially excludes consume operations. — end note]

12 A visible side effect $A$ on a scalar object or bit-field $M$ with respect to a value computation $B$ of $M$ satisfies the conditions:

(12.1) — $A$ happens before $B$ and

(12.2) — there is no other side effect $X$ to $M$ such that $A$ happens before $X$ and $X$ happens before $B$.

The value of a non-atomic scalar object or bit-field $M$, as determined by evaluation $B$, shall be the value stored by the visible side effect $A$. [Note: If there is ambiguity about which side effect to a non-atomic object or bit-field is visible, then the behavior is either unspecified or undefined. — end note] [Note: This states that operations on ordinary objects are not visibly reordered. This is not actually detectable without data races, but it is necessary to ensure that data races, as defined below, and with suitable restrictions on the use of atomics, correspond to data races in a simple interleaved (sequentially consistent) execution. — end note]

13 The value of an atomic object $M$, as determined by evaluation $B$, shall be the value stored by some side effect $A$ that modifies $M$, where $B$ does not happen before $A$. [Note: The set of such side effects is also restricted by the rest of the rules described here, and in particular, by the coherence requirements below. — end note]

14 If an operation $A$ that modifies an atomic object $M$ happens before an operation $B$ that modifies $M$, then $A$ shall be earlier than $B$ in the modification order of $M$. [Note: This requirement is known as write-write coherence. — end note]
If a value computation $A$ of an atomic object $M$ happens before a value computation $B$ of $M$, and $A$ takes its value from a side effect $X$ on $M$, then the value computed by $B$ shall either be the value stored by $X$ or the value stored by a side effect $Y$ on $M$, where $Y$ follows $X$ in the modification order of $M$. [Note: This requirement is known as read-read coherence. — end note]

If a value computation $A$ of an atomic object $M$ happens before an operation $B$ that modifies $M$, then $A$ shall take its value from a side effect $X$ on $M$, where $X$ precedes $B$ in the modification order of $M$. [Note: This requirement is known as read-write coherence. — end note]

If a side effect $X$ on an atomic object $M$ happens before a value computation $B$ of $M$, then the evaluation $B$ shall take its value from $X$ or from a side effect $Y$ that follows $X$ in the modification order of $M$. [Note: This requirement is known as write-read coherence. — end note]

[Note: The four preceding coherence requirements effectively disallow compiler reordering of atomic operations to a single object, even if both operations are relaxed loads. This effectively makes the cache coherence guarantee provided by most hardware available to C++ atomic operations. — end note]

[Note: The value observed by a load of an atomic depends on the “happens before” relation, which depends on the values observed by loads of atomics. The intended reading is that there must exist an association of atomic loads with modifications they observe that, together with suitably chosen modification orders and the “happens before” relation derived as described above, satisfy the resulting constraints as imposed here. — end note]

Two actions are potentially concurrent if

(20.1) they are performed by different threads, or

(20.2) they are unsequenced, at least one is performed by a signal handler, and they are not both performed by the same signal handler invocation.

The execution of a program contains a data race if it contains two potentially concurrent conflicting actions, at least one of which is not atomic, and neither happens before the other, except for the special case for signal handlers described below. Any such data race results in undefined behavior. [Note: It can be shown that programs that correctly use mutexes and memory_order_seq_cst operations to prevent all data races and use no other synchronization operations behave as if the operations executed by their constituent threads were simply interleaved, with each value computation of an object being taken from the last side effect on that object in that interleaving. This is normally referred to as “sequential consistency”. However, this applies only to data-race-free programs, and data-race-free programs cannot observe most program transformations that do not change single-threaded program semantics. In fact, most single-threaded program transformations continue to be allowed, since any program that behaves differently as a result must perform an undefined operation. — end note]

Two accesses to the same object of type volatile std::sig_atomic_t do not result in a data race if both occur in the same thread, even if one or more occurs in a signal handler. For each signal handler invocation, evaluations performed by the thread invoking a signal handler can be divided into two groups $A$ and $B$, such that no evaluations in $B$ happen before evaluations in $A$, and the evaluations of such volatile std::sig_atomic_t objects take values as though all evaluations in $A$ happened before the execution of the signal handler and the execution of the signal handler happened before all evaluations in $B$.

[Note: Compiler transformations that introduce assignments to a potentially shared memory location that would not be modified by the abstract machine are generally precluded by this International Standard, since such an assignment might overwrite another assignment by a different thread in cases in which an abstract machine execution would not have encountered a data race. This includes implementations of data member assignment that overwrite adjacent members in separate memory locations. Reordering of atomic loads in cases in which the atomics in question may alias is also generally precluded, since this may violate the coherence rules. — end note]

[Note: Transformations that introduce a speculative read of a potentially shared memory location may not
preserve the semantics of the C++ program as defined in this International Standard, since they potentially introduce a data race. However, they are typically valid in the context of an optimizing compiler that targets a specific machine with well-defined semantics for data races. They would be invalid for a hypothetical machine that is not tolerant of races or provides hardware race detection. —end note]

4.7.2 Forward progress [intro.progress]

1 The implementation may assume that any thread will eventually do one of the following:

(1.1) — terminate,

(1.2) — make a call to a library I/O function,

(1.3) — perform an access through a volatile glvalue, or

(1.4) — perform a synchronization operation or an atomic operation.

[Note: This is intended to allow compiler transformations such as removal of empty loops, even when termination cannot be proven. — end note]

2 Executions of atomic functions that are either defined to be lock-free (32.8) or indicated as lock-free (32.5) are lock-free executions.

(2.1) — If there is only one thread that is not blocked (3.6) in a standard library function, a lock-free execution in that thread shall complete. [Note: Concurrently executing threads may prevent progress of a lock-free execution. For example, this situation can occur with load-locked store-conditional implementations. This property is sometimes termed obstruction-free. — end note]

(2.2) — When one or more lock-free executions run concurrently, at least one should complete. [Note: It is difficult for some implementations to provide absolute guarantees to this effect, since repeated and particularly inopportune interference from other threads may prevent forward progress, e.g., by repeatedly stealing a cache line for unrelated purposes between load-locked and store-conditional instructions. Implementations should ensure that such effects cannot indefinitely delay progress under expected operating conditions, and that such anomalies can therefore safely be ignored by programmers. Outside this document, this property is sometimes termed lock-free. — end note]

3 During the execution of a thread of execution, each of the following is termed an execution step:

(3.1) — termination of the thread of execution,

(3.2) — performing an access through a volatile glvalue, or

(3.3) — completion of a call to a library I/O function, a synchronization operation, or an atomic operation.

4 An invocation of a standard library function that blocks (3.6) is considered to continuously execute execution steps while waiting for the condition that it blocks on to be satisfied. [Example: A library I/O function that blocks until the I/O operation is complete can be considered to continuously check whether the operation is complete. Each such check might consist of one or more execution steps, for example using observable behavior of the abstract machine. — end example]

5 [Note: Because of this and the preceding requirement regarding what threads of execution have to perform eventually, it follows that no thread of execution can execute forever without an execution step occurring. — end note]

6 A thread of execution makes progress when an execution step occurs or a lock-free execution does not complete because there are other concurrent threads that are not blocked in a standard library function (see above).

7 For a thread of execution providing concurrent forward progress guarantees, the implementation ensures that the thread will eventually make progress for as long as it has not terminated. [Note: This is required regardless of whether or not other threads of executions (if any) have been or are making progress. To eventually fulfill this requirement means that this will happen in an unspecified but finite amount of time. — end note]
It is implementation-defined whether the implementation-created thread of execution that executes `main` (6.6.1) and the threads of execution created by `std::thread` (33.3.2) provide concurrent forward progress guarantees. [Note: General-purpose implementations are encouraged to provide these guarantees. — end note]

For a thread of execution providing parallel forward progress guarantees, the implementation is not required to ensure that the thread will eventually make progress if it has not yet executed any execution step; once this thread has executed a step, it provides concurrent forward progress guarantees.

[Note: This does not specify a requirement for when to start this thread of execution, which will typically be specified by the entity that creates this thread of execution. For example, a thread of execution that provides concurrent forward progress guarantees and executes tasks from a set of tasks in an arbitrary order, one after the other, satisfies the requirements of parallel forward progress for these tasks. — end note]

For a thread of execution providing weakly parallel forward progress guarantees, the implementation does not ensure that the thread will eventually make progress.

[Note: Threads of execution providing weakly parallel forward progress guarantees cannot be expected to make progress regardless of whether other threads make progress or not; however, blocking with forward progress guarantee delegation, as defined below, can be used to ensure that such threads of execution make progress eventually. — end note]

Concurrent forward progress guarantees are stronger than parallel forward progress guarantees, which in turn are stronger than weakly parallel forward progress guarantees. [Note: For example, some kinds of synchronization between threads of execution may only make progress if the respective threads of execution provide parallel forward progress guarantees, but will fail to make progress under weakly parallel guarantees. — end note]

When a thread of execution \( P \) is specified to block with forward progress guarantee delegation on the completion of a set \( S \) of threads of execution, then throughout the whole time of \( P \) being blocked on \( S \), the implementation shall ensure that the forward progress guarantees provided by at least one thread of execution in \( S \) is at least as strong as \( P \)'s forward progress guarantees. [Note: It is unspecified which thread or threads of execution in \( S \) are chosen and for which number of execution steps. The strengthening is not permanent and not necessarily in place for the rest of the lifetime of the affected thread of execution. As long as \( P \) is blocked, the implementation has to eventually select and potentially strengthen a thread of execution in \( S \). — end note] Once a thread of execution in \( S \) terminates, it is removed from \( S \). Once \( S \) is empty, \( P \) is unblocked.

[Note: A thread of execution \( B \) thus can temporarily provide an effectively stronger forward progress guarantee for a certain amount of time, due to a second thread of execution \( A \) being blocked on it with forward progress guarantee delegation. In turn, if \( B \) then blocks with forward progress guarantee delegation on \( C \), this may also temporarily provide a stronger forward progress guarantee to \( C \). — end note]

[Note: If all threads of execution in \( S \) finish executing (e.g., they terminate and do not use blocking synchronization incorrectly), then \( P \)'s execution of the operation that blocks with forward progress guarantee delegation will not result in \( P \)'s progress guarantee being effectively weakened. — end note]

[Note: This does not remove any constraints regarding blocking synchronization for threads of execution providing parallel or weakly parallel forward progress guarantees because the implementation is not required to strengthen a particular thread of execution whose too-weak progress guarantee is preventing overall progress. — end note]

An implementation should ensure that the last value (in modification order) assigned by an atomic or synchronization operation will become visible to all other threads in a finite period of time.

5.1 Separate translation

The text of the program is kept in units called source files in this International Standard. A source file together with all the headers (20.5.1.2) and source files included (19.2) via the preprocessing directive #include, less any source lines skipped by any of the conditional inclusion (19.1) preprocessing directives, is called a translation unit. [Note: A C++ program need not all be translated at the same time. — end note]

[Note: Previously translated translation units and instantiation units can be preserved individually or in libraries. The separate translation units of a program communicate (6.5) by (for example) calls to functions whose identifiers have external linkage, manipulation of objects whose identifiers have external linkage, or manipulation of data files. Translation units can be separately translated and then later linked to produce an executable program (6.5). — end note]

5.2 Phases of translation

The precedence among the syntax rules of translation is specified by the following phases.

1. Physical source file characters are mapped, in an implementation-defined manner, to the basic source character set (introducing new-line characters for end-of-line indicators) if necessary. The set of physical source file characters accepted is implementation-defined. Any source file character not in the basic source character set (5.3) is replaced by the universal-character-name that designates that character. An implementation may use any internal encoding, so long as an actual extended character encountered in the source file, and the same extended character expressed in the source file as a universal-character-name (e.g., using the \uXXXX notation), are handled equivalently except where this replacement is reverted (5.4) in a raw string literal.

2. Each instance of a backslash character (\) immediately followed by a new-line character is deleted, splicing physical source lines to form logical source lines. Only the last backslash on any physical source line shall be eligible for being part of such a splice. Except for splices reverted in a raw string literal, if a splice results in a character sequence that matches the syntax of a universal-character-name, the behavior is undefined. A source file that is not empty and that does not end in a new-line character, or that ends in a new-line character immediately preceded by a backslash character before any such splicing takes place, shall be processed as if an additional new-line character were appended to the file.

3. The source file is decomposed into preprocessing tokens (5.4) and sequences of white-space characters (including comments). A source file shall not end in a partial preprocessing token or in a partial comment. Each comment is replaced by one space character. New-line characters are retained. Whether each nonempty sequence of white-space characters other than new-line is retained or replaced by one space character is unspecified. The process of dividing a source file’s characters into preprocessing tokens is context-dependent. [Example: see the handling of < within a #include preprocessing directive. — end example]

4. Preprocessing directives are executed, macro invocations are expanded, and _Pragma unary operator expressions are executed. If a character sequence that matches the syntax of a universal-character-name is produced by token concatenation (19.3.3), the behavior is undefined. A #include preprocessing
5. Each source character set member in a character literal or a string literal, as well as each escape sequence and universal-character-name in a character literal or a non-raw string literal, is converted to the corresponding member of the execution character set (5.13.3, 5.13.5); if there is no corresponding member, it is converted to an implementation-defined member other than the null (wide) character.  
6. Adjacent string literal tokens are concatenated.  
7. White-space characters separating tokens are no longer significant. Each preprocessing token is converted into a token (5.6). The resulting tokens are syntactically and semantically analyzed and translated as a translation unit. [Note: The process of analyzing and translating the tokens may occasionally result in one token being replaced by a sequence of other tokens (17.2). — end note] [Note: Source files, translation units and translated translation units need not necessarily be stored as files, nor need there be any one-to-one correspondence between these entities and any external representation. The description is conceptual only, and does not specify any particular implementation. — end note] 
8. Translated translation units and instantiation units are combined as follows: [Note: Some or all of these may be supplied from a library.—end note] Each translated translation unit is examined to produce a list of required instantiations. [Note: This may include instantiations which have been explicitly requested (17.7.2). — end note] The definitions of the required templates are located. It is implementation-defined whether the source of the translation units containing these definitions is required to be available. [Note: An implementation could encode sufficient information into the translated translation unit so as to ensure the source is not required here. — end note] All the required instantiations are performed to produce instantiation units. [Note: These are similar to translated translation units, but contain no references to uninstantiated templates and no template definitions. — end note] The program is ill-formed if any instantiation fails.  
9. All external entity references are resolved. Library components are linked to satisfy external references to entities not defined in the current translation. All such translator output is collected into a program image which contains information needed for execution in its execution environment.

5.3 Character sets

The basic source character set consists of 96 characters: the space character, the control characters representing horizontal tab, vertical tab, form feed, and new-line, plus the following 91 graphical characters: 

```
abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ0123456789_\{%\}[\()<>%::?*+-/\&\~\!
```

The universal-character-name construct provides a way to name other characters. 

```
\u hex-quad:
  hexadecimal-digit hexadecimal-digit hexadecimal-digit hexadecimal-digit

universal-character-name:
\u hex-quad
\U hex-quad hex-quad
```

The character designated by the universal-character-name \UNNNNNNNN is that character whose character short name in ISO/IEC 10646 is NNNNNNNN; the character designated by the universal-character-name \uNNNN

14) An implementation need not convert all non-corresponding source characters to the same execution character.  
15) The glyphs for the members of the basic source character set are intended to identify characters from the subset of ISO/IEC 10646 which corresponds to the ASCII character set. However, because the mapping from source file characters to the source character set (described in translation phase 1) is specified as implementation-defined, an implementation is required to document how the basic source characters are represented in source files.
is that character whose character short name in ISO/IEC 10646 is 0000NNNN. If the hexadecimal value for a universal-character-name corresponds to a surrogate code point (in the range 0xD800–0xDFFF, inclusive), the program is ill-formed. Additionally, if the hexadecimal value for a universal-character-name outside the c-char-sequence, s-char-sequence, or r-char-sequence of a character or string literal corresponds to a control character (in either of the ranges 0x00–0x1F or 0x7F–0x9F, both inclusive) or to a character in the basic source character set, the program is ill-formed.\footnote{A sequence of characters resembling a universal-character-name in an r-char-sequence (5.13.5) does not form a universal-character-name.}

3 The basic execution character set and the basic execution wide-character set shall each contain all the members of the basic source character set, plus control characters representing alert, backspace, and carriage return, plus a null character (respectively, null wide character), whose value is 0. For each basic execution character set, the values of the members shall be non-negative and distinct from one another. In both the source and execution basic character sets, the value of each character after 0 in the above list of decimal digits shall be one greater than the value of the previous. The execution character set and the execution wide-character set are implementation-defined supersets of the basic execution character set and the basic execution wide-character set, respectively. The values of the members of the execution character sets and the sets of additional members are locale-specific.

5.4 Preprocessing tokens

preprocessing-token:
  header-name
  identifier
  pp-number
  character-literal
  user-defined-character-literal
  string-literal
  user-defined-string-literal
  preprocessing-op-or-punc
  each non-white-space character that cannot be one of the above

1 Each preprocessing token that is converted to a token (5.6) shall have the lexical form of a keyword, an identifier, a literal, an operator, or a punctuator.

2 A preprocessing token is the minimal lexical element of the language in translation phases 3 through 6. The categories of preprocessing token are: header names, identifiers, preprocessing numbers, character literals (including user-defined character literals), string literals (including user-defined string literals), preprocessing operators and punctuators, and single non-white-space characters that do not lexically match the other preprocessing token categories. If a ‘’ or a ‘” character matches the last category, the behavior is undefined.

Preprocessing tokens can be separated by white space; this consists of comments (5.7), or white-space characters (space, horizontal tab, new-line, vertical tab, and form-feed), or both. As described in Clause 19, in certain circumstances during translation phase 4, white space (or the absence thereof) serves as more than preprocessing token separation. White space can appear within a preprocessing token only as part of a header name or between the quotation characters in a character literal or string literal.

3 If the input stream has been parsed into preprocessing tokens up to a given character:

(3.1) — If the next character begins a sequence of characters that could be the prefix and initial double quote of a raw string literal, such as R", the next preprocessing token shall be a raw string literal. Between the initial and final double quote characters of the raw string, any transformations performed in phases 1 and 2 (universal-character-names and line splicing) are reverted; this reversion shall apply before any d-char, r-char, or delimiting parenthesis is identified. The raw string literal is defined as the shortest sequence of characters that matches the raw-string pattern

encoding-prefix \text{opt} \ R \ raw-string
— Otherwise, if the next three characters are `<::` and the subsequent character is neither `:` nor `>`, the `<` is treated as a preprocessing token by itself and not as the first character of the alternative token `<:`.

— Otherwise, the next preprocessing token is the longest sequence of characters that could constitute a preprocessing token, even if that would cause further lexical analysis to fail, except that a *header-name* (5.8) is only formed within a `#include` directive (19.2).

```
#define R "x"
const char* s = R"y"; // ill-formed raw string, not "x" "y"
```

—end example]

4 [Example: The program fragment `0xe+foo` is parsed as a preprocessing number token (one that is not a valid floating or integer literal token), even though a parse as three preprocessing tokens `0xe`, `+`, and `foo` might produce a valid expression (for example, if `foo` were a macro defined as `1`). Similarly, the program fragment `1E1` is parsed as a preprocessing number (one that is a valid floating literal token), whether or not `E` is a macro name. —end example]

5 [Example: The program fragment `x+++++y` is parsed as `x ++ ++ + y`, which, if `x` and `y` have integral types, violates a constraint on increment operators, even though the parse `x ++ + ++ y` might yield a correct expression. —end example]

### 5.5 Alternative tokens

Alternative token representations are provided for some operators and punctuators.

In all respects of the language, each alternative token behaves the same, respectively, as its primary token, except for its spelling.

The set of alternative tokens is defined in Table 1.

<table>
<thead>
<tr>
<th>Alternative</th>
<th>Primary</th>
<th>Alternative</th>
<th>Primary</th>
<th>Alternative</th>
<th>Primary</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;%</code></td>
<td><code>{</code></td>

<td><code>#</code></td>
<td><code>compl</code></td>
<td><code>~</code></td>
<td><code>not_eq</code></td>
<td><code>!=</code></td>
</tr>
<tr>
<td><code>%;;</code></td>
<td><code>##</code></td>
<td><code>bitand</code></td>
<td><code>&amp;</code></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### 5.6 Tokens

<table>
<thead>
<tr>
<th>token:</th>
</tr>
</thead>
<tbody>
<tr>
<td>identifier</td>
</tr>
<tr>
<td>keyword</td>
</tr>
<tr>
<td>literal</td>
</tr>
<tr>
<td>operator</td>
</tr>
<tr>
<td>punctuator</td>
</tr>
</tbody>
</table>

There are five kinds of tokens: identifiers, keywords, literals, operators, and other separators. Blanks, horizontal and vertical tabs, newlines, formfeeds, and comments (collectively, “white space”), as described.

17) These include “digraphs” and additional reserved words. The term “digraph” (token consisting of two characters) is not perfectly descriptive, since one of the alternative preprocessing-tokens is `%:%`, and of course several primary tokens contain two characters. Nonetheless, those alternative tokens that aren’t lexical keywords are colloquially known as “digraphs”.

18) Thus the “stringized” values (19.3.2) of `[` and `<:` will be different, maintaining the source spelling, but the tokens can otherwise be freely interchanged.

19) Literals include strings and character and numeric literals.
below, are ignored except as they serve to separate tokens. [Note: Some white space is required to separate otherwise adjacent identifiers, keywords, numeric literals, and alternative tokens containing alphabetic characters. —end note]

5.7 Comments

The characters /* start a comment, which terminates with the characters */. These comments do not nest. The characters // start a comment, which terminates immediately before the next new-line character. If there is a form-feed or a vertical-tab character in such a comment, only white-space characters shall appear between it and the new-line that terminates the comment; no diagnostic is required. [Note: The comment characters //, /*, and */ have no special meaning within a // comment and are treated just like other characters. Similarly, the comment characters // and /* have no special meaning within a /* comment. —end note]

5.8 Header names

header-name:
  < h-char-sequence >
  " q-char-sequence "

h-char-sequence:
  h-char
  h-char-sequence h-char

h-char:
  any member of the source character set except new-line and >

q-char-sequence:
  q-char
  q-char-sequence q-char

q-char:
  any member of the source character set except new-line and "

[Note: Header name preprocessing tokens only appear within a #include preprocessing directive (see 5.4). —end note] The sequences in both forms of header-names are mapped in an implementation-defined manner to headers or to external source file names as specified in 19.2.

2 The appearance of either of the characters ’ or \ or of either of the character sequences /* or // in a q-char-sequence or an h-char-sequence is conditionally-supported with implementation-defined semantics, as is the appearance of the character ” in an h-char-sequence.20

5.9 Preprocessing numbers

pp-number:
  digit
  . digit
  pp-number digit
  pp-number identifier-nondigit
  pp-number ’ digit
  pp-number ’ nondigit
  pp-number e sign
  pp-number E sign
  pp-number p sign
  pp-number P sign
  pp-number .

20) Thus, a sequence of characters that resembles an escape sequence might result in an error, be interpreted as the character corresponding to the escape sequence, or have a completely different meaning, depending on the implementation.
1 Preprocessing number tokens lexically include all integer literal tokens (5.13.2) and all floating literal tokens (5.13.4).

2 A preprocessing number does not have a type or a value; it acquires both after a successful conversion to an integer literal token or a floating literal token.

5.10 Identifiers

identifier:
  identifier-nondigit
  identifier identifier-nondigit
  identifier digit

identifier-nondigit:
  nondigit
  universal-character-name

nondigit: one of
  a b c d e f g h i j k l m
  n o p q r s t u v w x y z
  A B C D E F G H I J K L M
  N O P Q R S T U V W X Y Z _

digit: one of
  0 1 2 3 4 5 6 7 8 9

An identifier is an arbitrarily long sequence of letters and digits. Each universal-character-name in an identifier shall designate a character whose encoding in ISO 10646 falls into one of the ranges specified in Table 2. The initial element shall not be a universal-character-name designating a character whose encoding falls into one of the ranges specified in Table 3. Upper- and lower-case letters are different. All characters are significant.21

Table 2 — Ranges of characters allowed

<table>
<thead>
<tr>
<th>00A8</th>

<td>90000–9FFF</td>
<td>A0000–AFFFD</td>
</tr>
<tr>
<td>B0000–BFFF</td>
<td>C0000–CFFD</td>
<td>D0000–DFFF</td>
<td>E0000–EFFFD</td>
<td></td>
</tr>
</tbody>
</table>

Table 3 — Ranges of characters disallowed initially (combining characters)

| 0300–036F | 1DC0–1DFF | 20D0–20FF | FE20–FE2F |

21) On systems in which linkers cannot accept extended characters, an encoding of the universal-character-name may be used in forming valid external identifiers. For example, some otherwise unused character or sequence of characters may be used to encode the \u in a universal-character-name. Extended characters may produce a long external identifier, but C++ does not place a translation limit on significant characters for external identifiers. In C++, upper- and lower-case letters are considered different for all identifiers, including external identifiers.
The identifiers in Table 4 have a special meaning when appearing in a certain context. When referred to in the grammar, these identifiers are used explicitly rather than using the `identifier` grammar production. Unless otherwise specified, any ambiguity as to whether a given `identifier` has a special meaning is resolved to interpret the token as a regular `identifier`.

Table 4 — Identifiers with special meaning

| override | final |

In addition, some identifiers are reserved for use by C++ implementations and shall not be used otherwise; no diagnostic is required.

- Each identifier that contains a double underscore `__` or begins with an underscore followed by an uppercase letter is reserved to the implementation for any use.

- Each identifier that begins with an underscore is reserved to the implementation for use as a name in the global namespace.

5.11 Keywords

The identifiers shown in Table 5 are reserved for use as keywords (that is, they are unconditionally treated as keywords in phase 7) except in an `attribute-token` (10.6.1):

Table 5 — Keywords

<table>
<thead>
<tr>
<th>alignas</th>
<th>continue</th>

</tr>
<tr>
<td>const_cast</td>
<td>for</td>
<td>public</td>
<td>throw</td>
<td></td>
</tr>
</tbody>
</table>

[Note: The `export` and `register` keywords are unused but are reserved for future use. — end note]

Furthermore, the alternative representations shown in Table 6 for certain operators and punctuators (5.5) are reserved and shall not be used otherwise:

Table 6 — Alternative representations

<table>
<thead>
<tr>
<th>and</th>
<th>and_eq</th>
<th>bitand</th>
<th>bitor</th>
<th>compl</th>
<th>not</th>
</tr>
</thead>
<tbody>
<tr>
<td>not_eq</td>
<td>or</td>
<td>or_eq</td>
<td>xor</td>
<td>xor_eq</td>
<td></td>
</tr>
</tbody>
</table>
5.12 Operators and punctuators

The lexical representation of C++ programs includes a number of preprocessing tokens which are used in the syntax of the preprocessor or are converted into tokens for operators and punctuators:

```
preprocessing-op-or-punct: one of
{  }    [  ]    #    ##    (  )
<:    >    <%    %>    %    %:    %:%    ;    :    ...
new    delete    ?    ::    .    .*    
+    -    *    /    %    %    -=    %==
!    !=    <=    >=    &&    ||    ++    --    ,    ->*
and    and_eq    bitand    bitor    compl    not    not_eq
or    or_eq    xor    xor_eq
```

Each `preprocessing-op-or-punct` is converted to a single token in translation phase 7 (5.2).

5.13 Literals

5.13.1 Kinds of literals

There are several kinds of literals.

```
literal:
  integer-literal
  character-literal
  floating-literal
  string-literal
  boolean-literal
  pointer-literal
  user-defined-literal
```

5.13.2 Integer literals

```
external-literal:
  binary-literal integer-suffixopt
  octal-literal integer-suffixopt
  decimal-literal integer-suffixopt
  hexadecimal-literal integer-suffixopt

binary-literal:
  0b binary-digit
  0B binary-digit
  binary-literal 'opt binary-digit

octal-literal:
  0
  octal-literal 'opt octal-digit

decimal-literal:
  nonzero-digit
  decimal-literal 'opt digit

hexadecimal-literal:
  hexadecimal-prefix hexadecimal-digit-sequence

binary-digit:
  0
  1
```

---

22) The term “literal” generally designates, in this International Standard, those tokens that are called “constants” in ISO C.
octal-digit: one of
    0 1 2 3 4 5 6 7
nonzero-digit: one of
    1 2 3 4 5 6 7 8 9
hexadecimal-prefix: one of
    0x 0X
hexadecimal-digit-sequence:
    hexadecimal-digit
    hexadecimal-digit-sequence ’opt hexadecimal-digit
hexadecimal-digit: one of
    0 1 2 3 4 5 6 7 8 9
    a b c d e f
    A B C D E F
integer-suffix:
    unsigned-suffix long-suffix opt
    unsigned-suffix long-long-suffix opt
    long-suffix unsigned-suffix opt
    long-long-suffix unsigned-suffix opt
unsigned-suffix: one of
    u U
long-suffix: one of
    l L
long-long-suffix: one of
    ll LL

An integer literal is a sequence of digits that has no period or exponent part, with optional separating single quotes that are ignored when determining its value. An integer literal may have a prefix that specifies its base and a suffix that specifies its type. The lexically first digit of the sequence of digits is the most significant. A binary integer literal (base two) begins with 0b or 0B and consists of a sequence of binary digits. An octal integer literal (base eight) begins with the digit 0 and consists of a sequence of octal digits. A decimal integer literal (base ten) begins with a digit other than 0 and consists of a sequence of decimal digits. A hexadecimal integer literal (base sixteen) begins with 0x or 0X and consists of a sequence of hexadecimal digits, which include the decimal digits and the letters a through f and A through F with decimal values ten through fifteen. [Example: The number twelve can be written 12, 014, 0XC, or 0b1100. The integer literals 1048576, 1’048’576, 0x100000, 0x10’0000, and 0’004’000’000 all have the same value. — end example]

The type of an integer literal is the first of the corresponding list in Table 7 in which its value can be represented.

<table>
<thead>
<tr>
<th>Suffix</th>
<th>Decimal literal</th>
<th>Binary, octal, or hexadecimal literal</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>int</td>
<td>int</td>
</tr>
<tr>
<td></td>
<td>long int</td>
<td>unsigned int</td>
</tr>
<tr>
<td></td>
<td>long long int</td>
<td>long int</td>
</tr>
<tr>
<td>u or U</td>
<td>unsigned int</td>
<td>unsigned long int</td>
</tr>
<tr>
<td></td>
<td>unsigned long int</td>
<td>unsigned int</td>
</tr>
</tbody>
</table>

2) The digits 8 and 9 are not octal digits.

§ 5.13.2
If an integer literal cannot be represented by any type in its list and an extended integer type (6.9.1) can represent its value, it may have that extended integer type. If all of the types in the list for the integer literal are signed, the extended integer type shall be signed. If all of the types in the list for the integer literal are unsigned, the extended integer type shall be unsigned. If the list contains both signed and unsigned types, the extended integer type may be signed or unsigned. A program is ill-formed if one of its translation units contains an integer literal that cannot be represented by any of the allowed types.

5.13.3 Character literals

character-literal:
  encoding-prefix_opt ' c-char-sequence ' 
encoding-prefix: one of
  u8  u  U  L 
c-char-sequence:
  c-char
  c-char-sequence c-char 
c-char:
  any member of the source character set except
    the single-quote ' , backslash \, or new-line character
  escape-sequence
  universal-character-name
escape-sequence:
  simple-escape-sequence
  octal-escape-sequence
  hexadecimal-escape-sequence
simple-escape-sequence: one of
  \' \" \? \\ 
  \a \b \f \n \r \t \v 
octal-escape-sequence:
  \ octal-digit 
  \ octal-digit octal-digit 
  \ octal-digit octal-digit octal-digit 
hexadecimal-escape-sequence:
  \x hexadecimal-digit hexadecimal-escape-sequence hexadecimal-digit
1. A character literal is one or more characters enclosed in single quotes, as in ‘x’, optionally preceded by \u8, \u, or L, as in u8\'w', \u'x', \U'y', or L'z', respectively.

2. A character literal that does not begin with u8, u, U, or L is an *ordinary character literal*. An ordinary character literal that contains a single c-char representable in the execution character set has type char, with value equal to the numerical value of the encoding of the c-char in the execution character set. An ordinary character literal that contains more than one c-char is a *multicharacter literal*. A multicharacter literal, or an ordinary character literal containing a single c-char not representable in the execution character set, is conditionally-supported, has type int, and has an implementation-defined value.

3. A character literal that begins with u8, such as u8\'w', is a character literal of type char, known as a *UTF-8 character literal*. The value of a UTF-8 character literal is equal to its ISO 10646 code point value, provided that the code point value is representable with a single UTF-8 code unit (that is, provided it is in the C0 Controls and Basic Latin Unicode block). If the value is not representable with a single UTF-8 code unit, the program is ill-formed. A UTF-8 character literal containing multiple c-chars is ill-formed.

4. A character literal that begins with the letter u, such as u'x', is a character literal of type char16_t. The value of a char16_t character literal containing a single c-char is equal to its ISO 10646 code point value, provided that the code point is representable with a single 16-bit code unit. (That is, provided it is a basic multi-lingual plane code point.) If the value is not representable within 16 bits, the program is ill-formed. A char16_t character literal containing multiple c-chars is ill-formed.

5. A character literal that begins with the letter U, such as U'y', is a character literal of type char32_t. The value of a char32_t character literal containing a single c-char is equal to its ISO 10646 code point value. A char32_t character literal containing multiple c-chars is ill-formed.

6. A character literal that begins with the letter L, such as L'z', is a *wide-character literal*. A wide-character literal has type wchar_t. The value of a wide-character literal containing a single c-char has value equal to the numerical value of the encoding of the c-char in the execution wide-character set, unless the c-char has no representation in the execution wide-character set, in which case the value is implementation-defined. [Note: The type wchar_t is able to represent all members of the execution wide-character set (see 6.9.1). —end note] The value of a wide-character literal containing multiple c-chars is implementation-defined.

7. Certain non-graphic characters, the single quote ’, the double quote “, the question mark ?,
{25} and the backslash \, can be represented according to Table 8. The double quote " and the question mark ?,
{25} can be represented as themselves or by the escape sequences \" and \? respectively, but the single quote ’
{25} and the backslash \ shall be represented by the escape sequences \' and \ respectively. Escape sequences
{25} in which the character following the backslash is not listed in Table 8 are conditionally-supported, with
implementation-defined semantics. An escape sequence specifies a single character.

8. The escape \
xhh consists of the backslash followed by one, two, or three octal digits that are taken to specify
the value of the desired character. The escape \
xh\hh consists of the backslash followed by x followed by one
or more hexadecimal digits that are taken to specify the value of the desired character. There is no limit to
the number of digits in a hexadecimal sequence. A sequence of octal or hexadecimal digits is terminated by
the first character that is not an octal digit or a hexadecimal digit, respectively. The value of a character
literal is implementation-defined if it falls outside of the implementation-defined range defined for char (for
character literals with no prefix) or wchar_t (for character literals prefixed by L). [Note: If the value of a
character literal prefixed by u, u8, or U is outside the range defined for its type, the program is ill-formed.
—end note]

9. A universal-character-name is translated to the encoding, in the appropriate execution character set, of
the character named. If there is no such encoding, the universal-character-name is translated to an implementation-defined encoding. [Note: In translation phase 1, a universal-character-name is introduced whenever an actual

---

24) They are intended for character sets where a character does not fit into a single byte.
25) Using an escape sequence for a question mark is supported for compatibility with ISO C++ 2014 and ISO C.
extended character is encountered in the source text. Therefore, all extended characters are described in terms of universal-character-names. However, the actual compiler implementation may use its own native character set, so long as the same results are obtained. — end note]

### 5.13.4 Floating literals

```
floating-literal:
decimal-floating-literal
hexadecimal-floating-literal
decimal-floating-literal:
  fractional-constant exponent-part_opt floating-suffix_opt
digit-sequence exponent-part floating-suffix_opt
hexadecimal-floating-literal:

fractional-constant:
  digit-sequence_opt . digit-sequence
digit-sequence
hexadecimal-fractional-constant:
  hexadecimal-digit-sequence_opt . hexadecimal-digit-sequence
  hexadecimal-digit-sequence
exponent-part:
  e sign_opt digit-sequence
  E sign_opt digit-sequence
binary-exponent-part:
  p sign_opt digit-sequence
  P sign_opt digit-sequence
sign: one of
  + -
digit-sequence:
  digit
digit-sequence _opt digit
```

§ 5.13.4 33
A floating literal consists of an optional prefix specifying a base, an integer part, a radix point, a fraction part, an e, E, p or P, an optionally signed integer exponent, and an optional type suffix. The integer and fraction parts both consist of a sequence of decimal (base ten) digits if there is no prefix, or hexadecimal (base sixteen) digits if the prefix is 0x or 0X. The floating literal is a decimal floating literal in the former case and a hexadecimal floating literal in the latter case. Optional separating single quotes in a digit-sequence or hexadecimal-digit-sequence are ignored when determining its value. [Example: The floating literals 1.602'176'565e-19 and 1.602176565e-19 have the same value. — end example] Either the integer part or the fraction part (not both) can be omitted. Either the radix point or the letter e or E and the exponent (not both) can be omitted from a decimal floating literal. The radix point (but not the exponent) can be omitted from a hexadecimal floating literal. The integer part, the optional radix point, and the optional fraction part, form the significand of the floating literal. In a decimal floating literal, the exponent, if present, indicates the power of 10 by which the significand is to be scaled. In a hexadecimal floating literal, the exponent indicates the power of 2 by which the significand is to be scaled. [Example: The floating literals 49.625 and 0xC.68p+2 have the same value. — end example] If the scaled value is in the range of representable values for its type, the result is the scaled value if representable, else the larger or smaller representable value nearest the scaled value, chosen in an implementation-defined manner. The type of a floating literal is double unless explicitly specified by a suffix. The suffixes f and F specify float, the suffixes l and L specify long double. If the scaled value is not in the range of representable values for its type, the program is ill-formed.

5.13.5 String literals

string-literal:
  encoding-prefix_opt " s-char-sequence_opt "
  encoding-prefix_opt R raw-string

s-char-sequence:
  s-char
  s-char-sequence s-char

s-char:
  any member of the source character set except
  the double-quote " , backslash \, or new-line character
  escape-sequence
  universal-character-name

raw-string:
  " d-char-sequence_opt ( r-char-sequence_opt ) d-char-sequence_opt "

r-char-sequence:
  r-char
  r-char-sequence r-char

r-char:
  any member of the source character set, except
  a right parenthesis ) followed by the initial d-char-sequence
  (which may be empty) followed by a double quote ".

d-char-sequence:
  d-char
  d-char-sequence d-char

d-char:
  any member of the basic source character set except:
  space, the left parenthesis (, the right parenthesis ), the backslash \,
  and the control characters representing horizontal tab,
  vertical tab, form feed, and newline.

§ 5.13.5
A *string-literal* is a sequence of characters (as defined in 5.13.3) surrounded by double quotes, optionally prefixed by `R`, `u8`, `u8R`, `u`, `uR`, `U`, `UR`, `L`, or `LR`, as in "...", `R"(...)"`, `u8"..."`, `u8R"**(...)**"`, `u"..."`, `uR"*(...)~("...")*"`, `U"..."`, `UR"zzz(...)zzz"`, `L"..."`, or `LR"(...)"`, respectively.

A *string-literal* that has an `R` in the prefix is a *raw string literal*. The d-char-sequence serves as a delimiter. The terminating d-char-sequence of a raw-string is the same sequence of characters as the initial d-char-sequence. A d-char-sequence shall consist of at most 16 characters.

[Note: The characters '(' and ')' are permitted in a raw-string. Thus, R"delimiter((a|b))delimiter" is equivalent to "(a|b)". — end note]

A source-file new-line in a raw string literal results in a new-line in the resulting execution string literal. Assuming no whitespace at the beginning of lines in the following example, the assert will succeed:

```c
const char* p = R"(a\nb\nc)";
assert(std::strcmp(p, "a\\nb\nc") == 0);
— end note]
```

[Example: The raw string

R"a("\n  )\n a"
](a")

is equivalent to "\n)\na\n". The raw string

R"(??)" is equivalent to "\?\?". The raw string

R"#(  )??="

)" is equivalent to "\n)\n?\?=". — end example]

After translation phase 6, a *string-literal* that does not begin with an encoding-prefix is an *ordinary string literal*, and is initialized with the given characters.

A *string-literal* that begins with `u8`, such as `u8"asdf"`, is a *UTF-8 string literal*.

Ordinary string literals and UTF-8 string literals are also referred to as narrow string literals. A narrow string literal has type “array of `n` const char”, where `n` is the size of the string as defined below, and has static storage duration (6.7).

For a UTF-8 string literal, each successive element of the object representation (6.9) has the value of the corresponding code unit of the UTF-8 encoding of the string.

A *string-literal* that begins with `u`, such as `u"asdf"`, is a *char16_t string literal*. A char16_t string literal has type “array of `n` const char16_t”, where `n` is the size of the string as defined below; it is initialized with the given characters. A single c-char may produce more than one char16_t character in the form of surrogate pairs.

A *string-literal* that begins with `U`, such as `U"asdf"`, is a *char32_t string literal*. A char32_t string literal has type “array of `n` const char32_t”, where `n` is the size of the string as defined below; it is initialized with the given characters.

A *string-literal* that begins with `L`, such as `L"asdf"`, is a *wide string literal*. A wide string literal has type “array of `n` const wchar_t”, where `n` is the size of the string as defined below; it is initialized with the given characters.
In translation phase 6 (5.2), adjacent *string-literals* are concatenated. If both *string-literals* have the same *encoding-prefix*, the resulting concatenated string literal has that *encoding-prefix*. If one *string-literal* has no *encoding-prefix*, it is treated as a *string-literal* of the same *encoding-prefix* as the other operand. If a UTF-8 string literal token is adjacent to a wide string literal token, the program is ill-formed. Any other concatenations are conditionally-supported with implementation-defined behavior. [Note: This concatenation is an interpretation, not a conversion. Because the interpretation happens in translation phase 6 (after each character from a string literal has been translated into a value from the appropriate character set), a *string-literal*'s initial rawness has no effect on the interpretation or well-formedness of the concatenation. — end note] Table 9 has some examples of valid concatenations.

<table>
<thead>
<tr>
<th>Source</th>
<th>Means</th>
</tr>
</thead>
<tbody>
<tr>
<td>\u&quot;a&quot;</td>
<td>\u&quot;b&quot;</td>
</tr>
<tr>
<td>\u&quot;a&quot;</td>
<td>&quot;b&quot;</td>
</tr>
<tr>
<td>\u&quot;a&quot;</td>
<td>&quot;b&quot;</td>
</tr>
<tr>
<td>\u&quot;a&quot;</td>
<td>\u&quot;b&quot;</td>
</tr>
</tbody>
</table>

Characters in concatenated strings are kept distinct.

[Example:
"\xA" "B"
contains the two characters '\xA' and 'B' after concatenation (and not the single hexadecimal character 'xAB'). — end example]

After any necessary concatenation, in translation phase 7 (5.2), '\0' is appended to every string literal so that programs that scan a string can find its end.

Escape sequences and *universal-character-names* in non-raw string literals have the same meaning as in character literals (5.13.3), except that the single quote ' is representable either by itself or by the escape sequence \, and the double quote " shall be preceded by a \, and except that a *universal-character-name* in a char16_t string literal may yield a surrogate pair. In a narrow string literal, a *universal-character-name* may map to more than one char element due to multibyte encoding. The size of a char32_t or wide string literal is the total number of escape sequences, *universal-character-names*, and other characters, plus one for the terminating u'\0' or L'\0'. The size of a char16_t string literal is the total number of escape sequences, *universal-character-names*, and other characters, plus one for each character requiring a surrogate pair, plus one for the terminating u'\0'. [Note: The size of a char16_t string literal is the number of code units, not the number of characters. — end note] Within char32_t and char16_t string literals, any *universal-character-names* shall be within the range 0x0 to 0x10FFFF. The size of a narrow string literal is the total number of escape sequences and other characters, plus at least one for the multibyte encoding of each *universal-character-name*, plus one for the terminating '\0'.

Evaluating a *string-literal* results in a string literal object with static storage duration, initialized from the given characters as specified above. Whether all string literals are distinct (that is, are stored in nonoverlapping objects) and whether successive evaluations of a *string-literal* yield the same or a different object is unspecified. [Note: The effect of attempting to modify a string literal is undefined. — end note]

5.13.6 Boolean literals

boolean-literal:
    false
    true

The Boolean literals are the keywords *false* and *true*. Such literals are prvalues and have type bool.
5.13.7 Pointer literals

`nullptr`

The pointer literal is the keyword `nullptr`. It is a prvalue of type `std::nullptr_t`. [Note: `std::nullptr_t` is a distinct type that is neither a pointer type nor a pointer to member type; rather, a prvalue of this type is a null pointer constant and can be converted to a null pointer value or null member pointer value. See 7.11 and 7.12. — end note]

5.13.8 User-defined literals

`user-defined-literal`:
- `user-defined-integer-literal`
- `user-defined-floating-literal`
- `user-defined-string-literal`
- `user-defined-character-literal`

`user-defined-integer-literal`:
- `decimal-literal ud-suffix`
- `octal-literal ud-suffix`
- `hexadecimal-literal ud-suffix`
- `binary-literal ud-suffix`

`user-defined-floating-literal`:
- `fractional-constant exponent-part opt ud-suffix`
- `digit-sequence exponent-part ud-suffix`
- `hexadecimal-prefix hexadecimal-fractional-constant binary-exponent-part ud-suffix`
- `hexadecimal-prefix hexadecimal-digit-sequence binary-exponent-part ud-suffix`

`user-defined-string-literal`:
- `string-literal ud-suffix`

`user-defined-character-literal`:
- `character-literal ud-suffix`

`ud-suffix`:
- `identifier`

1 If a token matches both `user-defined-literal` and another `literal` kind, it is treated as the latter. [Example: `123_km` is a `user-defined-literal`, but `12LL` is an `integer-literal`. — end example] The syntactic non-terminal preceding the `ud-suffix` in a `user-defined-literal` is taken to be the longest sequence of characters that could match that non-terminal.

2 A `user-defined-literal` is treated as a call to a literal operator or literal operator template (16.5.8). To determine the form of this call for a given `user-defined-literal L` with `ud-suffix X`, the `literal-operator-id` whose literal suffix identifier is `X` is looked up in the context of `L` using the rules for unqualified name lookup (6.4.1). Let `S` be the set of declarations found by this lookup. `S` shall not be empty.

3 If `L` is a `user-defined-integer-literal`, let `n` be the literal without its `ud-suffix`. If `S` contains a literal operator with parameter type `unsigned long long`, the literal `L` is treated as a call of the form

```
operator "" X(nULL)
```

Otherwise, `S` shall contain a raw literal operator or a literal operator template (16.5.8) but not both. If `S` contains a raw literal operator, the literal `L` is treated as a call of the form

```
operator "" X("n")
```

Otherwise (`S` contains a literal operator template), `L` is treated as a call of the form

```
operator "" X<"c1", "c2", ... "ck">()
```
where \( n \) is the source character sequence \( c_1c_2...c_k \). [Note: The sequence \( c_1c_2...c_k \) can only contain characters from the basic source character set. —end note]

4 If \( L \) is a user-defined-floating-literal, let \( f \) be the literal without its ud-suffix. If \( S \) contains a literal operator with parameter type \( \text{long double} \), the literal \( L \) is treated as a call of the form

\[
\text{operator } \Rightarrow X(f L)
\]

Otherwise, \( S \) shall contain a raw literal operator or a literal operator template (16.5.8) but not both. If \( S \) contains a raw literal operator, the literal \( L \) is treated as a call of the form

\[
\text{operator } \Rightarrow X("f")
\]

Otherwise (\( S \) contains a literal operator template), \( L \) is treated as a call of the form

\[
\text{operator } \Rightarrow X(<'c_1', 'c_2', ..., 'c_k'>())
\]

where \( f \) is the source character sequence \( c_1c_2...c_k \). [Note: The sequence \( c_1c_2...c_k \) can only contain characters from the basic source character set. —end note]

5 If \( L \) is a user-defined-string-literal, let \( str \) be the literal without its ud-suffix and let \( len \) be the number of code units in \( str \) (i.e., its length excluding the terminating null character). The literal \( L \) is treated as a call of the form

\[
\text{operator } \Rightarrow X(str, len)
\]

6 If \( L \) is a user-defined-character-literal, let \( ch \) be the literal without its ud-suffix. \( S \) shall contain a literal operator (16.5.8) whose only parameter has the type of \( ch \) and the literal \( L \) is treated as a call of the form

\[
\text{operator } \Rightarrow X(ch)
\]

[ Example:

\[
\begin{align*}
\text{long double } &\Rightarrow \_w(\text{long double}); \\
\text{std::string } &\Rightarrow \_w(\text{const char16_t*}, \text{std::size_t}); \\
\text{unsigned } &\Rightarrow \_w(\text{const char*}); \\
\text{int main() \{} \\
1.2_w; &\Rightarrow \text{calls operator } \Rightarrow \_w(1.2L) \\
u"one"_w; &\Rightarrow \text{calls operator } \Rightarrow \_w(u"one", 3) \\
12_w; &\Rightarrow \text{calls operator } \Rightarrow \_w("12") \\
"two"_w; &\Rightarrow \text{error: no applicable literal operator} \\
\text{\}}
\end{align*}
\]

— end example]

8 In translation phase 6 (5.2), adjacent string literals are concatenated and user-defined-string-literals are considered string literals for that purpose. During concatenation, ud-suffixes are removed and ignored and the concatenation process occurs as described in 5.13.5. At the end of phase 6, if a string literal is the result of a concatenation involving at least one user-defined-string-literal, all the participating user-defined-string-literals shall have the same ud-suffix and that suffix is applied to the result of the concatenation.

[ Example:

\[
\text{int main() \{} \\
\text{L"A" "B" "C"}_x; // OK: same as L"ABC"}_x \\
\text{"P"}_x "Q" "R"}_y; // error: two different ud-suffixes \\
\text{\}}
\]

— end example]
6 Basic concepts

1 [Note: This Clause presents the basic concepts of the C++ language. It explains the difference between an object and a name and how they relate to the value categories for expressions. It introduces the concepts of a declaration and a definition and presents C++’s notion of type, scope, linkage, and storage duration. The mechanisms for starting and terminating a program are discussed. Finally, this Clause presents the fundamental types of the language and lists the ways of constructing compound types from these. — end note]

2 [Note: This Clause does not cover concepts that affect only a single part of the language. Such concepts are discussed in the relevant Clauses. — end note]

3 An entity is a value, object, reference, function, enumerator, type, class member, bit-field, template, template specialization, namespace, or parameter pack.

4 A name is a use of an identifier (5.10), operator-function-id (16.5), literal-operator-id (16.5.8), conversion-function-id (15.3.2), or template-id (17.2) that denotes an entity or label (9.6.4, 9.1).

5 Every name that denotes an entity is introduced by a declaration. Every name that denotes a label is introduced either by a goto statement (9.6.4) or a labeled-statement (9.1).

6 A variable is introduced by the declaration of a reference other than a non-static data member or of an object. The variable’s name, if any, denotes the reference or object.

7 Some names denote types or templates. In general, whenever a name is encountered it is necessary to determine whether that name denotes one of these entities before continuing to parse the program that contains it. The process that determines this is called name lookup (6.4).

8 Two names are the same if

(8.1) — they are identifiers composed of the same character sequence, or
(8.2) — they are operator-function-ids formed with the same operator, or
(8.3) — they are conversion-function-ids formed with the same type, or
(8.4) — they are template-ids that refer to the same class, function, or variable (17.4), or
(8.5) — they are the names of literal operators (16.5.8) formed with the same literal suffix identifier.

9 A name used in more than one translation unit can potentially refer to the same entity in these translation units depending on the linkage (6.5) of the name specified in each translation unit.

6.1 Declarations and definitions

1 A declaration (Clause 10) may introduce one or more names into a translation unit or redefine names introduced by previous declarations. If so, the declaration specifies the interpretation and attributes of these names. A declaration may also have effects including:

(1.1) — a static assertion (Clause 10),
(1.2) — controlling template instantiation (17.7.2),
(1.3) — guiding template argument deduction for constructors (17.9),
(1.4) — use of attributes (Clause 10), and
(1.5) — nothing (in the case of an empty-declaration).

2 A declaration is a definition unless
it declares a function without specifying the function’s body (11.4),

— it contains the `extern` specifier (10.1.1) or a `linkage-specification`\(^{26}\) (10.5) and neither an `initializer` nor a `function-body`,

— it declares a non-inline static data member in a class definition (12.2, 12.2.3),

— it declares a static data member outside a class definition and the variable was defined within the class with the `constexpr` specifier (this usage is deprecated; see D.1),

— it is a class name declaration (12.1),

— it is an `opaque-enum-declaration` (10.2),

— it is a `template-parameter` (17.1),

— it is a `parameter-declaration` (11.3.5) in a function declarator that is not the `declarator` of a `function-definition`,

— it is a `typedef` declaration (10.1.3),

— it is an `alias-declaration` (10.1.3),

— it is a `using-declaration` (10.3.3),

— it is a `deduction-guide` (17.9),

— it is a `static_assert-declaration` (Clause 10),

— it is an `attribute-declaration` (Clause 10),

— it is an `empty-declaration` (Clause 10),

— it is a `using-directive` (10.3.4),

— it is an explicit instantiation declaration (17.7.2), or

— it is an explicit specialization (17.7.3) whose `declaration` is not a definition.

\[\text{Example:}\] All but one of the following are definitions:

```c
int a; // defines a
extern const int c = 1; // defines c
int f(int x) { return x+a; } // defines f and defines x
struct S { int a; int b; }; // defines S, S::a, and S::b
struct X { // defines X
  int x;      // defines non-static data member x
  static int y; // declares static data member y
X(): x(0) { } // defines a constructor of X
};
int X::y = 1; // defines X::y
enum { up, down }; // defines up and down
namespace N { int d; } // defines N and N::d
namespace N1 = N; // defines N1
X anX; // defines anX
```

whereas these are just declarations:

```c
extern int a; // declares a
extern const int c; // declares c
int f(int); // declares f
struct S; // declares S
typedef int Int; // declares Int
```

\(\text{26)}\) Appearing inside the braced-enclosed `declaration-seq` in a `linkage-specification` does not affect whether a declaration is a definition.
extern X anotherX;    // declares anotherX
using N::d;            // declares d

— end example] 3

[ Note: In some circumstances, C++ implementations implicitly define the default constructor (15.1), copy
constructor (15.8), move constructor (15.8), copy assignment operator (15.8), move assignment operator (15.8),
or destructor (15.4) member functions. — end note] [ Example: Given

```cpp
#include <string>

struct C {
    std::string s;       // std::string is the standard library class (Clause 24)
};

int main() {
    C a;
    C b = a;
    b = a;
}
```

the implementation will implicitly define functions to make the definition of C equivalent to

```cpp
struct C {
    std::string s;
    C() : s() { }
    C(const C& x): s(x.s) { }
    C(C&& x): s(static_cast<std::string&&>(x.s)) { }
    //: s(std::move(x.s)) { }
    C& operator=(const C& x) { s = x.s; return *this; }
    C& operator=(C&& x) { s = static_cast<std::string&&>(x.s); return *this; }
    //: s = std::move(x.s); return *this; }
    ~C() { }
};
```

— end example] 4

[ Note: A class name can also be implicitly declared by an elaborated-type-specifier (10.1.7.3). — end note] 5

A program is ill-formed if the definition of any object gives the object an incomplete type (6.9).

6.2 One-definition rule [basic.def.odr] 1

No translation unit shall contain more than one definition of any variable, function, class type, enumeration
type, or template.

2 An expression is potentially evaluated unless it is an unevaluated operand (Clause 8) or a subexpression
thereof. The set of potential results of an expression e is defined as follows:

(2.1) — If e is an id-expression (8.1.4), the set contains only e.
(2.2) — If e is a subscripting operation (8.2.1) with an array operand, the set contains the potential results of
that operand.
(2.3) — If e is a class member access expression (8.2.5), the set contains the potential results of the object
expression.
(2.4) — If e is a pointer-to-member expression (8.5) whose second operand is a constant expression, the set
contains the potential results of the object expression.
(2.5) — If e has the form (e1), the set contains the potential results of e1.
(2.6) — If e is a glvalue conditional expression (8.16), the set is the union of the sets of potential results of the

§ 6.2
second and third operands.

(2.7) If $e$ is a comma expression (8.19), the set contains the potential results of the right operand.

(2.8) Otherwise, the set is empty.

[Note: This set is a (possibly-empty) set of id-expressions, each of which is either $e$ or a subexpression of $e$.]

[Example: In the following example, the set of potential results of the initializer of $n$ contains the first $S::x$ subexpression, but not the second $S::x$ subexpression.]

```c
struct S { static const int x = 0; };  
const int &f(const int &r);  
n = b ? (1, S::x) // S::x is not odr-used here  
     : f(S::x); // S::x is odr-used here, so a definition is required
```

[end note]

A variable $x$ whose name appears as a potentially-evaluated expression $ex$ is odr-used by $ex$ unless applying the lvalue-to-rvalue conversion (7.1) to $x$ yields a constant expression (8.20) that does not invoke any non-trivial functions and, if $x$ is an object, $ex$ is an element of the set of potential results of an expression $e$, where either the lvalue-to-rvalue conversion (7.1) is applied to $e$, or $e$ is a discarded-value expression (Clause 8). This is odr-used if it appears as a potentially-evaluated expression (including as the result of the implicit transformation in the body of a non-static member function (12.2.2)). A virtual member function is odr-used if it is not pure. A function whose name appears as a potentially-evaluated expression is odr-used if it is the unique lookup result or the selected member of a set of overloaded functions (6.4, 16.3, 16.4), unless it is a pure virtual function and either its name is not explicitly qualified or the expression forms a pointer to member (8.3.1). [Note: This covers calls to named functions (8.2.2), operator overloading (Clause 16), user-defined conversions (15.3.2), allocation functions for placement new-expressions (8.3.4), as well as non-default initialization (11.6). A constructor selected to copy or move an object of class type is odr-used even if the call is actually elided by the implementation (15.8). —end note] An allocation or deallocation function for a class is odr-used by a new-expression appearing in a potentially-evaluated expression as specified in 8.3.4 and 15.5. A deallocation function for a class is odr-used by a delete expression appearing in a potentially-evaluated expression as specified in 8.3.5 and 15.5. A non-placement allocation or deallocation function for a class is odr-used by the definition of the destructor of that class, or by being selected by the lookup at the point of definition of a virtual destructor (15.4). An assignment operator function in a class is odr-used by an implicitly-defined copy-assignment or move-assignment function for another class as specified in 15.8. A constructor for a class is odr-used as specified in 11.6. A destructor for a class is odr-used if it is potentially invoked (15.4).

Every program shall contain exactly one definition of every non-inline function or variable that is odr-used in that program outside of a discarded statement (9.4.1); no diagnostic required. The definition can appear explicitly in the program, it can be found in the standard or a user-defined library, or (when appropriate) it is implicitly defined (see 15.1, 15.4 and 15.8). An inline function or variable shall be defined in every translation unit in which it is odr-used outside of a discarded statement.

Exactly one definition of a class is required in a translation unit if the class is used in a way that requires the class type to be complete. [Example: The following complete translation unit is well-formed, even though it never defines X:]

```c
struct X;  // declare X as a struct type
struct X* x1;  // use X in pointer formation
X* x2;  // use X in pointer formation
```

[end example] [Note: The rules for declarations and expressions describe in which contexts complete class

27) An implementation is not required to call allocation and deallocation functions from constructors or destructors; however, this is a permissible implementation technique.
types are required. A class type $T$ must be complete if:

- an object of type $T$ is defined (6.1), or
- a non-static class data member of type $T$ is declared (12.2), or
- $T$ is used as the allocated type or array element type in a new-expression (8.3.4), or
- an lvalue-to-rvalue conversion is applied to a glvalue referring to an object of type $T$ (7.1), or
- an expression is converted (either implicitly or explicitly) to type $T$ (Clause 7, 8.2.3, 8.2.7, 8.2.9, 8.4), or
- an expression that is not a null pointer constant, and has type other than cv void*, is converted to the type pointer to $T$ or reference to $T$ using a standard conversion (Clause 7), a dynamic_cast (8.2.7) or a static_cast (8.2.9), or
- a class member access operator is applied to an expression of type $T$ (8.2.5), or
- the typeid operator (8.2.8) or the sizeof operator (8.3.3) is applied to an operand of type $T$, or
- a function with a return type or argument type of type $T$ is defined (6.1) or called (8.2.2), or
- a class with a base class of type $T$ is defined (Clause 13), or
- an lvalue of type $T$ is assigned to (8.18), or
- the type $T$ is the subject of an alignof expression (8.3.6), or
- an exception-declaration has type $T$, reference to $T$, or pointer to $T$ (18.3).

— end note

There can be more than one definition of a class type (Clause 12), enumeration type (10.2), inline function with external linkage (10.1.6), inline variable with external linkage (10.1.6), class template (Clause 17), non-static function template (17.5.6), static data member of a class template (17.5.1.3), member function of a class template (17.5.1.1), or template specialization for which some template parameters are not specified (17.7, 17.5.5) in a program provided that each definition appears in a different translation unit, and provided the definitions satisfy the following requirements. Given such an entity named $D$ defined in more than one translation unit, then

- each definition of $D$ shall consist of the same sequence of tokens; and
- in each definition of $D$, corresponding names, looked up according to 6.4, shall refer to an entity defined within the definition of $D$, or shall refer to the same entity, after overload resolution (16.3) and after matching of partial template specialization (17.8.3), except that a name can refer to
  - a non-volatile const object with internal or no linkage if the object
    - has the same literal type in all definitions of $D$,
    - is initialized with a constant expression (8.20),
    - is not odr-used in any definition of $D$, and
    - has the same value in all definitions of $D$,
  or
  - a reference with internal or no linkage initialized with a constant expression such that the reference refers to the same entity in all definitions of $D$;
  and
- in each definition of $D$, corresponding entities shall have the same language linkage; and
- in each definition of $D$, the overloaded operators referred to, the implicit calls to conversion functions, constructors, operator new functions and operator delete functions, shall refer to the same function, or to a function defined within the definition of $D$; and

§ 6.2
(6.5) — in each definition of D, a default argument used by an (implicit or explicit) function call is treated as if its token sequence were present in the definition of D; that is, the default argument is subject to the requirements described in this paragraph (and, if the default argument has subexpressions with default arguments, this requirement applies recursively).\(^{28}\)

(6.6) — if D is a class with an implicitly-declared constructor (15.1), it is as if the constructor was implicitly defined in every translation unit where it is odr-used, and the implicit definition in every translation unit shall call the same constructor for a subobject of D. [Example:

```
// translation unit 1:
struct X {
    X(int, int);
    X(int, int, int);
};
X::X(int, int = 0) { }
class D {
    X x = 0;
};
D d1; //X(int, int) called by D()

// translation unit 2:
struct X {
    X(int, int);
    X(int, int, int);
};
X::X(int, int = 0, int = 0) { }
class D {
    X x = 0;
};
D d2;  //X(int, int, int) called by D();

//D()’s implicit definition violates the ODR
```

— end example]

If D is a template and is defined in more than one translation unit, then the preceding requirements shall apply both to names from the template’s enclosing scope used in the template definition (17.6.3), and also to dependent names at the point of instantiation (17.6.2). If the definitions of D satisfy all these requirements, then the behavior is as if there were a single definition of D. If the definitions of D do not satisfy these requirements, then the behavior is undefined.

### 6.3 Scope

#### 6.3.1 Declarative regions and scopes

Every name is introduced in some portion of program text called a *declarative region*, which is the largest part of the program in which that name is *valid*, that is, in which that name may be used as an unqualified name to refer to the same entity. In general, each particular name is valid only within some possibly discontiguous portion of program text called its *scope*. To determine the scope of a declaration, it is sometimes convenient to refer to the potential scope of a declaration. The scope of a declaration is the same as its potential scope unless the potential scope contains another declaration of the same name. In that case, the potential scope of the declaration in the inner (contained) declarative region is excluded from the scope of the declaration in the outer (containing) declarative region.

[Example: In

```
    int j = 24;
```

---

\(^{28}\) 11.3.6 describes how default argument names are looked up.
int main() {
    int i = j, j;
    j = 42;
}

the identifier j is declared twice as a name (and used twice). The declarative region of the first j includes
the entire example. The potential scope of the first j begins immediately after that j and extends to the end
of the program, but its (actual) scope excludes the text between the , and the }. The declarative region of
the second declaration of j (the j immediately before the semicolon) includes all the text between { and },
but its potential scope excludes the declaration of i. The scope of the second declaration of j is the same as
its potential scope. —end example]

3 The names declared by a declaration are introduced into the scope in which the declaration occurs, except
that the presence of a friend specifier (14.3), certain uses of the elaborated-type-specifier (10.1.7.3), and
using-directives (10.3.4) alter this general behavior.

4 Given a set of declarations in a single declarative region, each of which specifies the same unqualified name,
— (4.1) they shall all refer to the same entity, or all refer to functions and function templates; or
— (4.2) exactly one declaration shall declare a class name or enumeration name that is not a typedef name
and the other declarations shall all refer to the same variable, non-static data member, or enumerator,
or all refer to functions and function templates; in this case the class name or enumeration name is
hidden (6.3.10). [Note: A namespace name or a class template name must be unique in its declarative
region (10.3.2, Clause 17). —end note]

[ Note: These restrictions apply to the declarative region into which a name is introduced, which is not neces-
sarily the same as the region in which the declaration occurs. In particular, elaborated-type-specifiers (10.1.7.3)
and friend declarations (14.3) may introduce a (possibly not visible) name into an enclosing namespace; these
restrictions apply to that region. Local extern declarations (6.5) may introduce a name into the declarative
region where the declaration appears and also introduce a (possibly not visible) name into an enclosing
namespace; these restrictions apply to both regions. —end note]

5 [ Note: The name lookup rules are summarized in 6.4. —end note]

6.3.2 Point of declaration [basic.scope.pdecl]

1 The point of declaration for a name is immediately after its complete declarator (Clause 11) and before its
initializer (if any), except as noted below. [Example:

    unsigned char x = 12;
    { unsigned char x = x; }

Here the second x is initialized with its own (indeterminate) value. —end example]

2 [ Note: a name from an outer scope remains visible up to the point of declaration of the name that hides it.
[Example:

    const int i = 2;
    { int i[i]; }  

declares a block-scope array of two integers. —end example] —end note]

3 The point of declaration for a class or class template first declared by a class-specifier is immediately after
the identifier or simple-template-id (if any) in its class-head (Clause 12). The point of declaration for
an enumeration is immediately after the identifier (if any) in either its enum-specifier (10.2) or its first
opaque-enum-declaration (10.2), whichever comes first. The point of declaration of an alias or alias template
immediately follows the type-id to which the alias refers.

4 The point of declaration of a using-declarator that does not name a constructor is immediately after the
using-declarator (10.3.3).
The point of declaration for an enumerator is immediately after its \textit{enumerator-definition}. \textbf{[Example:}
\begin{verbatim}
const int x = 12;
{ enum { x = x }; }
\end{verbatim}
Here, the enumerator \texttt{x} is initialized with the value of the constant \texttt{x}, namely 12. \textbf{—end example]}

After the point of declaration of a class member, the member name can be looked up in the scope of its class. \textbf{[Note: This is true even if the class is an incomplete class. For example,}
\begin{verbatim}
struct X {
  enum E { z = 16 }
  int b[X::z]; // OK
};
\end{verbatim}\textbf{—end note]}

The point of declaration of a class first declared in an \textit{elaborated-type-specifier} is as follows:
\begin{enumerate}
  \item for a declaration of the form
    \begin{verbatim}
    class-key attribute-specifier-seq opt identifier ;
    \end{verbatim}
    the \textit{identifier} is declared to be a \textit{class-name} in the scope that contains the declaration, otherwise
  \item for an \textit{elaborated-type-specifier} of the form
    \begin{verbatim}
    class-key identifier
    \end{verbatim}
    if the \textit{elaborated-type-specifier} is used in the \textit{decl-specifier-seq} or \textit{parameter-declaration-clause} of a function defined in namespace scope, the \textit{identifier} is declared as a \textit{class-name} in the namespace that contains the declaration; otherwise, except as a friend declaration, the \textit{identifier} is declared in the smallest namespace or block scope that contains the declaration. \textbf{[Note: These rules also apply within templates. —end note] [Note: Other forms of \textit{elaborated-type-specifier} do not declare a new name, and therefore must refer to an existing \textit{type-name}. See 6.4.4 and 10.1.7.3. —end note]}
\end{enumerate}

The point of declaration for an \textit{injected-class-name} (Clause 12) is immediately following the opening brace of the class definition.

The point of declaration for a function-local predefined variable (11.4) is immediately before the \textit{function-body} of a function definition.

The point of declaration for a template parameter is immediately after its complete \textit{template-parameter}. \textbf{[Example:}
\begin{verbatim}
typedef unsigned char T;
template<class T = T // lookup finds the typedef name of unsigned char
    , T // lookup finds the template parameter
    N = 0> struct A { 
    
    —end example]}

\textbf{[Note: Friend declarations refer to functions or classes that are members of the nearest enclosing namespace, but they do not introduce new names into that namespace (10.3.1.2). Function declarations at block scope and variable declarations with the \texttt{extern} specifier at block scope refer to declarations that are members of an enclosing namespace, but they do not introduce new names into that scope. —end note]}

\textbf{[Note: For point of instantiation of a template, see 17.6.4.1. —end note]}

\textbf{6.3.3 Block scope \hfill [basic.scope.block]}

A name declared in a block (9.3) is local to that block; it has \textit{block scope}. Its potential scope begins at its point of declaration (6.3.2) and ends at the end of its block. A variable declared at block scope is a \textit{local variable}.  

\section*{§ 6.3.3}
The potential scope of a function parameter name (including one appearing in a lambda-declarator) or of a function-local predefined variable in a function definition (11.4) begins at its point of declaration. If the function has a function-try-block the potential scope of a parameter or of a function-local predefined variable ends at the end of the last associated handler, otherwise it ends at the end of the outermost block of the function definition. A parameter name shall not be redeclared in the outermost block of the function definition nor in the outermost block of any handler associated with a function-try-block.

The name declared in an exception-declaration is local to the handler and shall not be redeclared in the outermost block of the handler.

Names declared in the init-statement, the for-range-declaration, and in the condition of if, while, for, and switch statements are local to the if, while, for, or switch statement (including the controlled statement), and shall not be redeclared in a subsequent condition of that statement nor in the outermost block (or, for the if statement, any of the outermost blocks) of the controlled statement; see 9.4.

6.3.4 Function prototype scope
[basic.scope.proto]

In a function declaration, or in any function declarator except the declarator of a function definition (11.4), names of parameters (if supplied) have function prototype scope, which terminates at the end of the nearest enclosing function declarator.

6.3.5 Function scope
[basic.funscope]

Labels (9.1) have function scope and may be used anywhere in the function in which they are declared. Only labels have function scope.

6.3.6 Namespace scope
[basic.scope.namespace]

The declarative region of a namespace-definition is its namespace-body. Entities declared in a namespace-body are said to be members of the namespace, and names introduced by these declarations into the declarative region of the namespace are said to be member names of the namespace. A namespace member name has namespace scope. Its potential scope includes its namespace from the name’s point of declaration (6.3.2) onwards; and for each using-directive (10.3.4) that nominates the member’s namespace, the member’s potential scope includes that portion of the potential scope of the using-directive that follows the member’s point of declaration. [Example:

```c
namespace N {
  int i;
  int g(int a) { return a; }
  int j();
  void q();
}
namespace { int l=1; }
// the potential scope of l is from its point of declaration to the end of the translation unit

namespace N {
  int g(char a) { // overloads N::g(int)
    return l+a; // l is from unnamed namespace
  }

  int i; // error: duplicate definition
  int j(); // OK: duplicate function declaration

  int j() { // OK: definition of N::j()
    return g(i); // calls N::g(int)
  }
  int q(); // error: different return type
```

§ 6.3.6
A namespace member can also be referred to after the `::` scope resolution operator (8.1) applied to the name of its namespace or the name of a namespace which nominates the member’s namespace in a using-directive; see 6.4.3.2.

The outermost declarative region of a translation unit is also a namespace, called the global namespace. A name declared in the global namespace has global namespace scope (also called global scope). The potential scope of such a name begins at its point of declaration (6.3.2) and ends at the end of the translation unit that is its declarative region. A name with global namespace scope is said to be a global name.

### 6.3.7 Class scope

The potential scope of a name declared in a class consists not only of the declarative region following the name’s point of declaration, but also of all function bodies, default arguments, noexcept-specifiers, and brace-or-equal-initializers of non-static data members in that class (including such things in nested classes).

A name used in a class shall refer to the same declaration in its context and when re-evaluated in the completed scope of the class. No diagnostic is required for a violation of this rule.

A name declared within a member function hides a declaration of the same name whose scope extends to or past the end of the member function’s class.

The potential scope of a declaration that extends to or past the end of a class definition also extends to the regions defined by its member definitions, even if the members are defined lexically outside the class (this includes static data member definitions, nested class definitions, and member function definitions, including the member function body and any portion of the declarator part of such definitions which follows the declarator-id, including a parameter-declaration-clause and any default arguments (11.3.6)).

[Example:

```cpp
typedef int c;
enum { i = 1 };

class X {
    char v[i]; // error: i refers to ::i but when reevaluated is X::i
    int f() { return sizeof(c); } // OK: X::c
    char c;
    enum { i = 2 };
};

typedef char* T;
struct Y {
    T a; // error: T refers to ::T but when reevaluated is Y::T
    typedef long T;
    T b;
};

typedef int I;
class D {
    typedef I I; // error, even though no reordering involved
};

— end example]

The name of a class member shall only be used as follows:

— in the scope of its class (as described above) or a class derived (Clause 13) from its class,
(6.2) — after the . operator applied to an expression of the type of its class (8.2.5) or a class derived from its class,

(6.3) — after the -> operator applied to a pointer to an object of its class (8.2.5) or a class derived from its class,

(6.4) — after the :: scope resolution operator (8.1) applied to the name of its class or a class derived from its class.

6.3.8 Enumeration scope

The name of a scoped enumerator (10.2) has enumeration scope. Its potential scope begins at its point of declaration and terminates at the end of the enum-specifier.

6.3.9 Template parameter scope

The declarative region of the name of a template parameter of a template is the smallest template-parameter-list in which the name was introduced.

The declarative region of the name of a template parameter of a template is the smallest template-declaration in which the name was introduced. Only template parameter names belong to this declarative region; any other kind of name introduced by the declaration of a template-declaration is instead introduced into the same declarative region where it would be introduced as a result of a non-template declaration of the same name. [Example:

```cpp
namespace N {
    template<class T> struct A { };          // #1
    template<class U> void f(U) { }          // #2
    struct B {
        template<class V> friend int g(struct C*);  // #3
    };
}  
```

The declarative regions of T, U and V are the template-declarations on lines #1, #2, and #3, respectively. But the names A, f, g and C all belong to the same declarative region — namely, the namespace-body of N. (g is still considered to belong to this declarative region in spite of its being hidden during qualified and unqualified name lookup.) — end example]

3 The potential scope of a template parameter name begins at its point of declaration (6.3.2) and ends at the end of its declarative region. [Note: This implies that a template-parameter can be used in the declaration of subsequent template-parameters and their default arguments but cannot be used in preceding template-parameters or their default arguments. For example,

```cpp
    template<class T, T* p, class U = T> class X { /* ... */ };  
    template<class T> void f(T* p = new T);  
```

This also implies that a template-parameter can be used in the specification of base classes. For example,

```cpp
    template<class T> class X : public Array<T> { /* ... */ };  
    template<class T> class Y : public T { /* ... */ };  
```

The use of a template parameter as a base class implies that a class used as a template argument must be defined and not just declared when the class template is instantiated. — end note]

4 The declarative region of the name of a template parameter is nested within the immediately-enclosing declarative region. [Note: As a result, a template-parameter hides any entity with the same name in an enclosing scope (6.3.10). [Example:

```cpp
typedef int N;  
template<N X, typename N, template<N Y> class T> struct A;
```

§ 6.3.9
Here, \( X \) is a non-type template parameter of type \texttt{int} and \( Y \) is a non-type template parameter of the same type as the second template parameter of \( A \). \textit{— end example} \textit{— end note}

[\textbf{Note:} Because the name of a template parameter cannot be redeclared within its potential scope (17.6.1), a template parameter's scope is often its potential scope. However, it is still possible for a template parameter name to be hidden; see 17.6.1. \textit{— end note}]

\section*{6.3.10 Name hiding} \textit{[basic.scope.hiding]}

A name can be hidden by an explicit declaration of that same name in a nested declarative region or derived class (13.2).

A class name (12.1) or enumeration name (10.2) can be hidden by the name of a variable, data member, function, or enumerator declared in the same scope. If a class or enumeration name and a variable, data member, function, or enumerator are declared in the same scope (in any order) with the same name, the class or enumeration name is hidden wherever the variable, data member, function, or enumerator name is visible.

In a member function definition, the declaration of a name at block scope hides the declaration of a member of the class with the same name; see 6.3.7. The declaration of a member in a derived class (Clause 13) hides the declaration of a member of a base class of the same name; see 13.2.

During the lookup of a name qualified by a namespace name, declarations that would otherwise be made visible by a \texttt{using-directive} can be hidden by declarations with the same name in the namespace containing the \texttt{using-directive}; see 6.4.3.2.

If a name is in scope and is not hidden it is said to be \textit{visible}.

\section*{6.4 Name lookup} \textit{[basic.lookup]}

The name lookup rules apply uniformly to all names (including \texttt{typedef-names} (10.1.3), \texttt{namespace-names} (10.3), and \texttt{class-names} (12.1)) wherever the grammar allows such names in the context discussed by a particular rule. Name lookup associates the use of a name with a set of declarations (6.1) of that name. The declarations found by name lookup shall either all declare the same entity or shall all declare functions; in the latter case, the declarations are said to form a set of overloaded functions (16.1). Overload resolution (16.3) takes place after name lookup has succeeded. The access rules (Clause 14) are considered only once name lookup and function overload resolution (if applicable) have succeeded. Only after name lookup, function overload resolution (if applicable) and access checking have succeeded are the attributes introduced by the name's declaration used further in expression processing (Clause 8).

A name “looked up in the context of an expression” is looked up as an unqualified name in the scope where the expression is found.

The injected-class-name of a class (Clause 12) is also considered to be a member of that class for the purposes of name hiding and lookup.

[\textbf{Note:} 6.5 discusses linkage issues. The notions of scope, point of declaration and name hiding are discussed in 6.3. \textit{— end note}]

\section*{6.4.1 Unqualified name lookup} \textit{[basic.lookup.unqual]}

In all the cases listed in 6.4.1, the scopes are searched for a declaration in the order listed in each of the respective categories; name lookup ends as soon as a declaration is found for the name. If no declaration is found, the program is ill-formed.

The declarations from the namespace nominated by a \texttt{using-directive} become visible in a namespace enclosing the \texttt{using-directive}; see 10.3.4. For the purpose of the unqualified name lookup rules described in 6.4.1, the declarations from the namespace nominated by the \texttt{using-directive} are considered members of that enclosing namespace.
The lookup for an unqualified name used as the postfix-expression of a function call is described in 6.4.2. [Note: For purposes of determining (during parsing) whether an expression is a postfix-expression for a function call, the usual name lookup rules apply. The rules in 6.4.2 have no effect on the syntactic interpretation of an expression. For example,

```cpp
typedef int f;
namespace N {
    struct A {
        friend void f(A &);
        operator int();
        void g(A a) {
            int i = f(a); // f is the typedef, not the friend function: equivalent to int(a)
        }
    }
}
```

Because the expression is not a function call, the argument-dependent name lookup (6.4.2) does not apply and the friend function f is not found. —end note]

A name used in global scope, outside of any function, class or user-declared namespace, shall be declared before its use in global scope.

A name used in a user-declared namespace outside of the definition of any function or class shall be declared before its use in that namespace or before its use in a namespace enclosing its namespace.

In the definition of a function that is a member of namespace N, a name used after the function’s declarator-id shall be declared before its use in the block in which it is used or in one of its enclosing blocks (9.3) or shall be declared before its use in namespace N or, if N is a nested namespace, shall be declared before its use in one of N’s enclosing namespaces. [Example:

```cpp
namespace A {
    namespace N {
        void f();
    }
}
void A::N::f() {
    i = 5;
    // The following scopes are searched for a declaration of i:
    // 1) outermost block scope of A::N::f, before the use of i
    // 2) scope of namespace N
    // 3) scope of namespace A
    // 4) global scope, before the definition of A::N::f
}

—end example]

A name used in the definition of a class X outside of a member function body, default argument, noexcept-specifier, brace-or-equal-initializer of a non-static data member, or nested class definition shall be declared in one of the following ways:

(7.1) — before its use in class X or be a member of a base class of X (13.2), or
(7.2) — if X is a nested class of class Y (12.2.5), before the definition of X in Y, or shall be a member of a base class of Y (this lookup applies in turn to Y’s enclosing classes, starting with the innermost enclosing

---

29) This refers to unqualified names that occur, for instance, in a type or default argument in the parameter-declaration-clause or used in the function body.

30) This refers to unqualified names following the class name; such a name may be used in the base-clause or may be used in the class definition.
(7.3) — if \( X \) is a local class (12.4) or is a nested class of a local class, before the definition of class \( X \) in a block enclosing the definition of class \( X \), or

(7.4) — if \( X \) is a member of namespace \( N \), or is a nested class of a class that is a member of \( N \), or is a local class or a nested class within a local class of a function that is a member of \( N \), before the definition of class \( X \) in namespace \( N \) or in one of \( N \)'s enclosing namespaces.

[Example:

```cpp
namespace M {
    class B { }
};

namespace N {
    class Y : public M::B {
        class X {
            int a[i];
        };
    };
};
```

// The following scopes are searched for a declaration of \( i \):
// 1) scope of class \( N::Y::X \), before the use of \( i \)
// 2) scope of class \( N::Y \), before the definition of \( N::Y::X \)
// 3) scope of \( N::Y \)'s base class \( M::B \)
// 4) scope of namespace \( N \), before the definition of \( N::Y \)
// 5) global scope, before the definition of \( N \)

— end example] [Note: When looking for a prior declaration of a class or function introduced by a friend declaration, scopes outside of the innermost enclosing namespace scope are not considered; see 10.3.1.2. — end note] [Note: 6.3.7 further describes the restrictions on the use of names in a class definition. 12.2.5 further describes the restrictions on the use of names in nested class definitions. 12.4 further describes the restrictions on the use of names in local class definitions. — end note]

8 For the members of a class \( X \), a name used in a member function body, in a default argument, in a noexcept-specifier, in the brace-or-equal-initializer of a non-static data member (12.2), or in the definition of a class member outside of the definition of \( X \), following the member’s declarator-id\(^{32}\), shall be declared in one of the following ways:

(8.1) — before its use in the block in which it is used or in an enclosing block (9.3), or

(8.2) — shall be a member of class \( X \) or be a member of a base class of \( X \) (13.2), or

(8.3) — if \( X \) is a nested class of class \( Y \) (12.2.5), shall be a member of \( Y \), or shall be a member of a base class of \( Y \) (this lookup applies in turn to \( Y \)'s enclosing classes, starting with the innermost enclosing class),\(^ {33}\) or

(8.4) — if \( X \) is a local class (12.4) or is a nested class of a local class, before the definition of class \( X \) in a block enclosing the definition of class \( X \), or

(8.5) — if \( X \) is a member of namespace \( N \), or is a nested class of a class that is a member of \( N \), or is a local class or a nested class within a local class of a function that is a member of \( N \), before the use of the name, in namespace \( N \) or in one of \( N \)'s enclosing namespaces.

31) This lookup applies whether the definition of \( X \) is nested within \( Y \)'s definition or whether \( X \)'s definition appears in a namespace scope enclosing \( Y \)'s definition (12.2.5).

32) That is, an unqualified name that occurs, for instance, in a type in the parameter-declaration-clause or in the noexcept-specifier.

33) This lookup applies whether the member function is defined within the definition of class \( X \) or whether the member function is defined in a namespace scope enclosing \( X \)'s definition.

§ 6.4.1
Example:

```cpp
class B { }
namespace N {
    namespace M {
        class X : public B {
            void f();
        };
    }
}
void M::N::X::f() {
    i = 16;
}
```

// The following scopes are searched for a declaration of i:
// 1) outermost block scope of M::N::X::f, before the use of i
// 2) scope of class M::N::X
// 3) scope of M::N::X’s base class B
// 4) scope of namespace M::N
// 5) scope of namespace M
// 6) global scope, before the definition of M::N::X::f

— end example —

Note: 12.2.1 and 12.2.3 further describe the restrictions on the use of names in member function definitions. 12.2.5 further describes the restrictions on the use of names in the scope of nested classes. 12.4 further describes the restrictions on the use of names in local class definitions. — end note —

9 Name lookup for a name used in the definition of a friend function (14.3) defined inline in the class granting friendship shall proceed as described for lookup in member function definitions. If the friend function is not defined in the class granting friendship, name lookup in the friend function definition shall proceed as described for lookup in namespace member function definitions.

10 In a friend declaration naming a member function, a name used in the function declarator and not part of a template-argument in the declarator-id is first looked up in the scope of the member function’s class (13.2). If it is not found, or if the name is part of a template-argument in the declarator-id, the look up is as described for unqualified names in the definition of the class granting friendship. [Example:

```cpp
struct A {
    typedef int AT;
    void f1(AT);
    void f2(float);
    template <class T> void f3();
};
struct B {
    typedef char AT;
    typedef float BT;
    friend void A::f1(AT);  // parameter type is A::AT
    friend void A::f2(BT);  // parameter type is B::BT
    friend void A::f3<AT>(); // template argument is B::AT
};
— end example —
```

11 During the lookup for a name used as a default argument (11.3.6) in a function parameter-declaration-clause or used in the expression of a mem-initializer for a constructor (15.6.2), the function parameter names are visible and hide the names of entities declared in the block, class or namespace scopes containing the function declaration. [Note: 11.3.6 further describes the restrictions on the use of names in default arguments. 15.6.2 further describes the restrictions on the use of names in a ctor-initializer. — end note —

§ 6.4.1
During the lookup of a name used in the constant-expression of an enumerator-definition, previously declared enumerators of the enumeration are visible and hide the names of entities declared in the block, class, or namespace scopes containing the enum-specifier.

A name used in the definition of a static data member of class \( X \) (12.2.3.2) (after the qualified-id of the static member) is looked up as if the name was used in a member function of \( X \). \[ Note: 12.2.3.2 further describes the restrictions on the use of names in the definition of a static data member. — end note \]

If a variable member of a namespace is defined outside of the scope of its namespace then any name that appears in the definition of the member (after the declarator-id) is looked up as if the definition of the member occurred in its namespace. \[ Example: \]

```c
namespace N {
    int i = 4;
    extern int j;
}

int i = 2;

int N::j = i; // N::j == 4
— end example \]

A name used in the handler for a function-try-block (Clause 18) is looked up as if the name was used in the outermost block of the function definition. In particular, the function parameter names shall not be redeclared in the exception-declaration nor in the outermost block of a handler for the function-try-block. Names declared in the outermost block of the function definition are not found when looked up in the scope of a handler for the function-try-block. \[ Note: But function parameter names are found. — end note \]

[ Note: The rules for name lookup in template definitions are described in 17.6. — end note ]

6.4.2 Argument-dependent name lookup  \[ basic.lookup.argdep \]

When the postfix-expression in a function call (8.2.2) is an unqualified-id, other namespaces not considered during the usual unqualified lookup (6.4.1) may be searched, and in those namespaces, namespace-scope friend function or function template declarations (14.3) not otherwise visible may be found. These modifications to the search depend on the types of the arguments (and for template template arguments, the namespace of the template argument). \[ Example: \]

```c
namespace N {
    struct S { }
    void f(S);
}

void g() {
    N::S s;
    f(s); // OK: calls N::f
    (f)(s); // error: N::f not considered; parentheses prevent argument-dependent lookup
}
— end example \]

For each argument type \( T \) in the function call, there is a set of zero or more associated namespaces and a set of zero or more associated classes to be considered. The sets of namespaces and classes are determined entirely by the types of the function arguments (and the namespace of any template template argument). Typedef names and using-declarations used to specify the types do not contribute to this set. The sets of namespaces and classes are determined in the following way:

(2.1) — If \( T \) is a fundamental type, its associated sets of namespaces and classes are both empty.
If \( T \) is a class type (including unions), its associated classes are: the class itself; the class of which it is a member, if any; and its direct and indirect base classes. Its associated namespaces are the innermost enclosing namespaces of its associated classes. Furthermore, if \( T \) is a class template specialization, its associated namespaces and classes also include: the namespaces and classes associated with the types of the template arguments provided for template type parameters (excluding template template parameters); the namespaces of which any template template arguments are members; and the classes of which any member templates used as template template arguments are members. [Note: Non-type template arguments do not contribute to the set of associated namespaces. —end note]

If \( T \) is an enumeration type, its associated namespace is the innermost enclosing namespace of its declaration. If it is a class member, its associated class is the member’s class; else it has no associated class.

If \( T \) is a pointer to \( U \) or an array of \( U \), its associated namespaces and classes are those associated with \( U \).

If \( T \) is a function type, its associated namespaces and classes are those associated with the function parameter types and those associated with the return type.

If \( T \) is a pointer to a member function of a class \( X \), its associated namespaces and classes are those associated with the function parameter types and return type, together with those associated with \( X \).

If \( T \) is a pointer to a data member of class \( X \), its associated namespaces and classes are those associated with the member type together with those associated with \( X \).

If an associated namespace is an inline namespace (10.3.1), its enclosing namespace is also included in the set. If an associated namespace directly contains inline namespaces, those inline namespaces are also included in the set. In addition, if the argument is the name or address of a set of overloaded functions and/or function templates, its associated classes and namespaces are the union of those associated with each of the members of the set, i.e., the classes and namespaces associated with its parameter types and return type. Additionally, if the aforementioned set of overloaded functions is named with a template-id, its associated classes and namespaces also include those of its type template-arguments and its template template-arguments.

Let \( X \) be the lookup set produced by unqualified lookup (6.4.1) and let \( Y \) be the lookup set produced by argument dependent lookup (defined as follows). If \( X \) contains

- a declaration of a class member, or
- a block-scope function declaration that is not a using-declaration, or
- a declaration that is neither a function nor a function template

then \( Y \) is empty. Otherwise \( Y \) is the set of declarations found in the namespaces associated with the argument types as described below. The set of declarations found by the lookup of the name is the union of \( X \) and \( Y \). [Note: The namespaces and classes associated with the argument types can include namespaces and classes already considered by the ordinary unqualified lookup. —end note] [Example:

```cpp
namespace NS {
    class T { }
    void f(T);
    void g(T, int);
}
NS::T parm;
void g(NS::T, float);
int main() {
    f(parm);       // OK: calls NS::f
    extern void g(NS::T, float);
    g(parm, i);    // OK: calls g(NS::T, float)
}
—end example]

§ 6.4.2 55
4 When considering an associated namespace, the lookup is the same as the lookup performed when the associated namespace is used as a qualifier (6.4.3.2) except that:

(4.1) — Any using-directives in the associated namespace are ignored.

(4.2) — Any namespace-scope friend functions or friend function templates declared in associated classes are visible within their respective namespaces even if they are not visible during an ordinary lookup (14.3).

(4.3) — All names except those of (possibly overloaded) functions and function templates are ignored.

6.4.3 Qualified name lookup [basic.lookup.qual]

1 The name of a class or namespace member or enumerator can be referred to after the :: scope resolution operator (8.1) applied to a nested-name-specifier that denotes its class, namespace, or enumeration. If a :: scope resolution operator in a nested-name-specifier is not preceded by a decltype-specifier, lookup of the name preceding that :: considers only namespaces, types, and templates whose specializations are types. If the name found does not designate a namespace or a class, enumeration, or dependent type, the program is ill-formed. [Example:

```cpp
class A {
  public:
    static int n;
};
int main() {
  int A;
  A::n = 42;  // OK
  A b;  // ill-formed: A does not name a type
}
```
—end example]

2 [Note: Multiply qualified names, such as N1::N2::N3::n, can be used to refer to members of nested classes (12.2.5) or members of nested namespaces. — end note]

3 In a declaration in which the declarator-id is a qualified-id, names used before the qualified-id being declared are looked up in the defining namespace scope; names following the qualified-id are looked up in the scope of the member’s class or namespace. [Example:

```cpp
class X { }
class C {
  class X { }
  static const int number = 50;
  static X arr[number];
};
X C::arr[number];  // ill-formed:
                   // equivalent to ::X C::arr[C::number];
                   // and not to C::X C::arr[C::number];

— end example]
```

4 A name prefixed by the unary scope operator :: (8.1) is looked up in global scope, in the translation unit where it is used. The name shall be declared in global namespace scope or shall be a name whose declaration is visible in global scope because of a using-directive (6.4.3.2). The use of :: allows a global name to be referred to even if its identifier has been hidden (6.3.10).

5 A name prefixed by a nested-name-specifier that nominates an enumeration type shall represent an enumerator of that enumeration.

6 If a pseudo-destructor-name (8.2.4) contains a nested-name-specifier, the type-names are looked up as types in the scope designated by the nested-name-specifier. Similarly, in a qualified-id of the form:
nested-name-specifier\_opt class-name :: - class-name

the second class-name is looked up in the same scope as the first. [Example:

```c
struct C {
    typedef int I;
};
typedef int I1, I2;
extern int* p;
extern int* q;
p->C::I::~I(); // I is looked up in the scope of C
q->I1::~I2(); // I2 is looked up in the scope of the postfix-expression
```

```c
struct A {
    ~A();
};
typedef A AB;
int main() {
    AB* p;
p->AB::~AB(); // explicitly calls the destructor for A
}
```

—end example] [Note: 6.4.5 describes how name lookup proceeds after the . and -> operators. —end note]

6.4.3.1 Class members [class.\_qual]

1 If the nested-name-specifier of a qualified-id nominates a class, the name specified after the nested-name-specifier is looked up in the scope of the class (13.2), except for the cases listed below. The name shall represent one or more members of that class or of one of its base classes (Clause 13). [Note: A class member can be referred to using a qualified-id at any point in its potential scope (6.3.7). —end note] The exceptions to the name lookup rule above are the following:

(1.1) — the lookup for a destructor is as specified in 6.4.3;

(1.2) — a conversion-type-id of a conversion-function-id is looked up in the same manner as a conversion-type-id in a class member access (see 6.4.5);

(1.3) — the names in a template-argument of a template-id are looked up in the context in which the entire postfix-expression occurs.

(1.4) — the lookup for a name specified in a using-declaration (10.3.3) also finds class or enumeration names hidden within the same scope (6.3.10).

2 In a lookup in which function names are not ignored and the nested-name-specifier nominates a class C:

(2.1) — if the name specified after the nested-name-specifier, when looked up in C, is the injected-class-name of C (Clause 12), or

(2.2) — in a using-declarator of a using-declaration (10.3.3) that is a member-declaration, if the name specified after the nested-name-specifier is the same as the identifier or the simple-template-id’s template-name in the last component of the nested-name-specifier,

the name is instead considered to name the constructor of class C. [Note: For example, the constructor is not an acceptable lookup result in an elaborated-type-specifier so the constructor would not be used in place of the injected-class-name. —end note] Such a constructor name shall be used only in the declarator-id of a declaration that names a constructor or in a using-declaration. [Example:

```c
struct A { A();
};
struct B: public A { B();
};
```

34) Lookups in which function names are ignored include names appearing in a nested-name-specifier, an elaborated-type-specifier, or a base-specifier.

§ 6.4.3.1 57
A::A() { }
B::B() { }
B::A ba; // object of type A
A::A a; // error, A::A is not a type name
struct A::A a2; // object of type A

— end example

3 A class member name hidden by a name in a nested declarative region or by the name of a derived class member can still be found if qualified by the name of its class followed by the :: operator.

6.4.3.2 Namespace members  [namespace.qual]

1 If the nested-name-specifier of a qualified-id nominates a namespace (including the case where the nested-name-specifier is ::, i.e., nominating the global namespace), the name specified after the nested-name-specifier is looked up in the scope of the namespace. The names in a template-argument of a template-id are looked up in the context in which the entire postfix-expression occurs.

2 For a namespace X and name m, the namespace-qualified lookup set S(X,m) is defined as follows: Let S'(X,m) be the set of all declarations of m in X and the inline namespace set of X (10.3.1). If S'(X,m) is not empty, S(X,m) is S'(X,m); otherwise, S(X,m) is the union of S(Ni,m) for all namespaces Ni nominated by using-directives in X and its inline namespace set.

3 Given X::m (where X is a user-declared namespace), or given ::m (where X is the global namespace), if S(X,m) is the empty set, the program is ill-formed. Otherwise, if S(X,m) has exactly one member, or if the context of the reference is a using-declaration (10.3.3), S(X,m) is the required set of declarations of m. Otherwise if the use of m is not one that allows a unique declaration to be chosen from S(X,m), the program is ill-formed. [Example:

```cpp
int x;
namespace Y {
  void f(float);
  void h(int);
}

namespace Z {
  void h(double);
}

namespace A {
  using namespace Y;
  void f(int);
  void g(int);
  int i;
}

namespace B {
  using namespace Z;
  void f(char);
  int i;
}

namespace AB {
  using namespace A;
  using namespace B;
  void g();
```
void h()
{
    AB::g(); // g is declared directly in AB, therefore S is \{AB::g()\} and AB::g() is chosen
    AB::f(1); // f is not declared directly in AB so the rules are applied recursively to A and B;
               // namespace Y is not searched and Y::f(float) is not considered;
               // S is \{A::f(int),B::f(char)\} and overload resolution chooses A::f(int)
    AB::f('c'); // as above but resolution chooses B::f(char)
    AB::x++;    // x is not declared directly in AB, and is not declared in A or B, so the rules
               // are applied recursively to Y and Z, S is \{} so the program is ill-formed
    AB::i++;    // i is not declared directly in AB so the rules are applied recursively to A and B,
               // S is \{A::i,B::i\} so the use is ambiguous and the program is ill-formed
    AB::h(16.8); // h is not declared directly in AB and not declared directly in A or B so the rules
                   // are applied recursively to Y and Z, S is \{Y::h(int),Z::h(double)\} and
                   // overload resolution chooses Z::h(double)
}

— end example]

4 [Note: The same declaration found more than once is not an ambiguity (because it is still a unique declaration).
Example:

namespace A {
    int a;
}

namespace B {
    using namespace A;
}

namespace C {
    using namespace A;
}

namespace BC {
    using namespace B;
    using namespace C;
}

void f()
{
    BC::a++; // OK: S is \{A::a,A::a\}
}

namespace D {
    using A::a;
}

namespace BD {
    using namespace B;
    using namespace D;

§ 6.4.3.2
void g()
{
    BD::a++; // OK: S is {A::a,A::a}
}

—end example —end note—end example

Example: Because each referenced namespace is searched at most once, the following is well-defined:

namespace B {
    int b;
}

namespace A {
    using namespace B;
    int a;
}

namespace B {
    using namespace A;
}

void f()
{
    A::a++; // OK: a declared directly in A, S is {A::a}
    B::a++; // OK: both A and B searched (once), S is {A::a}
    A::b++; // OK: both A and B searched (once), S is {B::b}
    B::b++; // OK: b declared directly in B, S is {B::b}
}

—end example

During the lookup of a qualified namespace member name, if the lookup finds more than one declaration of the member, and if one declaration introduces a class name or enumeration name and the other declarations either introduce the same variable, the same enumerator or a set of functions, the non-type name hides the class or enumeration name if and only if the declarations are from the same namespace; otherwise (the declarations are from different namespaces), the program is ill-formed. [Example:

namespace A {
    struct x { }; 
    int x;
    int y;
}

namespace B {
    struct y { }; 
}

namespace C {
    using namespace A;
    using namespace B;
    int i = C::x; // OK, A::x (of type int)
    int j = C::y; // ambiguous, A::y or B::y
}

—end example]
In a declaration for a namespace member in which the declarator-id is a qualified-id, given that the qualified-id for the namespace member has the form

\[ \text{nested-name-specifier unqualified-id} \]

the unqualified-id shall name a member of the namespace designated by the nested-name-specifier or of an element of the inline namespace set (10.3.1) of that namespace. [Example:

```c
namespace A {
    namespace B {
        void f1(int);
        using namespace B;
    }
    void A::f1(int) { } // ill-formed, f1 is not a member of A
}
```

—end example] However, in such namespace member declarations, the nested-name-specifier may rely on using-directives to implicitly provide the initial part of the nested-name-specifier. [Example:

```c
namespace A {
    namespace B {
        void f1(int);
    }
}
namespace C {
    namespace D {
        void f1(int);
    }
}
using namespace A;
using namespace C::D;
void B::f1(int) { } // OK, defines A::B::f1(int)

—end example]

6.4.4 Elaborated type specifiers [basic.lookup.elab]

1 An elaborated-type-specifier (10.1.7.3) may be used to refer to a previously declared class-name or enum-name even though the name has been hidden by a non-type declaration (6.3.10).

2 If the elaborated-type-specifier has no nested-name-specifier, and unless the elaborated-type-specifier appears in a declaration with the following form:

```
class-key attribute-specifier-seq_opt identifier ;
```

the identifier is looked up according to 6.4.1 but ignoring any non-type names that have been declared. If the elaborated-type-specifier is introduced by the enum keyword and this lookup does not find a previously declared type-name, the elaborated-type-specifier is ill-formed. If the elaborated-type-specifier is introduced by the class-key and this lookup does not find a previously declared type-name, or if the elaborated-type-specifier appears in a declaration with the form:

```
class-key attribute-specifier-seq_opt identifier ;
```

the elaborated-type-specifier is a declaration that introduces the class-name as described in 6.3.2.

3 If the elaborated-type-specifier has a nested-name-specifier, qualified name lookup is performed, as described in 6.4.3, but ignoring any non-type names that have been declared. If the name lookup does not find a previously declared type-name, the elaborated-type-specifier is ill-formed. [Example:

```c
struct Node {

```
struct Node* Next; // OK: Refers to Node at global scope
struct Data* Data; // OK: Declares type Data

// at global scope and member Data
};

struct Data {
    struct Node* Node; // OK: Refers to Node at global scope
    friend struct ::Glob; // error: Glob is not declared, cannot introduce a qualified type (10.1.7.3)
    friend struct Glob;
/* ... */
};

struct Base {
    struct Data; // OK: Declares nested Data
    struct ::Data* thatData; // OK: Refers to ::Data
    struct Base::Data* thisData; // OK: Refers to nested Data
    friend class ::Data; // OK: global Data is a friend
    friend class Data; // OK: nested Data is a friend
    struct Data { /* ... */ }; // Defines nested Data
};

struct Data; // OK: Redeclares Data at global scope
struct ::Data; // error: cannot introduce a qualified type (10.1.7.3)
struct Base::Data; // error: cannot introduce a qualified type (10.1.7.3)
struct Base::Datum; // error: Datum undefined
struct Base::Data* pBase; // OK: refers to nested Data

— end example ]

6.4.5 Class member access [basic.lookup.classref]

1 In a class member access expression (8.2.5), if the . or -> token is immediately followed by an identifier
followed by a <, the identifier must be looked up to determine whether the < is the beginning of a template
argument list (17.2) or a less-than operator. The identifier is first looked up in the class of the object
expression. If the identifier is not found, it is then looked up in the context of the entire postfix-expression
and shall name a class template.

2 If the id-expression in a class member access (8.2.5) is an unqualified-id, and the type of the object expression
is of a class type C, the unqualified-id is looked up in the scope of class C. For a pseudo-destructor call (8.2.4),
the unqualified-id is looked up in the context of the complete postfix-expression.

3 If the unqualified-id is ~type-name, the type-name is looked up in the context of the entire postfix-expression.
If the type T of the object expression is of a class type C, the type-name is also looked up in the scope of class
C. At least one of the lookups shall find a name that refers to cv T. [ Example:

struct A { }

struct B {
    struct A { }
    void f(::A* a);
};

void B::f (::A* a) {
    a->~A(); // OK: lookup in *a finds the injected-class-name
}
— end example ]
If the id-expression in a class member access is a qualified-id of the form

```
class-name-or-namespace-name::...
```

the class-name-or-namespace-name following the . or -> operator is first looked up in the class of the object expression and the name, if found, is used. Otherwise it is looked up in the context of the entire postfix-expression. [Note: See 6.4.3, which describes the lookup of a name before ::, which will only find a type or namespace name. — end note]

If the qualified-id has the form

```
::class-name-or-namespace-name::...
```

the class-name-or-namespace-name is looked up in global scope as a class-name or namespace-name.

If the nested-name-specifier contains a simple-template-id (17.2), the names in its template-arguments are looked up in the context in which the entire postfix-expression occurs.

If the id-expression is a conversion-function-id, its conversion-type-id is first looked up in the class of the object expression and the name, if found, is used. Otherwise it is looked up in the context of the entire postfix-expression. In each of these lookups, only names that denote types or templates whose specializations are types are considered. [Example:

```c
struct A { };
namespace N {
    struct A {
        void g() { }
        template <class T> operator T();
    }
};

int main() {
    N::A a;
    a.operator A(); // calls N::A::operator N::A
}
```

— end example]

### 6.4.6 Using-directives and namespace aliases

[basic.lookup.udir]

In a using-directive or namespace-alias-definition, during the lookup for a namespace-name or for a name in a nested-name-specifier only namespace names are considered.

### 6.5 Program and linkage

[basic.link]

A program consists of one or more translation units (Clause 5) linked together. A translation unit consists of a sequence of declarations.

```
translation-unit:
  declaration-seq_opt
```

A name is said to have linkage when it might denote the same object, reference, function, type, template, namespace or value as a name introduced by a declaration in another scope:

1. When a name has external linkage, the entity it denotes can be referred to by names from scopes of other translation units or from other scopes of the same translation unit.
2. When a name has internal linkage, the entity it denotes can be referred to by names from other scopes in the same translation unit.
3. When a name has no linkage, the entity it denotes cannot be referred to by names from other scopes.

A name having namespace scope (6.3.6) has internal linkage if it is the name of

§ 6.5
— a variable, function or function template that is explicitly declared static; or,
— a non-inline variable of non-volatile const-qualified type that is neither explicitly declared extern nor previously declared to have external linkage; or
— a data member of an anonymous union.

An unnamed namespace or a namespace declared directly or indirectly within an unnamed namespace has internal linkage. All other namespaces have external linkage. A name having namespace scope that has not been given internal linkage above has the same linkage as the enclosing namespace if it is the name of
— a variable; or
— a function; or
— a named class (Clause 12), or an unnamed class defined in a typedef declaration in which the class has the typedef name for linkage purposes (10.1.3); or
— a named enumeration (10.2), or an unnamed enumeration defined in a typedef declaration in which the enumeration has the typedef name for linkage purposes (10.1.3); or
— a template.

In addition, a member function, static data member, a named class or enumeration of class scope, or an unnamed class or enumeration defined in a class-scope typedef declaration such that the class or enumeration has the typedef name for linkage purposes (10.1.3), has the same linkage, if any, as the name of the class of which it is a member.

The name of a function declared in block scope and the name of a variable declared by a block scope extern declaration have linkage. If there is a visible declaration of an entity with linkage having the same name and type, ignoring entities declared outside the innermost enclosing namespace scope, the block scope declaration declares that same entity and receives the linkage of the previous declaration. If there is more than one such matching entity, the program is ill-formed. Otherwise, if no matching entity is found, the block scope entity receives external linkage. If, within a translation unit, the same entity is declared with both internal and external linkage, the program is ill-formed. [Example:

```c
static void f();
static int i = 0; // #1
void g() {
    extern void f(); // internal linkage
    int i; // #2: i has no linkage
    {
        extern void f(); // internal linkage
        extern int i; // #3: external linkage, ill-formed
    }
}
```

Without the declaration at line #2, the declaration at line #3 would link with the declaration at line #1. Because the declaration with internal linkage is hidden, however, #3 is given external linkage, making the program ill-formed. — end example]

When a block scope declaration of an entity with linkage is not found to refer to some other declaration, then that entity is a member of the innermost enclosing namespace. However such a declaration does not introduce the member name in its namespace scope. [Example:

```c
namespace X {
    void p() {
        q(); // error: q not yet declared
        extern void q(); // q is a member of namespace X
    }
}
```

§ 6.5
void middle() {
    q(); // error: q not yet declared
}

void q() { /* ... */ } // definition of X::q

void q() { /* ... */ } // some other, unrelated q

Names not covered by these rules have no linkage. Moreover, except as noted, a name declared at block
scope (6.3.3) has no linkage. A type is said to have linkage if and only if:

(8.1) it is a class or enumeration type that is named (or has a name for linkage purposes (10.1.3)) and the
      name has linkage; or
(8.2) it is an unnamed class or unnamed enumeration that is a member of a class with linkage; or
(8.3) it is a specialization of a class template (Clause 17)35; or
(8.4) it is a fundamental type (6.9.1); or
(8.5) it is a compound type (6.9.2) other than a class or enumeration, compounded exclusively from types
      that have linkage; or
(8.6) it is a cv-qualified (6.9.3) version of a type that has linkage.

A type without linkage shall not be used as the type of a variable or function with external linkage unless

(8.7) the entity has C language linkage (10.5), or
(8.8) the entity is declared within an unnamed namespace (10.3.1), or
(8.9) the entity is not odr-used (6.2) or is defined in the same translation unit.

[Note: In other words, a type without linkage contains a class or enumeration that cannot be named outside
its translation unit. An entity with external linkage declared using such a type could not correspond to any
other entity in another translation unit of the program and thus must be defined in the translation unit if it
is odr-used. Also note that classes with linkage may contain members whose types do not have linkage, and
that typedef names are ignored in the determination of whether a type has linkage. —end note]

[Example:
    template <class T> struct B {
        void g(T) { }
        void h(T);
        friend void i(B, T) { }
    };

    void f() {
        struct A { int x; }; // no linkage
        A a = { 1 };
        B<A> ba; // declares B<A>::g(a) and B<A>::h(a)
        ba.g(a); // OK
        ba.h(a); // error: B<A>::h(a) not defined in the translation unit
        i(ba, a); // OK
    }

    —end example] 35 A class template has the linkage of the innermost enclosing class or namespace in which it is declared.

§ 6.5 65
Two names that are the same (Clause 6) and that are declared in different scopes shall denote the same variable, function, type, template or namespace if

(9.1) both names have external linkage or else both names have internal linkage and are declared in the same translation unit; and
(9.2) both names refer to members of the same namespace or to members, not by inheritance, of the same class; and
(9.3) when both names denote functions, the parameter-type-lists of the functions (11.3.5) are identical; and
(9.4) when both names denote function templates, the signatures (17.5.6.1) are the same.

After all adjustments of types (during which typedefs (10.1.3) are replaced by their definitions), the types specified by all declarations referring to a given variable or function shall be identical, except that declarations for an array object can specify array types that differ by the presence or absence of a major array bound (11.3.4). A violation of this rule on type identity does not require a diagnostic.

[ Note: Linkage to non-C++ declarations can be achieved using a linkage-specification (10.5). — end note ]

6.6 Start and termination

6.6.1 main function

A program shall contain a global function called main. Executing a program starts a main thread of execution (4.7, 33.3) in which the main function is invoked, and in which variables of static storage duration might be initialized (6.6.2) and destroyed (6.6.4). It is implementation-defined whether a program in a freestanding environment is required to define a main function. [ Note: In a freestanding environment, start-up and termination is implementation-defined; start-up contains the execution of constructors for objects of namespace scope with static storage duration; termination contains the execution of destructors for objects with static storage duration. — end note ]

An implementation shall not predefine the main function. This function shall not be overloaded. Its type shall have C++ language linkage and it shall have a declared return type of type int, but otherwise its type is implementation-defined. An implementation shall allow both

(2.1) a function of () returning int and
(2.2) a function of (int, pointer to pointer to char) returning int

as the type of main (11.3.5). In the latter form, for purposes of exposition, the first function parameter is called argc and the second function parameter is called argv, where argc shall be the number of arguments passed to the program from the environment in which the program is run. If argc is nonzero these arguments shall be supplied in argv[0] through argv[argc-1] as pointers to the initial characters of null-terminated multibyte strings (ntmbs) (20.4.2.1.5.2) and argv[0] shall be the pointer to the initial character of a NTMBS that represents the name used to invoke the program or "". The value of argc shall be non-negative. The value of argv[argc] shall be 0. [ Note: It is recommended that any further (optional) parameters be added after argv. — end note ]

The function main shall not be used within a program. The linkage (6.5) of main is implementation-defined. A program that defines main as deleted or that declares main to be inline, static, or constexpr is ill-formed. The main function shall not be declared with a linkage-specification (10.5). A program that declares a variable main at global scope or that declares the name main with C language linkage (in any namespace) is ill-formed. The name main is not otherwise reserved. [ Example: Member functions, classes, and enumerations can be called main, as can entities in other namespaces. — end example ]

Terminating the program without leaving the current block (e.g., by calling the function std::exit(int) (21.5)) does not destroy any objects with automatic storage duration (15.4). If std::exit is called to end a program during the destruction of an object with static or thread storage duration, the program has undefined behavior.

§ 6.6.1
A return statement in \texttt{main} has the effect of leaving the main function (destroying any objects with automatic storage duration) and calling \texttt{std::exit} with the return value as the argument. If control flows off the end of the \textit{compound-statement} of \texttt{main}, the effect is equivalent to a \texttt{return} with operand 0 (see also 18.3).

### 6.6.2 Static initialization

Variables with static storage duration are initialized as a consequence of program initiation. Variables with thread storage duration are initialized as a consequence of thread execution. Within each of these phases of initiation, initialization occurs as follows.

1. A constant initializer for a variable or temporary object \(o\) is an initializer whose full-expression is a constant expression, except that if \(o\) is an object, such an initializer may also invoke constexpr constructors for \(o\) and its subobjects even if those objects are of non-literal class types. [\textit{Note:} Such a class may have a non-trivial destructor. — \textit{end note}] Constant initialization is performed if a variable or temporary object with static or thread storage duration is initialized by a constant initializer for the entity. If constant initialization is not performed, a variable with static storage duration (6.7.1) or thread storage duration (6.7.2) is zero-initialized (11.6). Together, zero-initialization and constant initialization are called \textit{static initialization}; all other initialization is \textit{dynamic initialization}. All static initialization strongly happens before (4.7.1) any dynamic initialization. [\textit{Note:} The dynamic initialization of non-local variables is described in 6.6.3; that of local static variables is described in 9.7. — \textit{end note}]

2. An implementation is permitted to perform the initialization of a variable with static or thread storage duration as a static initialization even if such initialization is not required to be done statically, provided that

   (3.1) — the dynamic version of the initialization does not change the value of any other object of static or thread storage duration prior to its initialization, and

   (3.2) — the static version of the initialization produces the same value in the initialized variable as would be produced by the dynamic initialization if all variables not required to be initialized statically were initialized dynamically.

[\textit{Note:} As a consequence, if the initialization of an object \texttt{obj1} refers to an object \texttt{obj2} of namespace scope potentially requiring dynamic initialization and defined later in the same translation unit, it is unspecified whether the value of \texttt{obj2} used will be the value of the fully initialized \texttt{obj2} (because \texttt{obj2} was statically initialized) or will be the value of \texttt{obj2} merely zero-initialized. For example,

\begin{verbatim}
inline double fd() { return 1.0; }
extern double d1;
double d2 = d1;  // unspecified:
    // may be statically initialized to 0.0 or
    // dynamically initialized to 0.0 if d1 is
    // dynamically initialized, or 1.0 otherwise

double d1 = fd();  // may be initialized statically or dynamically to 1.0
\end{verbatim}

— \textit{end note}]

### 6.6.3 Dynamic initialization of non-local variables

Dynamic initialization of a non-local variable with static storage duration is unordered if the variable is an implicitly or explicitly instantiated specialization, is partially-ordered if the variable is an inline variable that is not an implicitly or explicitly instantiated specialization, and otherwise is ordered. [\textit{Note:} An explicitly specialized non-inline static data member or variable template specialization has ordered initialization. — \textit{end note}]

Dynamic initialization of non-local variables \(V\) and \(W\) with static storage duration are ordered as follows:

(2.1) — If \(V\) and \(W\) have ordered initialization and \(V\) is defined before \(W\) within a single translation unit, the initialization of \(V\) is sequenced before the initialization of \(W\).
If \( V \) has partially-ordered initialization, \( W \) does not have unordered initialization, and \( V \) is defined before \( W \) in every translation unit in which \( W \) is defined, then

- if the program starts a thread (4.7) other than the main thread (6.6.1), the initialization of \( V \) strongly happens before the initialization of \( W \);
- otherwise, the initialization of \( V \) is sequenced before the initialization of \( W \).

Otherwise, if the program starts a thread other than the main thread before either \( V \) or \( W \) is initialized, it is unspecified in which threads the initializations of \( V \) and \( W \) occur; the initializations are unsequenced if they occur in the same thread.

Otherwise, the initializations of \( V \) and \( W \) are indeterminately sequenced.

[Note: This definition permits initialization of a sequence of ordered variables concurrently with another sequence. — end note]

A non-initialization odr-use is an odr-use (6.2) not caused directly or indirectly by the initialization of a non-local static or thread storage duration variable.

It is implementation-defined whether the dynamic initialization of a non-local non-inline variable with static storage duration is sequenced before the first statement of \texttt{main} or is deferred. If it is deferred, it strongly happens before any non-initialization odr-use of any non-inline function or non-inline variable defined in the same translation unit as the variable to be initialized.\footnote{A non-local variable with static storage duration having initialization with side effects is initialized in this case, even if it is not itself odr-used (6.2, 6.7.1).} It is implementation-defined in which threads and at which points in the program such deferred dynamic initialization occurs. [Note: Such points should be chosen in a way that allows the programmer to avoid deadlocks. — end note]

\begin{verbatim}
// - File 1 -
#include "a.h"
#include "b.h"
B b;
A::A(){
    b.Use();
}

// - File 2 -
#include "a.h"
A a;

// - File 3 -
#include "a.h"
#include "b.h"
extern A a;
extern B b;

int main() {
    a.Use();
    b.Use();
}
\end{verbatim}

It is implementation-defined whether either \( a \) or \( b \) is initialized before \texttt{main} is entered or whether the initializations are delayed until \( a \) is first odr-used in \texttt{main}. In particular, if \( a \) is initialized before \texttt{main} is entered, it is not guaranteed that \( b \) will be initialized before it is odr-used by the initialization of \( a \), that is, before \texttt{A::A()} is called. If, however, \( a \) is initialized at some point after the first statement of \texttt{main}, \( b \) will be initialized prior to its use in \texttt{A::A}. — end example]
It is implementation-defined whether the dynamic initialization of a non-local inline variable with static storage duration is sequenced before the first statement of `main` or is deferred. If it is deferred, it strongly happens before any non-initialization odr-use of that variable. It is implementation-defined in which threads and at which points in the program such deferred dynamic initialization occurs.

It is implementation-defined whether the dynamic initialization of a non-local non-inline variable with thread storage duration is sequenced before the first statement of the initial function of a thread or is deferred. If it is deferred, the initialization associated with the entity for thread `t` is sequenced before the first non-initialization odr-use by `t` of any non-inline variable with thread storage duration defined in the same translation unit as the variable to be initialized. It is implementation-defined in which threads and at which points in the program such deferred dynamic initialization occurs.

If the initialization of a non-local variable with static or thread storage duration exits via an exception, `std::terminate` is called (18.5.1).

**6.6.4 Termination**

Destructors (15.4) for initialized objects (that is, objects whose lifetime (6.8) has begun) with static storage duration, and functions registered with `std::atexit`, are called as part of a call to `std::exit` (21.5). The call to `std::exit` is sequenced before the invocations of the destructors and the registered functions. [Note: Returning from `main` invokes `std::exit` (6.6.1). — end note]

Destructors for initialized objects with thread storage duration within a given thread are called as a result of returning from the initial function of that thread and as a result of that thread calling `std::exit`. The completions of the destructors for all initialized objects with thread storage duration within that thread strongly happen before the initiation of the destructors of any object with static storage duration.

If the completion of the constructor or dynamic initialization of an object with static storage duration strongly happens before that of another, the completion of the destructor of the second is sequenced before the initiation of the destructor of the first. If the completion of the constructor or dynamic initialization of an object with thread storage duration is sequenced before that of another, the completion of the destructor of the second is sequenced before the initiation of the destructor of the first. If an object is initialized statically, the object is destroyed in the same order as if the object was dynamically initialized. For an object of array or class type, all subobjects of that object are destroyed before any block-scope object with static storage duration initialized during the construction of the subobjects is destroyed. If the destruction of an object with static or thread storage duration exits via an exception, `std::terminate` is called (18.5.1).

If a function contains a block-scope object of static or thread storage duration that has been destroyed and the function is called during the destruction of an object with static or thread storage duration, the program has undefined behavior if the flow of control passes through the definition of the previously destroyed block-scope object. Likewise, the behavior is undefined if the block-scope object is used indirectly (i.e., through a pointer) after its destruction.

If the completion of the initialization of an object with static storage duration strongly happens before a call to `std::atexit` (see `<cstdlib>`, 21.5), the call to the function passed to `std::atexit` is sequenced before the call to the destructor for the object. If a call to `std::atexit` strongly happens before the completion of the initialization of an object with static storage duration, the call to the destructor for the object is sequenced before the call to the function passed to `std::atexit`. If a call to `std::atexit` strongly happens before another call to `std::atexit`, the call to the function passed to the second `std::atexit` call is sequenced before the call to the function passed to the first `std::atexit` call.

If there is a use of a standard library object or function not permitted within signal handlers (21.10) that does not happen before (4.7) completion of destruction of objects with static storage duration and execution of `std::atexit` registered functions (21.5), the program has undefined behavior. [Note: If there is a use of an object with static storage duration that does not happen before the object’s destruction, the program has undefined behavior. Terminating every thread before a call to `std::exit` or the exit from `main` is
sufficient, but not necessary, to satisfy these requirements. These requirements permit thread managers as static-storage-duration objects. — end note

Calling the function `std::abort()` declared in `<cstdlib>` terminates the program without executing any destructors and without calling the functions passed to `std::atexit()` or `std::at_quick_exit()`.

### 6.7 Storage duration [basic.stc]

The storage duration is the property of an object that defines the minimum potential lifetime of the storage containing the object. The storage duration is determined by the construct used to create the object and is one of the following:

- (1.1) static storage duration
- (1.2) thread storage duration
- (1.3) automatic storage duration
- (1.4) dynamic storage duration

Static, thread, and automatic storage durations are associated with objects introduced by declarations (6.1) and implicitly created by the implementation (15.2). The dynamic storage duration is associated with objects created by a `new-expression` (8.3.4).

The storage duration categories apply to references as well.

When the end of the duration of a region of storage is reached, the values of all pointers representing the address of any part of that region of storage become invalid pointer values (6.9.2). Indirection through an invalid pointer value and passing an invalid pointer value to a deallocation function have undefined behavior. Any other use of an invalid pointer value has implementation-defined behavior. 37

### 6.7.1 Static storage duration [basic.stc.static]

All variables which do not have dynamic storage duration, do not have thread storage duration, and are not local have static storage duration. The storage for these entities shall last for the duration of the program (6.6.2, 6.6.4).

If a variable with static storage duration has initialization or a destructor with side effects, it shall not be eliminated even if it appears to be unused, except that a class object or its copy/move may be eliminated as specified in 15.8.

The keyword `static` can be used to declare a local variable with static storage duration. [ Note: 9.7 describes the initialization of local static variables; 6.6.4 describes the destruction of local static variables. — end note ]

The keyword `static` applied to a class data member in a class definition gives the data member static storage duration.

### 6.7.2 Thread storage duration [basic.stc.thread]

All variables declared with the `thread_local` keyword have thread storage duration. The storage for these entities shall last for the duration of the thread in which they are created. There is a distinct object or reference per thread, and use of the declared name refers to the entity associated with the current thread.

A variable with thread storage duration shall be initialized before its first odr-use (6.2) and, if constructed, shall be destroyed on thread exit.

37) Some implementations might define that copying an invalid pointer value causes a system-generated runtime fault.
6.7.3 Automatic storage duration
1 Block-scope variables not explicitly declared static, thread_local, or extern have automatic storage duration. The storage for these entities lasts until the block in which they are created exits.

2 [Note: These variables are initialized and destroyed as described in 9.7. — end note]

3 If a variable with automatic storage duration has initialization or a destructor with side effects, an implementation shall not destroy it before the end of its block nor eliminate it as an optimization, even if it appears to be unused, except that a class object or its copy/move may be eliminated as specified in 15.8.

6.7.4 Dynamic storage duration
1 Objects can be created dynamically during program execution (4.6), using new-expressions (8.3.4), and destroyed using delete-expressions (8.3.5). A C++ implementation provides access to, and management of, dynamic storage via the global allocation functions operator new and operator new[] and the global deallocation functions operator delete and operator delete[]. [Note: The non-allocating forms described in 21.6.2.3 do not perform allocation or deallocation. — end note]

2 The library provides default definitions for the global allocation and deallocation functions. Some global allocation and deallocation functions are replaceable (21.6.2). A C++ program shall provide at most one definition of a replaceable allocation or deallocation function. Any such function definition replaces the default version provided in the library (20.5.4.6). The following allocation and deallocation functions (21.6) are implicitly declared in global scope in each translation unit of a program.

```cpp
void* operator new(std::size_t);
void* operator new(std::size_t, std::align_val_t);
void operator delete(void*) noexcept;
void operator delete(void*, std::size_t) noexcept;
void operator delete(void*, std::align_val_t) noexcept;
void operator delete(void*, std::size_t, std::align_val_t) noexcept;
void* operator new[](std::size_t);
void* operator new[](std::size_t, std::align_val_t);
void operator delete[](void*) noexcept;
void operator delete[](void*, std::size_t) noexcept;
void operator delete[](void*, std::align_val_t) noexcept;
void operator delete[](void*, std::size_t, std::align_val_t) noexcept;
```

These implicit declarations introduce only the function names operator new, operator new[], operator delete, and operator delete[]. [Note: The implicit declarations do not introduce the names std, std::size_t, std::align_val_t, or any other names that the library uses to declare these names. Thus, a new-expression, delete-expression or function call that refers to one of these functions without including the header <new> is well-formed. However, referring to std or std::size_t or std::align_val_t is ill-formed unless the name has been declared by including the appropriate header. — end note] Allocation and/or deallocation functions may also be declared and defined for any class (15.5).

3 Any allocation and/or deallocation functions defined in a C++ program, including the default versions in the library, shall conform to the semantics specified in 6.7.4.1 and 6.7.4.2.

6.7.4.1 Allocation functions
1 An allocation function shall be a class member function or a global function; a program is ill-formed if an allocation function is declared in a namespace scope other than global scope or declared static in global scope. The return type shall be void*. The first parameter shall have type std::size_t (21.2). The first parameter shall not have an associated default argument (11.3.6). The value of the first parameter shall be
interpreted as the requested size of the allocation. An allocation function can be a function template. Such a template shall declare its return type and first parameter as specified above (that is, template parameter types shall not be used in the return type and first parameter type). Template allocation functions shall have two or more parameters.

The allocation function attempts to allocate the requested amount of storage. If it is successful, it shall return the address of the start of a block of storage whose length in bytes shall be at least as large as the requested size. There are no constraints on the contents of the allocated storage on return from the allocation function. The order, contiguity, and initial value of storage allocated by successive calls to an allocation function are unspecified. The pointer returned shall be suitably aligned so that it can be converted to a pointer to any suitable complete object type (21.6.2.1) and then used to access the object or array in the storage allocated (until the storage is explicitly deallocated by a call to a corresponding deallocation function). Even if the size of the space requested is zero, the request can fail. If the request succeeds, the value returned shall be a non-null pointer value (7.11) \( p_0 \) different from any previously returned value \( p_1 \), unless that value \( p_1 \) was subsequently passed to an operator delete. Furthermore, for the library allocation functions in 21.6.2.1 and 21.6.2.2, \( p_0 \) shall represent the address of a block of storage disjoint from the storage for any other object accessible to the caller. The effect of indirecting through a pointer returned as a request for zero size is undefined.\(^{38}\)

An allocation function that fails to allocate storage can invoke the currently installed new-handler function (21.6.3.3), if any. [\textit{Note:} A program-supplied allocation function can obtain the address of the currently installed \texttt{new} handler using the \texttt{std::get_new_handler} function (21.6.3.4). -- end note] If an allocation function that has a non-throwing exception specification (18.4) fails to allocate storage, it shall return a null pointer. Any other allocation function that fails to allocate storage shall indicate failure only by throwing an exception (18.1) of a type that would match a handler (18.3) of type \texttt{std::bad_alloc} (21.6.3.1).

A global allocation function is only called as the result of a new expression (8.3.4), or called directly using the function call syntax (8.2.2), or called indirectly through calls to the functions in the C++ standard library. [\textit{Note:} In particular, a global allocation function is not called to allocate storage for objects with static storage duration (6.7.1), for objects or references with thread storage duration (6.7.2), for objects of type \texttt{std::type-info} (8.2.8), or for an exception object (18.1). -- end note]

### 6.7.4.2 Deallocation functions  \[\text{basic.stc.dynamic.deallocation}\]

Deallocation functions shall be class member functions or global functions; a program is ill-formed if deallocation functions are declared in a namespace scope other than global scope or declared static in global scope.

Each deallocation function shall return \texttt{void} and its first parameter shall be \texttt{void*}. A deallocation function may have more than one parameter. A \textit{usual deallocation function} is a deallocation function that has:

1. exactly one parameter; or
2. exactly two parameters, the type of the second being either \texttt{std::align_val_t} or \texttt{std::size_t}\(^{39}\); or
3. exactly three parameters, the type of the second being \texttt{std::size_t} and the type of the third being \texttt{std::align_val_t}.

A deallocation function may be an instance of a function template. Neither the first parameter nor the return type shall depend on a template parameter. [\textit{Note:} That is, a deallocation function template shall have a first parameter of type \texttt{void*} and a return type of \texttt{void} (as specified above). -- end note] A deallocation function template shall have two or more function parameters. A template instance is never a usual deallocation function, regardless of its signature.

\(^{38}\) The intent is to have \texttt{operator new()} implementable by calling \texttt{std::malloc()} or \texttt{std::calloc()}, so the rules are substantially the same. C++ differs from C in requiring a zero request to return a non-null pointer.

\(^{39}\) The global \texttt{operator delete(void*, std::size_t)} precludes use of an allocation function \texttt{void operator new(std::size_t, std::size_t)} as a placement allocation function (C.3.2).

\(\S\ 6.7.4.2\)
3 If a deallocation function terminates by throwing an exception, the behavior is undefined. The value of the first argument supplied to a deallocation function may be a null pointer value; if so, and if the deallocation function is one supplied in the standard library, the call has no effect.

4 If the argument given to a deallocation function in the standard library is a pointer that is not the null pointer value (7.11), the deallocation function shall deallocate the storage referenced by the pointer, ending the duration of the region of storage.

6.7.4.3 Safely-derived pointers

1 A **traceable pointer object** is

1.1 an object of an object pointer type (6.9.2), or
1.2 an object of an integral type that is at least as large as `std::intptr_t`, or
1.3 a sequence of elements in an array of narrow character type (6.9.1), where the size and alignment of the sequence match those of some object pointer type.

2 A pointer value is a **safely-derived pointer** to a dynamic object only if it has an object pointer type and it is one of the following:

2.1 the value returned by a call to the C++ standard library implementation of `::operator new(std::size_t)` or `::operator new(std::size_t, std::align_val_t);`,\(^{40}\)
2.2 the result of taking the address of an object (or one of its subobjects) designated by an lvalue resulting from indirection through a safely-derived pointer value;
2.3 the result of well-defined pointer arithmetic (8.7) using a safely-derived pointer value;
2.4 the result of a well-defined pointer conversion (7.11, 8.4) of a safely-derived pointer value;
2.5 the result of a `reinterpret_cast` of a safely-derived pointer value;
2.6 the result of a `reinterpret_cast` of an integer representation of a safely-derived pointer value;
2.7 the value of an object whose value was copied from a traceable pointer object, where at the time of the copy the source object contained a copy of a safely-derived pointer value.

3 An integer value is an **integer representation of a safely-derived pointer** only if its type is at least as large as `std::intptr_t` and it is one of the following:

3.1 the result of a `reinterpret_cast` of a safely-derived pointer value;
3.2 the result of a valid conversion of an integer representation of a safely-derived pointer value;
3.3 the value of an object whose value was copied from a traceable pointer object, where at the time of the copy the source object contained an integer representation of a safely-derived pointer value;
3.4 the result of an additive or bitwise operation, one of whose operands is an integer representation of a safely-derived pointer value `P`, if that result converted by `reinterpret_cast<void*>>` would compare equal to a safely-derived pointer computable from `reinterpret_cast<void*>(P)`.

4 An implementation may have **relaxed pointer safety**, in which case the validity of a pointer value does not depend on whether it is a safely-derived pointer value. Alternatively, an implementation may have **strict pointer safety**, in which case a pointer value referring to an object with dynamic storage duration that is not a safely-derived pointer value is an invalid pointer value unless the referenced complete object has previously been declared reachable (23.10.4).  

\[^{40}\) This section does not impose restrictions on indirection through pointers to memory not allocated by `::operator new`. This maintains the ability of many C++ implementations to use binary libraries and components written in other languages. In particular, this applies to C binaries, because indirection through pointers to memory allocated by `std::malloc` is not restricted.\]
compare equal to some safely-derived pointer value. —end note] It is implementation-defined whether an implementation has relaxed or strict pointer safety.

6.7.5 Duration of subobjects

The storage duration of subobjects and reference members is that of their complete object (4.5).

6.8 Object lifetime

The lifetime of an object or reference is a runtime property of the object or reference. An object is said to have non-vacuous initialization if it is of a class or aggregate type and it or one of its subobjects is initialized by a constructor other than a trivial default constructor. [Note: Initialization by a trivial copy/move constructor is non-vacuous initialization. —end note] The lifetime of an object of type \( T \) begins when:

(1.1) — storage with the proper alignment and size for type \( T \) is obtained, and
(1.2) — if the object has non-vacuous initialization, its initialization is complete,
except that if the object is a union member or subobject thereof, its lifetime only begins if that union member is the initialized member in the union (11.6.1, 15.6.2), or as described in 12.3. The lifetime of an object \( o \) of type \( T \) ends when:

(1.3) — if \( T \) is a class type with a non-trivial destructor (15.4), the destructor call starts, or
(1.4) — the storage which the object occupies is released, or is reused by an object that is not nested within \( o \) (4.5).

2 The lifetime of a reference begins when its initialization is complete. The lifetime of a reference ends as if it were a scalar object.

3 [Note: 15.6.2 describes the lifetime of base and member subobjects. —end note]

The properties ascribed to objects and references throughout this International Standard apply for a given object or reference only during its lifetime. [Note: In particular, before the lifetime of an object starts and after its lifetime ends there are significant restrictions on the use of the object, as described below, in 15.6.2 and in 15.7. Also, the behavior of an object under construction and destruction might not be the same as the behavior of an object whose lifetime has started and not ended. 15.6.2 and 15.7 describe the behavior of objects during the construction and destruction phases. —end note]

5 A program may end the lifetime of any object by reusing the storage which the object occupies or by explicitly calling the destructor for an object of a class type with a non-trivial destructor. For an object of a class type with a non-trivial destructor, the program is not required to call the destructor explicitly before the storage which the object occupies is reused or released; however, if there is no explicit call to the destructor or if a delete-expression (8.3.5) is not used to release the storage, the destructor shall not be implicitly called and any program that depends on the side effects produced by the destructor has undefined behavior.

6 Before the lifetime of an object has started but after the storage which the object will occupy has been allocated\(^1\) or, after the lifetime of an object has ended and before the storage which the object occupied is reused or released, any pointer that represents the address of the storage location where the object will be or was located may be used but only in limited ways. For an object under construction or destruction, see 15.7. Otherwise, such a pointer refers to allocated storage (6.7.4.2), and using the pointer as if the pointer were of type \( \text{void}^* \), is well-defined. Indirection through such a pointer is permitted but the resulting lvalue may only be used in limited ways, as described below. The program has undefined behavior if:

(6.1) — the object will be or was of a class type with a non-trivial destructor and the pointer is used as the operand of a delete-expression,
(6.2) — the pointer is used to access a non-static data member or call a non-static member function of the object, or

\(^1\) For example, before the construction of a global object of non-POD class type (15.7).
(6.3) — the pointer is implicitly converted (7.11) to a pointer to a virtual base class, or
(6.4) — the pointer is used as the operand of a \texttt{static
cast} (8.2.9), except when the conversion is to pointer to \texttt{cv
t void}, or to pointer to \texttt{cv
t void} and subsequently to pointer to \texttt{cv
t char}, \texttt{cv
t unsigned
c char}, or \texttt{cv
t std: :byte} (21.2.1), or
(6.5) — the pointer is used as the operand of a \texttt{dynamic
cast} (8.2.7).

\textbf{Example:}

```c
#include <cstdlib>

struct B {
    virtual void f();
    void mutate();
    virtual ~B();
};

struct D1 : B { void f(); };
struct D2 : B { void f(); };

void B::mutate() {
    new (this) D2; // reuses storage — ends the lifetime of \*this
    f(); // undefined behavior
    ... = this; // OK, this points to valid memory
}

void g() {
    void* p = std::malloc(sizeof(D1) + sizeof(D2));
    B* pb = new (p) D1;
    pb->mutate();
    \*pb; // OK: pb points to valid memory
    void* q = pb; // OK: pb points to valid memory
    pb->f(); // undefined behavior, lifetime of \*pb has ended
}

— end example
```

7 Similarly, before the lifetime of an object has started but after the storage which the object will occupy has been allocated or, after the lifetime of an object has ended and before the storage which the object occupied is reused or released, any glvalue that refers to the original object may be used but only in limited ways. For an object under construction or destruction, see 15.7. Otherwise, such a glvalue refers to allocated storage (6.7.4.2), and using the properties of the glvalue that do not depend on its value is well-defined. The program has undefined behavior if:

(7.1) — the glvalue is used to access the object, or
(7.2) — the glvalue is used to call a non-static member function of the object, or
(7.3) — the glvalue is bound to a reference to a virtual base class (11.6.3), or
(7.4) — the glvalue is used as the operand of a \texttt{dynamic
cast} (8.2.7) or as the operand of \texttt{typeid}.

8 If, after the lifetime of an object has ended and before the storage which the object occupied is reused or released, a new object is created at the storage location which the original object occupied, a pointer that pointed to the original object, a reference that referred to the original object, or the name of the original object will automatically refer to the new object and, once the lifetime of the new object has started, can be used to manipulate the new object, if:

(8.1) — the storage for the new object exactly overlays the storage location which the original object occupied,
and

(8.2) the new object is of the same type as the original object (ignoring the top-level cv-qualifiers), and

(8.3) the type of the original object is not const-qualified, and, if a class type, does not contain any non-static data member whose type is const-qualified or a reference type, and

(8.4) the original object was a most derived object (4.5) of type \( \text{T} \) and the new object is a most derived object of type \( \text{T} \) (that is, they are not base class subobjects).

[Example:

```cpp
struct C {
    int i;
    void f();
    const C& operator=( const C& );
};

const C& C::operator=( const C& other) {
    if ( this != &other ) {
        this->~C(); // lifetime of *this ends
        new (this) C(other); // new object of type C created
        f(); // well-defined
    }
    return *this;
}
```

```cpp
c C c1;
c C c2;
c1 = c2; // well-defined
c1.f(); // well-defined; c1 refers to a new object of type C
```

— end example]

[ Note: If these conditions are not met, a pointer to the new object can be obtained from a pointer that represents the address of its storage by calling `std::launder` (21.6). — end note]

9 If a program ends the lifetime of an object of type \( \text{T} \) with static (6.7.1), thread (6.7.2), or automatic (6.7.3) storage duration and if \( \text{T} \) has a non-trivial destructor, the program must ensure that an object of the original type occupies that same storage location when the implicit destructor call takes place; otherwise the behavior of the program is undefined. This is true even if the block is exited with an exception. [Example:

```cpp
class T { }
struct B {
    ~B();
};

void h() {
    B b;
    new (&b) T; // undefined behavior at block exit
}
```

— end example]

10 Creating a new object within the storage that a `const` complete object with static, thread, or automatic storage duration occupies, or within the storage that such a `const` object used to occupy before its lifetime ended, results in undefined behavior. [Example:

```cpp
struct B {
```

42) That is, an object for which a destructor will be called implicitly—upon exit from the block for an object with automatic storage duration, upon exit from the thread for an object with thread storage duration, or upon exit from the program for an object with static storage duration.
In this section, “before” and “after” refer to the “happens before” relation (4.7). [Note: Therefore, undefined behavior results if an object that is being constructed in one thread is referenced from another thread without adequate synchronization. —end note]

### 6.9 Types

[basic.types]

1 [Note: 6.9 and the subclauses thereof impose requirements on implementations regarding the representation of types. There are two kinds of types: fundamental types and compound types. Types describe objects (4.5), references (11.3.2), or functions (11.3.5). —end note]

2 For any object (other than a base-class subobject) of trivially copyable type $T$, whether or not the object holds a valid value of type $T$, the underlying bytes (4.4) making up the object can be copied into an array of `char`, `unsigned char`, or `std::byte (21.2.1).` If the content of that array is copied back into the object, the object shall subsequently hold its original value. [Example:

```c
#define N sizeof(T)
char buf[N];
T obj; // obj initialized to its original value
std::memcpy(buf, &obj, N); // between these two calls to std::memcpy, obj might be modified
std::memcpy(&obj, buf, N); // at this point, each subobject of obj of scalar type holds its original value
```

—end example]

3 For any trivially copyable type $T$, if two pointers to $T$ point to distinct $T$ objects $obj1$ and $obj2$, where neither $obj1$ nor $obj2$ is a base-class subobject, if the underlying bytes (4.4) making up $obj1$ are copied into $obj2$, $obj2$ shall subsequently hold the same value as $obj1$. [Example:

```c
T* t1p;
T* t2p;
// provided that t2p points to an initialized object ...
std::memcpy(t1p, t2p, sizeof(T));
// at this point, every subobject of trivially copyable type in *t1p contains
// the same value as the corresponding subobject in *t2p
```

—end example]

4 The object representation of an object of type $T$ is the sequence of $N$ `unsigned char` objects taken up by the object of type $T$, where $N$ equals `sizeof(T)`. The value representation of an object is the set of bits that hold the value of type $T$. For trivially copyable types, the value representation is a set of bits in the object representation that determines a value, which is one discrete element of an implementation-defined set of values.

5 A class that has been declared but not defined, an enumeration type in certain contexts (10.2), or an array of

---

43) By using, for example, the library functions (20.5.1.2) `std::memcpy` or `std::memmove`.

44) By using, for example, the library functions (20.5.1.2) `std::memcpy` or `std::memmove`.

45) The intent is that the memory model of C++ is compatible with that of ISO/IEC 9899 Programming Language C.
unknown bound or of incomplete element type, is an *incompletely-defined object type*. Incompletely-defined object types and *cv void* are *incomplete types* (6.9.1). Objects shall not be defined to have an incomplete type.

6 A class type (such as “*class X*”) might be incomplete at one point in a translation unit and complete later on; the type “*class X*” is the same type at both points. The declared type of an array object might be an array of incomplete class type and therefore incomplete; if the class type is completed later on in the translation unit, the array type becomes complete; the array type at those two points is the same type. The declared type of an array object might be an array of unknown bound and therefore be incomplete at one point in a translation unit and complete later on; the array types at those two points (“array of unknown bound of *T*” and “array of *N T*”) are different types. The type of a pointer to array of unknown bound, or of a type defined by a *typedef* declaration to be an array of unknown bound, cannot be completed. [Example:

```c
struct X { int i; };                     // now X is a complete type
int  arr[10];                           // now the type of arr is complete

X x;
void bar() {                           // OK; type is “pointer to X”
    xp = &x;
    arrp = &arr;
    xp++;                               // OK: X is complete
    arrp++;                              // OK: sizeof UNKA* is known
}

--- end example]
```

7 [Note: The rules for declarations and expressions describe in which contexts incomplete types are prohibited. —end note]

8 An *object type* is a (possibly cv-qualified) type that is not a function type, not a reference type, and not *cv void*.

9 Arithmetic types (6.9.1), enumeration types, pointer types, pointer to member types (6.9.2), *std::nullptr_t*, and cv-qualified (6.9.3) versions of these types are collectively called *scalar types*. Scalar types, POD classes (Clause 12), arrays of such types and cv-qualified versions of these types are collectively called *POD types*. Cv-unqualified scalar types, trivially copyable class types (Clause 12), arrays of such types, and cv-qualified versions of these types are collectively called *trivially copyable types*. Scalar types, trivial class types (Clause 12), arrays of such types and cv-qualified versions of these types are collectively called *trivial types*. Scalar types, standard-layout class types (Clause 12), arrays of such types and cv-qualified versions of these types are collectively called *standard-layout types*.

10 A type is a *literal type* if it is:

46) The size and layout of an instance of an incompletely-defined object type is unknown.
(10.1) — possibly cv-qualified \texttt{void}; or
(10.2) — a scalar type; or
(10.3) — a reference type; or
(10.4) — an array of literal type; or
(10.5) — a possibly cv-qualified class type (Clause 12) that has all of the following properties:

(10.5.1) — it has a trivial destructor,
(10.5.2) — it is either a closure type (8.1.5.1), an aggregate type (11.6.1), or has at least one constexpr constructor or constructor template (possibly inherited (10.3.3) from a base class) that is not a copy or move constructor,
(10.5.3) — if it is a union, at least one of its non-static data members is of non-volatile literal type, and
(10.5.4) — if it is not a union, all of its non-static data members and base classes are of non-volatile literal types.

[Note: A literal type is one for which it might be possible to create an object within a constant expression. It is not a guarantee that it is possible to create such an object, nor is it a guarantee that any object of that type will usable in a constant expression. — end note]

11 Two types \texttt{cv1 \textit{T1} and cv2 \textit{T2}} are \textit{layout-compatible} types if \textit{T1} and \textit{T2} are the same type, layout-compatible enumerations (10.2), or layout-compatible standard-layout class types (12.2).

6.9.1 Fundamental types

1 Objects declared as characters (\texttt{char}) shall be large enough to store any member of the implementation’s basic character set. If a character from this set is stored in a character object, the integral value of that character object is equal to the value of the single character literal form of that character. It is implementation-defined whether a \texttt{char} object can hold negative values. Characters can be explicitly declared \texttt{unsigned} or \texttt{signed}. Plain \texttt{char}, \texttt{signed char}, and \texttt{unsigned char} are three distinct types, collectively called \textit{narrow character types}. A \texttt{char}, a \texttt{signed char}, and an \texttt{unsigned char} occupy the same amount of storage and have the same alignment requirements (6.11); that is, they have the same object representation. For narrow character types, all bits of the object representation participate in the value representation. [Note: A bit-field of narrow character type whose length is larger than the number of bits in the object representation of that type has padding bits; see 12.2.4. — end note] For unsigned narrow character types, each possible bit pattern of the value representation represents a distinct number. These requirements do not hold for other types. In any particular implementation, a plain \texttt{char} object can take on either the same values as a \texttt{signed char} or an \texttt{unsigned char}; which one is implementation-defined. For each value \textit{i} of type \texttt{unsigned char} in the range 0 to 255 inclusive, there exists a value \textit{j} of type \texttt{char} such that the result of an integral conversion (7.8) from \textit{i} to \texttt{char} is \textit{j}, and the result of an integral conversion from \textit{j} to \texttt{unsigned char} is \textit{i}.

2 There are five \textit{standard signed integer types}：“\texttt{signed char}”, “\texttt{short int}”, “\texttt{int}”, “\texttt{long int}”, and “\texttt{long long int}”. In this list, each type provides at least as much storage as those preceding it in the list. There may also be implementation-defined \textit{extended signed integer types}. The standard and extended signed integer types are collectively called \textit{signed integer types}. Plain \texttt{ints} have the natural size suggested by the architecture of the execution environment\(^{47}\); the other signed integer types are provided to meet special needs.

3 For each of the standard signed integer types, there exists a corresponding (but different) \textit{standard unsigned integer type}：“\texttt{unsigned char}”, “\texttt{unsigned short int}”, “\texttt{unsigned int}”, “\texttt{unsigned long int}”, and “\texttt{unsigned long long int}”, each of which occupies the same amount of storage and has the same alignment requirements (6.11) as the corresponding signed integer type\(^{48}\); that is, each signed integer type has the same object representation as its corresponding unsigned integer type. Likewise, for each of the extended

\(^{47}\) \texttt{int} must also be large enough to contain any value in the range \([\texttt{INT_MIN}, \texttt{INT_MAX}]\), as defined in the header \texttt{<climits>}. 

\(^{48}\) See 10.1.7.2 regarding the correspondence between types and the sequences of \texttt{type-specifiers} that designate them.
signed integer types there exists a corresponding extended unsigned integer type with the same amount of storage and alignment requirements. The standard and extended unsigned integer types are collectively called unsigned integer types. The range of non-negative values of a signed integer type is a subrange of the corresponding unsigned integer type, the representation of the same value in each of the two types is the same, and the value representation of each corresponding signed/unsigned type shall be the same. The standard signed integer types and standard unsigned integer types are collectively called the standard integer types, and the extended signed integer types and extended unsigned integer types are collectively called the extended integer types. The signed and unsigned integer types shall satisfy the constraints given in the C standard, section 5.2.4.2.1.

4

Unsigned integers shall obey the laws of arithmetic modulo \(2^n\) where \(n\) is the number of bits in the value representation of that particular size of integer.\(^{49}\)

5

Type wchar_t is a distinct type whose values can represent distinct codes for all members of the largest extended character set specified among the supported locales (25.3.1). Type wchar_t shall have the same size, signedness, and alignment requirements (6.11) as one of the other integral types, called its underlying type. Types char16_t and char32_t denote distinct types with the same size, signedness, and alignment as uint_least16_t and uint_least32_t, respectively, in <cstdint>, called the underlying types.

6

Values of type bool are either true or false.\(^{50}\) [Note: There are no signed, unsigned, short, or long bool types or values. — end note] Values of type bool participate in integral promotions (7.6).

7

Types bool, char, char16_t, char32_t, wchar_t, and the signed and unsigned integer types are collectively called integral types.\(^{51}\) A synonym for integral type is integer type. The representations of integral types shall define values by use of a pure binary numeral system.\(^{52}\) [Example: This International Standard permits two’s complement, ones’ complement and signed magnitude representations for integral types. — end example]

8

There are three floating-point types: float, double, and long double. The type double provides at least as much precision as float, and the type long double provides at least as much precision as double. The set of values of the type float is a subset of the set of values of the type double; the set of values of the type double is a subset of the set of values of the type long double. The value representation of floating-point types is implementation-defined. [Note: This International Standard imposes no requirements on the accuracy of floating-point operations; see also 21.3. — end note] Integral and floating types are collectively called arithmetic types. Specializations of the standard library template std::numeric_limits (21.3) shall specify the maximum and minimum values of each arithmetic type for an implementation.

9

A type cv void is an incomplete type that cannot be completed; such a type has an empty set of values. It is used as the return type for functions that do not return a value. Any expression can be explicitly converted to type cv void (8.4). An expression of type cv void shall be used only as an expression statement (9.2), as an operand of a comma expression (8.19), as a second or third operand of ?: (8.16), as the operand of typeid, noexcept, or decltype, as the expression in a return statement (9.6.3) for a function with the return type cv void, or as the operand of an explicit conversion to type cv void.

10

A value of type std::nullptr_t is a null pointer constant (7.11). Such values participate in the pointer and the pointer to member conversions (7.11, 7.12). sizeof(std::nullptr_t) shall be equal to sizeof(void*).

[Note: Even if the implementation defines two or more basic types to have the same value representation,

\(^{49}\) This implies that unsigned arithmetic does not overflow because a result that cannot be represented by the resulting unsigned integer type is reduced modulo the number that is one greater than the largest value that can be represented by the resulting unsigned integer type.

\(^{50}\) Using a bool value in ways described by this International Standard as “undefined”, such as by examining the value of an uninitialized automatic object, might cause it to behave as if it is neither true nor false.

\(^{51}\) Therefore, enumerations (10.2) are not integral; however, enumerations can be promoted to integral types as specified in 7.6.

\(^{52}\) A positional representation for integers that uses the binary digits 0 and 1, in which the values represented by successive bits are additive, begin with 1, and are multiplied by successive integral power of 2, except perhaps for the bit with the highest position. (Adapted from the American National Dictionary for Information Processing Systems.)
they are nevertheless different types. — end note]

6.9.2 Compound types

1 Compound types can be constructed in the following ways:

(1.1) — arrays of objects of a given type, 11.3.4;
(1.2) — functions, which have parameters of given types and return void or references or objects of a given type, 11.3.5;
(1.3) — pointers to cv void or objects or functions (including static members of classes) of a given type, 11.3.1;
(1.4) — references to objects or functions of a given type, 11.3.2. There are two types of references:

(1.4.1) — lvalue reference
(1.4.2) — rvalue reference

(1.5) — classes containing a sequence of objects of various types (Clause 12), a set of types, enumerations and functions for manipulating these objects (12.2.1), and a set of restrictions on the access to these entities (Clause 14);
(1.6) — unions, which are classes capable of containing objects of different types at different times, 12.3;
(1.7) — enumerations, which comprise a set of named constant values. Each distinct enumeration constitutes a different enumerated type, 10.2;
(1.8) — pointers to non-static class members,53 which identify members of a given type within objects of a given class, 11.3.3.

2 These methods of constructing types can be applied recursively; restrictions are mentioned in 11.3.1, 11.3.4, 11.3.5, and 11.3.2. Constructing a type such that the number of bytes in its object representation exceeds the maximum value representable in the type std::size_t (21.2) is ill-formed.

3 The type of a pointer to cv void or a pointer to an object type is called an object pointer type. [Note: A pointer to void does not have a pointer-to-object type, however, because void is not an object type. — end note] The type of a pointer that can designate a function is called a function pointer type. A pointer to objects of type T is referred to as a “pointer to T”. [Example: A pointer to an object of type int is referred to as “pointer to int” and a pointer to an object of class X is called a “pointer to X”. — end example] Except for pointers to static members, text referring to “pointers” does not apply to pointers to members. Pointers to incomplete types are allowed although there are restrictions on what can be done with them (6.11). Every value of pointer type is one of the following:

(3.1) — a pointer to an object or function (the pointer is said to point to the object or function), or
(3.2) — a pointer past the end of an object (8.7), or
(3.3) — the null pointer value (7.11) for that type, or
(3.4) — an invalid pointer value.

A value of a pointer type that is a pointer to or past the end of an object represents the address of the first byte in memory (4.4) occupied by the object54 or the first byte in memory after the end of the storage occupied by the object, respectively. [Note: A pointer past the end of an object (8.7) is not considered to point to an unrelated object of the object’s type that might be located at that address. A pointer value becomes invalid when the storage it denotes reaches the end of its storage duration; see 6.7. — end note] For purposes of pointer arithmetic (8.7) and comparison (8.9, 8.10), a pointer past the end of the last element of an array x of n elements is considered to be equivalent to a pointer to a hypothetical element x[n]. The value representation of pointer types is implementation-defined. Pointers to layout-compatible types shall

53) Static class members are objects or functions, and pointers to them are ordinary pointers to objects or functions.
54) For an object that is not within its lifetime, this is the first byte in memory that it will occupy or used to occupy.
Two objects \(a\) and \(b\) are pointer-interconvertible if:

- they are the same object, or

- one is a standard-layout union object and the other is a non-static data member of that object (12.3), or

- one is a standard-layout class object and the other is the first non-static data member of that object, or, if the object has no non-static data members, the first base class subobject of that object (12.2), or

- there exists an object \(c\) such that \(a\) and \(c\) are pointer-interconvertible, and \(c\) and \(b\) are pointer-interconvertible.

If two objects are pointer-interconvertible, then they have the same address, and it is possible to obtain a pointer to one from a pointer to the other via a \texttt{reinterpret_cast} (8.2.10). [Note: An array object and its first element are not pointer-interconvertible, even though they have the same address. — end note]

A pointer to \texttt{cv}-qualified (6.9.3) or \texttt{cv}-unqualified \texttt{void} can be used to point to objects of unknown type. Such a pointer shall be able to hold any object pointer. An object of type \texttt{cv void*} shall have the same representation and alignment requirements as \texttt{cv char*}.

### 6.9.3 CV-qualifiers

A type mentioned in 6.9.1 and 6.9.2 is a \texttt{cv-unqualified type}. Each type which is a \texttt{cv-unqualified complete or incomplete object type} or is \texttt{void} (6.9) has three corresponding \texttt{cv-qualified} versions of its type: a \texttt{const-qualified} version, a \texttt{volatile-qualified} version, and a \texttt{const-volatile-qualified} version. The type of an object (4.5) includes the \texttt{cv-qualifiers} specified in the \texttt{decl-specifier-seq} (10.1), \texttt{declarator} (Clause 11), \texttt{type-id} (11.1), or \texttt{new-type-id} (8.3.4) when the object is created.

- A \texttt{const object} is an object of type \texttt{const T} or a non-mutable subobject of such an object.

- A \texttt{volatile object} is an object of type \texttt{volatile T}, a subobject of such an object, or a mutable subobject of a \texttt{const volatile} object.

- A \texttt{const volatile object} is an object of type \texttt{const volatile T}, a non-mutable subobject of such an object, a \texttt{const} subobject of a \texttt{volatile} object, or a non-mutable \texttt{volatile} subobject of a \texttt{const} object.

The \texttt{cv-qualified} or \texttt{cv-unqualified} versions of a type are distinct types; however, they shall have the same representation and alignment requirements (6.11).

A compound type (6.9.2) is not \texttt{cv-qualified} by the \texttt{cv-qualifiers} (if any) of the types from which it is compounded. Any \texttt{cv-qualifiers} applied to an array type affect the array element type (11.3.4).

See 11.3.5 and 12.2.2.1 regarding function types that have \texttt{cv-qualifiers}.

There is a partial ordering on \texttt{cv-qualifiers}, so that a type can be said to be \textit{more \texttt{cv-qualified}} than another. Table 10 shows the relations that constitute this ordering.

In this International Standard, the notation \texttt{cv} (or \texttt{cv1}, \texttt{cv2}, etc.), used in the description of types, represents an arbitrary set of \texttt{cv-qualifiers}, i.e., one of \{\texttt{const}\}, \{\texttt{volatile}\}, \{\texttt{const, volatile}\}, or the empty set. For a type \texttt{cv T}, the \textit{top-level \texttt{cv-qualifiers}} of that type are those denoted by \texttt{cv}. [Example: The type corresponding to the \texttt{type-id \texttt{const int}*} has no top-level \texttt{cv-qualifiers}. The type corresponding to the \texttt{type-id volatile int* \texttt{const}} has the top-level \texttt{cv-qualifier \texttt{const}}. For a class type \texttt{C}, the type corresponding to the \texttt{type-id void (C::* volatile)(int) \texttt{const}} has the top-level \texttt{cv-qualifier \texttt{volatile}. — end example]

---

55) The same representation and alignment requirements are meant to imply interchangeability as arguments to functions, return values from functions, and non-static data members of unions.
Table 10 — Relations on \texttt{const} and \texttt{volatile}

<table>
<thead>
<tr>
<th>no cv-qualifier</th>
<th>\texttt{const}</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{volatile}</td>
<td>\texttt{const}</td>
</tr>
<tr>
<td>\texttt{volatile}</td>
<td>\texttt{const}</td>
</tr>
</tbody>
</table>

Cv-qualifiers applied to an array type attach to the underlying element type, so the notation “\texttt{cv T}”, where \texttt{T} is an array type, refers to an array whose elements are so-qualified. An array type whose elements are cv-qualified is also considered to have the same cv-qualifications as its elements. [\textit{Example:}]

typedef char \texttt{CA}[5];
typedef const char \texttt{CC};
\texttt{CC arr1[5] = \{ 0 \};}
const \texttt{CA arr2 = \{ 0 \};}

The type of both \texttt{arr1} and \texttt{arr2} is “array of 5 \texttt{const char}”, and the array type is considered to be const-qualified. —\textit{end example}]

6.10 Lvalues and rvalues

Expressions are categorized according to the taxonomy in Figure 1.

- A \textit{glvalue} is an expression whose evaluation determines the identity of an object, bit-field, or function.
- A \textit{prvalue} is an expression whose evaluation initializes an object or a bit-field, or computes the value of the operand of an operator, as specified by the context in which it appears.
- An \textit{xvalue} is a glvalue that denotes an object or bit-field whose resources can be reused (usually because it is near the end of its lifetime). [\textit{Example:} Certain kinds of expressions involving rvalue references (11.3.2) yield xvalues, such as a call to a function whose return type is an rvalue reference or a cast to an rvalue reference type. —\textit{end example}]
- An \textit{lvalue} is a glvalue that is not an xvalue.
- An \textit{rvalue} is a prvalue or an xvalue.

[\textit{Note:} Historically, lvalues and rvalues were so-called because they could appear on the left- and right-hand side of an assignment (although this is no longer generally true); glvalues are “generalized” lvalues, prvalues are “pure” rvalues, and xvalues are “eXpiring” lvalues. Despite their names, these terms classify expressions, not values. —\textit{end note}] Every expression belongs to exactly one of the fundamental classifications in this taxonomy: lvalue, xvalue, or prvalue. This property of an expression is called its value category. [\textit{Note:} The discussion of each built-in operator in Clause 8 indicates the category of the value it yields and the value categories of the operands it expects. For example, the built-in assignment operators expect that the left
operand is an lvalue and that the right operand is a prvalue and yield an lvalue as the result. User-defined operators are functions, and the categories of values they expect and yield are determined by their parameter and return types. —end note]

2 The result of a prvalue is the value that the expression stores into its context. A prvalue whose result is the value \( V \) is sometimes said to have or name the value \( V \). The result object of a prvalue is the object initialized by the prvalue; a prvalue that is used to compute the value of an operand of an operator or that has type cv void has no result object. [Note: Except when the prvalue is the operand of a decltype-specifier, a prvalue of class or array type always has a result object. For a discarded prvalue, a temporary object is materialized; see Clause 8. —end note] The result of a glvalue is the entity denoted by the expression.

3 [Note: Whenever a glvalue appears in a context where a prvalue is expected, the glvalue is converted to a prvalue; see 7.1, 7.2, and 7.3. An attempt to bind an rvalue reference to an lvalue is not such a context; see 11.6.3. —end note] [Note: There are no prvalue bit-fields; if a bit-field is converted to a prvalue (7.1), a prvalue of the type of the bit-field is created, which might then be promoted (7.6). —end note]

4 [Note: Whenever a prvalue appears in a context where a glvalue is expected, the prvalue is converted to an xvalue; see 7.4. —end note]

5 The discussion of reference initialization in 11.6.3 and of temporaries in 15.2 indicates the behavior of lvalues and rvalues in other significant contexts.

6 Unless otherwise indicated (8.2.2), a prvalue shall always have complete type or the void type. A glvalue shall not have type cv void. [Note: A glvalue may have complete or incomplete non-void type. Class and array prvalues can have cv-qualified types; other prvalues always have cv-unqualified types. See Clause 8. —end note]

7 An lvalue is modifiable unless its type is const-qualified or is a function type. [Note: A program that attempts to modify an object through a non-modifiable lvalue expression or through an rvalue expression is ill-formed (8.18, 8.2.6, 8.3.2). —end note]

8 If a program attempts to access the stored value of an object through a glvalue of other than one of the following types the behavior is undefined:56

- the dynamic type of the object,
- a cv-qualified version of the dynamic type of the object,
- a type similar (as defined in 7.5) to the dynamic type of the object,
- a type that is the signed or unsigned type corresponding to the dynamic type of the object,
- a type that is the signed or unsigned type corresponding to a cv-qualified version of the dynamic type of the object,
- an aggregate or union type that includes one of the aforementioned types among its elements or non-static data members (including, recursively, an element or non-static data member of a subaggregate or contained union),
- a type that is a (possibly cv-qualified) base class type of the dynamic type of the object,
- a char, unsigned char, or \texttt{std::byte} type.

6.11 Alignment [basic.align]

1 Object types have alignment requirements (6.9.1, 6.9.2) which place restrictions on the addresses at which an object of that type may be allocated. An alignment is an implementation-defined integer value representing the number of bytes between successive addresses at which a given object can be allocated. An object type imposes an alignment requirement on every object of that type; stricter alignment can be requested using the alignment specifier (10.6.2).

56 The intent of this list is to specify those circumstances in which an object may or may not be aliased.
A fundamental alignment is represented by an alignment less than or equal to the greatest alignment supported by the implementation in all contexts, which is equal to `alignof(std::max_align_t)` (21.2). The alignment required for a type might be different when it is used as the type of a complete object and when it is used as the type of a subobject. [Example:

```cpp
struct B { long double d; }
struct D : virtual B { char c; }
```

When `D` is the type of a complete object, it will have a subobject of type `B`, so it must be aligned appropriately for a `long double`. If `D` appears as a subobject of another object that also has `B` as a virtual base class, the `B` subobject might be part of a different subobject, reducing the alignment requirements on the `D` subobject. — end example] The result of the `alignof` operator reflects the alignment requirement of the type in the complete-object case.

An extended alignment is represented by an alignment greater than `alignof(std::max_align_t)`. It is implementation-defined whether any extended alignments are supported and the contexts in which they are supported (10.6.2). A type having an extended alignment requirement is an over-aligned type. [Note: Every over-aligned type is or contains a class type to which extended alignment applies (possibly through a non-static data member). — end note] A new-extended alignment is represented by an alignment greater than `__STDCPP_DEFAULT_NEW_ALIGNMENT__` (19.8).

Alignments are represented as values of the type `std::size_t`. Valid alignments include only those values returned by an `alignof` expression for the fundamental types plus an additional implementation-defined set of values, which may be empty. Every alignment value shall be a non-negative integral power of two.

Alignments have an order from weaker to stronger or stricter alignments. Stricter alignments have larger alignment values. An address that satisfies an alignment requirement also satisfies any weaker valid alignment requirement.

The alignment requirement of a complete type can be queried using an `alignof` expression (8.3.6). Furthermore, the narrow character types (6.9.1) shall have the weakest alignment requirement. [Note: This enables the narrow character types to be used as the underlying type for an aligned memory area (10.6.2). — end note]

Comparing alignments is meaningful and provides the obvious results:

- Two alignments are equal when their numeric values are equal.
- Two alignments are different when their numeric values are not equal.
- When an alignment is larger than another it represents a stricter alignment.

[Note: The runtime pointer alignment function (23.10.5) can be used to obtain an aligned pointer within a buffer; the aligned-storage templates in the library (23.15.7.6) can be used to obtain aligned storage. — end note]

If a request for a specific extended alignment in a specific context is not supported by an implementation, the program is ill-formed.
Standard conversions

1 Standard conversions are implicit conversions with built-in meaning. Clause 7 enumerates the full set of such conversions. A *standard conversion sequence* is a sequence of standard conversions in the following order:

(1.1) — Zero or one conversion from the following set: lvalue-to-rvalue conversion, array-to-pointer conversion, and function-to-pointer conversion.

(1.2) — Zero or one conversion from the following set: integral promotions, floating-point promotion, integral conversions, floating-point conversions, floating-integral conversions, pointer conversions, pointer to member conversions, and boolean conversions.

(1.3) — Zero or one function pointer conversion.

(1.4) — Zero or one qualification conversion.

[Note: A standard conversion sequence can be empty, i.e., it can consist of no conversions. — end note] A standard conversion sequence will be applied to an expression if necessary to convert it to a required destination type.

2 [Note: Expressions with a given type will be implicitly converted to other types in several contexts:

(2.1) — When used as operands of operators. The operator’s requirements for its operands dictate the destination type (Clause 8).

(2.2) — When used in the condition of an if statement or iteration statement (9.4, 9.5). The destination type is bool.

(2.3) — When used in the expression of a switch statement. The destination type is integral (9.4).

(2.4) — When used as the source expression for an initialization (which includes use as an argument in a function call and use as the expression in a return statement). The type of the entity being initialized is (generally) the destination type. See 11.6, 11.6.3.

— end note]

3 An expression e can be *implicitly converted* to a type T if and only if the declaration T t=e; is well-formed, for some invented temporary variable t (11.6).

4 Certain language constructs require that an expression be converted to a Boolean value. An expression e appearing in such a context is said to be *contextually converted to bool* and is well-formed if and only if the declaration bool t(e); is well-formed, for some invented temporary variable t (11.6).

5 Certain language constructs require conversion to a value having one of a specified set of types appropriate to the construct. An expression e of class type E appearing in such a context is said to be *contextually implicitly converted* to a specified type T and is well-formed if and only if e can be implicitly converted to a type T that is determined as follows: E is searched for non-explicit conversion functions whose return type is cv T or reference to cv T such that T is allowed by the context. There shall be exactly one such T.

6 The effect of any implicit conversion is the same as performing the corresponding declaration and initialization and then using the temporary variable as the result of the conversion. The result is an lvalue if T is an lvalue reference type or an rvalue reference to function type (11.3.2), an xvalue if T is an rvalue reference to object type, and a prvalue otherwise. The expression e is used as a glvalue if and only if the initialization uses it as a glvalue.

7 [Note: For class types, user-defined conversions are considered as well; see 15.3. In general, an implicit conversion sequence (16.3.3.1) consists of a standard conversion sequence followed by a user-defined conversion]
followed by another standard conversion sequence. —end note]

[Note: There are some contexts where certain conversions are suppressed. For example, the lvalue-to-rvalue conversion is not done on the operand of the unary & operator. Specific exceptions are given in the descriptions of those operators and contexts. —end note]

7.1 Lvalue-to-rvalue conversion [conv.lval]

1 A glvalue (6.10) of a non-function, non-array type T can be converted to a prvalue.\(^{57}\) If T is an incomplete type, a program that necessitates this conversion is ill-formed. If T is a non-class type, the type of the prvalue is the cv-unqualified version of T. Otherwise, the type of the prvalue is T.\(^{58}\)

2 When an lvalue-to-rvalue conversion is applied to an expression e, and either

\(\text{(2.1)}\)

— e is not potentially evaluated, or

\(\text{(2.2)}\)

— the evaluation of e results in the evaluation of a member \(e_x\) of the set of potential results of e, and \(e_x\) names a variable \(x\) that is not odr-used by \(e_x\) (6.2),

the value contained in the referenced object is not accessed. [Example:

```c
struct S { int n; };
auto f() {
    S x { 1 };
    constexpr S y { 2 };
    return &[bool b) { return (b ? y : x).n; };
}
auto g = f();
int m = g(false); // undefined behavior due to access of x.n outside its lifetime
int n = g(true);  // OK, does not access y.n
```

—end example]

3 The result of the conversion is determined according to the following rules:

\(\text{(3.1)}\)

— If T is \(\text{cv std::nullptr_t}\), the result is a null pointer constant (7.11). [Note: Since no value is fetched from memory, there is no side effect for a volatile access (4.6), and an inactive member of a union (12.3) may be accessed. —end note]

\(\text{(3.2)}\)

— Otherwise, if T has a class type, the conversion copy-initializes the result object from the glvalue.

\(\text{(3.3)}\)

— Otherwise, if the object to which the glvalue refers contains an invalid pointer value (6.7.4.2, 6.7.4.3), the behavior is implementation-defined.

\(\text{(3.4)}\)

— Otherwise, the value contained in the object indicated by the glvalue is the prvalue result.

[Note: See also 6.10. —end note]

7.2 Array-to-pointer conversion [conv.array]

1 An lvalue or rvalue of type “array of \(N\) T” or “array of unknown bound of T” can be converted to a prvalue of type “pointer to T”. The temporary materialization conversion (7.4) is applied. The result is a pointer to the first element of the array.

\(^{57}\) For historical reasons, this conversion is called the “lvalue-to-rvalue” conversion, even though that name does not accurately reflect the taxonomy of expressions described in 6.10.

\(^{58}\) In C++ class and array prvalues can have cv-qualified types. This differs from ISO C, in which non-lvalues never have cv-qualified types.
7.3 Function-to-pointer conversion [conv.func]

An lvalue of function type \( T \) can be converted to a prvalue of type “pointer to \( T \)”. The result is a pointer to the function.\(^{59}\)

\[ \text{Note: See 16.4 for additional rules for the case where the function is overloaded. — end note} \]

7.4 Temporary materialization conversion [conv.rval]

A prvalue of type \( T \) can be converted to an xvalue of type \( T \). This conversion initializes a temporary object (15.2) of type \( T \) from the prvalue by evaluating the prvalue with the temporary object as its result object, and produces an xvalue denoting the temporary object. \( T \) shall be a complete type.\(^{60}\)

\[ \text{Example:} \]
\begin{verbatim}
struct X { int n; };
int k = X().n;  // OK, X() prvalue is converted to xvalue
\end{verbatim}

—end example

7.5 Qualification conversions [conv.qual]

A \( cv \)-decomposition of a type \( T \) is a sequence of \( cv_i \) and \( P_i \) such that \( T \) is “\( cv_0 \ P_0 \ cv_1 \ P_1 \cdots \ cv_{n-1} \ P_{n-1} \ cv_n \ \{U\} \) for \( n > 0 \),

where each \( cv_i \) is a set of \( cv \)-qualifiers (6.9.3), and each \( P_i \) is “pointer to” (11.3.1), “pointer to member of class \( C_i \) of type” (11.3.3), “array of \( N_i \)”, or “array of unknown bound of” (11.3.4). If \( P_i \) designates an array, the \( cv \)-qualifiers \( cv_{i+1} \) on the element type are also taken as the \( cv \)-qualifiers \( cv_i \) of the array.\(^{61}\)

\[ \text{Example: The type denoted by the type-id const int ** has two cv-decompositions, taking U as “int” and as “pointer to const int”. — end example} \]

The \( n \)-tuple of \( cv \)-qualifiers after the first one in the longest cv-decomposition of \( T \), that is, \( cv_1, cv_2, \ldots, cv_n \), is called the \( cv \)-qualification signature of \( T \).

Two types \( T_1 \) and \( T_2 \) are similar if they have cv-decompositions with the same \( n \) such that corresponding \( P_i \) components are the same and the types denoted by \( U \) are the same.

A prvalue expression of type \( T_1 \) can be converted to type \( T_2 \) if the following conditions are satisfied, where \( cv_i \) denotes the \( cv \)-qualifiers in the \( cv \)-qualification signature of \( T_j \).\(^{60}\)

\[ \begin{align*}
(3.1) & \quad T_1 \text{ and } T_2 \text{ are similar.} \\
(3.2) & \quad \text{For every } i > 0, \text{ if const is in } cv_1 \text{ then const is in } cv_2, \text{ and similarly for volatile.} \\
(3.3) & \quad \text{If the } cv_1 \text{ and } cv_2 \text{ are different, then const is in every } cv_k \text{ for } 0 < k < i.
\end{align*} \]

\[ \text{Note: If a program could assign a pointer of type } T** \text{ to a pointer of type } \text{const } T** \text{ (that is, if line #1 below were allowed), a program could inadvertently modify a const object (as it is done on line #2). For example,} \]
\begin{verbatim}
int main() {
  const char c = 'c';
  char* pc;
  const char** pcc = &pc;  // #1: not allowed
  *pcc = &c;
  *pc = 'C';  // #2: modifies a const object
}
\end{verbatim}

—end note

\(^{59}\) This conversion never applies to non-static member functions because an lvalue that refers to a non-static member function cannot be obtained.

\(^{60}\) These rules ensure that const-safety is preserved by the conversion.
Note: A prvalue of type “pointer to cv1 T” can be converted to a prvalue of type “pointer to cv2 T” if “cv2 T” is more cv-qualified than “cv1 T”. A prvalue of type “pointer to member of X of type cv1 T” can be converted to a prvalue of type “pointer to member of X of type cv2 T” if “cv2 T” is more cv-qualified than “cv1 T”. —end note

Note: Function types (including those used in pointer to member function types) are never cv-qualified (11.3.5). —end note

7.6 Integral promotions [conv.prom]

1 A prvalue of an integer type other than bool, char16_t, char32_t, or wchar_t whose integer conversion rank (7.15) is less than the rank of int can be converted to a prvalue of type int if int can represent all the values of the source type; otherwise, the source prvalue can be converted to a prvalue of type unsigned int.

2 A prvalue of type char16_t, char32_t, or wchar_t (6.9.1) can be converted to a prvalue of the first of the following types that can represent all the values of its underlying type: int, unsigned int, long int, unsigned long int, long long int, or unsigned long long int. If none of the types in that list can represent all the values of its underlying type, a prvalue of type char16_t, char32_t, or wchar_t can be converted to a prvalue of its underlying type.

3 A prvalue of an unscoped enumeration type whose underlying type is not fixed (10.2) can be converted to a prvalue of the first of the following types that can represent all the values of the enumeration (i.e., the values in the range b_min to b_max as described in 10.2): int, unsigned int, long int, unsigned long int, long long int, or unsigned long long int. If none of the types in that list can represent all the values of the enumeration, a prvalue of an unscoped enumeration type can be converted to a prvalue of the extended integer type with lowest integer conversion rank (7.15) greater than the rank of long long in which all the values of the enumeration can be represented. If there are two such extended types, the signed one is chosen.

4 A prvalue of an unscoped enumeration type whose underlying type is fixed (10.2) can be converted to a prvalue of its underlying type. Moreover, if integral promotion can be applied to its underlying type, a prvalue of an unscoped enumeration type whose underlying type is fixed can also be converted to a prvalue of the promoted underlying type.

5 A prvalue for an integral bit-field (12.2.4) can be converted to a prvalue of type int if int can represent all the values of the bit-field; otherwise, it can be converted to unsigned int if unsigned int can represent all the values of the bit-field. If the bit-field is larger yet, no integral promotion applies to it. If the bit-field has an enumerated type, it is treated as any other value of that type for promotion purposes.

6 A prvalue of type bool can be converted to a prvalue of type int, with false becoming zero and true becoming one.

7 These conversions are called integral promotions.

7.7 Floating-point promotion [conv.fpprom]

1 A prvalue of type float can be converted to a prvalue of type double. The value is unchanged.

2 This conversion is called floating-point promotion.

7.8 Integral conversions [conv.integral]

1 A prvalue of an integer type can be converted to a prvalue of another integer type. A prvalue of an unscoped enumeration type can be converted to a prvalue of an integer type.

2 If the destination type is unsigned, the resulting value is the least unsigned integer congruent to the source integer (modulo 2^n where n is the number of bits used to represent the unsigned type). [Note: In a two’s complement representation, this conversion is conceptual and there is no change in the bit pattern (if there is no truncation). —end note]
3 If the destination type is signed, the value is unchanged if it can be represented in the destination type; otherwise, the value is implementation-defined.

4 If the destination type is `bool`, see 7.14. If the source type is `bool`, the value `false` is converted to zero and the value `true` is converted to one.

5 The conversions allowed as integral promotions are excluded from the set of integral conversions.

7.9 Floating-point conversions

1 A prvalue of floating-point type can be converted to a prvalue of another floating-point type. If the source value can be exactly represented in the destination type, the result of the conversion is that exact representation. If the source value is between two adjacent destination values, the result of the conversion is an implementation-defined choice of either of those values. Otherwise, the behavior is undefined.

2 The conversions allowed as floating-point promotions are excluded from the set of floating-point conversions.

7.10 Floating-integral conversions

1 A prvalue of a floating-point type can be converted to a prvalue of an integer type. The conversion truncates; that is, the fractional part is discarded. The behavior is undefined if the truncated value cannot be represented in the destination type. [Note: If the destination type is `bool`, see 7.14. — end note]

2 A prvalue of an integer type or of an unscoped enumeration type can be converted to a prvalue of a floating-point type. The result is exact if possible. If the value being converted is in the range of values that can be represented but the value cannot be represented exactly, it is an implementation-defined choice of either the next lower or higher representable value. [Note: Loss of precision occurs if the integral value cannot be represented exactly as a value of the floating type. — end note] If the value being converted is outside the range of values that can be represented, the behavior is undefined. If the source type is `bool`, the value `false` is converted to zero and the value `true` is converted to one.

7.11 Pointer conversions

1 A null pointer constant is an integer literal (5.13.2) with value zero or a prvalue of type `std::nullptr_t`. A null pointer constant can be converted to a pointer type; the result is the null member pointer value of that type and is distinguishable from every other value of object pointer or function pointer type. Such a conversion is called a null pointer conversion. Two null pointer values of the same type shall compare equal. The conversion of a null pointer constant to a pointer to cv-qualified type is a single conversion, and not the sequence of a pointer conversion followed by a qualification conversion (7.5). A null pointer constant of integral type can be converted to a prvalue of type `std::nullptr_t`. [Note: The resulting prvalue is not a null pointer value. — end note]

2 A prvalue of type “pointer to cv T”, where T is an object type, can be converted to a prvalue of type “pointer to cv void”. The pointer value (6.9.2) is unchanged by this conversion.

3 A prvalue of type “pointer to cv D”, where D is a class type, can be converted to a prvalue of type “pointer to cv B”, where B is a base class (Clause 13) of D. If B is an inaccessible (Clause 14) or ambiguous (13.2) base class of D, a program that necessitates this conversion is ill-formed. The result of the conversion is a pointer to the base class subobject of the derived class object. The null pointer value is converted to the null pointer value of the destination type.

7.12 Pointer to member conversions

1 A null pointer constant (7.11) can be converted to a pointer to member type; the result is the null member pointer value of that type and is distinguishable from any pointer to member not created from a null pointer constant. Such a conversion is called a null member pointer conversion. Two null member pointer values of the same type shall compare equal. The conversion of a null pointer constant to a pointer to member of
cv-qualified type is a single conversion, and not the sequence of a pointer to member conversion followed by a qualification conversion (7.5).

2 A prvalue of type “pointer to member of \( B \) of type \( cv \ T \)”, where \( B \) is a class type, can be converted to a prvalue of type “pointer to member of \( D \) of type \( cv \ T \)”, where \( D \) is a derived class (Clause 13) of \( B \). If \( B \) is an inaccessible (Clause 14), ambiguous (13.2), or virtual (13.1) base class of \( D \), or a base class of a virtual base class of \( D \), a program that necessitates this conversion is ill-formed. The result of the conversion refers to the same member as the pointer to member before the conversion took place, but it refers to the base class member as if it were a member of the derived class. The result refers to the member in \( D \)’s instance of \( B \). Since the result has type “pointer to member of \( D \) of type \( cv \ T \)”, indirection through it with a \( D \) object is valid. The result is the same as if indirectioning through the pointer to member of \( B \) with the \( B \) subobject of \( D \). The null member pointer value is converted to the null member pointer value of the destination type.

7.13 Function pointer conversions

A prvalue of type “pointer to \texttt{noexcept} function” can be converted to a prvalue of type “pointer to function”. The result is a pointer to the function. A prvalue of type “pointer to member of type \texttt{noexcept} function” can be converted to a prvalue of type “pointer to member of type function”. The result points to the member function.

[Example:

```c
void (*p)();
void (**pp)() noexcept = &p; // error: cannot convert to pointer to noexcept function

struct S { typedef void (*p)(); operator p(); };  
void (*q)() noexcept = S();  // error: cannot convert to pointer to noexcept function

— end example]
```

7.14 Boolean conversions

A prvalue of arithmetic, unscoped enumeration, pointer, or pointer to member type can be converted to a prvalue of type \texttt{bool}. A zero value, null pointer value, or null member pointer value is converted to \texttt{false}; any other value is converted to \texttt{true}. For direct-initialization (11.6), a prvalue of type \texttt{std::nullptr_t} can be converted to a prvalue of type \texttt{bool}; the resulting value is \texttt{false}.

7.15 Integer conversion rank

Every integer type has an integer conversion rank defined as follows:

\begin{enumerate}
\item[(1.1)] No two signed integer types other than \texttt{char} and \texttt{signed char} (if \texttt{char} is signed) shall have the same rank, even if they have the same representation.
\item[(1.2)] The rank of a signed integer type shall be greater than the rank of any signed integer type with a smaller size.
\item[(1.3)] The rank of \texttt{long long int} shall be greater than the rank of \texttt{long int}, which shall be greater than the rank of \texttt{int}, which shall be greater than the rank of \texttt{short int}, which shall be greater than the rank of \texttt{signed char}.
\item[(1.4)] The rank of any unsigned integer type shall equal the rank of the corresponding signed integer type.
\item[(1.5)] The rank of any standard integer type shall be greater than the rank of any extended integer type with the same size.
\end{enumerate}

\footnote{The rule for conversion of pointers to members (from pointer to member of base to pointer to member of derived) appears inverted compared to the rule for pointers to objects (from pointer to derived to pointer to base) (7.11, Clause 13). This inversion is necessary to ensure type safety. Note that a pointer to member is not an object pointer or a function pointer and the rules for conversions of such pointers do not apply to pointers to members. In particular, a pointer to member cannot be converted to a \texttt{void*}.}
(1.6) — The rank of char shall equal the rank of signed char and unsigned char.

(1.7) — The rank of bool shall be less than the rank of all other standard integer types.

(1.8) — The ranks of char16_t, char32_t, and wchar_t shall equal the ranks of their underlying types (6.9.1).

(1.9) — The rank of any extended signed integer type relative to another extended signed integer type with the same size is implementation-defined, but still subject to the other rules for determining the integer conversion rank.

(1.10) — For all integer types T1, T2, and T3, if T1 has greater rank than T2 and T2 has greater rank than T3, then T1 shall have greater rank than T3.

[Note: The integer conversion rank is used in the definition of the integral promotions (7.6) and the usual arithmetic conversions (Clause 8). — end note]
8 Expressions

1 [Note: Clause 8 defines the syntax, order of evaluation, and meaning of expressions. An expression is a sequence of operators and operands that specifies a computation. An expression can result in a value and can cause side effects. — end note]

2 [Note: Operators can be overloaded, that is, given meaning when applied to expressions of class type (Clause 12) or enumeration type (10.2). Uses of overloaded operators are transformed into function calls as described in 16.5. Overloaded operators obey the rules for syntax and evaluation order specified in Clause 8, but the requirements of operand type and value category are replaced by the rules for function call. Relations between operators, such as ++a meaning a+=1, are not guaranteed for overloaded operators (16.5). — end note]

3 Clause 8 defines the effects of operators when applied to types for which they have not been overloaded. Operator overloading shall not modify the rules for the built-in operators, that is, for operators applied to types for which they are defined by this Standard. However, these built-in operators participate in overload resolution, and as part of that process user-defined conversions will be considered where necessary to convert the operands to types appropriate for the built-in operator. If a built-in operator is selected, such conversions will be applied to the operands before the operation is considered further according to the rules in Clause 8; see 16.3.1.2, 16.6.

4 If during the evaluation of an expression, the result is not mathematically defined or not in the range of representable values for its type, the behavior is undefined. [Note: Treatment of division by zero, forming a remainder using a zero divisor, and all floating-point exceptions vary among machines, and is sometimes adjustable by a library function. — end note]

5 If an expression initially has the type “reference to T” (11.3.2, 11.6.3), the type is adjusted to T prior to any further analysis. The expression designates the object or function denoted by the reference, and the expression is an lvalue or an xvalue, depending on the expression. [Note: Before the lifetime of the reference has started or after it has ended, the behavior is undefined (see 6.8). — end note]

6 If a prvalue initially has the type “cv T”, where T is a cv-unqualified non-class, non-array type, the type of the expression is adjusted to T prior to any further analysis.

7 [Note: An expression is an xvalue if it is:

(7.1) the result of calling a function, whether implicitly or explicitly, whose return type is an rvalue reference to object type,

(7.2) a cast to an rvalue reference to object type,

(7.3) a class member access expression designating a non-static data member of non-reference type in which the object expression is an xvalue, or

(7.4) a .* pointer-to-member expression in which the first operand is an xvalue and the second operand is a pointer to data member.

In general, the effect of this rule is that named rvalue references are treated as lvalues and unnamed rvalue references to objects are treated as xvalues; rvalue references to functions are treated as lvalues whether named or not. — end note]

[Example:
struct A {
    int m;
}

62) The precedence of operators is not directly specified, but it can be derived from the syntax.
A a;
A&& ar = static_cast<A&&>(a);

The expressions `f()`, `f().m`, `static_cast<A&&>(a)`, and `a + a` are xvalues. The expression `ar` is an lvalue.

In some contexts, unevaluated operands appear (8.2.8, 8.3.3, 8.3.7, 10.1.7.2). An unevaluated operand is not evaluated. [Note: In an unevaluated operand, a non-static class member may be named (8.1) and naming of objects or functions does not, by itself, require that a definition be provided (6.2). An unevaluated operand is considered a full-expression (4.6). — end note]

Whenever a glvalue expression appears as an operand of an operator that expects a prvalue for that operand, the lvalue-to-rvalue (7.1), array-to-pointer (7.2), or function-to-pointer (7.3) standard conversions are applied to convert the expression to a prvalue. [Note: Because cv-qualifiers are removed from the type of an expression of non-class type when the expression is converted to a prvalue, an lvalue expression of type `const int` can, for example, be used where a prvalue expression of type `int` is required. — end note]

Whenever a prvalue expression appears as an operand of an operator that expects a glvalue for that operand, the temporary materialization conversion (7.4) is applied to convert the expression to an xvalue.

Many binary operators that expect operands of arithmetic or enumeration type cause conversions and yield result types in a similar way. The purpose is to yield a common type, which is also the type of the result. This pattern is called the usual arithmetic conversions, which are defined as follows:

(11.1) — If either operand is of scoped enumeration type (10.2), no conversions are performed; if the other operand does not have the same type, the expression is ill-formed.

(11.2) — If either operand is of type `long double`, the other shall be converted to `long double`.

(11.3) — Otherwise, if either operand is `double`, the other shall be converted to `double`.

(11.4) — Otherwise, if either operand is `float`, the other shall be converted to `float`.

(11.5) — Otherwise, the integral promotions (7.6) shall be performed on both operands. Then the following rules shall be applied to the promoted operands:

(11.5.1) — If both operands have the same type, no further conversion is needed.

(11.5.2) — Otherwise, if both operands have signed integer types or both have unsigned integer types, the operand with the type of lesser integer conversion rank shall be converted to the type of the operand with greater rank.

(11.5.3) — Otherwise, if the operand that has unsigned integer type has rank greater than or equal to the rank of the type of the other operand, the operand with signed integer type shall be converted to the type of the operand with unsigned integer type.

(11.5.4) — Otherwise, if the type of the operand with signed integer type can represent all of the values of the type of the operand with unsigned integer type, the operand with unsigned integer type shall be converted to the type of the operand with signed integer type.

(11.5.5) — Otherwise, both operands shall be converted to the unsigned integer type corresponding to the type of the operand with signed integer type.

In some contexts, an expression only appears for its side effects. Such an expression is called a discarded-value expression. The array-to-pointer (7.2) and function-to-pointer (7.3) standard conversions are not applied.

Expressions
The lvalue-to-rvalue conversion (7.1) is applied if and only if the expression is a glvalue of volatile-qualified type and it is one of the following:

(12.1) — `(expression)`, where `expression` is one of these expressions,

(12.2) — `id-expression` (8.1.4),

(12.3) — subscripting (8.2.1),

(12.4) — class member access (8.2.5),

(12.5) — indirection (8.3.1),

(12.6) — pointer-to-member operation (8.5),

(12.7) — conditional expression (8.16) where both the second and the third operands are one of these expressions, or

(12.8) — comma expression (8.19) where the right operand is one of these expressions.

[Note: Using an overloaded operator causes a function call; the above covers only operators with built-in meaning. —end note]

If the expression is a prvalue after this optional conversion, the temporary materialization conversion (7.4) is applied. [Note: If the expression is an lvalue of class type, it must have a volatile copy constructor to initialize the temporary that is the result object of the lvalue-to-rvalue conversion. —end note] The glvalue expression is evaluated and its value is discarded.

The values of the floating operands and the results of floating expressions may be represented in greater precision and range than that required by the type; the types are not changed thereby.

The `cv-combined type` of two types `T1` and `T2` is a type `T3` similar to `T1` whose cv-qualification signature (7.5) is:

(14.1) — for every `i > 0`, `cv^3_i` is the union of `cv^1_i` and `cv^2_i`;

(14.2) — if the resulting `cv^3_i` is different from `cv^1_i` or `cv^2_i`, then `const` is added to every `cv^3_k` for `0 < k < i`.

[Note: Given similar types `T1` and `T2`, this construction ensures that both can be converted to `T3`. —end note]

The `composite pointer type` of two operands `p1` and `p2` having types `T1` and `T2`, respectively, where at least one is a pointer or pointer to member type or `std::nullptr_t`, is:

(15.1) — if both `p1` and `p2` are null pointer constants, `std::nullptr_t`;

(15.2) — if either `p1` or `p2` is a null pointer constant, `T2` or `T1`, respectively;

(15.3) — if `T1` or `T2` is “pointer to `cv1 void`” and the other type is “pointer to `cv2 T`”, where `T` is an object type or `void`, “pointer to `cv12 void`”, where `cv12` is the union of `cv1` and `cv2`;

(15.4) — if `T1` or `T2` is “pointer to `noexcept` function” and the other type is “pointer to function”, where the function types are otherwise the same, “pointer to function”;

(15.5) — if `T1` is “pointer to `cv1 C1`” and `T2` is “pointer to `cv2 C2`”, where `C1` is reference-related to `C2` or `C2` is reference-related to `C1` (11.6.3), the cv-combined type of `T1` and `T2` or the cv-combined type of `T2` and `T1`, respectively;

(15.6) — if `T1` is “pointer to member of `C1` of type `cv1 U1`” and `T2` is “pointer to member of `C2` of type `cv2 U2`” where `C1` is reference-related to `C2` or `C2` is reference-related to `C1` (11.6.3), the cv-combined type of `T2` and `T1` or the cv-combined type of `T1` and `T2`, respectively;

(15.7) — if `T1` and `T2` are similar types (7.5), the cv-combined type of `T1` and `T2`;

(15.8) — otherwise, a program that necessitates the determination of a composite pointer type is ill-formed.

64) The cast and assignment operators must still perform their specific conversions as described in 8.4, 8.2.9 and 8.18.
The composite pointer type of \texttt{p} and \texttt{q} is “pointer to \texttt{const void}”; the composite pointer type of \texttt{pi} and \texttt{pci} is “pointer to \texttt{const pointer to \texttt{const int}}”. — end example

8.1 Primary expressions

primary-expression:
literal
this
( expression )
id-expression
lambda-expression
fold-expression

8.1.1 Literals

A literal is a primary expression. Its type depends on its form (5.13). A string literal is an lvalue; all other literals are prvalues.

8.1.2 This

The keyword \texttt{this} names a pointer to the object for which a non-static member function (12.2.2.1) is invoked or a non-static data member’s initializer (12.2) is evaluated.

Otherwise, if a member-declarator declares a non-static data member (12.2) of a class \texttt{X}, the expression \texttt{this} is a prvalue of type “pointer to \texttt{X}” within the optional \texttt{cv-qualifier-seq} and the end of the \texttt{function-definition}, \texttt{member-declarator}, or \texttt{declarator}. It shall not appear before the optional \texttt{cv-qualifier-seq} and it shall not appear elsewhere in the \texttt{member-declarator}.

The expression \texttt{this} shall not appear in any other context. [Example:

```c
class Outer {
  int a[sizeof(*this)]; // error: not inside a member function
  unsigned int sz = sizeof(*this); // OK: in default member initializer

  void f() {
```
int b[sizeof(*this)];    // OK

struct Inner {
    int c[sizeof(*this)];    // error: not inside a member function of Inner
};
}

8.1.3 Parentheses

A parenthesized expression \((E)\) is a primary expression whose type, value, and value category are identical to those of \(E\). The parenthesized expression can be used in exactly the same contexts as those where \(E\) can be used, and with the same meaning, except as otherwise indicated.

8.1.4 Names

An \textit{id-expression} is a restricted form of a primary-expression. \[\text{Note: An id-expression can appear after } .\] and \(->\) operators (8.2.5). \[-end note\]

An \textit{id-expression} that denotes a non-static data member or non-static member function of a class can only be used:

\(\text{(2.1)}\) — as part of a class member access (8.2.5) in which the object expression refers to the member’s class\(^{65}\) or a class derived from that class, or

\(\text{(2.2)}\) — to form a pointer to member (8.3.1), or

\(\text{(2.3)}\) — if that \textit{id-expression} denotes a non-static data member and it appears in an unevaluated operand.

\[\text{Example:}\]
```
struct S {
    int m;
};
int i = sizeof(S::m);    // OK
int j = sizeof(S::m + 42);    // OK
```

\(-end example\)

8.1.4.1 Unqualified names

An \textit{identifier} is an \textit{id-expression} provided it has been suitably declared (Clause 10). \[\text{Note: For operator-function-ids, see } 16.5; \text{for conversion-function-ids, see } 15.3.2; \text{for literal-operator-ids, see } 16.5.8; \text{for template-ids, see } 17.2. \text{A class-name or decal-user-specifier prefixed by } \sim \text{ denotes a destructor; see } 15.4. \text{Within the definition of a non-static member function, an identifier that names a non-static member is transformed to a}\]

\(^{65}\) This also applies when the object expression is an implicit \((\ast this)\) (12.2.2).

§ 8.1.4.1
class member access expression (12.2.2). — end note] The type of the expression is the type of the identifier. The result is the entity denoted by the identifier. The expression is an lvalue if the entity is a function, variable, or data member and a prvalue otherwise; it is a bit-field if the identifier designates a bit-field (11.5).

8.1.4.2 Qualified names

qualified-id:
  nested-name-specifier template_opt unqualified-id

nested-name-specifier:
  ::
  type-name ::
  namespace-name ::
  decltype-specifier ::
  nested-name-specifier identifier ::
  nested-name-specifier template_opt simple-template-id ::

1 The type denoted by a decltype-specifier in a nested-name-specifier shall be a class or enumeration type.

2 A nested-name-specifier that denotes a class, optionally followed by the keyword template (17.2), and then followed by the name of a member of either that class (12.2) or one of its base classes (Clause 13), is a qualified-id: 6.4.3.1 describes name lookup for class members that appear in qualified-ids. The result is the member. The type of the result is the type of the member. The result is an lvalue if the member is a static member function or a data member and a prvalue otherwise. [Note: A class member can be referred to using a qualified-id at any point in its potential scope (6.3.7). — end note] Where class-name :: class-name is used, the two class-names shall refer to the same class; this notation names the destructor (15.4). The form ~ decltype-specifier also denotes the destructor, but it shall not be used as the unqualified-id in a qualified-id. [Note: A typedef-name that names a class is a class-name (12.1). — end note]

3 The nested-name-specifier :: names the global namespace. A nested-name-specifier that names a namespace (10.3), optionally followed by the keyword template (17.2), and then followed by the name of a member of that namespace (or the name of a member of a namespace made visible by a using-directive), is a qualified-id: 6.4.3.2 describes name lookup for namespace members that appear in qualified-ids. The result is the member. The type of the result is the type of the member. The result is an lvalue if the member is a function or a variable and a prvalue otherwise.

4 A nested-name-specifier that denotes an enumeration (10.2), followed by the name of an enumerator of that enumeration, is a qualified-id that refers to the enumerator. The result is the enumerator. The type of the result is the type of the enumeration. The result is a prvalue.

5 In a qualified-id, if the unqualified-id is a conversion-function-id, its conversion-type-id shall denote the same type in both the context in which the entire qualified-id occurs and in the context of the class denoted by the nested-name-specifier.

8.1.5 Lambda expressions

lambda-expression:
  lambda-introducer lambda-declarator_opt compound-statement
lambda-introducer:
  [ lambda-capture_opt ]
lambda-declarator:
  ( parameter-declaration-clause ) decl-specifier-seq_opt
  noexcept-specifier_opt attribute-specifier-seq_opt trailing-return-type_opt

1 Lambda expressions provide a concise way to create simple function objects. [Example:

```cpp
#include <algorithm>
#include <cmath>

void abssort(float* x, unsigned N) {
```
std::sort(x, x + N, [] (float a, float b) { return std::abs(a) < std::abs(b); });

— end example]

2 A lambda-expression is a prvalue whose result object is called the closure object. A lambda-expression shall not appear in an unevaluated operand (Clause 8), in a template-argument, in an alias-declaration, in a typedef declaration, or in the declaration of a function or function template outside its function body and default arguments. [Note: The intention is to prevent lambdas from appearing in a signature. — end note] [Note: A closure object behaves like a function object (23.14). — end note]

3 In the decl-specifier-seq of the lambda-declarator, each decl-specifier shall either be mutable or constexpr.

4 If a lambda-expression does not include a lambda-declarator, it is as if the lambda-declarator were (). The lambda return type is auto, which is replaced by the type specified by the trailing-return-type if provided and/or deduced from return statements as described in 10.1.7.4. [Example:

```cpp
auto x1 = [](int i){ return i; }; // OK: return type is int
auto x2 = [](int i, int j){ return { 1, 2 }; }; // error: deducing return type from braced-init-list
int j;
auto x3 = ()->auto&& { return j; }; // OK: return type is int&
— end example]

8.1.5.1 Closure types

1 The type of a lambda-expression (which is also the type of the closure object) is a unique, unnamed non-union class type, called the closure type, whose properties are described below.

2 The closure type is declared in the smallest block scope, class scope, or namespace scope that contains the corresponding lambda-expression. [Note: This determines the set of namespaces and classes associated with the closure type (6.4.2). The parameter types of a lambda-declarator do not affect these associated namespaces and classes. — end note] The closure type is not an aggregate type (11.6.1). An implementation may define the closure type differently from what is described below provided this does not alter the observable behavior of the program other than by changing:

(2.1) — the size and/or alignment of the closure type,
(2.2) — whether the closure type is trivially copyable (Clause 12),
(2.3) — whether the closure type is a standard-layout class (Clause 12), or
(2.4) — whether the closure type is a POD class (Clause 12).

An implementation shall not add members of rvalue reference type to the closure type.

3 The closure type for a non-generic lambda-expression has a public inline function call operator (16.5.4) whose parameters and return type are described by the lambda-expression’s parameter-declaration-clause and trailing-return-type respectively. For a generic lambda, the closure type has a public inline function call operator member template (17.5.2) whose template-parameter-list consists of one invented type template-parameter for each occurrence of auto in the lambda’s parameter-declaration-clause, in order of appearance. The invented type template-parameter is a parameter pack if the corresponding parameter-declaration declares a function parameter pack (11.3.5). The return type and function parameters of the function call operator template are derived from the lambda-expression’s trailing-return-type and parameter-declaration-clause by replacing each occurrence of auto in the decl-specifiers of the parameter-declaration-clause with the name of the corresponding invented template-parameter. [Example:

```cpp
auto glambda = [](auto a, auto&& b) { return a < b; };  // OK
bool b = glambda(3, 3.14);

auto vglambda = [] (auto printer) {
```
The function call operator or operator template is declared \texttt{const} (12.2.2) if and only if the \textit{lambda-expression}'s parameter-declaration-clause is not followed by \texttt{mutable}. It is neither virtual nor declared \texttt{volatile}. Any \texttt{noexcept-specifier} specified on a \textit{lambda-expression} applies to the corresponding function call operator or operator template. An \texttt{attribute-specifier-seq} in a \textit{lambda-declarator} appertains to the type of the corresponding function call operator or operator template. The function call operator or any given operator template specialization is a constexpr function if either the corresponding \textit{lambda-expression}'s parameter-declaration-clause is followed by \texttt{constexpr}, or it satisfies the requirements for a constexpr function (10.1.5). \[ Note: \] Names referenced in the \textit{lambda-declarator} are looked up in the context in which the \textit{lambda-expression} appears. \[ end note \] \[ Example: \]

```cpp
auto ID = [](auto a) { return a; };  
static_assert(ID(3) == 3); // OK

struct NonLiteral {
    NonLiteral(int n) : n(n) { }
    int n;
};
static_assert(ID(NonLiteral{3}).n == 3); // ill-formed
```

\[ end example \]

\[ Example: \]

```cpp
auto monoid = [](auto v) { return [=] { return v; }; };
auto add = [](auto m1) constexpr {
    auto ret = m1();
    return [=](auto m2) mutable {
        auto m1val = m1();
        auto plus = [=](auto m2val) mutable constexpr {
            return m1val += m2val;
        };
        ret = plus(m2());
        return monoid(ret);
    };
};
constexpr auto zero = monoid(0);
constexpr auto one = monoid(1);
static_assert(add(one)(zero)() == one()); // OK
```

// Since \texttt{two} below is not declared \texttt{constexpr}, an evaluation of its \texttt{constexpr} member function call operator
// cannot perform an lvalue-to-rvalue conversion on one of its subobjects (that represents its capture)
// in a constant expression.

```cpp
auto two = monoid(2);
assert(two() == 2); // OK, not a constant expression.
```
static_assert(add(one)(one)() == two()); // ill-formed: two() is not a constant expression
static_assert(add(one)(one)() == monoid(2)()); // OK

— end example

6 The closure type for a non-generic lambda-expression with no lambda-capture has a conversion function to pointer to function with C++ language linkage (10.5) having the same parameter and return types as the closure type’s function call operator. The conversion is to “pointer to noexcept function” if the function call operator has a no-throwing exception specification. The value returned by this conversion function is the address of a function F that, when invoked, has the same effect as invoking the closure type’s function call operator. F is a constexpr function if the function call operator is a constexpr function. For a generic lambda with no lambda-capture, the closure type has a conversion function template to pointer to function. The conversion function template has the same invented template-parameter-list, and the pointer to function has the same parameter types, as the function call operator template. The return type of the pointer to function shall behave as if it were a decltype-specifier
denoting the return type of the corresponding function call operator template specialization.

7 [ Note: If the generic lambda has no trailing-return-type or the trailing-return-type contains a placeholder type, return type deduction of the corresponding function call operator template specialization has to be done. The corresponding specialization is that instantiation of the function call operator template with the same template arguments as those deduced for the conversion function template. Consider the following:

```cpp
template<class T> auto operator()(T t) const { ... }
template<class T> static auto lambda_call_operator_invoker(T a) {
    // forwards execution to operator()(a) and therefore has
    // the same return type deduced
    ... } 

template<class T> using fptr_t = decltype(lambda_call_operator_invoker(declval<T>())) (*)(T);
```

The behavior of the conversion function of glambda above is like that of the following conversion function:

```cpp
struct Closure {
    template<class T> auto operator()(T t) const { ... } 
    template<class T> static auto lambda_call_operator_invoker(T a) {
        // forwards execution to operator()(a) and therefore has
        // the same return type deduced
        ...
    } 

    template<class T> using fptr_t = decltype(lambda_call_operator_invoker(declval<T>())) (*)(T);

    template<class T> operator fptr_t<T>() const
    { return &lambda_call_operator_invoker; } 
};
— end note
```

[Example:

```cpp
void f1(int (*)(int)) { } 
void f2(char (*)(int)) { } 

void g(int (*)(int)) { } // #1 
void g(char (*)(char)) { } // #2 

void h(int (*)(int)) { } // #3 
void h(char (*)(char)) { } // #4 

auto glambda = [](auto a) { return a; }; 
f1(glambda); // OK 
f2(glambda); // error: ID is not convertible 
g(glambda); // error: ambiguous 
h(glambda); // OK: calls #3 since it is convertible from ID
```

§ 8.1.5.1
int& (*fpi)(int*) = [](auto* a) -> auto& { return *a; }; // OK

—end example

The value returned by any given specialization of this conversion function template is the address of a function \( F \) that, when invoked, has the same effect as invoking the generic lambda’s corresponding function call operator template specialization. \( F \) is a constexpr function if the corresponding specialization is a constexpr function. [Note: This will result in the implicit instantiation of the generic lambda’s body. The instantiated generic lambda’s return type and parameter types shall match the return type and parameter types of the pointer to function. —end note] [Example:

```cpp
auto GL = [](auto a) { std::cout << a; return a; }; int (*GL_int)(int) = GL; // OK: through conversion function template
GL_int(3); // OK: same as GL(3)
—end example]

The conversion function or conversion function template is public, constexpr, non-virtual, non-explicit, const, and has a non-throwing exception specification (18.4). [Example:

```cpp
auto Fwd = [](int (*fp)(int), auto a) { return fp(a); }; auto C = [](auto a) { return a; };
static_assert(Fwd(C,3) == 3); // OK
// No specialization of the function call operator template can be constexpr (due to the local static).
auto NC = [](auto a) { static int s; return a; }; static_assert(Fwd(NC,3) == 3); // ill-formed
—end example]

The lambda-expression’s compound-statement yields the function-body (11.4) of the function call operator, but for purposes of name lookup (6.4), determining the type and value of this (12.2.1) and transforming id-expressions referring to non-static class members into class member access expressions using (*this) (12.2.2), the compound-statement is considered in the context of the lambda-expression. [Example:

```cpp
struct S1 {
    int x, y;
    int operator()(int);
    void f() {
        [=]()->int {
            return operator()(this->x + y); // equivalent to S1::operator()(this->x + (*this).y)
            // this has type S1*
        };
    }
};
—end example]

Further, a variable __func__ is implicitly defined at the beginning of the compound-statement of the lambda-expression, with semantics as described in 11.4.1.

The closure type associated with a lambda-expression has no default constructor and a deleted copy assignment operator. It has a defaulted copy constructor and a defaulted move constructor (15.8). [Note: These special member functions are implicitly defined as usual, and might therefore be defined as deleted. —end note]

The closure type associated with a lambda-expression has an implicitly-declared destructor (15.4).

A member of a closure type shall not be explicitly instantiated (17.7.2), explicitly specialized (17.7.3), or named in a friend declaration (14.3).
8.1.5.2 Captures

A lambda-expression whose smallest enclosing scope is a block scope (6.3.3) is a local lambda expression; any other lambda-expression shall not have a capture-default or simple-capture in its lambda-introducer. The reaching scope of a local lambda expression is the set of enclosing scopes up to and including the innermost enclosing function and its parameters. [Note: This reaching scope includes any intervening lambda-expressions. —end note]

The identifier in a simple-capture is looked up using the usual rules for unqualified name lookup (6.4.1); each such lookup shall find an entity. An entity that is designated by a simple-capture is said to be explicitly captured, and shall be *this when the simple-capture is “this” or “* this”) or a variable with automatic storage duration declared in the reaching scope of the local lambda expression.

1 The body of a lambda-expression may refer to variables with automatic storage duration and the *this object (if any) of enclosing block scopes by capturing those entities, as described below.

2 If a lambda-capture includes a capture-default that is & or =, each simple-capture of that lambda-capture shall be of the form “& identifier” or “* this”. [Note: The form [&,this] is redundant but accepted for compatibility with ISO C++ 2014. —end note] Ignoring appearances in initializers of init-captures, an identifier or this shall not appear more than once in a lambda-capture. [Example:

```c
struct S2 { void f(int i); }

void S2::f(int i) {
  [&][ ];  // OK
  [&,&][ ];  // error: i preceded by & when & is the default
  [=,*this][ ];  // OK
  [=,this][ ];  // error: this when = is the default
  [i,i][ ];  // error: i repeated
  [this,*this][ ];  // error: this appears twice
}
```

—end example]

3 A lambda-expression whose smallest enclosing scope is a block scope (6.3.3) is a local lambda expression; any other lambda-expression shall not have a capture-default or simple-capture in its lambda-introducer. The reaching scope of a local lambda expression is the set of enclosing scopes up to and including the innermost enclosing function and its parameters. [Note: This reaching scope includes any intervening lambda-expressions. —end note]

4 The identifier in a simple-capture is looked up using the usual rules for unqualified name lookup (6.4.1); each such lookup shall find an entity. An entity that is designated by a simple-capture is said to be explicitly captured, and shall be *this when the simple-capture is “this” or “* this”) or a variable with automatic storage duration declared in the reaching scope of the local lambda expression.
If an identifier in a simple-capture appears as the declarator-id of a parameter of the lambda-declarator's parameter-declaration-clause, the program is ill-formed. [Example:

```c
void f() {
    int x = 0;
    auto g = [x](int x) { return 0; }  // error: parameter and simple-capture have the same name
}

— end example]
```

An init-capture behaves as if it declares and explicitly captures a variable of the form “auto init-capture;” whose declarative region is the lambda-expression's compound-statement, except that:

(6.1) — if the capture is by copy (see below), the non-static data member declared for the capture and the variable are treated as two different ways of referring to the same object, which has the lifetime of the non-static data member, and no additional copy and destruction is performed, and

(6.2) — if the capture is by reference, the variable's lifetime ends when the closure object's lifetime ends.

[Note: This enables an init-capture like “x = std::move(x)”; the second “x” must bind to a declaration in the surrounding context. — end note] [Example:

```c
int x = 4;
auto y = [&x = x, x = x+1]()->int {
    r += 2;
    return x+2;
}();  // Updates ::x to 6, and initializes y to 7.

auto z = [a = 42](int a) { return 1; }  // error: parameter and local variable have the same name

— end example]
```

A lambda-expression with an associated capture-default that does not explicitly capture *this or a variable with automatic storage duration (this excludes any id-expression that has been found to refer to an init-capture's associated non-static data member), is said to implicitly capture the entity (i.e., *this or a variable) if the compound-statement:

(7.1) — odr-uses (6.2) the entity (in the case of a variable),

(7.2) — odr-uses (6.2) this (in the case of the object designated by *this), or

(7.3) — names the entity in a potentially-evaluated expression (6.2) where the enclosing full-expression depends on a generic lambda parameter declared within the reaching scope of the lambda-expression.

[Example:

```c
void f(int, const int (&)
```
An entity is captured if it is captured explicitly or implicitly. An entity captured by a lambda-expression is odr-used (6.2) in the scope containing the lambda-expression. If *this is captured by a local lambda expression, its nearest enclosing function shall be a non-static member function. If a lambda-expression or an instantiation of the function call operator template of a generic lambda odr-uses (6.2) this or a variable with automatic storage duration from its reaching scope, that entity shall be captured by the lambda-expression. If a lambda-expression captures an entity and that entity is not defined or captured in the immediately enclosing lambda expression or function, the program is ill-formed. [Example:

```c
void f1(int i) {
    int const N = 20;
    auto m1 = [=]{
        int const M = 30;
        auto m2 = [i]{
            int x[N][M];     // OK: N and M are not odr-used
            x[0][0] = i;     // OK: i is explicitly captured by m2 and implicitly captured by m1
        };
    };
    struct s1 {
        int f;
        void work(int n) {
            int m = n*n;
            int j = 40;
            auto m3 = [this,m] {
                auto m4 = [&j] {
                    int x = n;
                    x += m; // OK: m implicitly captured by m4 and explicitly captured by m3
                    x += i; // OK: this captured implicitly by m4 and explicitly captured by m3
                };
            };
        }
    };
    struct s2 {
        double ohseven = .007;
        auto f() {
            return [this] {
                return [*this] {
                    return ohseven; // OK
                }();
            }
        }
        auto g() {
            return [] {
                return [*this] { }; // error: *this not captured by outer lambda-expression
            }();
        }
    };
    — end example]
```

A lambda-expression appearing in a default argument shall not implicitly or explicitly capture any entity. [8]

§ 8.1.5.2
An entity is captured by copy if

(10.1) — it is implicitly captured, the capture-default is =, and the captured entity is not *this, or

(10.2) — it is explicitly captured with a capture that is not of the form this, & identifier, or & identifier initializer.

For each entity captured by copy, an unnamed non-static data member is declared in the closure type. The declaration order of these members is unspecified. The type of such a data member is the referenced type if the entity is a reference to an object, an lvalue reference to the referenced function type if the entity is a reference to a function, or the type of the corresponding captured entity otherwise. A member of an anonymous union shall not be captured by copy.

Every id-expression within the compound-statement of a lambda-expression that is an odr-use (6.2) of an entity captured by copy is transformed into an access to the corresponding unnamed data member of the closure type. [Note: An id-expression that is not an odr-use refers to the original entity, never to a member of the closure type. Furthermore, such an id-expression does not cause the implicit capture of the entity. — end note] If *this is captured by copy, each odr-use of this is transformed into a pointer to the corresponding unnamed data member of the closure type, cast (8.4) to the type of this. [Note: The cast ensures that the transformed expression is a prvalue. — end note] An id-expression within the compound-statement of a lambda-expression that is an odr-use of a reference captured by reference refers to the entity to which the captured reference is bound and not to the captured reference. [Note: The validity of such captures is determined by the lifetime of the object to which the reference refers, not by the lifetime of the reference itself. — end note] [Example:

§ 8.1.5.2
// The inner closure type must be a literal type regardless of how reference captures are represented.
static_assert(([] (int n) { return [&n] { return ++n; }(); })(3) == 4);

— end example] A bit-field or a member of an anonymous union shall not be captured by reference.

13 If a lambda-expression m2 captures an entity and that entity is captured by an immediately enclosing lambda-expression m1, then m2’s capture is transformed as follows:

(13.1) — if m1 captures the entity by copy, m2 captures the corresponding non-static data member of m1’s closure type;
(13.2) — if m1 captures the entity by reference, m2 captures the same entity captured by m1.

[Example: The nested lambda expressions and invocations below will output 123234.

```cpp
int a = 1, b = 1, c = 1;
auto m1 = [a, &b, &c]() mutable {
    auto m2 = [a, b, &c]() mutable {
        std::cout << a << b << c;
        a = 4; b = 4; c = 4;
    }
    a = 3; b = 3; c = 3;
    m2();
};
a = 2; b = 2; c = 2;
m1();
std::cout << a << b << c;
— end example]
```

14 Every occurrence of decltype((x)) where x is a possibly parenthesized id-expression that names an entity of automatic storage duration is treated as if x were transformed into an access to a corresponding data member of the closure type that would have been declared if x were an odr-use of the denoted entity. [Example:

```cpp
void f3() {
    float x, &r = x;
    [x] {
        decltype(x) y1; // y1 has type float
        decltype((x)) y2 = y1; // y2 has type float const& because this lambda is not mutable and x is an lvalue
        decltype(r) r1 = y1; // r1 has type float const& (transformation not considered)
        decltype((r)) r2 = y2; // r2 has type float const&
    }
}
— end example]
```

15 When the lambda-expression is evaluated, the entities that are captured by copy are used to direct-initialize each corresponding non-static data member of the resulting closure object, and the non-static data members corresponding to the init-captures are initialized as indicated by the corresponding initializer (which may be copy- or direct-initialization). (For array members, the array elements are direct-initialized in increasing subscript order.) These initializations are performed in the (unspecified) order in which the non-static data members are declared. [Note: This ensures that the destructions will occur in the reverse order of the constructions. — end note]

16 [Note: If a non-reference entity is implicitly or explicitly captured by reference, invoking the function call operator of the corresponding lambda-expression after the lifetime of the entity has ended is likely to result in undefined behavior. — end note]

17 A simple-capture followed by an ellipsis is a pack expansion (17.5.3). An init-capture followed by an ellipsis is ill-formed. [Example:
template<class... Args>
void f(Args... args) {
    auto lm = [&&, args...](Args... args) { return g(args...); };
    lm();
}

—end example—

8.1.6 Fold expressions

A fold expression performs a fold of a template parameter pack (17.5.3) over a binary operator.

fold-expression:
( cast-expression fold-operator ... )
( ... fold-operator cast-expression )
( cast-expression fold-operator ... fold-operator cast-expression )

fold-operator: one of
+ - * / % ^ & | << >> += -= *= /= %= ^= &= |= <<= >>= =
== != < > <= >= && || , .* ->*

An expression of the form (...) where op is a fold-operator is called a unary left fold. An expression of
the form (e op ...) where op is a fold-operator is called a unary right fold. Unary left folds and unary right
folds are collectively called unary folds. In a unary fold, the cast-expression shall contain an unexpanded
parameter pack (17.5.3).

An expression of the form (e1 op1 ... op2 e2) where op1 and op2 are fold-operators is called a binary fold.
In a binary fold, op1 and op2 shall be the same fold-operator, and either e1 shall contain an unexpanded
parameter pack or e2 shall contain an unexpanded parameter pack, but not both. If e2 contains an
unexpanded parameter pack, the expression is called a binary left fold. If e1 contains an unexpanded
parameter pack, the expression is called a binary right fold. [Example:

template<typename ...Args>
bool f(Args ...args) { return (true && ... && args); // OK }

template<typename ...Args>
bool f(Args ...args) { return (args + ... + args); // error: both operands contain unexpanded parameter packs }

—end example—

8.2 Postfix expressions

Postfix expressions group left-to-right.
postfix-expression:
  primary-expression
  postfix-expression [ expr-or-braced-init-list ]
  postfix-expression ( expression-list_opt )
  simple-type-specifier ( expression-list_opt )
  typename-specifier ( expression-list_opt )
  simple-type-specifier braced-init-list
type-name-specifier braced-init-list
  postfix-expression . template_opt id-expression
  postfix-expression -> template_opt id-expression
  postfix-expression , pseudo-destructor-name
  postfix-expression -> pseudo-destructor-name
  postfix-expression ++
  postfix-expression --
  dynamic_cast < type-id > ( expression )
  static_cast < type-id > ( expression )
  reinterpret_cast < type-id > ( expression )
  const_cast < type-id > ( expression )
typeid ( expression )
typeid ( type-id )

expression-list:
  initializer-list

pseudo-destructor-name:
  nested-name-specifier_opt type-name :: ~ type-name
  nested-name-specifier template simple-template-id :: ~ type-name
  ~ type-name
  ~ decltype-specifier

2 [ Note: The > token following the type-id in a dynamic_cast, static_cast, reinterpret_cast, or const_cast may be the product of replacing a >> token by two consecutive > tokens (17.2). — end note ]

8.2.1 Subscripting [expr.sub]

1 A postfix expression followed by an expression in square brackets is a postfix expression. One of the expressions shall be a glvalue of type “array of T” or a prvalue of type “pointer to T” and the other shall be a prvalue of unscoped enumeration or integral type. The result is of type “T”. The type “T” shall be a completely-defined object type.66 The expression E1[E2] is identical (by definition) to *((E1)+(E2)) [ Note: see 8.3 and 8.7 for details of * and + and 11.3.4 for details of arrays. — end note ] , except that in the case of an array operand, the result is an lvalue if that operand is an lvalue and an xvalue otherwise. The expression E1 is sequenced before the expression E2.

2 A braced-init-list shall not be used with the built-in subscript operator.

8.2.2 Function call [expr.call]

1 A function call is a postfix expression followed by parentheses containing a possibly empty, comma-separated list of initializer-clauses which constitute the arguments to the function. The postfix expression shall have function type or function pointer type. For a call to a non-member function or to a static member function, the postfix expression shall be either an lvalue that refers to a function (in which case the function-to-pointer standard conversion (7.3) is suppressed on the postfix expression), or it shall have function pointer type. Calling a function through an expression whose function type is different from the function type of the called function’s definition results in undefined behavior (10.5). For a call to a non-static member function, the postfix expression shall be an implicit (12.2.2, 12.2.3) or explicit class member access (8.2.5) whose

66) This is true even if the subscript operator is used in the following common idiom: &x[0].

§ 8.2.2
id-expression is a function member name, or a pointer-to-member expression (8.5) selecting a function member; the call is as a member of the class object referred to by the object expression. In the case of an implicit class member access, the implied object is the one pointed to by this. [Note: A member function call of the form f() is interpreted as (\*this).f() (see 12.2.2). —end note] If a function or member function name is used, the name can be overloaded (Clause 16), in which case the appropriate function shall be selected according to the rules in 16.3. If the selected function is non-virtual, or if the id-expression in the class member access expression is a qualified-id, that function is called. Otherwise, its final overrider (13.3) in the dynamic type of the object expression is called; such a call is referred to as a virtual function call. [Note: The dynamic type is the type of the object referred to by the current value of the object expression. 15.7 describes the behavior of virtual function calls when the object expression refers to an object under construction or destruction. —end note]

2 [Note: If a function or member function name is used, and name lookup (6.4) does not find a declaration of that name, the program is ill-formed. No function is implicitly declared by such a call. —end note]

3 If the postfix-expression designates a destructor (15.4), the type of the function call expression is void; otherwise, the type of the function call expression is the return type of the statically chosen function (i.e., ignoring the virtual keyword), even if the type of the function actually called is different. This return type shall be an object type, a reference type or \cv void.

4 When a function is called, each parameter (11.3.5) shall be initialized (11.6, 15.8, 15.1) with its corresponding argument. If the function is a non-static member function, the this parameter of the function (12.2.2.1) shall be initialized with a pointer to the object of the call, converted as if by an explicit type conversion (8.4). [Note: There is no access or ambiguity checking on this conversion; the access checking and disambiguation are done as part of the (possibly implicit) class member access operator. See 13.2, 14.2, and 8.2.5. —end note] When a function is called, the parameters that have object type shall have completely-defined object type. [Note: this still allows a parameter to be a pointer or reference to an incomplete class type. However, it prevents a passed-by-value parameter to have an incomplete class type. —end note] It is implementation-defined whether the lifetime of a parameter ends when the function in which it is defined returns or at the end of the enclosing full-expression. The initialization and destruction of each parameter occurs within the context of the calling function. [Example: The access of the constructor, conversion functions or destructor is checked at the point of call in the calling function. If a constructor or destructor for a function parameter throws an exception, the search for a handler starts in the scope of the calling function; in particular, if the function called has a function-try-block (Clause 18) with a handler that could handle the exception, this handler is not considered. —end example]

5 The postfix-expression is sequenced before each expression in the expression-list and any default argument. The initialization of a parameter, including every associated value computation and side effect, is indeterminately sequenced with respect to that of any other parameter. [Note: All side effects of argument evaluations are sequenced before the function is entered (see 4.6). —end note] [Example:

```cpp
void f() {
    std::string s = "but I have heard it works even if you don't believe in it";
    s.replace(0, 4, "").replace(s.find("even"), 4, "only").replace(s.find(" don't"), 6, "");
    assert(s == "I have heard it works only if you believe in it"); // OK
}

—end example] [Note: If an operator function is invoked using operator notation, argument evaluation is sequenced as specified for the built-in operator; see 16.3.1.2. —end note] [Example:

```cpp
struct S {
    S(int);
};
int operator<<(S, int);
int i, j;
int x = S(i=1) << (i=2);
```
int y = operator<<(S(j=1), j=2);

After performing the initializations, the value of i is 2 (see 8.8), but it is unspecified whether the value of j is 1 or 2. — end example]

6 The result of a function call is the result of the operand of the evaluated return statement (9.6.3) in the called function (if any), except in a virtual function call if the return type of the final overrider is different from the return type of the statically chosen function, the value returned from the final overrider is converted to the return type of the statically chosen function.

7 [Note: A function can change the values of its non-const parameters, but these changes cannot affect the values of the arguments except where a parameter is of a reference type (11.3.2); if the reference is to a const-qualified type, const_cast is required to be used to cast away the constness in order to modify the argument’s value. Where a parameter is of const reference type a temporary object is introduced if needed (10.1.7, 5.13, 5.13.5, 11.3.4, 15.2). In addition, it is possible to modify the values of non-constant objects through pointer parameters. — end note]

8 A function can be declared to accept fewer arguments (by declaring default arguments (11.3.6)) or more arguments (by using the ellipsis, ..., or a function parameter pack (11.3.5)) than the number of parameters in the function definition (11.4). [Note: This implies that, except where the ellipsis (...) or a function parameter pack is used, a parameter is available for each argument. — end note]

9 When there is no parameter for a given argument, the argument is passed in such a way that the receiving function can obtain the value of the argument by invoking va_arg (21.10). [Note: This paragraph does not apply to arguments passed to a function parameter pack. Function parameter packs are expanded during template instantiation (17.5.3), thus each such argument has a corresponding parameter when a function template specialization is actually called. — end note] The lvalue-to-rvalue (7.1), array-to-pointer (7.2), and function-to-pointer (7.3) standard conversions are performed on the argument expression. An argument that has type cv std::nullptr_t is converted to type void* (7.11). After these conversions, if the argument does not have arithmetic, enumeration, pointer, pointer to member, or class type, the program is ill-formed. Passing a potentially-evaluated argument of class type (Clause 12) having a non-trivial copy constructor, a non-trivial move constructor, or a non-trivial destructor, with no corresponding parameter, is conditionally-supported with implementation-defined semantics. If the argument has integral or enumeration type that is subject to the integral promotions (7.6), or a floating-point type that is subject to the floating-point promotion (7.7), the value of the argument is converted to the promoted type before the call. These promotions are referred to as the default argument promotions.

10 Recursive calls are permitted, except to the main function (6.6.1).

11 A function call is an lvalue if the result type is an lvalue reference type or an rvalue reference to function type, an xvalue if the result type is an rvalue reference to object type, and a prvalue otherwise.

8.2.3 Explicit type conversion (functional notation) [expr.type.conv]

1 A simple-type-specifier (10.1.7.2) or typename-specifier (17.6) followed by a parenthesized optional expression-list or by a braced-init-list (the initializer) constructs a value of the specified type given the initializer. If the type is a placeholder for a deduced class type, it is replaced by the return type of the function selected by overload resolution for class template deduction (16.3.1.8) for the remainder of this section.

2 If the initializer is a parenthesized single expression, the type conversion expression is equivalent (in definedness, and if defined in meaning) to the corresponding cast expression (8.4). If the type is cv void and the initializer is (), the expression is a prvalue of the specified type that performs no initialization. Otherwise, the expression is a prvalue of the specified type whose result object is direct-initialized (11.6) with the initializer. For an expression of the form T(), T shall not be an array type.
8.2.4 Pseudo destructor call

The use of a pseudo-destructor-name after a dot . or arrow -&gt; operator represents the destructor for the non-class type denoted by type-name or decltype-specifier. The result shall only be used as the operand for the function call operator (), and the result of such a call has type void. The only effect is the evaluation of the postfix-expression before the dot or arrow.

The left-hand side of the dot operator shall be of scalar type. The left-hand side of the arrow operator shall be of pointer to scalar type. This scalar type is the object type. The cv-unqualified versions of the object type and of the type designated by the pseudo-destructor-name shall be the same type. Furthermore, the two type-names in a pseudo-destructor-name of the form

```plaintext
nested-name-specifier exprtype type-name :: - type-name
```

shall designate the same scalar type (ignoring cv-qualification).

8.2.5 Class member access

A postfix expression followed by a dot . or an arrow -&gt;, optionally followed by the keyword template (17.2), and then followed by an id-expression, is a postfix expression. The postfix expression before the dot or arrow is evaluated, the result of that evaluation, together with the id-expression, determines the result of the entire postfix expression.

For the first option (dot) the first expression shall be a glvalue having complete class type. For the second option (arrow) the first expression shall be a prvalue having pointer to complete class type. The expression E1-&gt;E2 is converted to the equivalent form *(E1).E2; the remainder of 8.2.5 will address only the first option (dot).

In either case, the id-expression shall name a member of the class or of one of its base classes. [ Note: Because the name of a class is inserted in its class scope (Clause 12), the name of a class is also considered a nested member of that class. — end note] [ Note: 6.4.5 describes how names are looked up after the . and -&gt; operators. — end note]

Abbreviating postfix-expression.id-expression as E1.E2, E1 is called the object expression. If E2 is a bit-field, E1.E2 is a bit-field. The type and value category of E1.E2 are determined as follows. In the remainder of 8.2.5, cq represents either const or the absence of const and eq represents either volatile or the absence of volatile. cv represents an arbitrary set of cv-qualifiers, as defined in 6.9.3.

If E2 is declared to have type "reference to T", then E1.E2 is an lvalue; the type of E1.E2 is T. Otherwise, one of the following rules applies.

1. If E2 is a static data member and the type of E2 is T, then E1.E2 is an lvalue; the expression designates the named member of the class. The type of E1.E2 is T.
2. If E2 is a non-static data member and the type of E1 is "cq1 vq1 X", and the type of E2 is "cq2 vq2 T", the expression designates the named member of the object designated by the first expression. If E1 is an lvalue, then E1.E2 is an lvalue; otherwise E1.E2 is an xvalue. Let the notation vq12 stand for the "union" of vq1 and vq2; that is, if vq1 or vq2 is volatile, then vq12 is volatile. Similarly, let the notation cq12 stand for the "union" of cq1 and cq2; that is, if cq1 or cq2 is const, then cq12 is const. If E2 is declared to be a mutable member, then the type of E1.E2 is "eq12 T". If E2 is not declared to be a mutable member, then the type of E1.E2 is "cq12 vq12 T".
3. If E2 is a (possibly overloaded) member function, function overload resolution (16.3) is used to determine whether E1.E2 refers to a static or a non-static member function.
   (4.3.1) If it refers to a static member function and the type of E2 is "function of parameter-type-list returning T", then E1.E2 is an lvalue; the expression designates the static member function. The type of E1.E2 is the same type as that of E2, namely "function of parameter-type-list returning T".

---

67) If the class member access expression is evaluated, the subexpression evaluation happens even if the result is unnecessary to determine the value of the entire postfix expression, for example if the id-expression denotes a static member.

68) Note that *(E1)) is an lvalue.
(4.3.2) Otherwise, if $E1.E2$ refers to a non-static member function and the type of $E2$ is “function of parameter-type-list cv ref-qualifier opt returning T”, then $E1.E2$ is a prvalue. The expression designates a non-static member function. The expression can be used only as the left-hand operand of a member function call (12.2.1). [Note: Any redundant set of parentheses surrounding the expression is ignored (8.1). —end note] The type of $E1.E2$ is “function of parameter-type-list cv returning T”.

(4.4) If $E2$ is a nested type, the expression $E1.E2$ is ill-formed.

(4.5) If $E2$ is a member enumerator and the type of $E2$ is T, the expression $E1.E2$ is a prvalue. The type of $E1.E2$ is T.

If $E2$ is a non-static data member or a non-static member function, the program is ill-formed if the class of which $E2$ is directly a member is an ambiguous base (13.2) of the naming class (14.2) of $E2$. [Note: The program is also ill-formed if the naming class is an ambiguous base of the class type of the object expression; see 14.2. —end note]

### 8.2.6 Increment and decrement

The value of a postfix ++ expression is the value of its operand. [Note: The value obtained is a copy of the original value —end note] The operand shall be a modifiable lvalue. The type of the operand shall be an arithmetic type other than cv bool, or a pointer to a complete object type. The value of the operand object is modified by adding 1 to it. The value computation of the ++ expression is sequenced before the modification of the operand object. With respect to an indeterminately-sequenced function call, the operation of postfix ++ is a single evaluation. [Note: Therefore, a function call shall not intervene between the lvalue-to-rvalue conversion and the side effect associated with any single postfix ++ operator. —end note] The result is a prvalue. The type of the result is the cv-unqualified version of the type of the operand. If the operand is a bit-field that cannot represent the incremented value, the resulting value of the bit-field is implementation-defined. See also 8.7 and 8.18.

The operand of postfix -- is decremented analogously to the postfix ++ operator. [Note: For prefix increment and decrement, see 8.3.2. —end note]

### 8.2.7 Dynamic cast

The result of the expression dynamic_cast<T>(v) is the result of converting the expression v to type T. T shall be a pointer or reference to a complete class type, or “pointer to cv void”. The dynamic_cast operator shall not cast away constness (8.2.11).

If T is a pointer type, v shall be a prvalue of a pointer to complete class type, and the result is a prvalue of type T. If T is an lvalue reference type, v shall be an lvalue of a complete class type, and the result is an lvalue of the type referred to by T. If T is an rvalue reference type, v shall be a glvalue having a complete class type, and the result is an xvalue of the type referred to by T.

If the type of v is the same as T, or it is the same as T except that the class object type in T is more cv-qualified than the class object type in v, the result is v (converted if necessary).

If the value of v is a null pointer value in the pointer case, the result is the null pointer value of type T.

If T is “pointer to cv1 B” and v has type “pointer to cv2 D” such that B is a base class of D, the result is a pointer to the unique B subobject of the D object pointed to by v. Similarly, if T is “reference to cv1 B” and v has type cv2 D such that B is a base class of D, the result is the unique B subobject of the D object referred to by v. In both the pointer and reference cases, the program is ill-formed if cv2 has greater cv-qualification than cv1 or if B is an inaccessible or ambiguous base class of D. [Example:

```c
struct B { }
struct D : B { }
```

69) The most derived object (4.5) pointed or referred to by v can contain other B objects as base classes, but these are ignored.
void foo(D* dp) {
    B* bp = dynamic_cast<B*>(dp); // equivalent to B* bp = dp;
}

— end example

Otherwise, v shall be a pointer to or a glvalue of a polymorphic type (13.3).

7 If T is “pointer to cv void”, then the result is a pointer to the most derived object pointed to by v. Otherwise, a runtime check is applied to see if the object pointed or referred to by v can be converted to the type pointed or referred to by T.

8 If C is the class type to which T points or refers, the runtime check logically executes as follows:

(8.1) — If, in the most derived object pointed (referred) to by v, v points (refers) to a public base class subobject of a C object, and if only one object of type C is derived from the subobject pointed (referred) to by v the result points (refers) to that C object.

(8.2) — Otherwise, if v points (refers) to a public base class subobject of the most derived object, and the type of the most derived object has a base class, of type C, that is unambiguous and public, the result points (refers) to the C subobject of the most derived object.

(8.3) — Otherwise, the runtime check fails.

9 The value of a failed cast to pointer type is the null pointer value of the required result type. A failed cast to reference type throws an exception (18.1) of a type that would match a handler (18.3) of type std::bad_cast (21.7.3).

[Example:

    class A { virtual void f(); }; class B { virtual void g(); }; class D : public virtual A, private B { }; void g() {
D d;
    B* bp = (B*)&d; // cast needed to break protection
    A* ap = &d; // public derivation, no cast needed
D& dr = dynamic_cast<D&>(*bp); // fails
    ap = dynamic_cast<A*>(bp); // fails
    bp = dynamic_cast<B*>(ap); // fails
    ap = dynamic_cast<A&>(&d); // succeeds
    bp = dynamic_cast<B*>(&d); // ill-formed (not a runtime check)
}

class E : public D, public B { }; class F : public E, public D { }; void h() {
F f;
    A* ap = &f; // succeeds: finds unique A
D* dp = dynamic_cast<D*>(ap); // fails: yields null; f has two D subobjects
E* ep = (E*)ap; // ill-formed: cast from virtual base
E* ep1 = dynamic_cast<E*>(ap); // succeeds
}
— end example] [Note: 15.7 describes the behavior of a dynamic_cast applied to an object under construction or destruction. — end note]

8.2.8 Type identification [expr.typeid]

1 The result of a typeid expression is an lvalue of static type const std::type_info (21.7.2) and dynamic type const std::type_info or const name where name is an implementation-defined class publicly derived from

§ 8.2.8
std::type_info which preserves the behavior described in 21.7.2. The lifetime of the object referred to by
the lvalue extends to the end of the program. Whether or not the destructor is called for the std::type_info
object at the end of the program is unspecified.

2 When typeid is applied to a glvalue expression whose type is a polymorphic class type (13.3), the result refers
to a std::type_info object representing the type of the most derived object (4.5) (that is, the dynamic
type) to which the glvalue refers. If the glvalue expression is obtained by applying the unary * operator to a
pointer and the pointer is a null pointer value (7.11), the typeid expression throws an exception (18.1) of
a type that would match a handler of type std::bad_typeid exception (21.7.4).

3 When typeid is applied to an expression other than a glvalue of a polymorphic class type, the result
refers to a std::type_info object representing the static type of the expression. Lvalue-to-rvalue (7.1),
array-to-pointer (7.2), and function-to-pointer (7.3) conversions are not applied to the expression. If the
expression is a prvalue, the temporary materialization conversion (7.4) is applied. The expression is an
unevaluated operand (Clause 8).

4 When typeid is applied to a type-id, the result refers to a std::type_info object representing the type of
the type-id. If the type of the type-id is a reference to a possibly cv-qualified type, the result of the typeid
expression refers to a std::type_info object representing the cv-unqualified referenced type. If the type of
the type-id is a class type or a reference to a class type, the class shall be completely-defined.

5 If the type of the expression or type-id is a cv-qualified type, the result of the typeid expression refers to a
std::type_info object representing the cv-unqualified type. [Example:

```cpp
class D { /* ... */ };  
D d1;  
const D d2;

typeid(d1) == typeid(d2);    // yields true  
typeid(D) == typeid(const D); // yields true  
typeid(D) == typeid(d2);    // yields true  
typeid(D) == typeid(const D&); // yields true
```

— end example]

If the header <typeinfo> (21.7.2) is not included prior to a use of typeid, the program is ill-formed.

[Note: 15.7 describes the behavior of typeid applied to an object under construction or destruction. — end
note]

8.2.9 Static cast [expr.static.cast]

The result of the expression static_cast<T>(v) is the result of converting the expression v to type T. If T
is an lvalue reference type or an rvalue reference to function type, the result is an lvalue; if T is an
rvalue reference to object type, the result is an xvalue; otherwise, the result is a prvalue. The static_cast operator
shall not cast away constness (8.2.11).

2 An lvalue of type “cv1 B”, where B is a class type, can be cast to type “reference to cv2 D”, where D is a class
derived (Clause 13) from B, if cv2 is the same cv-qualification as, or greater cv-qualification than, cv1. If B is
a virtual base class of D or a base class of a virtual base class of D, or if no valid standard conversion from
“pointer to D” to “pointer to B” exists (7.11), the program is ill-formed. An xvalue of type “cv1 B” can be cast
to type “rvalue reference to cv2 D” with the same constraints as for an lvalue of type “cv1 B”. If the object of
type “cv1 B” is actually a base class subobject of an object of type D, the result refers to the enclosing object
of type D. Otherwise, the behavior is undefined. [Example:

```cpp
struct B { };  
```

70) The recommended name for such a class is extended_type_info.

71) If p is an expression of pointer type, then *p, (**p), (**(p)), and so on all meet this requirement.

§ 8.2.9
struct D : public B { }
D d;
B &br = d;

static_cast<D&>(br); // produces lvalue to the original d object

3 An lvalue of type “cv1 T1” can be cast to type “rvalue reference to cv2 T2” if “cv2 T2” is reference-compatible with “cv1 T1” (11.6.3). If the value is not a bit-field, the result refers to the object or the specified base class subobject thereof; otherwise, the lvalue-to-rvalue conversion (7.1) is applied to the bit-field and the resulting prvalue is used as the expression of the static_cast for the remainder of this section. If T2 is an inaccessible (Clause 14) or ambiguous (13.2) base class of T1, a program that necessitates such a cast is ill-formed.

4 An expression e can be explicitly converted to a type T if there is an implicit conversion sequence (16.3.3.1) from e to T, or if overload resolution for a direct-initialization (11.6) of an object or reference of type T from e would find at least one viable function (16.3.2). If T is a reference type, the effect is the same as performing the declaration and initialization

T t(e);

for some invented temporary variable t (11.6) and then using the temporary variable as the result of the conversion. Otherwise, the result object is direct-initialized from e. [Note: The conversion is ill-formed when attempting to convert an expression of class type to an inaccessible or ambiguous base class. —end note]

5 Otherwise, the static_cast shall perform one of the conversions listed below. No other conversion shall be performed explicitly using a static_cast.

6 Any expression can be explicitly converted to type cv void, in which case it becomes a discarded-value expression (Clause 8). [Note: However, if the value is in a temporary object (15.2), the destructor for that object is not executed until the usual time, and the value of the object is preserved for the purpose of executing the destructor. —end note]

7 The inverse of any standard conversion sequence (Clause 7) not containing an lvalue-to-rvalue (7.1), array-to-pointer (7.2), function-to-pointer (7.3), null pointer (7.11), null member pointer (7.12), boolean (7.14), or function pointer (7.13) conversion, can be performed explicitly using static_cast. A program is ill-formed if it uses static_cast to perform the inverse of an ill-formed standard conversion sequence. [Example:

struct B { }
struct D : private B { }
void f() {
    static_cast<D*>(B*)0); // error: B is a private base of D
    static_cast<int B::*>(int D::*0); // error: B is a private base of D
}

—end example]

8 The lvalue-to-rvalue (7.1), array-to-pointer (7.2), and function-to-pointer (7.3) conversions are applied to the operand. Such a static_cast is subject to the restriction that the explicit conversion does not cast away constness (8.2.11), and the following additional rules for specific cases:

9 A value of a scoped enumeration type (10.2) can be explicitly converted to an integral type. When that type is cv bool, the resulting value is false if the original value is zero and true for all other values. For the remaining integral types, the value is unchanged if the original value can be represented by the specified type. Otherwise, the resulting value is unspecified. A value of a scoped enumeration type can also be explicitly converted to a floating-point type; the result is the same as that of converting from the original value to the floating-point type.

10 A value of integral or enumeration type can be explicitly converted to a complete enumeration type. The value is unchanged if the original value is within the range of the enumeration values (10.2). Otherwise, the behavior

§ 8.2.9
is undefined. A value of floating-point type can also be explicitly converted to an enumeration type. The resulting value is the same as converting the original value to the underlying type of the enumeration (7.10), and subsequently to the enumeration type.

11 A prvalue of type “pointer to cv1 B”, where B is a class type, can be converted to a prvalue of type “pointer to cv2 D”, where D is a class derived (Clause 13) from B, if cv2 is the same cv-qualification as, or greater cv-qualification than, cv1. If B is a virtual base class of D or a base class of a virtual base class of D, or if no valid standard conversion from “pointer to D” to “pointer to B” exists (7.11), the program is ill-formed. The null pointer value (7.11) is converted to the null pointer value of the destination type. If the prvalue of type “pointer to cv1 B” points to a B that is actually a subobject of an object of type D, the resulting pointer points to the enclosing object of type D. Otherwise, the behavior is undefined.

12 A prvalue of type “pointer to member of D of type cv1 T” can be converted to a prvalue of type “pointer to member of B of type cv2 T”, where B is a base class (Clause 13) of D, if cv2 is the same cv-qualification as, or greater cv-qualification than, cv1. If no valid standard conversion from “pointer to member of B of type T” to “pointer to member of D of type T” exists (7.12), the program is ill-formed. The null member pointer value (7.12) is converted to the null member pointer value of the destination type. If class B contains the original member, or is a base or derived class of the class containing the original member, the resulting pointer to member points to the original member. Otherwise, the behavior is undefined. [ Note: Although class B need not contain the original member, the dynamic type of the object with which indirection through the pointer to member is performed must contain the original member; see 8.5. — end note ]

13 A prvalue of type “pointer to cv1 void” can be converted to a prvalue of type “pointer to cv2 T”, where T is an object type and cv2 is the same cv-qualification as, or greater cv-qualification than, cv1. If the original pointer value represents the address A of a byte in memory and A does not satisfy the alignment requirement of T, then the resulting pointer value is unspecified. Otherwise, if the original pointer value points to an object a, and there is an object b of type T (ignoring cv-qualification) that is pointer-interconvertible (6.9.2) with a, the result is a pointer to b. Otherwise, the pointer value is unchanged by the conversion. [ Example: ]

```c
T* p1 = new T;
const T* p2 = static_cast<const T*>(static_cast<void*>(p1));
bool b = p1 == p2;  // b will have the value true.
```

— end example ]

8.2.10 Reinterpret cast [ expr.reinterpret.cast ]

1 The result of the expression reinterpret_cast<T>(v) is the result of converting the expression v to type T. If T is an lvalue reference type or an rvalue reference to function type, the result is an lvalue; if T is an rvalue reference to object type, the result is an xvalue; otherwise, the result is a prvalue and the lvalue-to-rvalue (7.1) array-to-pointer (7.2), and function-to-pointer (7.3) standard conversions are performed on the expression v. Conversions that can be performed explicitly using reinterpret_cast are listed below. No other conversion can be performed explicitly using reinterpret_cast.

2 The reinterpret_cast operator shall not cast away constness (8.2.11). An expression of integral, enumeration, pointer, or pointer-to-member type can be explicitly converted to its own type; such a cast yields the value of its operand.

3 [ Note: The mapping performed by reinterpret_cast might, or might not, produce a representation different from the original value. — end note ]

4 A pointer can be explicitly converted to any integral type large enough to hold it. The mapping function is implementation-defined. [ Note: It is intended to be unsurprising to those who know the addressing structure of the underlying machine. — end note ] A value of type std::nullptr_t can be converted to an integral type; the conversion has the same meaning and validity as a conversion of (void*)0 to the integral type.

— end example ]

72) Function types (including those used in pointer to member function types) are never cv-qualified; see 11.3.5.
[Note: A reinterpret_cast cannot be used to convert a value of any type to the type std::nullptr_t.
—end note]

5 A value of integral type or enumeration type can be explicitly converted to a pointer. A pointer converted to
an integer of sufficient size (if any such exists on the implementation) and back to the same pointer type
will have its original value; mappings between pointers and integers are otherwise implementation-defined.
[Note: Except as described in 6.7.4.3, the result of such a conversion will not be a safely-derived pointer
value. —end note]

6 A function pointer can be explicitly converted to a function pointer of a different type. [Note: The effect of
calling a function through a pointer to a function type (11.3.5) that is not the same as the type used in
the definition of the function is undefined. —end note] Except that converting a prvalue of type “pointer to T1”
to the type “pointer to T2” (where T1 and T2 are function types) and back to its original type yields the
original pointer value, the result of such a pointer conversion is unspecified. [Note: See also 7.11 for more
details of pointer conversions. —end note]

7 An object pointer can be explicitly converted to an object pointer of a different type.\footnote{The types may have different cv-qualifiers, subject to the overall restriction that a reinterpret_cast cannot cast away constness.} When a prvalue v of
object pointer type is converted to the object pointer type “pointer to cv T”, the result is static_cast<
cv T*>(static_cast<
cv void*>(v)). [Note: Converting a prvalue of type “pointer to T1” to the type “pointer
to T2” (where T1 and T2 are object types and where the alignment requirements of T2 are no stricter than
those of T1) and back to its original type yields the original pointer value. —end note]

Converting a function pointer to an object pointer type or vice versa is conditionally-supported. The meaning
of such a conversion is implementation-defined, except that if an implementation supports conversions in both
directions, converting a prvalue of one type to the other type and back, possibly with different cv-qualification,
shall yield the original pointer value.

The null pointer value (7.11) is converted to the null pointer value of the destination type. [Note: A null
pointer constant of type std::nullptr_t cannot be converted to a pointer type, and a null pointer constant
of integral type is not necessarily converted to a null pointer value. —end note]

10 A prvalue of type “pointer to member of X of type T1” can be explicitly converted to a prvalue of a different
type “pointer to member of Y of type T2” if T1 and T2 are both function types or both object types.\footnote{T1 and T2 may have different cv-qualifiers, subject to the overall restriction that a reinterpret_cast cannot cast away constness.} The
null member pointer value (7.12) is converted to the null member pointer value of the destination type. The
result of this conversion is unspecified, except in the following cases:

\begin{enumerate}
\item Converting a prvalue of type “pointer to member function” to a different pointer to member function
type and back to its original type yields the original pointer to member value.
\item Converting a prvalue of type “pointer to data member of X of type T1” to the type “pointer to data

\begin{enumerate}
\item member of Y of type T2” (where the alignment requirements of T2 are no stricter than those of T1) and
back to its original type yields the original pointer to member value.

11 A glvalue expression of type T1 can be cast to the type “reference to T2” if an expression of type “pointer to
T1” can be explicitly converted to the type “pointer to T2” using a reinterpret_cast. The result refers to
the same object as the source glvalue, but with the specified type. [Note: That is, for lvalues, a reference
cast reinterpret_cast<T&>(x) has the same effect as the conversion *reinterpret_cast<T*>(&x) with
the built-in & and * operators (and similarly for reinterpret_cast<T&&>(x)). —end note] No temporary
is created, no copy is made, and constructors (15.1) or conversion functions (15.3) are not called.\footnote{This is sometimes referred to as a type pun.}
### 8.2.11 Const cast

The result of the expression `const_cast<T>(v)` is of type `T`. If `T` is an lvalue reference to object type, the result is an lvalue; if `T` is an rvalue reference to object type, the result is an xvalue; otherwise, the result is a prvalue and the lvalue-to-rvalue (7.1), array-to-pointer (7.2), and function-to-pointer (7.3) standard conversions are performed on the expression `v`. Conversions that can be performed explicitly using `const_cast` are listed below. No other conversion shall be performed explicitly using `const_cast`.

1. **Note:** Subject to the restrictions in this section, an expression may be cast to its own type using a `const_cast` operator. —end note

2. For two similar types `T1` and `T2` (7.5), a prvalue of type `T1` may be explicitly converted to the type `T2` using a `const_cast`. The result of a `const_cast` refers to the original entity. [Example:

   ```
   typedef int *A[3]; // array of 3 pointer to int
typedef const int *const CA[3]; // array of 3 const pointer to const int
   CA &&r = A{}; // OK, reference binds to temporary array object after qualification conversion to type CA
   A &&r1 = const_cast<A>(CA{}); // error: temporary array decayed to pointer
   A &&r2 = const_cast<A&&>(CA{}); // OK
   — end example]

3. For two object types `T1` and `T2`, if a pointer to `T1` can be explicitly converted to the type “pointer to `T2`” using a `const_cast`, then the following conversions can also be made:
   - (4.1) an lvalue of type `T1` can be explicitly converted to an lvalue of type `T2` using the cast `const_cast<T2&>`;
   - (4.2) a glvalue of type `T1` can be explicitly converted to an xvalue of type `T2` using the cast `const_cast<T2&&>`; and
   - (4.3) if `T1` is a class type, a prvalue of type `T1` can be explicitly converted to an xvalue of type `T2` using the cast `const_cast<T2&&>`.

   The result of a reference `const_cast` refers to the original object if the operand is a glvalue and to the result of applying the temporary materialization conversion (7.4) otherwise.

4. A null pointer value (7.11) is converted to the null pointer value of the destination type. The null member pointer value (7.12) is converted to the null member pointer value of the destination type.

5. **Note:** Depending on the type of the object, a write operation through the pointer, lvalue or pointer to data member resulting from a `const_cast` that casts away a const-qualifier may produce undefined behavior (10.1.7.1). —end note

6. A conversion from a type `T1` to a type `T2` casts away constness if `T1` and `T2` are different, there is a cv-decomposition (7.5) of `T1` yielding `n` such that `T2` has a cv-decomposition of the form
   
   \[
   cv_0^2 P_0^2 cv_1^2 P_1^2 \cdots cv_{n-1}^2 P_{n-1}^2 cv_n^2 u_2, 
   \]

   and there is no qualification conversion that converts `T1` to
   
   \[
   cv_0^2 P_0^1 cv_1^2 P_1^1 \cdots cv_{n-1}^2 P_{n-1}^1 cv_n^2 u_1. 
   \]

7. Casting from an lvalue of type `T1` to an lvalue of type `T2` using an lvalue reference cast or casting from an expression of type `T1` to an xvalue of type `T2` using an rvalue reference cast casts away constness if a cast from a prvalue of type “pointer to `T1`” to the type “pointer to `T2`” casts away constness.

8. **Note:** Some conversions which involve only changes in cv-qualification cannot be done using `const_cast`. For instance, conversions between pointers to functions are not covered because such conversions lead to values whose use causes undefined behavior. For the same reasons, conversions between pointers to member functions, and in particular, the conversion from a pointer to a const member function to a pointer to a

---

76) `const_cast` is not limited to conversions that cast away a const-qualifier.
non-const member function, are not covered. — end note]

8.3 Unary expressions [expr.unary]

1 Expressions with unary operators group right-to-left.

\[\text{unary-expression:} \]

\[\text{postfix-expression} \]

\[\text{++ cast-expression} \]

\[\text{-- cast-expression} \]

\[\text{unary-operator cast-expression} \]

\[\text{sizeof unary-expression} \]

\[\text{sizeof ( type-id )} \]

\[\text{sizeof ... ( identifier )} \]

\[\text{alignof ( type-id )} \]

\[\text{noexcept-expression} \]

\[\text{new-expression} \]

\[\text{unary-operator: one of} \]

\[* & + - ! \]

8.3.1 Unary operators [expr.unary.op]

1 The unary \[*\] operator performs \textit{indirection}: the expression to which it is applied shall be a pointer to an object type, or a pointer to a function type and the result is an lvalue referring to the object or function to which the expression points. If the type of the expression is “pointer to T”, the type of the result is “T”.

[Note: Indirection through a pointer to an incomplete type (other than \textit{cv void}) is valid. The lvalue thus obtained can be used in limited ways (to initialize a reference, for example); this lvalue must not be converted to a prvalue, see 7.1. — end note]

2 The result of each of the following unary operators is a prvalue.

3 The result of the unary \& operator is a pointer to its operand. The operand shall be an lvalue or a \textit{qualified-id}. If the operand is a \textit{qualified-id} naming a non-static or variant member \textit{m} of some class \textit{C} with type \textit{T}, the result has type “pointer to member of class \textit{C} of type \textit{T}” and is a prvalue designating \textit{C::m}. Otherwise, if the type of the expression is \textit{T}, the result has type “pointer to \textit{T}” and is a prvalue that is the address of the designated object (4.4) or a pointer to the designated function. [Note: In particular, the address of an object of type “\textit{cv T}” is “pointer to \textit{cv T}”, with the same \textit{cv}-qualification. — end note] For purposes of pointer arithmetic (8.7) and comparison (8.9, 8.10), an object that is not an array element whose address is taken in this way is considered to belong to an array with one element of type \textit{T}. [Example:

\begin{verbatim}
struct A { int i; };  
struct B : A { };  
... &B::i ...  // has type int A::*  
int a;  
int* p1 = &a;  
int* p2 = p1 + 1;  // defined behavior  
bool b = p2 > p1;  // defined behavior, with value true
\end{verbatim}

— end example] [Note: A pointer to member formed from a \texttt{mutable} non-static data member (10.1.1) does not reflect the \texttt{mutable} specifier associated with the non-static data member. — end note]

4 A pointer to member is only formed when an explicit \& is used and its operand is a \textit{qualified-id} not enclosed in parentheses. [Note: That is, the expression \&(\textit{qualified-id}), where the \textit{qualified-id} is enclosed in parentheses, does not form an expression of type “pointer to member”. Neither does \textit{qualified-id}, because there is no implicit conversion from a \textit{qualified-id} for a non-static member function to the type “pointer to member function” as there is from an lvalue of function type to the type “pointer to function” (7.3). Nor is \&\texttt{unqualified-id} a pointer to member, even within the scope of the \texttt{unqualified-id}'s class. — end note]

§ 8.3.1 120
If & is applied to an lvalue of incomplete class type and the complete type declares `operator&()`, it is unspecified whether the operator has the built-in meaning or the operator function is called. The operand of & shall not be a bit-field.

The address of an overloaded function (Clause 16) can be taken only in a context that uniquely determines which version of the overloaded function is referred to (see 16.4). [Note: Since the context might determine whether the operand is a static or non-static member function, the context can also affect whether the expression has type “pointer to function” or “pointer to member function”. — end note]

The operand of the unary + operator shall have arithmetic, unscoped enumeration, or pointer type and the result is the value of the argument. Integral promotion is performed on integral or enumeration operands. The type of the result is the type of the promoted operand.

The operand of the unary - operator shall have arithmetic or unscoped enumeration type and the result is the negation of its operand. Integral promotion is performed on integral or enumeration operands. The negative of an unsigned quantity is computed by subtracting its value from $2^n$, where $n$ is the number of bits in the promoted operand. The type of the result is the type of the promoted operand.

The operand of the logical negation operator ! is contextually converted to `bool` (Clause 7); its value is `true` if the converted operand is `false` and `false` otherwise. The type of the result is `bool`.

The operand of ~ shall have integral or unscoped enumeration type; the result is the ones’ complement of its operand. Integral promotions are performed. The type of the result is the type of the promoted operand. There is an ambiguity in the grammar when ~ is followed by a `class-name` or `decltype-specifier`. The ambiguity is resolved by treating ~ as the unary complement operator rather than as the start of an `unqualified-id` naming a destructor. [Note: Because the grammar does not permit an operator to follow the `.`, `->`, or `::` tokens, a ~ followed by a `class-name` or `decltype-specifier` in a member access expression or `qualified-id` is unambiguously parsed as a destructor name. — end note]

8.3.2 Increment and decrement [expr.pre.incr]

The operand of prefix ++ is modified by adding 1. The operand shall be a modifiable lvalue. The type of the operand shall be an arithmetic type other than `cv bool`, or a pointer to a completely-defined object type. The result is the updated operand; it is an lvalue, and it is a bit-field if the operand is a bit-field. The expression ++x is equivalent to x+=1. [Note: See the discussions of addition (8.7) and assignment operators (8.18) for information on conversions. — end note]

The operand of prefix -- is modified by subtracting 1. The requirements on the operand of prefix -- and the properties of its result are otherwise the same as those of prefix ++. [Note: For postfix increment and decrement, see 8.2.6. — end note]

8.3.3 Sizeof [expr.sizeof]

The `sizeof` operator yields the number of bytes in the object representation of its operand. The operand is either an expression, which is an unevaluated operand (Clause 8), or a parenthesized `type-id`. The `sizeof` operator shall not be applied to an expression that has function or incomplete type, to the parenthesized name of such types, or to a `gvalue` that designates a bit-field. `sizeof(char)`, `sizeof(signed char)` and `sizeof(unsigned char)` are 1. The result of `sizeof` applied to any other fundamental type (6.9.1) is implementation-defined. [Note: In particular, `sizeof(bool)`, `sizeof(char16_t)`, `sizeof(char32_t)`, and `sizeof(wchar_t)` are implementation-defined. — end note] [Note: See 4.4 for the definition of `byte` and 6.9 for the definition of `object representation`. — end note]

When applied to a reference or a reference type, the result is the size of the referenced type. When applied to a class, the result is the number of bytes in an object of that class including any padding required for placing objects of that type in an array. The size of a most derived class shall be greater than zero (4.5).

77) `sizeof(bool)` is not required to be 1.
The result of applying \texttt{sizeof} to a base class subobject is the size of the base class type.\footnote{78} When applied to an array, the result is the total number of bytes in the array. This implies that the size of an array of \textit{n} elements is \textit{n} times the size of an element.

3 The \texttt{sizeof} operator can be applied to a pointer to a function, but shall not be applied directly to a function.

4 The \texttt{Ivalue-to-rvalue} (7.1), \texttt{array-to-pointer} (7.2), and \texttt{function-to-pointer} (7.3) standard conversions are not applied to the operand of \texttt{sizeof}. If the operand is a \texttt{prvalue}, the temporary materialization conversion (7.4) is applied.

5 The identifier in a \texttt{sizeof...} expression shall name a parameter pack. The \texttt{sizeof...} operator yields the number of arguments provided for the parameter pack \texttt{identifier}. A \texttt{sizeof...} expression is a \texttt{pack expansion} (17.5.3). \textit{[Example:}

\begin{verbatim}
    template<class... Types>
    struct count {
        static const std::size_t value = sizeof...(Types);
    };
    \end{verbatim}

\textit{—end example]}

6 The result of \texttt{sizeof} and \texttt{sizeof...} is a constant of type \texttt{std::size\_t}. \textit{[Note: std::size\_t is defined in the standard header \texttt{<cstdlib>}} (21.2.1, 21.2.4). \textit{—end note]}

8.3.4 New \[expr.new]

1 The \texttt{new-expression} attempts to create an object of the \texttt{type-id} (11.1) or \texttt{new-type-id} to which it is applied. The type of that object is the \textit{allocated type}. This type shall be a complete object type, but not an abstract class type or array thereof (4.5, 6.9, 13.4). \textit{[Note: Because references are not objects, references cannot be created by \texttt{new-expressions}. \textit{—end note] [Note: The \texttt{type-id} may be a cv-qualified type, in which case the object created by the \texttt{new-expression} has a cv-qualified type. \textit{—end note]}

\begin{verbatim}
new-expression:
    ::opt new new-placement\_opt new-type-id new-initializer\_opt
    ::opt new new-placement\_opt ( type-id ) new-initializer\_opt

new-placement:
    ( expression-list )

new-type-id:
    type-specifier-seq new-declarator\_opt

new-declarator:
    ptr-operator new-declarator\_opt
    noptr-new-declarator

noptr-new-declarator:
    [ expression ] attribute-specifier-seq\_opt
    noptr-new-declarator [ constant-expression ] attribute-specifier-seq\_opt

new-initializer:
    ( expression-list\_opt )
    braced-init-list
\end{verbatim}

Entities created by a \texttt{new-expression} have dynamic storage duration (6.7.4). \textit{[Note: The lifetime of such an entity is not necessarily restricted to the scope in which it is created. \textit{—end note] If the entity is a non-array object, the \texttt{new-expression} returns a pointer to the object created. If it is an array, the \texttt{new-expression} returns a pointer to the initial element of the array.}

\textit{§ 8.3.4}
If a placeholder type (10.1.7.4) appears in the type-specifier-seq of a new-type-id or type-id of a new-expression, the allocated type is deduced as follows: Let \( \text{init} \) be the new-initializer, if any, and \( T \) be the new-type-id or type-id of the new-expression, then the allocated type is the type deduced for the variable \( x \) in the invented declaration (10.1.7.4):

\[
T \ x \ \text{init} ;
\]

[Example:

```c
new auto(1); // allocated type is int
auto x = new auto('a'); // allocated type is char, x is of type char*
```

```c
template<class T> struct A { A(T, T); }
```

```c
auto y = new A{1, 2}; // allocated type is A<int>
```

— end example]

The new-type-id in a new-expression is the longest possible sequence of new-declarators. [Note: This prevents ambiguities between the declarator operators &, &&, *, and [] and their expression counterparts. — end note] [Example:

```c
new int * i; // syntax error: parsed as (new int*) i, not as (new int)*i
```

The * is the pointer declarator and not the multiplication operator. — end example]

[Note: Parentheses in a new-type-id of a new-expression can have surprising effects. [Example:

```c
new int(*[10])(); // error
```

is ill-formed because the binding is

```c
(new int) ([*][10])(); // error
```

Instead, the explicitly parenthesized version of the new operator can be used to create objects of compound types (6.9.2):

```c
new (int (*[10])());
```

allocates an array of 10 pointers to functions (taking no argument and returning int). — end example] — end note]

When the allocated object is an array (that is, the noptr-new-declarator syntax is used or the new-type-id or type-id denotes an array type), the new-expression yields a pointer to the initial element (if any) of the array. [Note: Both new int and new int[10] have type int* and the type of new int[1][10] is int (**)10 — end note] The attribute-specifier-seq in a noptr-new-declarator appertains to the associated array type.

Every constant-expression in a noptr-new-declarator shall be a converted constant expression (8.20) of type std::size_t and shall evaluate to a strictly positive value. The expression in a noptr-new-declarator is implicitly converted to std::size_t. [Example: Given the definition int n = 42, new float[n][5] is well-formed (because n is the expression of a noptr-new-declarator), but new float[5][n] is ill-formed (because n is not a constant expression). — end example]

The expression in a noptr-new-declarator is erroneous if:

1. The expression is of non-class type and its value before converting to std::size_t is less than zero;
2. The expression is of class type and its value before application of the second standard conversion (16.3.3.1.2)\(^{79}\) is less than zero;
3. Its value is such that the size of the allocated object would exceed the implementation-defined limit (Annex B); or
4. The new-initializer is a braced-init-list and the number of array elements for which initializers are

\(\text{§ 8.3.4} \quad 123\)

\(^{79}\) If the conversion function returns a signed integer type, the second standard conversion converts to the unsigned type std::size_t and thus thwarts any attempt to detect a negative value afterwards.
provided (including the terminating ‘\0’ in a string literal (5.13.5)) exceeds the number of elements to initialize.

If the expression is erroneous after converting to std::size_t:

(7.5) — if the expression is a core constant expression, the program is ill-formed;
(7.6) — otherwise, an allocation function is not called; instead
(7.6.1) — if the allocation function that would have been called has a non-throwing exception specification (18.4), the value of the new-expression is the null pointer value of the required result type;
(7.6.2) — otherwise, the new-expression terminates by throwing an exception of a type that would match a handler (18.3) of type std::bad_array_new_length (21.6.3.2).

When the value of the expression is zero, the allocation function is called to allocate an array with no elements.

A new-expression may obtain storage for the object by calling an allocation function (6.7.4.1). If the new-expression terminates by throwing an exception, it may release storage by calling a deallocation function (6.7.4.2). If the allocated type is a non-array type, the allocation function’s name is operator new and the deallocation function’s name is operator delete. If the allocated type is an array type, the allocation function’s name is operator new[] and the deallocation function’s name is operator delete[]. [Note: An implementation shall provide default definitions for the global allocation functions (6.7.4, 21.6.2.1, 21.6.2.2). A C++ program can provide alternative definitions of these functions (20.5.4.6) and/or class-specific versions (15.5). The set of allocation and deallocation functions that may be called by a new-expression may include functions that do not perform allocation or deallocation; for example, see 21.6.2.3. — end note]

If the new-expression begins with a unary :: operator, the allocation function’s name is looked up in the global scope. Otherwise, if the allocated type is a class type T or array thereof, the allocation function’s name is looked up in the scope of T. If this lookup fails to find the name, or if the allocated type is not a class type, the allocation function’s name is looked up in the global scope.

An implementation is allowed to omit a call to a replaceable global allocation function (21.6.2.1, 21.6.2.2). When it does so, the storage is instead provided by the implementation or provided by extending the allocation of another new-expression. The implementation may extend the allocation of a new-expression e1 to provide storage for a new-expression e2 if the following would be true were the allocation not extended:

(10.1) — the evaluation of e1 is sequenced before the evaluation of e2, and
(10.2) — e2 is evaluated whenever e1 obtains storage, and
(10.3) — both e1 and e2 invoke the same replaceable global allocation function, and
(10.4) — if the allocation function invoked by e1 and e2 is throwing, any exceptions thrown in the evaluation of either e1 or e2 would be first caught in the same handler, and
(10.5) — the pointer values produced by e1 and e2 are operands to evaluated delete-expressions, and
(10.6) — the evaluation of e2 is sequenced before the evaluation of the delete-expression whose operand is the pointer value produced by e1.

[Example:

```cpp
void mergeable(int x) {
    // These allocations are safe for merging:
    std::unique_ptr<char[]> a(new (std::nothrow) char[8]);
    std::unique_ptr<char[]> b(new (std::nothrow) char[8]);
    std::unique_ptr<char[]> c(new (std::nothrow) char[x]);

    g(a.get(), b.get(), c.get());
}
```]
When a `new-expression` calls an allocation function and that allocation has not been extended, the `new-expression` passes the amount of space requested to the allocation function as the first argument of type `std::size_t`. That argument shall be no less than the size of the object being created; it may be greater than the size of the object being created only if the object is an array. For arrays of `char`, `unsigned char`, and `std::byte`, the difference between the result of the `new-expression` and the address returned by the allocation function shall be an integral multiple of the strictest fundamental alignment requirement (6.11) of any object type whose size is no greater than the size of the array being created.  

【Note: Because allocation functions are assumed to return pointers to storage that is appropriately aligned for objects of any type with fundamental alignment, this constraint on array allocation overhead permits the common idiom of allocating character arrays into which objects of other types will later be placed. — end note】

When a `new-expression` calls an allocation function and that allocation has been extended, the size argument to the allocation call shall be no greater than the sum of the sizes for the omitted calls as specified above, plus the size for the extended call had it not been extended, plus any padding necessary to align the allocated objects within the allocated memory.

The `new-placement` syntax is used to supply additional arguments to an allocation function; such an expression is called a `placement new-expression`.

Overload resolution is performed on a function call created by assembling an argument list. The first argument is the amount of space requested, and has type `std::size_t`. If the type of the allocated object has new-extended alignment, the next argument is the type's alignment, and has type `std::align_val_t`. If the `new-placement` syntax is used, the `initializer-clauses` in its `expression-list` are the succeeding arguments. If no matching function is found and the allocated object type has new-extended alignment, the alignment argument is removed from the argument list, and overload resolution is performed again.

【Example:】

(15.1) — `new T` results in one of the following calls:
   - `operator new(sizeof(T))`
   - `operator new(sizeof(T), std::align_val_t(alignof(T)))`

(15.2) — `new(2,f) T` results in one of the following calls:
   - `operator new(sizeof(T), 2, f)`
   - `operator new(sizeof(T), std::align_val_t(alignof(T)), 2, f)`

(15.3) — `new T[5]` results in one of the following calls:
   - `operator new[](sizeof(T) * 5 + x)`
   - `operator new[](sizeof(T) * 5 + x, std::align_val_t(alignof(T)))`

(15.4) — `new(2,f) T[5]` results in one of the following calls:
   - `operator new[](sizeof(T) * 5 + x, 2, f)`

§ 8.3.4
operator new[](sizeof(T) * 5 + x, std::align_val_t(alignof(T)), 2, f)

Here, each instance of x is a non-negative unspecified value representing array allocation overhead; the result of the new-expression will be offset by this amount from the value returned by operator new[]. This overhead may be applied in all array new-expressions, including those referencing the library function operator new[](std::size_t, void*) and other placement allocation functions. The amount of overhead may vary from one invocation of new to another. —end example]

16 [ Note: Unless an allocation function has a non-throwing exception specification (18.4), it indicates failure to allocate storage by throwing a std::bad_alloc exception (6.7.4.1, Clause 18, 21.6.3.1); it returns a non-null pointer otherwise. If the allocation function has a non-throwing exception specification, it returns null to indicate failure to allocate storage and a non-null pointer otherwise. — end note] If the allocation function is a non-allocating form (21.6.2.3) that returns null, the behavior is undefined. Otherwise, if the allocation function returns null, initialization shall not be done, the deallocation function shall not be called, and the value of the new-expression shall be null.

17 [ Note: When the allocation function returns a value other than null, it must be a pointer to a block of storage in which space for the object has been reserved. The block of storage is assumed to be appropriately aligned and of the requested size. The address of the created object will not necessarily be the same as that of the block if the object is an array. — end note]

18 A new-expression that creates an object of type T initializes that object as follows:

(18.1) — If the new-initializer is omitted, the object is default-initialized (11.6). [ Note: If no initialization is performed, the object has an indeterminate value. — end note]

(18.2) — Otherwise, the new-initializer is interpreted according to the initialization rules of 11.6 for direct-initialization.

19 The invocation of the allocation function is sequenced before the evaluations of expressions in the new-initializer. Initialization of the allocated object is sequenced before the value computation of the new-expression.

20 If the new-expression creates an object or an array of objects of class type, access and ambiguity control are done for the allocation function, the deallocation function (15.5), and the constructor (15.1). If the new-expression creates an array of objects of class type, the destructor is potentially invoked (15.4).

21 If any part of the object initialization described above80 terminates by throwing an exception and a suitable deallocation function can be found, the deallocation function is called to free the memory in which the object was being constructed, after which the exception continues to propagate in the context of the new-expression. If no unambiguous matching deallocation function can be found, propagating the exception does not cause the object’s memory to be freed. [ Note: This is appropriate when the called allocation function does not allocate memory; otherwise, it is likely to result in a memory leak. — end note]

22 If the new-expression begins with a unary :: operator, the deallocation function’s name is looked up in the global scope. Otherwise, if the allocated type is a class type T or an array thereof, the deallocation function’s name is looked up in the scope of T. If this lookup fails to find the name, or if the allocated type is not a class type or array thereof, the dealallocation function’s name is looked up in the global scope.

23 A declaration of a placement deallocation function matches the declaration of a placement allocation function if it has the same number of parameters and, after parameter transformations (11.3.5), all parameter types except the first are identical. If the lookup finds a single matching deallocation function, that function will be called; otherwise, no deallocation function will be called. If the lookup finds a usual deallocation function with a parameter of type std::size_t (6.7.4.2) and that function, considered as a placement deallocation function, would have been selected as a match for the allocation function, the program is ill-formed. For a non-placement allocation function, the normal deallocation function lookup is used to find the matching

80) This may include evaluating a new-initializer and/or calling a constructor.

§ 8.3.4
deallocation function (8.3.5) [Example:

```cpp
template struct S {
  // Placement allocation function:
  static void* operator new(std::size_t, std::size_t);

  // Usual (non-placement) deallocation function:
  static void operator delete(void*, std::size_t);
};
```

```cpp
S* p = new (0) S;  // ill-formed: non-placement deallocation function matches
                  // placement allocation function
```

— end example]

If a new-expression calls a deallocation function, it passes the value returned from the allocation function call as the first argument of type `void*`. If a placement deallocation function is called, it is passed the same additional arguments as were passed to the placement allocation function, that is, the same arguments as those specified with the new-placement syntax. If the implementation is allowed to make a copy of any argument as part of the call to the allocation function, it is allowed to make a copy (of the same original value) as part of the call to the deallocation function or to reuse the copy made as part of the call to the allocation function. If the copy is elided in one place, it need not be elided in the other.

8.3.5 Delete [expr.delete]

The delete-expression operator destroys a most derived object (4.5) or array created by a new-expression.

```cpp
delete-expression:
  ::opt delete cast-expression
  ::opt delete [ ] cast-expression
```

The first alternative is for non-array objects, and the second is for arrays. Whenever the `delete` keyword is immediately followed by empty square brackets, it shall be interpreted as the second alternative.\(^1\) The operand shall be of pointer to object type or of class type. If of class type, the operand is contextually implicitly converted (Clause 7) to a pointer to object type.\(^2\) The delete-expression's result has type `void`.\(^3\)

If the operand has a class type, the operand is converted to a pointer type by calling the above-mentioned conversion function, and the converted operand is used in place of the original operand for the remainder of this section. In the first alternative (delete object), the value of the operand of delete may be a null pointer value, a pointer to a non-array object created by a previous new-expression, or a pointer to a subobject (4.5) representing a base class of such an object (Clause 13). If not, the behavior is undefined. In the second alternative (delete array), the value of the operand of delete may be a null pointer value or a pointer value that resulted from a previous array new-expression.\(^3\) If not, the behavior is undefined. [Note: This means that the syntax of the delete-expression must match the type of the object allocated by new, not the syntax of the new-expression. — end note] [Note: A pointer to a const type can be the operand of a delete-expression; it is not necessary to cast away the constness (8.2.11) of the pointer expression before it is used as the operand of the delete-expression. — end note]

If the operand has a class type, the operand is converted to a pointer type by calling the above-mentioned conversion function, and the converted operand is used in place of the original operand for the remainder of this section. In the first alternative (delete object), the value of the operand of delete may be a null pointer value, a pointer to a non-array object created by a previous new-expression, or a pointer to a subobject (4.5) representing a base class of such an object (Clause 13). If not, the behavior is undefined. In the second alternative (delete array), the value of the operand of delete may be a null pointer value or a pointer value that resulted from a previous array new-expression.\(^3\) If not, the behavior is undefined. [Note: This means that the syntax of the delete-expression must match the type of the object allocated by new, not the syntax of the new-expression. — end note] [Note: A pointer to a const type can be the operand of a delete-expression; it is not necessary to cast away the constness (8.2.11) of the pointer expression before it is used as the operand of the delete-expression. — end note]

In the first alternative (delete object), if the static type of the object to be deleted is different from its dynamic type, the static type shall be a base class of the dynamic type of the object to be deleted and the static type shall have a virtual destructor or the behavior is undefined. In the second alternative (delete array) if the dynamic type of the object to be deleted differs from its static type, the behavior is undefined.

\(^1\) A lambda expression with a lambda-introducer that consists of empty square brackets can follow the delete keyword if the lambda expression is enclosed in parentheses.

\(^2\) This implies that an object cannot be deleted using a pointer of type `void*` because `void` is not an object type.

\(^3\) For nonzero-length arrays, this is the same as a pointer to the first element of the array created by that new-expression. Zero-length arrays do not have a first element.

§ 8.3.5
The *cast-expression* in a *delete-expression* shall be evaluated exactly once.

If the object being deleted has incomplete class type at the point of deletion and the complete class has a non-trivial destructor or a deallocation function, the behavior is undefined.

If the value of the operand of the *delete-expression* is not a null pointer value, the *delete-expression* will invoke the destructor (if any) for the object or the elements of the array being deleted. In the case of an array, the elements will be destroyed in order of decreasing address (that is, in reverse order of the completion of their constructor; see 15.6.2).

If the value of the operand of the *delete-expression* is not a null pointer value, then:

1. If the allocation call for the *new-expression* for the object to be deleted was not omitted and the allocation was not extended (8.3.4), the *delete-expression* shall call a deallocation function (6.7.4.2). The value returned from the allocation call of the *new-expression* shall be passed as the first argument to the deallocation function.

2. Otherwise, if the allocation was extended or was provided by extending the allocation of another *new-expression*, and the *delete-expression* for every other pointer value produced by a *new-expression* that had storage provided by the extended *new-expression* has been evaluated, the *delete-expression* shall call a deallocation function. The value returned from the allocation call of the extended *new-expression* shall be passed as the first argument to the deallocation function.

3. Otherwise, the *delete-expression* will not call a deallocation function.

[Note: The deallocation function is called regardless of whether the destructor for the object or some element of the array throws an exception. —end note] If the value of the operand of the *delete-expression* is a null pointer value, it is unspecified whether a deallocation function will be called as described above.

An implementation provides default definitions of the global deallocation functions `operator delete` for non-arrays (21.6.2.1) and `operator delete[]` for arrays (21.6.2.2). A C++ program can provide alternative definitions of these functions (20.5.4.6), and/or class-specific versions (15.5). —end note]

When the keyword `delete` in a *delete-expression* is preceded by the unary `::` operator, the deallocation function’s name is looked up in global scope. Otherwise, the lookup considers class-specific deallocation functions (15.5). If no class-specific deallocation function is found, the deallocation function’s name is looked up in global scope.

If deallocation function lookup finds more than one usual deallocation function, the function to be called is selected as follows:

1. If the type has new-extended alignment, a function with a parameter of type `std::align_val_t` is preferred; otherwise a function without such a parameter is preferred. If exactly one preferred function is found, that function is selected and the selection process terminates. If more than one preferred function is found, all non-preferred functions are eliminated from further consideration.

2. If the deallocation functions have class scope, the one without a parameter of type `std::size_t` is selected.

3. If the type is complete and if, for the second alternative (delete array) only, the operand is a pointer to a class type with a non-trivial destructor or a (possibly multi-dimensional) array thereof, the function with a parameter of type `std::size_t` is selected.

4. Otherwise, it is unspecified whether a deallocation function with a parameter of type `std::size_t` is selected.

When a *delete-expression* is executed, the selected deallocation function shall be called with the address of the most-derived object in the *delete object* case, or the address of the object suitably adjusted for the array allocation overhead (8.3.4) in the *delete array* case, as its first argument. If a deallocation function with a parameter of type `std::align_val_t` is used, the alignment of the type of the object to be deleted is
passed as the corresponding argument. If a deallocation function with a parameter of type `std::size_t` is used, the size of the most-derived type, or of the array plus allocation overhead, respectively, is passed as the corresponding argument.⁸⁴ [Note: If this results in a call to a usual deallocation function, and either the first argument was not the result of a prior call to a usual allocation function or the second argument was not the corresponding argument in said call, the behavior is undefined (21.6.2.1, 21.6.2.2). — end note]

12 Access and ambiguity control are done for both the deallocation function and the destructor (15.4, 15.5).

8.3.6 Alignof

An `alignof` expression yields the alignment requirement of its operand type. The operand shall be a `type-id` representing a complete object type, or an array thereof, or a reference to one of those types.

2 The result is an integral constant of type `std::size_t`.

3 When `alignof` is applied to a reference type, the result is the alignment of the referenced type. When `alignof` is applied to an array type, the result is the alignment of the element type.

8.3.7 noexcept operator

The `noexcept` operator determines whether the evaluation of its operand, which is an unevaluated operand (Clause 8), can throw an exception (18.1).

```cpp
noexcept-expression:
  noexcept ( expression )
```

2 The result of the `noexcept` operator is a constant of type `bool` and is a prvalue.

3 The result of the `noexcept` operator is `true` unless the `expression` is potentially-throwing (18.4).

8.4 Explicit type conversion (cast notation)

The result of the expression `(T)` `cast-expression` is of type `T`. The result is an lvalue if `T` is an lvalue reference type or an rvalue reference to function type and an xvalue if `T` is an rvalue reference to object type; otherwise the result is a prvalue. [Note: If `T` is a non-class type that is cv-qualified, the cv-qualifiers are discarded when determining the type of the resulting prvalue; see Clause 8. — end note]

2 An explicit type conversion can be expressed using functional notation (8.2.3), a type conversion operator (`dynamic_cast`, `static_cast`, `reinterpret_cast`, `const_cast`), or the `cast` notation.

```cpp
cast-expression:
  unary-expression
  ( type-id ) cast-expression
```

3 Any type conversion not mentioned below and not explicitly defined by the user (15.3) is ill-formed.

4 The conversions performed by

(4.1) — a `const_cast` (8.2.11),
(4.2) — a `static_cast` (8.2.9),
(4.3) — a `static_cast` followed by a `const_cast`,
(4.4) — a `reinterpret_cast` (8.2.10), or
(4.5) — a `reinterpret_cast` followed by a `const_cast`,

can be performed using the cast notation of explicit type conversion. The same semantic restrictions and behaviors apply, with the exception that in performing a `static_cast` in the following situations the conversion is valid even if the base class is inaccessible:

---

⁸⁴ If the static type of the object to be deleted is complete and is different from the dynamic type, and the destructor is not virtual, the size might be incorrect, but that case is already undefined, as stated above.
(4.6) — a pointer to an object of derived class type or an lvalue or rvalue of derived class type may be explicitly converted to a pointer or reference to an unambiguous base class type, respectively;

(4.7) — a pointer to member of derived class type may be explicitly converted to a pointer to member of an unambiguous non-virtual base class type;

(4.8) — a pointer to an object of an unambiguous non-virtual base class type, a glvalue of an unambiguous non-virtual base class type, or a pointer to member of an unambiguous non-virtual base class type may be explicitly converted to a pointer, a reference, or a pointer to member of a derived class type, respectively.

If a conversion can be interpreted in more than one of the ways listed above, the interpretation that appears first in the list is used, even if a cast resulting from that interpretation is ill-formed. If a conversion can be interpreted in more than one way as a static_cast followed by a const_cast, the conversion is ill-formed.

[Example:

```cpp
struct A { 
};
struct I1 : A { 
};
struct I2 : A { 
};
struct D : I1, I2 { 
};
A* foo( D* p ) {
    return (A*)( p );
    // ill-formed static_cast interpretation
}
```

—end example]

5 The operand of a cast using the cast notation can be a prvalue of type “pointer to incomplete class type”. The destination type of a cast using the cast notation can be “pointer to incomplete class type”. If both the operand and destination types are class types and one or both are incomplete, it is unspecified whether the static_cast or the reinterpret_cast interpretation is used, even if there is an inheritance relationship between the two classes. [Note: For example, if the classes were defined later in the translation unit, a multi-pass compiler would be permitted to interpret a cast between pointers to the classes as if the class types were complete at the point of the cast. —end note]

8.5 Pointer-to-member operators

1 The pointer-to-member operators ->* and .* group left-to-right.

```cpp
pm-expression:
cast-expression
pm-expression .* cast-expression
pm-expression ->* cast-expression
```

2 The binary operator .* binds its second operand, which shall be of type “pointer to member of T” to its first operand, which shall be a glvalue of class T or of a class of which T is an unambiguous and accessible base class. The result is an object or a function of the type specified by the second operand.

3 The binary operator ->* binds its second operand, which shall be of type “pointer to member of T” to its first operand, which shall be of type “pointer to U” where U is either T or a class of which T is an unambiguous and accessible base class. The expression E1->*E2 is converted into the equivalent form *(E1).*E2.

4 Abbreviating pm-expression.*cast-expression as E1.*E2, E1 is called the object expression. If the dynamic type of E1 does not contain the member to which E2 refers, the behavior is undefined. Otherwise, the expression E1 is sequenced before the expression E2.

5 The restrictions on cv-qualification, and the manner in which the cv-qualifiers of the operands are combined to produce the cv-qualifiers of the result, are the same as the rules for E1.E2 given in 8.2.5. [Note: It is not possible to use a pointer to member that refers to a mutable member to modify a const class object. For example,
struct S {
    S() : i(0) { }
    mutable int i;
};
void f()
{
    const S cs;
    int S::* pm = &S::i;         // pm refers to mutable member S::i
    cs.*pm = 88;                 // ill-formed: cs is a const object
}

// end note

6 If the result of . * or ->* is a function, then that result can be used only as the operand for the function call operator ().  [Example:

    (ptr_to_obj->ptr_to_mfct)(10);

calls the member function denoted by ptr_to_mfct for the object pointed to by ptr_to_obj.  — end example]
In a . * expression whose object expression is an rvalue, the program is ill-formed if the second operand is a pointer to member function with ref-qualifier &. In a . * expression whose object expression is an lvalue, the program is ill-formed if the second operand is a pointer to member function with ref-qualifier &&. The result of a . * expression whose second operand is a pointer to a data member is an lvalue if the first operand is an lvalue and an xvalue otherwise. The result of a . * expression whose second operand is a pointer to a member function is a prvalue. If the second operand is the null member pointer value (7.12), the behavior is undefined.

8.6 Multiplicative operators

1 The multiplicative operators *, /, and % group left-to-right.

    multiplicative-expression:
        pm-expression
    multiplicative-expression * pm-expression
    multiplicative-expression / pm-expression
    multiplicative-expression % pm-expression

2 The operands of * and / shall have arithmetic or unscoped enumeration type; the operands of % shall have integral or unscoped enumeration type. The usual arithmetic conversions are performed on the operands and determine the type of the result.

3 The binary * operator indicates multiplication.

4 The binary / operator yields the quotient, and the binary % operator yields the remainder from the division of the first expression by the second. If the second operand of / or % is zero the behavior is undefined. For integral operands the / operator yields the algebraic quotient with any fractional part discarded;85 if the quotient a/b is representable in the type of the result, (a/b)*b + a%b is equal to a; otherwise, the behavior of both a/b and a%b is undefined.

8.7 Additive operators

1 The additive operators + and - group left-to-right. The usual arithmetic conversions are performed for operands of arithmetic or enumeration type.

    additive-expression:
        multiplicative-expression
    additive-expression + multiplicative-expression
    additive-expression - multiplicative-expression

85) This is often called truncation towards zero.
For addition, either both operands shall have arithmetic or unscoped enumeration type, or one operand shall be a pointer to a completely-defined object type and the other shall have integral or unscoped enumeration type.

For subtraction, one of the following shall hold:

1. both operands have arithmetic or unscoped enumeration type; or
2. both operands are pointers to cv-qualified or cv-unqualified versions of the same completely-defined object type; or
3. the left operand is a pointer to a completely-defined object type and the right operand has integral or unscoped enumeration type.

The result of the binary + operator is the sum of the operands. The result of the binary - operator is the difference resulting from the subtraction of the second operand from the first.

When an expression that has integral type is added to or subtracted from a pointer, the result has the type of the pointer operand. If the expression \( P \) points to element \( x[i] \) of an array object \( x \) with \( n \) elements, the expressions \( P + J \) and \( J + P \) (where \( J \) has the value \( j \)) point to the (possibly-hypothetical) element \( x[i + j] \) if \( 0 \leq i + j \leq n \); otherwise, the behavior is undefined. Likewise, the expression \( P - J \) points to the (possibly-hypothetical) element \( x[i - j] \) if \( 0 \leq i - j \leq n \); otherwise, the behavior is undefined.

When two pointers to elements of the same array object are subtracted, the type of the result is an implementation-defined signed integral type; this type shall be the same type that is defined as \( \text{std::ptrdiff}_{-}\text{t} \) in the \(<\text{cstddef}>\) header (21.2). If the expressions \( P \) and \( Q \) point to, respectively, elements \( x[i] \) and \( x[j] \) of the same array object \( x \), the expression \( P - Q \) has the value \( i - j \); otherwise, the behavior is undefined. [Note: If the value \( i - j \) is not in the range of representable values of type \( \text{std::ptrdiff}_{-}\text{t} \), the behavior is undefined. —end note]

For addition or subtraction, if the expressions \( P \) or \( Q \) have type “pointer to cv T”, where \( T \) and the array element type are not similar (7.5), the behavior is undefined. [Note: In particular, a pointer to a base class cannot be used for pointer arithmetic when the array contains objects of a derived class type. —end note]

If the value 0 is added to or subtracted from a null pointer value, the result is a null pointer value. If two null pointer values are subtracted, the result compares equal to the value 0 converted to the type \( \text{std::ptrdiff}_{-}\text{t} \).

### 8.8 Shift operators

The shift operators \( << \) and \( >> \) group left-to-right.

\[
\text{shift-expression}:
\begin{align*}
\text{additive-expression} \\
\text{shift-expression} \ll \text{additive-expression} \\
\text{shift-expression} \gg \text{additive-expression}
\end{align*}
\]

The operands shall be of integral or unscoped enumeration type and integral promotions are performed. The type of the result is that of the promoted left operand. The behavior is undefined if the right operand is negative, or greater than or equal to the length in bits of the promoted left operand.

The value of \( E1 \ll E2 \) is \( E1 \) left-shifted \( E2 \) bit positions; vacated bits are zero-filled. If \( E1 \) has an unsigned type, the value of the result is \( E1 \times 2^{E2} \), reduced modulo one more than the maximum value representable in the result type. Otherwise, if \( E1 \) has a signed type and non-negative value, and \( E1 \times 2^{E2} \) is representable in the corresponding unsigned type of the result type, then that value, converted to the result type, is the resulting value; otherwise, the behavior is undefined.

---

86) An object that is not an array element is considered to belong to a single-element array for this purpose; see 8.3.1. A pointer past the last element of an array \( x \) of \( n \) elements is considered to be equivalent to a pointer to a hypothetical element \( x[n] \) for this purpose; see 6.9.2.
The value of $E1 >> E2$ is $E1$ right-shifted $E2$ bit positions. If $E1$ has an unsigned type or if $E1$ has a signed type and a non-negative value, the value of the result is the integral part of the quotient of $E1 / 2^{E2}$. If $E1$ has a signed type and a negative value, the resulting value is implementation-defined.

The expression $E1$ is sequenced before the expression $E2$.

### 8.9 Relational operators

The relational operators group left-to-right. [Example: $a<b<c$ means $(a<b) < c$ and not $(a<b) && (b<c)$. — end example]

```c
relational-expression:
  shift-expression
relational-expression < shift-expression
relational-expression > shift-expression
relational-expression <= shift-expression
relational-expression >= shift-expression
```

The operands shall have arithmetic, enumeration, or pointer type. The operators $<$ (less than), $>$ (greater than), $\leq$ (less than or equal to), and $\geq$ (greater than or equal to) all yield `false` or `true`. The type of the result is `bool`.

The usual arithmetic conversions are performed on operands of arithmetic or enumeration type. If both operands are pointers, pointer conversions (7.11) and qualification conversions (7.5) are performed to bring them to their composite pointer type (Clause 8). After conversions, the operands shall have the same type.

Comparing unequal pointers to objects\(^\text{87}\) is defined as follows:

1. If two pointers point to different elements of the same array, or to subobjects thereof, the pointer to the element with the higher subscript compares greater.
2. If two pointers point to different non-static data members of the same object, or to subobjects of such members, recursively, the pointer to the later declared member compares greater provided the two members have the same access control (Clause 14) and provided their class is not a union.
3. Otherwise, neither pointer compares greater than the other.

If two operands $p$ and $q$ compare equal (8.10), $p=q$ and $p!=q$ both yield `true` and $p\preceq q$ and $p\succeq q$ both yield `false`. Otherwise, if a pointer $p$ compares greater than a pointer $q$, $p>q$, $q\preceq p$, and $q\succeq p$ all yield `true` and $p<q$, $p<q$, $q=p$, and $q>p$ all yield `false`. Otherwise, the result of each of the operators is unspecified.

If both operands (after conversions) are of arithmetic or enumeration type, each of the operators shall yield `true` if the specified relationship is true and `false` if it is false.

### 8.10 Equality operators

The `==` (equal to) and the `!=` (not equal to) operators group left-to-right. The operands shall have arithmetic, enumeration, pointer, or pointer to member type, or type `std::nullptr_t`. The operators `==` and `!=` both yield `true` or `false`, i.e., a result of type `bool`. In each case below, the operands shall have the same type after the specified conversions have been applied.

\(^{87}\) An object that is not an array element is considered to belong to a single-element array for this purpose; see 8.3.1. A pointer past the last element of an array $x$ of $n$ elements is considered to be equivalent to a pointer to a hypothetical element $x[n]$ for this purpose; see 6.9.2.
If at least one of the operands is a pointer, pointer conversions (7.11), function pointer conversions (7.13), and qualification conversions (7.5) are performed on both operands to bring them to their composite pointer type (Clause 8). Comparing pointers is defined as follows:

1. If one pointer represents the address of a complete object, and another pointer represents the address one past the last element of a different complete object,\(^{88}\) the result of the comparison is unspecified.
2. Otherwise, if the pointers are both null, both point to the same function, or both represent the same address (6.9.2), they compare equal.
3. Otherwise, the pointers compare unequal.

If at least one of the operands is a pointer to member, pointer to member conversions (7.12) and qualification conversions (7.5) are performed on both operands to bring them to their composite pointer type (Clause 8). Comparing pointers to members is defined as follows:

1. If two pointers to members are both the null member pointer value, they compare equal.
2. If only one of two pointers to members is the null member pointer value, they compare unequal.
3. If either is a pointer to a virtual member function, the result is unspecified.
4. If one refers to a member of class \(C_1\) and the other refers to a member of a different class \(C_2\), where neither is a base class of the other, the result is unspecified. [Example:

```c
struct A {
    int x;
};
struct B : A {
    int x;
};

int A::*bx = (int(A::*))&B::x;
int A::*cx = (int(A::*))&C::x;

bool b1 = (bx == cx); // unspecified
```

— end example]
5. If both refer to (possibly different) members of the same union (12.3), they compare equal.
6. Otherwise, two pointers to members compare equal if they would refer to the same member of the same most derived object (4.5) or the same subobject if indirection with a hypothetical object of the associated class type were performed, otherwise they compare unequal. [Example:

```c
struct B {
    int f();
};
struct L : B {
};
struct R : B {
};
struct D : L, R {
};

int (B::*pb)() = &B::f;
int (L::*pl)() = pb;
int (R::*pr)() = pb;
int (D::*pdl)() = pl;
int (D::*pdr)() = pr;
bool x = (pdl == pdr); // false
bool y = (pb == pl); // true
```

— end example]

\(^{88}\) An object that is not an array element is considered to belong to a single-element array for this purpose; see 8.3.1.
Two operands of type `std::nullptr_t` or one operand of type `std::nullptr_t` and the other a null pointer constant compare equal.

If two operands compare equal, the result is `true` for the `==` operator and `false` for the `!=` operator. If two operands compare unequal, the result is `false` for the `==` operator and `true` for the `!=` operator. Otherwise, the result of each of the operators is unspecified.

If both operands are of arithmetic or enumeration type, the usual arithmetic conversions are performed on both operands; each of the operators shall yield `true` if the specified relationship is true and `false` if it is false.

### 8.11 Bitwise AND operator

```
and-expression:
  equality-expression
  and-expression & equality-expression
```

1. The usual arithmetic conversions are performed; the result is the bitwise AND function of the operands. The operator applies only to integral or unscoped enumeration operands.

### 8.12 Bitwise exclusive OR operator

```
exclusive-or-expression:
  and-expression
  exclusive-or-expression ^ and-expression
```

1. The usual arithmetic conversions are performed; the result is the bitwise exclusive OR function of the operands. The operator applies only to integral or unscoped enumeration operands.

### 8.13 Bitwise inclusive OR operator

```
inclusive-or-expression:
  exclusive-or-expression
  inclusive-or-expression | exclusive-or-expression
```

1. The usual arithmetic conversions are performed; the result is the bitwise inclusive OR function of its operands. The operator applies only to integral or unscoped enumeration operands.

### 8.14 Logical AND operator

```
logical-and-expression:
  inclusive-or-expression
  logical-and-expression && inclusive-or-expression
```

1. The `&&` operator groups left-to-right. The operands are both contextually converted to `bool` (Clause 7). The result is `true` if both operands are `true` and `false` otherwise. Unlike `&`, `&&` guarantees left-to-right evaluation: the second operand is not evaluated if the first operand is `false`.

2. The result is a `bool`. If the second expression is evaluated, every value computation and side effect associated with the first expression is sequenced before every value computation and side effect associated with the second expression.

### 8.15 Logical OR operator

```
logical-or-expression:
  logical-and-expression
  logical-or-expression || logical-and-expression
```

1. The `||` operator groups left-to-right. The operands are both contextually converted to `bool` (Clause 7). It returns `true` if either of its operands is `true`, and `false` otherwise. Unlike `|`, `||` guarantees left-to-right evaluation; moreover, the second operand is not evaluated if the first operand evaluates to `true`. 

§ 8.15
The result is a `bool`. If the second expression is evaluated, every value computation and side effect associated with the first expression is sequenced before every value computation and side effect associated with the second expression.

### 8.16 Conditional operator

#### conditional-expression [expr.cond]

- `logical-or-expression
  logical-or-expression ? expression : assignment-expression`

1. Conditional expressions group right-to-left. The first expression is contextually converted to `bool` (Clause 7). It is evaluated and if it is `true`, the result of the conditional expression is the value of the second expression, otherwise that of the third expression. Only one of the second and third expressions is evaluated. Every value computation and side effect associated with the first expression is sequenced before every value computation and side effect associated with the second or third expression.

2. If either the second or the third operand has type `void`, one of the following shall hold:
   - The second or the third operand (but not both) is a (possibly parenthesized) `throw-expression` (8.17); the result is of the type and value category of the other. The `conditional-expression` is a bit-field if that operand is a bit-field.
   - Both the second and the third operands have type `void`; the result is of type `void` and is a prvalue.

3. Otherwise, if the second and third operand are glvalue bit-fields of the same value category and of types `cv1 T` and `cv2 T`, respectively, the operands are considered to be of type `cv T` for the remainder of this section, where `cv` is the union of `cv1` and `cv2`.

4. Otherwise, if the second and third operand have different types and either has (possibly `cv`-qualified) class type, or if both are glvalues of the same value category and the same type except for `cv`-qualification, an attempt is made to form an implicit conversion sequence (16.3.3.1) from each of those operands to the type of the other. Attempts are made to form an implicit conversion sequence from an operand expression `E1` of type `T1` to a target type related to the type `T2` of the operand expression `E2` as follows:

   - If `E2` is an lvalue, the target type is “lvalue reference to `T2`”, subject to the constraint that in the conversion the reference must bind directly (11.6.3) to an lvalue.
   - If `E2` is an xvalue, the target type is “rvalue reference to `T2`”, subject to the constraint that the reference must bind directly.
   - If `E2` is a prvalue or if neither of the conversion sequences above can be formed and at least one of the operands has (possibly `cv`-qualified) class type:
     - if `T1` and `T2` are the same class type (ignoring `cv`-qualification), or one is a base class of the other, and `T2` is at least as `cv`-qualified as `T1`, the target type is `T2`.
     - otherwise, the target type is the type that `E2` would have after applying the lvalue-to-rvalue (7.1), array-to-pointer (7.2), and function-to-pointer (7.3) standard conversions.

Using this process, it is determined whether an implicit conversion sequence can be formed from the second operand to the target type determined for the third operand, and vice versa. If both sequences can be formed, or one can be formed but it is the ambiguous conversion sequence, the program is ill-formed. If no conversion sequence can be formed, the operands are left unchanged and further checking is performed as described below. Otherwise, if exactly one conversion sequence can be formed, that conversion is applied to the chosen operand and the converted operand is used in place of the original operand for the remainder of this section. [Note: The conversion might be ill-formed even if an implicit conversion sequence could be formed. — end note]
If the second and third operands are glvalues of the same value category and have the same type, the result is of that type and value category and it is a bit-field if the second or the third operand is a bit-field, or if both are bit-fields.

Otherwise, the result is a prvalue. If the second and third operands do not have the same type, and either has (possibly cv-qualified) class type, overload resolution is used to determine the conversions (if any) to be applied to the operands (16.3.1.2, 16.6). If the overload resolution fails, the program is ill-formed. Otherwise, the conversions thus determined are applied, and the converted operands are used in place of the original operands for the remainder of this section.

Lvalue-to-rvalue (7.1), array-to-pointer (7.2), and function-to-pointer (7.3) standard conversions are performed on the second and third operands. After those conversions, one of the following shall hold:

1. The second and third operands have the same type; the result is of that type and the result object is initialized using the selected operand.
2. The second and third operands have arithmetic or enumeration type; the usual arithmetic conversions are performed to bring them to a common type, and the result is of that type.
3. One or both of the second and third operands have pointer type; pointer conversions (7.11), function pointer conversions (7.13), and qualification conversions (7.5) are performed to bring them to their composite pointer type (Clause 8). The result is of the composite pointer type.
4. One or both of the second and third operands have pointer to member type; pointer to member conversions (7.12) and qualification conversions (7.5) are performed to bring them to their composite pointer type (Clause 8). The result is of the composite pointer type.
5. Both the second and third operands have type std::nullptr_t or one has that type and the other is a null pointer constant. The result is of type std::nullptr_t.

8.17 Throwing an exception [expr.throw]

A throw-expression is of type void.

Evaluating a throw-expression with an operand throws an exception (18.1); the type of the exception object is determined by removing any top-level cv-qualifiers from the static type of the operand and adjusting the type from “array of T” or function type T to “pointer to T”.

A throw-expression with no operand rethrows the currently handled exception (18.3). The exception is reactivated with the existing exception object; no new exception object is created. The exception is no longer considered to be caught. [Example: Code that must be executed because of an exception, but cannot completely handle the exception itself, can be written like this:

```cpp
try {
    // ...
} catch (...) {
    // catch all exceptions
    // respond (partially) to exception
    throw; // pass the exception to some other handler
}
```

§ 8.17
Assignment and compound assignment operators

The assignment operator (=) and the compound assignment operators all group right-to-left. All require a modifiable lvalue as their left operand and return an lvalue referring to the left operand. The result in all cases is a bit-field if the left operand is a bit-field. In all cases, the assignment is sequenced after the value computation of the right and left operands, and before the value computation of the assignment expression. The right operand is sequenced before the left operand. With respect to an indeterminately-sequenced function call, the operation of a compound assignment is a single evaluation. [Note: Therefore, a function call shall not intervene between the lvalue-to-rvalue conversion and the side effect associated with any single compound assignment operator. —end note]

**assignment-expression:**

```
conditional-expression
logical-or-expression assignment-operator initializer-clause
throw-expression
```

**assignment-operator:** one of

```
= *= /= %= += -= >>= <<= &= ^= |=
```

In simple assignment (=), the value of the expression replaces that of the object referred to by the left operand.

If the left operand is not of class type, the expression is implicitly converted (Clause 7) to the cv-unqualified type of the left operand.

If the left operand is of class type, the class shall be complete. Assignment to objects of a class is defined by the copy/move assignment operator (15.8, 16.5.3).

[Note: For class objects, assignment is not in general the same as initialization (11.6, 15.1, 15.6, 15.8). —end note]

When the left operand of an assignment operator is a bit-field that cannot represent the value of the expression, the resulting value of the bit-field is implementation-defined.

The behavior of an expression of the form \( E_1 \ op \ E_2 \) is equivalent to \( E_1 = E_1 \ op \ E_2 \) except that \( E_1 \) is evaluated only once. In \( += \) and \( -= \), \( E_1 \) shall either have arithmetic type or be a pointer to a possibly cv-qualified completely-defined object type. In all other cases, \( E_1 \) shall have arithmetic type.

If the value being stored in an object is read via another object that overlaps in any way the storage of the first object, then the overlap shall be exact and the two objects shall have the same type, otherwise the behavior is undefined. [Note: This restriction applies to the relationship between the left and right sides of the assignment operation; it is not a statement about how the target of the assignment may be aliased in general. See 6.10. —end note]

A **braced-init-list** may appear on the right-hand side of

(9.1) — an assignment to a scalar, in which case the initializer list shall have at most a single element. The meaning of \( x = \{v\} \), where \( T \) is the scalar type of the expression \( x \), is that of \( x = T\{v\} \). The meaning of \( x = \{\} \) is \( x = T\{\} \).

(9.2) — an assignment to an object of class type, in which case the initializer list is passed as the argument to the assignment operator function selected by overload resolution (16.5.3, 16.3).

[Example:

```
complex<double> z;
z = { 1, 2 }; // meaning z.operator=({1,2})
z += { 1, 2 }; // meaning z.operator+=(1,2)
int a, b;
a = b = { 1 }; // meaning a=b=1;
a = { 1 } = b; // syntax error
```
]
8.19 Comma operator

The comma operator groups left-to-right.

expression:
  assignment-expression
expression , assignment-expression

A pair of expressions separated by a comma is evaluated left-to-right; the left expression is a discarded-value expression (Clause 8). Every value computation and side effect associated with the left expression is sequenced before every value computation and side effect associated with the right expression. The type and value of the result are the type and value of the right operand; the result is of the same value category as its right operand, and is a bit-field if its right operand is a bit-field. If the right operand is a temporary expression (15.2), the result is a temporary expression.

In contexts where comma is given a special meaning, [Example: in lists of arguments to functions (8.2.2) and lists of initializers (11.6) — end example] the comma operator as described in Clause 8 can appear only in parentheses. [Example:

\texttt{f(a, (t=3, t+2), c);}

has three arguments, the second of which has the value 5. — end example]

8.20 Constant expressions

Certain contexts require expressions that satisfy additional requirements as detailed in this subclause; other contexts have different semantics depending on whether or not an expression satisfies these requirements. Expressions that satisfy these requirements, assuming that copy elision is performed, are called constant expressions. [Note: Constant expressions can be evaluated during translation. — end note]

constant-expression:
  conditional-expression

An expression \texttt{e} is a core constant expression unless the evaluation of \texttt{e}, following the rules of the abstract machine (4.6), would evaluate one of the following expressions:

(2.1) — \texttt{this} (8.1.2), except in a constexpr function or a constexpr constructor that is being evaluated as part of \texttt{e};

(2.2) — an invocation of a function other than a constexpr constructor for a literal class, a constexpr function, or an implicit invocation of a trivial destructor (15.4) [Note: Overload resolution (16.3) is applied as usual — end note] ;

(2.3) — an invocation of an undefined constexpr function or an undefined constexpr constructor;

(2.4) — an invocation of an instantiated constexpr function or constexpr constructor that fails to satisfy the requirements for a constexpr function or constexpr constructor (10.1.5);

(2.5) — an expression that would exceed the implementation-defined limits (see Annex B);

(2.6) — an operation that would have undefined behavior as specified in Clauses 4 through 19 of this International Standard [Note: including, for example, signed integer overflow (Clause 8), certain pointer arithmetic (8.7), division by zero (8.6), or certain shift operations (8.8) — end note] ;

(2.7) — an lvalue-to-rvalue conversion (7.1) unless it is applied to

(2.7.1) — a non-volatile glvalue of integral or enumeration type that refers to a complete non-volatile const object with a preceding initialization, initialized with a constant expression, or

(2.7.2) — a non-volatile glvalue that refers to a subobject of a string literal (5.13.5), or
— a non-volatile glvalue that refers to a non-volatile object defined with constexpr, or that refers to a non-mutable subobject of such an object, or

— a non-volatile glvalue of literal type that refers to a non-volatile object whose lifetime began within the evaluation of e;

— an lvalue-to-rvalue conversion (7.1) that is applied to a glvalue that refers to a non-active member of a union or a subobject thereof;

— an invocation of an implicitly-defined copy/move constructor or copy/move assignment operator for a union whose active member (if any) is mutable, unless the lifetime of the union object began within the evaluation of e;

— an assignment expression (8.18) or invocation of an assignment operator (15.8) that would change the active member of a union;

— an id-expression that refers to a variable or data member of reference type unless the reference has a preceding initialization and either

— it is initialized with a constant expression or

— its lifetime began within the evaluation of e;

— in a lambda-expression, a reference to this or to a variable with automatic storage duration defined outside that lambda-expression, where the reference would be an odr-use (6.2, 8.1.5): [Example:

```c
void g() {
    const int n = 0;
    [=] {
        constexpr int i = n; // OK, n is not odr-used and not captured here
        constexpr int j = *&n; // ill-formed, &n would be an odr-use of n
    };
}
```

— end example] [Note: If the odr-use occurs in an invocation of a function call operator of a closure type, it no longer refers to this or to an enclosing automatic variable due to the transformation (8.1.5.2) of the id-expression into an access of the corresponding data member. [Example:

```c
auto monad = [] (auto v) { return [=] { return v; }; };  
auto bind = [] (auto m) {
    return [=] (auto fvm) { return fvm (m()); }; 
};
```

// OK to have captures to automatic objects created during constant expression evaluation.
static_assert(bind (monad (2)) (monad) () == monad (2)());

— end example] — end note]

— a conversion from type cv void* to a pointer-to-object type;

— a dynamic cast (8.2.7);

— a reinterpret_cast (8.2.10);

— a pseudo-destructor call (8.2.4);

— modification of an object (8.18, 8.2.6, 8.3.2) unless it is applied to a non-volatile lvalue of literal type that refers to a non-volatile object whose lifetime began within the evaluation of e;

— a typeid expression (8.2.8) whose operand is a glvalue of a polymorphic class type;

— a new-expression (8.3.4);

— a delete-expression (8.3.5);
(2.21) — a relational (8.9) or equality (8.10) operator where the result is unspecified; or
(2.22) — a throw-expression (8.17).

If e satisfies the constraints of a core constant expression, but evaluation of e would evaluate an operation that has undefined behavior as specified in Clauses 20 through 33 of this International Standard, it is unspecified whether e is a core constant expression.

[Example:

```cpp
int x; // not constant
struct A {
    constexpr A(bool b) : m(b?42:x) { }
    int m;
};
constexpr int v = A(true).m; // OK: constructor call initializes m with the value 42
constexpr int w = A(false).m; // error: initializer for m is x, which is non-constant
constexpr int f1(int k) {
    constexpr int x = k; // error: x is not initialized by a constant expression
    // because lifetime of k began outside the initializer of x
    return x;
}
constexpr int f2(int k) { // OK: not required to be a constant expression
    int x = k; // because x is not constexpr
    return x;
}
constexpr int incr(int &n) { // OK: incr(k) is not required to be a core constant expression
    return ++n;
}
constexpr int g(int k) { // error: incr(k) is not a core constant expression
    constexpr int x = incr(k); // because lifetime of k began outside the expression incr(k)
    return x;
}
constexpr int h(int k) { // OK: incr(k) is not required to be a core constant expression
    int x = incr(k);
    return x;
}
constexpr int y = h(1); // OK: initializes y with the value 2
// h(1) is a core constant expression because
// the lifetime of k begins inside h(1)
```

— end example]

3 An integral constant expression is an expression of integral or unscoped enumeration type, implicitly converted to a prvalue, where the converted expression is a core constant expression. [Note: Such expressions may be used as bit-field lengths (12.2.4), as enumerator initializers if the underlying type is not fixed (10.2), and as alignments (10.6.2). — end note]

4 A converted constant expression of type T is an expression, implicitly converted to type T, where the converted expression is a constant expression and the implicit conversion sequence contains only

(4.1) — user-defined conversions,
(4.2) — lvalue-to-rvalue conversions (7.1),

§ 8.20
(4.3) — array-to-pointer conversions (7.2),
(4.4) — function-to-pointer conversions (7.3),
(4.5) — qualification conversions (7.5),
(4.6) — integral promotions (7.6),
(4.7) — integral conversions (7.8) other than narrowing conversions (11.6.4),
(4.8) — null pointer conversions (7.11) from `std::nullptr_t`,
(4.9) — null member pointer conversions (7.12) from `std::nullptr_t`, and
(4.10) — function pointer conversions (7.13),
and where the reference binding (if any) binds directly. [Note: Such expressions may be used in new expressions (8.3.4), as case expressions (9.4.2), as enumerator initializers if the underlying type is fixed (10.2), as array bounds (11.3.4), and as non-type template arguments (17.3). — end note] A contextually converted constant expression of type `bool` is an expression, contextually converted to `bool` (Clause7), where the converted expression is a constant expression and the conversion sequence contains only the conversions above.

5 A constant expression is either a glvalue core constant expression that refers to an entity that is a permitted result of a constant expression (as defined below), or a prvalue core constant expression whose value satisfies the following constraints:

(5.1) — if the value is an object of class type, each non-static data member of reference type refers to an entity that is a permitted result of a constant expression,
(5.2) — if the value is of pointer type, it contains the address of an object with static storage duration, the address past the end of such an object (8.7), the address of a function, or a null pointer value, and
(5.3) — if the value is an object of class or array type, each subobject satisfies these constraints for the value.

An entity is a permitted result of a constant expression if it is an object with static storage duration that is either not a temporary object or is a temporary object whose value satisfies the above constraints, or it is a function.

6 [Note: Since this International Standard imposes no restrictions on the accuracy of floating-point operations, it is unspecified whether the evaluation of a floating-point expression during translation yields the same result as the evaluation of the same expression (or the same operations on the same values) during program execution.89] [Example:

```cpp
def f() {
    char array[1 + int(1 + 0.2 - 0.1 - 0.1)]; // Must be evaluated during translation
    int size = 1 + int(1 + 0.2 - 0.1 - 0.1); // May be evaluated at runtime
    return sizeof(array) == size;
}
```

It is unspecified whether the value of `f()` will be `true` or `false`. — end example] — end note]

7 If an expression of literal class type is used in a context where an integral constant expression is required, then that expression is contextually implicitly converted (Clause 7) to an integral or unscoped enumeration type and the selected conversion function shall be `constexpr`. [Example:

```cpp
struct A {
    constexpr A(int i) : val(i) { }
    constexpr operator int() const { return val; }
    constexpr operator long() const { return 43; }
private:
```

89) Nonetheless, implementations are encouraged to provide consistent results, irrespective of whether the evaluation was performed during translation and/or during program execution.
```cpp
int val;
};
template<int> struct X { }; constexpr A a = 42;
X<a> x;    // OK: unique conversion to int
int ary[a];  // error: ambiguous conversion
—end example]
```
9 Statements

1. Except as indicated, statements are executed in sequence.

   statement:
   labeled-statement
   attribute-specifier-seq opt expression-statement
   attribute-specifier-seq opt compound-statement
   attribute-specifier-seq opt selection-statement
   attribute-specifier-seq opt iteration-statement
   attribute-specifier-seq opt jump-statement
   declaration-statement
   attribute-specifier-seq opt try-block

   init-statement:
   expression-statement
   simple-declaration

   condition:
   expression
   attribute-specifier-seq opt decl-specifier-seq declarator brace-or-equal-initializer

   The optional attribute-specifier-seq appertains to the respective statement.

2. The rules for conditions apply both to selection-statements and to the for and while statements (9.5). The declarator shall not specify a function or an array. The decl-specifier-seq shall not define a class or enumeration. If the auto type-specifier appears in the decl-specifier-seq, the type of the identifier being declared is deduced from the initializer as described in 10.1.7.4.

3. A name introduced by a declaration in a condition (either introduced by the decl-specifier-seq or the declarator of the condition) is in scope from its point of declaration until the end of the sub-statements controlled by the condition. If the name is redeclared in the outermost block of a substatement controlled by the condition, the declaration that redeclares the name is ill-formed. [Example:

   if (int x = f()) {
       int x;       // ill-formed, redeclaration of x
   }
   else {
       int x;       // ill-formed, redeclaration of x
   }

   — end example]

4. The value of a condition that is an initialized declaration in a statement other than a switch statement is the value of the declared variable contextually converted to bool (Clause 7). If that conversion is ill-formed, the program is ill-formed. The value of a condition that is an initialized declaration in a switch statement is the value of the declared variable if it has integral or enumeration type, or of that variable implicitly converted to integral or enumeration type otherwise. The value of a condition that is an expression is the value of the expression, contextually converted to bool for statements other than switch; if that conversion is ill-formed, the program is ill-formed. The value of the condition will be referred to as simply “the condition” where the usage is unambiguous.

5. If a condition can be syntactically resolved as either an expression or the declaration of a block-scope name, it is interpreted as a declaration.

6. In the decl-specifier-seq of a condition, each decl-specifier shall be either a type-specifier or constexpr.
9.1 Labeled statement

A statement can be labeled.

\[
\text{labeled-statement:} \\
\qquad \text{attribute-specifier-seq opt identifier : statement} \\
\qquad \text{attribute-specifier-seq opt case constant-expression : statement} \\
\qquad \text{attribute-specifier-seq opt default : statement}
\]

The optional \text{attribute-specifier-seq} appertains to the label. An \text{identifier label} declares the identifier. The only use of an identifier label is as the target of a \text{goto}. The scope of a label is the function in which it appears. Labels shall not be redeclared within a function. A label can be used in a \text{goto} statement before its declaration. Labels have their own name space and do not interfere with other identifiers. \[Note: A label may have the same name as another declaration in the same scope or a \text{template-parameter} from an enclosing scope. Unqualified name lookup (6.4.1) ignores labels. \ — end note]\n
2 Case labels and default labels shall occur only in switch statements.

9.2 Expression statement

Expression statements have the form

\[
\text{expression-statement:} \\
\qquad \text{expression opt ;}
\]

The expression is a discarded-value expression (Clause 8). All side effects from an expression statement are completed before the next statement is executed. An expression statement with the expression missing is called a \text{null statement}. \[Note: Most statements are expression statements — usually assignments or function calls. A null statement is useful to carry a label just before the \} of a compound statement and to supply a null body to an iteration statement such as a \text{while} statement (9.5.1). \ — end note]\n
9.3 Compound statement or block

So that several statements can be used where one is expected, the compound statement (also, and equivalently, called “block”) is provided.

\[
\text{compound-statement:} \\
\quad \{ \text{statement-seq opt} \} \\
\text{statement-seq:} \\
\quad \text{statement} \\
\quad \text{statement-seq statement}
\]

A compound statement defines a block scope (6.3). \[Note: A declaration is a \text{statement} (9.7). \ — end note]\n
9.4 Selection statements

Selection statements choose one of several flows of control.

\[
\text{selection-statement:} \\
\quad \text{if constexpr opt ( init-statement opt condition ) statement} \\
\quad \text{if constexpr opt ( init-statement opt condition ) statement else statement} \\
\quad \text{switch ( init-statement opt condition ) statement}
\]

See 11.3 for the optional \text{attribute-specifier-seq} in a condition. \[Note: An \text{init-statement} ends with a semicolon. \ — end note]\n
In Clause 9, the term \text{substatement} refers to the contained \text{statement} or \text{statements} that appear in the syntax notation. The substatement in a \text{selection-statement} (each substatement, in the \text{else} form of the \text{if} statement) implicitly defines a block scope (6.3). If the substatement in a selection-statement is a single statement and not a \text{compound-statement}, it is as if it was rewritten to be a compound-statement containing the original substatement. \[Example:\]

\[
\text{if (x)} \\
\quad \text{int i;}
\]
can be equivalently rewritten as

```c
if (x) {
    int i;
}
```

Thus after the if statement, i is no longer in scope.  — end example]

9.4.1 The if statement [stmt.if]

1 If the condition (9.4) yields true the first substatement is executed. If the else part of the selection statement is present and the condition yields false, the second substatement is executed. If the first substatement is reached via a label, the condition is not evaluated and the second substatement is not executed. In the second form of if statement (the one including else), if the first substatement is also an if statement then that inner if statement shall contain an else part.\textsuperscript{90}

2 If the if statement is of the form if constexpr, the value of the condition shall be a contextually converted constant expression of type bool (8.20); this form is called a constexpr if statement. If the value of the converted condition is false, the first substatement is a discarded statement, otherwise the second substatement, if present, is a discarded statement. During the instantiation of an enclosing templated entity (Clause 17), if the condition is not value-dependent after its instantiation, the discarded substatement (if any) is not instantiated. [Note: Odr-uses (6.2) in a discarded statement do not require an entity to be defined. — end note] A case or default label appearing within such an if statement shall be associated with a switch statement (9.4.2) within the same if statement. A label (9.1) declared in a substatement of a constexpr if statement shall only be referred to by a statement (9.6.4) in the same substatement. [Example:

```c
template<type T, typename ... Rest> void g(T&& p, Rest&& ...rs) {
    // ... handle p
    if constexpr (sizeof...(rs) > 0)
        g(rs...);  // never instantiated with an empty argument list
}
```

```c
extern int x;  // no definition of x required
```

```c
int f() {
    if constexpr (true)
        return 0;
    else if (x)
        return x;
    else
        return -x;

    — end example]
```

3 An if statement of the form

```c
if constexpr_{opt} ( init-statement condition ) statement
```

is equivalent to

```c
{
    init-statement
    if constexpr_{opt} ( condition ) statement
}
```

and an if statement of the form

\textsuperscript{90} In other words, the else is associated with the nearest un-elsed if.

§ 9.4.1
if constexpr\(\text{opt} \ (\text{init-statement condition}) \ \text{statement else statement}\)

is equivalent to

\[
\{ \\
\quad \text{init-statement} \\
\quad \text{if constexpr\(\text{opt} \ (\text{condition}) \ \text{statement else statement}\) \\
\}
\]

ext except that names declared in the init-statement are in the same declarative region as those declared in the condition.

9.4.2 The switch statement

1 The switch statement causes control to be transferred to one of several statements depending on the value of a condition.

2 The condition shall be of integral type, enumeration type, or class type. If of class type, the condition is contextually implicitly converted (Clause 7) to an integral or enumeration type. If the (possibly converted) type is subject to integral promotions (7.6), the condition is converted to the promoted type. Any statement within the switch statement can be labeled with one or more case labels as follows:

\[
\text{case constant-expression :}
\]

where the constant-expression shall be a converted constant expression (8.20) of the adjusted type of the switch condition. No two of the case constants in the same switch shall have the same value after conversion.

3 There shall be at most one label of the form

\[
\text{default :}
\]

within a switch statement.

4 Switch statements can be nested; a case or default label is associated with the smallest switch enclosing it.

5 When the switch statement is executed, its condition is evaluated and compared with each case constant. If one of the case constants is equal to the value of the condition, control is passed to the statement following the matched case label. If no case constant matches the condition, and if there is a default label, control passes to the statement labeled by the default label. If no case matches and if there is no default then none of the statements in the switch is executed.

6 case and default labels in themselves do not alter the flow of control, which continues unimpeded across such labels. To exit from a switch, see break, 9.6.1. [ Note: Usually, the substatement that is the subject of a switch is compound and case and default labels appear on the top-level statements contained within the (compound) substatement, but this is not required. Declarations can appear in the substatement of a switch statement. — end note ]

7 A switch statement of the form

\[
\text{switch (init-statement condition ) statement}
\]

is equivalent to

\[
\{ \\
\quad \text{init-statement} \\
\quad \text{switch (condition) statement} \\
\}
\]

ext except that names declared in the init-statement are in the same declarative region as those declared in the condition.

9.5 Iteration statements

1 Iteration statements specify looping.

§ 9.5
iteration-statement:
while ( condition ) statement 
do statement while ( expression );
for ( init-statement conditionopt ; expressionopt ) statement
for ( for-range-declaration : for-range-initializer ) statement

for-range-declaration:
attribute-specifier-seqopt decl-specifier-seq declarator
attribute-specifier-seqopt decl-specifier-seq ref-qualifieropt [ identifier-list ]

for-range-initializer:
expr-or-braced-init-list

See 11.3 for the optional attribute-specifier-seq in a for-range-declaration. [Note: An init-statement ends with a semicolon. — end note]

2 The substatement in an iteration-statement implicitly defines a block scope (6.3) which is entered and exited each time through the loop.

If the substatement in an iteration-statement is a single statement and not a compound-statement, it is as if it was rewritten to be a compound-statement containing the original statement. [Example:

```c
while (--x >= 0)
    int i;
```

can be equivalently rewritten as

```c
while (--x >= 0) {
    int i;
}
```

Thus after the while statement, i is no longer in scope. — end example]

3 If a name introduced in an init-statement or for-range-declaration is redeclared in the outermost block of the substatement, the program is ill-formed. [Example:

```c
void f() {
    for (int i = 0; i < 10; ++i)
        int i = 0; // error: redeclaration
    for (int i : { 1, 2, 3 })
        int i = 1; // error: redeclaration
}
```

— end example]

9.5.1 The while statement [stmt.while]

1 In the while statement the substatement is executed repeatedly until the value of the condition (9.4) becomes false. The test takes place before each execution of the substatement.

2 When the condition of a while statement is a declaration, the scope of the variable that is declared extends from its point of declaration (6.3.2) to the end of the while statement. A while statement of the form

```c
while (T t = x) statement
```

is equivalent to

```c
label:
{ // start of condition scope
    T t = x;
    if (t) {
        statement
        goto label;
    }
}
```
The variable created in a condition is destroyed and created with each iteration of the loop.  [Example:

```c
struct A {
    int val;
    A(int i) : val(i) {} 
    ~A() {} 
    operator bool() { return val != 0; }
};
int i = 1;
while (A a = i) {
    // ...
    i = 0;
}
```

In the while-loop, the constructor and destructor are each called twice, once for the condition that succeeds and once for the condition that fails.  —end example]

### 9.5.2 The do statement

1 The expression is contextually converted to `bool` (Clause 7); if that conversion is ill-formed, the program is ill-formed.

2 In the `do` statement the substatement is executed repeatedly until the value of the expression becomes `false`. The test takes place after each execution of the statement.

### 9.5.3 The for statement

1 The `for` statement

```c
for (init-statement condition_opt ; expression_opt ) statement
```

is equivalent to

```c
{
    init-statement
    while ( condition ) {
        statement
        expression ;
    }
}
```

except that names declared in the `init-statement` are in the same declarative region as those declared in the condition, and except that a `continue` in statement (not enclosed in another iteration statement) will execute expression before re-evaluating condition.  [Note: Thus the first statement specifies initialization for the loop; the condition (9.4) specifies a test, sequenced before each iteration, such that the loop is exited when the condition becomes `false`; the expression often specifies incrementing that is sequenced after each iteration.  —end note]

2 Either or both of the condition and the expression can be omitted. A missing condition makes the implied while clause equivalent to `while(true)`.

3 If the `init-statement` is a declaration, the scope of the name(s) declared extends to the end of the for statement.  [Example:

```c
int i = 42;
int a[10];
for (int i = 0; i < 10; i++)
    a[i] = i;
```

§ 9.5.3
int j = i;         // j = 42
— end example]  

9.5.4 The range-based for statement [stmt.ranged]

The range-based for statement

```
for (for-range-declaration : for-range-initializer) statement
```

is equivalent to

```
{
  auto &&__range = for-range-initializer;
  auto __begin = begin-exp;
  auto __end = end-exp;
  for ( ; __begin != __end; ++__begin ) {
    for-range-declaration = *__begin;
    statement
  }
}
```

where

1. if the for-range-initializer is an expression, it is regarded as if it were surrounded by parentheses (so that a comma operator cannot be reinterpreted as delimiting two init-declarators);
2. __range, __begin, and __end are variables defined for exposition only; and
3. begin-exp and end-exp are determined as follows:
   1.3.1 if the for-range-initializer is an expression of array type R, begin-exp and end-exp are __range and __range + __bound, respectively, where __bound is the array bound. If R is an array of unknown bound or an array of incomplete type, the program is ill-formed;
   1.3.2 if the for-range-initializer is an expression of class type C, the unqualified-ids begin and end are looked up in the scope of C as if by class member access lookup (6.4.5), and if either (or both) finds at least one declaration, begin-exp and end-exp are __range.begin() and __range.end(), respectively;
   1.3.3 otherwise, begin-exp and end-exp are begin(__range) and end(__range), respectively, where begin and end are looked up in the associated namespaces (6.4.2). [Note: Ordinary unqualified lookup (6.4.1) is not performed. —end note]

[Example:

```
int array[5] = { 1, 2, 3, 4, 5 };
for (int& x : array)
x *= 2;
— end example]
```

2 In the decl-specifier-seq of a for-range-declaration, each decl-specifier shall be either a type-specifier or constexpr. The decl-specifier-seq shall not define a class or enumeration.

9.6 Jump statements [stmt.jump]

Jump statements unconditionally transfer control.

```
jump-statement:
  break;
  continue;
  return expr-or-braced-init-list_opt;
  goto identifier;
```

§ 9.6 150
On exit from a scope (however accomplished), objects with automatic storage duration (6.7.3) that have been constructed in that scope are destroyed in the reverse order of their construction. [Note: For temporaries, see 15.2. — end note] Transfer out of a loop, out of a block, or back past an initialized variable with automatic storage duration involves the destruction of objects with automatic storage duration that are in scope at the point transferred from but not at the point transferred to. (See 9.7 for transfers into blocks). [Note: However, the program can be terminated (by calling \texttt{std::exit()} or \texttt{std::abort()} (21.5), for example) without destroying class objects with automatic storage duration. — end note]

9.6.1 The break statement

The \texttt{break} statement shall occur only in an iteration-statement or a switch statement and causes termination of the smallest enclosing iteration-statement or switch statement; control passes to the statement following the terminated statement, if any.

9.6.2 The continue statement

The \texttt{continue} statement shall occur only in an iteration-statement and causes control to pass to the loop-continuation portion of the smallest enclosing iteration-statement, that is, to the end of the loop. More precisely, in each of the statements

```cpp
while (foo) {
    do {
    
    } // ...
    // ...
    contin: ;
}
```

a \texttt{continue} not contained in an enclosed iteration statement is equivalent to \texttt{goto contin}.

9.6.3 The return statement

A function returns to its caller by the \texttt{return} statement.

A \texttt{expr-or-braced-init-list} of a return statement is called its operand. A return statement with no operand shall be used only in a function whose return type is \texttt{cv void}, a constructor (15.1), or a destructor (15.4). A return statement with an operand of type \texttt{void} shall be used only in a function whose return type is \texttt{cv void}. A return statement with any other operand shall be used only in a function whose return type is not \texttt{cv void}; the return statement initializes the glvalue result or prvalue result object of the (explicit or implicit) function call by copy-initialization (11.6) from the operand. [Note: A return statement can involve an invocation of a constructor to perform a copy or move of the operand if it is not a prvalue or if its type differs from the return type of the function. A copy operation associated with a return statement may be elided or converted to a move operation if an automatic storage duration variable is returned (15.8). — end note] Example:

```cpp
std::pair<std::string,int> f(const char* p, int x) {
    return {p,x};
}
```

— end example] Flowing off the end of a constructor, a destructor, or a function with a \texttt{cv void} return type is equivalent to a \texttt{return} with no operand. Otherwise, flowing off the end of a function other than \texttt{main} (6.6.1) results in undefined behavior.

The copy-initialization of the result of the call is sequenced before the destruction of temporaries at the end of the full-expression established by the operand of the return statement, which, in turn, is sequenced before the destruction of local variables (9.6) of the block enclosing the return statement.

9.6.4 The goto statement

The \texttt{goto} statement unconditionally transfers control to the statement labeled by the identifier. The identifier shall be a label (9.1) located in the current function.
9.7 Declaration statement

1 A declaration statement introduces one or more new identifiers into a block; it has the form

\[\text{declaration-statement:} \]

\[\text{block-declaration}\]

If an identifier introduced by a declaration was previously declared in an outer block, the outer declaration is hidden for the remainder of the block, after which it resumes its force.

2 Variables with automatic storage duration (6.7.3) are initialized each time their declaration-statement is executed. Variables with automatic storage duration declared in the block are destroyed on exit from the block (9.6).

3 It is possible to transfer into a block, but not in a way that bypasses declarations with initialization. A program that jumps\(^{91}\) from a point where a variable with automatic storage duration is not in scope to a point where it is in scope is ill-formed unless the variable has scalar type, class type with a trivial default constructor and a trivial destructor, a cv-qualified version of one of these types, or an array of one of the preceding types and is declared without an initializer (11.6). [Example:

```c
void f() {
  // ...
  goto lx;  // ill-formed: jump into scope of a
  // ...
  ly:
  X a = 1;
  // ...
  lx:
  goto ly;  // OK, jump implies destructor call for a followed by
  // construction again immediately following label ly
}
```
—end example] \(^{91}\)

4 Dynamic initialization of a block-scope variable with static storage duration (6.7.1) or thread storage duration (6.7.2) is performed the first time control passes through its declaration; such a variable is considered initialized upon the completion of its initialization. If the initialization exits by throwing an exception, the initialization is not complete, so it will be tried again the next time control enters the declaration. If control enters the declaration concurrently while the variable is being initialized, the concurrent execution shall wait for completion of the initialization.\(^{92}\) If control re-enters the declaration recursively while the variable is being initialized, the behavior is undefined. [Example:

```c
int foo(int i) {
  static int s = foo(2*i);  // recursive call - undefined
  return i+1;
}
```
—end example]

5 The destructor for a block-scope object with static or thread storage duration will be executed if and only if it was constructed. [Note: 6.6.4 describes the order in which block-scope objects with static and thread storage duration are destroyed. — end note]

9.8 Ambiguity resolution

1 There is an ambiguity in the grammar involving expression-statements and declarations: An expression-statement with a function-style explicit type conversion (8.2.3) as its leftmost subexpression can be indis-

\(^{91}\) The transfer from the condition of a switch statement to a case label is considered a jump in this respect.

\(^{92}\) The implementation must not introduce any deadlock around execution of the initializer. Deadlocks might still be caused by the program logic; the implementation need only avoid deadlocks due to its own synchronization operations.
tistinguishable from a declaration where the first declarator starts with a \( ( \). In those cases the statement is a declaration.

2 [Note: If the statement cannot syntactically be a declaration, there is no ambiguity, so this rule does not apply. The whole statement might need to be examined to determine whether this is the case. This resolves the meaning of many examples. [Example: Assuming \( T \) is a simple-type-specifier (10.1.7),

\[
\begin{align*}
T(a)->m = 7; & \quad \text{// expression-statement} \\
T(a)++; & \quad \text{// expression-statement} \\
T(a,5)<<c; & \quad \text{// expression-statement} \\
T(*d)(int); & \quad \text{// declaration} \\
T(e)[5]; & \quad \text{// declaration} \\
T(f) = \{ 1, 2 \}; & \quad \text{// declaration} \\
T(*g)(\text{double}(3)); & \quad \text{// declaration}
\end{align*}
\]

In the last example above, \( g \), which is a pointer to \( T \), is initialized to \( \text{double}(3) \). This is of course ill-formed for semantic reasons, but that does not affect the syntactic analysis. —end example]

The remaining cases are declarations. [Example:

\[
\begin{align*}
\text{class } T & \{ \\
\text{// ...} \\
\text{public:} \\
\quad T(); \\
\quad T\text{(int)}; \\
\quad T\text{(int, int);} \\
\}; \\
T(a); & \quad \text{// declaration} \\
T\text{(*b)();} & \quad \text{// declaration} \\
T\text{(c)=7;} & \quad \text{// declaration} \\
T\text{(d),e,f=3;} & \quad \text{// declaration} \\
\text{extern int h;} \\
T\text{(*)(h,2);} & \quad \text{// declaration}
\end{align*}
\]

—end example] —end note]

3 The disambiguation is purely syntactic; that is, the meaning of the names occurring in such a statement, beyond whether they are type-names or not, is not generally used in or changed by the disambiguation. Class templates are instantiated as necessary to determine if a qualified name is a type-name. Disambiguation precedes parsing, and a statement disambiguated as a declaration may be an ill-formed declaration. If, during parsing, a name in a template parameter is bound differently than it would be bound during a trial parse, the program is ill-formed. No diagnostic is required. [Note: This can occur only when the name is declared earlier in the declaration. —end note] [Example:

\[
\begin{align*}
\text{struct } T1 & \{ \\
\quad \text{T1 }& \text{operator()(int x) \{ return T1(x); \}} \\
\quad \text{int }& \text{operator=(int x) \{ return x; \}} \\
\quad T1\text{(int) \{} \text{ } \} \\
\}; \\
\text{struct } T2 \{ \text{T2(int)\{} \text{ } \} \}; \\
\text{int a, }& \text{(*(*b)(T2))\{} \text{int}, \text{ } c, \text{ } d; \\
\text{void }& f() \{ \\
\quad \text{// disambiguation requires this to be parsed as a declaration:} \\
\quad T1\text{(a) }& = 3, \\
\quad T2\text{(d),} & \quad \text{// T2 will be declared as a variable of type T1, but this will not} \\
& \quad \text{(*(*b)(T2(c)))\{} \text{int}(d)\}; & \quad \text{// allow the last part of the declaration to parse properly,} \\
& \quad \text{// since it depends on T2 being a type-name}
\end{align*}
\]

§ 9.8 153
}  
— *end example*]
10 Declarations [dcl.dcl]

Declarations generally specify how names are to be interpreted. Declarations have the form

\[
\text{declaration-seq:} \\
\text{declaration} \\
\text{declaration-seq declaration}
\]

\[
\text{declaration:} \\
\text{block-declaration} \\
\text{nodeclspec-function-declaration} \\
\text{function-definition} \\
\text{template-declaration} \\
\text{deduction-guide} \\
\text{explicit-instantiation} \\
\text{explicit-specialization} \\
\text{linkage-specification} \\
\text{namespace-definition} \\
\text{empty-declaration} \\
\text{attribute-declaration}
\]

\[
\text{block-declaration:} \\
\text{simple-declaration} \\
\text{asm-definition} \\
\text{namespace-alias-definition} \\
\text{using-declaration} \\
\text{using-directive} \\
\text{static_assert-declaration} \\
\text{alias-declaration} \\
\text{opaque-enum-declaration}
\]

\[
\text{nodeclspec-function-declaration:} \\
\text{attribute-specifier-seq}_\text{opt} \text{ declarator ;}
\]

\[
\text{alias-declaration:} \\
\text{using} \text{ identifier attribute-specifier-seq}_\text{opt} = \text{defining-type-id} ;
\]

\[
\text{simple-declaration:} \\
\text{decl-specifier-seq init-declarator-list}_\text{opt} ; \\
\text{attribute-specifier-seq decl-specifier-seq init-declarator-list} ; \\
\text{attribute-specifier-seq decl-specifier-seq ref-qualifier}_\text{opt} \left[ \text{identifier-list} \right] \text{initializer} ;
\]

\[
\text{static_assert-declaration:} \\
\text{static_assert} \left( \text{constant-expression} \right) ; \\
\text{static_assert} \left( \text{constant-expression} , \text{string-literal} \right) ;
\]

\[
\text{empty-declaration:} \\
\text{attribute-declaration:} \\
\text{attribute-specifier-seq} ;
\]

[\text{Note: \textit{asm-definition}s are described in 10.4, and \textit{linkage-specification}s are described in 10.5. \textit{Function-definition}s are described in 11.4 and \textit{template-declaration}s and \textit{deduction-guide}s are described in Clause 17. \textit{Namespace-definition}s are described in 10.3.1, \textit{using-declaration}s are described in 10.3.3 and \textit{using-directive}s are described in 10.3.4. —end note}\]
A simple-declaration or nodeclspec-function-declaration of the form

\[ \text{attribute-specifier-seq}^\text{opt} \ \text{decl-specifier-seq}^\text{opt} \ \text{init-declarator-list}^\text{opt} ; \]

is divided into three parts. Attributes are described in 10.6. decl-specifiers, the principal components of a decl-specifier-seq, are described in 10.1. declarators, the components of an init-declarator-list, are described in Clause 11. The attribute-specifier-seq appertains to each of the entities declared by the declarators of the init-declarator-list. [Note: In the declaration for an entity, attributes appertaining to that entity may appear at the start of the declaration and after the declarator-id for that declaration. — end note] [Example:

[[noreturn]] void f [[noreturn]] () ; // OK

— end example]

Except where otherwise specified, the meaning of an attribute-declaration is implementation-defined.

A declaration occurs in a scope (6.3); the scope rules are summarized in 6.4. A declaration that declares a function or defines a class, namespace, template, or function also has one or more scopes nested within it. These nested scopes, in turn, can have declarations nested within them. Unless otherwise stated, utterances in Clause 10 about components in, of, or contained by a declaration or subcomponent thereof refer only to those components of the declaration that are not nested within scopes nested within the declaration.

In a simple-declaration, the optional init-declarator-list can be omitted only when declaring a class (Clause 12) or enumeration (10.2), that is, when the decl-specifier-seq contains either a class-specifier, an elaborated-type-specifier with a class-key (12.1), or an enum-specifier. In these cases and whenever a class-specifier or enum-specifier is present in the decl-specifier-seq, the identifiers in these specifiers are among the names being declared by the declaration (as class-names, enum-names, or enumerators, depending on the syntax). In such cases, the decl-specifier-seq shall introduce one or more names into the program, or shall redeclare a name introduced by a previous declaration. [Example:

enum { } ; // ill-formed
typedef class { } ; // ill-formed

— end example]

In a static_assert-declaration, the constant-expression shall be a contextually converted constant expression of type bool (8.20). If the value of the expression when so converted is true, the declaration has no effect. Otherwise, the program is ill-formed, and the resulting diagnostic message (4.1) shall include the text of the string-literal, if one is supplied, except that characters not in the basic source character set (5.3) are not required to appear in the diagnostic message. [Example:

static_assert(char(-1) < 0, "this library requires plain 'char' to be signed");

— end example]

An empty-declaration has no effect.

A simple-declaration with an identifier-list is called a structured binding declaration (11.5). The decl-specifier-seq shall contain only the type-specifier auto (10.1.7.4) and cv-qualifiers. The initializer shall be of the form “= assignment-expression”, of the form “{ assignment-expression }”, or of the form “( assignment-expression )”, where the assignment-expression is of array or non-union class type.

Each init-declarator in the init-declarator-list contains exactly one declarator-id, which is the name declared by that init-declarator and hence one of the names declared by the declaration. The defining-type-specifiers (10.1.7) in the decl-specifier-seq and the recursive declarator structure of the init-declarator describe a type (11.3), which is then associated with the name being declared by the init-declarator.

If the decl-specifier-seq contains the typedef specifier, the declaration is called a typedef declaration and the name of each init-declarator is declared to be a typedef-name, synonymous with its associated type (10.1.3). If the decl-specifier-seq contains no typedef specifier, the declaration is called a function declaration if the type associated with the name is a function type (11.3.5) and an object declaration otherwise.
11 Syntactic components beyond those found in the general form of declaration are added to a function declaration to make a *function-definition*. An object declaration, however, is also a definition unless it contains the `extern` specifier and has no initializer (6.1). A definition causes the appropriate amount of storage to be reserved and any appropriate initialization (11.6) to be done.

12 A `nodeclspec-function-declaration` shall declare a constructor, destructor, or conversion function.93 [Note: A `nodeclspec-function-declaration` can only be used in a `template-declaration` (Clause 17), `explicit-instantiation` (17.7.2), or `explicit-specialization` (17.7.3). — end note]

### 10.1 Specifiers [dcl.spec]

1 The specifiers that can be used in a declaration are

```plaintext
  decl-specifier:
    storage-class-specifier
    defining-type-specifier
    function-specifier
    friend
typedef
constexpr
inline

  decl-specifier-seq:
    decl-specifier attribute-specifier-seqopt
    decl-specifier decl-specifier-seq
```

The optional `attribute-specifier-seq` in a `decl-specifier-seq` appertains to the type determined by the preceding `decl-specifiers` (11.3). The `attribute-specifier-seq` affects the type only for the declaration it appears in, not other declarations involving the same type.

2 Each `decl-specifier` shall appear at most once in a complete `decl-specifier-seq`, except that `long` may appear twice.

3 If a `type-name` is encountered while parsing a `decl-specifier-seq`, it is interpreted as part of the `decl-specifier-seq` if and only if there is no previous `defining-type-specifier` other than a `cv-qualifier` in the `decl-specifier-seq`. The sequence shall be self-consistent as described below. [Example:

```plaintext
typedef char* Pc;
static Pc;  // error: name missing
```

Here, the declaration `static Pc` is ill-formed because no name was specified for the static variable of type `Pc`. To get a variable called `Pc`, a `type-specifier` (other than `const` or `volatile`) has to be present to indicate that the `typedef-name` `Pc` is the name being (re)declared, rather than being part of the `decl-specifier` sequence. For another example,

```plaintext
void f(const Pc);  // void f(char* const) (not const char*)
void g(const int Pc);  // void g(const int)
```

— end example]

4 [Note: Since `signed`, `unsigned`, `long`, and `short` by default imply `int`, a `type-name` appearing after one of those specifiers is treated as the name being (re)declared. [Example:

```plaintext
void h(unsigned Pc);  // void h(unsigned int)
void k(unsigned int Pc);  // void k(unsigned int)
```

— end example] — end note]

### 10.1.1 Storage class specifiers [dcl.stc]

1 The storage class specifiers are

93) The “implicit int” rule of C is no longer supported.

§ 10.1.1
storage-class-specifier:
  static
  thread_local
  extern
  mutable

At most one storage-class-specifier shall appear in a given decl-specifier-seq, except that thread_local may appear with static or extern. If thread_local appears in any declaration of a variable it shall be present in all declarations of that entity. If a storage-class-specifier appears in a decl-specifier-seq, there can be no typedef specifier in the same decl-specifier-seq and the init-declarator-list or member-declarator-list of the declaration shall not be empty (except for an anonymous union declared in a named namespace or in the global namespace, which shall be declared static (12.3.1)). The storage-class-specifier applies to the name declared by each init-declarator in the list and not to any names declared by other specifiers. A storage-class-specifier other than thread_local shall not be specified in an explicit specialization (17.7.3) or an explicit instantiation (17.7.2) directive.

2 [Note: A variable declared without a storage-class-specifier at block scope or declared as a function parameter has automatic storage duration by default (6.7.3). — end note]

3 The thread_local specifier indicates that the named entity has thread storage duration (6.7.2). It shall be applied only to the names of variables of namespace or block scope and to the names of static data members. When thread_local is applied to a variable of block scope the storage-class-specifier static is implied if no other storage-class-specifier appears in the decl-specifier-seq.

4 The static specifier can be applied only to names of variables and functions and to anonymous unions (12.3.1). There can be no static function declarations within a block, nor any static function parameters. A static specifier used in the declaration of a variable declares the variable to have static storage duration (6.7.1), unless accompanied by the thread_local specifier, which declares the variable to have thread storage duration (6.7.2). A static specifier can be used in declarations of class members; 12.2.3 describes its effect. For the linkage of a name declared with a static specifier, see 6.5.

5 The extern specifier can be applied only to the names of variables and functions. The extern specifier cannot be used in the declaration of class members or function parameters. For the linkage of a name declared with an extern specifier, see 6.5. [Note: The extern keyword can also be used in explicit-instantiations and linkage-specifications, but it is not a storage-class-specifier in such contexts. — end note]

6 The linkages implied by successive declarations for a given entity shall agree. That is, within a given scope, each declaration declaring the same variable name or the same overloading of a function name shall imply the same linkage. Each function in a given set of overloaded functions can have a different linkage, however.

[Example:
  static char* f();  //f() has internal linkage
  char* f()
  { /* ... */ }

  char* g();        //g() has external linkage
  static char* g()
  { /* ... */ }

  void h();
  inline void h(); // external linkage

  inline void l();
  void l();        // external linkage

  inline void m();
  extern void m(); // external linkage

§ 10.1.1]
static void n();
inline void n(); // internal linkage

static int a; // a has internal linkage
int a; // error: two definitions

static int b; // b has internal linkage
extern int b; // b still has internal linkage

int c; // c has external linkage
static int c; // error: inconsistent linkage

extern int d; // d has external linkage
static int d; // error: inconsistent linkage

— end example]

7 The name of a declared but undefined class can be used in an extern declaration. Such a declaration can only be used in ways that do not require a complete class type. [Example:

    struct S;
    extern S a;
    extern S f();
    extern void g(S);

    void h() {
        g(a); // error: S is incomplete
        f(); // error: S is incomplete
    }

— end example]

8 The mutable specifier shall appear only in the declaration of a non-static data member (12.2) whose type is neither const-qualified nor a reference type. [Example:

    class X {
        mutable const int* p; // OK
        mutable int* const q; // ill-formed
    };

— end example]

9 The mutable specifier on a class data member nullifies a const specifier applied to the containing class object and permits modification of the mutable class member even though the rest of the object is const (10.1.7.1).

10.1.2 Function specifiers [dcl.fct.spec]

1 Function-specifiers can be used only in function declarations.

    function-specifier:
                  virtual
                  explicit

2 The virtual specifier shall be used only in the initial declaration of a non-static class member function; see 13.3.

3 The explicit specifier shall be used only in the declaration of a constructor or conversion function within its class definition; see 15.3.1 and 15.3.2.
10.1.3 The typedef specifier

Declarations containing the `typedef` specifier declare identifiers that can be used later for naming fundamental (6.9.1) or compound (6.9.2) types. The `typedef` specifier shall not be combined in a `decl-specifier-seq` with any other kind of specifier except a `defining-type-specifier`, and it shall not be used in the `decl-specifier-seq` of a parameter-declaration (11.3.5) nor in the `decl-specifier-seq` of a function-definition (11.4). If a `typedef` specifier appears in a declaration without a `declarator`, the program is ill-formed.

```
typedef-name: identifier
```

A name declared with the `typedef` specifier becomes a `typedef-name`. Within the scope of its declaration, a `typedef-name` is syntactically equivalent to a keyword and names the type associated with the identifier in the way described in Clause 11. A `typedef-name` is thus a synonym for another type. A `typedef-name` does not introduce a new type the way a class declaration (12.1) or enum declaration does. [Example: After

```
typedef int MILES, *KLICKSP;
```

the constructions

```
MILES distance;
extern KLICKSP metricp;
```

are all correct declarations; the type of `distance` is `int` and that of `metricp` is “pointer to `int`”. — end example]

2 A `typedef-name` can also be introduced by an `alias-declaration`. The identifier following the `using` keyword becomes a `typedef-name` and the optional `attribute-specifier-seq` following the `identifier` appertains to that `typedef-name`. Such a `typedef-name` has the same semantics as if it were introduced by the `typedef` specifier. In particular, it does not define a new type. [Example:

```
using handler_t = void (*)(int);
extern handler_t ignore;
extern void (*ignore)(int); // redefine ignore
using cell = pair<void*, cell*>; // ill-formed
```

— end example] The `defining-type-specifier-seq` of the `defining-type-id` shall not define a class or enumeration if the alias-declaration is the declaration of a template-declaration.

3 In a given non-class scope, a `typedef` specifier can be used to redefine the name of any type declared in that scope to refer to the type to which it already refers. [Example:

```
typedef struct s { /* ... */ } s;
typedef int I;
typedef int I;
typedef I I;
```

— end example]

4 In a given class scope, a `typedef` specifier can be used to redefine any `class-name` declared in that scope that is not also a `typedef-name` to refer to the type to which it already refers. [Example:

```
struct S {
    typedef struct A { } A; // OK
    typedef struct B B; // OK
    typedef A A; // error
};
```

— end example]

5 If a `typedef` specifier is used to redefine in a given scope an entity that can be referenced using an `elaborated-type-specifier`, the entity can continue to be referenced by an `elaborated-type-specifier` or as an enumeration or class name in an enumeration or class definition respectively. [Example:
struct S;
typedef struct S S;
int main() {
    struct S* p;      // OK
}
struct S { };      // OK
—end example

6 In a given scope, a typedef specifier shall not be used to redefine the name of any type declared in that scope to refer to a different type. [Example:

```c
class complex { /* ... */ };  
typedef int complex;          // error: redefinition
—end example
```

7 Similarly, in a given scope, a class or enumeration shall not be declared with the same name as a typedef-name that is declared in that scope and refers to a type other than the class or enumeration itself. [Example:

```c
typedef int complex;  
class complex { /* ... */ };  // error: redefinition
—end example
```

8 [Note: A typedef-name that names a class type, or a cv-qualified version thereof, is also a class-name (12.1). If a typedef-name is used to identify the subject of an elaborated-type-specifier (10.1.7.3), a class definition (Clause 12), a constructor declaration (15.1), or a destructor declaration (15.4), the program is ill-formed. —end note] [Example:

```c
struct S {
    S();
    ~S();
};

typedef struct S T;
S a = T();      // OK
struct T * p;   // error
—end example
```

9 If the typedef declaration defines an unnamed class (or enum), the first typedef-name declared by the declaration to be that class type (or enum type) is used to denote the class type (or enum type) for linkage purposes only (6.5). [Example:

```c
typedef struct { } *ps, S;      // S is the class name for linkage purposes
—end example
```

10.1.4 The friend specifier [dcl.friend]

1 The friend specifier is used to specify access to class members; see 14.3.

10.1.5 The constexpr specifier [dcl.constexpr]

1 The constexpr specifier shall be applied only to the definition of a variable or variable template or the declaration of a function or function template. A function or static data member declared with the constexpr specifier is implicitly an inline function or variable (10.1.6). If any declaration of a function or function template has a constexpr specifier, then all its declarations shall contain the constexpr specifier. [Note: An explicit specialization can differ from the template declaration with respect to the constexpr specifier. —end note] [Note: Function parameters cannot be declared constexpr. —end note] [Example:
constexpr void square(int &x);  // OK: declaration
constexpr int bufsz = 1024;   // OK: definition
constexpr struct pixel {  // error: pixel is a type
  int x;
  int y;
  constexpr pixel(int);  // OK: declaration
};
constexpr pixel::pixel(int a)  // OK: definition
  : x(a), y(x)  
{ square(x); }
constexpr pixel small(2);  // error: square not defined, so small(2)
                          // not constant (8.20) so constexpr not satisfied

constexpr void square(int &x) {  // OK: definition
  x *= x;
}  
constexpr pixel large(4);  // OK: square defined
int next(constexpr int x) {  // error: not for parameters
  return x + 1;
}
extern constexpr int memsz;  // error: not a definition
— end example]

2 A constexpr specifier used in the declaration of a function that is not a constructor declares that function to be a constexpr function. Similarly, a constexpr specifier used in a constructor declaration declares that constructor to be a constexpr constructor.

3 The definition of a constexpr function shall satisfy the following requirements:
   (3.1) — it shall not be virtual (13.3);
   (3.2) — its return type shall be a literal type;
   (3.3) — each of its parameter types shall be a literal type;
   (3.4) — its function-body shall be = delete, = default, or a compound-statement that does not contain
           (3.4.1) — an asm-definition,
           (3.4.2) — a goto statement,
           (3.4.3) — an identifier label (9.1),
           (3.4.4) — a try-block, or
           (3.4.5) — a definition of a variable of non-literal type or of static or thread storage duration or for which no initialization is performed.

[ Example:
  constexpr int square(int x)
  { return x * x; }  // OK
  constexpr long long_max()  // OK
  { return 2147483647; }
  constexpr int abs(int x) {
    if (x < 0)
      x = -x;
    return x;  // OK
  }
  constexpr int first(int n) {
    static int value = n;  // error: variable has static storage duration
  }

§ 10.1.5
4

The definition of a constexpr constructor shall satisfy the following requirements:

(4.1) the class shall not have any virtual base classes;
(4.2) each of the parameter types shall be a literal type;
(4.3) its function-body shall not be a function-try-block.

In addition, either its function-body shall be = delete, or it shall satisfy the following requirements:

(4.4) either its function-body shall be = default, or the compound-statement of its function-body shall satisfy the requirements for a function-body of a constexpr function;
(4.5) every non-variant non-static data member and base class subobject shall be initialized (15.6.2);
(4.6) if the class is a union having variant members (12.3), exactly one of them shall be initialized;
(4.7) if the class is a union-like class, but is not a union, for each of its anonymous union members having variant members, exactly one of them shall be initialized;
(4.8) for a non-delegating constructor, every constructor selected to initialize non-static data members and base class subobjects shall be a constexpr constructor;
(4.9) for a delegating constructor, the target constructor shall be a constexpr constructor.

[Example:

```cpp
struct Length {
    constexpr explicit Length(int i = 0) : val(i) {} 
private:
    int val;
};
```
—end example]

5 For a constexpr function or constexpr constructor that is neither defaulted nor a template, if no argument values exist such that an invocation of the function or constructor could be an evaluated subexpression of a core constant expression (8.20), or, for a constructor, a constant initializer for some object (6.6.2), the program is ill-formed, no diagnostic required. [Example:

```cpp
constexpr int f(bool b) {
    return b ? throw 0 : 0; }
constexpr int f() { return f(true); }       // ill-formed, no diagnostic required
```

```cpp
struct B {
    constexpr B(int x) : i(0) {}           // x is unused
    int i;
};
```

§ 10.1.5
int global;

struct D : B {
    constexpr D() : B(global) { } // ill-formed, no diagnostic required
    // lvalue-to-rvalue conversion on non-constant global
};

—end example]

6 If the instantiated template specialization of a constexpr function template or member function of a class template would fail to satisfy the requirements for a constexpr function or constexpr constructor, that specialization is still a constexpr function or constexpr constructor, even though a call to such a function cannot appear in a constant expression. If no specialization of the template would satisfy the requirements for a constexpr function or constexpr constructor when considered as a non-template function or constructor, the template is ill-formed, no diagnostic required.

7 A call to a constexpr function produces the same result as a call to an equivalent non-constexpr function in all respects except that

(7.1) — a call to a constexpr function can appear in a constant expression (8.20) and
(7.2) — copy elision is mandatory in a constant expression (15.8).

8 The constexpr specifier has no effect on the type of a constexpr function or a constexpr constructor. [Example:
    constexpr int bar(int x, int y) // OK
    { return x + y + x*y; }
    // ...
    int bar(int x, int y) // error: redefinition of bar
    { return x * 2 + 3 * y; }

—end example]

9 A constexpr specifier used in an object declaration declares the object as const. Such an object shall have literal type and shall be initialized. In any constexpr variable declaration, the full-expression of the initialization shall be a constant expression (8.20). [Example:
    struct pixel {
      int x, y;
    }; constexpr pixel ur = { 1294, 1024 }; // OK
    constexpr pixel origin; // error: initializer missing

—end example]

10.1.6 The inline specifier [dcl.inline]

1 The inline specifier can be applied only to the declaration or definition of a variable or function.

2 A function declaration (11.3.5, 12.2.1, 14.3) with an inline specifier declares an inline function. The inline specifier indicates to the implementation that inline substitution of the function body at the point of call is to be preferred to the usual function call mechanism. An implementation is not required to perform this inline substitution at the point of call; however, even if this inline substitution is omitted, the other rules for inline functions specified in this section shall still be respected.

3 A variable declaration with an inline specifier declares an inline variable.

4 A function defined within a class definition is an inline function.
The **inline** specifier shall not appear on a block scope declaration.\(^{94}\) If the **inline** specifier is used in a friend function declaration, that declaration shall be a definition or the function shall have previously been declared inline.

An inline function or variable shall be defined in every translation unit in which it is odr-used and shall have exactly the same definition in every case (6.2). [Note: A call to the inline function or a use of the inline variable may be encountered before its definition appears in the translation unit. —end note] If the definition of a function or variable appears in a translation unit before its first declaration as inline, the program is ill-formed. If a function or variable with external linkage is declared inline in one translation unit, it shall be declared inline in all translation units in which it appears; no diagnostic is required. An inline function or variable with external linkage shall have the same address in all translation units. [Note: A static local variable in an inline function with external linkage always refers to the same object. A type defined within the body of an inline function with external linkage is the same type in every translation unit. —end note]

### 10.1.7 Type specifiers

The type-specifiers are

\[
\begin{align*}
\text{type-specifier:} & \quad \text{simple-type-specifier} \\
& \quad \text{elaborated-type-specifier} \\
& \quad \text{typename-specifier} \\
& \quad \text{cv-qualifier} \\
\text{type-specifier-seq:} & \quad \text{type-specifier attribute-specifier-seq\text{\text{\text{\text{seq}}\text{\text{\text{\text{opt}}}}}}} \\
& \quad \text{type-specifier type-specifier-seq} \\
\text{defining-type-specifier:} & \quad \text{type-specifier} \\
& \quad \text{class-specifier} \\
& \quad \text{enum-specifier} \\
\text{defining-type-specifier-seq:} & \quad \text{defining-type-specifier attribute-specifier-seq\text{\text{\text{\text{seq}}\text{\text{\text{\text{opt}}}}}}} \\
& \quad \text{defining-type-specifier defining-type-specifier-seq} \\
\text{The optional attribute-specifier-seq in a type-specifier-seq or a defining-type-specifier-seq appertains to the type denoted by the preceding type-specifiers or defining-type-specifiers (11.3). The attribute-specifier-seq affects the type only for the declaration it appears in, not other declarations involving the same type.}
\end{align*}
\]

As a general rule, at most one defining-type-specifier is allowed in the complete decl-specifier-seq of a declaration or in a defining-type-specifier-seq, and at most one type-specifier is allowed in a type-specifier-seq. The only exceptions to this rule are the following:

- (2.1) **const** can be combined with any type specifier except itself.
- (2.2) **volatile** can be combined with any type specifier except itself.
- (2.3) **signed** or **unsigned** can be combined with **char**, **long**, **short**, or **int**.
- (2.4) **short** or **long** can be combined with **int**.
- (2.5) **long** can be combined with **double**.
- (2.6) **long** can be combined with **long**.

\(^{94}\) The **inline** keyword has no effect on the linkage of a function.
Except in a declaration of a constructor, destructor, or conversion function, at least one defining-type-specifier that is not a cv-qualifier shall appear in a complete type-specifier-seq or a complete decl-specifier-seq.

[Note: enum-specifiers, class-specifiers, and typename-specifiers are discussed in 10.2, Clause 12, and 17.6, respectively. The remaining type-specifiers are discussed in the rest of this section. — end note]

10.1.7.1 The cv-qualifiers

There are two cv-qualifiers, const and volatile. Each cv-qualifier shall appear at most once in a cv-qualifier-seq. If a cv-qualifier appears in a decl-specifier-seq, the init-declarator-list or member-declarator-list of the declaration shall not be empty. [Note: 6.9.3 and 11.3.5 describe how cv-qualifiers affect object and function types. — end note] Redundant cv-qualifications are ignored. [Note: For example, these could be introduced by typedefs. — end note]

[Note: Declaring a variable const can affect its linkage (10.1.1) and its usability in constant expressions (8.20). As described in 11.6, the definition of an object or subobject of const-qualified type must specify an initializer or be subject to default-initialization. — end note]

A pointer or reference to a cv-qualified type need not actually point or refer to a cv-qualified object, but it is treated as if it does; a const-qualified access path cannot be used to modify an object even if the object referenced is a non-const object and can be modified through some other access path. [Note: Cv-qualifiers are supported by the type system so that they cannot be subverted without casting (8.2.11). — end note]

Except that any class member declared mutable (10.1.1) can be modified, any attempt to modify a const object during its lifetime (6.8) results in undefined behavior. [Example:

```c
const int ci = 3; // cv-qualified (initialized as required)
ci = 4; // ill-formed: attempt to modify const

int i = 2; // not cv-qualified
const int* cip; // pointer to const int
cip = &i; // OK: cv-qualified access path to unqualified
*cip = 4; // ill-formed: attempt to modify through ptr to const

int* ip;
ip = const_cast<int*>(cip); // cast needed to convert const int* to int*
*ip = 4; // defined: *ip points to i, a non-const object

const int* ciq = new const int (3); // initialized as required
int* iq = const_cast<int*>(ciq); // cast required
*iq = 4; // undefined: modifies a const object
```

For another example,

```c
struct X {
    mutable int i;
    int j;
};
struct Y {
    X x;
    Y y;
};

const Y y;
y.x.i++; // well-formed: mutable member can be modified
y.x.j++; // ill-formed: const-qualified member modified
```

There is no special provision for a decl-specifier-seq that lacks a type-specifier or that has a type-specifier that only specifies cv-qualifiers. The “implicit int” rule of C is no longer supported.
Y* p = const_cast<Y*>(y); // cast away const-ness of y
p->x.i = 99; // well-formed: mutable member can be modified
p->x.j = 99; // undefined: modifies a const member

— end example —

The semantics of an access through a volatile glvalue are implementation-defined. If an attempt is made to
access an object defined with a volatile-qualified type through the use of a non-volatile glvalue, the behavior
is undefined.

[ Note: volatile is a hint to the implementation to avoid aggressive optimization involving the object because
the value of the object might be changed by means undetectable by an implementation. Furthermore, for
some implementations, volatile might indicate that special hardware instructions are required to access the
object. See 4.6 for detailed semantics. In general, the semantics of volatile are intended to be the same in
C++ as they are in C. — end note ]

10.1.7.2 Simple type specifiers [dcl.type.simple]

The simple type specifiers are

\[ \text{simple-type-specifier:} \]
\[ \text{nested-name-specifier}_\text{opt} \text{ type-name} \]
\[ \text{nested-name-specifier template simple-template-id} \]
\[ \text{nested-name-specifier}_\text{opt} \text{ template-name} \]
char
char16_t
char32_t
wchar_t
bool
short
int
long
signed
unsigned
float
double
void
auto
decltype-specifier

type-name:
\[ \text{class-name} \]
\[ \text{enum-name} \]
\[ \text{typedef-name} \]
\[ \text{simple-template-id} \]

decltype-specifier:
decltype ( expression )
decltype ( auto )

The \text{simple-type-specifier auto} is a placeholder for a type to be deduced (10.1.7.4). A \text{type-specifier} of the form
\text{typename}_\text{opt} \text{ nested-name-specifier}_\text{opt} \text{ template-name} is a placeholder for a deduced class type (10.1.7.5). The
\text{template-name} shall name a class template that is not an injected-class-name. The other \text{simple-type-specifiers}
specify either a previously-declared type, a type determined from an expression, or one of the fundamental
types (6.9.1). Table 11 summarizes the valid combinations of \text{simple-type-specifiers} and the types they specify.

When multiple \text{simple-type-specifiers} are allowed, they can be freely intermixed with other \text{decl-specifiers} in
any order. [ Note: It is implementation-defined whether objects of char type are represented as signed or
unsigned quantities. The \text{signed} specifier forces char objects to be signed; it is redundant in other contexts.
Table 11 — simple-type-specifiers and the types they specify

</tbody>
</table>

— end note —

4 For an expression e, the type denoted by `decltype(e)` is defined as follows:

(4.1) — if e is an unparenthesized `id-expression` naming a structured binding (11.5), `decltype(e)` is the referenced type as given in the specification of the structured binding declaration;
— otherwise, if \( e \) is an unparenthesized id-expression or an unparenthesized class member access (8.2.5), `decltype(e)` is the type of the entity named by \( e \). If there is no such entity, or if \( e \) names a set of overloaded functions, the program is ill-formed;

— otherwise, if \( e \) is an xvalue, `decltype(e)` is `T&&`, where `T` is the type of \( e \);

— otherwise, if \( e \) is an lvalue, `decltype(e)` is `T&`, where `T` is the type of \( e \);

— otherwise, `decltype(e)` is the type of \( e \).

The operand of the `decltype` specifier is an unevaluated operand (Clause 8).

[Example:]

```cpp
class A {
    double x;
};

int i;

A* a = new A();

decltype(A) x1 = 17;  // type is const int&
decltype(i) x2;        // type is int
decltype(a->x) x3;    // type is double
decltype((a->x)) x4 = x3; // type is const double
```

— end example] [Note: The rules for determining types involving `decltype(auto)` are specified in 10.1.7.4. — end note]

If the operand of a `decltype-specifier` is a prvalue, the temporary materialization conversion is not applied (7.4) and no result object is provided for the prvalue. The type of the prvalue may be incomplete. [Note: As a result, storage is not allocated for the prvalue and it is not destroyed. Thus, a class type is not instantiated as a result of being the type of a function call in this context. In this context, the common purpose of writing the expression is merely to refer to its type. In that sense, a `decltype-specifier` is analogous to a use of a `typedef-name`, so the usual reasons for requiring a complete type do not apply. In particular, it is not necessary to allocate storage for a temporary object or to enforce the semantic constraints associated with invoking the type’s destructor. — end note] [Note: Unlike the preceding rule, parentheses have no special meaning in this context. — end note]

[Example:]

```cpp
template<class T> struct A { ~A() = delete; };

template<class T> auto h()
    -> A<T>;

template<class T> auto i(T)
    -> T;

template<class T> auto f(T)
    -> decltype(i(h<T>()));  // forces completion of A<T> and implicitly uses A<T>::~A()
    // for the temporary introduced by the use of h().
    // (A temporary is not introduced as a result of the use of i().)

template<class T> auto f(T)
    -> void;

template<class T> auto q(T)
    -> decltype((h<T>()));  // does not force completion of A<T>::~A() is not implicitly used within the context of this decltype-specifier

template<class T> auto f(T)
    -> void {
        // OK; calls #2. (#1 is not a viable candidate: type deduction
        // fails 17.8.2) because A<int>::~A() is implicitly used in its
        // decltype-specifier
    }

template<class T> auto q(T)
    -> decltype((h<T>()));  // Error: deduction against q succeeds, so overload resolution selects
    // the specialization “q(T) -> decltype((h<T>()) [with T=] int)”.
    // The return type is A<int>, so a temporary is introduced and its
```
10.1.7.3 Elaborated type specifiers

elaborated-type-specifier:
   elaborated-type-specifier
   class-key attribute-specifier-seqopt nested-name-specifieropt identifier
   class-key simple-template-id
   class-key nested-name-specifier templateopt simple-template-id
   enum nested-name-specifieropt identifier

1 An attribute-specifier-seq shall not appear in an elaborated-type-specifier unless the latter is the sole constituent of a declaration. If an elaborated-type-specifier is the sole constituent of a declaration, the declaration is ill-formed unless it is an explicit specialization (17.7.3), an explicit instantiation (17.7.2) or it has one of the following forms:

   class-key attribute-specifier-seqopt identifier
   friend class-key ::opt identifier
   friend class-key ::opt simple-template-id
   friend class-key nested-name-specifier identifier
   friend class-key nested-name-specifier templateopt simple-template-id

In the first case, the attribute-specifier-seq, if any, appertains to the class being declared; the attributes in the attribute-specifier-seq are thereafter considered attributes of the class whenever it is named.

2 6.4.4 describes how name lookup proceeds for the identifier in an elaborated-type-specifier. If the identifier resolves to a class-name or enum-name, the elaborated-type-specifier introduces it into the declaration the same way a simple-type-specifier introduces its type-name. If the identifier resolves to a typedef-name or the simple-template-id resolves to an alias template specialization, the elaborated-type-specifier is ill-formed.

[Note: This implies that, within a class template with a template type-parameter T, the declaration

   friend class T;

is ill-formed. However, the similar declaration friend T; is allowed (14.3). — end note]

3 The class-key or enum keyword present in the elaborated-type-specifier shall agree in kind with the declaration to which the name in the elaborated-type-specifier refers. This rule also applies to the form of elaborated-type-specifier that declares a class-name or friend class since it can be construed as referring to the definition of the class. Thus, in any elaborated-type-specifier, the enum keyword shall be used to refer to an enumeration (10.2), the union class-key shall be used to refer to a union (Clause 12), and either the class or struct class-key shall be used to refer to a class (Clause 12) declared using the class or struct class-key. [Example:

   enum class E { a, b };
   enum E x = E::a;  // OK

— end example]

10.1.7.4 The auto specifier

The auto and decltype(auto) type-specifiers are used to designate a placeholder type that will be replaced later by deduction from an initializer. The auto type-specifier is also used to introduce a function type having a trailing-return-type or to signify that a lambda is a generic lambda (8.1.5.1). The auto type-specifier is also used to introduce a structured binding declaration (11.5).

The placeholder type can appear with a function declarator in the decl-specifier-seq, type-specifier-seq, conversion-function-id, or trailing-return-type, in any context where such a declarator is valid. If the function declarator includes a trailing-return-type (11.3.5), that trailing-return-type specifies the declared return type of the function. Otherwise, the function declarator shall declare a function. If the declared return type of the

§ 10.1.7.4
function contains a placeholder type, the return type of the function is deduced from non-discarded return statements, if any, in the body of the function (9.4.1).

3 If the auto type-specifier appears as one of the decl-specifiers in the decl-specifier-seq of a parameter-declaration of a lambda-expression, the lambda is a generic lambda (8.1.5.1). [Example:

```c
auto glambda = [](int i, auto a) { return i; };  // OK: a generic lambda
```
—end example]

The type of a variable declared using auto or decltype(auto) is deduced from its initializer. This use is allowed in an initializing declaration (11.6) of a variable. auto or decltype(auto) shall appear as one of the decl-specifiers in the decl-specifier-seq and the decl-specifier-seq shall be followed by one or more declarators, each of which shall be followed by a non-empty initializer. In an initializer of the form

```
(expression-list)
```

the expression-list shall be a single assignment-expression. [Example:

```c
auto x = 5;  // OK: x has type int
const auto *v = &x, u = 6;  // OK: v has type const int*, u has type int
static auto y = 0.0;  // OK: y has type double
auto int r;  // error: auto is not a storage-class-specifier
auto f() -> int;  // OK: f returns int
auto g() { return 0.0; }  // OK: g returns double
auto h();  // OK: h’s return type will be deduced when it is defined
```
—end example]

5 A placeholder type can also be used in the type-specifier-seq in the new-type-id or type-id of a new-expression (8.3.4) and as a decl-specifier of the parameter-declaration’s decl-specifier-seq in a template-parameter (17.1).

6 A program that uses auto or decltype(auto) in a context not explicitly allowed in this section is ill-formed.

7 If the init-declarator-list contains more than one init-declarator, they shall all form declarations of variables. The type of each declared variable is determined by placeholder type deduction (10.1.7.4.1), and if the type that replaces the placeholder type is not the same in each deduction, the program is ill-formed.

[Example:

```c
auto x = 5, *y = &x;  // OK: auto is int
auto a = 5, b = { 1, 2 };  // error: different types for auto
```
—end example]

8 If a function with a declared return type that contains a placeholder type has multiple non-discarded return statements, the return type is deduced for each such return statement. If the type deduced is not the same in each deduction, the program is ill-formed.

9 If a function with a declared return type that uses a placeholder type has no non-discarded return statements, the return type is deduced as though from a return statement with no operand at the closing brace of the function body. [Example:

```c
auto f() {}  // OK, return type is void
auto* g() {}  // error, cannot deduce auto* from void()
```
—end example]

10 If the type of an entity with an undeduced placeholder type is needed to determine the type of an expression, the program is ill-formed. Once a non-discarded return statement has been seen in a function, however, the return type deduced from that statement can be used in the rest of the function, including in other return statements. [Example:
auto n = n;  // error, n's type is unknown
auto f();
void g() { &f; }  // error, f's return type is unknown
auto sum(int i) {
  if (i == 1)
    return i;  // sum's return type is int
  else
    return sum(i-1)+i;  // OK, sum's return type has been deduced
}

—end example

11 Return type deduction for a function template with a placeholder in its declared type occurs when the
definition is instantiated even if the function body contains a return statement with a non-type-dependent
operand. [Note: Therefore, any use of a specialization of the function template will cause an implicit
instantiation. Any errors that arise from this instantiation are not in the immediate context of the function
type and can result in the program being ill-formed (17.8.2). —end note] [Example:

\begin{verbatim}
template <class T> auto f(T t) { return t; }  // return type deduced at instantiation time
typedef decltype(f(1)) fint_t;  // instantiates f<int> to deduce return type
template<class T> auto f(T* t) { return *t; }  // instantiates both fs to determine return types,
  // chooses second
\end{verbatim}

—end example

12 Redeclarations or specializations of a function or function template with a declared return type that uses a
placeholder type shall also use that placeholder, not a deduced type. [Example:

\begin{verbatim}
auto f();
auto f() { return 42; }  // return type is int
auto f();  // OK
int f();  // error, cannot be overloaded with auto f()
decltype(auto) f();  // error, auto and decltype(auto) don't match

template <typename T> auto g(T t) { return t; }  // #1

template auto g(int);  // OK, return type is int
template char g(char);  // error, no matching template
template<> auto g(double);  // OK, forward declaration with unknown return type

template <class T> T g(T t) { return t; }  // OK, not functionally equivalent to #1
template char g(char);  // OK, now there is a matching template
template auto g(float);  // still matches #1

void h() { return g(42); }  // error, ambiguous
\end{verbatim}

—end example

13 A function declared with a return type that uses a placeholder type shall not be virtual (13.3).

14 An explicit instantiation declaration (17.7.2) does not cause the instantiation of an entity declared using a
placeholder type, but it also does not prevent that entity from being instantiated as needed to determine its
type. [Example:

\begin{verbatim}
template <typename T> auto f(T t) { return t; }
\end{verbatim}

§ 10.1.7.4
10.1.7.4.1 Placeholder type deduction

Placeholder type deduction is the process by which a type containing a placeholder type is replaced by a deduced type.

A type T containing a placeholder type, and a corresponding initializer e, are determined as follows:

1. For a non-discarded return statement that occurs in a function declared with a return type that contains a placeholder type, T is the declared return type and e is the operand of the return statement. If the return statement has no operand, then e is void();

2. For a variable declared with a type that contains a placeholder type, T is the declared type of the variable and e is the initializer. If the initialization is direct-list-initialization, the initializer shall be a braced-init-list containing only a single assignment-expression and e is the assignment-expression;

3. For a non-type template parameter declared with a type that contains a placeholder type, T is the declared type of the non-type template parameter and e is the corresponding template argument.

In the case of a return statement with no operand or with an operand of type void, T shall be either decltype(auto) or cv auto.

If the deduction is for a return statement and e is a braced-init-list (11.6.4), the program is ill-formed.

If the placeholder is the auto type-specifier, the deduced type T' replacing T is determined using the rules for template argument deduction. Obtain P from T by replacing the occurrences of auto with either a new invented type template parameter U or, if the initialization is copy-list-initialization, with std::initializer_list<U>. Deduce a value for U using the rules of template argument deduction from a function call (17.8.2.1), where P is a function template parameter type and the corresponding argument is e. If the deduction fails, the declaration is ill-formed. Otherwise, T' is obtained by substituting the deduced U into P. [Example:

```cpp
class X { public: int x; };  // X template
auto x1 = {1, 2};  // decltype(x1) is std::initializer_list<int>
auto x2 = {1, 2.0};  // error: cannot deduce element type
auto x3 = {1, 2};  // error: not a single element
auto x4 = {3};  // decltype(x4) is std::initializer_list<int>
auto x5 = 3;  // decltype(x5) is int
```

— end example]

The type of i is the deduced type of the parameter u in the call f(expr) of the following invented function template:

```cpp
template <class U> void f(const U& u);
```

— end example]

If the placeholder is the decltype(auto) type-specifier, T shall be the placeholder alone. The type deduced for T is determined as described in 10.1.7.2, as though e had been the operand of the decltype. [Example:

```cpp
int i;
int& f();
auto x2a(i);  // decltype(x2a) is int
decltype(auto) x2d(i);  // decltype(x2d) is int
auto x3a = i;  // decltype(x3a) is int
decltype(auto) x3d = i;  // decltype(x3d) is int
```
auto x4a = (i); // decltype(x4a) is int
dcltype(auto) x4d = (i); // decltype(x4d) is int&
auto x5a = f(); // decltype(x5a) is int
dcltype(auto) x5d = f(); // decltype(x5d) is int&&
auto x6a = {1, 2}; // decltype(x6a) is std::initializer_list<int>
dcltype(auto) x6d = {1, 2}; // error, {1, 2} is not an expression
auto *x7a = &i; // decltype(x7a) is int*
dcltype(auto)*x7d = &i; // error, declared type is not plain decltype(auto)

— end example

10.1.7.5 Deduced class template specialization types

If a placeholder for a deduced class type appears as a decl-specifier in the decl-specifier-seq of an initializing declaration (11.6) of a variable, the placeholder is replaced by the return type of the function selected by overload resolution for class template deduction (16.3.1.8). If the decl-specifier-seq is followed by an init-declarator-list or member-declarator-list containing more than one declarator, the type that replaces the placeholder shall be the same in each deduction.

A placeholder for a deduced class type can also be used in the type-specifier-seq in the new-type-id or type-id of a new-expression (8.3.4), or as the simple-type-specifier in an explicit type conversion (functional notation) (8.2.3). A placeholder for a deduced class type shall not appear in any other context.

[Example:

```cpp
template<class T> struct container {
    container(T t) {};
    template<class Iter> container(Iter beg, Iter end);
};
template<class Iter>
container(Iter b, Iter e) -> container<typename std::iterator_traits<Iter>::value_type>;
std::vector<double> v = { /* ... */ };

container c(7); // OK, deduces int for T
auto d = container(v.begin(), v.end()); // OK, deduces double for T
container e{5, 6}; // error, int is not an iterator
```

— end example]

10.2 Enumeration declarations

An enumeration is a distinct type (6.9.2) with named constants. Its name becomes an enum-name within its scope.

```cpp
enum-name: identifier
enum-specifier:
    enum-head { enumerator-list_opt }  
    enum-head { enumerator-list , }
enum-head:
    enum-key attribute-specifier-seq_opt enum-head-name_opt enum-base_opt
enum-head-name:
    nested-name-specifier_opt identifier
opaque-enum-declaration:
    enum-key attribute-specifier-seq_opt nested-name-specifier_opt identifier enum-base_opt ;
```
enum-key:
  enum
  enum class
  enum struct

enum-base:
  : type-specifier-seq

enumerator-list:
  enumerator-definition
  enumerator-list , enumerator-definition

enumerator-definition:
  enumerator
  enumerator = constant-expression

enumerator:
  identifier attribute-specifier-seq opt

The optional attribute-specifier-seq in the enum-head and the opaque-enum-declaration appertains to the enumeration; the attributes in that attribute-specifier-seq are thereafter considered attributes of the enumeration whenever it is named. A : following “enum nested-name-specifier_opt identifier” within the decl-specifier-seq of a member-declaration is parsed as part of an enum-base. [Note: This resolves a potential ambiguity between the declaration of an enumeration with an enum-base and the declaration of an unnamed bit-field of enumeration type. [Example:

```c
struct S {
  enum E : int {};
  enum E : int {}; // error: redeclaration of enumeration
};
```

— end example] — end note] If an opaque-enum-declaration contains a nested-name-specifier, the declaration shall be an explicit specialization (17.7.3).

2 The enumeration type declared with an enum-key of only enum is an unscoped enumeration, and its enumerators are unscoped enumerators. The enum-keys enum class and enum struct are semantically equivalent; an enumeration type declared with one of these is a scoped enumeration, and its enumerators are scoped enumerators. The optional identifier shall not be omitted in the declaration of a scoped enumeration. The type-specifier-seq of an enum-base shall name an integral type; any cv-qualification is ignored. An opaque-enum-declaration declaring an unscoped enumeration shall not omit the enum-base. The identifiers in an enumerator-list are declared as constants, and can appear wherever constants are required. An enumerator-definition with = gives the associated enumerator the value indicated by the constant-expression. If the first enumerator has no initializer, the value of the corresponding constant is zero. An enumerator-definition without an initializer gives the enumerator the value obtained by increasing the value of the previous enumerator by one. [Example:

```c
enum { a, b, c=0 {};
enum { d, e, f=e+2 {};
```

defines a, c, and d to be zero, b and e to be 1, and f to be 3. — end example] The optional attribute-specifier-seq in an enumerator appertains to that enumerator.

3 An opaque-enum-declaration is either a redeclaration of an enumeration in the current scope or a declaration of a new enumeration. [Note: An enumeration declared by an opaque-enum-declaration has fixed underlying type and is a complete type. The list of enumerators can be provided in a later redeclaration with an enum-specifier. — end note] A scoped enumeration shall not be later redeclared as unscoped or with a different underlying type. An unscoped enumeration shall not be later redeclared as scoped and each redeclaration shall include an enum-base specifying the same underlying type as in the original declaration.

§ 10.2 175
If the `enum-key` is followed by a `nested-name-specifier`, the `enum-specifier` shall refer to an enumeration that was previously declared directly in the class or namespace to which the `nested-name-specifier` refers (i.e., neither inherited nor introduced by a `using-declaration`), and the `enum-specifier` shall appear in a namespace enclosing the previous declaration.

Each enumeration defines a type that is different from all other types. Each enumeration also has an underlying type. The underlying type can be explicitly specified using an `enum-base`. For a scoped enumeration type, the underlying type is `int` if it is not explicitly specified. In both of these cases, the underlying type is said to be fixed. Following the closing brace of an `enum-specifier`, each enumerator has the type of its enumeration. If the underlying type is fixed, the type of each enumerator prior to the closing brace is the underlying type and the `constant-expression` in the `enumerator-definition` shall be a converted constant expression of the underlying type (8.20). If the underlying type is not fixed, the type of each enumerator prior to the closing brace is determined as follows:

1. If an initializer is specified for an enumerator, the `constant-expression` shall be an integral constant expression (8.20). If the expression has unscoped enumeration type, the enumerator has the underlying type of that enumeration type, otherwise it has the same type as the expression.

2. If no initializer is specified for the first enumerator, its type is an unspecified signed integral type.

3. Otherwise the type of the enumerator is the same as that of the preceding enumerator unless the incremented value is not representable in that type, in which case the type is an unspecified integral type sufficient to contain the incremented value. If no such type exists, the program is ill-formed.

An enumeration whose underlying type is fixed is an incomplete type from its point of declaration (6.3.2) to immediately after its `enum-base` (if any), at which point it becomes a complete type. An enumeration whose underlying type is not fixed is an incomplete type from its point of declaration to immediately after the closing `}` of its `enum-specifier`, at which point it becomes a complete type.

For an enumeration whose underlying type is not fixed, the underlying type is an integral type that can represent all the enumerator values defined in the enumeration. If no integral type can represent all the enumerator values, the enumeration is ill-formed. It is implementation-defined which integral type is used as the underlying type except that the underlying type shall not be larger than `int` unless the value of an enumerator cannot fit in an `int` or unsigned `int`. If the `enumerator-list` is empty, the underlying type is as if the enumeration had a single enumerator with value 0.

For an enumeration whose underlying type is fixed, the values of the enumeration are the values of the underlying type. Otherwise, for an enumeration where `e_min` is the smallest enumerator and `e_max` is the largest, the values of the enumeration are the values in the range `b_min` to `b_max`, defined as follows: Let `K` be 1 for a two’s complement representation and 0 for a ones’ complement or sign-magnitude representation. `b_max` is the smallest value greater than or equal to `max(|e_min|−K,|e_max|)` and equal to `2^M−1`, where `M` is a non-negative integer. `b_min` is zero if `e_min` is non-negative and `−(b_max+K)` otherwise. The size of the smallest bit-field large enough to hold all the values of the enumeration type is `max(M,1)` if `b_min` is zero and `M+1` otherwise. It is possible to define an enumeration that has values not defined by any of its enumerators. If the `enumerator-list` is empty, the values of the enumeration are as if the enumeration had a single enumerator with value 0.

Two enumeration types are layout-compatible enumerations if they have the same underlying type.

The value of an enumerator or an object of an unscoped enumeration type is converted to an integer by integral promotion (7.6). [Example:

```c
enum color { red, yellow, green=20, blue }

color col = red;
color* cp = &col;
```

96] This set of values is used to define promotion and conversion semantics for the enumeration type. It does not preclude an expression of enumeration type from having a value that falls outside this range.

§ 10.2
makes color a type describing various colors, and then declares col as an object of that type, and cp as a pointer to an object of that type. The possible values of an object of type color are red, yellow, green, blue; these values can be converted to the integral values 0, 1, 20, and 21. Since enumerations are distinct types, objects of type color can be assigned only values of type color.

```cpp
if (*cp == blue)    // ...
```

Note that this implicit enum to int conversion is not provided for a scoped enumeration:

```cpp
color c = 1;   // error: type mismatch, no conversion from int to color
int i = yellow;   // OK: yellow converted to integral value 1, integral promotion
```

Each enum-name and each unscoped enumerator is declared in the scope that immediately contains the enum-specifier. Each scoped enumerator is declared in the scope of the enumeration. These names obey the scope rules defined for all names in 6.3 and 6.4. [Example:

```cpp
enum direction { left='l', right='r' };

void g() {
    direction d;    // OK
    d = left;        // OK
    d = direction::right;    // OK
}
```

```cpp
enum class altitude { high='h', low='l' };

void h() {
    altitude a;    // OK
    a = high;      // error: high not in scope
    a = altitude::low;    // OK
}
```

— end example] 11 An enumerator declared in class scope can be referred to using the class member access operators (::, . (dot) and -> (arrow)), see 8.2.5. [Example:

```cpp
struct X {
    enum direction { left='l', right='r' };
    int f(int i) { return i==left ? 0 : i==right ? 1 : 2; }
};

void g(X* p) {
    direction d;    // error: direction not in scope
    int i;
    i = p->f(left);    // error: left not in scope
    i = p->f(X::right);    // OK
    i = p->f(p->left);    // OK
    // ...
}
```

— end example]

12 If an enum-head contains a nested-name-specifier, the enum-specifier shall refer to an enumeration that was previously declared directly in the class or namespace to which the nested-name-specifier refers, or in an
element of the inline namespace set (10.3.1) of that namespace (i.e., not merely inherited or introduced by a
using-declaration), and the enum-specifier shall appear in a namespace enclosing the previous declaration. In
such cases, the nested-name-specifier of the enum-head of the definition shall not begin with a decltype-specifier.

10.3 Namespaces

A namespace is an optionally-named declarative region. The name of a namespace can be used to access
entities declared in that namespace; that is, the members of the namespace. Unlike other declarative regions,
the definition of a namespace can be split over several parts of one or more translation units.

The outermost declarative region of a translation unit is a namespace; see 6.3.6.

10.3.1 Namespace definition

Every namespace-definition shall appear in the global scope or in a namespace scope (6.3.6).

In a named-namespace-definition, the identifier is the name of the namespace. If the identifier, when
looked up (6.4.1), refers to a namespace-name (but not a namespace-alias) that was introduced in the
namespace in which the named-namespace-definition appears or that was introduced in a member of the
inline namespace set of that namespace, the namespace-definition extends the previously-declared namespace.
Otherwise, the identifier is introduced as a namespace-name into the declarative region in which the
named-namespace-definition appears.

Because a namespace-definition contains declarations in its namespace-body and a namespace-definition is
itself a declaration, it follows that namespace definitions can be nested. [Example:

```cpp
namespace Outer {
    int i;
    namespace Inner {
        void f() { i++; } // Outer::i
        int i;
        void g() { i++; } // Inner::i
    }
}
```
— end example]

The enclosing namespaces of a declaration are those namespaces in which the declaration lexically appears,
except for a redeclaration of a namespace member outside its original namespace (e.g., a definition as specified in 10.3.1.2). Such a redeclaration has the same enclosing namespaces as the original declaration.

[Example:

```cpp
namespace Q {
    namespace V {
        void f(); // enclosing namespaces are the global namespace, Q, and Q::V
        class C { void m(); };
    }
    void V::f() {
        // enclosing namespaces are the global namespace, Q, and Q::V
        extern void h(); // ... so this declares Q::V::h
    }
    void V::C::m() { // enclosing namespaces are the global namespace, Q, and Q::V
    }
}
```

— end example]

5 If the optional initial `inline` keyword appears in a `namespace-definition` for a particular namespace, that namespace is declared to be an `inline namespace`. The `inline` keyword may be used on a `namespace-definition` that extends a namespace only if it was previously used on the `namespace-definition` that initially declared the namespace-name for that namespace.

6 The optional `attribute-specifier-seq` in a `named-namespace-definition` appertains to the namespace being defined or extended.

7 Members of an inline namespace can be used in most respects as though they were members of the enclosing namespace. Specifically, the inline namespace and its enclosing namespace are both added to the set of associated namespaces used in argument-dependent lookup (6.4.2) whenever one of them is, and a `using-directive` (10.3.4) that names the inline namespace is implicitly inserted into the enclosing namespace as for an unnamed namespace (10.3.1.1). Furthermore, each member of the inline namespace can subsequently be partially specialized (17.5.5), explicitly instantiated (17.7.2), or explicitly specialized (17.7.3) as though it were a member of the enclosing namespace. Finally, looking up a name in the enclosing namespace via explicit qualification (6.4.3.2) will include members of the inline namespace brought in by the `using-directive` even if there are declarations of that name in the enclosing namespace.

8 These properties are transitive: if a namespace `N` contains an inline namespace `M`, which in turn contains an inline namespace `O`, then the members of `O` can be used as though they were members of `M` or `N`. The `inline namespace set` of `N` is the transitive closure of all inline namespaces in `N`. The `enclosing namespace set` of `O` is the set of namespaces consisting of the innermost non-inline namespace enclosing an inline namespace `O`, together with any intervening inline namespaces.

9 A `nested-namespace-definition` with an `enclosing-namespace-specifier E`, `identifier I` and `namespace-body B` is equivalent to

```cpp
namespace E { namespace I { B } }
```

[Example:

```cpp
namespace A::B::C {
    int i;
}
```

The above has the same effect as:

```cpp
namespace A {
    namespace B {
        namespace C {
            int i;
        }
    }
```
10.3.1.1 Unnamed namespaces

An **unnamed-namespace-definition** behaves as if it were replaced by

```c
inlineopt namespace unique { /* empty body */ } using namespace unique;
namespace unique { namespace-body }
```

where **inline** appears if and only if it appears in the **unnamed-namespace-definition** and all occurrences of **unique** in a translation unit are replaced by the same identifier, and this identifier differs from all other identifiers in the translation unit. The optional **attribute-specifier-seq** in the **unnamed-namespace-definition** appertains to **unique**. **[Example:]**

```c
namespace { int i; } // unique::i
void f() { i++; } // unique::i++

namespace A {
  namespace {
    int i; // A::unique::i
    int j; // A::unique::j
  }
  void g() { i++; } // A::unique::i++
}

using namespace A;
void h() {
  i++; // error: unique::i or A::unique::i
  A::i++; // A::unique::i
  j++; // A::unique::j
}
```

— end example —

10.3.1.2 Namespace member definitions

A declaration in a namespace **N** (excluding declarations in nested scopes) whose **declarator-id** is an **unqualified-id** (**11.3**), whose **class-head-name** (Clause 12) or **enum-head-name** (**10.2**) is an **identifier**, or whose **elaborated-type-specifier** is of the form **class-key attribute-specifier-seqopt identifier** (**10.1.7.3**), or that is an **opaque-enum-declaration**, declares (or redeclares) its **unqualified-id** or **identifier** as a member of **N**. **[Note:** An explicit instantiation (**17.7.2**) or explicit specialization (**17.7.3**) of a template does not introduce a name and thus may be declared using an **unqualified-id** in a member of the enclosing namespace set, if the primary template is declared in an inline namespace. — end note] **[Example:]**

```c
namespace X {
  void f() { /* ... */ } // OK: introduces X::f()
}

namespace M {
  void g(); // OK: introduces X::M::g()
}
using M::g;
void g(); // error: conflicts with X::M::g()
```

— end example —

§ 10.3.1.2
Members of a named namespace can also be defined outside that namespace by explicit qualification (6.4.3.2) of the name being defined, provided that the entity being defined was already declared in the namespace and the definition appears after the point of declaration in a namespace that encloses the declaration’s namespace.

Example:

```cpp
namespace Q {
    namespace V {
        void f();
    }
    void V::f() { /* ... */ } // OK
    void V::g() { /* ... */ } // error: g() is not yet a member of V
    namespace V {
        void g();
    }
}

namespace R {
    void Q::V::g() { /* ... */ } // error: R doesn't enclose Q
}
```

—end example

If a friend declaration in a non-local class first declares a class, function, class template or function template\(^{97}\) the friend is a member of the innermost enclosing namespace. The friend declaration does not by itself make the name visible to unqualified lookup (6.4.1) or qualified lookup (6.4.3). [Note: The name of the friend will be visible in its namespace if a matching declaration is provided at namespace scope (either before or after the class definition granting friendship). —end note] If a friend function or function template is called, its name may be found by the name lookup that considers functions from namespaces and classes associated with the types of the function arguments (6.4.2). If the name in a friend declaration is neither qualified nor a template-id and the declaration is a function or an elaborated-type-specifier, the lookup to determine whether the entity has been previously declared shall not consider any scopes outside the innermost enclosing namespace. [Note: The other forms of friend declarations cannot declare a new member of the innermost enclosing namespace and thus follow the usual lookup rules. —end note] Example:

```cpp
// Assume f and g have not yet been declared.
void h(int);
template <class T> void f2(T);
namespace A {
    class X {
        friend void f(X); // A::f(X) is a friend
    }
    class Y {
        friend void g(); // A::g is a friend
        friend void h(int); // A::h is a friend
        // ::h not considered
        friend void f2<int>(); // ::f2<int>() is a friend
    };
}
```

\(^{97}\) this implies that the name of the class or function is unqualified.

§ 10.3.1.2
using A::x;

void h() {
    A::f(x);
    A::X::f(x); // error: f is not a member of A::X
    A::X::Y::g(); // error: g is not a member of A::X::Y
}

—end example]

10.3.2 Namespace alias [namespace.alias]

A namespace-alias-definition declares an alternate name for a namespace according to the following grammar:

\[
\text{namespace-alias-definition:} \\
\text{namespace alias = qualified-namespace-specifier;}
\]

The identifier in a namespace-alias-definition is a synonym for the name of the namespace denoted by the qualified-namespace-specifier and becomes a namespace-alias. [Note: When looking up a namespace-name in a namespace-alias-definition, only namespace names are considered, see 6.4.6. — end note]

In a declarative region, a namespace-alias-definition can be used to redefine a namespace-alias declared in that declarative region to refer only to the namespace to which it already refers. [Example: The following declarations are well-formed:

\[
\text{namespace Company_with_very_long_name \{ /* ... */ \}} \\
\text{namespace CWVLN = Company_with_very_long_name;} \\
\text{namespace CWVLN = Company_with_very_long_name; // OK: duplicate} \\
\text{namespace CWVLN = CWVLN;}
\]

— end example]

10.3.3 The using declaration [namespace.udecl]

\[
\text{using-declaration:} \\
\text{using using-declarator-list ;}
\]

\[
\text{using-declarator-list:} \\
\text{using-declarator \ldots opt} \\
\text{using-declarator-list , using-declarator \ldots opt}
\]

\[
\text{using-declarator:} \\
\text{typename opt nested-name-specifier unqualified-id}
\]

Each using-declarator in a using-declaration introduces a set of declarations into the declarative region in which the using-declaration appears. The set of declarations introduced by the using-declarator is found by performing qualified name lookup (6.4.3, 13.2) for the name in the using-declarator, excluding functions that are hidden as described below. If the using-declarator does not name a constructor, the unqualified-id is declared in the declarative region in which the using-declaration appears as a synonym for each declaration introduced by the using-declarator. [Note: Only the specified name is so declared; specifying an enumeration name in a using-declaration does not declare its enumerators in the using-declaration’s declarative region.

---

98) A using-declaration with more than one using-declarator is equivalent to a corresponding sequence of using-declarations with one using-declarator each.
If the using-declarator names a constructor, it declares that the class inherits the set of constructor declarations introduced by the using-declarator from the nominated base class.

2 Every using-declaration is a declaration and a member-declaration and can therefore be used in a class definition. [Example:

```c
struct B {
    void f(char);
    void g(char);
    enum E { e };
    union { int x; };
};

struct D : B {
    using B::f;
    void f(int) { f('c'); } // calls B::f(char)
    void g(int) { g('c'); } // recursively calls D::g(int)
};
```

—end example]

3 In a using-declaration used as a member-declaration, each using-declarator’s nested-name-specifier shall name a base class of the class being defined. If a using-declarator names a constructor, its nested-name-specifier shall name a direct base class of the class being defined. [Example:

```c
template <typename... bases>
struct X : bases... {
    using bases::g...;
};
X<B, D> x; // OK: B::g and D::g introduced
```

—end example] [Example:

```c
class C {
    int g();
};

class D2 : public B {
    using B::f;          // OK: B is a base of D2
    using B::e;          // OK: e is an enumerator of base B
    using B::x;          // OK: x is a union member of base B
    using C::g;          // error: C isn’t a base of D2
};
```

—end example]

4 [Note: Since destructors do not have names, a using-declaration cannot refer to a destructor for a base class. Since specializations of member templates for conversion functions are not found by name lookup, they are not considered when a using-declaration specifies a conversion function (17.5.2). — end note] If a constructor or assignment operator brought from a base class into a derived class has the signature of a copy/move constructor or assignment operator for the derived class (15.8), the using-declaration does not by itself suppress the implicit declaration of the derived class member; the member from the base class is hidden or overridden by the implicitly-declared copy/move constructor or assignment operator of the derived class, as described below.

5 A using-declaration shall not name a template-id. [Example:

```c
struct A {
    template <class T> void f(T);
};
```
template <class T> struct X { }
};
struct B : A {
    using A::f<double>;         // ill-formed
    using A::X<int>;            // ill-formed
};
—end example]
6 A using-declaration shall not name a namespace.
7 A using-declaration shall not name a scoped enumerator.
8 A using-declaration that names a class member shall be a member-declaration. [Example:
    struct X {
        int i;
        static int s;
    };
    void f() {
        using X::i;               // error: X::i is a class member and this is not a member declaration.
        using X::s;               // error: X::s is a class member and this is not a member declaration.
    }
—end example]
9 Members declared by a using-declaration can be referred to by explicit qualification just like other member names (6.4.3.2). [Example:
    void f();
    namespace A {
        void g();
    }
    namespace X {
        using ::f;         // global f
        using A::g;        // A’s g
    }
    void h() {
        X::f();           // calls ::f
        X::g();           // calls A::g
    }
—end example]
10 A using-declaration is a declaration and can therefore be used repeatedly where (and only where) multiple declarations are allowed. [Example:
    namespace A {
        int i;
    }
    namespace A1 {
        using A::i, A::i;       // OK: double declaration
    }
    struct B {

§ 10.3.3
int i;
};

struct X : B {
    using B::i, B::i;       // error: double member declaration
};

/* end example */

11 [Note: For a using-declaration whose nested-name-specifier names a namespace, members added to the namespace after the using-declaration are not in the set of introduced declarations, so they are not considered when a use of the name is made. Thus, additional overloads added after the using-declaration are ignored, but default function arguments (11.3.6), default template arguments (17.1), and template specializations (17.5.5, 17.7.3) are considered. —end note] [Example:

namespace A {
    void f(int);
}

using A::f;       // f is a synonym for A::f; that is, for A::f(int).
namespace A {
    void f(char);
}

void foo() {
    f('a');      // calls f(int), even though f(char) exists.
}

void bar() {
    using A::f;       // f is a synonym for A::f; that is, for A::f(int) and A::f(char).
    f('a');       // calls f(char)
}

/* end example */

12 [Note: Partial specializations of class templates are found by looking up the primary class template and then considering all partial specializations of that template. If a using-declaration names a class template, partial specializations introduced after the using-declaration are effectively visible because the primary template is visible (17.5.5). —end note]

13 Since a using-declaration is a declaration, the restrictions on declarations of the same name in the same declarative region (6.3) also apply to using-declarations. [Example:

namespace A {
    int x;
}

namespace B {
    int i;
    struct g { };  // OK: hides struct g
    struct x { }
    void f(int);
    void f(double);
    void g(char);
}

void func() {
    int i;

§ 10.3.3
If a function declaration in namespace scope or block scope has the same name and the same parameter-type-list (11.3.5) as a function introduced by a `using-declaration`, and the declarations do not declare the same function, the program is ill-formed. If a function template declaration in namespace scope has the same name, parameter-type-list, return type, and template parameter list as a function template introduced by a `using-declaration`, the program is ill-formed. [Note: Two `using-declarations` may introduce functions with the same name and the same parameter-type-list. If, for a call to an unqualified function name, function overload resolution selects the functions introduced by such `using-declarations`, the function call is ill-formed.  

**Example:**

```cpp
namespace B {
    void f(int);
    void f(double);
}

namespace C {
    void f(int);
    void f(double);
    void f(char);
}

void h() {
    using B::f; // B::f(int) and B::f(double)
    using C::f; // C::f(int), C::f(double), and C::f(char)
    f('h'); // calls C::f(char)
    f(1); // error: ambiguous: B::f(int) or C::f(int)?
    void f(int); // error: f(int) conflicts with C::f(int) and B::f(int)
}
```

— end example] — end note]

When a `using-declarator` brings declarations from a base class into a derived class, member functions and member function templates in the derived class override and/or hide member functions and member function templates with the same name, parameter-type-list (11.3.5), cv-qualification, and ref-qualifier (if any) in a base class (rather than conflicting). Such hidden or overridden declarations are excluded from the set of declarations introduced by the `using-declarator`. [Example:

```cpp
struct B {
    virtual void f(int);
    virtual void f(char);
    void g(int);
    void h(int);
};
```
struct D : B {
    using B::f;
    void f(int); // OK: D::f(int) overrides B::f(int);

    using B::g;
    void g(char); // OK

    using B::h;
    void h(int); // OK: D::h(int) hides B::h(int)
};

void k(D* p)
{
    p->f(1); // calls D::f(int)
    p->f('a'); // calls B::f(char)
    p->g(1); // calls B::g(int)
    p->g('a'); // calls D::g(char)
}

struct B1 {
    B1(int);
};

struct B2 {
    B2(int);
};

struct D1 : B1, B2 {
    using B1::B1;
    using B2::B2;
};

D1 d1(0); // ill-formed: ambiguous

struct D2 : B1, B2 {
    using B1::B1;
    using B2::B2;
    D2(int); // OK: D2::D2(int) hides B1::B1(int) and B2::B2(int)
};

D2 d2(0); // calls D2::D2(int)

— end example

For the purpose of overload resolution, the functions that are introduced by a using-declaration into a derived class are treated as though they were members of the derived class. In particular, the implicit this parameter shall be treated as if it were a pointer to the derived class rather than to the base class. This has no effect on the type of the function, and in all other respects the function remains a member of the base class. Likewise, constructors that are introduced by a using-declaration are treated as though they were constructors of the derived class when looking up the constructors of the derived class (6.4.3.1) or forming a set of overload candidates (16.3.1.3, 16.3.1.4, 16.3.1.7). If such a constructor is selected to perform the initialization of an object of class type, all subobjects other than the base class from which the constructor originated are implicitly initialized (15.6.3).

In a using-declarator that does not name a constructor, all members of the set of introduced declarations shall be accessible. In a using-declarator that names a constructor, no access check is performed. In particular, if a derived class uses a using-declarator to access a member of a base class, the member name shall be accessible. If the name is that of an overloaded member function, then all functions named shall be accessible. The base

§ 10.3.3
class members mentioned by a using-declarator shall be visible in the scope of at least one of the direct base classes of the class where the using-declarator is specified.

[Note: Because a using-declarator designates a base class member (and not a member subobject or a member function of a base class subobject), a using-declarator cannot be used to resolve inherited member ambiguities.]

Example:

```cpp
struct A { int x(); };  
struct B : A { };  
struct C : A {  
  using A::x;  
  int x(int);  
};  

struct D : B, C {  
  using C::x;  
  int x(double);  
};  
int f(D* d) {  
  return d->x();  // error: overload resolution selects A::x, but A is an ambiguous base class
}
```

—end example — end note]

A synonym created by a using-declaration has the usual accessibility for a member-declaration. A using-declarator that names a constructor does not create a synonym; instead, the additional constructors are accessible if they would be accessible when used to construct an object of the corresponding base class, and the accessibility of the using-declaration is ignored. [Example:

```cpp
class A {  
  private:  
    void f(char);  
  public:  
    void f(int);  
  protected:  
    void g();  
};  

class B : public A {  
  using A::f;  // error: A::f(char) is inaccessible  
  public:  
    using A::g;  // B::g is a public synonym for A::g
};  
```

—end example]

If a using-declarator uses the keyword typename and specifies a dependent name (17.6.2), the name introduced by the using-declaration is treated as a typedef-name (10.1.3).

10.3.4 Using directive [namespace.udir]

```cpp
using-directive:  
  attribute-specifier-seq_opt using namespace nested-name-specifier_opt namespace-name;
```

1 A using-directive shall not appear in class scope, but may appear in namespace scope or in block scope. [Note: When looking up a namespace-name in a using-directive, only namespace names are considered, see 6.4.6. — end note] The optional attribute-specifier-seq appertains to the using-directive.

2 A using-directive specifies that the names in the nominated namespace can be used in the scope in which the using-directive appears after the using-directive. During unqualified name lookup (6.4.1), the names appear
as if they were declared in the nearest enclosing namespace which contains both the using-directive and the nominated namespace. [Note: In this context, “contains” means “contains directly or indirectly”. — end note]

3 A using-directive does not add any members to the declarative region in which it appears. [Example:

```cpp
namespace A {
    int i;
}
namespace B {
    namespace C {
        int i;
    }
    using namespace A::B::C;
    void f1() {
        i = 5;     // OK, C::i visible in B and hides A::i
    }
}
namespace D {
    using namespace B;
    using namespace C;
    void f2() {
        i = 5;     // ambiguous, B::C::i or A::i?
    }
    void f3() {
        i = 5;     // uses A::i
    }
    void f4() {
        i = 5;     // ill-formed; neither i is visible
    }
}

— end example]

4 For unqualified lookup (6.4.1), the using-directive is transitive: if a scope contains a using-directive that nominates a second namespace that itself contains using-directives, the effect is as if the using-directives from the second namespace also appeared in the first. [Note: For qualified lookup, see 6.4.3.2. — end note]

[Example:

```cpp
namespace M {
    int i;
}
namespace N {
    int i;
    using namespace M;
}

void f() {
    using namespace N;
    i = 7;     // error: both M::i and N::i are visible

For another example,
```

```cpp
namespace A {
    int i;
}
```
namespace B {
  int i;
  int j;
  namespace C {
    namespace D {
      using namespace A;
      int j;
      int k;
      int a = i; // B::i hides A::i
    }
    using namespace D;
    int k = 89; // no problem yet
    int l = k; // ambiguous: C::k or D::k
    int m = i; // B::i hides A::i
    int n = j; // D::j hides B::j
  }
}

— end example]

5 If a namespace is extended (10.3.1) after a using-directive for that namespace is given, the additional members of the extended namespace and the members of namespaces nominated by using-directives in the extending namespace-definition can be used after the extending namespace-definition.

6 If name lookup finds a declaration for a name in two different namespaces, and the declarations do not declare the same entity and do not declare functions, the use of the name is ill-formed. [Note: In particular, the name of a variable, function or enumerator does not hide the name of a class or enumeration declared in a different namespace. For example,

namespace A {
  class X { };
  extern "C"  int g();
  extern "C++" int h();
}
namespace B {
  void X(int);
  extern "C"  int g();
  extern "C++" int h(int);
}
using namespace A;
using namespace B;

void f() {
  X(1); // error: name X found in two namespaces
  g(); // OK: name g refers to the same entity
  h(); // OK: overload resolution selects A::h
}

— end note]

7 During overload resolution, all functions from the transitive search are considered for argument matching. The set of declarations found by the transitive search is unordered. [Note: In particular, the order in which namespaces were considered and the relationships among the namespaces implied by the using-directives do not cause preference to be given to any of the declarations found by the search. — end note] An ambiguity exists if the best match finds two functions with the same signature, even if one is in a namespace reachable
through using-directives in the namespace of the other.\footnote{During name lookup in a class hierarchy, some ambiguities may be resolved by considering whether one member hides the other along some paths (13.2). There is no such disambiguation when considering the set of names found as a result of following using-directives.}

[Example:

```cpp
namespace D {
    int d1;
    void f(char);
}
using namespace D;

int d1;       // OK: no conflict with D::d1

namespace E {
    int e;
    void f(int);
}

namespace D { // namespace extension
    int d2;
    using namespace E;
    void f(int);
}

void f() {
    d1++;        // error: ambiguous ::d1 or D::d1?
    ::d1++;      // OK
    D::d1++;     // OK
    d2++;        // OK: D::d2
    e++;         // OK: E::e
    f(1);        // error: ambiguous: D::f(int) or E::f(int)?
    f('a');     // OK: D::f(char)
}
```
]

— end example]

10.4 The `asm` declaration

An `asm` declaration has the form

```cpp
asm-definition:
    attribute-specifier-seq_opt asm ( string-literal ) ;
```

The `asm` declaration is conditionally-supported; its meaning is implementation-defined. The optional `attribute-specifier-seq` in an `asm-definition` appertains to the `asm` declaration. [Note: Typically it is used to pass information through the implementation to an assembler. — end note]

10.5 Linkage specifications

All function types, function names with external linkage, and variable names with external linkage have a language linkage. [Note: Some of the properties associated with an entity with language linkage are specific to each implementation and are not described here. For example, a particular language linkage may be associated with a particular form of representing names of objects and functions with external linkage, or with a particular calling convention, etc. — end note] The default language linkage of all function types, function names, and variable names is C++ language linkage. Two function types with different language linkages are distinct types even if they are otherwise identical.

Linkage (6.5) between C++ and non-C++ code fragments can be achieved using a `linkage-specification:`
The *string-literal* indicates the required language linkage. This International Standard specifies the semantics for the *string-literals* "C" and "C++". Use of a *string-literal* other than "C" or "C++" is conditionally-supported, with implementation-defined semantics. [Note: Therefore, a linkage-specification with a *string-literal* that is unknown to the implementation requires a diagnostic. — end note] [Note: It is recommended that the spelling of the *string-literal* be taken from the document defining that language. For example, Ada (not ADA) and Fortran or FORTRAN, depending on the vintage. — end note]

Every implementation shall provide for linkage to functions written in the C programming language, "C", and linkage to C++ functions, "C++". [Example:

```c
complex sqrt(complex); // C++ linkage by default
extern "C" {
    double sqrt(double); // C linkage
}
```

— end example] A C language linkage is ignored in determining the language linkage of the names of class
members and the function type of class member functions.  [Example:

```c
extern "C" typedef void FUNC_c();

class C {
  void mf1(FUNC_c*);
  // the name of the function mf1 and the member function's type have
  // C++ language linkage; the parameter has type "pointer to C function"

  FUNC_c mf2;
  // the name of the function mf2 and the member function's type have
  // C++ language linkage

  static FUNC_c* q;
  // the name of the data member q has C++ language linkage and
  // the data member's type is "pointer to C function"
};
```

```c
extern "C" {
  class X {
    void mf();
    // the name of the function mf and the member function's type have
    // C++ language linkage

    void mf2(void(*)());
    // the name of the function mf2 has C++ language linkage;
    // the parameter has type "pointer to C function"
  }
};
```

—end example—

5 If two declarations declare functions with the same name and parameter-type-list (11.3.5) to be members of the same namespace or declare objects with the same name to be members of the same namespace and the declarations give the names different language linkages, the program is ill-formed; no diagnostic is required if the declarations appear in different translation units. Except for functions with C++ linkage, a function declaration without a linkage specification shall not precede the first linkage specification for that function. A function can be declared without a linkage specification after an explicit linkage specification has been seen; the linkage explicitly specified in the earlier declaration is not affected by such a function declaration.

6 At most one function with a particular name can have C language linkage. Two declarations for a function with C language linkage with the same function name (ignoring the namespace names that qualify it) that appear in different namespace scopes refer to the same function. Two declarations for a variable with C language linkage with the same name (ignoring the namespace names that qualify it) that appear in different namespace scopes refer to the same variable. An entity with C language linkage shall not be declared with the same name as a variable in global scope, unless both declarations denote the same entity; no diagnostic is required if the declarations appear in different translation units. A variable with C language linkage shall not be declared with the same name as a function with C language linkage (ignoring the namespace names that qualify the respective names); no diagnostic is required if the declarations appear in different translation units. [Note: Only one definition for an entity with a given name with C language linkage may appear in the program (see 6.2); this implies that such an entity must not be defined in more than one namespace scope. —end note]  [Example:

```c
int x;
namespace A {
  extern "C" int f();
  extern "C" int g() { return 1; }
  extern "C" int h();
  extern "C" int x(); // ill-formed: same name as global-space object x
}

namespace B {
```

§ 10.5
extern "C" int f();  // A::f and B::f refer to the same function
extern "C" int g() { return 1; }  // ill-formed, the function g with C language linkage has two definitions
}

int A::f() { return 98; }  // definition for the function f with C language linkage
extern "C" int h() { return 97; }  // definition for the function h with C language linkage
extern "C" static void g();  // A::h and ::h refer to the same function
— end example

A declaration directly contained in a linkage-specification is treated as if it contains the extern specifier (10.1.1) for the purpose of determining the linkage of the declared name and whether it is a definition. Such a declaration shall not specify a storage class. [Example:

extern "C" double f();
static double f();  // error
extern "C" int i;
extern "C" {
  int i;
}
extern "C" static void g();  // error
— end example]

[Note: Because the language linkage is part of a function type, when indirecting through a pointer to C function, the function to which the resulting lvalue refers is considered a C function. — end note]

Linkage from C++ to objects defined in other languages and to objects defined in C++ from other languages is implementation-defined and language-dependent. Only where the object layout strategies of two language implementations are similar enough can such linkage be achieved.

10.6 Attributes

10.6.1 Attribute syntax and semantics

Attributes specify additional information for various source constructs such as types, variables, names, blocks, or translation units.

attribute-specifier-seq:
  attribute-specifier-seq_opt attribute-specifier

attribute-specifier:
  [ [ attribute-using-prefix_opt attribute-list ] ]

alignment-specifier:
  alignas ( type-id ...opt )
  alignas ( constant-expression ...opt )

attribute-using-prefix:
  using attribute-namespace :

attribute-list:
  attribute_opt
  attribute-list , attribute_opt
  attribute ...
  attribute-list , attribute ...

attribute:
  attribute-token attribute-argument-clause_opt

§ 10.6.1
attribute-token:
  identifier
  attribute-scoped-token

attribute-scoped-token:
  attribute-namespace :: identifier

attribute-namespace:
  identifier

attribute-argument-clause:
  ( balanced-token-seq_opt )

balanced-token-seq:
  balanced-token
  balanced-token-seq balanced-token

balanced-token:
  ( balanced-token-seq_opt )
  [ balanced-token-seq_opt ]
  { balanced-token-seq_opt }
  any token other than a parenthesis, a bracket, or a brace

2 If an attribute-specifier contains an attribute-using-prefix, the attribute-list following that attribute-using-prefix shall not contain an attribute-scoped-token and every attribute-token in that attribute-list is treated as if its identifier were prefixed with N::, where N is the attribute-namespace specified in the attribute-using-prefix. [Note: This rule imposes no constraints on how an attribute-using-prefix affects the tokens in an attribute-argument-clause. —end note] [Example:

```c
[[using CC: opt(1), debug]] // same as [[CC::opt(1), CC::debug]]
void f() {}
[[using CC: opt(1)]] [[CC::debug]] // same as [[CC::opt(1)]] [[CC::debug]]
void g() {}
[[using CC: CC::opt(1)]] // error: cannot combine using and scoped attribute token
void h() {}
```
—end example]

3 [Note: For each individual attribute, the form of the balanced-token-seq will be specified. —end note]

4 In an attribute-list, an ellipsis may appear only if that attribute's specification permits it. An attribute followed by an ellipsis is a pack expansion (17.5.3). An attribute-specifier that contains no attributes has no effect. The order in which the attribute-tokens appear in an attribute-list is not significant. If a keyword (5.11) or an alternative token (5.5) that satisfies the syntactic requirements of an identifier (5.10) is contained in an attribute-token, it is considered an identifier. No name lookup (6.4) is performed on any of the identifiers contained in an attribute-token. The attribute-token determines additional requirements on the attribute-argument-clause (if any).

5 Each attribute-specifier-seq is said to appertain to some entity or statement, identified by the syntactic context where it appears (Clause 9, Clause 10, Clause 11). If an attribute-specifier-seq that appertains to some entity or statement contains an attribute or alignment-specifier that is not allowed to apply to that entity or statement, the program is ill-formed. If an attribute-specifier-seq appertains to a friend declaration (14.3), that declaration shall be a definition. No attribute-specifier-seq shall appertain to an explicit instantiation (17.7.2).

6 For an attribute-token (including an attribute-scoped-token) not specified in this International Standard, the behavior is implementation-defined. Any attribute-token that is not recognized by the implementation is ignored. [Note: Each implementation should choose a distinctive name for the attribute-namespace in an attribute-scoped-token. —end note]

7 Two consecutive left square bracket tokens shall appear only when introducing an attribute-specifier or within the balanced-token-seq of an attribute-argument-clause. [Note: If two consecutive left square brackets appear
where an attribute-specifier is not allowed, the program is ill-formed even if the brackets match an alternative grammar production. — end note]  

Example:

```c
int p[10];
void f() {
    int x = 42, y[5];
    int(p[x] { return x; }()); // error: invalid attribute on a nested declarator-id and 
    // not a function-style cast of an element of p.
    y[[] { return 2; }()] = 2; // error even though attributes are not allowed in this context.
    int i [([vendor::attr([[]])])](); // well-formed implementation-defined attribute.
}
```

— end example

10.6.2 Alignment specifier [dcl.align]

1 An alignment-specifier may be applied to a variable or to a class data member, but it shall not be applied to a bit-field, a function parameter, or an exception-declaration (18.3). An alignment-specifier may also be applied to the declaration or definition of a class (in an elaborated-type-specifier (10.1.7.3) or class-head (Clause 12), respectively) and to the declaration or definition of an enumeration (in an opaque_enum-declaration or enum-head, respectively (10.2)). An alignment-specifier with an ellipsis is a pack expansion (17.5.3).

2 When the alignment-specifier is of the form `alignas(constant-expression);`
   2.1 the constant-expression shall be an integral constant expression
   2.2 if the constant expression does not evaluate to an alignment value (6.11), or evaluates to an extended alignment and the implementation does not support that alignment in the context of the declaration, the program is ill-formed.

3 An alignment-specifier of the form `alignas(type-id)` has the same effect as `alignas(alignmentof(type-id));` (8.3.6).

4 The alignment requirement of an entity is the strictest nonzero alignment specified by its alignment-specifiers, if any; otherwise, the alignment-specifiers have no effect.

5 The combined effect of all alignment-specifiers in a declaration shall not specify an alignment that is less strict than the alignment that would be required for the entity being declared if all alignment-specifiers appertaining to that entity were omitted.  
   Example:
   ```c
   struct alignas(8) S {};
   struct alignas(1) U {
       S s;
   };
   // error: U specifies an alignment that is less strict than if the alignas(1) were omitted.
   ```  
   — end example

6 If the defining declaration of an entity has an alignment-specifier, any non-defining declaration of that entity shall either specify equivalent alignment or have no alignment-specifier. Conversely, if any declaration of an entity has an alignment-specifier, every defining declaration of that entity shall specify an equivalent alignment. No diagnostic is required if declarations of an entity have different alignment-specifiers in different translation units.  
   Example:
   ```c
   // Translation unit #1:
   struct S { int x; } s, *p = &s;
   // Translation unit #2:
   struct alignas(16) S; // error: definition of S lacks alignment, no diagnostic required
   extern S* p;
   ```  
   — end example

§ 10.6.2
Example: An aligned buffer with an alignment requirement of \texttt{A} and holding \texttt{N} elements of type \texttt{T} can be declared as:

\begin{verbatim}
    alignas(T) alignas(A) T buffer[N];
\end{verbatim}

Specifying \texttt{alignas(T)} ensures that the final requested alignment will not be weaker than \texttt{alignof(T)}, and therefore the program will not be ill-formed. — end example

Example:

\begin{verbatim}
    alignas(double) void f();                     // error: alignment applied to function
    alignas(double) unsigned char c[sizeof(double)]; // array of characters, suitably aligned for a double
    extern unsigned char c[sizeof(double)];         // no alignas necessary
    alignas(float)
    extern unsigned char c[sizeof(double)];        // error: different alignment in declaration
\end{verbatim}

— end example

10.6.3 Carries dependency attribute

The \texttt{carries_dependency} attribute specifies dependency propagation into and out of functions. It shall appear at most once in each \textit{attribute-list} and no \textit{attribute-argument-clause} shall be present. The attribute may be applied to the \texttt{declarator-id} of a \texttt{parameter-declaration} in a function declaration or lambda, in which case it specifies that the initialization of the parameter carries a dependency to (4.7) each lvalue-to-rvalue conversion (7.1) of that object. The attribute may also be applied to the \texttt{declarator-id} of a function declaration, in which case it specifies that the return value, if any, carries a dependency to the evaluation of the function call expression.

The first declaration of a function shall specify the \texttt{carries_dependency} attribute for its \texttt{declarator-id} if any declaration of the function specifies the \texttt{carries_dependency} attribute. Furthermore, the first declaration of a function shall specify the \texttt{carries_dependency} attribute for a parameter if any declaration of that function specifies the \texttt{carries_dependency} attribute for that parameter. If a function or one of its parameters is declared with the \texttt{carries_dependency} attribute in its first declaration in one translation unit and the same function or one of its parameters is declared without the \texttt{carries_dependency} attribute in its first declaration in another translation unit, the program is ill-formed, no diagnostic required.

[Note: The \texttt{carries_dependency} attribute does not change the meaning of the program, but may result in generation of more efficient code. — end note]

Example:

\begin{verbatim}
    struct foo { int* a; int* b; };
    std::atomic<struct foo *> foo_head[10];
    int foo_array[10][10];

    [[carries_dependency]] struct foo* f(int i) {
        return foo_head[i].load(memory_order_consume);
    }

    int g(int* x, int* y [[carries_dependency]]) {
        return kill_dependency(foo_array[*x][*y]);
    }

    // Translation unit B. */

    [[carries_dependency]] struct foo* f(int i);
    int g(int* x, int* y [[carries_dependency]]);
\end{verbatim}

§ 10.6.3
int c = 3;

void h(int i) {
    struct foo* p;
    p = f(i);
    do_something_with(g(&c, p->a));
    do_something_with(g(p->a, &c));
}

The carries dependency attribute on function f means that the return value carries a dependency out of f, so that the implementation need not constrain ordering upon return from f. Implementations of f and its caller may choose to preserve dependencies instead of emitting hardware memory ordering instructions (a.k.a. fences).

Function g's second parameter has a carries dependency attribute, but its first parameter does not. Therefore, function h's first call to g carries a dependency into g, but its second call does not. The implementation might need to insert a fence prior to the second call to g.

— end example]

10.6.4 Deprecated attribute [dcl.attr.deprecated]

1 The attribute-token deprecated can be used to mark names and entities whose use is still allowed, but is discouraged for some reason. [Note: In particular, deprecated is appropriate for names and entities that are deemed obsolescent or unsafe. —end note] It shall appear at most once in each attribute-list. An attribute-argument-clause may be present and, if present, it shall have the form:

( string-literal )

[Note: The string-literal in the attribute-argument-clause could be used to explain the rationale for deprecation and/or to suggest a replacing entity. —end note]

2 The attribute may be applied to the declaration of a class, a typedef-name, a variable, a non-static data member, a function, a namespace, an enumeration, an enumerator, or a template specialization.

3 A name or entity declared without the deprecated attribute can later be redeclared with the attribute and vice-versa. [Note: Thus, an entity initially declared without the attribute can be marked as deprecated by a subsequent redeclaration. However, after an entity is marked as deprecated, later redeclarations do not un-deprecate the entity. —end note] Redeclarations using different forms of the attribute (with or without the attribute-argument-clause or with different attribute-argument-clauses) are allowed.

4 [Note: Implementations may use the deprecated attribute to produce a diagnostic message in case the program refers to a name or entity other than to declare it, after a declaration that specifies the attribute. The diagnostic message may include the text provided within the attribute-argument-clause of any deprecated attribute applied to the name or entity. —end note]

10.6.5 Fallthrough attribute [dcl.attr.fallthrough]

1 The attribute-token fallthrough may be applied to a null statement (9.2); such a statement is a fallthrough statement. The attribute-token fallthrough shall appear at most once in each attribute-list and no attribute-argument-clause shall be present. A fallthrough statement may only appear within an enclosing switch statement (9.4.2). The next statement that would be executed after a fallthrough statement shall be a labeled statement whose label is a case label or default label for the same switch statement. The program is ill-formed if there is no such statement.

2 [Note: The use of a fallthrough statement is intended to suppress a warning that an implementation might otherwise issue for a case or default label that is reachable from another case or default label along some
path of execution. Implementations are encouraged to issue a warning if a fallthrough statement is not dynamically reachable. —end note]

3 [Example:
    void f(int n) {
      void g(), h(), i();
      switch (n) {
        case 1:
        case 2:
          g();
          [[fallthrough]];
        case 3: // warning on fallthrough discouraged
          h();
        case 4: // implementation may warn on fallthrough
          i();
          [[fallthrough]]; // ill-formed
      }
    }
  } —end example]

10.6.6 Maybe unused attribute

The attribute-token maybe_unused indicates that a name or entity is possibly intentionally unused. It shall appear at most once in each attribute-list and no attribute-argument-clause shall be present. The attribute may be applied to the declaration of a class, a typedef-name, a variable, a non-static data member, a function, an enumeration, or an enumerator. [Note: For an entity marked maybe_unused, implementations are encouraged not to emit a warning that the entity is unused, or that the entity is used despite the presence of the attribute. —end note]

A name or entity declared without the maybe_unused attribute can later be redeclared with the attribute and vice versa. An entity is considered marked after the first declaration that marks it.

5 [Example:
    [[maybe_unused]] void f([[maybe_unused]] bool thing1,
      [[maybe_unused]] bool thing2) {
      [[maybe_unused]] bool b = thing1 && thing2;
      assert(b);
    }
  } Implementations are encouraged not to warn that b is unused, whether or not NDEBUG is defined. —end example]

10.6.7 Nodiscard attribute

The attribute-token nodiscard may be applied to the declarator-id in a function declaration or to the declaration of a class or enumeration. It shall appear at most once in each attribute-list and no attribute-argument-clause shall be present.

[Note: A nodiscard call is a function call expression that calls a function previously declared nodiscard, or whose return type is a possibly cv-qualified class or enumeration type marked nodiscard. Appearance of a nodiscard call as a potentially-evaluated discarded-value expression (Clause 8) is discouraged unless explicitly cast to void. Implementations are encouraged to issue a warning in such cases. This is typically because discarding the return value of a nodiscard call has surprising consequences. —end note]

3 [Example:
    struct [[nodiscard]] error_info { /* ... */ };

§ 10.6.7 199
error_info enable_missile_safety_mode();
void launch_missiles();
void test_missiles()
{
    enable_missile_safety_mode(); // warning encouraged
    launch_missiles();
}
error_info &foo();
void f() { foo(); } // warning not encouraged: not a nodiscard call, because neither
// the (reference) return type nor the function is declared nodiscard

— end example

10.6.8 Noreturn attribute [dcl.attr.noreturn]

The attribute-token noreturn specifies that a function does not return. It shall appear at most once in
each attribute-list and no attribute-argument-clause shall be present. The attribute may be applied to
the declarator-id in a function declaration. The first declaration of a function shall specify the noreturn
attribute if any declaration of that function specifies the noreturn attribute. If a function is declared with
the noreturn attribute in one translation unit and the same function is declared without the noreturn
attribute in another translation unit, the program is ill-formed, no diagnostic required.

2 If a function f is called where f was previously declared with the noreturn attribute and f eventually returns,
the behavior is undefined. [Note: The function may terminate by throwing an exception. —end note]
[Note: Implementations are encouraged to issue a warning if a function marked [[noreturn]] might return.
—end note]

3 [Example:
    [[ noreturn ]] void f() {
        throw "error"; // OK
    }

    [[ noreturn ]] void q(int i) { // behavior is undefined if called with an argument <= 0
        if (i > 0)
            throw "positive";
    }
—end example]
11 Declarators

1 A declarator declares a single variable, function, or type, within a declaration. The *init-declarator-list* appearing in a declaration is a comma-separated sequence of declarators, each of which can have an initializer.

   *init-declarator-list*:
   *init-declarator*  
   *init-declarator-list*, *init-declarator*

   *init-declarator*:
   declarator initializer_opt

2 The three components of a *simple-declaration* are the attributes (10.6), the specifiers (*decl-specifier-seq*; 10.1) and the declarators (*init-declarator-list*). The specifiers indicate the type, storage class or other properties of the entities being declared. The declarators specify the names of these entities and (optionally) modify the type of the specifiers with operators such as * (pointer to) and () (function returning). Initial values can also be specified in a declarator; initializers are discussed in 11.6 and 15.6.

3 Each *init-declarator* in a declaration is analyzed separately as if it was in a declaration by itself.  

   Note: A declaration with several declarators is usually equivalent to the corresponding sequence of declarations each with a single declarator. That is

   \[ T \ D_1, \ D_2, \ldots, \ D_n; \]

   is usually equivalent to

   \[ T \ D_1; T \ D_2; \ldots; T \ D_n; \]

   where \( T \) is a *decl-specifier-seq* and each \( D_i \) is an *init-declarator*. One exception is when a name introduced by one of the declarators hides a type name used by the *decl-specifiers*, so that when the same *decl-specifiers* are used in a subsequent declaration, they do not have the same meaning, as in

   ```c
   struct S { ... };  // declare two instances of struct S
   S S, T;            // error
   S T;               // error
   ```

   Another exception is when \( T \) is auto (10.1.7.4), for example:

   ```c
   auto i = 1, j = 2.0;  // error: deduced types for i and j do not match
   ```

   as opposed to

   ```c
   auto i = 1;            // OK: i deduced to have type int
   auto j = 2.0;          // OK: j deduced to have type double
   ```

   — end note ]

4 Declarators have the syntax

   declarator:
   ptr-declarator
   nptr-declarator parameters-and-qualifiers trailing-return-type

   ptr-declarator:
   nptr-declarator
   ptr-operator ptr-declarator
To specify type conversions explicitly, and as an argument of `sizeof`, `alignof`, `new`, or `typeid`, the name of a type shall be specified. This can be done with a `type-id`, which is syntactically a declaration for a variable or function of that type that omits the name of the entity.

```
type-id:
  type-specifier-seq abstract-declarator_opt
defining-type-id:
  defining-type-specifier-seq abstract-declarator_opt
abstract-declarator:
  ptr-abstract-declarator
  noptr-abstract-declarator_opt parameters-and-qualifiers trailing-return-type
abstract-pack-declarator
ptr-abstract-declarator:
  noptr-abstract-declarator
  ptr-operator ptr-abstract-declarator_opt
noptr-abstract-declarator:
  noptr-abstract-declarator_opt parameters-and-qualifiers
  noptr-abstract-declarator_opt [ constant-expression_opt ] attribute-specifier-seq_opt
  ( ptr-abstract-declarator )
abstract-pack-declarator:
  noptr-abstract-pack-declarator
  ptr-operator abstract-pack-declarator
```
It is possible to identify uniquely the location in the abstract-declarator where the identifier would appear if the construction were a declarator in a declaration. The named type is then the same as the type of the hypothetical identifier. [Example:

```c
int     // int i
int *    // int *pi
int *[3] // int *[3]
int (*)(3) // int (*)(3)
int *()   // int *(a)
int (*)(double) // int (*)(double)
```

name respectively the types “int”, “pointer to int”, “array of 3 pointers to int”, “pointer to array of 3 int”, “function of (no parameters) returning pointer to int”, and “pointer to a function of (double) returning int”. —end example]

A type can also be named (often more easily) by using a typedef (10.1.3).

### 11.2 Ambiguity resolution

The ambiguity arising from the similarity between a function-style cast and a declaration mentioned in 9.8 can also occur in the context of a declaration. In that context, the choice is between a function declaration with a redundant set of parentheses around a parameter name and an object declaration with a function-style cast as the initializer. Just as for the ambiguities mentioned in 9.8, the resolution is to consider any construct that could possibly be a declaration a declaration. [Note: A declaration can be explicitly disambiguated by adding parentheses around the argument. The ambiguity can be avoided by use of copy-initialization or list-initialization syntax, or by use of a non-function-style cast. —end note] [Example:

```c
struct S {
    S(int);
};

void foo(double a) {
    S w(int(a));          // function declaration
    S x(int());           // function declaration
    S y(int(a));          // object declaration
    S y(int);             // object declaration
    S z = int(a);         // object declaration
}
```

—end example]

An ambiguity can arise from the similarity between a function-style cast and a type-id. The resolution is that any construct that could possibly be a type-id in its syntactic context shall be considered a type-id. [Example:

```c
template <class T> struct X {};
template <int N> struct Y {};
X<int()> a;               // type-id
X<int()> b;               // expression (ill-formed)
Y<int()> c;               // type-id (ill-formed)
Y<int()> d;               // expression

template <class T> struct X {};
```

§ 11.2
Another ambiguity arises in a parameter-declaration-clause when a type-name is nested in parentheses. In this case, the choice is between the declaration of a parameter of type pointer to function and the declaration of a parameter with redundant parentheses around the declarator-id. The resolution is to consider the type-name as a simple-type-specifier rather than a declarator-id. [Example:

```c
class C { };
void f(int(C)) { } // void f(int(*fp)(C c)) { }
// not: void f(int C) {

int g(C);

void foo() {
    f(1); // error: cannot convert 1 to function pointer
    f(g); // OK
}
```

For another example,

```c
class C { };
void h(int *(C[10])); // void h(int *(*_fp)(C _parm[10]));
// not: void h(int *C[10]);
```

— end example]

### 11.3 Meaning of declarators

A declarator contains exactly one declarator-id; it names the identifier that is declared. An unqualified-id occurring in a declarator-id shall be a simple identifier except for the declaration of some special functions (15.1, 15.3, 15.4, 16.5) and for the declaration of template specializations or partial specializations (17.7). When the declarator-id is qualified, the declaration shall refer to a previously declared member of the class or namespace to which the qualifier refers (or, in the case of a namespace, of an element of the inline namespace set of that namespace (10.3.1)) or to a specialization thereof; the member shall not merely have been introduced by a using-declaration in the scope of the class or namespace nominated by the nested-name-specifier of the declarator-id. The nested-name-specifier of a qualified declarator-id shall not begin with a decltype-specifier. [Note: If the qualifier is the global :: scope resolution operator, the declarator-id refers to a name declared in the global namespace scope. — end note] The optional attribute-specifier-seq following a declarator-id appertains to the entity that is declared.

2 A static, thread_local, extern, mutable, friend, inline, virtual, constexpr, explicit, or typedef specifier applies directly to each declarator-id in an init-declarator-list or member-declarator-list; the type specified for each declarator-id depends on both the decl-specifier-seq and its declarator.

3 Thus, a declaration of a particular identifier has the form

\[ T D \]

where \( T \) is of the form attribute-specifier-seq opt decl-specifier-seq and \( D \) is a declarator. Following is a recursive procedure for determining the type specified for the contained declarator-id by such a declaration.

4 First, the decl-specifier-seq determines a type. In a declaration

\[ \text{sizeof}(\text{int}(a)); \quad \text{expression} \]
\[ \text{sizeof}(\text{int}(\text{unsigned}(a))); \quad \text{type-id (ill-formed)} \]
\[ (\text{int}())+1; \quad \text{type-id (ill-formed)} \]
\[ (\text{int}(a))+1; \quad \text{expression} \]
\[ (\text{int}(\text{unsigned}(a)))+1; \quad \text{type-id (ill-formed)} \]
the `decl-specifier-seq` \( T \) determines the type \( T \). \[ Example: \] In the declaration

```c
int unsigned i;
```
the type specifiers `int unsigned` determine the type "unsigned int" (10.1.7.2). — end example]

5 In a declaration `attribute-specifier-seq_opt \( T \) D` where \( D \) is an unadorned identifier the type of this identifier is "\( T \)".

6 In a declaration \( T \) \( D \) where \( D \) has the form

```c
(D1)
```
the type of the contained `declarator-id` is the same as that of the contained `declarator-id` in the declaration

```c
T D1
```
Parentheses do not alter the type of the embedded `declarator-id`, but they can alter the binding of complex declarators.

### 11.3.1 Pointers

1 In a declaration \( T \) \( D \) where \( D \) has the form

```c
* attribute-specifier-seq_opt cv-qualifier-seq_opt D1
```
and the type of the identifier in the declaration \( T \) \( D1 \) is "derived-declarator-type-list \( T \)", then the type of the identifier of \( D \) is "derived-declarator-type-list cv-qualifier-seq pointer to \( T \)". The `cv-qualifiers` apply to the pointer and not to the object pointed to. Similarly, the optional `attribute-specifier-seq` (10.6.1) appertains to the pointer and not to the object pointed to.

[Example: The declarations]

```c
const int ci = 10, *pc = &ci, *const cpc = pc, **ppc;
int i, *p, *const cp = &i;
```
declare \( ci \), a constant integer; \( pc \), a pointer to a constant integer; \( cpc \), a constant pointer to a constant integer; \( ppc \), a pointer to a pointer to a constant integer; \( i \), an integer; \( p \), a pointer to integer; and \( cp \), a constant pointer to integer. The value of \( ci \), \( cpc \), and \( cp \) cannot be changed after initialization. The value of \( pc \) can be changed, and so can the object pointed to by \( cp \). Examples of some correct operations are

```c
i = ci;
*cp = ci;
pc++;
p = cpc;
p = p;
ppc = &pc;
```

Examples of ill-formed operations are

```c
ci = 1;       // error
ci++;        // error
*pc = 2;      // error
cp = &ci;     // error
cpc++;       // error
p = pc;       // error
ppc = &p;     // error
```

Each is unacceptable because it would either change the value of an object declared `const` or allow it to be changed through a cv-unqualified pointer later, for example:

```c
*ppc = &ci;    // OK, but would make p point to ci because of previous error
*p = 5;       // clobber ci
```
3 See also 8.18 and 11.6.

4 [Note: Forming a pointer to reference type is ill-formed; see 11.3.2. Forming a function pointer type is ill-formed if the function type has 
\textit{cv-qualifiers} or a \textit{ref-qualifier}; see 11.3.5. Since the address of a bit-field (12.2.4) cannot be taken, a pointer can never point to a bit-field. —end note]

11.3.2 References [\texttt{dcl.ref}]

1 In a declaration \texttt{T D} where \texttt{D} has either of the forms

\begin{verbatim}
& attribute-specifier-seq\opt D1
&& attribute-specifier-seq\opt D1
\end{verbatim}

and the type of the identifier in the declaration \texttt{T D1} is \textit{"derived-declarator-type-list T"}, then the type of the identifier of \texttt{D} is \textit{"derived-declarator-type-list reference to T"}. The optional \texttt{attribute-specifier-seq} appertains to the reference type. Cv-qualified references are ill-formed except when the cv-qualifiers are introduced through the use of a \texttt{typedef-name} (10.1.3, 17.1) or \texttt{decltype-specifier} (10.1.7.2), in which case the cv-qualifiers are ignored. [Example:

\begin{verbatim}
typedef int& A;
const A aref = 3;  // ill-formed; lvalue reference to non-\texttt{const} initialized with \texttt{rvalue}
\end{verbatim}

The type of \texttt{aref} is \textit{"lvalue reference to int"}, not \textit{"lvalue reference to \texttt{const int}"}. —end example] [Note: A reference can be thought of as a name of an object. —end note] A declarator that specifies the type “reference to \textit{cv void}” is ill-formed.

2 A reference type that is declared using \& is called an \textit{lvalue reference}, and a reference type that is declared using \&& is called an \textit{rvalue reference}. Lvalue references and rvalue references are distinct types. Except where explicitly noted, they are semantically equivalent and commonly referred to as references.

3 [Example:

\begin{verbatim}
void f(double& a) { a += 3.14; }
// ...
double d = 0;
f(d);
\end{verbatim}

declares \texttt{a} to be a reference parameter of \texttt{f} so the call \texttt{f(d)} will add \texttt{3.14} to \texttt{d}.

\begin{verbatim}
int v[20];
// ...
int& g(int i) { return v[i]; }
// ...
g(3) = 7;
\end{verbatim}

declares the function \texttt{g()} to return a reference to an integer so \texttt{g(3)=7} will assign \texttt{7} to the fourth element of the array \texttt{v}. For another example,

\begin{verbatim}
struct link {
  link* next;
};

link* first;
\end{verbatim}

\begin{verbatim}
void h(link*& p) {  // p is a reference to pointer
  p->next = first;
  first = p;
  p = 0;
}
\end{verbatim}

§ 11.3.2
void k() {
  link* q = new link;
  h(q);
}

declares \texttt{p} to be a reference to a pointer to \texttt{link} so \texttt{h(q)} will leave \texttt{q} with the value zero. See also \ref{11.6.3}. —end example

4 It is unspecified whether or not a reference requires storage (6.7).

5 There shall be no references to references, no arrays of references, and no pointers to references. The declaration of a reference shall contain an \textit{initializer} (11.6.3) except when the declaration contains an explicit \texttt{extern} specifier (10.1.1), is a class member (12.2) declaration within a class definition, or is the declaration of a parameter or a return type (11.3.5); see 6.1. A reference shall be initialized to refer to a valid object or function. [\Note: In particular, a null reference cannot exist in a well-defined program, because the only way to create such a reference would be to bind it to the “object” obtained by indirection through a null pointer, which causes undefined behavior. As described in 12.2.4, a reference cannot be bound directly to a bit-field. —end note]

6 If a \texttt{typedef-name} (10.1.3, 17.1) or a \texttt{decltype-specifier} (10.1.7.2) denotes a type \texttt{TR} that is a reference to a type \texttt{T}, an attempt to create the type “lvalue reference to \texttt{cv TR}” creates the type “lvalue reference to \texttt{T}”, while an attempt to create the type “rvalue reference to \texttt{cv TR}” creates the type \texttt{TR}. [\Note: This rule is known as reference collapsing. —end note] [Example:

\begin{verbatim}
int i;
typedef int& LRI;
typedef int&& RRI;

LRI& r1 = i;        // \texttt{r1} has the type \texttt{int&}  
const LRI& r2 = i;  // \texttt{r2} has the type \texttt{int&}  
const LRI&& r3 = i; // \texttt{r3} has the type \texttt{int&&} 

RRI& r4 = i;        // \texttt{r4} has the type \texttt{int&}  
RRI&& r5 = 5;       // \texttt{r5} has the type \texttt{int&&} 

declaype(r2)& r6 = i; // \texttt{r6} has the type \texttt{int&}  
declaype(r2)&& r7 = i; // \texttt{r7} has the type \texttt{int&&} 
\end{verbatim}

—end example]

7 [\Note: Forming a reference to function type is ill-formed if the function type has \texttt{cv-qualifiers} or a \texttt{ref-qualifier}; see 11.3.5. —end note]

11.3.3 Pointers to members [dcl.mpbr]

In a declaration \texttt{T D} where \texttt{D} has the form

\begin{verbatim}
nested-name-specifier * attribute-specifier-seq_opt cv-qualifier-seq_opt D1
\end{verbatim}

and the \texttt{nested-name-specifier} denotes a class, and the type of the identifier in the declaration \texttt{T D1} is “\texttt{derived-declarator-type-list} \texttt{T}”, then the type of the identifier of \texttt{D} is “\texttt{derived-declarator-type-list} \texttt{cv-qualifier-seq} pointer to member of class \texttt{nested-name-specifier} of type \texttt{T}”. The optional \texttt{attribute-specifier-seq} (10.6.1) appertains to the pointer-to-member.

2 [Example:

\begin{verbatim}
struct X {  
  void f(int);
  int a;
};
\end{verbatim}

§ 11.3.3
struct Y;

int X::* pmi = &X::a;
void (X::* pmf)(int) = &X::f;
double X::* pmd;
char Y::* pmc;

declares pmi, pmf, pmd and pmc to be a pointer to a member of X of type int, a pointer to a member of X of type void(int), a pointer to a member of X of type double and a pointer to a member of Y of type char respectively. The declaration of pmd is well-formed even though X has no members of type double. Similarly, the declaration of pmc is well-formed even though Y is an incomplete type. pmi and pmf can be used like this:

X obj;
// ...
obj.*pmi = 7;  // assign 7 to an integer member of obj
(obj.*pmf)(7); // call a function member of obj with the argument 7

—end example—

3 A pointer to member shall not point to a static member of a class (12.2.3), a member with reference type, or “cv void”.

[Note: See also 8.3 and 8.5. The type “pointer to member” is distinct from the type “pointer”, that is, a pointer to member is declared only by the pointer to member declarator syntax, and never by the pointer declarator syntax. There is no “reference-to-member” type in C++. —end note]

11.3.4 Arrays

In a declaration T D where D has the form

    D [ constant-expression opt ] attribute-specifier-seq opt

and the type of the identifier in the declaration T D1 is “derived-declarator-type-list T”, then the type of the identifier of D contains the auto type-specifier, the program is ill-formed. T is called the array element type; this type shall not be a reference type, cv void, a function type or an abstract class type. If the constant-expression (8.20) is present, it shall be a converted constant expression of type std::size_t and its value shall be greater than zero. The constant expression specifies the bound of (number of elements in) the array. If the value of the constant expression is N, the array has N elements numbered 0 to N-1, and the type of the identifier of D is “derived-declarator-type-list array of N T”. An object of array type contains a contiguously allocated non-empty set of N subobjects of type T. Except as noted below, if the constant expression is omitted, the type of the identifier of D is “derived-declarator-type-list array of unknown bound of T”, an incomplete object type. The type “derived-declarator-type-list array of N T” is a different type from the type “derived-declarator-type-list array of unknown bound of T”, see 6.9. Any type of the form “cv-qualifier-seq array of N T” is adjusted to “array of N cv-qualifier-seq T”, and similarly for “array of unknown bound of T”. The optional attribute-specifier-seq appertains to the array. [Example:

typedef int A[5], AA[2][3];
typedef const A CA;  // type is “array of 5 const int”
typedef const AA CAA; // type is “array of 2 array of 3 const int”

—end example] [Note: An “array of N cv-qualifier-seq T” has cv-qualified type; see 6.9.3. —end note]

2 An array can be constructed from one of the fundamental types (except void), from a pointer, from a pointer to member, from a class, from an enumeration type, or from another array.

3 When several “array of” specifications are adjacent, a multidimensional array type is created; only the first of the constant expressions that specify the bounds of the arrays may be omitted. In addition to declarations in which an incomplete object type is allowed, an array bound may be omitted in some cases in the declaration of a function parameter (11.3.5). An array bound may also be omitted when the declarator is followed by an

§ 11.3.4
initializer (11.6) or when a declarator for a static data member is followed by a brace-or-equal-initializer (12.2). In both cases the bound is calculated from the number of initial elements (say, \(N\)) supplied (11.6.1), and the type of the identifier of \(D\) is “array of \(N\) \(T\)”. Furthermore, if there is a preceding declaration of the entity in the same scope in which the bound was specified, an omitted array bound is taken to be the same as in that earlier declaration, and similarly for the definition of a static data member of a class.

4 [Example:]

```c
float fa[17], *afp[17];
```

declares an array of `float` numbers and an array of pointers to `float` numbers. For another example,

```c
static int x3d[3][5][7];
```

declares a static three-dimensional array of integers, with rank \(3 \times 5 \times 7\). In complete detail, \(x3d\) is an array of three items; each item is an array of five arrays; each of the latter arrays is an array of seven integers. Any of the expressions \(x3d\), \(x3d[i]\), \(x3d[i][j]\), \(x3d[i][j][k]\) can reasonably appear in an expression. Finally,

```c
extern int x[10];
```  
struct S {
  static int y[10];
};

```c
int x[]; // OK: bound is 10
int S::y[]; // OK: bound is 10
```

```c
void f() {
  extern int x[];
  struct S {
    static int y[10];
  };

  int x[]; // OK: bound is 10
  int S::y[]; // OK: bound is 10

  void f() {
    extern int x[];
    int i = sizeof(x); // error: incomplete object type
  }
}
```

—end example]

5 [Note: Conversions affecting expressions of array type are described in 7.2. Objects of array types cannot be modified, see 6.10. —end note]

6 [Note: Except where it has been declared for a class (16.5.5), the subscript operator \([\]\) is interpreted in such a way that \(E1[E2]\) is identical to \(*((E1)+(E2))\) (8.2.1). Because of the conversion rules that apply to +, if \(E1\) is an array and \(E2\) an integer, then \(E1[E2]\) refers to the \(E2\)-th member of \(E1\). Therefore, despite its asymmetric appearance, subscripting is a commutative operation. —end note]

7 [Note: A consistent rule is followed for multidimensional arrays. If \(E\) is an \(n\)-dimensional array of rank \(i \times j \times \cdots \times k\), then \(E\) appearing in an expression that is subject to the array-to-pointer conversion (7.2) is converted to a pointer to an \((n-1)\)-dimensional array with rank \(j \times \cdots \times k\). If the \(*\) operator, either explicitly or implicitly as a result of subscripting, is applied to this pointer, the result is the pointed-to \((n-1)\)-dimensional array, which itself is immediately converted into a pointer. [Example: Consider]

```c
int x[3][5];
```

Here \(x\) is a \(3 \times 5\) array of integers. When \(x\) appears in an expression, it is converted to a pointer to (the first of three) five-membered arrays of integers. In the expression \(x[i]\) which is equivalent to \(*\(x+i\)\), \(x\) is first converted to a pointer as described; then \(x+i\) is converted to the type of \(x\), which involves multiplying \(i\) by the length of the object to which the pointer points, namely five integer objects. The results are added and indirection applied to yield an array (of five integers), which in turn is converted to a pointer to the first of the integers. If there is another subscript the same argument applies again; this time the result is an integer. —end example] —end note]

8 [Note: It follows from all this that arrays in C++ are stored row-wise (last subscript varies fastest) and that the first subscript in the declaration helps determine the amount of storage consumed by an array but plays no other part in subscript calculations. —end note]
11.3.5 Functions

1 In a declaration \( T \, D \) where \( D \) has the form

\[
D_1 ( \text{parameter-declaration-clause} ) \text{cv-qualifier-seq}_\text{opt} \text{ref-qualifier}_\text{opt} \text{noexcept-specifier}_\text{opt} \text{attribute-specifier-seq}_\text{opt}.
\]

and the type of the contained declarator-id in the declaration \( T \, D_1 \) is “derived-declarator-type-list \( T \)”, the type of the declarator-id in \( D \) is “derived-declarator-type-list noexcept\_opt function of (parameter-declaration-clause) cv-qualifier-seq\_opt ref-qualifier\_opt returning \( T \)”, where the optional noexcept is present if and only if the exception specification (18.4) is non-throwing. The optional attribute-specifier-seq appertains to the function type.

2 In a declaration \( T \, D \) where \( D \) has the form

\[
D_1 ( \text{parameter-declaration-clause} ) \text{cv-qualifier-seq}_\text{opt} \text{ref-qualifier}_\text{opt} \text{noexcept-specifier}_\text{opt} \text{attribute-specifier-seq}_\text{opt} \text{trailing-return-type}
\]

and the type of the contained declarator-id in the declaration \( T \, D_1 \) is “derived-declarator-type-list \( T \)”, \( T \) shall be the single type-specifier auto. The type of the declarator-id in \( D \) is “derived-declarator-type-list noexcept\_opt function of (parameter-declaration-clause) cv-qualifier-seq\_opt ref-qualifier\_opt returning \( U \)”, where \( U \) is the type specified by the trailing-return-type, and where the optional noexcept is present if and only if the exception specification is non-throwing. The optional attribute-specifier-seq appertains to the function type.

3 A type of either form is a function type.\(^{100}\)

\[
\begin{align*}
\text{parameter-declaration-clause:} & \quad \text{parameter-declaration-list}_\text{opt} \ldots \text{opt} \\
& \quad \text{parameter-declaration-list} \ldots \\
\text{parameter-declaration-list:} & \quad \text{parameter-declaration} \\
& \quad \text{parameter-declaration-list} \ldots \text{parameter-declaration} \\
\text{parameter-declaration:} & \quad \text{attribute-specifier-seq}_\text{opt} \text{decl-specifier-seq} \text{declarator} \\
& \quad \text{attribute-specifier-seq}_\text{opt} \text{decl-specifier-seq} \text{declarator} = \text{initializer-clause} \\
& \quad \text{attribute-specifier-seq}_\text{opt} \text{decl-specifier-seq} \text{abstract-declarator}_\text{opt} \\
& \quad \text{attribute-specifier-seq}_\text{opt} \text{decl-specifier-seq} \text{abstract-declarator}_\text{opt} = \text{initializer-clause}
\end{align*}
\]

The optional attribute-specifier-seq in a parameter-declaration appertains to the parameter.

4 The parameter-declaration-clause determines the arguments that can be specified, and their processing, when the function is called. [Note: The parameter-declaration-clause is used to convert the arguments specified on the function call; see 8.2.2. —end note] If the parameter-declaration-clause is empty, the function takes no arguments. A parameter list consisting of a single unnamed parameter of non-dependent type void is equivalent to an empty parameter list. Except for this special case, a parameter shall not have type cv void. If the parameter-declaration-clause terminates with an ellipsis or a function parameter pack (17.5.3), the number of arguments shall be equal to or greater than the number of parameters that do not have a default argument and are not function parameter packs. Where syntactically correct and where “...” is not part of an abstract-declarator, “, ...” is synonymous with “...”. [Example: The declaration

\[
\text{int printf(const char*, ...);} \\
\text{printf("hello world");} \\
\text{printf("a=\%d b=\%d", a, b);} \\
\]

However, the first argument must be of a type that can be converted to a const char* —end example] [Note: The standard header <cstdarg> contains a mechanism for accessing arguments passed using the

\(^{100}\) As indicated by syntax, cv-qualifiers are a significant component in function return types.
A single name can be used for several different functions in a single scope; this is function overloading (Clause 16). All declarations for a function shall agree exactly in both the return type and the parameter-type-list. The type of a function is determined using the following rules. The type of each parameter (including function parameter packs) is determined from its own decl-specifier-seq and declarator. After determining the type of each parameter, any parameter of type “array of T” or of function type T is adjusted to be “pointer to T”. After producing the list of parameter types, any top-level cv-qualifiers modifying a parameter type are deleted when forming the function type. The resulting list of transformed parameter types and the presence or absence of the ellipsis or a function parameter pack is the function’s parameter-type-list.

[Note: This transformation does not affect the types of the parameters. For example, int(*)(const int p, decltype(p)*), and int(*)(int, const int*) are identical types. — end note]

A function type with a cv-qualifier-seq or a ref-qualifier (including a type named by typedef-name (10.1.3, 17.1)) shall appear only as:

1. the function type for a non-static member function,
2. the function type to which a pointer to member refers,
3. the top-level function type of a function typedef declaration or alias-declaration,
4. the type-id in the default argument of a type-parameter (17.1), or
5. the type-id of a template-argument for a type-parameter (17.3.1).

[Example:

typedef int FIC(int) const;
FIC f; // ill-formed: does not declare a member function
struct S {
  FIC f; // OK
};
FIC S::*pm = &S::f; // OK
— end example]

The return type, the parameter-type-list, the ref-qualifier, the cv-qualifier-seq, and the exception specification, but not the default arguments (11.3.6), are part of the function type. [Note: Function types are checked during the assignments and initializations of pointers to functions, references to functions, and pointers to member functions. — end note]

[Example: The declaration

    int fseek(FILE*, long, int);

decrates a function taking three arguments of the specified types, and returning int (10.1.7). — end example]

Functions shall not have a return type of type array or function, although they may have a return type of type pointer or reference to such things. There shall be no arrays of functions, although there can be arrays of pointers to functions.
Types shall not be defined in return or parameter types. The type of a parameter or the return type for a function definition shall not be an incomplete (possibly cv-qualified) class type in the context of the function definition unless the function is deleted (11.4.3).

A typedef of function type may be used to declare a function but shall not be used to define a function (11.4).

> Example:

```cpp
typedef void F();
F fv; // OK: equivalent to void fv();
F fv {} // ill-formed
void fv() {} // OK: definition of fv
```

— end example]

An identifier can optionally be provided as a parameter name; if present in a function definition (11.4), it names a parameter. [Note: In particular, parameter names are also optional in function definitions and names used for a parameter in different declarations and the definition of a function need not be the same. If a parameter name is present in a function declaration that is not a definition, it cannot be used outside of its function declarator because that is the extent of its potential scope (6.3.4). — end note]

> Example: The declaration

```cpp
int i,
    *pi,
    f(),
    *fpi(int),
    (*fpi)(const char*, const char*),
    (*fpif(int))(int);
```

declares an integer `i`, a pointer `pi` to an integer, a function `f` taking no arguments and returning an integer, a function `fpi` taking an integer argument and returning a pointer to an integer, a pointer `pif` to a function which takes two pointers to constant characters and returns an integer, a function `fpif` taking an integer argument and returning a pointer to a function that takes an integer argument and returns an integer. It is especially useful to compare `fpi` and `pif`. The binding of `*fpi(int)` is `*(fpi(int))`, so the declaration suggests, and the same construction in an expression requires, the calling of a function `fpi`, and then using indirection through the (pointer) result to yield an integer. In the declarator `(fpi)(const char*, const char*)`, the extra parentheses are necessary to indicate that indirection through a pointer to a function yields a function, which is then called. — end example] [Note: Typedefs and trailing-return-types are sometimes convenient when the return type of a function is complex. For example, the function `fpif` above could have been declared

```cpp
typedef int IFUNC(int);
IFUNC* fpif(int);
```

or

```cpp
auto fpif(int)->int(*)(int);
```

A trailing-return-type is most useful for a type that would be more complicated to specify before the declarator-id:

```cpp
template <class T, class U> auto add(T t, U u) -> decltype(t + u);
```

rather than

```cpp
template <class T, class U> decltype((*(T*)0) + (*(U*)0)) add(T t, U u);
```

— end note]

A non-template function is a function that is not a function template specialization. [Note: A function template is not a function. — end note]
A declarator-id or abstract-declarator containing an ellipsis shall only be used in a parameter-declaration. Such a parameter-declaration is a parameter pack (17.5.3). When it is part of a parameter-declaration-clause, the parameter pack is a function parameter pack (17.5.3). [Note: Otherwise, the parameter-declaration is part of a template-parameter-list and the parameter pack is a template parameter pack; see 17.1. —end note] A function parameter pack is a pack expansion (17.5.3). [Example:

```cpp
template<typename... T> void f(T (* ...t)(int, int));
int add(int, int);
float subtract(int, int);

void g() {
  f(add, subtract);
}
—end example]
```

There is a syntactic ambiguity when an ellipsis occurs at the end of a parameter-declaration-clause without a preceding comma. In this case, the ellipsis is parsed as part of the abstract-declarator if the type of the parameter either names a template parameter pack that has not been expanded or contains auto; otherwise, it is parsed as part of the parameter-declaration-clause.\(^{101}\)

### 11.3.6 Default arguments

[decl.fct.default]

1 If an initializer-clause is specified in a parameter-declaration this initializer-clause is used as a default argument. Default arguments will be used in calls where trailing arguments are missing.

2 [Example: The declaration

```cpp
void point(int = 3, int = 4);
```

declares a function that can be called with zero, one, or two arguments of type int. It can be called in any of these ways:

```cpp
point(1,2); point(1); point();
```

The last two calls are equivalent to point(1,4) and point(3,4), respectively. —end example]

3 A default argument shall be specified only in the parameter-declaration-clause of a function declaration or lambda-declarator or in a template-parameter (17.1); in the latter case, the initializer-clause shall be an assignment-expression. A default argument shall not be specified for a parameter pack. If it is specified in a parameter-declaration-clause, it shall not occur within a declarator or abstract-declarator of a parameter-declaration.\(^{102}\)

4 For non-template functions, default arguments can be added in later declarations of a function in the same scope. Declarations in different scopes have completely distinct sets of default arguments. That is, declarations in inner scopes do not acquire default arguments from declarations in outer scopes, and vice versa. In a given function declaration, each parameter subsequent to a parameter with a default argument shall have a default argument supplied in this or a previous declaration or shall be a function parameter pack. A default argument shall not be redefined by a later declaration (not even to the same value). [Example:

```cpp
void g(int = 0, ...); // OK, ellipsis is not a parameter so it can follow
void f(int, int); // a parameter with a default argument
void f(int, int = 7);
```

\(^{101}\) One can explicitly disambiguate the parse either by introducing a comma (so the ellipsis will be parsed as part of the parameter-declaration-clause) or by introducing a name for the parameter (so the ellipsis will be parsed as part of the declarator-id).

\(^{102}\) This means that default arguments cannot appear, for example, in declarations of pointers to functions, references to functions, or typedef declarations.
void h() {
    f(3); // OK, calls f(3, 7)
    void f(int = 1, int); // error: does not use default from surrounding scope
}

void m() {
    void f(int, int); // has no defaults
    f(4); // error: wrong number of arguments
    void f(int, int = 5); // OK
    f(4); // OK, calls f(4, 5);
    void f(int, int = 5); // error: cannot redefine, even to same value
}

void n() {
    f(6); // OK, calls f(6, 7)
}

— end example —

For a given inline function defined in different translation units, the accumulated sets of default arguments at the end of the translation units shall be the same; see 6.2. If a friend declaration specifies a default argument expression, that declaration shall be a definition and shall be the only declaration of the function or function template in the translation unit.

The default argument has the same semantic constraints as the initializer in a declaration of a variable of the parameter type, using the copy-initialization semantics (11.6). The names in the default argument are bound, and the semantic constraints are checked, at the point where the default argument appears. Name lookup and checking of semantic constraints for default arguments in function templates and in member functions of class templates are performed as described in 17.7.1. [Example: In the following code, g will be called with the value f(2):

```
int a = 1;
int f(int);
int g(int x = f(a)); // default argument: f(\texttt{::a})
```

void h() {
    a = 2;
    {
        int a = 3;
        g(); // g( f(\texttt{::a}) )
    }
}

— end example —

[Note: In member function declarations, names in default arguments are looked up as described in 6.4.1. Access checking applies to names in default arguments as described in Clause 14. — end note]

Except for member functions of class templates, the default arguments in a member function definition that appears outside of the class definition are added to the set of default arguments provided by the member function declaration in the class definition; the program is ill-formed if a default constructor (15.1), copy or move constructor, or copy or move assignment operator (15.8) is so declared. Default arguments for a member function of a class template shall be specified on the initial declaration of the member function within the class template. [Example:

```
class C {
    void f(int i = 3);
    void g(int i, int j = 99);
};
```

```
void C::f(int i = 3) {} // error: default argument already specified in class scope
void C::g(int i = 88, int j) {} // in this translation unit, C::g can be called with no argument
```

§ 11.3.6 214
A local variable shall not appear as a potentially-evaluated expression in a default argument.  

```c
void f() {
    int i;
    extern void g(int x = i); // error
    extern void h(int x = sizeof(i)); // OK
    // ...
}
```

— end example —

The keyword `this` may not appear in a default argument of a member function; see 8.1.2.  

```c
class A {
    void f(A* p = this) { } // error
};
```

— end example — end note

A default argument is evaluated each time the function is called with no argument for the corresponding parameter. A parameter shall not appear as a potentially-evaluated expression in a default argument. Parameters of a function declared before a default argument are in scope and can hide namespace and class member names.  

```c
int a;
int f(int a, int b = a); // error: parameter a used as default argument
typedef int I;
int g(float I, int b = I(2)); // error: parameter I found
int h(int a, int b = sizeof(a)); // OK, unevaluated operand
```

— end example —

A non-static member shall not appear in a default argument unless it appears as the `id-expression` of a class member access expression (8.2.5) or unless it is used to form a pointer to member (8.3.1).  

```c
int b;
class X {
    int a;
    int mem1(int i = a); // error: non-static member a used as default argument
    int mem2(int i = b); // OK; use X::b
    static int b;
};
```

The declaration of `X::mem2()` is meaningful, however, since no object is needed to access the static member `X::b`. Classes, objects, and members are described in Clause 12.  

— end example —

A default argument is not part of the type of a function.  

```c
int f(int = 0);
void h() {
    int j = f(1);
    int k = f(); // OK, means f(0)
}
```

```c
int (*p1)(int) = &f;
int (*p2)() = &f; // error: type mismatch
```

— end example —

When a declaration of a function is introduced by way of a `using-declaration` (10.3.3), any default argument information associated with the declaration is made known as well. If the function is
redeclared thereafter in the namespace with additional default arguments, the additional arguments are also
known at any point following the redeclaration where the using-declaration is in scope.

10 A virtual function call (13.3) uses the default arguments in the declaration of the virtual function determined
by the static type of the pointer or reference denoting the object. An overriding function in a derived class
does not acquire default arguments from the function it overrides. [Example:

```c
struct A {
    virtual void f(int a = 7);
};
struct B : public A {
    void f(int a);
};
void m() {
    B* pb = new B;
    A* pa = pb;
    pa->f();  // OK, calls pa->B::f(7)
    pb->f();  // error: wrong number of arguments for B::f()
}
```

—end example]

11.4 Function definitions

11.4.1 In general

Function definitions have the form

```
function-definition:
    attribute-specifier-seqopt decl-specifier-seqopt declarator virt-specifier-seqopt function-body

function-body:
    ctor-initializeropt compound-statement
    function-try-block
    = default ;
    = delete ;
```

Any informal reference to the body of a function should be interpreted as a reference to the non-terminal
function-body. The optional attribute-specifier-seq in a function-definition appertains to the function. A
virt-specifier-seq can be part of a function-definition only if it is a member-declaration (12.2).

2 In a function-definition, either void declarator ; or declarator ; shall be a well-formed function declaration
as described in 11.3.5. A function shall be defined only in namespace or class scope.

3 [Example: A simple example of a complete function definition is

```c
int max(int a, int b, int c) {
    int m = (a > b) ? a : b;
    return (m > c) ? m : c;
}
```

Here int is the decl-specifier-seq; max(int a, int b, int c) is the declarator; { /* ... */ } is the
function-body. — end example]

4 A ctor-initializer is used only in a constructor; see 15.1 and 15.6.

5 [Note: A cv-qualifier-seq affects the type of this in the body of a member function; see 11.3.2. — end note]

6 [Note: Unused parameters need not be named. For example,

```c
void print(int a, int) {
    std::printf("a = %d\n",a);
}
```
In the function-body, a function-local predefined variable denotes a block-scope object of static storage duration that is implicitly defined (see 6.3.3).

The function-local predefined variable `__func__` is defined as if a definition of the form

```c
static const char __func__[] = "function-name";
```

had been provided, where `function-name` is an implementation-defined string. It is unspecified whether such a variable has an address distinct from that of any other object in the program.103

```c
struct S {
    S() : s(__func__) { } // OK
    const char* s;
};
void f(const char* s = __func__); // error: __func__ is undeclared
```

--- end example

### 11.4.2 Explicitly-defaulted functions

A function definition of the form:

```c
attribute-specifier-seq\text{opt} \hspace{1em} decl-specifier-seq\text{opt} \hspace{1em} declarator \hspace{1em} virt-specifier-seq\text{opt} = default ;
```

is called an explicitly-defaulted definition. A function that is explicitly defaulted shall

1. be a special member function,
2. have the same declared function type (except for possibly differing `ref-qualifiers` and except that in the case of a copy constructor or copy assignment operator, the parameter type may be “reference to non-const T”, where T is the name of the member function’s class) as if it had been implicitly declared, and
3. not have default arguments.

An explicitly-defaulted function that is not defined as deleted may be declared `constexpr` only if it would have been implicitly declared as `constexpr`. If a function is explicitly defaulted on its first declaration, it is implicitly considered to be `constexpr` if the implicit declaration would be.

If a function that is explicitly defaulted is declared with a `noexcept-specifier` that does not produce the same exception specification as the implicit declaration (18.4), then

1. if the function is explicitly defaulted on its first declaration, it is defined as deleted;
2. otherwise, the program is ill-formed.

```c
struct S {
    constexpr S() = default; // ill-formed: implicit S() is not constexpr
    S(int a = 0) = default;  // ill-formed: default argument
    void operator=(const S&) = default; // ill-formed: non-matching return type
    ~S() noexcept(false) = default; // deleted: exception specification does not match
private:
    int i;
    S(S&); // OK: private copy constructor
};
S::S(S&) = default; // OK: defines copy constructor
```

--- end example

103 Implementations are permitted to provide additional predefined variables with names that are reserved to the implementation (5.10). If a predefined variable is not odr-used (6.2), its string value need not be present in the program image.
Explicitly-defaulted functions and implicitly-declared functions are collectively called *defaulted* functions, and the implementation shall provide implicit definitions for them (15.1 15.4, 15.8), which might mean defining them as deleted. A function is *user-provided* if it is user-declared and not explicitly defaulted or deleted on its first declaration. A user-provided explicitly-defaulted function (i.e., explicitly defaulted after its first declaration) is defined at the point where it is explicitly defaulted; if such a function is implicitly defined as deleted, the program is ill-formed. [Note: Declaring a function as defaulted after its first declaration can provide efficient execution and concise definition while enabling a stable binary interface to an evolving code base. —end note]

[Example:

```cpp
struct trivial {
   trivial() = default;
   trivial(const trivial&) = default;
   trivial(trivial&&) = default;
   trivial& operator=(const trivial&) = default;
   trivial& operator=(trivial&&) = default;
   ~trivial() = default;
};

struct nontrivial1 {
   nontrivial1();
};
nontrivial1::nontrivial1() = default; // not first declaration
```
—end example]

### 11.4.3 Deleted definitions

A function definition of the form:

```cpp
attribute-specifier-seqopt decl-specifier-seqopt declarator virt-specifier-seqopt = delete;
```

is called a *deleted definition*. A function with a deleted definition is also called a *deleted function*.

[Note: This includes calling the function implicitly or explicitly and forming a pointer or pointer-to-member to the function. It applies even for references in expressions that are not potentially-evaluated. If a function is overloaded, it is referenced only if the function is selected by overload resolution. The implicit odr-use (6.2) of a virtual function does not, by itself, constitute a reference. —end note]

[Example: One can enforce non-default-initialization and non-integral initialization with

```cpp
struct onlydouble {
   onlydouble() = delete; // OK, but redundant
   onlydouble(std::intmax_t) = delete;
   onlydouble(double);
};
```
—end example]

[Example: One can prevent use of a class in certain *new-expressions* by using deleted definitions of a user-declared *operator new* for that class.

```cpp
struct sometype {
   void* operator new(std::size_t) = delete;
   void* operator new[](std::size_t) = delete;
};

sometype* p = new sometype; // error, deleted class operator new
sometype* q = new sometype[3]; // error, deleted class operator new[]
```
A deleted function is implicitly an inline function (10.1.6). [Note: The one-definition rule (6.2) applies to deleted definitions. —end note] A deleted definition of a function shall be the first declaration of the function or, for an explicit specialization of a function template, the first declaration of that specialization. An implicitly declared allocation or deallocation function (6.7.4) shall not be defined as deleted. [Example:

```cpp
struct sometype {
    sometype();
};
sometype::sometype() = delete; // ill-formed; not first declaration
—end example
```

11.5 Structured binding declarations [dcl.struct.bind]

A structured binding declaration introduces the identifiers \(v_0, v_1, v_2, \ldots\) of the identifier-list as names (6.3.1), called structured bindings. Let \(cv\) denote the cv-qualifiers in the decl-specifier-seq. First, a variable with a unique name \(e\) is introduced. If the assignment-expression in the initializer has array type \(A\) and no ref-qualifier is present, \(e\) has type \(cv\ A\) and each element is copy-initialized or direct-initialized from the corresponding element of the assignment-expression as specified by the form of the initializer. Otherwise, \(e\) is defined as-if by

```cpp
attribute-specifier-seq\opt decl-specifier-seq\opt ref-qualifier\opt e initializer ;
```

where the declaration is never interpreted as a function declaration and the parts of the declaration other than the declarator-id are taken from the corresponding structured binding declaration. The type of the id-expression \(e\) is called \(E\). [Note: \(E\) is never a reference type (Clause 8). —end note]

If \(E\) is an array type with element type \(T\), the number of elements in the identifier-list shall be equal to the number of elements of \(E\). Each \(v_i\) is the name of an lvalue that refers to the element \(i\) of the array and whose type is \(T\); the referenced type is \(T\). [Note: The top-level cv-qualifiers of \(T\) are \(cv\). —end note] [Example:

```cpp
auto f() -> int&[2];
auto [ x, y ] = f(); // x and y refer to elements in a copy of the array return value
auto& [ xr, yr ] = f(); // xr and yr refer to elements in the array referred to by f's return value
—end example
```

Otherwise, if the qualified-id std::tuple_size<E> names a complete type, the expression std::tuple_size<E>::value shall be a well-formed integral constant expression and the number of elements in the identifier-list shall be equal to the value of that expression. The unqualified-id get is looked up in the scope of \(E\) by class member access lookup (6.4.5), and if that finds at least one declaration, the initializer is \(e.get<i>()\).
Otherwise, the initializer is `get<i>(e)`, where `get` is looked up in the associated namespaces (6.4.2). In either case, `get<i>` is interpreted as a template-id. [Note: Ordinary unqualified lookup (6.4.1) is not performed. —end note] In either case, `e` is an lvalue if the type of the entity `e` is an lvalue reference and an xvalue otherwise. Given the type `T_i` designated by `std::tuple_element<i, E>::type`, each `v_i` is a variable of type “reference to `T_i`” initialized with the initializer, where the reference is an lvalue reference if the initializer is an lvalue and an rvalue reference otherwise; the referenced type is `T_i`.

Otherwise, all of `E`’s non-static data members shall be public direct members of `E` or of the same unambiguous public base class of `E`. `E` shall not have an anonymous union member, and the number of elements in the identifier-list shall be equal to the number of non-static data members of `E`. Designating the non-static data members of `E` as `m_0, m_1, m_2, ...` (in declaration order), each `v_i` is the name of an lvalue that refers to the member `m_i` of `e` and whose type is `cv T_i`, where `T_i` is the declared type of that member; the referenced type is `cv T_i`. The lvalue is a bit-field if that member is a bit-field. [Example:

```
struct S { int x1 : 2; volatile double y1; };  
S f();  
const auto [ x, y ] = f();
```

The type of the id-expression `x` is “`const int`”, the type of the id-expression `y` is “`const volatile double`”. —end example]

### 11.6 Initializers

1 A declarator can specify an initial value for the identifier being declared. The identifier designates a variable being initialized. The process of initialization described in the remainder of 11.6 applies also to initializations specified by other syntactic contexts, such as the initialization of function parameters (8.2.2) or the initialization of return values (9.6.3).

```
initializer:
    brace-or-equal-initializer
    ( expression-list )

brace-or-equal-initializer:
    = initializer-clause
    braced-init-list

initializer-clause:
    assignment-expression
    braced-init-list

initializer-list:
    initializer-clause ... opt
    initializer-list , initializer-clause ... opt

braced-init-list:
    { initializer-list , opt }
    { }

expr-or-braced-init-list:
    expression
    braced-init-list
```

2 Except for objects declared with the `constexpr` specifier, for which see 10.1.5, an `initializer` in the definition of a variable can consist of arbitrary expressions involving literals and previously declared variables and functions, regardless of the variable’s storage duration. [Example:

```
int f(int);  
int a = 2;  
int b = f(a);  
int c(b);  
```
A declaration of a block-scope variable with external or internal linkage that has an *initializer* is ill-formed.

To **zero-initialize** an object or reference of type \( T \) means:

1. If \( T \) is a scalar type (6.9), the object is initialized to the value obtained by converting the integer literal 0 (zero) to \( T \).
2. If \( T \) is a (possibly cv-qualified) non-union class type, each non-static data member, each non-virtual base class subobject, and, if the object is not a base class subobject, each virtual base class subobject is zero-initialized and padding is initialized to zero bits;
3. If \( T \) is a (possibly cv-qualified) union type, the object’s first non-static named data member is zero-initialized and padding is initialized to zero bits;
4. If \( T \) is an array type, each element is zero-initialized;
5. If \( T \) is a reference type, no initialization is performed.

To **default-initialize** an object of type \( T \) means:

1. If \( T \) is a (possibly cv-qualified) class type (Clause 12), constructors are considered. The applicable constructors are enumerated (16.3.1.3), and the best one for the *initializer* () is chosen through overload resolution (16.3). The constructor thus selected is called, with an empty argument list, to initialize the object.
2. If \( T \) is an array type, each element is default-initialized.
3. Otherwise, no initialization is performed.

A class type \( T \) is **const-default-constructible** if default-initialization of \( T \) would invoke a user-provided constructor of \( T \) (not inherited from a base class) or if

1. Each direct non-variant non-static data member \( M \) of \( T \) has a default member initializer or, if \( M \) is of class type \( X \) (or array thereof), \( X \) is const-default-constructible,
2. If \( T \) is a union with at least one non-static data member, exactly one variant member has a default member initializer,
3. If \( T \) is not a union, for each anonymous union member with at least one non-static data member (if any), exactly one non-static data member has a default member initializer, and
4. Each potentially constructed base class of \( T \) is const-default-constructible.

If a program calls for the default-initialization of an object of a const-qualified type \( T \), \( T \) shall be a const-default-constructible class type or array thereof.

To **value-initialize** an object of type \( T \) means:

1. If \( T \) is a (possibly cv-qualified) class type (Clause 12) with either no default constructor (15.1) or a default constructor that is user-provided or deleted, then the object is default-initialized;
2. If \( T \) is a (possibly cv-qualified) class type without a user-provided or deleted default constructor, then the object is zero-initialized and the semantic constraints for default-initialization are checked, and if \( T \) has a non-trivial default constructor, the object is default-initialized;
3. If \( T \) is an array type, then each element is value-initialized;

---

104) As specified in 7.11, converting an integer literal whose value is 0 to a pointer type results in a null pointer value.
otherwise, the object is zero-initialized.

A program that calls for default-initialization or value-initialization of an entity of reference type is ill-formed.

[Note: Every object of static storage duration is zero-initialized at program startup before any other initialization takes place. In some cases, additional initialization is done later. — end note]

An object whose initializer is an empty set of parentheses, i.e., \( () \), shall be value-initialized.

[Note: Since \( () \) is not permitted by the syntax for initializer,
\( X \ a(); \)

is not the declaration of an object of class \( X \), but the declaration of a function taking no argument and returning an \( X \). The form \( () \) is permitted in certain other initialization contexts (8.3.4, 8.2.3, 15.6.2). — end note]

If no initializer is specified for an object, the object is default-initialized. When storage for an object with automatic or dynamic storage duration is obtained, the object has an indeterminate value, and if no initialization is performed for the object, that object retains an indeterminate value until that value is replaced (8.18). [Note: Objects with static or thread storage duration are zero-initialized, see 6.6.2. — end note] If an indeterminate value is produced by an evaluation, the behavior is undefined except in the following cases:

1. If an indeterminate value of unsigned narrow character type (6.9.1) or \( \text{std::byte} \) type (21.2.1) is produced by the evaluation of:
   
   1.1. the second or third operand of a conditional expression (8.16),
   1.1.2. the right operand of a comma expression (8.19),
   1.1.3. the operand of a cast or conversion (7.8, 8.2.3, 8.2.9, 8.4) to an unsigned narrow character type or \( \text{std::byte} \) type (21.2.1), or
   1.1.4. a discarded-value expression (Clause 8),

   then the result of the operation is an indeterminate value.

2. If an indeterminate value of unsigned narrow character type or \( \text{std::byte} \) type is produced by the evaluation of the right operand of a simple assignment operator (8.18) whose first operand is an lvalue of unsigned narrow character type or \( \text{std::byte} \) type, an indeterminate value replaces the value of the object referred to by the left operand.

3. If an indeterminate value of unsigned narrow character type is produced by the evaluation of the initialization expression when initializing an object of unsigned narrow character type, that object is initialized to an indeterminate value.

4. If an indeterminate value of unsigned narrow character type or \( \text{std::byte} \) type is produced by the evaluation of the initialization expression when initializing an object of \( \text{std::byte} \) type, that object is initialized to an indeterminate value.

[Example:

\[
\text{int } f(\text{bool } b) \{ \\
\text{unsigned } \text{char } c; \\
\text{unsigned } \text{char } d = c; \quad \text{// OK, } d \text{ has an indeterminate value} \\
\text{int } e = d; \quad \text{// undefined behavior} \\
\text{return } b \text{ ? } d : 0; \quad \text{// undefined behavior if } b \text{ is true} \\
\}\]

— end example]

An initializer for a static member is in the scope of the member’s class. [Example:

\[
\text{int } a; \\
\]

§ 11.6
If the entity being initialized does not have class type, the *expression-list* in a parenthesized initializer shall be a single expression.

The initialization that occurs in the = form of a *brace-or-equal-initializer* or *condition* (9.4), as well as in argument passing, function return, throwing an exception (18.1), handling an exception (18.3), and aggregate member initialization (11.6.1), is called *copy-initialization*. [Note: Copy-initialization may invoke a move (15.8). — end note]

The initialization that occurs in the forms

```c
T x(a);
T x{a};
```

as well as in *new* expressions (8.3.4), *static_cast* expressions (8.2.9), functional notation type conversions (8.2.3), *mem-initializers* (15.6.2), and the *braced-init-list* form of a *condition* is called *direct-initialization*.

The semantics of initializers are as follows. The *destination type* is the type of the object or reference being initialized and the *source type* is the type of the initializer expression. If the initializer is not a single (possibly parenthesized) expression, the source type is not defined.

(17.1) — If the initializer is a (non-parenthesized) *braced-init-list* or is = *braced-init-list*, the object or reference is list-initialized (11.6.4).

(17.2) — If the destination type is a reference type, see 11.6.3.

(17.3) — If the destination type is an array of characters, an array of char16_t, an array of char32_t, or an array of wchar_t, and the initializer is a string literal, see 11.6.2.

(17.4) — If the initializer is (), the object is value-initialized.

(17.5) — Otherwise, if the destination type is an array, the program is ill-formed.

(17.6) — If the destination type is a (possibly cv-qualified) class type:

(17.6.1) — If the initializer expression is a prvalue and the cv-unqualified version of the source type is the same class as the class of the destination, the initializer expression is used to initialize the destination object. [Example: T x = T(T(T())); calls the T default constructor to initialize x. — end example]

(17.6.2) — Otherwise, if the initialization is direct-initialization, or if it is copy-initialization where the cv-unqualified version of the source type is the same class as, or a derived class of, the class of the destination, constructors are considered. The applicable constructors are enumerated (16.3.1.3), and the best one is chosen through overload resolution (16.3). The constructor so selected is called to initialize the object, with the initializer expression or *expression-list* as its argument(s). If no constructor applies, or the overload resolution is ambiguous, the initialization is ill-formed.

(17.6.3) — Otherwise (i.e., for the remaining copy-initialization cases), user-defined conversion sequences that can convert from the source type to the destination type or (when a conversion function is used) to a derived class thereof are enumerated as described in 16.3.1.4, and the best one is chosen through overload resolution (16.3). If the conversion cannot be done or is ambiguous, the initialization is ill-formed. The function selected is called with the initializer expression as its argument; if the

§ 11.6
function is a constructor, the call is a prvalue of the cv-unqualified version of the destination type whose result object is initialized by the constructor. The call is used to direct-initialize, according to the rules above, the object that is the destination of the copy-initialization.

(17.7) — Otherwise, if the source type is a (possibly cv-qualified) class type, conversion functions are considered. The applicable conversion functions are enumerated (16.3.1.5), and the best one is chosen through overload resolution (16.3). The user-defined conversion so selected is called to convert the initializer expression into the object being initialized. If the conversion cannot be done or is ambiguous, the initialization is ill-formed.

(17.8) — Otherwise, the initial value of the object being initialized is the (possibly converted) value of the initializer expression. Standard conversions (Clause 7) will be used, if necessary, to convert the initializer expression to the cv-unqualified version of the destination type; no user-defined conversions are considered. If the conversion cannot be done, the initialization is ill-formed. When initializing a bit-field with a value that it cannot represent, the resulting value of the bit-field is implementation-defined. [ Note: An expression of type “cv1 T” can initialize an object of type “cv2 T” independently of the cv-qualifiers cv1 and cv2. ]

```
int a;
const int b = a;
int c = b;
end note]
```

18 An initializer-clause followed by an ellipsis is a pack expansion (17.5.3).

19 If the initializer is a parenthesized expression-list, the expressions are evaluated in the order specified for function calls (8.2.2).

20 An object whose initialization has completed is deemed to be constructed, even if no constructor of the object’s class is invoked for the initialization. [ Note: Such an object might have been value-initialized or initialized by aggregate initialization (11.6.1) or by an inherited constructor (15.6.3). — end note ]

21 A declaration that specifies the initialization of a variable, whether from an explicit initializer or by default-initialization, is called the initializing declaration of that variable. [ Note: In most cases this is the defining declaration (6.1) of the variable, but the initializing declaration of a non-inline static data member (12.2.3.2) might be the declaration within the class definition and not the definition at namespace scope. — end note ]

11.6.1 Aggregates

1 An aggregate is an array or a class (Clause 12) with

(1.1) — no user-provided, explicit, or inherited constructors (15.1),

(1.2) — no private or protected non-static data members (Clause 14),

(1.3) — no virtual functions (13.3), and

(1.4) — no virtual, private, or protected base classes (13.1).

[ Note: Aggregate initialization does not allow accessing protected and private base class’ members or constructors. — end note ]

2 The elements of an aggregate are:

(2.1) — for an array, the array elements in increasing subscript order, or

(2.2) — for a class, the direct base classes in declaration order, followed by the direct non-static data members (12.2) that are not members of an anonymous union, in declaration order.

3 When an aggregate is initialized by an initializer list as specified in 11.6.4, the elements of the initializer list are taken as initializers for the elements of the aggregate, in order. Each element is copy-initialized from the corresponding initializer-clause. If the initializer-clause is an expression and a narrowing conversion (11.6.4)
is required to convert the expression, the program is ill-formed. [Note: If an initializer-clause is itself an initializer list, the element is list-initialized, which will result in a recursive application of the rules in this section if the element is an aggregate. — end note] [Example:

```c
struct A {
    int x;
    struct B {
        int i;
        int j;
    } b;
} a = { 1, { 2, 3 } };
```

initializes `a.x` with 1, `a.b.i` with 2, `a.b.j` with 3.

```c
struct base1 { int b1, b2 = 42; };
struct base2 {
    base2() {
        b3 = 42;
    }
    int b3;
};
struct derived : base1, base2 {
    int d;
};
```

derived d1{{1, 2}, {}, 4};
derived d2{{}, {}, 4};

initializes `d1.b1` with 1, `d1.b2` with 2, `d1.b3` with 42, `d1.d` with 4, and `d2.b1` with 0, `d2.b2` with 42, `d2.b3` with 42, `d2.d` with 4. — end example]

4 An aggregate that is a class can also be initialized with a single expression not enclosed in braces, as described in 11.6.

5 An array of unknown bound initialized with a brace-enclosed initializer-list containing `n` initializer-clauses, where `n` shall be greater than zero, is defined as having `n` elements (11.3.4). [Example:

```c
int x[] = { 1, 3, 5 };
```

declares and initializes `x` as a one-dimensional array that has three elements since no size was specified and there are three initializers. — end example] An empty initializer list `{}` shall not be used as the initializer-clause for an array of unknown bound.105 [Note: A default member initializer does not determine the bound for a member array of unknown bound. Since the default member initializer is ignored if a suitable mem-initializer is present (15.6.2), the default member initializer is not considered to initialize the array of unknown bound. [Example:

```c
struct S {
    int y[] = { 0 }; // error: non-static data member of incomplete type
};
```

— end example] — end note]

6 [Note: Static data members and unnamed bit-fields are not considered elements of the aggregate. [Example:

```c
struct A {
    int i;
    static int s;
    int j;
    int :17;
```

---

105) The syntax provides for empty initializer-lists, but nonetheless C++ does not have zero length arrays.
int k;
} a = { 1, 2, 3 };

Here, the second initializer 2 initializes a.j and not the static data member A::s, and the third initializer 3 initializes a.k and not the unnamed bit-field before it. — end example — end note

An initializer-list is ill-formed if the number of initializer-clauses exceeds the number of elements to initialize. [Example:
char cv[4] = { 'a', 's', 'd', 'f', 0 }; // error
is ill-formed. — end example]

If there are fewer initializer-clauses in the list than there are elements in a non-union aggregate, then each element not explicitly initialized is initialized as follows:

(8.1) — If the element has a default member initializer (12.2), the element is initialized from that initializer.
(8.2) — Otherwise, if the element is not a reference, the element is copy-initialized from an empty initializer list (11.6.4).
(8.3) — Otherwise, the program is ill-formed.

If the aggregate is a union and the initializer list is empty, then
(8.4) — if any variant member has a default member initializer, that member is initialized from its default member initializer;
(8.5) — otherwise, the first member of the union (if any) is copy-initialized from an empty initializer list.

[Example:
struct S { int a; const char* b; int c; int d = b[a]; };
S ss = { 1, "asdf" }; initializes ss.a with 1, ss.b with "asdf", ss.c with the value of an expression of the form int{} (that is, 0), and ss.d with the value of ss.b[ss.a] (that is, 's'), and in
struct X { int i, j, k = 42; };
X a[] = { 1, 2, 3, 4, 5, 6 };
X b[2] = { { 1, 2, 3 }, { 4, 5, 6 } };
a and b have the same value — end example]

If a reference member is initialized from its default member initializer and a potentially-evaluated subexpression thereof is an aggregate initialization that would use that default member initializer, the program is ill-formed. [Example:
struct A;
extern A a;
struct A {
    const A& a1 { A(a,a) }; // OK
    const A& a2 { A{} }; // error
};
a a(a,a); // OK
— end example]

If an aggregate class C contains a subaggregate element e with no elements, the initializer-clause for e shall not be omitted from an initializer-list for an object of type C unless the initializer-clauses for all elements of C following e are also omitted. [Example:
struct S { } s;
struct A {
    S s1;
When initializing a multi-dimensional array, the *initializer-clauses* initialize the elements with the last (rightmost) index of the array varying the fastest (11.3.4). [Example:

```c
int x[2][2] = { 3, 1, 4, 2 };
```

initializes \( x[0][0] \) to 3, \( x[0][1] \) to 1, \( x[1][0] \) to 4, and \( x[1][1] \) to 2. On the other hand,

```c
float y[4][3] = {
    { 1 }, { 2 }, { 3 }, { 4 }
};
```

initializes the first column of \( y \) (regarded as a two-dimensional array) and leaves the rest zero. —end example]

Braces can be elided in an *initializer-list* as follows. If the *initializer-list* begins with a left brace, then the succeeding comma-separated list of *initializer-clauses* initializes the elements of a subaggregate; it is erroneous for there to be more *initializer-clauses* than elements. If, however, the *initializer-list* for a subaggregate does not begin with a left brace, then only enough *initializer-clauses* from the list are taken to initialize the elements of the subaggregate; any remaining *initializer-clauses* are left to initialize the next element of the aggregate of which the current subaggregate is an element. [Example:

```c
float y[4][3] = {
    { 1, 3, 5 },
    { 2, 4, 6 },
    { 3, 5, 7 },
};
```

is a completely-braced initialization: 1, 3, and 5 initialize the first row of the array \( y[0] \), namely \( y[0][0] \), \( y[0][1] \), and \( y[0][2] \). Likewise the next two lines initialize \( y[1] \) and \( y[2] \). The initializer ends early and therefore \( y[3] \)'s elements are initialized as if explicitly initialized with an expression of the form \( \text{float}() \), that is, are initialized with 0.0. In the following example, braces in the *initializer-list* are elided; however the *initializer-list* has the same effect as the completely-braced *initializer-list* of the above example,

```c
float y[4][3] = {
    1, 3, 5, 2, 4, 6, 3, 5, 7
};
```

The initializer for \( y \) begins with a left brace, but the one for \( y[0] \) does not, therefore three elements from the list are used. Likewise the next three are taken successively for \( y[1] \) and \( y[2] \). —end example]

All implicit type conversions (Clause 7) are considered when initializing the element with an *assignment-expression*. If the *assignment-expression* can initialize an element, the element is initialized. Otherwise, if the element is itself a subaggregate, brace elision is assumed and the *assignment-expression* is considered for the initialization of the first element of the subaggregate. [Note: As specified above, brace elision cannot apply to subaggregates with no elements; an *initializer-clause* for the entire subobject is required. —end note]

[Example:
struct A {
    int i;
    operator int();
};
struct B {
    A a1, a2;
    int z;
};
A a;
B b = { 4, a, a };

Braces are elided around the *initializer-clause* for `b.a1.i`. `b.a1.i` is initialized with 4, `b.a2` is initialized with `a`, `b.z` is initialized with whatever `a.operator int()` returns.  —end example

[Note: An aggregate array or an aggregate class may contain elements of a class type with a user-provided constructor (15.1). Initialization of these aggregate objects is described in 15.6.1. —end note]

When a union is initialized with a brace-enclosed initializer, the braces shall only contain an *initializer-clause* for the first non-static data member of the union.  [Example:

```c
union u { int a; const char* b; };
    u a = { 1 };
    u b = a;
    u c = 1;  // error
    u d = { 0, "asdf" };  // error
    u e = { "asdfs" };  // error

—end example]

[Note: As described above, the braces around the *initializer-clause* for a union member can be omitted if the union is a member of another aggregate. —end note]

### 11.6.2 Character arrays

[dcl.init.string]

An array of narrow character type (6.9.1), `char16_t` array, `char32_t` array, or `wchar_t` array can be initialized by a narrow string literal, `char16_t` string literal, `char32_t` string literal, or wide string literal, respectively, or by an appropriately-typed string literal enclosed in braces (5.13.5). Successive characters of the value of the string literal initialize the elements of the array.  [Example:

```c
char msg[] = "Syntax error on line %s\n";
```

shows a character array whose members are initialized with a *string-literal*. Note that because `\n` is a single character and because a trailing `\0` is appended, `sizeof(msg)` is 25.  —end example]

There shall not be more initializers than there are array elements.  [Example:

```c
char cv[4] = "asdf";  // error
```

is ill-formed since there is no space for the implied trailing `\0`.  —end example]

If there are fewer initializers than there are array elements, each element not explicitly initialized shall be zero-initialized (11.6).

### 11.6.3 References

[dcl.init.ref]

A variable whose declared type is “reference to type T” (11.3.2) shall be initialized.  [Example:

```c
int g(int) noexcept;
void f() {
    int i;
```
2 A reference cannot be changed to refer to another object after initialization. [Note: Assignment to a reference assigns to the object referred to by the reference (8.18). —end note] Argument passing (8.2.2) and function value return (9.6.3) are initializations.

3 The initializer can be omitted for a reference only in a parameter declaration (11.3.5), in the declaration of a function return type, in the declaration of a class member within its class definition (12.2), and where the extern specifier is explicitly used. [Example:

```c
int& r1; // error: initializer missing
extern int& r2; // OK
```
—end example]

4 Given types “cv1 T1” and “cv2 T2”, “cv1 T1” is reference-related to “cv2 T2” if T1 is the same type as T2, or T1 is a base class of T2. “cv1 T1” is reference-compatible with “cv2 T2” if

(4.1) T1 is reference-related to T2, or

(4.2) T2 is “noexcept function” and T1 is “function”, where the function types are otherwise the same, and cv1 is the same cv-qualification as, or greater cv-qualification than, cv2. In all cases where the reference-related or reference-compatible relationship of two types is used to establish the validity of a reference binding, and T1 is a base class of T2, a program that necessitates such a binding is ill-formed if T1 is an inaccessible (Clause 14) or ambiguous (13.2) base class of T2.

5 A reference to type “cv1 T1” is initialized by an expression of type “cv2 T2” as follows:

(5.1) If the reference is an lvalue reference and the initializer expression

(5.1.1) is an lvalue (but is not a bit-field), and “cv1 T1” is reference-compatible with “cv2 T2”, or

(5.1.2) has a class type (i.e., T2 is a class type), where T1 is not reference-related to T2, and can be converted to an lvalue of type “cv3 T3”, where “cv1 T1” is reference-compatible with “cv3 T3” (this conversion is selected by enumerating the applicable conversion functions (16.3.1.6) and choosing the best one through overload resolution (16.3)),

then the reference is bound to the initializer expression lvalue in the first case and to the lvalue result of the conversion in the second case (or, in either case, to the appropriate base class subobject of the object). [Note: The usual lvalue-to-rvalue (7.1), array-to-pointer (7.2), and function-to-pointer (7.3) standard conversions are not needed, and therefore are suppressed, when such direct bindings to lvalues are done. —end note]

[Example:

```c
double d = 2.0;
double& rd = d; // rd refers to d
const double& rcd = d; // rcd refers to d
```

106) This requires a conversion function (15.3.2) returning a reference type.
struct A {};  
struct B : A { operator int&(); } b;  
A& ra = b; // ra refers to A subobject in b  
const A& rca = b; // rca refers to A subobject in b  
int& ir = B(); // ir refers to the result of B::operator int&

— end example ]

(5.2) — Otherwise, the reference shall be an lvalue reference to a non-volatile const type (i.e., cv1 shall be const), or the reference shall be an rvalue reference. [ Example:

double& rd2 = 2.0; // error: not an lvalue and reference not const  
int i = 2;  
double& rd3 = i; // error: type mismatch and reference not const

— end example ]

(5.2.1) — If the initializer expression

(5.2.1.1) — is an rvalue (but not a bit-field) or function lvalue and “cv1 T1” is reference-compatible with “cv2 T2”, or

(5.2.1.2) — has a class type (i.e., T2 is a class type), where T1 is not reference-related to T2, and can be converted to an rvalue or function lvalue of type “cv3 T3”, where “cv1 T1” is reference-compatible with “cv3 T3” (see 16.3.1.6),

then the value of the initializer expression in the first case and the result of the conversion in the second case is called the converted initializer. If the converted initializer is a prvalue, its type T4 is adjusted to type “cv1 T4” (7.5) and the temporary materialization conversion (7.4) is applied. In any case, the reference is bound to the resulting glvalue (or to an appropriate base class subobject).

[ Example:

struct A {};  
struct B : A { } b;  
extern B f();  
const & rca2 = f(); // bound to the A subobject of the B rvalue.  
A& rra = f(); // same as above  
struct X {
  operator B();  
  operator int&();  
} x;  
const & r = x; // bound to the A subobject of the result of the conversion  
int i2 = 42;  
int& rri = static_cast<int&>(i2); // bound directly to i2  
B& rrb = x; // bound directly to the result of operator B

— end example ]

(5.2.2) — Otherwise:

(5.2.2.1) — If T1 or T2 is a class type and T1 is not reference-related to T2, user-defined conversions are considered using the rules for copy-initialization of an object of type “cv1 T1” by user-defined conversion (11.6, 16.3.1.4, 16.3.1.5); the program is ill-formed if the corresponding non-reference copy-initialization would be ill-formed. The result of the call to the conversion function, as described for the non-reference copy-initialization, is then used to direct-initialize the reference. For this direct-initialization, user-defined conversions are not considered.

(5.2.2.2) — Otherwise, the initializer expression is implicitly converted to a prvalue of type “cv1 T1”. The temporary materialization conversion is applied and the reference is bound to the result.

§ 11.6.3
If T1 is reference-related to T2:

(5.2.2.3) — cvT1 shall be the same cv-qualification as, or greater cv-qualification than, cvT2; and

(5.2.2.4) — if the reference is an rvalue reference, the initializer expression shall not be an lvalue.

[Example:

```c
struct Banana {;
struct Enigma { operator const Banana(); };
struct Alaska { operator Banana&(); };
void enigmatic()
{
    typedef const Banana ConstBanana;
    Banana &&banana1 = ConstBanana(); // ill-formed
    Banana &&banana2 = Enigma();      // ill-formed
    Banana &&banana3 = Alaska();      // ill-formed
}
const double& rcd2 = 2;       // rcd2 refers to temporary with value 2.0
double&& rrd = 2;             // rrd refers to temporary with value 2.0
const volatile int cvi = 1;
const int& r2 = cvi;          // error: cv-qualifier dropped
struct A { operator volatile int&(); } a;
const int& r3 = a;            // error: cv-qualifier dropped
                          // from result of conversion function
double d2 = 1.0;
double&& rrd2 = d2;          // error: initializer is lvalue of related type
struct X { operator int&&(); }; int&& rri2 = X();   // error: result of conversion function is lvalue of related type
int i3 = 2;
double&& rrd3 = i3;          // rrd3 refers to temporary with value 2.0
```

— end example]

In all cases except the last (i.e., implicitly converting the initializer expression to the underlying type of the reference), the reference is said to bind directly to the initializer expression.

[Note: 15.2 describes the lifetime of temporaries bound to references. — end note]

### 11.6.4 List-initialization

List-initialization is initialization of an object or reference from a braced-init-list. Such an initializer is called an initializer list, and the comma-separated initializer-clauses of the list are called the elements of the initializer list. An initializer list may be empty. List-initialization can occur in direct-initialization or copy-initialization contexts; list-initialization in a direct-initialization context is called direct-list-initialization and list-initialization in a copy-initialization context is called copy-list-initialization. [Note: List-initialization can be used

(1.1) — as the initializer in a variable definition (11.6)
(1.2) — as the initializer in a new-expression (8.3.4)
(1.3) — in a return statement (9.6.3)
(1.4) — as a for-range-initializer (9.5)
(1.5) — as a function argument (8.2.2)
(1.6) — as a subscript (8.2.1)
(1.7) — as an argument to a constructor invocation (11.6, 8.2.3)
(1.8) — as an initializer for a non-static data member (12.2)
A constructor is an *initializer-list constructor* if its first parameter is of type `std::initializer_list<E>` or reference to possibly cv-qualified `std::initializer_list<E>` for some type `E`, and either there are no other parameters or else all other parameters have default arguments (11.3.6). [Note: Initializer-list constructors are favored over other constructors in list-initialization (16.3.1.7). Passing an initializer list as the argument to the constructor template `template<class T> C(T)` of a class `C` does not create an initializer-list constructor, because an initializer list argument causes the corresponding parameter to be a non-deduced context (17.8.2.1). —end note] The template `std::initializer_list` is not predefined; if the header `<initializer_list>` is not included prior to a use of `std::initializer_list` — even an implicit use in which the type is not named (10.1.7.4) — the program is ill-formed.

3 List-initialization of an object or reference of type `T` is defined as follows:

(3.1) If `T` is an aggregate class and the initializer list has a single element of type `cv U`, where `U` is `T` or a class derived from `T`, the object is initialized from that element (by copy-initialization for copy-list-initialization, or by direct-initialization for direct-list-initialization).

(3.2) Otherwise, if `T` is a character array and the initializer list has a single element that is an appropriately-typed string literal (11.6.2), initialization is performed as described in that section.

(3.3) Otherwise, if `T` is an aggregate, aggregate initialization is performed (11.6.1).

[Example:
```cpp
double ad[] = { 1, 2.0 };       // OK
int a1[] = { 1, 2.0 };          // error: narrowing

struct S2 {
    int m1;
    double m2, m3;
};
S2 s21 = { 1, 2, 3.0 };         // OK
S2 s22 { 1.0, 2, 3 };           // error: narrowing
S2 s23 { };                     // OK: default to 0,0,0
```
—end example]

(3.4) Otherwise, if the initializer list has no elements and `T` is a class type with a default constructor, the object is value-initialized.

(3.5) Otherwise, if `T` is a specialization of `std::initializer_list<E>`, the object is constructed as described below.

(3.6) Otherwise, if `T` is a class type, constructors are considered. The applicable constructors are enumerated and the best one is chosen through overload resolution (16.3, 16.3.1.7). If a narrowing conversion (see below) is required to convert any of the arguments, the program is ill-formed.

§ 11.6.4
Example:

```cpp
struct S {
    S(std::initializer_list<double>); // #1
    S(std::initializer_list<int>);  // #2
    S();                           // #3

    S s1 = { 1.0, 2.0, 3.0 };       // invoke #1
    S s2 = { 1, 2, 3 };             // invoke #2
    S s3 = { };                    // invoke #3
} — end example
```

Example:

```cpp
struct Map {
    Map(std::initializer_list<std::pair<std::string,int>>);
};
Map ship = {{"Sophie",14}, {"Surprise",28}};
— end example
```

Example:

```cpp
struct S {
    // no initializer-list constructors
    S(int, double, double);     // #1
    S();                       // #2

    S s1 = { 1, 2, 3.0 };       // OK: invoke #1
    S s2 = { 1.0, 2, 3 };       // error: narrowing
    S s3 = { };                // OK: invoke #2
} — end example
```

— (3.7) — Otherwise, if T is an enumeration with a fixed underlying type (10.2), the initializer-list has a single element v, and the initialization is direct-list-initialization, the object is initialized with the value T(v) (8.2.3); if a narrowing conversion is required to convert v to the underlying type of T, the program is ill-formed.  

Example:

```cpp
enum byte : unsigned char { };
byte b { 42 };                   // OK
byte c = { 42 };                // error
byte d = byte{ 42 };            // OK; same value as b
byte e { -1 };                  // error

struct A { byte b; };
A a1 = { { 42 } };              // error
A a2 = { byte{ 42 } };          // OK

void f(byte);
f({ 42 });                     // error
```

— (3.8) — Otherwise, if the initializer list has a single element of type E and either T is not a reference type or its

§ 11.6.4
referenced type is reference-related to \( \mathbf{E} \), the object or reference is initialized from that element (by copy-initialization for copy-list-initialization, or by direct-initialization for direct-list-initialization); if a narrowing conversion (see below) is required to convert the element to \( \mathbf{T} \), the program is ill-formed.

[Example:

\[
\begin{align*}
\text{int } x1 \{2\}; & \quad \text{// OK} \\
\text{int } x2 \{2.0\}; & \quad \text{// error: narrowing}
\end{align*}
\]

— end example]

(3.9)

— Otherwise, if \( \mathbf{T} \) is a reference type, a prvalue of the type referenced by \( \mathbf{T} \) is generated. The prvalue initializes its result object by copy-list-initialization or direct-list-initialization, depending on the kind of initialization for the reference. The prvalue is then used to direct-initialize the reference. [Note: As usual, the binding will fail and the program is ill-formed if the reference type is an lvalue reference to a non-const type. — end note]

[Example:

\[
\begin{align*}
\text{struct } \& r1 = \{1, 2, 3.0\}; & \quad \text{// OK: invoke #1} \\
\text{const } \& r2 \{\text{"Spinach"}\}; & \quad \text{// OK: invoke #2} \\
\text{S&& } r3 = \{1, 2, 3\}; & \quad \text{// error: initializer is not an lvalue} \\
\text{const } \& i1 = \{1\}; & \quad \text{// OK} \\
\text{const } \& i2 = \{1.1\}; & \quad \text{// error: narrowing} \\
\text{const int } (&i2)[2] = \{1, 2\}; & \quad \text{// OK: i2 is bound to temporary array}
\end{align*}
\]

— end example]

(3.10)

— Otherwise, if the initializer list has no elements, the object is value-initialized.

[Example:

\[
\begin{align*}
\text{int** } pp \{\}; & \quad \text{// initialized to null pointer}
\end{align*}
\]

— end example]

(3.11)

— Otherwise, the program is ill-formed.

[Example:

\[
\begin{align*}
\text{struct A } \{ \text{int } i; \text{int } j; \}; \\
A a1 \{1, 2\}; & \quad \text{// aggregate initialization} \\
A a2 \{1.2\}; & \quad \text{// error: narrowing} \\
\text{struct B } \{ \\
B(\text{std::initializer_list<int>}); \}
\end{align*}
\]

— end example]

\[ \text{§ 11.6.4} \]
Within the *initializer-list* of a *braced-init-list*, the *initializer-clauses*, including any that result from pack expansions (17.5.3), are evaluated in the order in which they appear. That is, every value computation and side effect associated with a given *initializer-clause* is sequenced before every value computation and side effect associated with any *initializer-clause* that follows it in the comma-separated list of the *initializer-list*. [Note: This evaluation ordering holds regardless of the semantics of the initialization; for example, it applies when the elements of the *initializer-list* are interpreted as arguments of a constructor call, even though ordinarily there are no sequencing constraints on the arguments of a call. — end note]

An object of type `std::initializer_list<E>` is constructed from an initializer list as if the implementation generated and materialized (7.4) a prvalue of type “array of N const E”, where N is the number of elements in the initializer list. Each element of that array is copy-initialized with the corresponding element of the initializer list, and the `std::initializer_list<E>` object is constructed to refer to that array. [Note: A constructor or conversion function selected for the copy shall be accessible (Clause 14) in the context of the initializer list. — end note] If a narrowing conversion is required to initialize any of the elements, the program is ill-formed. [Example:

```c++
struct X {
    X(std::initializer_list<double> v);
};
X x{1,2,3};
```

The initialization will be implemented in a way roughly equivalent to this:

```c++
const double __a[3] = {double{1}, double{2}, double{3}};
X x(std::initializer_list<double>(__a, __a+3));
```

assuming that the implementation can construct an *initializer_list* object with a pair of pointers. — end example]

The array has the same lifetime as any other temporary object (15.2), except that initializing an *initializer_list* object from the array extends the lifetime of the array exactly like binding a reference to a temporary. [Example:

```c++
typedef std::complex<double> cmplx;
std::vector<cmplx> v1 = {1, 2, 3};
void f() {
    std::vector<cmplx> v2{1, 2, 3};
    std::initializer_list<int> i3 = {1, 2, 3};
}
```

For v1 and v2, the *initializer_list* object is a parameter in a function call, so the array created for `{1, 2, 3}` has full-expression lifetime. For i3, the *initializer_list* object is a variable, so the array persists for the lifetime of the variable. For i4, the *initializer_list* object is initialized in the constructor’s *ctor-initializer* as if by binding a temporary array to a reference member, so the program is ill-formed (15.6.2). — end example] [Note: The implementation is free to allocate the array in read-only memory if an explicit array with the same initializer could be so allocated. — end note]

A *narrowing conversion* is an implicit conversion

(7.1) from a floating-point type to an integer type, or

(7.2) from `long double` to `double` or `float`, or from `double` to `float`, except where the source is a constant expression and the actual value after conversion is within the range of values that can be represented
(even if it cannot be represented exactly), or

(7.3)  — from an integer type or unscoped enumeration type to a floating-point type, except where the source is a constant expression and the actual value after conversion will fit into the target type and will produce the original value when converted back to the original type, or

(7.4)  — from an integer type or unscoped enumeration type to an integer type that cannot represent all the values of the original type, except where the source is a constant expression whose value after integral promotions will fit into the target type.

[Note: As indicated above, such conversions are not allowed at the top level in list-initializations. — end note]  [Example:

```
int x = 999;            // x is not a constant expression
const int y = 999;
const int z = 99;
char c1 = x;             // OK, though it might narrow (in this case, it does narrow)
char c2{x};              // error: might narrow
char c3{y};              // error: narrows (assuming char is 8 bits)
char c4{z};              // OK: no narrowing needed
unsigned char uc1 = {5}; // OK: no narrowing needed
unsigned char uc2 = {-1}; // error: narrows
unsigned int ui1 = {-1}; // error: narrows
signed int si1 =
  { (unsigned int)-1 };  // error: narrows
int ii = {2.0};          // error: narrows
float f1 { x };          // error: might narrow
float f2 { 7 };          // OK: 7 can be exactly represented as a float
int f(int);
int a[] =
  { 2, f(2), f(2.0) };  // OK: the double-to-int conversion is not at the top level
  
— end example]
12 Classes

A class is a type. Its name becomes a class-name (12.1) within its scope.

class-name:
  identifier
  simple-template-id

Class-specifiers and elaborated-type-specifiers (10.1.7.3) are used to make class-names. An object of a class consists of a (possibly empty) sequence of members and base class objects.

class-specifier:
  class-head { member-specification_{opt} }

class-head:
  class-key attribute-specifier-seq_{opt} class-head-name class-virt-specifier_{opt} base-clause_{opt}
  class-key attribute-specifier-seq_{opt} base-clause_{opt}

class-head-name:
  nested-name-specifier_{opt} class-name

class-virt-specifier:
  final

class-key:
  class
  struct
  union

A class-specifier whose class-head omits the class-head-name defines an unnamed class. [ Note: An unnamed class thus can’t be final. —end note ]

A class-name is inserted into the scope in which it is declared immediately after the class-name is seen. The class-name is also inserted into the scope of the class itself; this is known as the injected-class-name. For purposes of access checking, the injected-class-name is treated as if it were a public member name. A class-specifier is commonly referred to as a class definition. A class is considered defined after the closing brace of its class-specifier has been seen even though its member functions are in general not yet defined. The optional attribute-specifier-seq appertains to the class; the attributes in the attribute-specifier-seq are thereafter considered attributes of the class whenever it is named.

If a class is marked with the class-virt-specifier final and it appears as a class-or-decltype in a base-clause (Clause 13), the program is ill-formed. Whenever a class-key is followed by a class-head-name, the identifier final, and a colon or left brace, final is interpreted as a class-virt-specifier. [ Example:

```c
struct A;
struct A final {} ;  // OK: definition of struct A,
                      // not value-initialization of variable final

struct X {
  struct C { constexpr operator int() { return 5 ; } } ;
  struct B final : C{ } ;  // OK: definition of nested class B,
                          // not declaration of a bit-field member final
};
```

—end example ]
Complete objects and member subobjects of class type shall have nonzero size.\(^\text{107}\) [Note: Class objects can be assigned, passed as arguments to functions, and returned by functions (except objects of classes for which copying or moving has been restricted; see 15.8). Other plausible operators, such as equality comparison, can be defined by the user; see 16.5. — end note]

A union is a class defined with the class-key union; it holds at most one data member at a time (12.3). [Note: Aggregates of class type are described in 11.6.1. — end note]

A trivially copyable class is a class:

\(\begin{align*}
\text{(6.1)} & \quad \text{— where each copy constructor, move constructor, copy assignment operator, and move assignment operator (15.8, 16.5.3) is either deleted or trivial,} \\
\text{(6.2)} & \quad \text{— that has at least one non-deleted copy constructor, move constructor, copy assignment operator, or move assignment operator, and} \\
\text{(6.3)} & \quad \text{— that has a trivial, non-deleted destructor (15.4).}
\end{align*}\)

A trivial class is a class that is trivially copyable and has one or more default constructors (15.1), all of which are either trivial or deleted and at least one of which is not deleted. [Note: In particular, a trivially copyable or trivial class does not have virtual functions or virtual base classes. — end note]

A class \(S\) is a standard-layout class if it:

\(\begin{align*}
\text{(7.1)} & \quad \text{— has no non-static data members of type non-standard-layout class (or array of such types) or reference,} \\
\text{(7.2)} & \quad \text{— has no virtual functions (13.3) and no virtual base classes (13.1),} \\
\text{(7.3)} & \quad \text{— has the same access control (Clause 14) for all non-static data members,} \\
\text{(7.4)} & \quad \text{— has no non-standard-layout base classes,} \\
\text{(7.5)} & \quad \text{— has at most one base class subobject of any given type,} \\
\text{(7.6)} & \quad \text{— has all non-static data members and bit-fields in the class and its base classes first declared in the same class, and} \\
\text{(7.7)} & \quad \text{— has no element of the set } M(S) \text{ of types (defined below) as a base class}.\(^\text{108}\)
\end{align*}\)

\(M(X)\) is defined as follows:

\(\begin{align*}
\text{(7.8)} & \quad \text{— If } X \text{ is a non-union class type with no (possibly inherited (Clause 13)) non-static data members, the set } M(X) \text{ is empty.} \\
\text{(7.9)} & \quad \text{— If } X \text{ is a non-union class type whose first non-static data member has type } X_0 \text{ (where said member may be an anonymous union), the set } M(X) \text{ consists of } X_0 \text{ and the elements of } M(X_0). \\
\text{(7.10)} & \quad \text{— If } X \text{ is a union type, the set } M(X) \text{ is the union of all } M(U_i) \text{ and the set containing all } U_i, \text{ where each } U_i \text{ is the type of the } i\text{th non-static data member of } X. \\
\text{(7.11)} & \quad \text{— If } X \text{ is an array type with element type } X_e, \text{ the set } M(X) \text{ consists of } X_e \text{ and the elements of } M(X_e). \\
\text{(7.12)} & \quad \text{— If } X \text{ is a non-class, non-array type, the set } M(X) \text{ is empty.}
\end{align*}\)

[Note: \(M(X)\) is the set of the types of all non-base-class subobjects that are guaranteed in a standard-layout class to be at a zero offset in \(X\). — end note]

[Example:

\begin{verbatim}
struct B { int i; };  // standard-layout class
struct C : B { };  // standard-layout class
struct D : C { };  // standard-layout class
struct E : D { char : 4; };  // not a standard-layout class
\end{verbatim}\]

\(^{107}\) Base class subobjects are not so constrained.

\(^{108}\) This ensures that two subobjects that have the same class type and that belong to the same most derived object are not allocated at the same address (8.10).
struct Q {};  
struct S : Q { };  
struct T : Q { };  
struct U : S, T { };  // not a standard-layout class

— end example]

8 A standard-layout struct is a standard-layout class defined with the class-key struct or the class-key class. A standard-layout union is a standard-layout class defined with the class-key union.

9 [ Note: Standard-layout classes are useful for communicating with code written in other programming languages. Their layout is specified in 12.2. — end note ]

10 A POD struct\textsuperscript{109} is a non-union class that is both a trivial class and a standard-layout class, and has no non-static data members of type non-POD struct, non-POD union (or array of such types). Similarly, a POD union is a union that is both a trivial class and a standard-layout class, and has no non-static data members of type non-POD struct, non-POD union (or array of such types). A POD class is a class that is either a POD struct or a POD union.

[ Example:

struct N {  // neither trivial nor standard-layout
int i;
int j;
virtual ~N();
};

struct T {  // trivial but not standard-layout
int i;
private:
int j;
};

struct SL {  // standard-layout but not trivial
int i;
int j;
~SL();
};

struct POD {  // both trivial and standard-layout
int i;
int j;
};

— end example ]

11 If a class-head-name contains a nested-name-specifier, the class-specifier shall refer to a class that was previously declared directly in the class or namespace to which the nested-name-specifier refers, or in an element of the inline namespace set (10.3.1) of that namespace (i.e., not merely inherited or introduced by a using-declaration), and the class-specifier shall appear in a namespace enclosing the previous declaration. In such cases, the nested-name-specifier of the class-head-name of the definition shall not begin with a decltype-specifier.

12.1 Class names

A class definition introduces a new type. [ Example:  

109) The acronym POD stands for “plain old data”.

§ 12.1 239
struct X { int a; };
struct Y { int a; };
X a1;
Y a2;
int a3;

declares three variables of three different types. This implies that

a1 = a2; // error: Y assigned to X
a1 = a3; // error: int assigned to X

are type mismatches, and that

int f(X);
in f(Y);

declare an overloaded (Clause 16) function f() and not simply a single function f() twice. For the same reason,

struct S { int a; };
struct S { int a; }; // error, double definition

is ill-formed because it defines S twice. — end example

A class declaration introduces the class name into the scope where it is declared and hides any class, variable, function, or other declaration of that name in an enclosing scope (6.3). If a class name is declared in a scope where a variable, function, or enumerator of the same name is also declared, then when both declarations are in scope, the class can be referred to only using an elaborated-type-specifier (6.4.4). [ Example:

```c
struct stat {
    // ...
};

stat gstat; // use plain stat to define variable
int stat(struct stat*); // redeclare stat as function

void f() {
    struct stat* ps; // struct prefix needed to name struct stat
    stat(ps); // call stat()
}
```
— end example ] A declaration consisting solely of class-key identifier is either a redeclaration of the name in the current scope or a forward declaration of the identifier as a class name. It introduces the class name into the current scope. [ Example:

```c
struct s { int a; };

void g() {
    struct s; // hide global struct s with a block-scope declaration
    s* p; // refer to local struct s
    struct s { char* p; }; // define local struct s
    struct s; // redeclaration, has no effect
}
```
— end example ] [ Note: Such declarations allow definition of classes that refer to each other. [ Example:

```c
class Vector;

class Matrix {
    // ...
    friend Vector operator*(const Matrix&, const Vector&);
```

§ 12.1 240
class Vector {
    // ...
    friend Vector operator*(const Matrix&, const Vector&);
};

Declaration of friends is described in 14.3, operator functions in 16.5. — end example — end note]

[Note: An elaborated-type-specifier (10.1.7.3) can also be used as a type-specifier as part of a declaration. It differs from a class declaration in that if a class of the elaborated name is in scope the elaborated name will refer to it. — end note] [Example:

```cpp
struct s { int a; }

void g(int s) {
    struct s* p = new struct s; // global s
    p->a = s; // parameter s
}

— end example]

[Note: The declaration of a class name takes effect immediately after the identifier is seen in the class definition or elaborated-type-specifier. For example,

```cpp
class A * A;
```

first specifies A to be the name of a class and then redefines it as the name of a pointer to an object of that class. This means that the elaborated form class A must be used to refer to the class. Such artistry with names can be confusing and is best avoided. — end note]

A typedef-name (10.1.3) that names a class type, or a cv-qualified version thereof, is also a class-name. If a typedef-name that names a cv-qualified class type is used where a class-name is required, the cv-qualifiers are ignored. A typedef-name shall not be used as the identifier in a class-head.

12.2 Class members

member-specification:

```cpp
member-declaration member-specification opt
access-specifier : member-specification opt
```

member-declaration:

```cpp
attribute-specifier-seq opt decl-specifier-seq opt member-declarator-list opt ;
function-definition
using-declaration
static_assert-declaration
template-declaration
deduction-guide
alias-declaration
empty-declaration
```

member-declarator-list:

```cpp
member-declarator
member-declarator-list , member-declarator
```

member-declarator:

```cpp
declarator virt-specifier-seq opt pure-specifier opt
declarator brace-or-equal-initializer opt
identifier opt attribute-specifier-seq opt : constant-expression
```
The member-specification in a class definition declares the full set of members of the class; no member can be added elsewhere. A direct member of a class \( X \) is a member of \( X \) that was first declared within the member-specification of \( X \), including anonymous union objects (12.3.1) and direct members thereof. Members of a class are data members, member functions (12.2.1), nested types, enumerators, and member templates (17.5.2) and specializations thereof. [Note: A specialization of a static data member template is a static data member. A specialization of a member function template is a member function. A specialization of a member class template is a nested class. — end note]

A member-declaration does not declare new members of the class if it is

(2.1) — a friend declaration (14.3),

(2.2) — a static_assert-declaration,

(2.3) — a using-declaration (10.3.3), or

(2.4) — an empty-declaration.

For any other member-declaration, each declared entity that is not an unnamed bit-field (12.2.4) is a member of the class, and each such member-declaration shall either declare at least one member name of the class or declare at least one unnamed bit-field.

A data member is a non-function member introduced by a member-declarator. A member function is a member that is a function. Nested types are classes (12.1, 12.2.5) and enumerations (10.2) declared in the class and arbitrary types declared as members by use of a typedef declaration (10.1.3) or alias-declaration. The enumerators of an unscoped enumeration (10.2) defined in the class are members of the class.

A data member or member function may be declared static in its member-declaration, in which case it is a static member (see 12.2.3) (a static data member (12.2.3.2) or static member function (12.2.3.1), respectively) of the class. Any other data member or member function is a non-static member (a non-static data member or non-static member function (12.2.2), respectively). [Note: A non-static data member of non-reference type is a member subobject of a class object (4.5). — end note]

A member shall not be declared twice in the member-specification, except that

(5.1) — a nested class or member class template can be declared and then later defined, and

(5.2) — an enumeration can be introduced with an opaque-enum-declaration and later redeclared with an enum-specifier.

[Note: A single name can denote several member functions provided their types are sufficiently different (Clause 16). — end note]

A class is considered a completely-defined object type (6.9) (or complete type) at the closing } of the class-specifier. Within the class member-specification, the class is regarded as complete within function bodies, default arguments, noexcept-specifiers, and default member initializers (including such things in nested classes). Otherwise it is regarded as incomplete within its own class member-specification.

In a member-declarator, an = immediately following the declarator is interpreted as introducing a pure-specifier if the declarator-id has function type, otherwise it is interpreted as introducing a brace-or-equal-initializer. [Example:
struct S {
    using T = void();
    T * p = 0;    // OK: brace-or-equal-initializer
    virtual T f = 0; // OK: pure-specifier
};
—end example]

A brace-or-equal-initializer shall appear only in the declaration of a data member. (For static data members, see 12.2.3.2; for non-static data members, see 15.6.2 and 11.6.1). A brace-or-equal-initializer for a non-static data member specifies a default member initializer for the member, and shall not directly or indirectly cause the implicit definition of a defaulted default constructor for the enclosing class or the exception specification of that constructor.

A member shall not be declared with the extern storage-class-specifier. Within a class definition, a member shall not be declared with the thread_local storage-class-specifier unless also declared static.

The decl-specifier-seq may be omitted in constructor, destructor, and conversion function declarations only; when declaring another kind of member the decl-specifier-seq shall contain a type-specifier that is not a cv-qualifier. The member-declarator-list can be omitted only after a class-specifier or an enum-specifier or in a friend declaration (14.3). A pure-specifier shall be used only in the declaration of a virtual function (13.3) that is not a friend declaration.

The optional attribute-specifier-seq in a member-declaration appertains to each of the entities declared by the member-declarators; it shall not appear if the optional member-declarator-list is omitted.

A virt-specifier-seq shall contain at most one of each virt-specifier. A virt-specifier-seq shall appear only in the declaration of a virtual member function (13.3).

Non-static data members shall not have incomplete types. In particular, a class C shall not contain a non-static member of class C, but it can contain a pointer or reference to an object of class C.

[Note: See 8.1 for restrictions on the use of non-static data members and non-static member functions. —end note]

[Note: The type of a non-static member function is an ordinary function type, and the type of a non-static data member is an ordinary object type. There are no special member function types or data member types. —end note]

[Example: A simple example of a class definition is

struct tnode {
    char tword[20];
    int count;
    tnode* left;
    tnode* right;
};

which contains an array of twenty characters, an integer, and two pointers to objects of the same type. Once this definition has been given, the declaration

tnode s, *sp;

declares s to be a tnode and sp to be a pointer to a tnode. With these declarations, sp->count refers to the count member of the object to which sp points; s.left refers to the left subtree pointer of the object s; and s.right->tword[0] refers to the initial character of the tword member of the right subtree of s. —end example]

Non-static data members of a (non-union) class with the same access control (Clause 14) are allocated so that later members have higher addresses within a class object. The order of allocation of non-static data members with different access control is unspecified (Clause 14). Implementation alignment requirements

§ 12.2
might cause two adjacent members not to be allocated immediately after each other; so might requirements for space for managing virtual functions (13.3) and virtual base classes (13.1).

18 If T is the name of a class, then each of the following shall have a name different from T:

18.1 every static data member of class T;
18.2 every member function of class T [Note: This restriction does not apply to constructors, which do not have names (15.1) — end note];
18.3 every member of class T that is itself a type;
18.4 every member template of class T;
18.5 every enumerator of every member of class T that is an unscoped enumerated type; and
18.6 every member of every anonymous union that is a member of class T.

19 In addition, if class T has a user-declared constructor (15.1), every non-static data member of class T shall have a name different from T.

20 The common initial sequence of two standard-layout struct (Clause 12) types is the longest sequence of non-static data members and bit-fields in declaration order, starting with the first such entity in each of the structs, such that corresponding entities have layout-compatible types and either neither entity is a bit-field or both are bit-fields with the same width. [Example:

```c
struct A { int a; char b; };
struct B { const int b1; volatile char b2; };
struct C { int c; unsigned : 0; char b; };
struct D { int d; char b : 4; };
struct E { unsigned int e; char b; };
```

The common initial sequence of A and B comprises all members of either class. The common initial sequence of A and C and of A and D comprises the first member in each case. The common initial sequence of A and E is empty. — end example]

21 Two standard-layout struct (Clause 12) types are layout-compatible classes if their common initial sequence comprises all members and bit-fields of both classes (6.9).

22 Two standard-layout unions are layout-compatible if they have the same number of non-static data members and corresponding non-static data members (in any order) have layout-compatible types (6.9).

23 In a standard-layout union with an active member (12.3) of struct type T1, it is permitted to read a non-static data member m of another union member of struct type T2 provided m is part of the common initial sequence of T1 and T2; the behavior is as if the corresponding member of T1 were nominated. [Example:

```c
struct T1 { int a, b; };
struct T2 { int c; double d; };
union U { T1 t1; T2 t2; };
int f() {
    U u = { { 1, 2 } }; // active member is t1
    return u.t2.c; // OK, as if u.t1.a were nominated
}
```

— end example] [Note: Reading a volatile object through a non-volatile glvalue has undefined behavior (10.1.7.1). — end note]

24 If a standard-layout class object has any non-static data members, its address is the same as the address of its first non-static data member. Otherwise, its address is the same as the address of its first base class subobject (if any). [Note: There might therefore be unnamed padding within a standard-layout struct object, but not at its beginning, as necessary to achieve appropriate alignment. — end note] [Note: The object and its first subobject are pointer-interconvertible (6.9.2, 8.2.9). — end note]
12.2.1 Member functions

A member function may be defined (11.4) in its class definition, in which case it is an inline member function (10.1.6), or it may be defined outside of its class definition if it has already been declared but not defined in its class definition. A member function definition that appears outside of the class definition shall appear in a namespace scope enclosing the class definition. Except for member function definitions that appear outside of a class definition, and except for explicit specializations of member functions of class templates and member function templates (17.7) appearing outside of the class definition, a member function shall not be redeclared.

An inline member function (whether static or non-static) may also be defined outside of its class definition provided either its declaration in the class definition or its definition outside of the class definition declares the function as inline or constexpr. [Note: Member functions of a class in namespace scope have the linkage of that class. Member functions of a local class (12.4) have no linkage. See 6.5. — end note]

[Note: There can be at most one definition of a non-inline member function in a program. There may be more than one inline member function definition in a program. See 6.2 and 10.1.6. — end note]

If the definition of a member function is lexically outside its class definition, the member function name shall be qualified by its class name using the :: operator. [Note: A name used in a member function definition (that is, in the parameter-declaration-clause including the default arguments (11.3.6) or in the member function body) is looked up as described in 6.4. — end note] [Example:

```c
struct X {
    typedef int T;
    static T count;
    void f(T);
};
void X::f(T t = count) { }
```

The member function f of class X is defined in global scope; the notation X::f specifies that the function f is a member of class X and in the scope of class X. In the function definition, the parameter type T refers to the typedef member T declared in class X and the default argument count refers to the static data member count declared in class X. —end example]

[Note: A static local variable or local type in a member function always refers to the same entity, whether or not the member function is inline. — end note]

Previously declared member functions may be mentioned in friend declarations.

Member functions of a local class shall be defined inline in their class definition, if they are defined at all.

[Note: A member function can be declared (but not defined) using a typedef for a function type. The resulting member function has exactly the same type as it would have if the function declarator were provided explicitly, see 11.3.5. For example,

```c
typedef void fv();
typedef void fvc() const;
struct S {
    fv memfunc1; // equivalent to: void memfunc1();
    void memfunc2();
    fvc memfunc3; // equivalent to: void memfunc3() const;
};
fv S::* pmfv1 = &S::memfunc1;
fv S::* pmfv2 = &S::memfunc2;
fvc S::* pmfv3 = &S::memfunc3;
```

Also see 17.3. — end note]
12.2.2 Non-static member functions [class.mfct.non-static]

1 A non-static member function may be called for an object of its class type, or for an object of a class derived (Clause 13) from its class type, using the class member access syntax (8.2.5, 16.3.1.1). A non-static member function may also be called directly using the function call syntax (8.2.2, 16.3.1.1) from within the body of a member function of its class or of a class derived from its class.

2 If a non-static member function of a class X is called for an object that is not of type X, or of a type derived from X, the behavior is undefined.

3 When an id-expression (8.1) that is not part of a class member access syntax (8.2.5) and not used to form a pointer to member (8.3.1) is used in a member of class X in a context where this can be used (8.1.2), if name lookup (6.4) resolves the name in the id-expression to a non-static non-type member of some class C, and if either the id-expression is potentially evaluated or C is X or a base class of X, the id-expression is transformed into a class member access expression (8.2.5) using (*this) (12.2.2.1) as the postfix-expression to the left of the . operator. [Note: If C is not X or a base class of X, the class member access expression is ill-formed. — end note] Similarly during name lookup, when an unqualified-id (8.1) used in the definition of a member function for class X resolves to a static member, an enumerator or a nested type of class X or of a base class of X, the unqualified-id is transformed into a qualified-id (8.1) in which the nested-name-specifier names the class of the member function. These transformations do not apply in the template definition context (17.6.2.1). [Example:

```c
struct tnode {
    char tword[20];
    int count;
    tnode* left;
    tnode* right;
    void set(const char*, tnode* l, tnode* r);
};

void tnode::set(const char* w, tnode* l, tnode* r) {
    count = strlen(w)+1;
    if (sizeof(tword)<=count)
        perror("tnode string too long");
    strcpy(tword,w);
    left = l;
    right = r;
}

void f(tnode n1, tnode n2) {
    n1.set("abc", &n2, 0);
    n2.set("def", 0, 0);
}
```

In the body of the member function tnode::set, the member names tword, count, left, and right refer to members of the object for which the function is called. Thus, in the call n1.set("abc", &n2, 0), tword refers to n1.tword, and in the call n2.set("def", 0, 0), it refers to n2.tword. The functions strlen, perror, and strcpy are not members of the class tnode and should be declared elsewhere.110 — end example]

4 A non-static member function may be declared const, volatile, or const volatile. These cv-qualifiers affect the type of the this pointer (12.2.2.1). They also affect the function type (11.3.5) of the member function; a member function declared const is a const member function, a member function declared volatile is a volatile member function and a member function declared const volatile is a const volatile member function. [Example:

```c

110) See, for example, <cstring> (24.5).

§ 12.2.2 246
struct X {
    void g() const;
    void h() const volatile;
};

X::g is a const member function and X::h is a const volatile member function. — end example

5 A non-static member function may be declared with a ref-qualifier (11.3.5); see 16.3.1.

6 A non-static member function may be declared virtual (13.3) or pure virtual (13.4).

12.2.2.1 The this pointer

In the body of a non-static (12.2.1) member function, the keyword this is a prvalue expression whose value is the address of the object for which the function is called. The type of this in a member function of a class X is X*. If the member function is declared const, the type of this is const X*, if the member function is declared volatile, the type of this is volatile X*, and if the member function is declared const volatile, the type of this is const volatile X*. [Note: Thus in a const member function, the object for which the function is called is accessed through a const access path. — end note] [Example:

```c
struct s {
    int a;
    int f() const;
    int g() { return a++; }
    int h() const { return a++; } // error
};

int s::f() const { return a; }
```

The a++ in the body of s::h is ill-formed because it tries to modify (a part of) the object for which s::h() is called. This is not allowed in a const member function because this is a pointer to const; that is, *this has const type. — end example]

2 Similarly, volatile semantics (10.1.7.1) apply in volatile member functions when accessing the object and its non-static data members.

3 A cv-qualified member function can be called on an object-expression (8.2.5) only if the object-expression is as cv-qualified or less-cv-qualified than the member function. [Example:

```c
void k(s& x, const s& y) {
    x.f();
    x.g();
    y.f();
    y.g();
    // error
}
```

The call y.g() is ill-formed because y is const and s::g() is a non-const member function, that is, s::g() is less-qualified than the object-expression y. — end example]

4 Constructors (15.1) and destructors (15.4) shall not be declared const, volatile or const volatile. [Note: However, these functions can be invoked to create and destroy objects with cv-qualified types, see 15.1 and 15.4. — end note]

12.2.3 Static members

A static member s of class X may be referred to using the qualified-id expression X::s; it is not necessary to use the class member access syntax (8.2.5) to refer to a static member. A static member may be referred to using the class member access syntax, in which case the object expression is evaluated. [Example:

```c
struct process {
    static void reschedule();
};
```

§ 12.2.3
void f() {
    process::reschedule(); // OK: no object necessary
    g().reschedule(); // g() is called
}

A static member may be referred to directly in the scope of its class or in the scope of a class derived (Clause 13) from its class; in this case, the static member is referred to as if a qualified-id expression was used, with the nested-name-specifier of the qualified-id naming the class scope from which the static member is referenced. [Example:

```cpp
int g();
struct X {
    static int g();
};
struct Y : X {
    static int i;
};
int Y::i = g(); // equivalent to Y::g();
```
—end example]

If an unqualified-id (8.1) is used in the definition of a static member following the member’s declarator-id, and name lookup (6.4.1) finds that the unqualified-id refers to a static member, enumerator, or nested type of the member’s class (or of a base class of the member’s class), the unqualified-id is transformed into a qualified-id expression in which the nested-name-specifier names the class scope from which the member is referenced. [Note: See 8.1 for restrictions on the use of non-static data members and non-static member functions. —end note]

Static members obey the usual class member access rules (Clause 14). When used in the declaration of a class member, the static specifier shall only be used in the member declarations that appear within the member-specification of the class definition. [Note: It cannot be specified in member declarations that appear in namespace scope. —end note]

### 12.2.3.1 Static member functions

[Class.static.mfct]

1 [Note: The rules described in 12.2.1 apply to static member functions. —end note]

2 [Note: A static member function does not have a this pointer (12.2.2.1). —end note] A static member function shall not be virtual. There shall not be a static and a non-static member function with the same name and the same parameter types (16.1). A static member function shall not be declared const, volatile, or const volatile.

### 12.2.3.2 Static data members

[Class.static.data]

1 A static data member is not part of the subobjects of a class. If a static data member is declared thread-local there is one copy of the member per thread. If a static data member is not declared thread_local there is one copy of the data member that is shared by all the objects of the class.

2 The declaration of a non-inline static data member in its class definition is not a definition and may be of an incomplete type other than cv void. The definition for a static data member that is not defined inline in the class definition shall appear in a namespace scope enclosing the member’s class definition. In the definition at namespace scope, the name of the static data member shall be qualified by its class name using the :: operator. The initializer expression in the definition of a static data member is in the scope of its class (6.3.7). [Example:
class process {
    static process* run_chain;
    static process* running;
};

process* process::running = get_main();
process* process::run_chain = running;

The static data member run_chain of class process is defined in global scope; the notation process::run_chain specifies that the member run_chain is a member of class process and in the scope of class process. In the static data member definition, the initializer expression refers to the static data member running of class process. —end example

[Note: Once the static data member has been defined, it exists even if no objects of its class have been created. [Example: In the example above, run_chain and running exist even if no objects of class process are created by the program. —end example]

If a non-volatile non-inline const static data member is of integral or enumeration type, its declaration in the class definition can specify a brace-or-equal-initializer in which every initializer-clause that is an assignment-expression is a constant expression (8.20). The member shall still be defined in a namespace scope if it is odr-used (6.2) in the program and the namespace scope definition shall not contain an initializer. An inline static data member may be defined in the class definition and may specify a brace-or-equal-initializer. If the member is declared with the constexpr specifier, it may be redeclared in namespace scope with no initializer (this usage is deprecated; see D.1). Declarations of other static data members shall not specify a brace-or-equal-initializer.

[Note: There shall be exactly one definition of a static data member that is odr-used (6.2) in a program; no diagnostic is required. —end note] Unnamed classes and classes contained directly or indirectly within unnamed classes shall not contain static data members.

[Note: Static data members of a class in namespace scope have the linkage of that class (6.5). A local class cannot have static data members (12.4). —end note]

Static data members are initialized and destroyed exactly like non-local variables (6.6.2, 6.6.3, 6.6.4).

A static data member shall not be mutable (10.1.1).

12.2.4 Bit-fields

1 A member-declarator of the form

    identifier[optional attribute-specifier-seq] : constant-expression

specifies a bit-field; its length is set off from the bit-field name by a colon. The optional attribute-specifier-seq appertains to the entity being declared. The bit-field attribute is not part of the type of the class member. The constant-expression shall be an integral constant expression with a value greater than or equal to zero. The value of the integral constant expression may be larger than the number of bits in the object representation (6.9) of the bit-field’s type; in such cases the extra bits are used as padding bits and do not participate in the value representation (6.9) of the bit-field. Allocation of bit-fields within a class object is implementation-defined. Alignment of bit-fields is implementation-defined. Bit-fields are packed into some addressable allocation unit. [Note: Bit-fields straddle allocation units on some machines and not on others. Bit-fields are assigned right-to-left on some machines, left-to-right on others. —end note]

2 A declaration for a bit-field that omits the identifier declares an unnamed bit-field. Unnamed bit-fields are not members and cannot be initialized. [Note: An unnamed bit-field is useful for padding to conform to externally-imposed layouts. —end note] As a special case, an unnamed bit-field with a width of zero specifies alignment of the next bit-field at an allocation unit boundary. Only when declaring an unnamed bit-field may the value of the constant-expression be equal to zero.
A bit-field shall not be a static member. A bit-field shall have integral or enumeration type (6.9.1). A bool value can successfully be stored in a bit-field of any nonzero size. The address-of operator & shall not be applied to a bit-field, so there are no pointers to bit-fields. A non-const reference shall not be bound to a bit-field (11.6.3). [Note: If the initializer for a reference of type *const T& is an lvalue that refers to a bit-field, the reference is bound to a temporary initialized to hold the value of the bit-field; the reference is not bound to the bit-field directly. See 11.6.3. — end note]

If the value true or false is stored into a bit-field of type bool of any size (including a one bit bit-field), the original bool value and the value of the bit-field shall compare equal. If the value of an enumerator is stored into a bit-field of the same enumeration type and the number of bits in the bit-field is large enough to hold all the values of that enumeration type (10.2), the original enumerator value and the value of the bit-field shall compare equal. [Example:

```c
enum BOOL { FALSE=0, TRUE=1 }
struct A {
    BOOL b:1;
};
A a;
void f() {
    a.b = TRUE;
    if (a.b == TRUE) // yields true
        { /* ... */ }
}
—end example]

12.2.5 Nested class declarations [class.nest]

A class can be declared within another class. A class declared within another is called a nested class. The name of a nested class is local to its enclosing class. The nested class is in the scope of its enclosing class. [Note: See 8.1 for restrictions on the use of non-static data members and non-static member functions. —end note]

[Example:

```c
int x;
int y;

struct enclose {
    int x;
    static int s;

    struct inner {
        void f(int i) {
            int a = sizeof(x); // OK: operand of sizeof is an unevaluated operand
            x = i; // error: assign to enclose::x
            s = i; // OK: assign to enclose::s
            ::x = i; // OK: assign to global x
            y = i; // OK: assign to global y
        }
        void g(enclose* p, int i) {
            p->x = i; // OK: assign to enclose::x
        }
    }
};
inner* p = 0; // error: inner not in scope
```

§ 12.2.5 250
Member functions and static data members of a nested class can be defined in a namespace scope enclosing the definition of their class.  

```cpp
struct enclose {
    struct inner {
        static int x;
        void f(int i);
    };

    int enclose::inner::x = 1;

    void enclose::inner::f(int i) { /* ... */ }
};
```

If class X is defined in a namespace scope, a nested class Y may be declared in class X and later defined in the definition of class X or be later defined in a namespace scope enclosing the definition of class X.  

```cpp
class E {
    class I1; // forward declaration of nested class
    class I2;
    class I1 { }; // definition of nested class
};
class E::I2 { }; // definition of nested class
```

Like a member function, a friend function (14.3) defined within a nested class is in the lexical scope of that class; it obeys the same rules for name binding as a static member function of that class (12.2.3), but it has no special access rights to members of an enclosing class.

**12.2.6 Nested type names**

Type names obey exactly the same scope rules as other names. In particular, type names defined within a class definition cannot be used outside their class without qualification.  

```cpp
struct X {
    typedef int I;
    class Y { /* ... */ }; // error
    I a;
};

I b; // error
Y c; // error
X::Y d; // OK
X::I e; // OK
```

**12.3 Unions**

In a union, a non-static data member is *active* if its name refers to an object whose lifetime has begun and has not ended (6.8). At most one of the non-static data members of an object of union type can be active at any time, that is, the value of at most one of the non-static data members can be stored in a union at any time.  

*Note:* One special guarantee is made in order to simplify the use of unions: If a standard-layout union contains several standard-layout structs that share a common initial sequence (12.2), and if a non-static data member of an object of this standard-layout union type is active and is one of the standard-layout structs, it
The size of a union is sufficient to contain the largest of its non-static data members. Each non-static data member is allocated as if it were the sole member of a struct. [Note: A union object and its non-static data members are pointer-interconvertible (6.9.2, 8.2.9). As a consequence, all non-static data members of a union object have the same address. —end note]

A union can have member functions (including constructors and destructors), but it shall not have virtual (13.3) functions. A union shall not have base classes. A union shall not be used as a base class. If a union contains a non-static data member of reference type the program is ill-formed. [Note: Absent default member initializers (12.2), if any non-static data member of a union has a non-trivial default constructor (15.1), copy constructor (15.8), move constructor (15.8), copy assignment operator (15.8), move assignment operator (15.8), or destructor (15.4), the corresponding member function of the union must be user-provided or it will be implicitly deleted (11.4.3) for the union. —end note]

[Example: Consider the following union:

```c
union U {
  int i;
  float f;
  std::string s;
};
```

Since `std::string` (24.3) declares non-trivial versions of all of the special member functions, `U` will have an implicitly deleted default constructor, copy/move constructor, copy/move assignment operator, and destructor. To use `U`, some or all of these member functions must be user-provided. —end example]

When the left operand of an assignment operator involves a member access expression (8.2.5) that nominates a union member, it may begin the lifetime of that union member, as described below. For an expression `E`, define the set `S(E)` of subexpressions of `E` as follows:

1. If `E` is of the form `A.B`, `S(E)` contains the elements of `S(A)`, and also contains `A.B` if `B` names a union member of a non-class, non-array type, or of a class type with a trivial default constructor that is not deleted, or an array of such types.

2. If `E` is of the form `A[B]` and is interpreted as a built-in array subscripting operator, `S(E)` is `S(A)` if `A` is of array type, `S(B)` if `B` is of array type, and empty otherwise.

3. Otherwise, `S(E)` is empty.

In an assignment expression of the form `E1 = E2` that uses either the built-in assignment operator (8.18) or a trivial assignment operator (15.8), for each element of `S(E1)` that would have undefined behavior under 6.8, an object of the type of that element is implicitly created in the nominated storage; no initialization is performed and the beginning of its lifetime is sequenced after the value computation of the left and right operands and before the assignment. [Note: This ends the lifetime of the previously-active member of the union, if any (6.8). —end note] [Example:

```c
union A { int x; int y[4]; }; struct B { A a; }; union C { B b; int k; }; int f() {
  C c; // does not start lifetime of any union member
  // creates objects to hold union members c.b and c.b.a.
  return c.b.a.y[3]; // OK: c.b.a.y refers to newly created object (see 6.8)
}
```
union Y { X x; int k; };  
void g() {
    Y y = { { 1, 2 } };  // OK, y.x is active union member (12.2)
    int n = y.x.a;          // OK: ends lifetime of y.x, y.k is active member of union
    y.k = 4;                // undefined behavior: y.x.b modified outside its lifetime,
    y.x.b = n;             // S(y.x.b) is empty because X’s default constructor is deleted,
    // so union member y.x’s lifetime does not implicitly start
}

—end example

[Note: In general, one must use explicit destructor calls and placement new-expression to change the active member of a union. —end note] [Example: Consider an object u of a union type U having non-static data members m of type M and n of type N. If M has a non-trivial destructor and N has a non-trivial constructor (for instance, if they declare or inherit virtual functions), the active member of u can be safely switched from m to n using the destructor and placement new-expression as follows:

```
    u.m.~M();
    new (&u.n) N;
```
—end example]

12.3.1 Anonymous unions [class.union.anon]

A union of the form

```
union { member-specification }
```

is called an anonymous union; it defines an unnamed type and an unnamed object of that type called an anonymous union object. Each member-declaration in the member-specification of an anonymous union shall either define a non-static data member or be a static_assert-declaration. [Note: Nested types, anonymous unions, and functions cannot be declared within an anonymous union. —end note] The names of the members of an anonymous union shall be distinct from the names of any other entity in the scope in which the anonymous union is declared. For the purpose of name lookup, after the anonymous union definition, the members of the anonymous union are considered to have been defined in the scope in which the anonymous union is declared. [Example:

```
void f() {
    union { int a; const char* p; };  
    a = 1;
    p = "Jennifer";
}
```

Here a and p are used like ordinary (non-member) variables, but since they are union members they have the same address. —end example]

2 Anonymous unions declared in a named namespace or in the global namespace shall be declared static. Anonymous unions declared at block scope shall be declared with any storage class allowed for a block-scope variable, or with no storage class. A storage class is not allowed in a declaration of an anonymous union in a class scope. An anonymous union shall not have private or protected members (Clause 14). An anonymous union shall not have member functions.

3 A union for which objects, pointers, or references are declared is not an anonymous union. [Example:

```
void f() {
    union { int aa; char* p; } obj, *ptr = &obj;
    aa = 1;   // error
    ptr->aa = 1;  // OK
}
```
The assignment to plain `aa` is ill-formed since the member name is not visible outside the union, and even if it were visible, it is not associated with any particular object. —end example] [Note: Initialization of unions with no user-declared constructors is described in 11.6.1. —end note]

4 A union-like class is a union or a class that has an anonymous union as a direct member. A union-like class `X` has a set of variant members. If `X` is a union, a non-static data member of `X` that is not an anonymous union is a variant member of `X`. In addition, a non-static data member of an anonymous union that is a member of `X` is also a variant member of `X`. At most one variant member of a union may have a default member initializer. [Example:

```c
union U {
    int x = 0;
    union {
        int k;
    };
    union {
        int z;
        int y = 1;  // error: initialization for second variant member of U
    };
};
—end example]
```

12.4 Local class declarations [class.local]

1 A class can be declared within a function definition; such a class is called a local class. The name of a local class is local to its enclosing scope. The local class is in the scope of the enclosing scope, and has the same access to names outside the function as does the enclosing function. Declarations in a local class shall not odr-use (6.2) a variable with automatic storage duration from an enclosing scope. [Example:

```c
int x;
void f() {
    static int s;
    int x;
    const int N = 5;
    extern int q();

    struct local {
        int g() { return x; }  // error: odr-use of automatic variable x
        int h() { return s; }   // OK
        int k() { return ::x; } // OK
        int l() { return q(); } // OK
        int m() { return N; }  // OK: not an odr-use
        int* n() { return &N; } // error: odr-use of automatic variable N
    }
};

local* p = 0;  // error: local not in scope
—end example]
```

2 An enclosing function has no special access to members of the local class; it obeys the usual access rules (Clause 14). Member functions of a local class shall be defined within their class definition, if they are defined at all.

3 If class `X` is a local class a nested class `Y` may be declared in class `X` and later defined in the definition of class `X` or be later defined in the same scope as the definition of class `X`. A class nested within a local class is a local class.
4 A local class shall not have static data members.
13 Derived classes

A list of base classes can be specified in a class definition using the notation:

```plaintext
base-clause:
  : base-specifier-list

base-specifier-list:
  base-specifier ... opt
  base-specifier-list , base-specifier ... opt

base-specifier:
  attribute-specifier-seq opt class-or-decltype
  attribute-specifier-seq opt virtual access-specifier_opt class-or-decltype
  attribute-specifier-seq opt access-specifier virtual_opt class-or-decltype

class-or-decltype:
  nested-name-specifier_opt class-name
  nested-name-specifier template simple-template-id
dcltype-specifier

access-specifier:
  private
  protected
  public
```

The optional attribute-specifier-seq appertains to the base-specifier.

A class-or-decltype shall denote a class type that is not an incompletely defined class (Clause 12). The class denoted by the class-or-decltype of a base-specifier is called a direct base class for the class being defined. During the lookup for a base class name, non-type names are ignored (6.3.10). If the name found is not a class-name, the program is ill-formed. A class B is a base class of a class D if it is a direct base class of D or a direct base class of one of D’s base classes. A class is an indirect base class of another if it is a base class but not a direct base class. A class is said to be (directly or indirectly) derived from its (direct or indirect) base classes. [Note: See Clause 14 for the meaning of access-specifier. — end note] Unless redeclared in the derived class, members of a base class are also considered to be members of the derived class. Members of a base class other than constructors are said to be inherited by the derived class. Constructors of a base class can also be inherited as described in 10.3.3. Inherited members can be referred to in expressions in the same manner as other members of the derived class, unless their names are hidden or ambiguous (13.2). [Note: The scope resolution operator :: (8.1) can be used to refer to a direct or indirect base member explicitly. This allows access to a name that has been redeclared in the derived class. A derived class can itself serve as a base class subject to access control; see 14.2. A pointer to a derived class can be implicitly converted to a pointer to an accessible unambiguous base class (7.11). An lvalue of a derived class type can be bound to a reference to an accessible unambiguous base class (11.6.3). — end note]

The base-specifier-list specifies the type of the base class subobjects contained in an object of the derived class type. [Example:

```plaintext
struct Base {
  int a, b, c;
};

struct Derived : Base {
  int b;
};
```
struct Derived2 : Derived {
    int c;
};

Here, an object of class Derived2 will have a subobject of class Derived which in turn will have a subobject of class Base. — end example

4 A base-specifier followed by an ellipsis is a pack expansion (17.5.3).

5 The order in which the base class subobjects are allocated in the most derived object (4.5) is unspecified. [ Note: A derived class and its base class subobjects can be represented by a directed acyclic graph (DAG) where an arrow means “directly derived from”. An arrow need not have a physical representation in memory. A DAG of subobjects is often referred to as a “subobject lattice”.

| Base
|   ▲ Derived1
|       ▲ Derived2

Figure 2 — Directed acyclic graph

— end note]

6 [ Note: Initialization of objects representing base classes can be specified in constructors; see 15.6.2. — end note]

7 [ Note: A base class subobject might have a layout (6.7) different from the layout of a most derived object of the same type. A base class subobject might have a polymorphic behavior (15.7) different from the polymorphic behavior of a most derived object of the same type. A base class subobject may be of zero size (Clause 12); however, two subobjects that have the same class type and that belong to the same most derived object must not be allocated at the same address (8.10). — end note]

13.1 Multiple base classes [class.mi]

1 A class can be derived from any number of base classes. [ Note: The use of more than one direct base class is often called multiple inheritance. — end note] [ Example:

    class A { /* ... */ };
    class B { /* ... */ };
    class C { /* ... */ };
    class D : public A, public B, public C { /* ... */ };

— end example]

2 [ Note: The order of derivation is not significant except as specified by the semantics of initialization by constructor (15.6.2), cleanup (15.4), and storage layout (12.2, 14.1). — end note]

3 A class shall not be specified as a direct base class of a derived class more than once. [ Note: A class can be an indirect base class more than once and can be a direct and an indirect base class. There are limited things that can be done with such a class. The non-static data members and member functions of the direct base class cannot be referred to in the scope of the derived class. However, the static members, enumerations and types can be unambiguously referred to. — end note] [ Example:

    class X { /* ... */ };
    class Y : public X, public X { /* ... */ }; // ill-formed

§ 13.1
class L { public: int next; /* ... */ };  
class A : public L { /* ... */ };  
class B : public L { /* ... */ };  
class C : public A, public B { void f(); /* ... */ };  // well-formed  
class D : public A, public L { void f(); /* ... */ };  // well-formed

—end example

4 A base class specifier that does not contain the keyword \texttt{virtual} specifies a \textit{non-virtual base class}. A base class specifier that contains the keyword \texttt{virtual} specifies a \textit{virtual base class}. For each distinct occurrence of a non-virtual base class in the class lattice of the most derived class, the most derived object (4.5) shall contain a corresponding distinct base class subobject of that type. For each distinct base class that is specified virtual, the most derived object shall contain a single base class subobject of that type.

5 \textit{Note}: For an object of class type \texttt{C}, each distinct occurrence of a (non-virtual) base class \texttt{L} in the class lattice of \texttt{C} corresponds one-to-one with a distinct \texttt{L} subobject within the object of type \texttt{C}. Given the class \texttt{C} defined above, an object of class \texttt{C} will have two subobjects of class \texttt{L} as shown in Figure 3.

![Figure 3 — Non-virtual base](image)

In such lattices, explicit qualification can be used to specify which subobject is meant. The body of function \texttt{C::~f} could refer to the member \texttt{next} of each \texttt{L} subobject:

\begin{verbatim}
void C::f() { A::next = B::next; }  // well-formed
\end{verbatim}

Without the \texttt{A::} or \texttt{B::} qualifiers, the definition of \texttt{C::~f} above would be ill-formed because of ambiguity (13.2).

—end note

6 \textit{Note}: In contrast, consider the case with a virtual base class:

\begin{verbatim}
class V { /* ... */ };  
class A : virtual public V { /* ... */ };  
class B : virtual public V { /* ... */ };  
class C : public A, public B { /* ... */ };  
\end{verbatim}

![Figure 4 — Virtual base](image)

For an object \texttt{c} of class type \texttt{C}, a single subobject of type \texttt{V} is shared by every base class subobject of \texttt{c}.

§ 13.1 258
that has a virtual base class of type \( V \). Given the class \( C \) defined above, an object of class \( C \) will have one subobject of class \( V \), as shown in Figure 4. — end note

7 [Note: A class can have both virtual and non-virtual base classes of a given type.]

\[
\begin{align*}
\text{class } & B \{ /* ... */ \}; \\
\text{class } & X : \text{virtual public } B \{ /* ... */ \}; \\
\text{class } & Y : \text{virtual public } B \{ /* ... */ \}; \\
\text{class } & Z : \text{public } B \{ /* ... */ \}; \\
\text{class } & AA : \text{public } X, \text{public } Y, \text{public } Z \{ /* ... */ \};
\end{align*}
\]

For an object of class \( AA \), all virtual occurrences of base class \( B \) in the class lattice of \( AA \) correspond to a single \( B \) subobject within the object of type \( AA \), and every other occurrence of a (non-virtual) base class \( B \) in the class lattice of \( AA \) corresponds one-to-one with a distinct \( B \) subobject within the object of type \( AA \). Given the class \( AA \) defined above, class \( AA \) has two subobjects of class \( B \): \( Z \)'s \( B \) and the virtual \( B \) shared by \( X \) and \( Y \), as shown in Figure 5.

![Figure 5 — Virtual and non-virtual base](image)

— end note]

13.2 Member name lookup [class.member.lookup]

1 Member name lookup determines the meaning of a name \((id-expression)\) in a class scope (6.3.7). Name lookup can result in an ambiguity, in which case the program is ill-formed. For an \( id-expression \), name lookup begins in the class scope of \( this \); for a \( qualified-id \), name lookup begins in the scope of the \( nested-name-specifier \). Name lookup takes place before access control (6.4, Clause 14).

2 The following steps define the result of name lookup for a member name \( f \) in a class scope \( C \).

3 The lookup set for \( f \) in \( C \), called \( S(f, C) \), consists of two component sets: the declaration set, a set of members named \( f \); and the subobject set, a set of subobjects where declarations of these members (possibly including using-declarations) were found. In the declaration set, using-declarations are replaced by the set of designated members that are not hidden or overridden by members of the derived class (10.3.3), and type declarations (including injected-class-names) are replaced by the types they designate. \( S(f, C) \) is calculated as follows:

4 If \( C \) contains a declaration of the name \( f \), the declaration set contains every declaration of \( f \) declared in \( C \) that satisfies the requirements of the language construct in which the lookup occurs. [Note: Looking up a name in an elaborated-type-specifier (6.4.4) or base-specifier (Clause 13), for instance, ignores all non-type declarations, while looking up a name in a nested-name-specifier (6.4.3) ignores function, variable, and enumerator declarations. As another example, looking up a name in a using-declaration (10.3.3) includes the declaration of a class or enumeration that would ordinarily be hidden by another declaration of that name in the same scope. — end note] If the resulting declaration set is not empty, the subobject set contains \( C \) itself, and calculation is complete.

5 Otherwise (i.e., \( C \) does not contain a declaration of \( f \) or the resulting declaration set is empty), \( S(f, C) \) is initially empty. If \( C \) has base classes, calculate the lookup set for \( f \) in each direct base class subobject \( B_i \), and merge each such lookup set \( S(f, B_i) \) in turn into \( S(f, C) \).
The following steps define the result of merging lookup set \( S(f, B_i) \) into the intermediate \( S(f, C) \):

1. If each of the subobject members of \( S(f, B_i) \) is a base class subobject of at least one of the subobject members of \( S(f, C) \), or if \( S(f, B_i) \) is empty, \( S(f, C) \) is unchanged and the merge is complete. Conversely, if each of the subobject members of \( S(f, C) \) is a base class subobject of at least one of the subobject members of \( S(f, B_i) \), or if \( S(f, C) \) is empty, the new \( S(f, C) \) is a copy of \( S(f, B_i) \).

2. Otherwise, if the declaration sets of \( S(f, B_i) \) and \( S(f, C) \) differ, the merge is ambiguous: the new \( S(f, C) \) is a lookup set with an invalid declaration set and the union of the subobject sets. In subsequent merges, an invalid declaration set is considered different from any other.

3. Otherwise, the new \( S(f, C) \) is a lookup set with the shared set of declarations and the union of the subobject sets.

The result of name lookup for \( f \) in \( C \) is the declaration set of \( S(f, C) \). If it is an invalid set, the program is ill-formed. [Example:

```c
struct A { int x; };          // S(x,A) = { { A::x }, { A } }
struct B { float x; };       // S(x,B) = { { B::x }, { B } }
struct C: public A, public B { };  // S(x,C) = { invalid, { A in C, B in C } }
struct D: public virtual C { };      // S(x,D) = S(x,C)
struct E: public virtual C { char x; };  // S(x,E) = { { E::x }, { E } }
struct F: public D, public E { };    // S(x,F) = S(x,E)
int main() {
    F f;
    f.x = 0;              // OK, lookup finds E::x
}
```

\( S(x,F) \) is unambiguous because the \( A \) and \( B \) base class subobjects of \( D \) are also base class subobjects of \( E \), so \( S(x,D) \) is discarded in the first merge step. —end example]

If the name of an overloaded function is unambiguously found, overload resolution (16.3) also takes place before access control. Ambiguities can often be resolved by qualifying a name with its class name. [Example:

```c
struct A {
    int f();
};
struct B {
    int f();
};
struct C : A, B {
    int f() { return A::f() + B::f(); }
};
—end example]

[Note: A static member, a nested type or an enumerator defined in a base class \( T \) can unambiguously be found even if an object has more than one base class subobject of type \( T \). Two base class subobjects share the non-static member subobjects of their common virtual base classes. —end note] [Example:

```c
struct V {
    int v;
};
struct A {
    int a;
    static int s;
    enum { e };
};
struct B : A, virtual V {
};
```
struct C : A, virtual V { }
struct D : B, C { }

void f(D* pd) {
    pd->v++; // OK: only one v (virtual)
    pd->s++; // OK: only one s (static)
    int i = pd->e; // OK: only one e (enumerator)
    pd->a++; // error, ambiguous: two a as in D
}

—end example]

10 [ Note: When virtual base classes are used, a hidden declaration can be reached along a path through the subobject lattice that does not pass through the hiding declaration. This is not an ambiguity. The identical use with non-virtual base classes is an ambiguity; in that case there is no unique instance of the name that hides all the others. —end note] [Example:

struct V { int f(); int x; };
struct W { int g(); int y; };
struct B : virtual V, W {
    int f(); int x;
    int g(); int y;
};
struct C : virtual V, W { };

struct D : B, C { void glorp(); };

\[ \text{Figure 6 — Name lookup} \]

The names declared in V and the left-hand instance of W are hidden by those in B, but the names declared in the right-hand instance of W are not hidden at all.

void D::glorp() {
    x++; // OK: B::x hides V::x
    f(); // OK: B::f() hides V::f()
    y++; // error: B::y and C’s W::y
    g(); // error: B::g() and C’s W::g()
}

—end example]

11 An explicit or implicit conversion from a pointer to or an expression designating an object of a derived class to a pointer or reference to one of its base classes shall unambiguously refer to a unique object representing the base class. [Example:

struct V { };
struct A { };
struct B : A, virtual V { };
struct C : A, virtual V { };

§ 13.2 261
struct D : B, C { };

void g() {
  D d;
  B* pb = &d;
  A* pa = &d;  // error, ambiguous: C’s A or B’s A?
  V* pv = &d;  // OK: only one V subobject
}

—end example]

Note: Even if the result of name lookup is unambiguous, use of a name found in multiple subobjects might still be ambiguous (7.12, 8.2.5, 14.2). —end note] [Example:

struct B1 {
  void f();
  static void f(int);
  int i;
};
struct B2 {
  void f(double);
};
struct I1: B1 { };
struct I2: B1 { };

struct D: I1, I2, B2 {  
using B1::f;
using B2::f;
void g() {
  f();  // Ambiguous conversion of this
  f(0);  // Unambiguous (static)
  f(0.0);  // Unambiguous (only one B2)
  int B1::* mpB1 = &D::i;  // Unambiguous
  int D::* mpD = &D::i;  // Ambiguous conversion
}
}
—end example]

13.3 Virtual functions [class.virtual]

Note: Virtual functions support dynamic binding and object-oriented programming. —end note] A class that declares or inherits a virtual function is called a polymorphic class.

If a virtual member function vf is declared in a class Base and in a class Derived, derived directly or indirectly from Base, a member function vf with the same name, parameter-type-list (11.3.5), cv-qualification, and ref-qualifier (or absence of same) as Base::vf is declared, then Derived::vf is also virtual (whether or not it is so declared) and it overrides Base::vf. For convenience we say that any virtual function overrides itself. A virtual member function C::vf of a class object S is a final overrider unless the most derived class (4.5) of which S is a base class subobject (if any) declares or inherits another member function that overrides vf. In a derived class, if a virtual member function of a base class subobject has more than one final overrider the program is ill-formed. [Example:

struct A {
  virtual void f();
}

111) A function with the same name but a different parameter list (Clause 16) as a virtual function is not necessarily virtual and does not override. The use of the virtual specifier in the declaration of an overriding function is legal but redundant (has empty semantics). Access control (Clause 14) is not considered in determining overriding.
struct B : virtual A {
    virtual void f();
};
struct C : B, virtual A {
    using A::f;
};

void foo() {
    C c;
    c.f(); // calls B::f, the final overrider
    c.C::f(); // calls A::f because of the using-declaration
}

— end example ]

[ Example: 
struct A { virtual void f(); }; 
struct B : A { }; 
struct C : A { void f(); }; 
struct D : B, C {} ; // OK: A::f and C::f are the final overriders 
// for the B and C subobjects, respectively
— end example ]

Note: A virtual member function does not have to be visible to be overridden, for example,

struct B {
    virtual void f();
};
struct D : B {
    void f(int);
};
struct D2 : D {
    void f();
};

the function f(int) in class D hides the virtual function f() in its base class B; D::f(int) is not a virtual function. However, f() declared in class D2 has the same name and the same parameter list as B::f(), and therefore is a virtual function that overrides the function B::f() even though B::f() is not visible in class D2. — end note ]

If a virtual function f in some class B is marked with the virt-specifier final and in a class D derived from B a function D::f overrides B::f, the program is ill-formed. [ Example: 

struct B {
    virtual void f() const final;
};

struct D : B {
    void f() const; // error: D::f attempts to override final B::f
};

— end example ]

If a virtual function is marked with the virt-specifier override and does not override a member function of a base class, the program is ill-formed. [ Example: 

struct B {
    virtual void f(int);
Although destructors are not inherited, a destructor in a derived class overrides a base class destructor declared virtual; see 15.4 and 15.5.

The return type of an overriding function shall be either identical to the return type of the overridden function or covariant with the classes of the functions. If a function $D::f$ overrides a function $B::f$, the return types of the functions are covariant if they satisfy the following criteria:

1. Both are pointers to classes, both are lvalue references to classes, or both are rvalue references to classes\(^{112}\)
2. The class in the return type of $B::f$ is the same class as the class in the return type of $D::f$, or is an unambiguous and accessible direct or indirect base class of the class in the return type of $D::f$
3. Both pointers or references have the same cv-qualification and the class type in the return type of $D::f$ has the same cv-qualification as or less cv-qualification than the class type in the return type of $B::f$.

If the class type in the covariant return type of $D::f$ differs from that of $B::f$, the class type in the return type of $D::f$ shall be complete at the point of declaration of $D::f$ or shall be the class type $D$. When the overriding function is called as the final overrider of the overridden function, its result is converted to the type returned by the (statically chosen) overridden function (8.2.2). [Example:

```c
class B { }
class D : private B { friend class Derived; };
struct Base {
    virtual void vf1();
    virtual void vf2();
    virtual void vf3();
    virtual B* vf4();
    virtual B* vf5();
    void f();
};

struct No_good : public Base {
    D* vf4(); // error: B (base class of D) inaccessible
};

class A;
struct Derived : public Base {
    void vf1(); // virtual and overrides Base::vf1()
    void vf2(int); // not virtual, hides Base::vf2()
    char vf3(); // error: invalid difference in return type only
    D* vf4(); // OK: returns pointer to derived class
    A* vf5(); // error: returns pointer to incomplete class
    void f();
};

void g() {
    Derived d;
}
```

\(^{112}\) Multi-level pointers to classes or references to multi-level pointers to classes are not allowed.
Base* bp = &d;
// standard conversion:
// Derived* to Base*
bp->vf1();
// calls Derived::vf1()
bp->vf2();
// calls Base::vf2()
bp->f();
// calls Base::f() (not virtual)
B* p = bp->vf4();
// calls Derived::pf() and converts the
// result to B*
Derived* dp = &d;
D* q = dp->vf4();
// calls Derived::pf() and does not
// convert the result to B*
dp->vf2();
// ill-formed: argument mismatch
}

— end example

[Note: The interpretation of the call of a virtual function depends on the type of the object for which it is called (the dynamic type), whereas the interpretation of a call of a non-virtual member function depends only on the type of the pointer or reference denoting that object (the static type) (8.2.2). — end note]

[Note: The virtual specifier implies membership, so a virtual function cannot be a non-member (10.1.2) function. Nor can a virtual function be a static member, since a virtual function call relies on a specific object for determining which function to invoke. A virtual function declared in one class can be declared a friend in another class. — end note]

A virtual function declared in a class shall be defined, or declared pure (13.4) in that class, or both; no diagnostic is required (6.2).

[Example: Here are some uses of virtual functions with multiple base classes:

```
struct A {
  virtual void f();
};

struct B1 : A {
  void f();
};

struct B2 : A {
  void f();
};

struct D : B1, B2 {
  // D has two separate A subobjects
};

void foo() {
  D d;
  // A* ap = &d; // would be ill-formed: ambiguous
  B1* b1p = &d;
  A* ap = b1p;
  D* dp = &d;
  ap->f();
  // calls D::B1::f
  dp->f();
  // ill-formed: ambiguous
}
```

In class D above there are two occurrences of class A and hence two occurrences of the virtual member function A::f. The final overrider of B1::A::f is B1::f and the final overrider of B2::A::f is B2::f. — end example]

[Example: The following example shows a function that does not have a unique final overrider:

§ 13.3

265
struct A {
    virtual void f();
};

struct VB1 : virtual A {    // note virtual derivation
    void f();
};

struct VB2 : virtual A {
    void f();
};

struct Error : VB1, VB2 {
    // ill-formed
};

struct Okay : VB1, VB2 {
    void f();
};

Both VB1::f and VB2::f override A::f but there is no overrider of both of them in class Error. This
element is therefore ill-formed. Class Okay is well formed, however, because Okay::f is a final overrider.
— end example

[Example: The following example uses the well-formed classes from above.

struct VB1a : virtual A {    // does not declare f
};

struct Da : VB1a, VB2 {
};

void foe() {
    VB1a* vblap = new Da;
    vblap->f();          // calls VB2::f
}
— end example]

Explicit qualification with the scope operator (8.1) suppresses the virtual call mechanism. [Example:

class B { public: virtual void f(); }; 

class D : public B { public: void f(); }; 

void D::f() { /* ... */ B::f(); } }

Here, the function call in D::f really does call B::f and not D::f. — end example]

A function with a deleted definition (11.4) shall not override a function that does not have a deleted
definition. Likewise, a function that does not have a deleted definition shall not override a function with a deleted
definition.

13.4 Abstract classes

[Note: The abstract class mechanism supports the notion of a general concept, such as a shape, of which
only more concrete variants, such as circle and square, can actually be used. An abstract class can also be
used to define an interface for which derived classes provide a variety of implementations. — end note]

An abstract class is a class that can be used only as a base class of some other class; no objects of an abstract
class can be created except as subobjects of a class derived from it. A class is abstract if it has at least one pure virtual function. [Note: Such a function might be inherited: see below. — end note] A virtual
function is specified pure by using a pure-specifier (12.2) in the function declaration in the class definition. A pure virtual function need be defined only if called with, or as if with (15.4), the qualified-id syntax (8.1).

Example:

```cpp
class point { /* ... */ }; 
class shape { // abstract class 
    point center;
    public:
        point where() { return center; }
        void move(point p) { center=p; draw(); }
        virtual void rotate(int) = 0; // pure virtual
        virtual void draw() = 0; // pure virtual
    }
} 

// end example
```

Note: A function declaration cannot provide both a pure-specifier and a definition — end note

Example:

```cpp
struct C { 
    virtual void f() = 0 { }; // ill-formed
};

// end example
```

An abstract class shall not be used as a parameter type, as a function return type, or as the type of an explicit conversion. Pointers and references to an abstract class can be declared. [Example:

```cpp
shape x; // error: object of abstract class
shape* p; // OK
shape f(); // error
void g(shape);
shape& h(shape&); // OK

// end example
```

A class is abstract if it contains or inherits at least one pure virtual function for which the final overrider is pure virtual. [Example:

```cpp
class ab_circle : public shape { 
    int radius;
    public:
        void rotate(int) { } // ab_circle::draw() is a pure virtual
    }

Since shape::draw() is a pure virtual function ab_circle::draw() is a pure virtual by default. The alternative declaration,

```cpp
class circle : public shape { 
    int radius;
    public:
        void rotate(int) { } 
        void draw(); // a definition is required somewhere
    }
```

would make class circle non-abstract and a definition of circle::draw() must be provided. — end example

Note: An abstract class can be derived from a class that is not abstract, and a pure virtual function may override a virtual function which is not pure. — end note

Member functions can be called from a constructor (or destructor) of an abstract class; the effect of making a virtual call (13.3) to a pure virtual function directly or indirectly for the object being created (or destroyed)
from such a constructor (or destructor) is undefined.
14 Member access control [class.access]

1 A member of a class can be
(1.1) — **private**; that is, its name can be used only by members and friends of the class in which it is declared.
(1.2) — **protected**; that is, its name can be used only by members and friends of the class in which it is declared, by classes derived from that class, and by their friends (see 14.4).
(1.3) — **public**; that is, its name can be used anywhere without access restriction.

2 A member of a class can also access all the names to which the class has access. A local class of a member function may access the same names that the member function itself may access. 113

3 Members of a class defined with the keyword **class** are **private** by default. Members of a class defined with the keywords **struct** or **union** are **public** by default. [Example:

```cpp
class X {
  int a;  // X::a is private by default
};

struct S {
  int a;  // S::a is public by default
};
```

—end example]

4 Access control is applied uniformly to all names, whether the names are referred to from declarations or expressions. [Note: Access control applies to names nominated by **friend** declarations (14.3) and **using-declarations** (10.3.3). — end note] In the case of overloaded function names, access control is applied to the function selected by overload resolution. [Note: Because access control applies to names, if access control is applied to a typedef name, only the accessibility of the typedef name itself is considered. The accessibility of the entity referred to by the typedef is not considered. For example,

```cpp
class A {
  class B {};  
  public:
  typedef B BB;
};

void f() {
  A::BB x;  // OK, typedef name A::BB is public
  A::B y;  // access error, A::B is private
}
```

—end note]

5 It should be noted that it is **access** to members and base classes that is controlled, not their **visibility**. Names of members are still visible, and implicit conversions to base classes are still considered, when those members and base classes are inaccessible. The interpretation of a given construct is established without regard to access control. If the interpretation established makes use of inaccessible member names or base classes, the construct is ill-formed.

6 All access controls in Clause 14 affect the ability to access a class member name from the declaration of a particular entity, including parts of the declaration preceding the name of the entity being declared and, if

113) Access permissions are thus transitive and cumulative to nested and local classes.
the entity is a class, the definitions of members of the class appearing outside the class’s member-specification.

[Note: This access also applies to implicit references to constructors, conversion functions, and destructors. —end note]

[Example:

```cpp
class A {
    typedef int I; // private member
    I f();
    friend I g(I);
    static I x;
    template<int> struct Q;
    template<int> friend struct R;
    protected:
        struct B { 
        };
};

A::I A::f() { return 0; }
A::I g(A::I p = A::x);
A::I g(A::I p) { return 0; }
A::I A::x = 0;
template<A::I> struct A::Q { 
};
template<A::I> struct R { 
};

struct D: A::B, A { 
};
```

Here, all the uses of A::I are well-formed because A::f, A::x, and A::Q are members of class A and g and R are friends of class A. This implies, for example, that access checking on the first use of A::I must be deferred until it is determined that this use of A::I is as the return type of a member of class A. Similarly, the use of A::B as a base-specifier is well-formed because D is derived from A, so checking of base-specifiers must be deferred until the entire base-specifier-list has been seen. —end example]

8 The names in a default argument (11.3.6) are bound at the point of declaration, and access is checked at that point rather than at any points of use of the default argument. Access checking for default arguments in function templates and in member functions of class templates is performed as described in 17.7.1.

9 The names in a default template-argument (17.1) have their access checked in the context in which they appear rather than at any points of use of the default template-argument. [Example:

```cpp
class B { 
};
template <class T> class C {
    protected:
        typedef T TT;
    
};

template <class U, class V = typename U::TT>
class D : public U { 
};

D <C<B> $* d; // access error, C::TT is protected

—end example]
```

14.1 Access specifiers [class.access.spec]

Member declarations can be labeled by an access-specifier (Clause 13):

```
access-specifier : member-specification_opt
```

An access-specifier specifies the access rules for members following it until the end of the class or until another access-specifier is encountered. [Example:
class X {
    int a; // X::a is private by default: class used
public:
    int b; // X::b is public
    int c; // X::c is public
};

— end example]

2 Any number of access specifiers is allowed and no particular order is required. [Example:

struct S {
    int a; // S::a is public by default: struct used
protected:
    int b; // S::b is protected
private:
    int c; // S::c is private
public:
    int d; // S::d is public
};
— end example]

3 [ Note: The effect of access control on the order of allocation of data members is described in 12.2. — end note]

4 When a member is redeclared within its class definition, the access specified at its redeclaration shall be the
same as at its initial declaration. [Example:

struct S {
    class A;
    enum E : int;
private:
    class A {}; // error: cannot change access
    enum E: int { e0 }; // error: cannot change access
};
— end example]

5 [ Note: In a derived class, the lookup of a base class name will find the injected-class-name instead of the
name of the base class in the scope in which it was declared. The injected-class-name might be less accessible
than the name of the base class in the scope in which it was declared. — end note]

[Example:

class A {};
class B : private A {};
class C : public B {
    A* p; // error: injected-class-name A is inaccessible
    ::A* q; // OK
};
— end example]

14.2 Accessibility of base classes and base class members [class.access.base]

1 If a class is declared to be a base class (Clause 13) for another class using the public access specifier, the
public members of the base class are accessible as public members of the derived class and protected
members of the base class are accessible as protected members of the derived class. If a class is declared to
be a base class for another class using the protected access specifier, the public and protected members
of the base class are accessible as protected members of the derived class. If a class is declared to be a base
class for another class using the `private` access specifier, the `public` and `protected` members of the base class are accessible as `private` members of the derived class\(^\text{114}\).

2 In the absence of an access-specifier for a base class, `public` is assumed when the derived class is defined with the class-key `struct` and `private` is assumed when the class is defined with the class-key `class`. [Example:

```cpp
class B { /* ... */ };  
class D1 : private B { /* ... */ };  
class D2 : public B { /* ... */ };  
class D3 : B { /* ... */ };  // B private by default  
struct D4 : public B { /* ... */ };  
struct D5 : private B { /* ... */ };  
struct D6 : B { /* ... */ };  // B public by default  
class D7 : protected B { /* ... */ };  
struct D8 : protected B { /* ... */ };  
```

Here `B` is a public base of `D2`, `D4`, and `D6`, a private base of `D1`, `D3`, and `D5`, and a protected base of `D7` and `D8`. —end example]

3 [Note: A member of a private base class might be inaccessible as an inherited member name, but accessible directly. Because of the rules on pointer conversions (7.11) and explicit casts (8.4), a conversion from a pointer to a derived class to a pointer to an inaccessible base class might be ill-formed if an implicit conversion is used, but well-formed if an explicit cast is used. For example,

```cpp
class B {
  public:
    int mi;  // non-static member
    static int si; // static member
};
class D : private B {
};
class DD : public D {
  void f();
};

void DD::f() {
  mi = 3;  // error: mi is private in D
  si = 3;  // error: si is private in D
  ::B b;
  b.mi = 3;  // OK (b.mi is different from this->mi)
  b.si = 3;  // OK (b.si is different from this->si)
  ::B::si = 3;  // OK
  ::B* bp1 = this;
  ::B* bp2 = (::B*)this;
  bp2->mi = 3;  // OK: access through a pointer to B.
}
—end note]

4 A base class `B` of `N` is `accessible` at `R`, if

- (4.1) an invented public member of `B` would be a public member of `N`, or
- (4.2) `R` occurs in a member or friend of class `N`, and an invented public member of `B` would be a private or protected member of `N`, or
- (4.3) `R` occurs in a member or friend of a class `P` derived from `N`, and an invented public member of `B` would

\(^{114}\) As specified previously in Clause 14, private members of a base class remain inaccessible even to derived classes unless `friend` declarations within the base class definition are used to grant access explicitly.
be a private or protected member of \( P \), or

(4.4) — there exists a class \( S \) such that \( B \) is a base class of \( S \) accessible at \( R \) and \( S \) is a base class of \( N \) accessible at \( R \).

[Example:

```cpp
class B {
    public:
        int m;
};

class S: private B {
    friend class N;
};

class N: private S {
    void f() {
        B* p = this;  // OK because class S satisfies the fourth condition above: B is a base class of
                       // accessible in f() because B is an accessible base class of S and S is an accessible
                       // base class of N.
    }
};

— end example]

5 If a base class is accessible, one can implicitly convert a pointer to a derived class to a pointer to that base class (7.11, 7.12). [Note: It follows that members and friends of a class \( X \) can implicitly convert an \( X* \) to a pointer to a private or protected immediate base class of \( X \). — end note] The access to a member is affected by the class in which the member is named. This naming class is the class in which the member name was looked up and found. [Note: This class can be explicit, e.g., when a qualified-id is used, or implicit, e.g., when a class member access operator (8.2.5) is used (including cases where an implicit “this->” is added). If both a class member access operator and a qualified-id are used to name the member (as in \( p->T::m \)), the class naming the member is the class denoted by the nested-name-specifier of the qualified-id (that is, \( T \)). — end note] A member \( m \) is accessible at the point \( R \) when named in class \( N \) if

(5.1) — \( m \) as a member of \( N \) is public, or

(5.2) — \( m \) as a member of \( N \) is private, and \( R \) occurs in a member or friend of class \( N \), or

(5.3) — \( m \) as a member of \( N \) is protected, and \( R \) occurs in a member or friend of class \( N \), or in a member of a class \( P \) derived from \( N \), where \( m \) as a member of \( P \) is public, private, or protected, or

(5.4) — there exists a base class \( B \) of \( N \) that is accessible at \( R \), and \( m \) is accessible at \( R \) when named in class \( B \).

[Example:

```cpp
class B;
class A {
    private:
        int i;
        friend void f(B*);
    }
;
class B : public A { }

void f(B* p) {
    p->i = 1;  // OK: B* can be implicitly converted to A*, and f has access to i in A
}

— end example]

6 If a class member access operator, including an implicit “this->”, is used to access a non-static data member
or non-static member function, the reference is ill-formed if the left operand (considered as a pointer in the “.” operator case) cannot be implicitly converted to a pointer to the naming class of the right operand. [Note: This requirement is in addition to the requirement that the member be accessible as named. — end note]

14.3 Friends

A friend of a class is a function or class that is given permission to use the private and protected member names from the class. A class specifies its friends, if any, by way of friend declarations. Such declarations give special access rights to the friends, but they do not make the nominated friends members of the befriending class. [Example: The following example illustrates the differences between members and friends:

```cpp
class X {
  int a;
  friend void friend_set(X*, int);
public:
  void member_set(int);
};

void friend_set(X* p, int i) { p->a = i; }
void X::member_set(int i) { a = i; }

void f() {
  X obj;
  friend_set(&obj,10);
  obj.member_set(10);
}

— end example]

Declaring a class to be a friend implies that the names of private and protected members from the class granting friendship can be accessed in the base-specifiers and member declarations of the befriended class. [Example:

```cpp
class A {
  class B { };    // OK: A::B accessible to friend
  friend class X;
};

struct X : A::B {    // OK: A::B accessible to member of friend
  A::B mx;
  class Y {
    A::B my;    // OK: A::B accessible to nested member of friend
  };
};

— end example]  [Example:

```cpp
class X {
  enum { a=100 };    // OK, Y is a friend of X
  friend class Y;
};

class Y {
  int v[X::a];
};

class Z {
  int v[X::a];    // error: X::a is private
};
```
A class shall not be defined in a friend declaration. [Example:

class A {
    friend class B { };  // error: cannot define class in friend declaration
};
— end example]

A friend declaration that does not declare a function shall have one of the following forms:

friend elaborated-type-specifier;
friend simple-type-specifier;
friend typename-specifier;

[Note: A friend declaration may be the declaration in a template-declaration (Clause 17, 17.5.4). — end note] If the type specifier in a friend declaration designates a (possibly cv-qualified) class type, that class is declared as a friend; otherwise, the friend declaration is ignored. [Example:

class C;
typedef C Ct;

class X1 {
    friend C;        // OK: class C is a friend
};
class X2 {
    friend Ct;      // OK: class C is a friend
    friend D;      // error: no type-name D in scope
    friend class D; // OK: elaborated-type-specifier declares new class
};
template <typename T> class R {
    friend T;
};
R<C> rc; // class C is a friend of R<C>
R<int> Ri; // OK: “friend int;” is ignored
— end example]

A function first declared in a friend declaration has the linkage of the namespace of which it is a member (6.5). Otherwise, the function retains its previous linkage (10.1.1).

When a friend declaration refers to an overloaded name or operator, only the function specified by the parameter types becomes a friend. A member function of a class X can be a friend of a class Y. [Example:

class Y {
    friend char* X::foo(int);
    friend X::X(char);   // constructors can be friends
    friend X::~X();      // destructors can be friends
};
— end example]

A function can be defined in a friend declaration of a class if and only if the class is a non-local class (12.4), the function name is unqualified, and the function has namespace scope. [Example:

class M {
    friend void f() { } // definition of global f, a friend of M,

§ 14.3
Such a function is implicitly an inline function (10.1.6). A **friend** function defined in a class is in the (lexical) scope of the class in which it is defined. A friend function defined outside the class is not (6.4.1).

No **storage-class-specifier** shall appear in the **decl-specifier-seq** of a friend declaration.

A name nominated by a friend declaration shall be accessible in the scope of the class containing the friend declaration. The meaning of the friend declaration is the same whether the friend declaration appears in the **private**, **protected** or **public** (12.2) portion of the class **member-specification**.

Friendship is neither inherited nor transitive. [Example:

```cpp
class A {
    friend class B;
    int a;
};

class B {
    friend class C;
};

class C {
    void f(A* p) {
        p->a++;            // error: C is not a friend of A despite being a friend of a friend
    }
};

class D : public B {
    void f(A* p) {
        p->a++;            // error: D is not a friend of A despite being derived from a friend
    }
};
```

— end example ]

If a friend declaration appears in a local class (12.4) and the name specified is an unqualified name, a prior declaration is looked up without considering scopes that are outside the innermost enclosing non-class scope. For a friend function declaration, if there is no prior declaration, the program is ill-formed. For a friend class declaration, if there is no prior declaration, the class that is specified belongs to the innermost enclosing non-class scope, but if it is subsequently referenced, its name is not found by name lookup until a matching declaration is provided in the innermost enclosing non-class scope. [ Example:

```cpp
class X;
void a();
void f() {
    class Y;
    extern void b();
    class A {
        friend class X;  // OK, but X is a local class, not ::X
        friend class Y;  // OK
        friend class Z;  // OK, introduces local class Z
        friend void a(); // error, ::a is not considered
        friend void b(); // OK
        friend void c(); // error
    };
```
14.4 Protected member access

An additional access check beyond those described earlier in Clause 14 is applied when a non-static data member or non-static member function is a protected member of its naming class (14.2)\textsuperscript{115} As described earlier, access to a protected member is granted because the reference occurs in a friend or member of some class C. If the access is to form a pointer to member (8.3.1), the nested-name-specifier shall denote C or a class derived from C. All other accesses involve a (possibly implicit) object expression (8.2.5). In this case, the class of the object expression shall be C or a class derived from C. [Example:

```cpp
class B {
protected:
    int i;
    static int j;
};

class D1 : public B {
};

class D2 : public B {
    friend void fr(B*, D1*, D2*);
    void mem(B*, D1*);
};

void fr(B* pb, D1* p1, D2* p2) {
    pb->i = 1; // ill-formed
    p1->i = 2; // ill-formed
    p2->i = 3; // OK (access through a D2)
    p2->B::i = 4; // OK (access through a D2, even though naming class is B)
    int B::* pmi_B = &B::i; // ill-formed
    int B::* pmi_B2 = &D2::i; // OK (type of &D2::i is int B::*
    B::j = 5; // ill-formed (not a friend of naming class B)
    D2::j = 6; // OK (because refers to static member)
}

void D2::mem(B* pb, D1* p1) {
    pb->i = 1; // ill-formed
    p1->i = 2; // ill-formed
    i = 3; // OK (access through this)
    B::i = 4; // OK (access through this, qualification ignored)
    int B::* pmi_B = &B::i; // ill-formed
    int B::* pmi_B2 = &D2::i; // OK
    j = 5; // OK (because j refers to static member)
    B::j = 6; // OK (because B::j refers to static member)
}

void g(B* pb, D1* p1, D2* p2) {
    pb->i = 1; // ill-formed
    p1->i = 2; // ill-formed
    p2->i = 3; // ill-formed
}
```

\textsuperscript{115} This additional check does not apply to other members, e.g., static data members or enumerator member constants.
14.5 Access to virtual functions

The access rules (Clause 14) for a virtual function are determined by its declaration and are not affected by the rules for a function that later overrides it. [Example:

```cpp
class B {
public:
    virtual int f();
};

class D : public B {
private:
    int f();
};

void f() {
    D d;
    B* pb = &d;
    D* pd = &d;

    pb->f(); // OK: B::f() is public, D::f() is invoked
    pd->f(); // error: D::f() is private
}
```

—end example]

1 Access is checked at the call point using the type of the expression used to denote the object for which the member function is called (B* in the example above). The access of the member function in the class in which it was defined (D in the example above) is in general not known.

14.6 Multiple access

If a name can be reached by several paths through a multiple inheritance graph, the access is that of the path that gives most access. [Example:

```cpp
class W { public: void f(); }
class A : private virtual W { }
class B : public virtual W { }
class C : public A, public B {
    void f() { W::f(); }  // OK
};
```

Since W::f() is available to C::f() along the public path through B, access is allowed. —end example]

14.7 Nested classes

A nested class is a member and as such has the same access rights as any other member. The members of an enclosing class have no special access to members of a nested class; the usual access rules (Clause 14) shall be obeyed. [Example:

```cpp
class E {
    int x;
    class B { }
};

class I {
    B b;  // OK: E::I can access E::B
```
int y;
void f(E* p, int i) {
    p->x = i; // OK: E::x can access E::x
}

int g(I* p) {
    return p->y; // error: I::y is private
}

—end example]
15 Special member functions

The default constructor (15.1), copy constructor and copy assignment operator (15.8), move constructor and move assignment operator (15.8), and destructor (15.4) are special member functions. [Note: The implementation will implicitly declare these member functions for some class types when the program does not explicitly declare them. The implementation will implicitly define them if they are odr-used (6.2). See 15.1, 15.4 and 15.8. —end note] An implicitly-declared special member function is declared at the closing } of the class-specifier. Programs shall not define implicitly-declared special member functions.

Programs may explicitly refer to implicitly-declared special member functions. [Example: A program may explicitly call, take the address of, or form a pointer to member to an implicitly-declared special member function.]

struct A { }; // implicitly declared A::operator=
struct B : A {
    B& operator=(const B&);
};
B& B::operator=(const B& s) {
    this->A::operator=(s); // well formed
    return *this;
}
—end example

[Note: The special member functions affect the way objects of class type are created, copied, moved, and destroyed, and how values can be converted to values of other types. Often such special member functions are called implicitly. —end note]

Special member functions obey the usual access rules (Clause 14). [Example: Declaring a constructor protected ensures that only derived classes and friends can create objects using it. —end example]

For a class, its non-static data members, its non-virtual direct base classes, and, if the class is not abstract (13.4), its virtual base classes are called its potentially constructed subobjects.

15.1 Constructors

Constructors do not have names. In a declaration of a constructor, the declarator is a function declarator (11.3.5) of the form

\[ \text{ptr-declarator ( parameter-declaration-clause ) noexcept-specifier \ attribute-specifier-seq} \]

where the ptr-declarator consists solely of an id-expression, an optional attribute-specifier-seq, and optional surrounding parentheses, and the id-expression has one of the following forms:

1. in a member-declaration that belongs to the member-specification of a class but is not a friend declaration (14.3), the id-expression is the injected-class-name (Clause 12) of the immediately-enclosing class;
2. in a member-declaration that belongs to the member-specification of a class template but is not a friend declaration, the id-expression is a class-name that names the current instantiation (17.6.2.1) of the immediately-enclosing class template; or
3. in a declaration at namespace scope or in a friend declaration, the id-expression is a qualified-id that names a constructor (6.4.3.1).
The class-name shall not be a typedef-name. In a constructor declaration, each decl-specifier in the optional decl-specifier-seq shall be friend, inline, explicit, or constexpr. [Example:

```c
struct S {
    S(); // declares the constructor
};
S::S() { } // defines the constructor
— end example]
```

2 A constructor is used to initialize objects of its class type. Because constructors do not have names, they are never found during name lookup; however an explicit type conversion using the functional notation (8.2.3) will cause a constructor to be called to initialize an object. [Note: For initialization of objects of class type see 15.6. — end note]

3 A constructor can be invoked for a const, volatile or const volatile object. const and volatile semantics (10.1.7.1) are not applied on an object under construction. They come into effect when the constructor for the most derived object (4.5) ends.

4 A default constructor for a class X is a constructor of class X for which each parameter that is not a function parameter pack has a default argument (including the case of a constructor with no parameters). If there is no user-declared constructor for class X, a non-explicit constructor having no parameters is implicitly declared as defaulted (11.4). An implicitly-declared default constructor is an inline public member of its class.

5 A defaulted default constructor for class X is defined as deleted if:

(5.1) — X is a union that has a variant member with a non-trivial default constructor and no variant member of X has a default member initializer,

(5.2) — X is a non-union class that has a variant member M with a non-trivial default constructor and no variant member of the anonymous union containing M has a default member initializer,

(5.3) — any non-static data member with no default member initializer (12.2) is of reference type,

(5.4) — any non-variant non-static data member of const-qualified type (or array thereof) with no brace-or-equal-initializer does not have a user-provided default constructor,

(5.5) — X is a union and all of its variant members are of const-qualified type (or array thereof),

(5.6) — X is a non-union class and all members of any anonymous union member are of const-qualified type (or array thereof),

(5.7) — any potentially constructed subobject, except for a non-static data member with a brace-or-equal-initializer, has class type M (or array thereof) and either M has no default constructor or overload resolution (16.3) as applied to find M’s corresponding constructor results in an ambiguity or in a function that is deleted or inaccessible from the defaulted default constructor, or

(5.8) — any potentially constructed subobject has a type with a destructor that is deleted or inaccessible from the defaulted default constructor.

6 A default constructor is trivial if it is not user-provided and if:

(6.1) — its class has no virtual functions (13.3) and no virtual base classes (13.1), and

(6.2) — no non-static data member of its class has a default member initializer (12.2), and

(6.3) — all the direct base classes of its class have trivial default constructors, and

(6.4) — for all the non-static data members of its class that are of class type (or array thereof), each such class has a trivial default constructor.

Otherwise, the default constructor is non-trivial.
A default constructor that is defaulted and not defined as deleted is *implicitly defined* when it is odr-used (6.2) to create an object of its class type (4.5) or when it is explicitly defaulted after its first declaration. The implicitly-defined default constructor performs the set of initializations of the class that would be performed by a user-written default constructor for that class with no *ctor-initializer* (15.6.2) and an empty compound-statement. If that user-written default constructor would be ill-formed, the program is ill-formed. If that user-written default constructor would satisfy the requirements of a constexpr constructor (10.1.5), the implicitly-defined default constructor is constexpr. Before the defaulted default constructor for a class is implicitly defined, all the non-user-provided default constructors for its base classes and its non-static data members shall have been implicitly defined. [Note: An implicitly-declared default constructor has an exception specification (18.4). An explicitly-defaulted definition might have an implicit exception specification, see 11.4. —end note]

Default constructors are called implicitly to create class objects of static, thread, or automatic storage duration (6.7.1, 6.7.2, 6.7.3) defined without an initializer (11.6), are called to create class objects of dynamic storage duration (6.7.4) created by a *new-expression* in which the *new-initializer* is omitted (8.3.4), or are called when the explicit type conversion syntax (8.2.3) is used. A program is ill-formed if the default constructor for an object is implicitly used and the constructor is not accessible (Clause 14).

A *return* statement in the body of a constructor shall not specify a return value. The address of a constructor shall not be taken.

A functional notation type conversion (8.2.3) can be used to create new objects of its type. [Note: The syntax looks like an explicit call of the constructor. —end note] [Example:

```cpp
complex zz = complex(1,2.3);
cprint( complex(7.8,1.2) );
```

—end example]

An object created in this way is unnamed. [Note: 15.2 describes the lifetime of temporary objects. —end note] [Note: Explicit constructor calls do not yield lvalues, see 6.10. —end note]

[Note: Some language constructs have special semantics when used during construction; see 15.6.2 and 15.7. —end note]

During the construction of an object, if the value of the object or any of its subobjects is accessed through a glvalue that is not obtained, directly or indirectly, from the constructor’s *this* pointer, the value of the object or subobject thus obtained is unspecified. [Example:

```cpp
struct C;
void no_opt(C*);

struct C {
  int c;
  C() : c(0) { no_opt(this); }
};

const C cobj;

void no_opt(C* cpotr) {
  int i = cobj.c * 100;   // value of cobj.c is unspecified
  cpotr->c = 1;
  cout << cobj.c * 100    // value of cobj.c is unspecified
       << 'n';
}
```
extern struct D d;
struct D {
  D(int a) : a(a), b(d.a) {} 
  int a, b;
};
D d = D(1); // value of d.b is unspecified
—end example

15.2 Temporary objects

Temporary objects are created

(1.1) — when a prvalue is materialized so that it can be used as a glvalue (7.4),
(1.2) — when needed by the implementation to pass or return an object of trivially-copyable type (see below), and
(1.3) — when throwing an exception (18.1). [Note: The lifetime of exception objects is described in 18.1. — end note]

Even when the creation of the temporary object is unevaluated (Clause 8), all the semantic restrictions shall be respected as if the temporary object had been created and later destroyed. [Note: This includes accessibility (Clause 14) and whether it is deleted, for the constructor selected and for the destructor. However, in the special case of the operand of a decltype-specifier (8.2.2), no temporary is introduced, so the foregoing does not apply to such a prvalue. — end note]

The materialization of a temporary object is generally delayed as long as possible in order to avoid creating unnecessary temporary objects. [Note: Temporary objects are materialized:

(2.1) — when binding a reference to a prvalue (11.6.3, 8.2.3, 8.2.7, 8.2.9, 8.2.11, 8.4),
(2.2) — when performing member access on a class prvalue (8.2.5, 8.5),
(2.3) — when performing an array-to-pointer conversion or subscripting on an array prvalue (7.2, 8.2.1),
(2.4) — when initializing an object of type std::initializer_list<T> from a braced-init-list (11.6.4),
(2.5) — for certain unevaluated operands (8.2.8, 8.3.3), and
(2.6) — when a prvalue appears as a discarded-value expression (Clause 8). — end note] [Example: Consider the following code:

class X {
  public:
    X(int);
    X(const X&);
    X& operator=(const X&);
    ~X();
  };

class Y {
  public:
    Y(int);
    Y(Y&&);
    ~Y();
  };

  X f(X);
  Y g(Y);
void h() {
  X a(1);
  X b = f(X(2));
  Y c = g(Y(3));
  a = f(a);
}

X(2) is constructed in the space used to hold \( f() \)'s argument and Y(3) is constructed in the space used to hold \( g() \)'s argument. Likewise, \( f() \)'s result is constructed directly in b and \( g() \)'s result is constructed directly in c. On the other hand, the expression \( a = f(a) \) requires a temporary for the result of \( f(a) \), which is materialized so that the reference parameter of \( A::operator=(\text{const } A&) \) can bind to it. — end example]

3 When an object of class type X is passed to or returned from a function, if each copy constructor, move constructor, and destructor of X is either trivial or deleted, and X has at least one non-deleted copy or move constructor, implementations are permitted to create a temporary object to hold the function parameter or result object. The temporary object is constructed from the function argument or return value, respectively, and the function's parameter or return object is initialized as if by using the non-deleted trivial constructor to copy the temporary (even if that constructor is inaccessible or would not be selected by overload resolution to perform a copy or move of the object). [Note: This latitude is granted to allow objects of class type to be passed to or returned from functions in registers. — end note]

4 When an implementation introduces a temporary object of a class that has a non-trivial constructor (15.1, 15.8), it shall ensure that a constructor is called for the temporary object. Similarly, the destructor shall be called for a temporary with a non-trivial destructor (15.4). Temporary objects are destroyed as the last step in evaluating the full-expression (4.6) that (lexically) contains the point where they were created. This is true even if that evaluation ends in throwing an exception. The value computations and side effects of destroying a temporary object are associated only with the full-expression, not with any specific subexpression.

5 There are three contexts in which temporaries are destroyed at a different point than the end of the full-expression. The first context is when a default constructor is called to initialize an element of an array with no corresponding initializer (11.6). The second context is when a copy constructor is called to copy an element of an array while the entire array is copied (8.1.5.2, 15.8). In either case, if the constructor has one or more default arguments, the destruction of every temporary created in a default argument is sequenced before the construction of the next array element, if any.

6 The third context is when a reference is bound to a temporary.\[116\] The temporary to which the reference is bound or the temporary that is the complete object of a subobject to which the reference is bound persists for the lifetime of the reference except:

(6.1) A temporary object bound to a reference parameter in a function call (8.2.2) persists until the completion of the full-expression containing the call.

(6.2) The lifetime of a temporary bound to the returned value in a function return statement (9.6.3) is not extended; the temporary is destroyed at the end of the full-expression in the return statement.

(6.3) A temporary bound to a reference in a new-initializer (8.3.4) persists until the completion of the full-expression containing the new-initializer. [Example:

```cpp
struct S { int mi; const std::pair<int,int>& mp; };  
S a { 1, {2,3} };  
S* p = new S{ 1, {2,3} };  // Creates dangling reference
— end example] [Note: This may introduce a dangling reference, and implementations are encouraged to issue a warning in such a case. — end note]

\[116\] The same rules apply to initialization of an initializer_list object (11.6.4) with its underlying temporary array.
The destruction of a temporary whose lifetime is not extended by being bound to a reference is sequenced before the destruction of every temporary which is constructed earlier in the same full-expression. If the lifetime of two or more temporaries to which references are bound ends at the same point, these temporaries are destroyed at that point in the reverse order of the completion of their construction. In addition, the destruction of temporaries bound to references shall take into account the ordering of destruction of objects with static, thread, or automatic storage duration (6.7.1, 6.7.2, 6.7.3); that is, if \texttt{obj1} is an object with the same storage duration as the temporary and created before the temporary is created the temporary shall be destroyed before \texttt{obj1} is destroyed; if \texttt{obj2} is an object with the same storage duration as the temporary and created after the temporary is created the temporary shall be destroyed after \texttt{obj2} is destroyed.

\begin{example}
\begin{lstlisting}
struct S {
    S();
    S(int);
    friend S operator+(const S&, const S&);
    ~S();
};
S obj1;
const S& cr = S(16)+S(23);
S obj2;
\end{lstlisting}
\end{example}

the expression \texttt{S(16) + S(23)} creates three temporaries: a first temporary \texttt{T1} to hold the result of the expression \texttt{S(16)}, a second temporary \texttt{T2} to hold the result of the expression \texttt{S(23)}, and a third temporary \texttt{T3} to hold the result of the addition of these two expressions. The temporary \texttt{T3} is then bound to the reference \texttt{cr}. It is unspecified whether \texttt{T1} or \texttt{T2} is created first. On an implementation where \texttt{T1} is created before \texttt{T2}, \texttt{T2} shall be destroyed before \texttt{T1}. The temporaries \texttt{T1} and \texttt{T2} are bound to the reference parameters of \texttt{operator+}; these temporaries are destroyed at the end of the full-expression containing the call to \texttt{operator+}. The temporary \texttt{T3} bound to the reference \texttt{cr} is destroyed at the end of \texttt{cr}'s lifetime, that is, at the end of the program. In addition, the order in which \texttt{T3} is destroyed takes into account the destruction order of other objects with static storage duration. That is, because \texttt{obj1} is constructed before \texttt{T3}, and \texttt{T3} is constructed before \texttt{obj2}, \texttt{obj2} shall be destroyed before \texttt{T3}, and \texttt{T3} shall be destroyed before \texttt{obj1}. — end example

15.3 Conversions

Type conversions of class objects can be specified by constructors and by conversion functions. These conversions are called user-defined conversions and are used for implicit type conversions (Clause 7), for initialization (11.6), and for explicit type conversions (8.4, 8.2.9).

User-defined conversions are applied only where they are unambiguous (13.2, 15.3.2). Conversions obey the access control rules (Clause 14). Access control is applied after ambiguity resolution (6.4).

[Note: See 16.3 for a discussion of the use of conversions in function calls as well as examples below. — end note]

At most one user-defined conversion (constructor or conversion function) is implicitly applied to a single value. [Example:
\begin{lstlisting}
struct X {
    operator int();
};

struct Y {
    operator X();
};

Y a;
int b = a;      // error, a.operator X().operator int() not tried
\end{lstlisting}
§ 15.3 285]
int c = X(a);       // OK: a.operator X().operator int()
— end example]

User-defined conversions are used implicitly only if they are unambiguous. A conversion function in a derived
class does not hide a conversion function in a base class unless the two functions convert to the same
type. Function overload resolution (16.3.3) selects the best conversion function to perform the conversion.
[Example:

```c++
struct X {
    operator int();
};
struct Y : X {
    operator char();
};
void f(Y& a) {
    if (a) { // ill-formed: X::operator int() or Y::operator char()
    }
}
— end example]

15.3.1 Conversion by constructor [class.convctor]

A constructor declared without the function-specifier explicit specifies a conversion from the types of its
parameters (if any) to the type of its class. Such a constructor is called a converting constructor. [Example:

```c++
struct X {
    X(int);
    X(const char*, int = 0);
    X(int, int);
};
void f(X arg) {
    X a = 1;       // a = X(1)
    X b = "Jessie"; // b = X("Jessie", 0)
    a = 2;         // a = X(2)
    f(3);          // f(X(3))
    f({1, 2});     // f(X(1, 2))
}
— end example]
```

1 [Note: An explicit constructor constructs objects just like non-explicit constructors, but does so only where
the direct-initialization syntax (11.6) or where casts (8.2.9, 8.4) are explicitly used; see also 16.3.1.4. A default
constructor may be an explicit constructor; such a constructor will be used to perform default-initialization
or value-initialization (11.6). [Example:

```c++
struct Z {
    explicit Z();
    explicit Z(int);
    explicit Z(int, int);
};
Z a;          // OK: default-initialization performed
Z b{};        // OK: direct initialization syntax used
Z c = {};     // error: copy-list-initialization
```
A non-explicit copy/move constructor (15.8) is a converting constructor. [Note: An implicitly-declared copy/move constructor is not an explicit constructor; it may be called for implicit type conversions. —end note]

15.3.2 Conversion functions

1 A member function of a class \(X\) having no parameters with a name of the form

\[
\text{operator conversion-type-id}:
\]

\[
\text{conversion-type-id}:
\text{type-specifier-seq conversion-declarator}_{\text{opt}}
\]

\[
\text{conversion-declarator}:
\text{ptr-operator conversion-declarator}_{\text{opt}}
\]

specifies a conversion from \(X\) to the type specified by the \(\text{conversion-type-id}\). Such functions are called conversion functions. A \(\text{decl-specifier}\) in the \(\text{decl-specifier-seq}\) of a conversion function (if any) shall be neither a \(\text{defining-type-specifier}\) nor \(\text{static}\). The type of the conversion function (11.3.5) is “function taking no parameter returning conversion-type-id”. A conversion function is never used to convert a (possibly cv-qualified) object to the (possibly cv-qualified) same object type (or a reference to it), to a (possibly cv-qualified) base class of that type (or a reference to it), or to (possibly cv-qualified) void.\(^{117}\) [Example:

\[
\text{struct X} \{
\quad \text{operator int}();
\quad \text{operator auto()} \to \text{short}; \quad \text{// error: trailing return type}
\};
\]

\[
\text{void f(X a) } \{
\quad \text{int i = int(a);}
\quad \text{i = (int)a;}
\quad \text{i = a;}
\}\]

In all three cases the value assigned will be converted by \(X::\text{operator int}()\). —end example]

2 A conversion function may be explicit (10.1.2), in which case it is only considered as a user-defined conversion for direct-initialization (11.6). Otherwise, user-defined conversions are not restricted to use in assignments and initializations. [Example:

\[
\text{class Y } \{
\};
\text{struct Z } \{
\quad \text{explicit operator Y() const;}
\};
\]

\(^{117}\) These conversions are considered as standard conversions for the purposes of overload resolution (16.3.3.1, 16.3.3.1.4) and therefore initialization (11.6) and explicit casts (8.2.9). A conversion to \text{void} does not invoke any conversion function (8.2.9). Even though never directly called to perform a conversion, such conversion functions can be declared and can potentially be reached through a call to a virtual conversion function in a base class.

§ 15.3.2 287
void h(Z z) {
    Y y1(z);       // OK: direct-initialization
    Y y2 = z;      // ill-formed: copy-initialization
    Y y3 = (Y)z;   // OK: cast notation
}

void g(X a, X b) {
    int i = (a) ? 1+a : 0;
    int j = (a&&b) ? a+b : i;
    if (a) {
    }
}
—end example

3 The conversion-type-id shall not represent a function type nor an array type. The conversion-type-id in a conversion-function-id is the longest sequence of tokens that could possibly form a conversion-type-id. [Note: This prevents ambiguities between the declarator operator * and its expression counterparts. [Example:

&ac.operator int*i; // syntax error:
    // parsed as: &&(ac.operator int *)i
    // not as: &(ac.operator int)*i

The * is the pointer declarator and not the multiplication operator. —end example] This rule also prevents ambiguities for attributes. [Example:

    operator int [[noreturn]] () { // error: noreturn attribute applied to a type
        } —end example] —end note]

4 Conversion functions are inherited.

5 Conversion functions can be virtual.

6 A conversion function template shall not have a deduced return type (10.1.7.4). [Example:

    struct S {
        operator auto() const { return 10; }  // OK
        template<class T>
        operator auto() const { return 1.2; }  // error: conversion function template
    };

—end example]

15.4 Destructors [class.dtor]

1 In a declaration of a destructor, the declarator is a function declarator (11.3.5) of the form

    ptr-declarator ( parameter-declaration-clause ) noexcept-specifier_opt attribute-specifier-seq_opt

where the ptr-declarator consists solely of an id-expression, an optional attribute-specifier-seq, and optional surrounding parentheses, and the id-expression has one of the following forms:

(1.1) — in a member-declaration that belongs to the member-specification of a class but is not a friend declaration (14.3), the id-expression is ~class-name and the class-name is the injected-class-name (Clause 12) of the immediately-enclosing class;

(1.2) — in a member-declaration that belongs to the member-specification of a class template but is not a friend declaration, the id-expression is ~class-name and the class-name names the current instantiation (17.6.2.1) of the immediately-enclosing class template; or

(1.3) — in a declaration at namespace scope or in a friend declaration, the id-expression is nested-name-specifier ~class-name and the class-name names the same class as the nested-name-specifier.

§ 15.4
The class-name shall not be a typedef-name. A destructor shall take no arguments (11.3.5). Each decl-specifier of the decl-specifier-seq of a destructor declaration (if any) shall be friend, inline, or virtual.

A destructor is used to destroy objects of its class type. The address of a destructor shall not be taken. A destructor can be invoked for a const, volatile or const volatile object. const and volatile semantics (10.1.7.1) are not applied on an object under destruction. They stop being in effect when the destructor for the most derived object (4.5) starts.

[Note: A declaration of a destructor that does not have a noexcept-specifier has the same exception specification as if had been implicitly declared (18.4). — end note]

If a class has no user-declared destructor, a destructor is implicitly declared as defaulted (11.4). An implicitly-declared destructor is an inline public member of its class.

A defaulted destructor for a class X is defined as deleted if:

(5.1) X is a union-like class that has a variant member with a non-trivial destructor,
(5.2) any potentially constructed subobject has class type M (or array thereof) and M has a deleted destructor or a destructor that is inaccessible from the defaulted destructor,
(5.3) or, for a virtual destructor, lookup of the non-array deallocation function results in an ambiguity or in a function that is deleted or inaccessible from the defaulted destructor.

A destructor is trivial if it is not user-provided and if:

(6.1) the destructor is not virtual,
(6.2) all of the direct base classes of its class have trivial destructors, and
(6.3) for all of the non-static data members of its class that are of class type (or array thereof), each such class has a trivial destructor.

Otherwise, the destructor is non-trivial.

A destructor that is defaulted and not defined as deleted is implicitly defined when it is odr-used (6.2) or when it is explicitly defaulted after its first declaration.

Before the defaulted destructor for a class is implicitly defined, all the non-user-provided destructors for its base classes and its non-static data members shall have been implicitly defined.

After executing the body of the destructor and destroying any automatic objects allocated within the body, a destructor for class X calls the destructors for X’s direct non-variant non-static data members, the destructors for X’s non-virtual direct base classes and, if X is the type of the most derived class (15.6.2), its destructor calls the destructors for X’s virtual base classes. All destructors are called as if they were referenced with a qualified name, that is, ignoring any possible virtual overriding destructors in more derived classes. Bases and members are destroyed in the reverse order of the completion of their constructor (see 15.6.2). A return statement (9.6.3) in a destructor might not directly return to the caller; before transferring control to the caller, the destructors for the members and bases are called. Destructors for elements of an array are called in reverse order of their construction (see 15.6).

A destructor can be declared virtual (13.3) or pure virtual (13.4); if any objects of that class or any derived class are created in the program, the destructor shall be defined. If a class has a base class with a virtual destructor, its destructor (whether user- or implicitly-declared) is virtual.

[Note: Some language constructs have special semantics when used during destruction; see 15.7. — end note]

A destructor is invoked implicitly

(12.1) for a constructed object with static storage duration (6.7.1) at program termination (6.6.4),
(12.2) for a constructed object with thread storage duration (6.7.2) at thread exit,
(12.3) — for a constructed object with automatic storage duration (6.7.3) when the block in which an object is created exits (9.7),
(12.4) — for a constructed temporary object when its lifetime ends (7.4, 15.2).

In each case, the context of the invocation is the context of the construction of the object. A destructor is also invoked implicitly through use of a delete-expression (8.3.5) for a constructed object allocated by a new-expression (8.3.4); the context of the invocation is the delete-expression. [Note: An array of class type contains several subobjects for each of which the destructor is invoked. — end note] A destructor can also be invoked explicitly. A destructor is potentially invoked if it is invoked or as specified in 8.3.4, 15.6.2, and 18.1. A program is ill-formed if a destructor that is potentially invoked is deleted or not accessible from the context of the invocation.

13 At the point of definition of a virtual destructor (including an implicit definition (15.8)), the non-array deallocation function is determined as if for the expression delete this appearing in a non-virtual destructor of the destructor’s class (see 8.3.5). If the lookup fails or if the deallocation function has a deleted definition (11.4), the program is ill-formed. [Note: This assures that a deallocation function corresponding to the dynamic type of an object is available for the delete-expression (15.5). — end note]

14 In an explicit destructor call, the destructor is specified by a ~ followed by a type-name or decltype-specifier that denotes the destructor’s class type. The invocation of a destructor is subject to the usual rules for member functions (12.2.1); that is, if the object is not of the destructor’s class type and not of a class derived from the destructor’s class type (including when the destructor is invoked via a null pointer value), the program has undefined behavior. [Note: Invoking delete on a null pointer does not call the destructor; see 8.3.5. — end note] [Example:

    struct B {
      virtual ~B() { }
    };  
    struct D : B {
      ~D() { }
    };  
    D D_object;
    typedef B B_alias;
    B* B_ptr = &D_object;
    void f() {
      D_object.B::~B();    // calls B’s destructor
      B_ptr->~B();        // calls D’s destructor
      B_ptr->~B_alias();  // calls D’s destructor
      B_ptr->B_alias::~B(); // calls B’s destructor
      B_ptr->B_alias::~B_alias(); // calls B’s destructor
    }
    — end example] [Note: An explicit destructor call must always be written using a member access operator (8.2.5) or a qualified-id (8.1); in particular, the unary-expression ~X() in a member function is not an explicit destructor call (8.3.1). — end note]

[Note: Explicit calls of destructors are rarely needed. One use of such calls is for objects placed at specific addresses using a placement new-expression. Such use of explicit placement and destruction of objects can be necessary to cope with dedicated hardware resources and for writing memory management facilities. For example,

    void* operator new(std::size_t, void* p) { return p; }
    struct X {
      X(int);
    }  

§ 15.4
-X();

};

void f(X* p);

void g() {
    // rare, specialized use:
    char* buf = new char[sizeof(X)];
    X* p = new(buf) X(222);   // use buf[] and initialize
    f(p);
    p->X::~X();   // cleanup
}

} — end note

Once a destructor is invoked for an object, the object no longer exists; the behavior is undefined if the
destructor is invoked for an object whose lifetime has ended (6.8). [Example: If the destructor for an
automatic object is explicitly invoked, and the block is subsequently left in a manner that would ordinarily
invoke implicit destruction of the object, the behavior is undefined. — end example]

[Note: The notation for explicit call of a destructor can be used for any scalar type name (8.2.4). Allowing
this makes it possible to write code without having to know if a destructor exists for a given type. For example:

    typedef int I;
    I* p;
    p->I::~I();

— end note]

15.5 Free store [class.free]

Any allocation function for a class T is a static member (even if not explicitly declared static).

[Example:

    class Arena;
    struct B {
        void* operator new(std::size_t, Arena*);
    };
    struct D1 : B {
    };

    Arena* ap;
    void foo(int i) {
        new (ap) D1;  // calls B::operator new(std::size_t, Arena*)
        new D1[i];    // calls ::operator new[](std::size_t)
        new D1;       // ill-formed: ::operator new(std::size_t) hidden
    }

— end example]

When an object is deleted with a delete-expression (8.3.5), a deallocation function (operator delete() for
non-array objects or operator delete[]() for arrays) is (implicitly) called to reclaim the storage occupied
by the object (6.7.4.2).

Class-specific deallocation function lookup is a part of general deallocation function lookup (8.3.5) and
occurs as follows. If the delete-expression is used to deallocate a class object whose static type has a virtual
destructor, the deallocation function is the one selected at the point of definition of the dynamic type’s
virtual destructor (15.4).118 Otherwise, if the delete-expression is used to deallocate an object of class T or
array thereof, the static and dynamic types of the object shall be identical and the deallocation function’s

[Note 118] A similar provision is not needed for the array version of operator delete because 8.3.5 requires that in this situation, the

§ 15.5 291

118) A similar provision is not needed for the array version of operator delete because 8.3.5 requires that in this situation, the
name is looked up in the scope of T. If this lookup fails to find the name, general deallocation function lookup \((8.3.5)\) continues. If the result of the lookup is ambiguous or inaccessible, or if the lookup selects a placement deallocation function, the program is ill-formed.

5 Any deallocation function for a class X is a static member (even if not explicitly declared \texttt{static}). [Example:

```cpp
class X {
    void operator delete(void*);
    void operator delete[](void*, std::size_t);
};

class Y {
    void operator delete(void*, std::size_t);
    void operator delete[](void*);
};
@end example]
```

6 Since member allocation and deallocation functions are \texttt{static} they cannot be virtual. [Note: However, when the \textit{cast-expression} of a \textit{delete-expression} refers to an object of class type, because the deallocation function actually called is looked up in the scope of the class that is the dynamic type of the object, if the destructor is virtual, the effect is the same. For example,

```cpp
struct B {
    virtual ~B();
    void operator delete(void*, std::size_t);
};

struct D : B {
    void operator delete(void*);
};

void f() {
    B* bp = new D;
    delete bp; // 1: uses D::operator delete(void*)
}
```

Here, storage for the non-array object of class D is deallocated by \texttt{D::operator delete()}, due to the virtual destructor. —end note] [Note: Virtual destructors have no effect on the deallocation function actually called when the \textit{cast-expression} of a \textit{delete-expression} refers to an array of objects of class type. For example,

```cpp
struct B {
    virtual ~B();
    void operator delete[](void*, std::size_t);
};

struct D : B {
    void operator delete[](void*, std::size_t);
};

void f(int i) {
    D* dp = new D[i];
    delete [] dp; // uses D::operator delete[](void*, std::size_t)
    B* bp = new D[i];
    delete[] bp;  // undefined behavior
}
```

static type of the object to be deleted be the same as its dynamic type.

§ 15.5 292
Access to the deallocation function is checked statically. Hence, even though a different one might actually be executed, the statically visible deallocation function is required to be accessible. [Example: For the call on line “// 1” above, if \texttt{B::operator delete()} had been \texttt{private}, the delete expression would have been ill-formed. — end example]

[Note: If a deallocation function has no explicit \texttt{noexcept-specifier}, it has a non-throwing exception specification (18.4). — end note]

15.6 Initialization

1 When no initializer is specified for an object of (possibly cv-qualified) class type (or array thereof), or the initializer has the form \texttt{(\)}, the object is initialized as specified in 11.6.

2 An object of class type (or array thereof) can be explicitly initialized; see 15.6.1 and 15.6.2.

3 When an array of class objects is initialized (either explicitly or implicitly) and the elements are initialized by constructor, the constructor shall be called for each element of the array, following the subscript order; see 11.3.4. [Note: Destructors for the array elements are called in reverse order of their construction. — end note]

15.6.1 Explicit initialization

1 An object of class type can be initialized with a parenthesized \texttt{expression-list}, where the \texttt{expression-list} is construed as an argument list for a constructor that is called to initialize the object. Alternatively, a single \texttt{assignment-expression} can be specified as an \texttt{initializer} using the \texttt{=} form of initialization. Either direct-initialization semantics or copy-initialization semantics apply; see 11.6. [Example:

   \begin{verbatim}
   struct complex {
   complex();
   complex(double);
   complex(double,double);
   
   complex sqrt(complex,complex);
   
   complex a(1);         // initialize by a call of complex(double)
   complex b = a;        // initialize by a copy of a
   complex c = complex(1,2);    // construct complex(1,2) using complex(double,double),
                                // copy/move it into c
   complex d = sqrt(b,c);   // call sqrt(complex,complex) and copy/move the result into d
   complex e;              // initialize by a call of complex()
   complex f = 3;          // construct complex(3) using complex(double), copy/move it into f
   complex g = { 1, 2 };   // initialize by a call of complex(double, double)
   \end{verbatim}

— end example] [Note: Overloading of the assignment operator (16.5.3) has no effect on initialization. — end note]

2 An object of class type can also be initialized by a \texttt{braced-init-list}. List-initialization semantics apply; see 11.6 and 11.6.4. [Example:

   \begin{verbatim}
   complex v[6] = { 1, complex(1,2), complex(), 2 };  
   \end{verbatim}

Here, \texttt{complex::complex(double)} is called for the initialization of \texttt{v[0]} and \texttt{v[3]}, \texttt{complex::complex(double, double)} is called for the initialization of \texttt{v[1]}, \texttt{complex::complex()} is called for the initialization \texttt{v[2]}, \texttt{v[4]}, and \texttt{v[5]}. For another example,

   \begin{verbatim}
   struct X {
   int i;
   \end{verbatim}
float f;
complex c;
} x = { 99, 88.8, 77.7 };  

Here, \( x.i \) is initialized with 99, \( x.f \) is initialized with 88.8, and \texttt{complex::complex(double)} is called for the initialization of \( x.c \).  \[ \text{end example} \]  

\[ \text{Note:} \text{ Braces can be elided in the initializer-list for any aggregate, even if the aggregate has members of a class type with user-defined type conversions; see 11.6.1.} \[ \text{end note} \]  

3 \[ \text{Note:} \text{ If } T \text{ is a class type with no default constructor, any declaration of an object of type } T \text{ (or array thereof) is ill-formed if no } \text{initializer} \text{ is explicitly specified (see 15.6 and 11.6).} \[ \text{end note} \]  

4 \[ \text{Note: The order in which objects with static or thread storage duration are initialized is described in 6.6.3 and 9.7.} \[ \text{end note} \]  

15.6.2 Initializing bases and members \[ \text{class.base.init} \]  

1 In the definition of a constructor for a class, initializers for direct and virtual base class subobjects and non-static data members can be specified by a \texttt{ctor-initializer}, which has the form  

\[ \texttt{ctor-initializer:} \]

\[ \texttt{: mem-initializer-list} \]

\[ \texttt{mem-initializer-list:} \]

\[ \texttt{mem-initializer \ldots \text{opt}} \]

\[ \texttt{mem-initializer-list \text{, mem-initializer \ldots \text{opt}}} \]

\[ \texttt{mem-initializer:} \]

\[ \texttt{mem-initializer-id ( expression-list_{opt} )} \]

\[ \texttt{mem-initializer-id braced-init-list} \]

\[ \texttt{mem-initializer-id:} \]

\[ \texttt{class-or-decltype} \]

\[ \texttt{identifier} \]

2 In a \texttt{mem-initializer-id} an initial unqualified \texttt{identifier} is looked up in the scope of the constructor’s class and, if not found in that scope, it is looked up in the scope containing the constructor’s definition. \[ \text{Note:} \text{ If the constructor’s class contains a member with the same name as a direct or virtual base class of the class, a } \texttt{mem-initializer-id} \text{ naming the member or base class and composed of a single identifier refers to the class member. A } \texttt{mem-initializer-id} \text{ for the hidden base class may be specified using a qualified name.} \[ \text{end note} \]  

Unless the \texttt{mem-initializer-id} names the constructor’s class, a non-static data member of the constructor’s class, or a direct or virtual base of that class, the \texttt{mem-initializer} is ill-formed.  

3 A \texttt{mem-initializer-list} can initialize a base class using any \texttt{class-or-decltype} that denotes that base class type. \[ \text{Example:} \]

\[ \texttt{struct A \{ A(); \};} \]

\[ \texttt{typedef A global_A;} \]

\[ \texttt{struct B \{ ;} \]

\[ \texttt{struct C: public A, public B \{ C(); \};} \]

\[ \texttt{C::C(): global_A \{ \} \quad // mem-initializer for base A} \]

\[ \text{— end example} \]  

4 If a \texttt{mem-initializer-id} is ambiguous because it designates both a direct non-virtual base class and an inherited virtual base class, the \texttt{mem-initializer} is ill-formed. \[ \text{Example:} \]

\[ \texttt{struct A \{ A(); \};} \]

\[ \texttt{struct B: public virtual A \{ ;} \]

\[ \texttt{struct C: public A, public B \{ C(); \};} \]

\[ \texttt{C::C(): A() \{ \} \quad // ill-formed: which A?} \]
A ctor-initializer may initialize a variant member of the constructor’s class. If a ctor-initializer specifies more than one mem-initializer for the same member or for the same base class, the ctor-initializer is ill-formed.

A mem-initializer-list can delegate to another constructor of the constructor’s class using any class-or-decltype that denotes the constructor’s class itself. If a mem-initializer-id designates the constructor’s class, it shall be the only mem-initializer; the constructor is a delegating constructor, and the constructor selected by the mem-initializer is the target constructor. The target constructor is selected by overload resolution. Once the target constructor returns, the body of the delegating constructor is executed. If a constructor delegates to itself directly or indirectly, the program is ill-formed, no diagnostic required. [ Example:

```c
struct C {
    C( int ) { } // #1: non-delegating constructor
    C(): C(42) { } // #2: delegates to #1
    C( char c ) : C(42.0) { } // #3: ill-formed due to recursion with #4
    C( double d ) : C('a') { } // #4: ill-formed due to recursion with #3
};
```
—end example]

The expression-list or braced-init-list in a mem-initializer is used to initialize the designated subobject (or, in the case of a delegating constructor, the complete class object) according to the initialization rules of 11.6 for direct-initialization. [ Example:

```c
struct B1 { B1(int); /* ... */ };  
struct B2 { B2(int); /* ... */ };  
struct D : B1, B2 {
    D(int);
    B1 b;
    const int c;
};

D::D(int a) : B2(a+1), B1(a+2), c(a+3), b(a+4) { /* ... */ }
```
— end example] [ Note: The initialization performed by each mem-initializer constitutes a full-expression (4.6). Any expression in a mem-initializer is evaluated as part of the full-expression that performs the initialization. —end note] A mem-initializer where the mem-initializer-id denotes a virtual base class is ignored during execution of a constructor of any class that is not the most derived class.

A temporary expression bound to a reference member in a mem-initializer is ill-formed. [ Example:

```c
struct A {
    A() : v(42) { } // error
    const int& v;
};
```
— end example]

In a non-delegating constructor, if a given potentially constructed subobject is not designated by a mem-initializer-id (including the case where there is no mem-initializer-list because the constructor has no ctor-initializer), then

- if the entity is a non-static data member that has a default member initializer (12.2) and either
  - the constructor’s class is a union (12.3), and no other variant member of that union is designated by a mem-initializer-id or
  - the constructor’s class is not a union, and, if the entity is a member of an anonymous union, no other member of that union is designated by a mem-initializer-id,
the entity is initialized from its default member initializer as specified in 11.6:

(9.2) — otherwise, if the entity is an anonymous union or a variant member (12.3.1), no initialization is performed;

(9.3) — otherwise, the entity is default-initialized (11.6).

[Note: An abstract class (13.4) is never a most derived class, thus its constructors never initialize virtual base classes, therefore the corresponding mem-initializers may be omitted. — end note] An attempt to initialize more than one non-static data member of a union renders the program ill-formed. [Note: After the call to a constructor for class X for an object with automatic or dynamic storage duration has completed, if the constructor was not invoked as part of value-initialization and a member of X is neither initialized nor given a value during execution of the compound-statement of the body of the constructor, the member has an indeterminate value. — end note] [Example:

```cpp
struct A {
    A();
};

struct B {
    B(int);
};

struct C {
    C() { } // initializes members as follows:
    A a; // OK: calls A::A()
    const B b; // error: B has no default constructor
    int i; // OK: i has indeterminate value
    int j = 5; // OK: j has the value 5
};

// end example]
```

10 If a given non-static data member has both a default member initializer and a mem-initializer, the initialization specified by the mem-initializer is performed, and the non-static data member’s default member initializer is ignored. [Example: Given

```cpp
struct A {
    int i = /* some integer expression with side effects */ ;
    A(int arg) : i(arg) { }
    // ...
};
```

the A(int) constructor will simply initialize i to the value of arg, and the side effects in i’s default member initializer will not take place. — end example]

11 A temporary expression bound to a reference member from a default member initializer is ill-formed. [Example:

```cpp
struct A {
    A() = default; // OK
    A(int v) : v(v) { } // OK
    const int& v = 42; // OK
};

A a1; // error: ill-formed binding of temporary to reference
A a2(1); // OK, unfortunately
```

— end example]
In a non-delegating constructor, the destructor for each potentially constructed subobject of class type is potentially invoked (15.4). [Note: This provision ensures that destructors can be called for fully-constructed subobjects in case an exception is thrown (18.2). — end note]

In a non-delegating constructor, initialization proceeds in the following order:

13.1 First, and only for the constructor of the most derived class (4.5), virtual base classes are initialized in the order they appear on a depth-first left-to-right traversal of the directed acyclic graph of base classes, where “left-to-right” is the order of appearance of the base classes in the derived class base-specifier-list.

13.2 Then, direct base classes are initialized in declaration order as they appear in the base-specifier-list (regardless of the order of the mem-initializers).

13.3 Then, non-static data members are initialized in the order they were declared in the class definition (again regardless of the order of the mem-initializers).

13.4 Finally, the compound-statement of the constructor body is executed.

[Note: The declaration order is mandated to ensure that base and member subobjects are destroyed in the reverse order of initialization. — end note]

Example:

```c++
struct V {
    V();
    V(int);
};

struct A : virtual V {
    A();
    A(int);
};

struct B : virtual V {
    B();
    B(int);
};

struct C : A, B, virtual V {
    C();
    C(int);
};

A::A(int i) : V(i) { /* ... */ }
B::B(int i) { /* ... */ }
C::C(int i) { /* ... */ }
```

Names in the expression-list or braced-init-list of a mem-initializer are evaluated in the scope of the constructor for which the mem-initializer is specified. [Example:

```c++
class X {
    int a;
    int b;
```
int i;
int j;
public:
    const int& r;
    X(int i): r(a), b(i), i(i), j(this->i) { }
};

initializes $X::r$ to refer to $X::a$, initializes $X::b$ with the value of the constructor parameter $i$, initializes $X::i$ with the value of the constructor parameter $i$, and initializes $X::j$ with the value of $X::i$; this takes place each time an object of class $X$ is created. —end example] [Note: Because the mem-initializer are evaluated in the scope of the constructor, the this pointer can be used in the expression-list of a mem-initializer to refer to the object being initialized. —end note]

16 Member functions (including virtual member functions, 13.3) can be called for an object under construction. Similarly, an object under construction can be the operand of the typeid operator (8.2.8) or of a dynamic_cast (8.2.7). However, if these operations are performed in a ctor-initializer (or in a function called directly or indirectly from a ctor-initializer) before all the mem-initializers for base classes have completed, the program has undefined behavior. [Example:

class A {
    public:
        A(int);
};

class B : public A {
    int j;
    public:
        int f();
        B() : A(f()), // undefined: calls member function but base A not yet initialized
            j(f()) { } // well-defined: bases are all initialized
};

class C {
    public:
        C(int);
};

class D : public B, C {
    int i;
    public:
        D() : C(f()), // undefined: calls member function but base C not yet initialized
                i(f()) { } // well-defined: bases are all initialized
};

—end example]

17 [Note: 15.7 describes the result of virtual function calls, typeid and dynamic_casts during construction for the well-defined cases; that is, describes the polymorphic behavior of an object under construction. —end note]

18 A mem-initializer followed by an ellipsis is a pack expansion (17.5.3) that initializes the base classes specified by a pack expansion in the base-specifier-list for the class. [Example:

    template<class... Mixins>
    class X : public Mixins... {
        public:
            X(const Mixins&... mixins) : Mixins(mixins)... { }
    };

§ 15.6.2
15.6.3 Initialization by inherited constructor  

When a constructor for type \( B \) is invoked to initialize an object of a different type \( D \) (that is, when the constructor was inherited (10.3.3)), initialization proceeds as if a defaulted default constructor were used to initialize the \( D \) object and each base class subobject from which the constructor was inherited, except that the \( B \) subobject is initialized by the invocation of the inherited constructor. The complete initialization is considered to be a single function call; in particular, the initialization of the inherited constructor’s parameters is sequenced before the initialization of any part of the \( D \) object. [Example:

```c
struct B1 {
    B1(int, ...) { }
};

struct B2 {
    B2(double) { }
};

int get();

struct D1 : B1 {
    using B1::B1; // inherits B1(int, ...)
    int x;
    int y = get();
};

void test() {
    D1 d(2, 3, 4); // OK: B1 is initialized by calling B1(2, 3, 4),
    // then d.x is default-initialized (no initialization is performed),
    // then d.y is initialized by calling get()
    D1 e; // error: D1 has a deleted default constructor
}

struct D2 : B2 {
    using B2::B2;
    B1 b;
};

D2 f(1.0); // error: B1 has a deleted default constructor
```

`© ISO/IEC N4659 — end example`]

2 If the constructor was inherited from multiple base class subobjects of type \( B \), the program is ill-formed. [Example:
When an object is initialized by an inherited constructor, initialization of the object is complete when the initialization of all subobjects is complete.

15.7 Construction and destruction

For an object with a non-trivial constructor, referring to any non-static member or base class of the object before the constructor begins execution results in undefined behavior. For an object with a non-trivial destructor, referring to any non-static member or base class of the object after the destructor finishes execution results in undefined behavior. [Example:

```c
struct X { int i; };  // non-trivial
struct Y : X { Y(); };  // non-trivial
struct A { int a; };  // non-trivial
struct B : public A { int j; Y y; };  // non-trivial

extern B bobj;
B* pb = &bobj;  // OK
int* p1 = &bobj.a;  // undefined, refers to base class member
int* p2 = &bobj.y.i;  // undefined, refers to member’s member

A* pa = &bobj;  // undefined, upcast to a base class type
B bobj;  // definition of bobj

extern X xobj;
int* p3 = &xobj.i;  // OK, X is a trivial class
```
X xobj;

For another example,

```c
struct W { int j; };
struct X : public virtual W { };
struct Y {
    int* p;
    X x;
    Y() : p(&x.j) { // undefined, x is not yet constructed
        // undefined, x is not yet constructed
    }
};
```

—end example—

2 To explicitly or implicitly convert a pointer (a glvalue) referring to an object of class X to a pointer (reference) to a direct or indirect base class B of X, the construction of X and the construction of all of its direct or indirect bases that directly or indirectly derive from B shall have started and the destruction of these classes shall not have completed, otherwise the conversion results in undefined behavior. To form a pointer to (or access the value of) a direct non-static member of an object obj, the construction of obj shall have started and its destruction shall not have completed, otherwise the computation of the pointer value (or accessing the member value) results in undefined behavior. [Example:

```c
struct A { };
struct B : virtual A { };
struct C : B { };
struct D : virtual A { D(A*); };
struct X { X(A*); };

struct E : C, D, X {
    E() : D(this), // undefined: upcast from E* to A* might use path E* → D* → A*
        // but D is not constructed
        // “D((C*)this)” would be defined: E* → C* is defined because E() has started,
        // and C* → A* is defined because C is fully constructed
    X(this) {} // defined: upon construction of X, C/B/D/A sublattice is fully constructed
};
```

—end example—

3 Member functions, including virtual functions (13.3), can be called during construction or destruction (15.6.2). When a virtual function is called directly or indirectly from a constructor or from a destructor, including during the construction or destruction of the class’s non-static data members, and the object to which the call applies is the object (call it x) under construction or destruction, the function called is the final overrider in the constructor’s or destructor’s class and not one overriding it in a more-derived class. If the virtual function call uses an explicit class member access (8.2.5) and the object expression refers to the complete object of x or one of that object’s base class subobjects but not x or one of its base class subobjects, the behavior is undefined. [Example:

```c
struct V {
    virtual void f();
    virtual void g();
};

struct A : virtual V {
    virtual void f();
};
```
struct B : virtual V {
    virtual void g();
    B(V*, A*);
};

struct D : A, B {
    virtual void f();
    virtual void g();
    D() : B((A*)this, this) { }
};

B::B(V* v, A* a) {
    f(); // calls V::f, not A::f
    g(); // calls B::g, not D::g
    v->g(); // v is base of B, the call is well-defined, calls B::g
    a->f(); // undefined behavior, a's type not a base of B
}

— end example

4 The typeid operator (8.2.8) can be used during construction or destruction (15.6.2). When typeid is used in a constructor (including the mem-initializer or default member initializer (12.2) for a non-static data member) or in a destructor, or used in a function called (directly or indirectly) from a constructor or destructor, if the operand of typeid refers to the object under construction or destruction, typeid yields the std::type_info object representing the constructor or destructor’s class. If the operand of typeid refers to the object under construction or destruction and the static type of the operand is neither the constructor or destructor’s class nor one of its bases, the behavior is undefined.

5 dynamic_casts (8.2.7) can be used during construction or destruction (15.6.2). When a dynamic_cast is used in a constructor (including the mem-initializer or default member initializer for a non-static data member) or in a destructor, or used in a function called (directly or indirectly) from a constructor or destructor, if the operand of the dynamic_cast refers to the object under construction or destruction, this object is considered to be a most derived object that has the type of the constructor or destructor’s class. If the operand of the dynamic_cast refers to the object under construction or destruction and the static type of the operand is not a pointer to or object of the constructor or destructor’s own class or one of its bases, the dynamic_cast results in undefined behavior. [Example:

struct V {
    virtual void f();
};

struct A : virtual V { };  

struct B : virtual V {
    B(V*, A*);
};

struct D : A, B {
    D() : B((A*)this, this) { }
};

B::B(V* v, A* a) {
    typeid(*this); // type_info for B
    typeid(*v);    // well-defined: *v has type V, a base of B yields type_info for B
    typeid(*a);   // undefined behavior: type A not a base of B

§ 15.7
dynamic_cast<B*>(v);  // well-defined: v of type V*, V base of B results in B*
dynamic_cast<B*>(a);  // undefined behavior, a has type A*, A not a base of B
}

— end example]

15.8 Copying and moving class objects

A class object can be copied or moved in two ways: by initialization (15.1, 11.6), including for function argument passing (8.2.2) and for function value return (9.6.3); and by assignment (8.18). Conceptually, these two operations are implemented by a copy/move constructor (15.1) and copy/move assignment operator (16.5.3).

A program is ill-formed if the copy/move constructor or the copy/move assignment operator for an object is implicitly odr-used and the special member function is not accessible (Clause 14). [Note: Copying/moving one object into another using the copy/move constructor or the copy/move assignment operator does not change the layout or size of either object. — end note]

15.8.1 Copy/move constructors

A non-template constructor for class X is a copy constructor if its first parameter is of type X&, const X&, volatile X&, or const volatile X&, and either there are no other parameters or else all other parameters have default arguments (11.3.6). [Example: X::X(const X&) and X::X(X&, int=1) are copy constructors.

struct X {
    X(int);
    X(const X&, int = 1);
};
X a(1);  // calls X(int);
X b(a, 0);  // calls X(const X&, int);
X c = b;  // calls X(const X&, int);
— end example]

A non-template constructor for class X is a move constructor if its first parameter is of type X&&, const X&&, volatile X&&, or const volatile X&&, and either there are no other parameters or else all other parameters have default arguments (11.3.6). [Example: Y::Y(Y&&) is a move constructor.

struct Y {
    Y(const Y&);
    Y(Y&&);
};
extern Y f(int);
Y d(f(1));  // calls Y(Y&&)
Y e = d;  // calls Y(const Y&)
— end example]

[Note: All forms of copy/move constructor may be declared for a class. [Example:

struct X {
    X(const X&);
    X(X&);
    X(X&&);
    X(const X&&);  // OK, but possibly not sensible
};
— end example] — end note]

[Note: If a class X only has a copy constructor with a parameter of type X&, an initializer of type const X or volatile X cannot initialize an object of type (possibly cv-qualified) X. [Example:
struct X {
    X(); // default constructor
    X(X&); // copy constructor with a non-const parameter
};

const X cx;
X x = cx; // error: X::X(X&) cannot copy cx into x

— end example] — end note]

A declaration of a constructor for a class X is ill-formed if its first parameter is of type (optionally cv-qualified) X and either there are no other parameters or else all other parameters have default arguments. A member function template is never instantiated to produce such a constructor signature. [Example:

struct S {
    template<typename T> S(T);
    S();
};

S g;

void h() {
    S a(g); // does not instantiate the member template to produce S::S<S>(S);
    // uses the implicitly declared copy constructor
}
— end example]

If the class definition does not explicitly declare a copy constructor, a non-explicit one is declared implicitly. If the class definition declares a move constructor or move assignment operator, the implicitly declared copy constructor is defined as deleted; otherwise, it is defined as defaulted (11.4). The latter case is deprecated if the class has a user-declared copy assignment operator or a user-declared destructor.

The implicitly-declared copy constructor for a class X will have the form

X::X(const X&) if each potentially constructed subobject of a class type M (or array thereof) has a copy constructor whose first parameter is of type const M& or const volatile M&.119 Otherwise, the implicitly-declared copy constructor will have the form

X::X(X&)

If the definition of a class X does not explicitly declare a move constructor, a non-explicit one will be implicitly declared as defaulted if and only if

(8.1) — X does not have a user-declared copy constructor,
(8.2) — X does not have a user-declared copy assignment operator,
(8.3) — X does not have a user-declared move assignment operator, and
(8.4) — X does not have a user-declared destructor.

[Note: When the move constructor is not implicitly declared or explicitly supplied, expressions that otherwise would have invoked the move constructor may instead invoke a copy constructor. — end note]

The implicitly-declared move constructor for class X will have the form

X::X(X&&)

An implicitly-declared copy/move constructor is an inline public member of its class. A defaulted

119) This implies that the reference parameter of the implicitly-declared copy constructor cannot bind to a volatile lvalue; see C.1.9.
A copy/move constructor for a class \( X \) is defined as deleted (11.4.3) if \( X \) has:

1. a variant member with a non-trivial corresponding constructor and \( X \) is a union-like class,
2. a potentially constructed subobject type \( M \) (or array thereof) that cannot be copied/moved because overload resolution (16.3), as applied to find \( M \)'s corresponding constructor, results in an ambiguity or a function that is deleted or inaccessible from the defaulted constructor,
3. any potentially constructed subobject of a type with a destructor that is deleted or inaccessible from the defaulted constructor, or,
4. for the copy constructor, a non-static data member of rvalue reference type.

A deleted move constructor that is defined as deleted is ignored by overload resolution (16.3, 16.4). [Note: A deleted move constructor would otherwise interfere with initialization from an rvalue which can use the copy constructor instead. —end note]

A copy/move constructor for class \( X \) is trivial if it is not user-provided and if:

1. class \( X \) has no virtual functions (13.3) and no virtual base classes (13.1), and
2. the constructor selected to copy/move each direct base class subobject is trivial, and
3. for each non-static data member of \( X \) that is of class type (or array thereof), the constructor selected to copy/move that member is trivial;

otherwise the copy/move constructor is non-trivial.

A copy/move constructor that is defaulted and not defined as deleted is implicitly defined if it is odr-used (6.2) or when it is explicitly defaulted after its first declaration. [Note: The copy/move constructor is implicitly defined even if the implementation elided its odr-use (6.2, 15.2). —end note] If the implicitly-defined constructor would satisfy the requirements of a constexpr constructor (10.1.5), the implicitly-defined constructor is constexpr.

Before the defaulted copy/move constructor for a class is implicitly defined, all non-user-provided copy/move constructors for its potentially constructed subobjects shall have been implicitly defined. [Note: An implicitly-declared copy/move constructor has an implied exception specification (18.4). —end note]

The implicitly-defined copy/move constructor for a non-union class \( X \) performs a memberwise copy/move of its bases and members. [Note: Default member initializers of non-static data members are ignored. See also the example in 15.6.2. —end note] The order of initialization is the same as the order of initialization of bases and members in a user-defined constructor (see 15.6.2). Let \( x \) be either the parameter of the constructor or, for the move constructor, an \( x \)value referring to the parameter. Each base or non-static data member is copied/moved in the manner appropriate to its type:

1. if the member is an array, each element is direct-initialized with the corresponding subobject of \( x \);
2. if a member \( m \) has rvalue reference type \( T&& \), it is direct-initialized with \( \text{static
d cast}<T&&>(x.m) \);
3. otherwise, the base or member is direct-initialized with the corresponding base or member of \( x \).

Virtual base class subobjects shall be initialized only once by the implicitly-defined copy/move constructor (see 15.6.2).

The implicitly-defined copy/move constructor for a union \( X \) copies the object representation (6.9) of \( X \).

### 15.8.2 Copy/move assignment operator

A user-declared copy assignment operator \( X::\text{operator=} \) is a non-static non-template member function of class \( X \) with exactly one parameter of type \( X, X&, \text{const } X&, \text{volatile } X& \) or \( \text{const volatile } X& \). [Note: Because a template assignment operator or an assignment operator taking an rvalue reference parameter is never a copy assignment operator, the presence of such an assignment operator does not suppress the implicit declaration of a copy assignment operator. Such assignment operators participate in overload resolution with other assignment operators, including...]

§ 15.8.2
An overloaded assignment operator must be declared to have only one parameter; see 16.5.3. — end note

[Note: More than one form of copy assignment operator may be declared for a class. — end note] [Note: If a class \( X \) only has a copy assignment operator with a parameter of type \( X\& \), an expression of type \( \text{const } X \) cannot be assigned to an object of type \( X \). [Example:

```c
struct X {
    X();
    X& operator=(X&); // overloaded
};

const X cx;
X x;
void f() {
    x = cx;       // error: X::operator=(X&) cannot assign cx into x
}
```

— end example] — end note]

2 If the class definition does not explicitly declare a copy assignment operator, one is declared implicitly. If the class definition declares a move constructor or move assignment operator, the implicitly declared copy assignment operator is defined as deleted; otherwise, it is defined as defaulted (11.4). The latter case is deprecated if the class has a user-declared copy constructor or a user-declared destructor. The implicitly-declared copy assignment operator for a class \( X \) will have the form

\[
X& X::\text{operator}=(\text{const } X&)
\]

if

(2.1) — each direct base class \( B \) of \( X \) has a copy assignment operator whose parameter is of type \( \text{const } B\& \), \( \text{const volatile } B\& \) or \( B \), and

(2.2) — for all the non-static data members of \( X \) that are of a class type \( M \) (or array thereof), each such class type has a copy assignment operator whose parameter is of type \( \text{const } M\& \), \( \text{const volatile } M\& \) or \( M \).121

Otherwise, the implicitly-declared copy assignment operator will have the form

\[
X& X::\text{operator}=(X&)
\]

3 A user-declared move assignment operator \( X::\text{operator=} \) is a non-static non-template member function of class \( X \) with exactly one parameter of type \( X\&\& \), \( \text{const } X\&\& \), \( \text{volatile } X\&\& \), or \( \text{const volatile } X\&\& \). [Note: An overloaded assignment operator must be declared to have only one parameter; see 16.5.3. — end note] [Note: More than one form of move assignment operator may be declared for a class. — end note]

4 If the definition of a class \( X \) does not explicitly declare a move assignment operator, one will be implicitly declared as defaulted if and only if

(4.1) — \( X \) does not have a user-declared copy constructor,

(4.2) — \( X \) does not have a user-declared move constructor,

(4.3) — \( X \) does not have a user-declared copy assignment operator, and

(4.4) — \( X \) does not have a user-declared destructor.

[Example: The class definition

```c
struct S {
    int a;
    S& operator=(const S&) = default;
};
```

copy assignment operators, and, if selected, will be used to assign an object.

121) This implies that the reference parameter of the implicitly-declared copy assignment operator cannot bind to a \text{volatile} lvalue; see C.1.9.
will not have a default move assignment operator implicitly declared because the copy assignment operator has been user-declared. The move assignment operator may be explicitly defaulted.

```cpp
struct S {
    int a;
    S& operator=(const S&) = default;
    S& operator=(S&&) = default;
};
```

— end example —

The implicitly-declared move assignment operator for a class X will have the form

```cpp
X& X::operator=(X&&);
```

The implicitly-declared copy/move assignment operator for class X has the return type X&; it returns the object for which the assignment operator is invoked, that is, the object assigned to. An implicitly-declared copy/move assignment operator is an inline public member of its class.

A defaulted copy/move assignment operator for class X is defined as deleted if X has:

1. a variant member with a non-trivial corresponding assignment operator and X is a union-like class, or
2. a non-static data member of const non-class type (or array thereof), or
3. a non-static data member of reference type, or
4. a direct non-static data member of class type M (or array thereof) or a direct base class M that cannot be copied/moved because overload resolution (16.3), as applied to find M’s corresponding assignment operator, results in an ambiguity or a function that is deleted or inaccessible from the defaulted assignment operator.

A defaulted move assignment operator that is defined as deleted is ignored by overload resolution (16.3, 16.4).

Because a copy/move assignment operator is implicitly declared for a class if not declared by the user, a base class copy/move assignment operator is always hidden by the corresponding assignment operator of a derived class (16.5.3). A using-declaration (10.3.3) that brings in from a base class an assignment operator with a parameter type that could be that of a copy/move assignment operator for the derived class is not considered an explicit declaration of such an operator and does not suppress the implicit declaration of the derived class operator; the operator introduced by the using-declaration is hidden by the implicitly-declared operator in the derived class.

A copy/move assignment operator for class X is trivial if it is not user-provided and if:

1. class X has no virtual functions (13.3) and no virtual base classes (13.1), and
2. the assignment operator selected to copy/move each direct base class subobject is trivial, and
3. for each non-static data member of X that is of class type (or array thereof), the assignment operator selected to copy/move that member is trivial;

otherwise the copy/move assignment operator is non-trivial.

A copy/move assignment operator for a class X that is defaulted and not defined as deleted is implicitly defined when it is odr-used (6.2) (e.g., when it is selected by overload resolution to assign to an object of its class type) or when it is explicitly defaulted after its first declaration. The implicitly-defined copy/move assignment operator is constexpr if:

1. X is a literal type, and
2. the assignment operator selected to copy/move each direct base class subobject is a constexpr function, and
3. for each non-static data member of X that is of class type (or array thereof), the assignment operator is constexpr.
selected to copy/move that member is a constexpr function.

Before the defaulted copy/move assignment operator for a class is implicitly defined, all non-user-provided copy/move assignment operators for its direct base classes and its non-static data members shall have been implicitly defined. \[ \text{Note: An implicitly-declared copy/move assignment operator has an implied exception specification (18.4). — end note} \]

The implicitly-defined copy/move assignment operator for a non-union class \( X \) performs memberwise copy/move assignment of its subobjects. The direct base classes of \( X \) are assigned first, in the order of their declaration in the base-specifier-list, and then the immediate non-static data members of \( X \) are assigned, in the order in which they were declared in the class definition. Let \( x \) be either the parameter of the function or, for the move operator, an xvalue referring to the parameter. Each subobject is assigned in the manner appropriate to its type:

(12.1) — if the subobject is of class type, as if by a call to `operator=` with the subobject as the object expression and the corresponding subobject of \( x \) as a single function argument (as if by explicit qualification; that is, ignoring any possible virtual overriding functions in more derived classes);

(12.2) — if the subobject is an array, each element is assigned, in the manner appropriate to the element type;

(12.3) — if the subobject is of scalar type, the built-in assignment operator is used.

It is unspecified whether subobjects representing virtual base classes are assigned more than once by the implicitly-defined copy/move assignment operator. \[ \text{Example:} \]

```c
struct V { }
struct A : virtual V { }
struct B : virtual V { }
struct C : B, A { }
```

It is unspecified whether the virtual base class subobject \( V \) is assigned twice by the implicitly-defined copy/move assignment operator for \( C \). — end example]

The implicitly-defined copy assignment operator for a union \( X \) copies the object representation (6.9) of \( X \).

\section*{15.8.3 Copy/move elision} \[\text{class.copy.elision}\]

When certain criteria are met, an implementation is allowed to omit the copy/move construction of a class object, even if the constructor selected for the copy/move operation and/or the destructor for the object have side effects. In such cases, the implementation treats the source and target of the omitted copy/move operation as simply two different ways of referring to the same object. If the first parameter of the selected constructor is an rvalue reference to the object’s type, the destruction of that object occurs when the target would have been destroyed; otherwise, the destruction occurs at the later of the times when the two objects would have been destroyed without the optimization. \[122\] This elision of copy/move operations, called \textit{copy elision}, is permitted in the following circumstances (which may be combined to eliminate multiple copies):

(1.1) — in a \texttt{return} statement in a function with a class return type, when the \texttt{expression} is the name of a non-volatile automatic object (other than a function parameter or a variable introduced by the \textit{exception-declaration} of a \textit{handler} (18.3)) with the same type (ignoring cv-qualification) as the function return type, the copy/move operation can be omitted by constructing the automatic object directly into the function call’s return object

(1.2) — in a \texttt{throw-expression} (8.17), when the operand is the name of a non-volatile automatic object (other than a function or catch-clause parameter) whose scope does not extend beyond the end of the innermost enclosing \texttt{try-block} (if there is one), the copy/move operation from the operand to the exception object (18.1) can be omitted by constructing the automatic object directly into the exception object

\[122\) Because only one object is destroyed instead of two, and one copy/move constructor is not executed, there is still one object destroyed for each one constructed.
when the exception-declaration of an exception handler (Clause 18) declares an object of the same type (except for cv-qualification) as the exception object (18.1), the copy operation can be omitted by treating the exception-declaration as an alias for the exception object if the meaning of the program will be unchanged except for the execution of constructors and destructors for the object declared by the exception-declaration.  \[ \text{Note: There cannot be a move from the exception object because it is always an lvalue. — end note} \]

Copy elision is required where an expression is evaluated in a context requiring a constant expression (8.20) and in constant initialization (6.6.2).  \[ \text{Note: Copy elision might not be performed if the same expression is evaluated in another context. — end note} \]

\[ \text{Example:} \]

```cpp
class Thing {
public:
    Thing();
    ~Thing();
    Thing(const Thing&);
};

Thing f() {
    Thing t;
    return t;
}

Thing t2 = f();

struct A {
    void *p;
    constexpr A(): p(this) {}
};

constexpr A g() {
    A a;
    return a;
}

constexpr A a; // well-formed, a.p points to a
constexpr A b = g(); // well-formed, b.p points to b

void g() {
    A c = g(); // well-formed, c.p may point to c or to an ephemeral temporary
}
```

Here the criteria for elision can eliminate the copying of the local automatic object \( t \) into the result object for the function call \( f() \), which is the global object \( t2 \). Effectively, the construction of the local object \( t \) can be viewed as directly initializing the global object \( t2 \), and that object’s destruction will occur at program exit. Adding a move constructor to \texttt{Thing} has the same effect, but it is the move construction from the local automatic object to \( t2 \) that is elided.  \[ \text{— end example} \]

In the following copy-initialization contexts, a move operation might be used instead of a copy operation:

\[ \text{(3.1) — If the expression in a return statement (9.6.3) is a (possibly parenthesized) id-expression that names an object with automatic storage duration declared in the body or parameter-declaration-clause of the innermost enclosing function or lambda-expression, or} \]

\[ \text{(3.2) — if the operand of a throw-expression (8.17) is the name of a non-volatile automatic object (other than} \]
a function or catch-clause parameter) whose scope does not extend beyond the end of the innermost
enclosing try-block (if there is one),

overload resolution to select the constructor for the copy is first performed as if the object were designated
by an rvalue. If the first overload resolution fails or was not performed, or if the type of the first parameter
of the selected constructor is not an rvalue reference to the object’s type (possibly cv-qualified), overload
resolution is performed again, considering the object as an lvalue. [Note: This two-stage overload resolution
must be performed regardless of whether copy elision will occur. It determines the constructor to be called if
elision is not performed, and the selected constructor must be accessible even if the call is elided. — end
note]

4 [Example:

class Thing {
public:
  Thing();
  ~Thing();
  Thing(Thing&&);
private:
  Thing(const Thing&);
};

Thing f(bool b) {
  Thing t;
  if (b)
    throw t; // OK: Thing(Thing&&) used (or elided) to throw t
  return t; // OK: Thing(Thing&&) used (or elided) to return t
}

Thing t2 = f(false); // OK: no extra copy/move performed, t2 constructed by call to f

struct Weird {
  Weird();
  Weird(Weird&); 
};

Weird g() {
  Weird w;
  return w; // OK: first overload resolution fails, second overload resolution selects Weird(Weird&)
}

— end example]
16 Overloading

When two or more different declarations are specified for a single name in the same scope, that name is said to be overloaded. By extension, two declarations in the same scope that declare the same name but with different types are called overloaded declarations. Only function and function template declarations can be overloaded; variable and type declarations cannot be overloaded.

When an overloaded function name is used in a call, which overloaded function declaration is being referenced is determined by comparing the types of the arguments at the point of use with the types of the parameters in the overloaded declarations that are visible at the point of use. This function selection process is called overload resolution and is defined in 16.3. [Example:

```c
double abs(double);
int abs(int);
abs(1);  // calls abs(int);
abs(1.0);  // calls abs(double);
```

— end example]

16.1 Overloadable declarations

Not all function declarations can be overloaded. Those that cannot be overloaded are specified here. A program is ill-formed if it contains two such non-overloadable declarations in the same scope. [Note: This restriction applies to explicit declarations in a scope, and between such declarations and declarations made through a using-declaration (10.3.3). It does not apply to sets of functions fabricated as a result of name lookup (e.g., because of using-directives) or overload resolution (e.g., for operator functions). — end note]

Certain function declarations cannot be overloaded:

2.1 Function declarations that differ only in the return type, the exception specification (18.4), or both cannot be overloaded.

2.2 Member function declarations with the same name and the same parameter-type-list (11.3.5) cannot be overloaded if any of them is a static member function declaration (12.2.3). Likewise, member function template declarations with the same name, the same parameter-type-list, and the same template parameter lists cannot be overloaded if any of them is a static member function template declaration. The types of the implicit object parameters constructed for the member functions for the purpose of overload resolution (16.3.1) are not considered when comparing parameter-type-lists for enforcement of this rule. In contrast, if there is no static member function declaration among a set of member function declarations with the same name and the same parameter-type-list, then these member function declarations can be overloaded if they differ in the type of their implicit object parameter. [Example:

The following illustrates this distinction:

```c
class X {
    static void f();
    void f();  // ill-formed
    void f() const;  // ill-formed
    void f() const volatile;  // ill-formed
    void g();
    void g() const;  // OK: no static g
    void g() const volatile;  // OK: no static g
};
```
Member function declarations with the same name and the same parameter-type-list (11.3.5) as well as member function template declarations with the same name, the same parameter-type-list, and the same template parameter lists cannot be overloaded if any of them, but not all, have a ref-qualifier (11.3.5).

Example:
```cpp
class Y {
    void h() &; // OK
    void h() const &; // OK, all declarations have a ref-qualifier
    void i() &;&; // ill-formed, prior declaration of i
                   // has a ref-qualifier
};
```

Note: As specified in 11.3.5, function declarations that have equivalent parameter declarations declare the same function and therefore cannot be overloaded:

Parameter declarations that differ only in the use of equivalent typedef “types” are equivalent. A `typedef` is not a separate type, but only a synonym for another type (10.1.3).

Example:
```cpp
typedef int Int;
void f(int i); // OK: redeclaration of f(int)
void f(Int i); // error: redefinition of f(int)
```

Enumerations, on the other hand, are distinct types and can be used to distinguish overloaded function declarations.

Example:
```cpp
enum E { a };
void f(int i) { /* ... */ } // OK
void f(E i) { /* ... */ } // error
```

Parameter declarations that differ only in a pointer * versus an array [] are equivalent. That is, the array declaration is adjusted to become a pointer declaration (11.3.5). Only the second and subsequent array dimensions are significant in parameter types (11.3.4).

Example:
```cpp
int f(char*);
int f(char[]); // same as f(char*);
int f(char[7]); // same as f(char*);
int f(char[9]); // same as f(char*);

int g(char*)([10]);
int g(char[5][10]); // same as g(char*)([10]);
int g(char[7][10]); // same as g(char*)([10]);
int g(char(*)([20])); // different from g(char(*)([10]));
```

Parameter declarations that differ only in that one is a function type and the other is a pointer to the same function type are equivalent. That is, the function type is adjusted to become a pointer to function type (11.3.5).

Example:
void h(int());
void h(int (*)(())); // redeclaration of h(int())
void h(int x()); { } // definition of h(int())
void h(int (*)(x)) { } // ill-formed: redefinition of h(int())
— end example ]

(3.4) — Parameter declarations that differ only in the presence or absence of \texttt{const} and/or \texttt{volatile} are equivalent. That is, the \texttt{const} and \texttt{volatile} type-specifiers for each parameter type are ignored when determining which function is being declared, defined, or called. [\textit{Example:}]

typedef const int cInt;

int f (int);
int f (const int); // redeclaration of f(int)
int f (int) { /* ... */ } // definition of f(int)
int f (cInt) { /* ... */ } // error: redefinition of f(int)
— end example]

Only the \texttt{const} and \texttt{volatile} type-specifiers at the outermost level of the parameter type specification are ignored in this fashion; \texttt{const} and \texttt{volatile} type-specifiers buried within a parameter type specification are significant and can be used to distinguish overloaded function declarations. In particular, for any type \( T \), “pointer to \( T \)”, “pointer to \texttt{const} \( T \)”, and “pointer to \texttt{volatile} \( T \)” are considered distinct parameter types, as are “reference to \( T \)”, “reference to \texttt{const} \( T \)”, and “reference to \texttt{volatile} \( T \)”. (3.5) — Two parameter declarations that differ only in their default arguments are equivalent. [\textit{Example:}]

Consider the following:

void f (int i, int j);
void f (int i, int j = 99); // OK: redeclaration of f(int, int)
void f (int i = 88, int j); // OK: redeclaration of f(int, int)
void f (); // OK: overloaded declaration of f

void prog () {
  f (1, 2); // OK: call f(int, int)
  f (1); // OK: call f(int, int)
  f (); // Error: f(int, int) or f()?
}

— end example]

end note]

16.2 Declaration matching [over.dcl]

Two function declarations of the same name refer to the same function if they are in the same scope and have equivalent parameter declarations (16.1). A function member of a derived class is \textit{not} in the same scope as a function member of the same name in a base class. [\textit{Example:}]

```c
struct B {
  int f(int);
};

struct D : B {
  int f(const char*);
}
```

123) When a parameter type includes a function type, such as in the case of a parameter type that is a pointer to function, the \texttt{const} and \texttt{volatile} type-specifiers at the outermost level of the parameter type specifications for the inner function type are also ignored.
Here $D::f(const\ char*)$ hides $B::f(int)$ rather than overloading it.

```cpp
void h(D* pd) {
    pd->f(1); // error:
    // $D::f(const\ char*)$ hides $B::f(int)$
    pd->B::f(1); // OK
    pd->f("Ben"); // OK, calls $D::f$
}
```

— end example —

2 A locally declared function is not in the same scope as a function in a containing scope. [Example:

```cpp
void f(const char*);
void g() {
    extern void f(int);
    f("asdf"); // error: $f(int)$ hides $f(const\ char*)$
    // so there is no $f(const\ char*)$ in this scope
}
```

```cpp
void caller() {
    extern void callee(int, int);
    {
        extern void callee(int); // hides $callee(int,\ int)$
        callee(88, 99); // error: only $callee(int)$ in scope
    }
}
```

— end example —

3 Different versions of an overloaded member function can be given different access rules. [Example:

```cpp
class buffer {
private:
    char* p;
    int size;
protected:
    buffer(int s, char* store) { size = s; p = store; }
public:
    buffer(int s) { p = new char[size = s]; }
};
```

— end example —

### 16.3 Overload resolution [over.match]

Overload resolution is a mechanism for selecting the best function to call given a list of expressions that are
to be the arguments of the call and a set of candidate functions that can be called based on the context of
the call. The selection criteria for the best function are the number of arguments, how well the arguments
match the parameter-type-list of the candidate function, how well (for non-static member functions) the
object matches the implicit object parameter, and certain other properties of the candidate function. [Note:
The function selected by overload resolution is not guaranteed to be appropriate for the context. Other
restrictions, such as the accessibility of the function, can make its use in the calling context ill-formed. — end
note]

Overload resolution selects the function to call in seven distinct contexts within the language:

1. invocation of a function named in the function call syntax (16.3.1.1.1);
2. invocation of a function call operator, a pointer-to-function conversion function, a reference-to-pointer-
to-function conversion function, or a reference-to-function conversion function on a class object named
in the function call syntax (16.3.1.1.2);

(2.3) — invocation of the operator referenced in an expression (16.3.1.2);

(2.4) — invocation of a constructor for default- or direct-initialization (11.6) of a class object (16.3.1.3);

(2.5) — invocation of a user-defined conversion for copy-initialization (11.6) of a class object (16.3.1.4);

(2.6) — invocation of a conversion function for initialization of an object of a non-class type from an expression
of class type (16.3.1.5); and

(2.7) — invocation of a conversion function for conversion to a glvalue or class prvalue to which a reference (11.6.3)
will be directly bound (16.3.1.6).

Each of these contexts defines the set of candidate functions and the list of arguments in its own unique way.
But, once the candidate functions and argument lists have been identified, the selection of the best function
is the same in all cases:

(2.8) — First, a subset of the candidate functions (those that have the proper number of arguments and meet
 certain other conditions) is selected to form a set of viable functions (16.3.2).

(2.9) — Then the best viable function is selected based on the implicit conversion sequences (16.3.3.1) needed
to match each argument to the corresponding parameter of each viable function.

3 If a best viable function exists and is unique, overload resolution succeeds and produces it as the result.
Otherwise overload resolution fails and the invocation is ill-formed. When overload resolution succeeds,
and the best viable function is not accessible (Clause 14) in the context in which it is used, the program is
ill-formed.

16.3.1 Candidate functions and argument lists [over.match.funcs]

1 The subclauses of 16.3.1 describe the set of candidate functions and the argument list submitted to overload
resolution in each of the seven contexts in which overload resolution is used. The source transformations
and constructions defined in these subclauses are only for the purpose of describing the overload resolution
process. An implementation is not required to use such transformations and constructions.

2 The set of candidate functions can contain both member and non-member functions to be resolved against
the same argument list. So that argument and parameter lists are comparable within this heterogeneous set,
a member function is considered to have an extra parameter, called the implicit object parameter, which
represents the object for which the member function has been called. For the purposes of overload resolution,
both static and non-static member functions have an implicit object parameter, but constructors do not.

3 Similarly, when appropriate, the context can construct an argument list that contains an implied object
argument to denote the object to be operated on. Since arguments and parameters are associated by position
within their respective lists, the convention is that the implicit object parameter, if present, is always the
first parameter and the implied object argument, if present, is always the first argument.

4 For non-static member functions, the type of the implicit object parameter is

(4.1) — “lvalue reference to cv X” for functions declared without a ref-qualifier or with the & ref-qualifier

(4.2) — “rvalue reference to cv X” for functions declared with the && ref-qualifier

where X is the class of which the function is a member and cv is the cv-qualification on the member function
declaration. [Example: For a const member function of class X, the extra parameter is assumed to have
type “reference to const X”. — end example] For conversion functions, the function is considered to be
a member of the class of the implied object argument for the purpose of defining the type of the implicit
object parameter. For non-conversion functions introduced by a using-declaration into a derived class, the
function is considered to be a member of the derived class for the purpose of defining the type of the implicit
object parameter. For static member functions, the implicit object parameter is considered to match any
During overload resolution, the implied object argument is indistinguishable from other arguments. The implicit object parameter, however, retains its identity since no user-defined conversions can be applied to achieve a type match with it. For non-static member functions declared without a ref-qualifier, an additional rule applies:

even if the implicit object parameter is not const-qualified, an rvalue can be bound to the parameter as long as in all other respects the argument can be converted to the type of the implicit object parameter. 

Because other than in list-initialization only one user-defined conversion is allowed in an implicit conversion sequence, special rules apply when selecting the best user-defined conversion (16.3.3, 16.3.3.1). 

Example:

```cpp
class T {
public:
    T();
};

class C : T {
public:
    C(int);
};
T a = 1; // ill-formed: T(C(1)) not tried
```

In each case where a candidate is a function template, candidate function template specializations are generated using template argument deduction (17.8.3, 17.8.2). Those candidates are then handled as candidate functions in the usual way. A given name can refer to one or more function templates and also to a set of overloaded non-template functions. In such a case, the candidate functions generated from each function template are combined with the set of non-template candidate functions.

A defaulted move constructor or assignment operator (15.8) that is defined as deleted is excluded from the set of candidate functions in all contexts.

16.3.1.1 Function call syntax

1 In a function call (8.2.2)

```
postfix-expression ( expression-list_opt )
```

if the postfix-expression denotes a set of overloaded functions and/or function templates, overload resolution is applied as specified in 16.3.1.1.1. If the postfix-expression denotes an object of class type, overload resolution is applied as specified in 16.3.1.1.2.

2 If the postfix-expression denotes the address of a set of overloaded functions and/or function templates, overload resolution is applied using that set as described above. If the function selected by overload resolution is a non-static member function, the program is ill-formed. 

Note: The resolution of the address of an overload set in other contexts is described in 16.4.

---

124) The process of argument deduction fully determines the parameter types of the function template specializations, i.e., the parameters of function template specializations contain no template parameter types. Therefore, except where specified otherwise, function template specializations and non-template functions (11.3.5) are treated equivalently for the remainder of overload resolution.

---

© ISO/IEC N4659
16.3.1.1.1 Call to named function  \[over.call.func\]

Of interest in 16.3.1.1 are only those function calls in which the \texttt{postfix-expression} ultimately contains a name that denotes one or more functions that might be called. Such a \texttt{postfix-expression}, perhaps nested arbitrarily deep in parentheses, has one of the following forms:

\[
\text{postfix-expression:} \\
\quad \text{postfix-expression , id-expression} \\
\quad \text{postfix-expression \to id-expression} \\
\quad \text{primary-expression}
\]

These represent two syntactic subcategories of function calls: qualified function calls and unqualified function calls.

In qualified function calls, the name to be resolved is an \texttt{id-expression} and is preceded by an \texttt{\to} or \texttt{.} operator. Since the construct \texttt{A\to B} is generally equivalent to (\texttt{\star A}) \texttt{. B}, the rest of Clause 16 assumes, without loss of generality, that all member function calls have been normalized to the form that uses an object and the \texttt{.} operator. Furthermore, Clause 16 assumes that the \texttt{postfix-expression} that is the left operand of the \texttt{.} operator has type \texttt{“cv T”} where \texttt{T} denotes a class\textsuperscript{125}. Under this assumption, the \texttt{id-expression} in the call is looked up as a member function of \texttt{T} following the rules for looking up names in classes (13.2). The function declarations found by that lookup constitute the set of candidate functions. The argument list is the \texttt{expression-list} in the call augmented by the addition of the left operand of the \texttt{.} operator in the normalized member function call as the implied object argument (16.3.1).

In unqualified function calls, the name is not qualified by an \texttt{\to} or \texttt{.} operator and has the more general form of a \texttt{primary-expression}. The name is looked up in the context of the function call following the normal rules for name lookup in function calls (6.4). The function declarations found by that lookup constitute the set of candidate functions. Because of the rules for name lookup, the set of candidate functions consists (1) entirely of non-member functions or (2) entirely of member functions of some class \texttt{T}. In case (1), the argument list is the same as the \texttt{expression-list} in the call. In case (2), the argument list is the \texttt{expression-list} in the call augmented by the addition of an implied object argument as in a qualified function call. If the keyword \texttt{this} (12.2.2.1) is in scope and refers to class \texttt{T}, or a derived class of \texttt{T}, then the implied object argument is (\texttt{\star this}). If the keyword \texttt{this} is not in scope or refers to another class, then a contrived object of type \texttt{T} becomes the implied object argument\textsuperscript{126}. If the argument list is augmented by a contrived object and overload resolution selects one of the non-static member functions of \texttt{T}, the call is ill-formed.

16.3.1.1.2 Call to object of class type  \[over.call.object\]

If the \texttt{primary-expression} \texttt{E} in the function call syntax evaluates to a class object of type \texttt{“cv T”}, then the set of candidate functions includes at least the function call operators of \texttt{T}. The function call operators of \texttt{T} are obtained by ordinary lookup of the name \texttt{operator()} in the context of \texttt{(E).operator()}.

In addition, for each non-explicit conversion function declared in \texttt{T} of the form

\[
\text{operator conversion-type-id () cv-qualifier ref-qualifier_{opt} noexcept-specifier_{opt} attribute-specifier-seq_{opt} ;}
\]

where \texttt{cv-qualifier} is the same cv-qualification as, or a greater cv-qualification than, \texttt{cv}, and where \texttt{conversion-type-id} denotes the type “pointer to function of (\texttt{P}_{1}, \ldots, \texttt{P}_{n}) returning \texttt{R}”, or the type “reference to pointer to function of (\texttt{P}_{1}, \ldots, \texttt{P}_{n}) returning \texttt{R}”, or the type “reference to function of (\texttt{P}_{1}, \ldots, \texttt{P}_{n}) returning \texttt{R}”, a surrogate call function with the unique name \texttt{call-function} and having the form

\[
\text{R call-function ( conversion-type-id F, P}_{1} \ a_{1}, \ldots, \ P_{n} \ a_{n} \) \{ \text{return F (a}_{1}, \ldots, \ a_{n}) \; ; \}
\]

is also considered as a candidate function. Similarly, surrogate call functions are added to the set of candidate functions for each non-explicit conversion function declared in a base class of \texttt{T} provided the function is not

\textsuperscript{125} Note that cv-qualifiers on the type of objects are significant in overload resolution for both glvalue and class prvalue objects.

\textsuperscript{126} An implied object argument must be contrived to correspond to the implicit object parameter attributed to member functions during overload resolution. It is not used in the call to the selected function. Since the member functions all have the same implicit object parameter, the contrived object will not be the cause to select or reject a function.
hidden within T by another intervening declaration\(^{127}\).

3 If such a surrogate call function is selected by overload resolution, the corresponding conversion function will be called to convert E to the appropriate function pointer or reference, and the function will then be invoked with the arguments of the call. If the conversion function cannot be called (e.g., because of an ambiguity), the program is ill-formed.

4 The argument list submitted to overload resolution consists of the argument expressions present in the function call syntax preceded by the implied object argument (E). [Note: When comparing the call against the function call operators, the implied object argument is compared against the implicit object parameter of the function call operator. When comparing the call against a surrogate call function, the implied object argument is compared against the first parameter of the surrogate call function. The conversion function from which the surrogate call function was derived will be used in the conversion sequence for that parameter since it converts the implied object argument to the appropriate function pointer or reference required by that first parameter. —end note] [Example:

```cpp
int f1(int);
int f2(float);
typedef int (*fp1)(int);
typedef int (*fp2)(float);
struct A {
    operator fp1() { return f1; }
    operator fp2() { return f2; }
} a;
int i = a(1); // calls f1 via pointer returned from conversion function
```

—end example]

16.3.1.2 Operators in expressions [over.match.oper]

1 If no operand of an operator in an expression has a type that is a class or an enumeration, the operator is assumed to be a built-in operator and interpreted according to Clause 8. [Note: Because ., .*, and :: cannot be overloaded, these operators are always built-in operators interpreted according to Clause 8. ?: cannot be overloaded, but the rules in this subclause are used to determine the conversions to be applied to the second and third operands when they have class or enumeration type (8.16). —end note] [Example:

```cpp
struct String {
    String (const String&);
    String (const char*);
    operator const char* () {
    }
};
String operator + (const String&, const String&);

void f() {
    const char* p = "one" + "two"; // ill-formed because neither operand has class or enumeration type
    int I = 1 + 1; // always evaluates to 2 even if class or enumeration types exist
    // that would perform the operation.
}
```

—end example]

2 If either operand has a type that is a class or an enumeration, a user-defined operator function might be declared that implements this operator or a user-defined conversion can be necessary to convert the operand to a type that is appropriate for a built-in operator. In this case, overload resolution is used to determine which operator function or built-in operator is to be invoked to implement the operator. Therefore, the operator

\(^{127}\) Note that this construction can yield candidate call functions that cannot be differentiated one from the other by overload resolution because they have identical declarations or differ only in their return type. The call will be ambiguous if overload resolution cannot select a match to the call that is uniquely better than such undifferentiable functions.
notation is first transformed to the equivalent function-call notation as summarized in Table 12 (where @ denotes one of the operators covered in the specified subclause). However, the operands are sequenced in the order prescribed for the built-in operator (Clause 8).

Table 12 — Relationship between operator and function call notation

3 For a unary operator @ with an operand of a type whose cv-unqualified version is T1, and for a binary operator @ with a left operand of a type whose cv-unqualified version is T1 and a right operand of a type whose cv-unqualified version is T2, three sets of candidate functions, designated member candidates, non-member candidates and built-in candidates, are constructed as follows:

(3.1) — If T1 is a complete class type or a class currently being defined, the set of member candidates is the result of the qualified lookup of T1::operator@ (16.3.1.1.1); otherwise, the set of member candidates is empty.

(3.2) — The set of non-member candidates is the result of the unqualified lookup of operator@ in the context of the expression according to the usual rules for name lookup in unqualified function calls (6.4.2) except that all member functions are ignored. However, if no operand has a class type, only those non-member functions in the lookup set that have a first parameter of type T1 or “reference to cv T1”, when T1 is an enumeration type, or (if there is a right operand) a second parameter of type T2 or “reference to cv T2”, when T2 is an enumeration type, are candidate functions.

(3.3) — For the operator ,, the unary operator &, or the operator ->, the built-in candidates set is empty. For all other operators, the built-in candidates include all of the candidate operator functions defined in 16.6 that, compared to the given operator,

(3.3.1) — have the same operator name, and

(3.3.2) — accept the same number of operands, and

(3.3.3) — accept operand types to which the given operand or operands can be converted according to 16.3.3.1, and

(3.3.4) — do not have the same parameter-type-list as any non-member candidate that is not a function template specialization.

4 For the built-in assignment operators, conversions of the left operand are restricted as follows:

(4.1) — no temporaries are introduced to hold the left operand, and

(4.2) — no user-defined conversions are applied to the left operand to achieve a type match with the left-most parameter of a built-in candidate.

5 For all other operators, no such restrictions apply.

6 The set of candidate functions for overload resolution is the union of the member candidates, the non-member candidates, and the built-in candidates. The argument list contains all of the operands of the operator. The best function from the set of candidate functions is selected according to 16.3.2 and 16.3.3.128

[128] If the set of candidate functions is empty, overload resolution is unsuccessful.

§ 16.3.1.2
struct A {
    operator int();
};
A operator+(const A&, const A&);
void m() {
    A a, b;
    a + b; // operator+(a, b) chosen over int(a) + int(b)
}

If a built-in candidate is selected by overload resolution, the operands of class type are converted to the
types of the corresponding parameters of the selected operation function, except that the second standard
conversion sequence of a user-defined conversion sequence (16.3.3.1.2) is not applied. Then the operator is
treated as the corresponding built-in operator and interpreted according to Clause 8. [Example:

```cpp
default
```

If the value returned by the operator-\* function has class type, this may result in selecting and calling another
operator-\* function. The process repeats until an operator-\* function returns a value of non-class type.

---

129) If the value returned by the operator-\* function has class type, this may result in selecting and calling another operator-\* function. The process repeats until an operator-\* function returns a value of non-class type.
16.3.1.3 Initialization by constructor

When objects of class type are direct-initialized (11.6), copy-initialized from an expression of the same or a derived class type (11.6), or default-initialized (11.6), overload resolution selects the constructor. For direct-initialization or default-initialization that is not in the context of copy-initialization, the candidate functions are all the constructors of the class of the object being initialized. For copy-initialization, the candidate functions are all the converting constructors (15.3.1) of that class. The argument list is the expression-list or assignment-expression of the initializer.

16.3.1.4 Copy-initialization of class by user-defined conversion

Under the conditions specified in 11.6, as part of a copy-initialization of an object of class type, a user-defined conversion can be invoked to convert an initializer expression to the type of the object being initialized. Overload resolution is used to select the user-defined conversion to be invoked. [Note: The conversion performed for indirect binding to a reference to a possibly cv-qualified class type is determined in terms of a corresponding non-reference copy-initialization. — end note] Assuming that “cv1 T” is the type of the object being initialized, with T a class type, the candidate functions are selected as follows:

1. The converting constructors (15.3.1) of T are candidate functions.
2. When the type of the initializer expression is a class type “cv S”, the non-explicit conversion functions of S and its base classes are considered. When initializing a temporary to be bound to the first parameter of a constructor where the parameter is of type “reference to possibly cv-qualified T” and the constructor is called with a single argument in the context of direct-initialization of an object of type “cv2 T”, explicit conversion functions are also considered. Those that are not hidden within S and yield a type whose cv-unqualified version is the same type as T or is a derived class thereof are candidate functions. Conversion functions that return “reference to X” return lvalues or xvalues, depending on the type of reference, of type X and are therefore considered to yield X for this process of selecting candidate functions.

In both cases, the argument list has one argument, which is the initializer expression. [Note: This argument will be compared against the first parameter of the constructors and against the implicit object parameter of the conversion functions. — end note]

16.3.1.5 Initialization by conversion function

Under the conditions specified in 11.6, as part of an initialization of an object of non-class type, a conversion function can be invoked to convert an initializer expression of class type to the type of the object being initialized. Overload resolution is used to select the conversion function to be invoked. Assuming that “cv1 T” is the type of the object being initialized, and “cv S” is the type of the initializer expression, with S a class type, the candidate functions are selected as follows:

1. The conversion functions of S and its base classes are considered. Those non-explicit conversion functions that are not hidden within S and yield type T or a type that can be converted to type T via a standard conversion sequence (16.3.3.1.1) are candidate functions. For direct-initialization, those explicit conversion functions that are not hidden within S and yield type T or a type that can be converted to type T with a qualification conversion (7.5) are also candidate functions. Conversion functions that return a cv-qualified type are considered to yield the cv-unqualified version of that type for this process of selecting candidate functions. Conversion functions that return “reference to cv2 X” return lvalues or xvalues, depending on the type of reference, of type “cv2 X” and are therefore considered to yield X for this process of selecting candidate functions.

The argument list has one argument, which is the initializer expression. [Note: This argument will be compared against the implicit object parameter of the conversion functions. — end note]
16.3.1.6 Initialization by conversion function for direct reference binding

Under the conditions specified in 11.6.3, a reference can be bound directly to a glvalue or class prvalue that is the result of applying a conversion function to an initializer expression. Overload resolution is used to select the conversion function to be invoked. Assuming that “reference to cv1 T” is the type of the reference being initialized, and “cv S” is the type of the initializer expression, with S a class type, the candidate functions are selected as follows:

1. The conversion functions of S and its base classes are considered. Those non-explicit conversion functions that are not hidden within S and yield type “lvalue reference to cv2 T2” (when initializing an lvalue reference or an rvalue reference to function) or “cv2 T2” or “rvalue reference to cv2 T2” (when initializing an rvalue reference or an lvalue reference to function), where “cv1 T” is reference-compatible (11.6.3) with “cv2 T2”, are candidate functions. For direct-initialization, those explicit conversion functions that are not hidden within S and yield type “lvalue reference to cv2 T2” or “cv2 T2” or “rvalue reference to cv2 T2”, respectively, where T2 is the same type as T or can be converted to type T with a qualification conversion (7.5), are also candidate functions.

2. The argument list has one argument, which is the initializer expression. [Note: This argument will be compared against the implicit object parameter of the conversion functions. —end note]

16.3.1.7 Initialization by list-initialization

When objects of non-aggregate class type T are list-initialized such that 11.6.4 specifies that overload resolution is performed according to the rules in this section, overload resolution selects the constructor in two phases:

1. Initially, the candidate functions are the initializer-list constructors (11.6.4) of the class T and the argument list consists of the initializer list as a single argument.

2. If no viable initializer-list constructor is found, overload resolution is performed again, where the candidate functions are all the constructors of the class T and the argument list consists of the elements of the initializer list.

If the initializer list has no elements and T has a default constructor, the first phase is omitted. In copy-list-initialization, if an explicit constructor is chosen, the initialization is ill-formed. [Note: This differs from other situations (16.3.1.3, 16.3.1.4), where only converting constructors are considered for copy-initialization. This restriction only applies if this initialization is part of the final result of overload resolution. —end note]

16.3.1.8 Class template argument deduction

A set of functions and function templates is formed comprising:

1. For each constructor of the primary class template designated by the template-name, if the template is defined, a function template with the following properties:

2. The template parameters are the template parameters of the class template followed by the template parameters (including default template arguments) of the constructor, if any.

3. The types of the function parameters are those of the constructor.

4. The return type is the class template specialization designated by the template-name and template arguments corresponding to the template parameters obtained from the class template.

5. If the primary class template C is not defined or does not declare any constructors, an additional function template derived as above from a hypothetical constructor C().

6. An additional function template derived as above from a hypothetical constructor C(C), called the copy deduction candidate.

7. For each deduction-guide, a function or function template with the following properties:

8. The template parameters, if any, and function parameters are those of the deduction-guide.
The return type is the `simple-template-id` of the `deduction-guide`.

Initialization and overload resolution are performed as described in 11.6 and 16.3.1.3, 16.3.1.4, or 16.3.1.7 (as appropriate for the type of initialization performed) for an object of a hypothetical class type, where the selected functions and function templates are considered to be the constructors of that class type for the purpose of forming an overload set, and the initializer is provided by the context in which class template argument deduction was performed. Each such notional constructor is considered to be explicit if the function or function template was generated from a constructor or `deduction-guide` that was declared `explicit`. All such notional constructors are considered to be public members of the hypothetical class type.

Example:

```cpp
template <class T> struct A {
    explicit A(const T&, ...) noexcept; // #1
    A(T&&, ...); // #2
};

int i;
A a1 = {i, i}; // error: explicit constructor #1 selected in copy-list-initialization during deduction,
                // cannot deduce from non-forwarding rvalue reference in #2

A a2{i, i}; // OK, #1 deduces to A<int> and also initializes
A a3{0, i}; // OK, #2 deduces to A<int> and also initializes
A a4 = {0, i}; // OK, #2 deduces to A<int> and also initializes

template <class T> A(const T&, const T&) -> A<T&>; // #3
template <class T> explicit A(T&&, T&&) -> A<T>; // #4

A a5 = {0, 1}; // error: explicit deduction guide #4 selected in copy-list-initialization during deduction
A a6{0,i}; // OK, #4 deduces to A<int> and #2 initializes
A a7 = {0, i}; // error: #3 deduces to A<int&>, #1 and #2 declare same constructor
A a8{0,i}; // error: #3 deduces to A<int&>, #1 and #2 declare same constructor

template <class T> struct B {
    template <class U> using TA = T;
    template <class U> B(U, TA<U>); // #5
};

B b{(int*)0, (char*)0}; // OK, deduces B<char*> — end example
```

16.3.2 Viable functions

From the set of candidate functions constructed for a given context (16.3.1), a set of viable functions is chosen, from which the best function will be selected by comparing argument conversion sequences for the best fit (16.3.3). The selection of viable functions considers relationships between arguments and function parameters other than the ranking of conversion sequences.

First, to be a viable function, a candidate function shall have enough parameters to agree in number with the arguments in the list.

1. If there are \( m \) arguments in the list, all candidate functions having exactly \( m \) parameters are viable.
2. A candidate function having fewer than \( m \) parameters is viable only if it has an ellipsis in its parameter list (11.3.5). For the purposes of overload resolution, any argument for which there is no corresponding parameter is considered to “match the ellipsis” (16.3.3.1.3).
3. A candidate function having more than \( m \) parameters is viable only if the \((m+1)\)-st parameter has a
default argument (11.3.6). For the purposes of overload resolution, the parameter list is truncated on the right, so that there are exactly \( m \) parameters.

Second, for \( F \) to be a viable function, there shall exist for each argument an implicit conversion sequence (16.3.3.1) that converts that argument to the corresponding parameter of \( F \). If the parameter has reference type, the implicit conversion sequence includes the operation of binding the reference, and the fact that an lvalue reference to non-\texttt{const} cannot be bound to an rvalue and that an rvalue reference cannot be bound to an lvalue can affect the viability of the function (see 16.3.3.1.4).

### 16.3.3 Best viable function

Define \( \text{ICS}_i(F) \) as follows:

1. If \( F \) is a static member function, \( \text{ICS}_1(F) \) is defined such that \( \text{ICS}_1(F) \) is neither better nor worse than \( \text{ICS}_1(G) \) for any function \( G \), and, symmetrically, \( \text{ICS}_1(G) \) is neither better nor worse than \( \text{ICS}_1(F) \); otherwise,

2. Let \( \text{ICS}_i(F) \) denote the implicit conversion sequence that converts the \( i \)-th argument in the list to the type of the \( i \)-th parameter of viable function \( F \). 16.3.3.1 defines the implicit conversion sequences and 16.3.3.2 defines what it means for one implicit conversion sequence to be a better conversion sequence or worse conversion sequence than another.

Given these definitions, a viable function \( F_1 \) is defined to be a better function than another viable function \( F_2 \) if for all arguments \( i \), \( \text{ICS}_i(F_1) \) is not a worse conversion sequence than \( \text{ICS}_i(F_2) \), and then

1. For some argument \( j \), \( \text{ICS}_j(F_1) \) is a better conversion sequence than \( \text{ICS}_j(F_2) \), or, if not that,

2. The context is an initialization by user-defined conversion (see 11.6, 16.3.1.5, and 16.3.1.6) and the standard conversion sequence from the return type of \( F_1 \) to the destination type (i.e., the type of the entity being initialized) is a better conversion sequence than the standard conversion sequence from the return type of \( F_2 \) to the destination type \[ \text{Example:} \]

```c
struct A {
    A();
    operator int();
    operator double();
} a;

int i = a; \quad // a \text{operator int()} \text{ followed by no conversion is better than}
\quad // a \text{operator double()} \text{ followed by a conversion to int}
float x = a; \quad // ambiguous: both possibilities require conversions,
\quad // and neither is better than the other
```

--- end example --- or, if not that,

3. The context is an initialization by conversion function for direct reference binding (16.3.1.6) of a reference to function type, the return type of \( F_1 \) is the same kind of reference (i.e., lvalue or rvalue) as the reference being initialized, and the return type of \( F_2 \) is not \[ \text{Example:} \]

```c
template <class T> struct A {
    operator T&(); \quad \text{// #1}
    operator T&&(); \quad \text{// #2}
};

typedef int Fn();
A<Fn> a;
Fn& lf = a; \quad \text{// calls #1}
Fn& rf = a; \quad \text{// calls #2}
```

--- Example: ---

130) According to 11.3.6, parameters following the \((m+1)\)-st parameter must also have default arguments.

131) If a function is a static member function, this definition means that the first argument, the implied object argument, has no effect in the determination of whether the function is better or worse than any other function.
— end example] or, if not that,

(1.6) — F1 is not a function template specialization and F2 is a function template specialization, or, if not that,

(1.7) — F1 and F2 are function template specializations, and the function template for F1 is more specialized than the template for F2 according to the partial ordering rules described in 17.5.6.2, or, if not that,

(1.8) — F1 is generated from a deduction-guide (16.3.1.8) and F2 is not, or, if not that,

(1.9) — F1 is the copy deduction candidate (16.3.1.8) and F2 is not, or, if not that,

(1.10) — F1 is generated from a non-template constructor and F2 is generated from a constructor template.

[Example:

```cpp
template <class T> struct A {
  using value_type = T;
  A(value_type); // #1
  A(const &);    // #2
  A(T, T, int);  // #3
  template<class U>
  A(int, T, U); // #4
  // #5 is the copy deduction candidate, A(A)
};
```

A x(1, 2, 3); // uses #3, generated from a non-template constructor

```cpp
template <class T>
A(T) -> A<T>; // #6, less specialized than #5
A a(42);      // uses #6 to deduce A<int> and #1 to initialize
A b = a;       // uses #5 to deduce A<int> and #2 to initialize
```

```cpp
template <class T>
A(A<T>) -> A<A<T>>; // #7, as specialized as #5
A b2 = a;          // uses #7 to deduce A<A<int>> and #1 to initialize
```

— end example]

2 If there is exactly one viable function that is a better function than all other viable functions, then it is the one selected by overload resolution; otherwise the call is ill-formed.132 [Example:

```cpp
void Fcn(const int*, short);
void Fcn(int*, int);
```

```cpp
int i;
short s = 0;
```

```cpp
void f() {
  Fcn(&i, s); // is ambiguous because &i -> int* is better than &i -> const int*
              // but s -> short is also better than s -> int
  Fcn(&i, 1L); // calls Fcn(int*, int), because &i -> int* is better than &i -> const int*
              // and 1L -> short and 1L -> int are indistinguishable
```

132) The algorithm for selecting the best viable function is linear in the number of viable functions. Run a simple tournament to find a function W that is not worse than any opponent it faced. Although another function F that W did not face might be at least as good as W, F cannot be the best function because at some point in the tournament F encountered another function G such that F was not better than G. Hence, W is either the best function or there is no best function. So, make a second pass over the viable functions to verify that W is better than all other functions.

§ 16.3.3
Fcn(&i, 'c');  // calls Fcn(int*, int), because &i → int* is better than &i → const int*
              // and c → int is better than c → short
}
— end example]

3 If the best viable function resolves to a function for which multiple declarations were found, and if at least
  two of these declarations — or the declarations they refer to in the case of using-declarations — specify a
default argument that made the function viable, the program is ill-formed. [Example:

  namespace A {
    extern "C" void f(int = 5);
  }
  namespace B {
    extern "C" void f(int = 5);
  }
  using A::f;
  using B::f;

  void use() {
    f(3);  // OK, default argument was not used for viability
    f();   // Error: found default argument twice
  }
— end example]

16.3.3.1 Implicit conversion sequences [over.best.ics]

1 An *implicit conversion sequence* is a sequence of conversions used to convert an argument in a function call
to the type of the corresponding parameter of the function being called. The sequence of conversions is an
implicit conversion as defined in Clause 7, which means it is governed by the rules for initialization of an
object or reference by a single expression (11.6, 11.6.3).

2 Implicit conversion sequences are concerned only with the type, cv-qualification, and value category of the
argument and how these are converted to match the corresponding properties of the parameter. Other
properties, such as the lifetime, storage class, alignment, accessibility of the argument, whether the argument
is a bit-field, and whether a function is deleted (11.4.3), are ignored. So, although an implicit conversion
sequence can be defined for a given argument-parameter pair, the conversion from the argument to the
parameter might still be ill-formed in the final analysis.

3 A well-formed implicit conversion sequence is one of the following forms:

  (3.1) — a *standard conversion sequence* (16.3.3.1.1),

  (3.2) — a *user-defined conversion sequence* (16.3.3.1.2), or

  (3.3) — an *ellipsis conversion sequence* (16.3.3.1.3).

4 However, if the target is

  (4.1) — the first parameter of a constructor or

  (4.2) — the implicit object parameter of a user-defined conversion function

  and the constructor or user-defined conversion function is a candidate by

  (4.3) — 16.3.1.3, when the argument is the temporary in the second step of a class copy-initialization,

  (4.4) — 16.3.1.4, 16.3.1.5, or 16.3.1.6 (in all cases), or

  (4.5) — the second phase of 16.3.1.7 when the initializer list has exactly one element that is itself an initializer

§ 16.3.3.1
user-defined conversion sequences are not considered. \[\text{Note: These rules prevent more than one user-defined conversion from being applied during overload resolution, thereby avoiding infinite recursion. — end note}\]

\[\text{Example:}\]
```cpp
struct Y { Y(int); };  
struct A { operator int(); };  
Y y1 = A();  // \text{error: A::operator int() is not a candidate}
```

```cpp
struct X { };  
struct B { operator X(); };  
B b;  
X x(b);  // \text{error: B::operator X() is not a candidate}
```

— end example

For the case where the parameter type is a reference, see 16.3.3.1.4.

When the parameter type is not a reference, the implicit conversion sequence models a copy-initialization of the parameter from the argument expression. The implicit conversion sequence is the one required to convert the argument expression to a prvalue of the type of the parameter. \[\text{Note: When the parameter has a class type, this is a conceptual conversion defined for the purposes of Clause 16; the actual initialization is defined in terms of constructors and is not a conversion. — end note}\]

Any difference in top-level cv-qualification is subsumed by the initialization itself and does not constitute a conversion. \[\text{Example: A parameter of type A can be initialized from an argument of type const A. The implicit conversion sequence for that case is the identity sequence; it contains no “conversion” from const A to A. — end example}\]

When the parameter has a class type and the argument expression has the same type, the implicit conversion sequence is an identity conversion. When the parameter has a class type and the argument expression has a derived class type, the implicit conversion sequence is a derived-to-base Conversion from the derived class to the base class. \[\text{Note: There is no such standard conversion; this derived-to-base Conversion exists only in the description of implicit conversion sequences. — end note}\] A derived-to-base Conversion has Conversion rank (16.3.3.1.1).

In all contexts, when converting to the implicit object parameter or when converting to the left operand of an assignment operation only standard conversion sequences are allowed.

If no conversions are required to match an argument to a parameter type, the implicit conversion sequence is the standard conversion sequence consisting of the identity conversion (16.3.3.1.1).

If no sequence of conversions can be found to convert an argument to a parameter type, an implicit conversion sequence cannot be formed.

If several different sequences of conversions exist that each convert the argument to the parameter type, the implicit conversion sequence associated with the parameter is defined to be the unique conversion sequence designated the ambiguous conversion sequence. For the purpose of ranking implicit conversion sequences as described in 16.3.3.2, the ambiguous conversion sequence is treated as a user-defined conversion sequence that is indistinguishable from any other user-defined conversion sequence. \[\text{Note: This rule prevents a function from becoming non-viable because of an ambiguous conversion sequence for one of its parameters. — end note}\]

\[\text{Example:}\]
```cpp
class B;  
class A { A (B&); };  
class B { operator A (); };  
class C { C (B&); };  
void f(A) { }  
void f(C) { }  
B b;  
f(b);  // \text{ill-formed: ambiguous because there is a conversion b \rightarrow C (via constructor)}
```

16.3.3.1.3
If a function that uses the ambiguous conversion sequence is selected as the
best viable function, the call will be ill-formed because the conversion of one of the arguments in the call is
ambiguous.

The three forms of implicit conversion sequences mentioned above are defined in the following subclauses.

16.3.3.1.1 Standard conversion sequences

Table 13 summarizes the conversions defined in Clause 7 and partitions them into four disjoint categories:
Lvalue Transformation, Qualification Adjustment, Promotion, and Conversion. [Note: These categories are
orthogonal with respect to value category, cv-qualification, and data representation: the Lvalue Transformations
do not change the cv-qualification or data representation of the type; the Qualification Adjustments do
not change the value category or data representation of the type; and the Promotions and Conversions do
not change the value category or cv-qualification of the type. —end note]

[Note: As described in Clause 7, a standard conversion sequence is either the Identity conversion by itself
(that is, no conversion) or consists of one to three conversions from the other four categories. If there
are two or more conversions in the sequence, the conversions are applied in the canonical order:
Lvalue Transformation, Promotion or Conversion, Qualification Adjustment. —end note]

Each conversion in Table 13 also has an associated rank (Exact Match, Promotion, or Conversion). These are
used to rank standard conversion sequences (16.3.3.2). The rank of a conversion sequence is determined by
considering the rank of each conversion in the sequence and the rank of any reference binding (16.3.3.1.4). If
any of those has Conversion rank, the sequence has Conversion rank; otherwise, if any of those has Promotion
rank, the sequence has Promotion rank; otherwise, the sequence has Exact Match rank.

16.3.3.1.2 User-defined conversion sequences

A user-defined conversion sequence consists of an initial standard conversion sequence followed by a user-
defined conversion (15.3) followed by a second standard conversion sequence. If the user-defined conversion
is specified by a constructor (15.3.1), the initial standard conversion sequence converts the source type to the
type required by the argument of the constructor. If the user-defined conversion is specified by a conversion

§ 16.3.3.1.2
function (15.3.2), the initial standard conversion sequence converts the source type to the implicit object parameter of the conversion function.

2 The second standard conversion sequence converts the result of the user-defined conversion to the target type for the sequence. Since an implicit conversion sequence is an initialization, the special rules for initialization by user-defined conversion apply when selecting the best user-defined conversion for a user-defined conversion sequence (see 16.3.3 and 16.3.3.1).

3 If the user-defined conversion is specified by a specialization of a conversion function template, the second standard conversion sequence shall have exact match rank.

4 A conversion of an expression of class type to the same class type is given Exact Match rank, and a conversion of an expression of class type to a base class of that type is given Conversion rank, in spite of the fact that a constructor (i.e., a user-defined conversion function) is called for those cases.

16.3.3.1.3 Ellipsis conversion sequences [over.ics.ellipsis]

1 An ellipsis conversion sequence occurs when an argument in a function call is matched with the ellipsis parameter specification of the function called (see 8.2.2).

16.3.3.1.4 Reference binding [over.ics.ref]

1 When a parameter of reference type binds directly (11.6.3) to an argument expression, the implicit conversion sequence is the identity conversion, unless the argument expression has a type that is a derived class of the parameter type, in which case the implicit conversion sequence is a derived-to-base Conversion (16.3.3.1).

Example:

```c
struct A {};
struct B : public A {} b;
int f(A&);
int f(B&);
int i = f(b); // calls f(B&), an exact match, rather than f(A&), a conversion
```

—end example] If the parameter binds directly to the result of applying a conversion function to the argument expression, the implicit conversion sequence is a user-defined conversion sequence (16.3.3.1.2), with the second standard conversion sequence either an identity conversion or, if the conversion function returns an entity of a type that is a derived class of the parameter type, a derived-to-base Conversion.

2 When a parameter of reference type is not bound directly to an argument expression, the conversion sequence is the one required to convert the argument expression to the referenced type according to 16.3.3.1. Conceptually, this conversion sequence corresponds to copy-initializing a temporary of the referenced type with the argument expression. Any difference in top-level cv-qualification is subsumed by the initialization itself and does not constitute a conversion.

3 Except for an implicit object parameter, for which see 16.3.1, a standard conversion sequence cannot be formed if it requires binding an lvalue reference other than a reference to a non-volatile const type to an rvalue or binding an rvalue reference to an lvalue other than a function lvalue. [ Note: This means, for example, that a candidate function cannot be a viable function if it has a non-const lvalue reference parameter (other than the implicit object parameter) and the corresponding argument would require a temporary to be created to initialize the lvalue reference (see 11.6.3). — end note ]

4 Other restrictions on binding a reference to a particular argument that are not based on the types of the reference and the argument do not affect the formation of a standard conversion sequence, however. [ Example: A function with an “lvalue reference to int” parameter can be a viable candidate even if the corresponding argument is an int bit-field. The formation of implicit conversion sequences treats the int bit-field as an int lvalue and finds an exact match with the parameter. If the function is selected by overload resolution, the call will nonetheless be ill-formed because of the prohibition on binding a non-const lvalue reference to a bit-field (11.6.3). — end example ]
16.3.3.1.5 List-initialization sequence

When an argument is an initializer list (11.6.4), it is not an expression and special rules apply for converting it to a parameter type.

If the parameter type is an aggregate class \(X\) and the initializer list has a single element of type \(cvU\), where \(U\) is \(X\) or a class derived from \(X\), the implicit conversion sequence is the one required to convert the element to the parameter type.

Otherwise, if the parameter type is a character array\(^{133}\) and the initializer list has a single element that is an appropriately-typed string literal (11.6.2), the implicit conversion sequence is the identity conversion.

Otherwise, if the parameter type is \(\text{std::initializer_list}\{X\}\) and all the elements of the initializer list can be implicitly converted to \(X\), the implicit conversion sequence is the worst conversion necessary to convert an element of the list to \(X\), or if the initializer list has no elements, the identity conversion. This conversion can be a user-defined conversion even in the context of a call to an initializer-list constructor. [*Example:*

```c
void f(std::initializer_list<int>);  
f( {} ); // OK: f(initializer_list<int>) identity conversion
f( {1,2,3} ); // OK: f(initializer_list<int>) identity conversion
f( {'a','b'} ); // OK: f(initializer_list<int>) integral promotion
f( {1.0} ); // error: narrowing
```

struct A {
    A(std::initializer_list<double>);  // #1
    A(std::initializer_list<complex<double>>);  // #2
    A(std::initializer_list<std::string>);  // #3
};
A a{ 1.0,2.0 };  // OK, uses #1

void g(A);
g({"foo", "bar"}); // OK, uses #3

typedef int IA[3];
void h(const IA&);
h({1, 2, 3});  // OK: identity conversion

— end example]

5 Otherwise, if the parameter type is “array of \(N\) \(X\)”, if there exists an implicit conversion sequence for each element of the array from the corresponding element of the initializer list (or from {}) if there is no such element), the implicit conversion sequence is the worst such implicit conversion sequence.

6 Otherwise, if the parameter is a non-aggregate class \(X\) and overload resolution per 16.3.1.7 chooses a single best constructor \(C\) of \(X\) to perform the initialization of an object of type \(X\) from the argument initializer list:

- If \(C\) is not an initializer-list constructor and the initializer list has a single element of type \(cvU\), where \(U\) is \(X\) or a class derived from \(X\), the implicit conversion sequence has Exact Match rank if \(U\) is \(X\), or Conversion rank if \(U\) is derived from \(X\).

- Otherwise, the implicit conversion sequence is a user-defined conversion sequence with the second standard conversion sequence an identity conversion.

If multiple constructors are viable but none is better than the others, the implicit conversion sequence is the ambiguous conversion sequence. User-defined conversions are allowed for conversion of the initializer list elements to the constructor parameter types except as noted in 16.3.3.1. [*Example:*

```c
struct A {
    A(std::initializer_list<int>);
```
};

void f(A);
f( {'a', 'b'} );          // OK: f(A(std::initializer_list<int>)) user-defined conversion

struct B {
    B(int, double);
};

void g(B);
g( {'a', 'b'} );          // OK: g(B(int, double)) user-defined conversion
g( {1.0, 1.0} );          // error: narrowing

void f(B);
f( {'a', 'b'} );          // error: ambiguous f(A) or f(B)

struct C {
    C(std::string);
};

void h(C);
h( "foo" );              // OK: h(C(std::string("foo")))

struct D {
    D(A, C);
};

void i(D);
i({ {1,2}, {"bar"} });  // OK: i(D(A(std::initializer_list<int>{1,2}), C(std::string("bar"))))
—end example

7 Otherwise, if the parameter has an aggregate type which can be initialized from the initializer list according to the rules for aggregate initialization (11.6.1), the implicit conversion sequence is a user-defined conversion sequence with the second standard conversion sequence an identity conversion. [Example:

struct A {
    int m1;
    double m2;
};

void f(A);
f( {'a', 'b'} );          // OK: f(A(int,double)) user-defined conversion
f( {1.0} );                // error: narrowing
—end example]

8 Otherwise, if the parameter is a reference, see 16.3.1.4. [Note: The rules in this section will apply for initializing the underlying temporary for the reference. —end note] [Example:

struct A {
    int m1;
    double m2;
};

void f(const A&);
f( {'a', 'b'} );          // OK: f(A(int,double)) user-defined conversion
f( {1.0} );                // error: narrowing

void g(const double &);
g({1});                     // same conversion as int to double
—end example]
Otherwise, if the parameter type is not a class:

- if the initializer list has one element that is not itself an initializer list, the implicit conversion sequence is the one required to convert the element to the parameter type; [Example:
  
  ```c++
  void f(int);
  f( {'a'} );  // OK: same conversion as char to int
  f( {1.0} );  // error: narrowing
  ```
  — end example]

- if the initializer list has no elements, the implicit conversion sequence is the identity conversion. [Example:
  
  ```c++
  void f(int);
  f( { } );  // OK: identity conversion
  ```
  — end example]

In all cases other than those enumerated above, no conversion is possible.

### 16.3.3.2 Ranking implicit conversion sequences [over.ics.rank]

This subclause defines a partial ordering of implicit conversion sequences based on the relationships better conversion sequence and better conversion. If an implicit conversion sequence S1 is defined by these rules to be a better conversion sequence than S2, then it is also the case that S2 is a worse conversion sequence than S1. If conversion sequence S1 is neither better than nor worse than conversion sequence S2, S1 and S2 are said to be indistinguishable conversion sequences.

When comparing the basic forms of implicit conversion sequences (as defined in 16.3.3.1)

- a standard conversion sequence (16.3.3.1.1) is a better conversion sequence than a user-defined conversion sequence or an ellipsis conversion sequence, and

- a user-defined conversion sequence (16.3.3.1.2) is a better conversion sequence than an ellipsis conversion sequence (16.3.3.1.3).

Two implicit conversion sequences of the same form are indistinguishable conversion sequences unless one of the following rules applies:

- List-initialization sequence L1 is a better conversion sequence than list-initialization sequence L2 if
  - L1 converts to `std::initializer_list<X>` for some X and L2 does not, or, if not that,
  - L1 converts to type “array of N1 T”, L2 converts to type “array of N2 T”, and N1 is smaller than N2, even if one of the other rules in this paragraph would otherwise apply. [Example:
    
    ```c++
    void f1(int);
    void f1(std::initializer_list<long>);  // #1
    void g1() { f1({42}); }  // chooses #2
    ```
    
    ```c++
    void f2(std::pair<const char*, const char*>); // #3
    void f2(std::initializer_list<std::string>);  // #4
    void g2() { f2(“foo”, “bar”); }  // chooses #4
    ```
    — end example]

- Standard conversion sequence S1 is a better conversion sequence than standard conversion sequence S2 if
  - S1 is a proper subsequence of S2 (comparing the conversion sequences in the canonical form defined by 16.3.3.1.1, excluding any Lvalue Transformation; the identity conversion sequence is considered to be a subsequence of any non-identity conversion sequence) or, if not that,
(3.2.2) the rank of \( S_1 \) is better than the rank of \( S_2 \), or \( S_1 \) and \( S_2 \) have the same rank and are distinguishable by the rules in the paragraph below, or, if not that,

(3.2.3) \( S_1 \) and \( S_2 \) are reference bindings (11.6.3) and neither refers to an implicit object parameter of a non-static member function declared without a ref-qualifier, and \( S_1 \) binds an rvalue reference to an rvalue and \( S_2 \) binds an lvalue reference [\textit{Example:}]

```c
int i;
int f1();
int&& f2();
int g(const int&);
int g(const int&&);
int j = g(i); // calls g(const int&)
int k = g(f1()); // calls g(const int&&)
int l = g(f2()); // calls g(const int&&)
```

```c
struct A {
    A& operator<<(int);
    void p() &;
    void p() &&;
};
A& operator<<(A&&, char);
A() << 1; // calls A::operator<<(int)
A() << 'c'; // calls operator<<(A&&, char)
A a;
a << 1; // calls A::operator<<(int)
a << 'c'; // calls A::operator<<(int)
A().p(); // calls A::p()&
a.p(); // calls A::p()&
```

— end example] or, if not that,

(3.2.4) \( S_1 \) and \( S_2 \) are reference bindings (11.6.3) and \( S_1 \) binds an lvalue reference to a function lvalue and \( S_2 \) binds an rvalue reference to a function lvalue [\textit{Example:}]

```c
int f(void&)(); // #1
int f(void&&())(); // #2
void g();
int i1 = f(g); // calls #1
```

— end example] or, if not that,

(3.2.5) \( S_1 \) and \( S_2 \) differ only in their qualification conversion and yield similar types \( T_1 \) and \( T_2 \) (7.5), respectively, and the cv-qualification signature of type \( T_1 \) is a proper subset of the cv-qualification signature of type \( T_2 \) [\textit{Example:}]

```c
int f(const volatile int *);
int f(const int *);
int i;
int j = f(&i); // calls f(const int*)
```

— end example] or, if not that,

(3.2.6) \( S_1 \) and \( S_2 \) are reference bindings (11.6.3), and the types to which the references refer are the same type except for top-level cv-qualifiers, and the type to which the reference initialized by \( S_2 \) refers is more cv-qualified than the type to which the reference initialized by \( S_1 \) refers. [\textit{Example:}]

```c
int f(const int &);
int f(int &);
int g(const int &);
```
int g(int);

int i;
int j = f(i);    // calls f(int &)
int k = g(i);    // ambiguous

struct X {
  void f() const;
  void f();
};
void g(const X& a, X b) {
  a.f();          // calls X::f() const
  b.f();          // calls X::f()
}

— end example

User-defined conversion sequence U1 is a better conversion sequence than another user-defined conversion sequence U2 if they contain the same user-defined conversion function or constructor or they initialize the same class in an aggregate initialization and in either case the second standard conversion sequence of U1 is better than the second standard conversion sequence of U2. [Example:

struct A {
  operator short();
} a;
int f(int);
int f(float);
int i = f(a);                      // calls f(int), because short → int is
                                // better than short → float.

— end example]

Standard conversion sequences are ordered by their ranks: an Exact Match is a better conversion than a Promotion, which is a better conversion than a Conversion. Two conversion sequences with the same rank are indistinguishable unless one of the following rules applies:

— A conversion that does not convert a pointer, a pointer to member, or std::nullptr_t to bool is better than one that does.

— A conversion that promotes an enumeration whose underlying type is fixed to its underlying type is better than one that promotes to the promoted underlying type, if the two are different.

— If class B is derived directly or indirectly from class A, conversion of B* to A* is better than conversion of B* to void*, and conversion of A* to void* is better than conversion of B* to void*.

— If class B is derived directly or indirectly from class A and class C is derived directly or indirectly from B, conversion of C* to B* is better than conversion of C* to A*, [Example:

struct A {};
struct B : public A {};
struct C : public B {}
C* pc;
int f(A*);
int f(B*);
int i = f(pc);                     // calls f(B*)

— end example]

— binding of an expression of type C to a reference to type B is better than binding an expression of type C to a reference to type A,
(4.4.3) — conversion of \texttt{A::*} to \texttt{B::*} is better than conversion of \texttt{A::*} to \texttt{C::*},

(4.4.4) — conversion of \texttt{C} to \texttt{B} is better than conversion of \texttt{C} to \texttt{A},

(4.4.5) — conversion of \texttt{B*} to \texttt{A*} is better than conversion of \texttt{C*} to \texttt{A*},

(4.4.6) — binding of an expression of type \texttt{B} to a reference to type \texttt{A} is better than binding an expression of type \texttt{C} to a reference to type \texttt{A},

(4.4.7) — conversion of \texttt{B::*} to \texttt{C::*} is better than conversion of \texttt{A::*} to \texttt{C::*}, and

(4.4.8) — conversion of \texttt{B} to \texttt{A} is better than conversion of \texttt{C} to \texttt{A}.

[Note: Compared conversion sequences will have different source types only in the context of comparing the second standard conversion sequence of an initialization by user-defined conversion (see 16.3.3); in all other contexts, the source types will be the same and the target types will be different. — end note]

16.4 Address of overloaded function

A use of an overloaded function name without arguments is resolved in certain contexts to a function, a pointer to function or a pointer to member function for a specific function from the overload set. A function template name is considered to name a set of overloaded functions in such contexts. A function with type \texttt{F} is selected for the function type \texttt{FT} of the target type required in the context if \texttt{F} (after possibly applying the function pointer conversion (7.13)) is identical to \texttt{FT}. [Note: That is, the class of which the function is a member is ignored when matching a pointer-to-member-function type. — end note] The target can be

1. an object or reference being initialized (11.6, 11.6.3, 11.6.4),
2. the left side of an assignment (8.18),
3. a parameter of a function (8.2.2),
4. a parameter of a user-defined operator (16.5),
5. the return value of a function, operator function, or conversion (9.6.3),
6. an explicit type conversion (8.2.3, 8.2.9, 8.4), or
7. a non-type template-parameter (17.3.2).

The overloaded function name can be preceded by the \& operator. An overloaded function name shall not be used without arguments in contexts other than those listed. [Note: Any redundant set of parentheses surrounding the overloaded function name is ignored (8.1). — end note]

2 If the name is a function template, template argument deduction is done (17.8.2.2), and if the argument deduction succeeds, the resulting template argument list is used to generate a single function template specialization, which is added to the set of overloaded functions considered. [Note: As described in 17.8.1, if deduction fails and the function template name is followed by an explicit template argument list, the \texttt{template-id} is then examined to see whether it identifies a single function template specialization. If it does, the \texttt{template-id} is considered to be an lvalue for that function template specialization. The target type is not used in that determination. — end note]

3 Non-member functions and static member functions match targets of function pointer type or reference to function type. Non-static member functions match targets of pointer to member function type. If a non-static member function is selected, the reference to the overloaded function name is required to have the form of a pointer to member as described in 8.3.1.

4 If more than one function is selected, any function template specializations in the set are eliminated if the set also contains a function that is not a function template specialization, and any given function template specialization \texttt{F1} is eliminated if the set contains a second function template specialization whose function template is more specialized than the function template of \texttt{F1} according to the partial ordering rules of 17.5.6.2. After such eliminations, if any, there shall remain exactly one selected function.
Example:

```c
int f(double);
int f(int);
int (*pf)(double) = &f; // selects f(double)
int (*pf)(int) = &f; // selects f(int)
int (*pf)(...) = &f; // error: type mismatch
int (&rf)(int) = f; // selects f(int)
int (*pfe)(...) = &f; // error: type mismatch

void g() {
    (int (*)(int))&f; // cast expression as selector
}
```

The initialization of `pfe` is ill-formed because no `f()` with type `int(...)` has been declared, and not because of any ambiguity. For another example,

```c
struct X {
    int f(int);
    static int f(long);
};

int (X::*p1)(int) = &X::f; // OK
int (*p2)(int) = &X::f; // error: mismatch
int (X::*p3)(long) = &X::f; // OK
int (X::*p4)(long) = &X::f; // error: mismatch
int (X::*p5)(int) = &X::f; // error: wrong syntax for
// pointer to member
int (X::*p6)(long) = &X::f; // OK
```

—end example—

Note: If `f()` and `g()` are both overloaded functions, the cross product of possibilities must be considered to resolve `f(&g)`, or the equivalent expression `f(g)`. —end note—

Note: Even if `B` is a public base of `D`, we have

```c
D* f();
B* (*p1)() = &f; // error
void g(B*);
void (*p2)(B*) = &g; // error
```

—end note—

16.5 Overloaded operators

A function declaration having one of the following operator-function-ids as its name declares an operator function. A function template declaration having one of the following operator-function-ids as its name declares an operator function template. A specialization of an operator function template is also an operator function. An operator function is said to implement the operator named in its operator-function-id.

operator-function-id:

operator function

operator: one of

- `new` `delete` `new[]` `delete[]` `+` `-` `*` `/` `%` `-` `&` `|` `~` `^` `&=` `|=` `|=` `<<` `>>` `>>=` `<<=` `==` `!=` `<=` `>=` `&&` `||` `++` `--` `->` `->`

§ 16.5
Both the unary and binary forms of
\[ + - \ast \& \]
can be overloaded.

The following operators cannot be overloaded:
\[ . \ast :: ?: \]
nor can the preprocessing symbols \# and \#
(Clause 19).

Operator functions are usually not called directly; instead they are invoked to evaluate the operators they implement (16.5.1 – 16.5.7). They can be explicitly called, however, using the \texttt{operator-function-id} as the name of the function in the function call syntax (8.2.2). \texttt{Example:}

\begin{verbatim}
complex z = a.operator+(b); //complex z = a+b;
void* p = operator new(sizeof(int)*n);
\end{verbatim}

The allocation and deallocation functions, \texttt{operator new}, \texttt{operator new[]} , \texttt{operator delete} and \texttt{operator delete[]}, are described completely in 6.7.4. The attributes and restrictions found in the rest of this subclause do not apply to them unless explicitly stated in 6.7.4.

An operator function shall either be a non-static member function or be a non-member function that has at least one parameter whose type is a class, a reference to a class, an enumeration, or a reference to an enumeration. The meaning of the operators =, (unary) & , and , (comma), predefined for each type, can be changed for specific class and enumeration types by defining operator functions that implement these operators. Operator functions are inherited in the same manner as other base class functions.

The identities among certain predefined operators applied to basic types (for example, \texttt{++a} \equiv \texttt{a+=1}) need not hold for operator functions. Some predefined operators, such as +=, require an operand to be an lvalue when applied to basic types; this is not required by operator functions.

An operator function cannot have default arguments (11.3.6), except where explicitly stated below. Operator functions cannot have more or fewer parameters than the number required for the corresponding operator, as described in the rest of this subclause.

Operators not mentioned explicitly in subclauses 16.5.3 through 16.5.7 act as ordinary unary and binary operators obeying the rules of 16.5.1 or 16.5.2.

16.5.1 Unary operators \[over.unary\]
A prefix unary operator shall be implemented by a non-static member function (12.2.1) with no parameters or a non-member function with one parameter. Thus, for any prefix unary operator \&\& or \&\&, can be interpreted as either \texttt{x.operator@()} or \texttt{operator@}(x). If both forms of the operator function have been declared, the rules in 16.3.1.2 determine which, if any, interpretation is used. See 16.5.7 for an explanation of the postfix unary operators ++ and --.

The unary and binary forms of the same operator are considered to have the same name. \texttt{Note: Consequently, a unary operator can hide a binary operator from an enclosing scope, and vice versa. —end note}
the rules in 16.3.1.2 determine which, if any, interpretation is used.

16.5.3 Assignment

1 An assignment operator shall be implemented by a non-static member function with exactly one parameter. Because a copy assignment operator operator= is implicitly declared for a class if not declared by the user (15.8), a base class assignment operator is always hidden by the copy assignment operator of the derived class.

2 Any assignment operator, even the copy and move assignment operators, can be virtual. [Note: For a derived class D with a base class B for which a virtual copy/move assignment has been declared, the copy/move assignment operator in D does not override B’s virtual copy/move assignment operator.]

```cpp
struct B {
  virtual int operator=(int);
  virtual B& operator=(const B&);
};
struct D : B {
  virtual int operator=(int);
  virtual D& operator=(const B&);
};
D dobj1;
D dobj2;
B* bptr = &dobj1;
void f() {
  bptr->operator=(99); // calls D::operator=(int)
  *bptr = 99; // ditto
  bptr->operator=(dobj2); // calls D::operator=(const B&)
  *bptr = dobj2; // ditto
  dobj1 = dobj2; // calls implicitly-declared D::operator=(const D&)
}
```

—end example | —end note

16.5.4 Function call

1 operator() shall be a non-static member function with an arbitrary number of parameters. It can have default arguments. It implements the function call syntax

postfix-expression ( expression-list(opt) )

where the postfix-expression evaluates to a class object and the possibly empty expression-list matches the parameter list of an operator() member function of the class. Thus, a call x(arg1, ...) is interpreted as x.operator()(arg1, ...) for a class object x of type T if T::operator()(T1, T2, T3) exists and if the operator is selected as the best match function by the overload resolution mechanism (16.3.3).

16.5.5 Subscripting

1 operator[] shall be a non-static member function with exactly one parameter. It implements the subscripting syntax

postfix-expression [ expr-or-braced-init-list ]

Thus, a subscripting expression x[y] is interpreted as x.operator[](y) for a class object x of type T if T::operator[](T1) exists and if the operator is selected as the best match function by the overload resolution mechanism (16.3.3). [Example:

```cpp
struct X {
  Z operator[](std::initializer_list<int>);
};
```
16.5.6 Class member access

\textbf{operator->} shall be a non-static member function taking no parameters. It implements the class member access syntax that uses \texttt{->}.

\begin{verbatim}
postfix-expression -> template_opt id-expression
postfix-expression -> pseudo-destructor-name
\end{verbatim}

An expression \(x->m\) is interpreted as \((x.\text{operator->()})->m\) for a class object \(x\) of type \(T\) if \(T::\text{operator->()}\) exists and if the operator is selected as the best match function by the overload resolution mechanism (16.3).

16.5.7 Increment and decrement

The user-defined function called \textbf{operator++} implements the prefix and postfix ++ operator. If this function is a non-static member function with no parameters, or a non-member function with one parameter, it defines the prefix increment operator ++ for objects of that type. If the function is a non-static member function with one parameter (which shall be of type \texttt{int}) or a non-member function with two parameters (the second of which shall be of type \texttt{int}), it defines the postfix increment operator ++ for objects of that type. When the postfix increment is called as a result of using the ++ operator, the \texttt{int} argument will have value zero.\footnote{Calling \texttt{operator++} explicitly, as in expressions like \texttt{a.operator++(2)}, has no special properties: The argument to \texttt{operator++} is 2.}

\begin{verbatim}
Example:

struct X {
  X& operator++();  // prefix ++a
  X operator++(int);  // postfix a++
};

struct Y {
};

Y& operator++(Y&);  // prefix ++b
Y operator++(Y&, int);  // postfix b++

void f(X a, Y b) {
  ++a;  // a.operator++();
  a++;  // a.operator++(0);
  ++b;  // operator++(b);
  b++;  // operator++(b, 0);

  a.operator++();  // explicit call: like ++a;
  a.operator++(0);  // explicit call: like a++;
  operator++(b);  // explicit call: like ++b;
  operator++(b, 0);  // explicit call: like b++;
}
\end{verbatim}

--- end example]

The prefix and postfix decrement operators -- are handled analogously.
16.5.8 User-defined literals

literal-operator-id:
  operator string-literal identifier
  operator user-defined-string-literal

1 The string-literal or user-defined-string-literal in a literal-operator-id shall have no encoding-prefix and shall contain no characters other than the implicit terminating ‘\0’. The ud-suffix of the user-defined-string-literal or the identifier in a literal-operator-id is called a literal suffix identifier. Some literal suffix identifiers are reserved for future standardization; see 20.5.4.3.5. A declaration whose literal-operator-id uses such a literal suffix identifier is ill-formed, no diagnostic required.

2 A declaration whose declarator-id is a literal-operator-id shall be a declaration of a namespace-scope function or function template (it could be a friend function (14.3)), an explicit instantiation or specialization of a function template, or a using-declaration (10.3.3). A function declared with a literal-operator-id is a literal operator. A function template declared with a literal-operator-id is a literal operator template.

3 The declaration of a literal operator shall have a parameter-declaration-clause equivalent to one of the following:

```c
const char*
unsigned long long int
long double
char
wchar_t
char16_t
char32_t
const char*, std::size_t
const wchar_t*, std::size_t
const char16_t*, std::size_t
const char32_t*, std::size_t
```

If a parameter has a default argument (11.3.6), the program is ill-formed.

4 A raw literal operator is a literal operator with a single parameter whose type is const char*.

5 The declaration of a literal operator template shall have an empty parameter-declaration-clause and its template-parameter-list shall have a single template-parameter that is a non-type template parameter pack (17.5.3) with element type char.

6 Literal operators and literal operator templates shall not have C language linkage.

7 [Note: Literal operators and literal operator templates are usually invoked implicitly through user-defined literals (5.13.8). However, except for the constraints described above, they are ordinary namespace-scope functions and function templates. In particular, they are looked up like ordinary functions and function templates and they follow the same overload resolution rules. Also, they can be declared inline or constexpr, they may have internal or external linkage, they can be called explicitly, their addresses can be taken, etc. — end note]

8 [Example:

```c
void operator " _km(long double); // OK
string operator " _i8n(const char*, std::size_t); // OK
template <char...> double operator " _U03C0(); // OK: UCN for lowercase pi
float operator " _e(const char*); // OK
float operator "E(const char*); // error: reserved literal suffix (20.5.4.3.5, 5.13.8)
double operator" _Bq(long double); // OK: does not use the reserved identifier _Bq (5.10)
double operator" _Bq(const char*); // uses the reserved identifier _Bq (5.10)
float operator "B(const char*); // error: non-empty string-literal
string operator " 5X(const char*, std::size_t); // error: invalid literal suffix identifier
```

§ 16.5.8
double operator "" _miles(double); // error: invalid parameter-declaration-clause

template <char...> int operator "" _j(const char*); // error: invalid parameter-declaration-clause

extern "C" void operator "" _m(long double); // error: C language linkage

—end example]}

16.6 Built-in operators [over.built]

The candidate operator functions that represent the built-in operators defined in Clause 8 are specified in this subclause. These candidate functions participate in the operator overload resolution process as described in 16.3.1.2 and are used for no other purpose. [Note: Because built-in operators take only operands with non-class type, and operator overload resolution occurs only when an operand expression originally has class or enumeration type, operator overload resolution can resolve to a built-in operator only when an operand has a class type that has a user-defined conversion to a non-class type appropriate for the operator, or when an operand has an enumeration type that can be converted to a type appropriate for the operator. Also note that some of the candidate operator functions given in this subclause are more permissive than the built-in operators themselves. As described in 16.3.1.2, after a built-in operator is selected by overload resolution the expression is subject to the requirements for the built-in operator given in Clause 8, and therefore to any additional semantic constraints given there. If there is a user-written candidate with the same name and parameter types as a built-in candidate operator function, the built-in operator function is hidden and is not included in the set of candidate functions. —end note]

In this subclause, the term promoted integral type is used to refer to those integral types which are preserved by integral promotion (7.6) (including e.g. int and long but excluding e.g. char). Similarly, the term promoted arithmetic type refers to floating types plus promoted integral types. [Note: In all cases where a promoted integral type or promoted arithmetic type is required, an operand of enumeration type will be acceptable by way of the integral promotions. —end note]

In the remainder of this section, \( vq \) represents either volatile or no cv-qualifier.

For every pair \((T, vq)\), where \(T\) is an arithmetic type other than bool, there exist candidate operator functions of the form
\[
vq T k& operator++(vq T&);
T operator++(vq T&, int);
\]

For every pair \((T, vq)\), where \(T\) is an arithmetic type other than bool, there exist candidate operator functions of the form
\[
vq T k& operator--(vq T&);
T operator--(vq T&, int);
\]

For every pair \((T, vq)\), where \(T\) is a cv-qualified or cv-unqualified object type, there exist candidate operator functions of the form
\[
T* vq& operator++(T*vq&);
T* vq& operator--(T*vq&);
T* operator++(T*vq&, int);
T* operator--(T*vq&, int);
\]

For every cv-qualified or cv-unqualified object type \(T\), there exist candidate operator functions of the form
\[
T k& operator*(T*);
\]

For every function type \(T\) that does not have cv-qualifiers or a ref-qualifier, there exist candidate operator functions of the form
\[
T k& operator*(T*);
\]

For every type \(T\) there exist candidate operator functions of the form
\[
T* operator+(T*);
\]
For every promoted arithmetic type \( T \), there exist candidate operator functions of the form
\[
T \ operator+(T);
T \ operator-(T);
\]

For every promoted integral type \( T \), there exist candidate operator functions of the form
\[
T \ operator-(T);
\]

For every quintuple \((C1, C2, T, cv1, cv2)\), where \( C2 \) is a class type, \( C1 \) is the same type as \( C2 \) or is a derived class of \( C2 \), and \( T \) is an object type or a function type, there exist candidate operator functions of the form
\[
cv12 \ T& \ operator->*\(\(cv1 \ C1*\), \ cv2 \ T \ C2::*\);
\]
where \( cv12 \) is the union of \( cv1 \) and \( cv2 \). The return type is shown for exposition only; see 8.5 for the determination of the operator’s result type.

For every pair of promoted arithmetic types \( L \) and \( R \), there exist candidate operator functions of the form
\[
LR \ operator*(L, R);
LR \ operator/(L, R);
LR \ operator+(L, R);
LR \ operator-(L, R);
bool \ operator<(L, R);
bool \ operator>(L, R);
bool \ operator<=(L, R);
bool \ operator>=(L, R);
bool \ operator==(L, R);
bool \ operator!=(L, R);
\]
where \( LR \) is the result of the usual arithmetic conversions between types \( L \) and \( R \).

For every cv-qualified or cv-unqualified object type \( T \) there exist candidate operator functions of the form
\[
T* \ operator+(T*, std::ptrdiff_t);
Tk \ operator[](T*, std::ptrdiff_t);
T* \ operator-(T*, std::ptrdiff_t);
T* \ operator+(std::ptrdiff_t, T*);
Tk \ operator[](std::ptrdiff_t, T*);
\]

For every \( T \), where \( T \) is a pointer to object type, there exist candidate operator functions of the form
\[
std::ptrdiff_t \ operator-(T, T);
\]

For every \( T \), where \( T \) is an enumeration type or a pointer type, there exist candidate operator functions of the form
\[
bool \ operator<(T, T);
bool \ operator>(T, T);
bool \ operator<=(T, T);
bool \ operator>=(T, T);
bool \ operator==(T, T);
bool \ operator!=(T, T);
\]

For every pointer to member type \( T \) or type \texttt{std::nullptr_t} there exist candidate operator functions of the form
\[
bool \ operator==(T, T);
bool \ operator!=(T, T);
\]

For every pair of promoted integral types \( L \) and \( R \), there exist candidate operator functions of the form
\[
LR \ operator%(L, R);
LR \ operator&,(L, R);
LR \ operator^(L, R);
\]
\[ LR \text{ operator|}(L, R); \]
\[ L \text{ operator<<(L, R);} \]
\[ L \text{ operator>>(L, R);} \]

where \( LR \) is the result of the usual arithmetic conversions between types \( L \) and \( R \).

For every triple \((L, vq, R)\), where \( L \) is an arithmetic type, and \( R \) is a promoted arithmetic type, there exist candidate operator functions of the form
\[ vq \text{ } Lk \text{ }\text{ operator=}=(vq \text{ } Lk, R); \]
\[ vq \text{ } Lk \text{ }\text{ operator}*=(vq \text{ } Lk, R); \]
\[ vq \text{ } Lk \text{ }\text{ operator}/=(vq \text{ } Lk, R); \]
\[ vq \text{ } Lk \text{ }\text{ operator}+=(vq \text{ } Lk, R); \]
\[ vq \text{ } Lk \text{ }\text{ operator}--=(vq \text{ } Lk, R); \]

For every pair \((T, vq)\), where \( T \) is any type, there exist candidate operator functions of the form
\[ T*vqk \text{ }\text{ operator=}=(T*vqk, T*); \]

For every pair \((T, vq)\), where \( T \) is an enumeration or pointer to member type, there exist candidate operator functions of the form
\[ vq \text{ } Tk \text{ }\text{ operator=}=(vq \text{ } Tk, T); \]

For every pair \((T, vq)\), where \( T \) is a cv-qualified or cv-unqualified object type, there exist candidate operator functions of the form
\[ T*vqk \text{ }\text{ operator}+=(T*vqk, \text{ std::ptrdiff_t}); \]
\[ T*vqk \text{ }\text{ operator}--=(T*vqk, \text{ std::ptrdiff_t}); \]

For every triple \((L, vq, R)\), where \( L \) is an integral type, and \( R \) is a promoted integral type, there exist candidate operator functions of the form
\[ vq \text{ } Lk \text{ }\text{ operator}%=(vq \text{ } Lk, R); \]
\[ vq \text{ } Lk \text{ }\text{ operator}<==(vq \text{ } Lk, R); \]
\[ vq \text{ } Lk \text{ }\text{ operator}>==(vq \text{ } Lk, R); \]
\[ vq \text{ } Lk \text{ }\text{ operator}%==(vq \text{ } Lk, R); \]
\[ vq \text{ } Lk \text{ }\text{ operator}%==(vq \text{ } Lk, R); \]
\[ vq \text{ } Lk \text{ }\text{ operator}|=(vq \text{ } Lk, R); \]

There also exist candidate operator functions of the form
\[ \text{ bool } \text{ operator}!=(\text{ bool}); \]
\[ \text{ bool } \text{ operator}&=(\text{ bool}, \text{ bool}); \]
\[ \text{ bool } \text{ operator}!|(\text{ bool}, \text{ bool}); \]

For every pair of promoted arithmetic types \( L \) and \( R \), there exist candidate operator functions of the form
\[ LR \text{ }\text{ operator}?:(\text{ bool}, L, R); \]

where \( LR \) is the result of the usual arithmetic conversions between types \( L \) and \( R \). [Note: As with all these descriptions of candidate functions, this declaration serves only to describe the built-in operator for purposes of overload resolution. The operator “?:” cannot be overloaded. — end note]

For every type \( T \), where \( T \) is a pointer, pointer-to-member, or scoped enumeration type, there exist candidate operator functions of the form
\[ T \text{ }\text{ operator}?:(\text{ bool}, T, T); \]
17 Templates [temp]

1 A template defines a family of classes, functions, or variables, or an alias for a family of types.

- **template-declaration:**
  
  - template `< template-parameter-list > declaration`

  - **template-parameter-list:**
    
    - template-parameter

    template-parameter-list , template-parameter

  [Note: The `>` token following the template-parameter-list of a template-declaration may be the product of replacing a `>>` token by two consecutive `>` tokens (17.2). — end note]

  The declaration in a template-declaration shall

  (1.1) — declare or define a function, a class, or a variable, or

  (1.2) — define a member function, a member class, a member enumeration, or a static data member of a class

      template or of a class nested within a class template, or

  (1.3) — define a member template of a class or class template, or

  (1.4) — be a deduction-guide, or

  (1.5) — be an alias-declaration.

  A template-declaration is a declaration. A template-declaration is also a definition if its declaration defines a

      function, a class, a variable, or a static data member. A declaration introduced by a template declaration of

      a variable is a variable template. A variable template at class scope is a static data member template.

  [Example:

  ```
  template<class T>
  constexpr T pi = T(3.1415926535897932385L);

  template<class T>
  T circular_area(T r) {
    return pi<T> * r * r;
  }

  struct matrix_constants {
    template<class T>
      using pauli = hermitian_matrix<T, 2>;
    template<class T>
    constexpr pauli<T> sigma1 = { { 0, 1 }, { 1, 0 } };
    template<class T>
    constexpr pauli<T> sigma2 = { { 0, -1i }, { 1i, 0 } };
    template<class T>
    constexpr pauli<T> sigma3 = { { 1, 0 }, { 0, -1 } };
  };
  ```

  — end example]

2 A template-declaration can appear only as a namespace scope or class scope declaration. In a function template declaration, the last component of the declarator-id shall not be a template-id. [Note: That last component may be an identifier, an operator-function-id, a conversion-function-id, or a literal-operator-id. In a class template declaration, if the class name is a simple-template-id, the declaration declares a class template partial specialization (17.5.5). — end note]
3 In a template-declaration, explicit specialization, or explicit instantiation the init-declarator-list in the declaration shall contain at most one declarator. When such a declaration is used to declare a class template, no declarator is permitted.

4 A template name has linkage (6.5). Specializations (explicit or implicit) of a template that has internal linkage are distinct from all specializations in other translation units. A template, a template explicit specialization (17.7.3), and a class template partial specialization shall not have C linkage. Use of a linkage specification other than "C" or "C++" with any of these constructs is conditionally-supported, with implementation-defined semantics. Template definitions shall obey the one-definition rule (6.2). [Note: Default arguments for function templates and for member functions of class templates are considered definitions for the purpose of template instantiation (17.5) and must also obey the one-definition rule. —end note]

5 A class template shall not have the same name as any other template, class, function, variable, enumeration, enumerator, namespace, or type in the same scope (6.3), except as specified in 17.5.5. Except that a function template can be overloaded either by non-template functions (11.3.5) with the same name or by other function templates with the same name (17.8.3), a template name declared in namespace scope or in class scope shall be unique in that scope.

6 A templated entity is

(6.1) — a template,

(6.2) — an entity defined (6.1) or created (15.2) in a templated entity,

(6.3) — a member of a templated entity,

(6.4) — an enumerator for an enumeration that is a templated entity, or

(6.5) — the closure type of a lambda-expression (8.1.5.1) appearing in the declaration of a templated entity.

[Note: A local class, a local variable, or a friend function defined in a templated entity is a templated entity. —end note]

7 A function template, member function of a class template, variable template, or static data member of a class template shall be defined in every translation unit in which it is implicitly instantiated (17.7.1) unless the corresponding specialization is explicitly instantiated (17.7.2) in some translation unit; no diagnostic is required.

17.1 Template parameters [temp.param]

The syntax for template-parameters is:

template-parameter:
  type-parameter
  parameter-declaration

  type-parameter:
    type-parameter-key ...opt identifier opt
    type-parameter-key identifier opt = type-id
    template < template-parameter-list > type-parameter-key ...opt identifier opt
    template < template-parameter-list > type-parameter-key identifier opt = id-expression

type-parameter-key:
  class
  typename

[Note: The > token following the template-parameter-list of a type-parameter may be the product of replacing a >> token by two consecutive > tokens (17.2). —end note]

There is no semantic difference between class and typename in a type-parameter-key. typename followed by an unqualified-id names a template type parameter. typename followed by a qualified-id denotes the type in
a non-type\textsuperscript{135} parameter-declaration. A template-parameter of the form \texttt{class identifier} is a type-parameter. [Example:

\begin{verbatim}
class T { /* ... */ };  
int i;

template<class T, T i> void f(T t) {
    T t1 = i;  // template-parameters T and i
    ::T t2 = ::i;  // global namespace members T and i
}
\end{verbatim}

Here, the template \texttt{f} has a type-parameter called \texttt{T}, rather than an unnamed non-type template-parameter of class \texttt{T}. — end example] A storage class shall not be specified in a template-parameter declaration. Types shall not be defined in a template-parameter declaration.

3 A type-parameter whose identifier does not follow an ellipsis defines its identifier to be a typedef-name (if declared without template) or template-name (if declared with template) in the scope of the template declaration. [Note: A template argument may be a class template or alias template. For example,

\begin{verbatim}
template<class T> class myarray { /* ... */ };  

template<class K, class V, template<class T> class C = myarray>
class Map {
    C<K> key;
    C<V> value;
};
\end{verbatim}

— end note]

4 A non-type template-parameter shall have one of the following (optionally cv-qualified) types:

\begin{enumerate}
\item integral or enumeration type,
\item pointer to object or pointer to function,
\item lvalue reference to object or lvalue reference to function,
\item pointer to member,
\item \texttt{std::nullptr_t}, or
\item a type that contains a placeholder type (10.1.7.4).
\end{enumerate}

5 [Note: Other types are disallowed either explicitly below or implicitly by the rules governing the form of template-arguments (17.3). — end note] The top-level cv-qualifiers on the template-parameter are ignored when determining its type.

6 A non-type non-reference template-parameter is a prvalue. It shall not be assigned to or in any other way have its value changed. A non-type non-reference template-parameter cannot have its address taken. When a non-type non-reference template-parameter is used as an initializer for a reference, a temporary is always used. [Example:

\begin{verbatim}
template<const X& x, int i> void f() {
    i++;  // error: change of template-parameter value
    &x;  // OK
    &i;  // error: address of non-reference template-parameter
    int& ri = i;  // error: non-const reference bound to temporary
    const int& cri = i;  // OK: const reference bound to temporary
\end{verbatim}

\textsuperscript{135} Since template template-parameters and template template-arguments are treated as types for descriptive purposes, the terms non-type parameter and non-type argument are used to refer to non-type, non-template parameters and arguments.

§ 17.1 346
A non-type template-parameter shall not be declared to have floating-point, class, or void type. [Example:

```cpp
template<double d> class X; // error
template<double* pd> class Y; // OK
template<double& rd> class Z; // OK
```]

A non-type template-parameter of type “array of T” or of function type T is adjusted to be of type “pointer to T”. [Example:

```cpp
template<int* a> struct R { /* ... */ };  // OK
template<int b[5]> struct S { /* ... */ };  // OK due to implicit argument conversion
```]

A default template-argument is a template-argument (17.3) specified after = in a template-parameter. A default template-argument may be specified for any kind of template-parameter (type, non-type, template) that is not a template parameter pack (17.5.3). A default template-argument may be specified in the template-parameter-lists of the definition of a member of a class template that appears outside of the member’s class. A default template-argument shall not be specified in a friend class template declaration. If a friend function template declaration specifies a default template-argument, that declaration shall be a definition and shall be the only declaration of the function template in the translation unit.

The set of default template-arguments available for use is obtained by merging the default arguments from all prior declarations of the template in the same way default function arguments are (11.3.6). [Example:

```cpp
template<class T1, class T2 = int> class A;  // OK
template<class T1 = int, class T2> class A;  // OK due to both adjustment and conversion
```]

If a template-parameter of a class template, variable template, or alias template has a default template-argument, each subsequent template-parameter shall either have a default template-argument supplied or be a template parameter pack. If a template-parameter of a primary class template, primary variable template, or alias template is a template parameter pack, it shall be the last template-parameter. A template parameter pack of a function template shall not be followed by another template parameter unless that template parameter can be deduced from the parameter-type-list (11.3.5) of the function template or has a default argument (17.8.2). A template parameter of a deduction guide template (17.9) that does not have a default argument shall be deducible from the parameter-type-list of the deduction guide template. [Example:

```cpp
// U can be neither deduced from the parameter-type-list nor specified
template<class... T, class... U> void f() { }  // error
template<class... T, class U> void g() { }  // error
```]
A template-parameter shall not be given default arguments by two different declarations in the same scope. [Example:
```c
template<class T = int> class X;
template<class T = int> class X { /* ... */ }; // error
```
— end example]

When parsing a default template-argument for a non-type template-parameter, the first non-nested > is taken as the end of the template-parameter-list rather than a greater-than operator. [Example:
```c
template<int i = 3 > 4 > class X { /* ... */ }; // syntax error
template<int i = (3 > 4) > class Y { /* ... */ }; // OK
```
— end example]

A template-parameter of a template template-parameter is permitted to have a default template-argument. When such default arguments are specified, they apply to the template template-parameter in the scope of the template template-parameter. [Example:
```c
template <class T = float> struct B {};
template <template <class TT = float> class T> struct A {
    inline void f();
    inline void g();
};
template <template <class TT> class T> void A<T>::f() {
    T<> t; // error - TT has no default template argument
}
template <template <class TT = char> class T> void A<T>::g() {
    T<> t; // OK - T<char
}
```
— end example]

If a template-parameter is a type-parameter with an ellipsis prior to its optional identifier or is a parameter-declaration that declares a parameter pack (11.3.5), then the template-parameter is a template parameter pack (17.5.3). A template parameter pack that is a parameter-declaration whose type contains one or more unexpanded parameter packs is a pack expansion. Similarly, a template parameter pack that is a type-parameter with a template-parameter-list containing one or more unexpanded parameter packs is a pack expansion. A template parameter pack that is a pack expansion shall not expand a parameter pack declared in the same template-parameter-list. [Example:
```c
template <class... Types> class Tuple; // Types is a template type parameter pack
    // but not a pack expansion
template <class T, int... Dims> struct multi_array; // Dims is a non-type template parameter pack
    // but not a pack expansion
template<class... T> struct value_holder {
    template<T... Values> struct apply { }; // Values is a non-type template parameter pack
    // and a pack expansion
};
template<class... T, T... Values> struct static_array; // error: Values expands template type parameter pack
    // T within the same template parameter list
```
— end example]
17.2 Names of template specializations

A template specialization (17.7) can be referred to by a template-id:

- simple-template-id:
  - template-name < template-argument-list_opt >

- template-id:
  - simple-template-id
  - operator-function-id < template-argument-list_opt >
  - literal-operator-id < template-argument-list_opt >

- template-name:
  - identifier

- template-argument-list:
  - template-argument ... opt
  - template-argument-list , template-argument ... opt

- template-argument:
  - constant-expression
  - type-id
  - id-expression

[Note: The name lookup rules (6.4) are used to associate the use of a name with a template declaration; that is, to identify a name as a template-name. — end note]

For a template-name to be explicitly qualified by the template arguments, the name must be known to refer to a template.

After name lookup (6.4) finds that a name is a template-name or that an operator-function-id or a literal-operator-id refers to a set of overloaded functions any member of which is a function template, if this is followed by a <, the < is always taken as the delimiter of a template-argument-list and never as the less-than operator. When parsing a template-argument-list, the first non-nested > is always taken as the delimiter of a template-argument-list and never as the greater-than operator. Similarly, the first non-nested >> is treated as two consecutive but distinct > tokens, the first of which is taken as the end of the template-argument-list and completes the template-id. [Note: The second > token produced by this replacement rule may terminate an enclosing template-id construct or it may be part of a different construct (e.g. a cast). — end note] [Example:

```cpp
template<int i> class X { /* ... */ };
X< 1>2 > x1; // syntax error
X<(1>2)> x2; // OK

template<class T> class Y { /* ... */ };
Y<X<1>> x3; // OK, same as Y<X<1> > x3;
Y<X<6>>1>> x4; // syntax error
Y<X<(6>>1)>> x5; // OK
```
— end example]

The keyword template is said to appear at the top level in a qualified-id if it appears outside of a template-argument-list or decltype-specifier. In a qualified-id of a declarator-id or in a qualified-id formed by a class-head-name (Clause 12) or enum-head-name (10.2), the keyword template shall not appear at the top level. In a qualified-id used as the name in a typename-specifier (17.6), elaborated-type-specifier (10.1.7.3), using-declaration (10.3.3), or class-or-decltype (Clause 13), an optional keyword template appearing at the top level is ignored. In these contexts, a < token is always assumed to introduce a template-argument-list. In all other contexts, when naming a template specialization of a member of an unknown specialization (17.6.2.1),

[136] A > that encloses the type-id of a dynamic_cast, static_cast, reinterpret_cast or const_cast, or which encloses the template-arguments of a subsequent template-id, is considered nested for the purpose of this description.
the member template name shall be prefixed by the keyword \texttt{template}. [\textit{Example:}

\begin{verbatim}
struct X {
    template<typename size_t> X* alloc();
    template<typename size_t> static X* adjust();
};
template<class T> void f(T* p) {
    T* p1 = p->alloc<200>(); // ill-formed: \texttt{<} means less than
    T* p2 = p->template alloc<200>(); // OK: \texttt{<} starts template argument list
    T::adjust<100>(); // ill-formed: \texttt{<} means less than
    T::template adjust<100>(); // OK: \texttt{<} starts template argument list
}
\end{verbatim}

--- end example ---

5 A name prefixed by the keyword \texttt{template} shall be a \textit{template-id} or the name shall refer to a class template or an alias template. [\textit{Note:} The keyword \texttt{template} may not be applied to non-template members of class templates. --- end note] [\textit{Note:} As is the case with the \texttt{typename} prefix, the \texttt{template} prefix is allowed in cases where it is not strictly necessary; i.e., when the \texttt{nested-name-specifier} or the expression on the left of the \texttt{->} or \texttt{.} is not dependent on a \textit{template-parameter}, or the use does not appear in the scope of a template. --- end note] [\textit{Example:}

\begin{verbatim}
template <class T> struct A {
    void f(int);
    template <class U> void f(U);
};

template <class T> void f(T t) {
    A<T> a;
    a.template f<t>(); // OK: calls template
    a.template f(t); // error: not a template-id
}
\end{verbatim}

--- end example ---

6 A \textit{simple-template-id} that names a class template specialization is a \textit{class-name} (Clause 12).

7 A \textit{template-id} that names an alias template specialization is a \textit{type-name}.

\subsection*{17.3 Template arguments \texttt{[temp.arg]}}

There are three forms of \textit{template-argument}, corresponding to the three forms of \textit{template-parameter}: type, non-type and template. The type and form of each \textit{template-argument} specified in a \textit{template-id} shall match the type and form specified for the corresponding parameter declared by the template in its \textit{template-parameter-list}. When the parameter declared by the template is a template parameter pack (17.5.3), it will correspond to zero or more \textit{template-arguments}. [\textit{Example:}

\begin{verbatim}
template<
\end{verbatim}

\section*{§ 17.3}
explicit Array(int);
T& operator[](int);  
T& elem(int i) { return v[i]; }
};

Array<int> v1(20);
typedef std::complex<double> dcomplex;  // std::complex is a standard library template
Array<dcomplex> v2(30);
Array<dcomplex> v3(40);

void bar() {
v1[3] = 7;
v2[3] = v3.elem(4) = dcomplex(7,8);
}
—end example

2 In a template-argument, an ambiguity between a type-id and an expression is resolved to a type-id, regardless of the form of the corresponding template-parameter.  

Example:

template<class T> void f();
template<int I> void f();

void g() {
f<int>();  // int() is a type-id: call the first f()
}
—end example

3 The name of a template-argument shall be accessible at the point where it is used as a template-argument.  

[Note: If the name of the template-argument is accessible at the point where it is used as a template-argument, there is no further access restriction in the resulting instantiation where the corresponding template-parameter name is used. — end note]  

Example:

class Y {
private:
    struct S { /* ... */ };  
    X<S> x;  // OK: S is accessible  
    // X<Y::S> has a static member of type Y::S  
    // OK: even though Y::S is private
};

X<Y::S> y;  // error: S not accessible
—end example

For a template-argument that is a class type or a class template, the template definition has no special access rights to the members of the template-argument.  

Example:

template <template <class TT> class T> class A {
    typename T<int>::S s;
};

template <class U> class B {
private:
137) There is no such ambiguity in a default template-argument because the form of the template-parameter determines the allowable forms of the template-argument.
struct S { /* ... */ }; 
};

A<B> b; // ill-formed: A has no access to B::S

— end example

4 When template argument packs or default template-arguments are used, a template-argument list can be empty. In that case the empty <> brackets shall still be used as the template-argument-list. [Example:

template<class T = char> class String;
String<> p; // OK: String<char>
String* q; // syntax error
template<class ... Elements> class Tuple;
Tuple<> t; // OK: Elements is empty
Tuple* u; // syntax error

— end example]

5 An explicit destructor call (15.4) for an object that has a type that is a class template specialization may explicitly specify the template-arguments. [Example:

template<class T> struct A {
    ~A();
};

void f(A<int>*, A<int>* q) {
    p->A<int>::~A(); // OK: destructor call
    q->A<int>::~A<int>(); // OK: destructor call
}

— end example]

6 If the use of a template-argument gives rise to an ill-formed construct in the instantiation of a template specialization, the program is ill-formed.

7 When the template in a template-id is an overloaded function template, both non-template functions in the overload set and function templates in the overload set for which the template-arguments do not match the template-parameters are ignored. If none of the function templates have matching template-parameters, the program is ill-formed.

8 When a simple-template-id does not name a function, a default template-argument is implicitly instantiated (17.7.1) when the value of that default argument is needed. [Example:

template<typename T, typename U = int> struct S { }
S<bool>* p; // the type of p is S<bool, int>*
The default argument for U is instantiated to form the type S<bool, int>.* — end example]

9 A template-argument followed by an ellipsis is a pack expansion (17.5.3).

17.3.1 Template type arguments

[template.type]

1 A template-argument for a template-parameter which is a type shall be a type-id.

2 [Example:

template <class T> class X { }
template <class T> void f(T t) { }
struct {} unnamed_obj;

void f() {
    struct A { {};
    enum { e1 };}
**17.3.2 Template non-type arguments**

1 If the type of a template-parameter contains a placeholder type (10.1.7.4, 17.1), the deduced parameter type is determined from the type of the template-argument by placeholder type deduction (10.1.7.4.1). If a deduced parameter type is not permitted for a template-parameter declaration (17.1), the program is ill-formed.

2 A template-argument for a non-type template-parameter shall be a converted constant expression (8.20) of the type of the template-parameter. For a non-type template-parameter of reference or pointer type, the value of the constant expression shall not refer to (or for a pointer type, shall not be the address of):

   1. a subobject (4.5),
   2. a temporary object (15.2),
   3. a string literal (5.13.5),
   4. the result of a typeid expression (8.2.8), or
   5. a predefined __func__ variable (11.4.1).

   [Note: If the template-argument represents a set of overloaded functions (or a pointer or member pointer to such), the matching function is selected from the set (16.4). — end note]

3 [Example:

```c
    template<const int* pci> struct X { /* ... */ };  
    int ai[10];                                       
    X<ai> xi;                                         
                                                   // array to pointer and qualification conversions
    struct Y { /* ... */ };                         
    template<const Y& b> struct Z { /* ... */ };    
    Y y;                                             
    Z<y> z;                                          
                                                   // no conversion, but note extra cv-qualification
    template<int (&pa)[5]> struct W { /* ... */ };   
    int b[5];                                        
    W<b> w;                                          
                                                   // no conversion
    void f(char);                                    
    void f(int);                                     
    template<void (*pf)(int)> struct A { /* ... */ }; 
    A<&f> a;                                         
                                                   // selects f(int)
    template<html n> struct B { /* ... */ };         
    B<5> b1;                                         
                                                   // OK: template parameter type is int
    B<'a'> b2;                                       
                                                   // OK: template parameter type is char
    B<2.5> b3;                                       
                                                   // error: template parameter type cannot be double
```

§ 17.3.2
4 [Note: A string literal (5.13.5) is not an acceptable template-argument.  [Example:

```cpp
template<class T, const char* p> class X {
/
... */
};

X<int, "Studebaker"> x1; // error: string literal as template-argument

const char p[] = "Vivisectionist";
X<int, p> x2; // OK
```
—end example] — end note]

5 [Note: The address of an array element or non-static data member is not an acceptable template-argument.  [Example:

```cpp
template<int* p> class X { };

int a[10];
struct S { int m; static int s; } s;

X<&a[2]> x3; // error: address of array element
X<&a.m> x4; // error: address of non-static member
X<&a.s> x5; // OK: address of static member
X<&S::s> x6; // OK: address of static member
```
—end example] — end note]

6 [Note: A temporary object is not an acceptable template-argument when the corresponding template-parameter has reference type.  [Example:

```cpp
template<const int& CRI> struct B { /* ... */ };

B<1> b2; // error: temporary would be required for template argument

int c = 1;
B<c> b1; // OK
```
—end example] — end note]

17.3.3 Template template arguments
[tem arg.template]

A template-argument for a template template-parameter shall be the name of a class template or an alias template, expressed as id-expression. When the template-argument names a class template, only primary class templates are considered when matching the template template argument with the corresponding parameter; partial specializations are not considered even if their parameter lists match that of the template template parameter.

Any partial specializations (17.5.5) associated with the primary class template or primary variable template are considered when a specialization based on the template template-parameter is instantiated. If a specialization is not visible at the point of instantiation, and it would have been selected had it been visible, the program is ill-formed, no diagnostic required.  [Example:

```cpp
template<class T> class A { // primary template
    int x;
};
template<class T> class A<T*> { // partial specialization
    long x;
};
```
A template-argument matches a template template-parameter \( P \) when \( P \) is at least as specialized as the template-argument \( A \). If \( P \) contains a parameter pack, then \( A \) also matches \( P \) if each of \( A \)'s template parameters matches the corresponding template parameter in the template-parameter-list of \( P \). Two template parameters match if they are of the same kind (type, non-type, template), for non-type template-parameters, their types are equivalent (17.5.6.1), and for template template-parameters, each of their corresponding template-parameters matches, recursively. When \( P \)'s template-parameter-list contains a template parameter pack (17.5.3), the template parameter pack will match zero or more template parameters or template parameter packs in the template-parameter-list of \( A \) with the same type and form as the template parameter pack in \( P \) (ignoring whether those template parameters are template parameter packs).

**Example:**

```cpp
template<class T> class A { /* ... */ };  
template<class T, class U = T> class B { /* ... */ };  
template<class ... Types> class C { /* ... */ };  
template<auto n> class D { /* ... */ };  
template<template<class> class P> class X { /* ... */ };  
template<template<class ...> class Q> class Y { /* ... */ };  
template<template<int> class R> class Z { /* ... */ };  

X<A> xa;  // OK  
X<B> xb;  // OK  
X<C> xc;  // OK  
Y<A> ya;  // OK  
Y<B> yb;  // OK  
Y<C> yc;  // OK  
Z<D> zd;  // OK
```

**— end example**

**Example:**

```cpp
template<class T> struct eval;

template<template<class, class...> class TT, class T1, class... Rest>  
struct eval<TT<T1, Rest...>> { };  

template<class T1> struct A;  
template<class T1, class T2> struct B;  
template<int N> struct C;  
template<class T1, int N> struct D;  
template<class T1, class T2, int N = 17> struct E;
```

```cpp
eval<A<int>> eA;  // OK: matches partial specialization of eval  
eval<B<int, float>> eB;  // OK: matches partial specialization of eval  
eval<C<int>> eC;  // error: C does not match TT in partial specialization  
eval<D<int, 17>> eD;  // error: D does not match TT in partial specialization  
eval<E<int, float>> eE;  // error: E does not match TT in partial specialization
```

**— end example**
A template template-parameter \( P \) is at least as specialized as a template template-argument \( A \) if, given the following rewrite to two function templates, the function template corresponding to \( P \) is at least as specialized as the function template corresponding to \( A \) according to the partial ordering rules for function templates (17.5.6.2). Given an invented class template \( X \) with the template parameter list of \( A \) (including default arguments):

\[(4.1) \quad \text{Each of the two function templates has the same template parameters, respectively, as} \ P \ \text{or} \ A.\]

\[(4.2) \quad \text{Each function template has a single function parameter whose type is a specialization of} \ X \ \text{with template arguments corresponding to the template parameters from the respective function template where, for each template parameter} \ PP \ \text{in the template parameter list of the function template, a corresponding template argument} \ AA \ \text{is formed. If} \ PP \ \text{declares a parameter pack, then} \ AA \ \text{is the id-expression} \ PP.\]

If the rewrite produces an invalid type, then \( P \) is not at least as specialized as \( A \).

17.4 Type equivalence

Two template-ids refer to the same class, function, or variable if

\[(1.1) \quad \text{their template-names, operator-function-ids, or literal-operator-ids refer to the same template and}\]

\[(1.2) \quad \text{their corresponding type template-arguments are the same type and}\]

\[(1.3) \quad \text{their corresponding non-type template arguments of integral or enumeration type have identical values}\]

\[(1.4) \quad \text{and their corresponding non-type template-arguments of pointer type refer to the same object or function}\]

\[(1.5) \quad \text{or are both the null pointer value and}\]

\[(1.6) \quad \text{their corresponding non-type template-arguments of pointer-to-member type refer to the same class}\]

\[(1.7) \quad \text{member or are both the null member pointer value and}\]

\[(1.8) \quad \text{their corresponding non-type template-arguments of reference type refer to the same object or function}\]

\[(1.9) \quad \text{and their corresponding template template-arguments refer to the same template.}\]

[Example:

\[
\text{template<class E, int size> class buffer \{ /* \ldots */ \};}\\
\text{buffer<char,2*512> x;}\\
\text{buffer<char,1024> y;}\\
\]

declares \( x \) and \( y \) to be of the same type, and

\[
\text{template<class T, void(*err_fct)()> class list \{ /* \ldots */ \};}\\
\text{list<int,&error_handler1> x1;}\\
\text{list<int,&error_handler2> x2;}\\
\text{list<int,&error_handler2> x3;}\\
\text{list<char,&error_handler2> x4;}\\
\]

declares \( x_2 \) and \( x_3 \) to be of the same type. Their type differs from the types of \( x_1 \) and \( x_4 \).

\[
\text{template<class T> struct X \{ \};}\\
\text{template<class> struct Y \{ \};}\\
\text{template<class T> using Z = Y<T>;}\\
\text{X<Y<int>> > y;}\\
\text{X<Z<int>> > z;}\\
\]

declares \( y \) and \( z \) to be of the same type. — end example]

2 If an expression \( e \) is type-dependent (17.6.2.2), \( \text{decltype}(e) \) denotes a unique dependent type. Two such decltype-specifiers refer to the same type only if their expressions are equivalent (17.5.6.1). [Note: However,
such a type may be aliased, e.g., by a typedef-name. — end note]

17.5 Template declarations [temp.decls]

1 A template-id, that is, the template-name followed by a template-argument-list shall not be specified in the declaration of a primary template declaration. [Example:

```c
// error
template<class T1, class T2, int I> class A<T1, T2, I> { }

// error
template<class T1, int I> void sort<T1, I>(T1 data[I]);
```

— end example] [Note: However, this syntax is allowed in class template partial specializations (17.5.5). — end note]

2 For purposes of name lookup and instantiation, default arguments and noexcept-specifiers of function templates and default arguments and noexcept-specifiers of member functions of class templates are considered definitions; each default argument or noexcept-specifier is a separate definition which is unrelated to the function template definition or to any other default arguments or noexcept-specifiers. For the purpose of instantiation, the substatements of a constexpr if statement (9.4.1) are considered definitions.

3 Because an alias-declaration cannot declare a template-id, it is not possible to partially or explicitly specialize an alias template.

17.5.1 Class templates [temp.class]

1 A class template defines the layout and operations for an unbounded set of related types.

2 [Example: A single class template List might provide an unbounded set of class definitions: one class List<T> for every type T, each describing a linked list of elements of type T. Similarly, a class template Array describing a contiguous, dynamic array might be defined like this:

```c
// error
template<class T1, class T2> struct A {
  void f1();
  void f2();
};

// error
template<class T2, class T1> void A<T2,T1>::f1() { } // OK
```

The prefix template<class T> specifies that a template is being declared and that a type-name T may be used in the declaration. In other words, Array is a parameterized type with T as its parameter. — end example]

3 When a member function, a member class, a member enumeration, a static data member or a member template of a class function is defined outside of the class template definition, the member definition is defined as a template definition in which the template-parameters are those of the class template. The names of the template parameters used in the definition of the member may be different from the template parameter names used in the class template definition. The template argument list following the class template name in the member definition shall name the parameters in the same order as the one used in the template parameter list of the member. Each template parameter pack shall be expanded with an ellipsis in the template argument list. [Example:

```c
// error
template<class T2, class T1> void A<T1,T2>::f2() { } // error
```
template<class ... Types> struct B {
    void f3();
    void f4();
};

template<class ... Types> void B<Types ...>::f3() { } // OK
template<class ... Types> void B<Types>::f4() { } // error

—end example

In a redeclaration, partial specialization, explicit specialization or explicit instantiation of a class template, the class-key shall agree in kind with the original class template declaration (10.1.7.3).

17.5.1.1 Member functions of class templates [temp.mem.func]

1 A member function of a class template may be defined outside of the class template definition in which it is declared. [Example:

```cpp
template<class T> class Array {
    T* v;
    int sz;
public:
    explicit Array(int);
    T& operator[](int);
    T& elem(int i) { return v[i]; }
};
```
declares three function templates. The subscript function might be defined like this:

```cpp
template<class T> T& Array<T>::operator[](int i) {
    if (i<0 || sz<=i) error("Array: range error");
    return v[i];
}
```

—end example

2 The template-arguments for a member function of a class template are determined by the template-arguments of the type of the object for which the member function is called. [Example: The template-argument for Array<T>::operator[]() will be determined by the Array to which the subscripting operation is applied.

```cpp
Array<int> v1(20);
Array<dcomplex> v2(30);
```

```cpp
v1[3] = 7; // Array<int>::operator[]("
```

—end example

17.5.1.2 Member classes of class templates [temp.mem.class]

1 A member class of a class template may be defined outside the class template definition in which it is declared. [Note: The member class must be defined before its first use that requires an instantiation (17.7.1). For example,

```cpp
template<class T> struct A {
    class B;
};
A<int>::B* b1; // OK: requires A to be defined but not A::B
```

```cpp
template<class T> class A<T>::B { }
A<int>::B b2; // OK: requires A::B to be defined
```

—end note]
17.5.1.3 Static data members of class templates

A definition for a static data member or static data member template may be provided in a namespace scope enclosing the definition of the static member's class template. [Example:

```cpp
template<class T> class X {
    static T s;
};
template<class T> T X<T>::s = 0;
```

```cpp
struct limits {
    template<class T>
        static const T min;  // declaration
};
```

```cpp
template<class T>
    const T limits::min = { };  // definition
```

—end example

An explicit specialization of a static data member declared as an array of unknown bound can have a different bound from its definition, if any. [Example:

```cpp
template <class T> struct A {
    static int i[];
};
template <class T> int A<T>::i[] = { 1 };  // OK: 1 element
```

—end example

17.5.1.4 Enumeration members of class templates

An enumeration member of a class template may be defined outside the class template definition. [Example:

```cpp
template<class T> struct A {
    enum E : T;
};
A<int> a;
template<class T> enum A<T>::E : T { e1, e2 };  // 4 elements
A<int>::E e = A<int>::e1;
```

—end example

17.5.2 Member templates

A template can be declared within a class or class template; such a template is called a member template. A member template can be defined within or outside its class definition or class template definition. A member template of a class template that is defined outside of its class template definition shall be specified with the template-parameters of the class template followed by the template-parameters of the member template. [Example:

```cpp
template<class T> struct string {
    template<class T2> int compare(const T2&);
    template<class T2> string(const string<T2>& s) { /* ... */ }
};
```

```cpp
template<class T> template<class T2> int string<T>::compare(const T2& s) {
}
```

—end example

§ 17.5.2
A local class of non-closure type shall not have member templates. Access control rules (Clause 14) apply to member template names. A destructor shall not be a member template. A non-template member function (11.3.5) with a given name and type and a member function template of the same name, which could be used to generate a specialization of the same type, can both be declared in a class. When both exist, a use of that name and type refers to the non-template member unless an explicit template argument list is supplied. [Example:

```cpp
template <class T> struct A {
  void f(int);
  template <class T2> void f(T2);
};

template <> void A<int>::f(int) { }  // non-template member function
template <> template <> void A<int>::f<>(int) { }  // member function template specialization

int main() {
  A<char> ac;
  ac.f(1);  // non-template
  ac.f('c');  // template
  ac.f<>(1);  // template
}
—end example]

A member function template shall not be virtual. [Example:

```cpp
template <class T> struct AA {
  template <class C> virtual void g(C);  // error
  virtual void f();  // OK
};

—end example]

A specialization of a member function template does not override a virtual function from a base class. [Example:

```cpp
class B {
  virtual void f(int);
};

class D : public B {
  template <class T> void f(T);  // does not override B::f(int)
  void f(int i) { f<>(i); }  // overriding function that calls the template instantiation
};

—end example]

A specialization of a conversion function template is referenced in the same way as a non-template conversion function that converts to the same type. [Example:

```cpp
struct A {
  template <class T> operator T*() {
  }
};
template <class T> A::operator T*(){ return 0; }
template <> A::operator char*(){ return 0; }  // specialization
template A::operator void*();  // explicit instantiation

int main() {
  A a;
  int* ip;
```
ip = a.operator int*(); // explicit call to template operator A::operator int*()
}

— end example] [ Note: Because the explicit template argument list follows the function template name, and because conversion member function templates and constructor member function templates are called without using a function name, there is no way to provide an explicit template argument list for these function templates. — end note]

6 A specialization of a conversion function template is not found by name lookup. Instead, any conversion function templates visible in the context of the use are considered. For each such operator, if argument deduction succeeds (17.8.2.3), the resulting specialization is used as if found by name lookup.

7 A using-declaration in a derived class cannot refer to a specialization of a conversion function template in a base class.

8 Overload resolution (16.3.3.2) and partial ordering (17.5.6.2) are used to select the best conversion function among multiple specializations of conversion function templates and/or non-template conversion functions.

17.5.3 Variadic templates [temp.variadic]

1 A template parameter pack is a template parameter that accepts zero or more template arguments. [Example:

```cpp
template<class ... Types> struct Tuple {};
Tuple<> t0; // Types contains no arguments
Tuple<int> t1; // Types contains one argument: int
Tuple<int, float> t2; // Types contains two arguments: int and float
Tuple<0> error; // error: 0 is not a type
— end example]
```

2 A function parameter pack is a function parameter that accepts zero or more function arguments. [Example:

```cpp
template<class ... Types> void f(Types ... args);
f(); // OK: args contains no arguments
f(1); // OK: args contains one argument: int
f(2, 1.0); // OK: args contains two arguments: int and double
— end example]
```

3 A parameter pack is either a template parameter pack or a function parameter pack.

4 A pack expansion consists of a pattern and an ellipsis, the instantiation of which produces zero or more instantiations of the pattern in a list (described below). The form of the pattern depends on the context in which the expansion occurs. Pack expansions can occur in the following contexts:

- In a function parameter pack (11.3.5); the pattern is the parameter-declaration without the ellipsis.
- In a using-declaration (10.3.3); the pattern is a using-declarator.
- In a template parameter pack that is a pack expansion (17.1):
  - if the template parameter pack is a parameter-declaration; the pattern is the parameter-declaration without the ellipsis;
  - if the template parameter pack is a type-parameter with a template-parameter-list; the pattern is the corresponding type-parameter without the ellipsis.
- In an initializer-list (11.6); the pattern is an initializer-clause.
- In a base-specifier-list (Clause 13); the pattern is a base-specifier.
- In a mem-initializer-list (15.6.2) for a mem-initializer whose mem-initializer-id denotes a base class; the pattern is the mem-initializer.
— In a template-argument-list (17.3); the pattern is a template-argument.

— In an attribute-list (10.6.1); the pattern is an attribute.

— In an alignment-specifier (10.6.2); the pattern is the alignment-specifier without the ellipsis.

— In a capture-list (8.1.5); the pattern is a capture.

— In a sizeof... expression (8.3.3); the pattern is an identifier.

— In a fold-expression (8.1.6); the pattern is the cast-expression that contains an unexpanded parameter pack.

[ Example:

```cpp
template<class ... Types> void f(Types ... rest);
template<class ... Types> void g(Types ... rest) {
    f(&rest ...);  // "&rest ..." is a pack expansion; "&rest" is its pattern
}
```
— end example ]

5 For the purpose of determining whether a parameter pack satisfies a rule regarding entities other than parameter packs, the parameter pack is considered to be the entity that would result from an instantiation of the pattern in which it appears.

6 A parameter pack whose name appears within the pattern of a pack expansion is expanded by that pack expansion. An appearance of the name of a parameter pack is only expanded by the innermost enclosing pack expansion. The pattern of a pack expansion shall name one or more parameter packs that are not expanded by a nested pack expansion; such parameter packs are called unexpanded parameter packs in the pattern. All of the parameter packs expanded by a pack expansion shall have the same number of arguments specified. An appearance of a name of a parameter pack that is not expanded is ill-formed. [ Example:

```cpp
template<typename...> struct Tuple {};  
template<typename T1, typename T2> struct Pair {};  

template<class ... Args1> struct zip {
    template<class ... Args2> struct with {
        typedef Tuple<Pair<Args1, Args2> ... > type;
    };
};

typedef zip<short, int>::with<unsigned short, unsigned>::type T1;  // T1 is Tuple<Pair<short, unsigned short>, Pair<int, unsigned>>
typedef zip<short>::with<unsigned short, unsigned>::type T2;  // error: different number of arguments specified for Args1 and Args2

template<class ... Args>
void g(Args ... args) {
    // OK: Args is expanded by the function parameter pack args
    f(const_cast<const Args*>(&args)...);  // OK: “Args” and “args” are expanded
    f(5 ...);  // error: pattern does not contain any parameter packs
    f(args);  // error: parameter pack “args” is not expanded
    f(h(args ...) + args ...);  // OK: first “args” expanded within h,
    // second “args” expanded within f
}
```
— end example ]

7 The instantiation of a pack expansion that is neither a sizeof... expression nor a fold-expression produces a list \( E_1, E_2, \ldots, E_N \), where \( N \) is the number of elements in the pack expansion parameters. Each \( E_i \) is generated by instantiating the pattern and replacing each pack expansion parameter with its ith element. Such an
element, in the context of the instantiation, is interpreted as follows:

(7.1) — if the pack is a template parameter pack, the element is a template parameter (17.1) of the corresponding kind (type or non-type) designating the type or value from the template argument; otherwise,

(7.2) — if the pack is a function parameter pack, the element is an id-expression designating the function parameter that resulted from the instantiation of the pattern where the pack is declared.

All of the \(E_i\) become elements in the enclosing list. [Note: The variety of list varies with the context: expression-list, base-specifier-list, template-argument-list, etc. — end note] When \(N\) is zero, the instantiation of the expansion produces an empty list. Such an instantiation does not alter the syntactic interpretation of the enclosing construct, even in cases where omitting the list entirely would otherwise be ill-formed or would result in an ambiguity in the grammar. [Example:

```cpp
#include <iostream>

template<class... T> struct X : T... { }

template<class... T> void f(T... values)
{   
    X<T...> x(values...);
}

// OK: X<> has no base classes
// x is a variable of type X<> that is value-initialized
```

— end example]

8 The instantiation of a sizeof... expression (8.3.3) produces an integral constant containing the number of elements in the parameter pack it expands.

9 The instantiation of a fold-expression produces:

(9.1) — \((E_1 \textit{op} E_2 \textit{op} \cdots) \textit{op} E_N\) for a unary left fold,

(9.2) — \(E_1 \textit{op} (\cdots \textit{op} (E_{N-1} \textit{op} E_N))\) for a unary right fold,

(9.3) — \(((E \textit{op} E_1) \textit{op} E_2) \textit{op} \cdots \textit{op} E_N\) for a binary left fold, and

(9.4) — \(E_1 \textit{op} (\cdots \textit{op} (E_{N-1} \textit{op} (E_N \textit{op} E)))\) for a binary right fold.

In each case, \(\textit{op}\) is the fold-operator, \(N\) is the number of elements in the pack expansion parameters, and each \(E_i\) is generated by instantiating the pattern and replacing each pack expansion parameter with its \(i\)th element. For a binary fold-expression, \(E\) is generated by instantiating the cast-expression that did not contain an unexpanded parameter pack. [Example:

```cpp
#include <iostream>

template<typename ...Args> bool all(Args ...args) { return (... & args); }

bool b = all(true, true, true, false);  
```

Within the instantiation of \(\text{all}\), the returned expression expands to \(((\text{true } & \text{true}) & \text{true} & \text{true}) & \text{false})\), which evaluates to \text{false}. — end example] If \(N\) is zero for a unary fold-expression, the value of the expression is shown in Table 14; if the operator is not listed in Table 14, the instantiation is ill-formed.

§ 17.5.3 363
### 17.5.4 Friends

1 A friend of a class or class template can be a function template or class template, a specialization of a function template or class template, or a non-template function or class. For a friend function declaration that is not a template declaration:

1.1 if the name of the friend is a qualified or unqualified template-id, the friend declaration refers to a specialization of a function template, otherwise,

1.2 if the name of the friend is a qualified-id and a matching non-template function is found in the specified class or namespace, the friend declaration refers to that function, otherwise,

1.3 if the name of the friend is a qualified-id and a matching function template is found in the specified class or namespace, the friend declaration refers to the deduced specialization of that function template (17.8.2.6), otherwise,

1.4 the name shall be an unqualified-id that declares (or redeclares) a non-template function.

[Example:

```cpp
template<class T> class task;
template<class T> task<T>* preempt(task<T>*);

template<class T> class task {
    friend void next_time();
    friend void process(task<T>*);
    friend task<T>* preempt<T>(task<T>*);
    template<class C> friend int func(C);

    friend class task<int>;
    template<class P> friend class frd;
};
```

Here, each specialization of the `task` class template has the function `next_time` as a friend; because `process` does not have explicit template-arguments, each specialization of the `task` class template has an appropriately typed function `process` as a friend, and this friend is not a function template specialization; because the friend `preempt` has an explicit template-argument `T`, each specialization of the `task` class template has the appropriate specialization of the function template `preempt` as a friend; and each specialization of the `task` class template has all specializations of the function template `func` as friends. Similarly, each specialization of the `task` class template has the class template specialization `task<int>` as a friend, and has all specializations of the class template `frd` as friends.

—end example]

2 A friend template may be declared within a class or class template. A friend function template may be defined within a class or class template, but a friend class template may not be defined in a class or class template. In these cases, all specializations of the friend class or friend function template are friends of the class or class template granting friendship. [Example:

```cpp
class A {
    template<class T> friend class B; // OK
    template<class T> friend void f(T){ /* ... */ } // OK
};

—end example]

3 A template friend declaration specifies that all specializations of that template, whether they are implicitly instantiated (17.7.1), partially specialized (17.5.5) or explicitly specialized (17.7.3), are friends of the class containing the template friend declaration. [Example:

```cpp
class X {
    template<class T> friend struct A;
    class Y { }
};
```

§ 17.5.4
A member of a class template may be declared to be a friend of a non-template class. In this case, the corresponding member of every specialization of the primary class template and class template partial specializations thereof is a friend of the class granting friendship. For explicit specializations and specializations of partial specializations, the corresponding member is the member (if any) that has the same name, kind (type, function, class template, or function template), template parameters, and signature as the member of the class template instantiation that would otherwise have been generated. 

```
template<class T> struct A {
struct B { }
void f();
struct D {
    void g();
};
};
template<> struct A<int> {
struct B { }
int f();
struct D {
    void g();
};
};
class C {
    template<class T> friend struct A<T>::B;          // grants friendship to A<int>::B even though
    template<class T> friend void A<T>::f();          // it is not a specialization of A<T>::B
    template<class T> friend void A<T>::D::g();       // does not grant friendship to A<int>::D::g()
    // because its return type does not match
    template<class T> friend void A<T>::D::g();       // does not grant friendship to A<int>::D::g()
    // because A<int>::D is not a specialization of A<T>::D
};
```

--- end example

4 A member of a class template may be declared to be a friend of a non-template class. In this case, the corresponding member of every specialization of the primary class template and class template partial specializations thereof is a friend of the class granting friendship. For explicit specializations and specializations of partial specializations, the corresponding member is the member (if any) that has the same name, kind (type, function, class template, or function template), template parameters, and signature as the member of the class template instantiation that would otherwise have been generated. 

```
template<class T> struct A {
    struct B { }
    void f();
    struct D {
        void g();
    };
};
template<class T> struct A<T*> { X::Y ab; };                     // OK
```

--- end example

5 [ Note: A friend declaration may first declare a member of an enclosing namespace scope (17.6.5). ]

--- end note

6 A friend template shall not be declared in a local class.

7 Friend declarations shall not declare partial specializations. 

```
template<class T> class A { }
class X {
    template<class T> friend class A<T*>;       // error
};
```

--- end example

8 When a friend declaration refers to a specialization of a function template, the function parameter declarations shall not include default arguments, nor shall the inline specifier be used in such a declaration.
17.5.5 Class template partial specializations

A primary class template declaration is one in which the class template name is an identifier. A template declaration in which the class template name is a simple-template-id is a partial specialization of the class template named in the simple-template-id. A partial specialization of a class template provides an alternative definition of the template that is used instead of the primary definition when the arguments in a specialization match those given in the partial specialization (17.5.5.1). The primary template shall be declared before any specializations of that template. A partial specialization shall be declared before the first use of a class template specialization that would make use of the partial specialization as the result of an implicit or explicit instantiation in every translation unit in which such a use occurs; no diagnostic is required.

Each class template partial specialization is a distinct template and definitions shall be provided for the members of a template partial specialization (17.5.5.3).

The template parameters are specified in the angle bracket enclosed list that immediately follows the keyword template. For partial specializations, the template argument list is explicitly written immediately following the class template name. For primary templates, this list is implicitly described by the template parameter list. Specifically, the order of the template arguments is the sequence in which they appear in the template parameter list. [Example: The template argument list for the primary template in the example above is <T1, T2, I>. — end example] [Note: The template argument list shall not be specified in the primary template declaration. For example, template<class T1, class T2, int I> class A<T1, T2, I> { }; // error — end note]

A class template partial specialization may be declared in any scope in which the corresponding primary template may be defined (10.3.1.2, 12.2, 17.5.2). [Example:]

```
template<class T> struct A {
    struct C {
        template<class T2> struct B { }; // partial specialization #1
    };
};

// partial specialization of A<T>::C::B<T2>
template<class T> template<class T2>
    struct A<T>::C::B<T2> { }; // #2

A<short>::C::B<int*> absip; // uses partial specialization #2
— end example]
```

Partial specialization declarations themselves are not found by name lookup. Rather, when the primary template name is used, any previously-declared partial specializations of the primary template are also considered. One consequence is that a using-declaration which refers to a class template does not restrict the set of partial specializations which may be found through the using-declaration. [Example:
namespace N {
    template<class T1, class T2> class A { }; // primary template
}
using N::A; // refers to the primary template
namespace N {
    template<class T> class A<T, T*> { }; // partial specialization
}
A<int,int*> a; // uses the partial specialization, which is found through the using-declaration
    // which refers to the primary template

—end example—

A non-type argument is non-specialized if it is the name of a non-type parameter. All other non-type arguments are specialized.

Within the argument list of a class template partial specialization, the following restrictions apply:

(8.1) — The type of a template parameter corresponding to a specialized non-type argument shall not be dependent on a parameter of the specialization. [Example:
    template <class T, T t> struct C {}; 
    template <class T> struct C<T, 1>; // error
    template< int X, int (*array_ptr)[X] > class A {}; 
    int array[5];
    template< int X > class A<X,&array> { }; // error
—end example—

(8.2) — The specialization shall be more specialized than the primary template (17.5.5.2).

(8.3) — The template parameter list of a specialization shall not contain default template argument values.138

(8.4) — An argument shall not contain an unexpanded parameter pack. If an argument is a pack expansion (17.5.3), it shall be the last argument in the template argument list.

17.5.5.1 Matching of class template partial specializations [temp.class.spec.match]

When a class template is used in a context that requires an instantiation of the class, it is necessary to determine whether the instantiation is to be generated using the primary template or one of the partial specializations. This is done by matching the template arguments of the class template specialization with the template argument lists of the partial specializations.

(1.1) — If exactly one matching specialization is found, the instantiation is generated from that specialization.

(1.2) — If more than one matching specialization is found, the partial order rules (17.5.5.2) are used to determine whether one of the specializations is more specialized than the others. If none of the specializations is more specialized than all of the other matching specializations, then the use of the class template is ambiguous and the program is ill-formed.

(1.3) — If no matches are found, the instantiation is generated from the primary template.

A partial specialization matches a given actual template argument list if the template arguments of the partial specialization can be deduced from the actual template argument list (17.8.2). [Example:

template<class T1, class T2, int I> class A { }; // #1
template<class T, int I> class A<T, T*, I> { }; // #2
template<class T1, class T2, int I> class A<T1*, T2, I> { }; // #3

138) There is no way in which they could be used.
template<class T> class A<int, T*, 5> { }; // #4

// #5

template<class T1, class T2, int I> class A<T1, T2*, I> { }

A<int, int, 1> a1; // uses #1
A<int, int*, 1> a2; // uses #2, T is int, I is 1
A<int, char*, 5> a3; // uses #4, T is char
A<int, char*, 1> a4; // uses #5, T1 is int, T2 is char, I is 1
A<int*, int*, 2> a5; // ambiguous: matches #3 and #5

— end example]

3 If the template arguments of a partial specialization cannot be deduced because of the structure of its template-parameter-list and the template-id, the program is ill-formed. [Example:

    template <int I, int J> struct A {}
    template <int I> struct A<I+5, I*2> {}; // error
    template <int I> struct A<I, I> {}; // OK
    
    template <int I, int J, int K> struct B {}
    template <int I> struct B<I, I*2, 2> {}; // OK

— end example]

4 In a type name that refers to a class template specialization, (e.g., A<int, int, 1>) the argument list shall match the template parameter list of the primary template. The template arguments of a specialization are deduced from the arguments of the primary template.

17.5.5.2 Partial ordering of class template specializations [temp.class.order]

1 For two class template partial specializations, the first is more specialized than the second if, given the following rewrite to two function templates, the first function template is more specialized than the second according to the ordering rules for function templates (17.5.6.2):

(1.1) — Each of the two function templates has the same template parameters as the corresponding partial specialization.

(1.2) — Each function template has a single function parameter whose type is a class template specialization where the template arguments are the corresponding template parameters from the function template for each template argument in the template-argument-list of the simple-template-id of the partial specialization.

2 [Example:

    template<int I, int J, class T> class X {}
    template<int I, int J> class X<I, J, int> {}
    template<int I> class X<I, J, int> {}
    // #1
    template<int I0, int J0> void f(X<I0, J0, int>);
    template<int I0> void f(X<I0, I0, int>);
    // A
    // B
    
    template <auto v> class Y
    template <auto* p> class Y<p>
    template <auto** pp> class Y<pp> {}
    // #3
    // #4
    
    template <auto* p0> void g(Y<p0>);
    template <auto** pp0> void g(Y<pp0>); // #4

According to the ordering rules for function templates, the function template B is more specialized than the function template A and the function template D is more specialized than the function template C.

§ 17.5.5.2
Therefore, the partial specialization #2 is more specialized than the partial specialization #1 and the partial specialization #4 is more specialized than the partial specialization #3. — end example

17.5.5.3 Members of class template specializations [temp.class.spec.mfunc]

The template parameter list of a member of a class template partial specialization shall match the template parameter list of the class template partial specialization. The template argument list of a member of a class template partial specialization shall match the template argument list of the class template partial specialization. A class template specialization is a distinct template. The members of the class template partial specialization are unrelated to the members of the primary template. Class template partial specialization members that are used in a way that requires a definition shall be defined; the definitions of members of the primary template are never used as definitions for members of a class template partial specialization. An explicit specialization of a member of a class template partial specialization is declared in the same way as an explicit specialization of the primary template. [Example:

```cpp
// primary class template
template<class T, int I> struct A {
    void f();
};

// member of primary class template
template<class T, int I> void A<T,I>::f() {}

// class template partial specialization
template<class T> struct A<T,2> {
    void f();
    void g();
    void h();
};

// member of class template partial specialization
template<class T> void A<T,2>::g() {}

// explicit specialization
template<> void A<char,2>::h() {

int main() {
    A<char,0> a0;
    A<char,2> a2;
    a0.f(); // OK, uses definition of primary template's member
    a2.g(); // OK, uses definition of partial specialization's member
    a2.h(); // OK, uses definition of explicit specialization's member
    a2.f(); // ill-formed, no definition of f for A<T,2>; the primary template is not used here
}
```

— end example]

2 If a member template of a class template is partially specialized, the member template partial specializations are member templates of the enclosing class template; if the enclosing class template is instantiated (17.7.1, 17.7.2), a declaration for every member template partial specialization is also instantiated as part of creating the members of the class template specialization. If the primary member template is explicitly specialized for a given (implicit) specialization of the enclosing class template, the partial specializations of the member template are ignored for this specialization of the enclosing class template. If a partial specialization of the member template is explicitly specialized for a given (implicit) specialization of the enclosing class template, the primary member template and its other partial specializations are still considered for this specialization of the enclosing class template. [Example:
template<class T> struct A {
    template<class T2> struct B {}; // #1
    template<class T2> struct B<T2*> {}; // #2
};

template<> template<class T2> struct A<short>::B {}; // #3

A<char>::B<int*> abcip; // uses #2
A<short>::B<int*> absip; // uses #3
A<char>::B<int> abci; // uses #1

—end example—

17.5.6 Function templates [temp.fct]

1 A function template defines an unbounded set of related functions. [Example: A family of sort functions
might be declared like this:

```cpp
template<class T> class Array { };
template<class T> void sort(Array<T>&);
```

—end example—

2 A function template can be overloaded with other function templates and with non-template functions (11.3.5).
A non-template function is not related to a function template (i.e., it is never considered to be a specialization),
even if it has the same name and type as a potentially generated function template specialization.\[139\]

17.5.6.1 Function template overloading [temp.over.link]

1 It is possible to overload function templates so that two different function template specializations have the
same type. [Example:

```cpp
// translation unit 1:
// translation unit 2:
template<class T> void f(T*);
template<class T> void f(T);
void g(int* p) {
    f(p); // calls f<int>(int*)
}
void h(int* p) {
    f(p); // calls f<int*>(int*)
}
```

—end example—

2 Such specializations are distinct functions and do not violate the one-definition rule (6.2).

3 The signature of a function template is defined in Clause 3. The names of the template parameters are
significant only for establishing the relationship between the template parameters and the rest of the signature.
[Note: Two distinct function templates may have identical function return types and function parameter
lists, even if overload resolution alone cannot distinguish them.

```cpp
template<class T> void f();
template<int I> void f(); // OK: overloads the first template
distinguishable with an explicit template argument list
```

—end note—

4 When an expression that references a template parameter is used in the function parameter list or the return
type in the declaration of a function template, the expression that references the template parameter is part
of the signature of the function template. This is necessary to permit a declaration of a function template in
one translation unit to be linked with another declaration of the function template in another translation

\[139\] That is, declarations of non-template functions do not merely guide overload resolution of function template specializations
with the same name. If such a non-template function is odr-used (6.2) in a program, it must be defined; it will not be implicitly
instantiated using the function template definition.

§ 17.5.6.1 370
unit and, conversely, to ensure that function templates that are intended to be distinct are not linked with one another. [Example:

```c
template <int I, int J> A<I+J> f(A<I>, A<J>); // #1
template <int K, int L> A<K+L> f(A<K>, A<L>); // same as #1
template <int I, int J> A<I-J> f(A<I>, A<J>); // different from #1
```
—end example] [Note: Most expressions that use template parameters use non-type template parameters, but it is possible for an expression to reference a type parameter. For example, a template type parameter can be used in the `sizeof` operator. —end note]

Two expressions involving template parameters are considered *equivalent* if two function definitions containing the expressions would satisfy the one-definition rule (6.2), except that the tokens used to name the template parameters may differ as long as a token used to name a template parameter in one expression is replaced by another token that names the same template parameter in the other expression. For determining whether two dependent names (17.6.2) are equivalent, only the name itself is considered, not the result of name lookup in the context of the template. If multiple declarations of the same function template differ in the result of this name lookup, the result for the first declaration is used. [Example:

```c
template <int I, int J> void f(A<I+J>); // #1
template <int K, int L> void f(A<K+L>); // same as #1

template <class T> decltype(g(T())) h();
int g(int);

template <class T> decltype(g(T())) h() // redeclaration of h() uses the earlier lookup
  { return g(T()); } }
int i = h<int>(); // template argument substitution fails; g(int) // was not in scope at the first declaration of h()
```
—end example] Two expressions involving template parameters that are not equivalent are *functionally equivalent* if, for any given set of template arguments, the evaluation of the expression results in the same value.

Two function templates are *equivalent* if they are declared in the same scope, have the same name, have identical template parameter lists, and have return types and parameter lists that are equivalent using the rules described above to compare expressions involving template parameters. Two function templates are *functionally equivalent* if they are equivalent except that one or more expressions that involve template parameters in the return types and parameter lists are functionally equivalent using the rules described above to compare expressions involving template parameters. If a program contains declarations of function templates that are functionally equivalent but not equivalent, the program is ill-formed, no diagnostic required.

[Note: This rule guarantees that equivalent declarations will be linked with one another, while not requiring implementations to use heroic efforts to guarantee that functionally equivalent declarations will be treated as distinct. For example, the last two declarations are functionally equivalent and would cause a program to be ill-formed:

```c
// Guaranteed to be the same
template <int I> void f(A<I>, A<I+10>);
template <int I> void f(A<I>, A<I+10>);

// Guaranteed to be different
template <int I> void f(A<I>, A<I+10>);
template <int I> void f(A<I>, A<I+11>);

// Ill-formed, no diagnostic required
template <int I> void f(A<I>, A<I+10>);
template <int I> void f(A<I>, A<I+1+2+3+4>);
```
]§ 17.5.6.1
17.5.6.2 Partial ordering of function templates

If a function template is overloaded, the use of a function template specialization might be ambiguous because template argument deduction (17.8.2) may associate the function template specialization with more than one function template declaration. Partial ordering of overloaded function template declarations is used in the following contexts to select the function template to which a function template specialization refers:

1. During overload resolution for a call to a function template specialization (16.3.3);
2. When the address of a function template specialization is taken;
3. When a placement operator delete that is a function template specialization is selected to match a placement operator new (6.7.4.2, 8.3.4);
4. When a friend function declaration (17.5.4), an explicit instantiation (17.7.2) or an explicit specialization (17.7.3) refers to a function template specialization.

Partial ordering selects which of two function templates is more specialized than the other by transforming each template in turn and performing template argument deduction using the function type. The deduction process determines whether one of the templates is more specialized than the other. If so, the more specialized template is the one chosen by the partial ordering process.

To produce the transformed template, for each type, non-type, or template template parameter (including template parameter packs (17.5.3) thereof) synthesize a unique type, value, or class template respectively and substitute it for each occurrence of that parameter in the function type of the template. [Note: The type replacing the placeholder in the type of the value synthesized for a non-type template parameter is also a unique synthesized type. —end note] If only one of the function templates M is a non-static member of some class A, M is considered to have a new first parameter inserted in its function parameter list. Given cv as the cv-qualifiers of M (if any), the new parameter is of type “rvalue reference to cv A” if the optional ref-qualifier of M is && or if M has no ref-qualifier and the first parameter of the other template has rvalue reference type. Otherwise, the new parameter is of type “lvalue reference to cv A”. [Note: This allows a non-static member to be ordered with respect to a non-member function and for the results to be equivalent to the ordering of two equivalent non-members. —end note] [Example:

```
struct A { };
template<class T> struct B {
    template<class R> int operator*(R&);
};
template<class T, class R> int operator*(T&, R&);  // #2

// The declaration of B::operator* is transformed into the equivalent of
// template<class R> int operator*(B<A>&, R&);  // #1a

int main() {
    A a;
    B<A> b;
    b * a;  // calls #1a
}
```

Using the transformed function template’s function type, perform type deduction against the other template as described in 17.8.2.4.

[Example:

```
template<class T> struct A { A(); };```
template<class T> void f(T);
template<class T> void f(T*);
template<class T> void f(const T*);

template<class T> void g(T);
template<class T> void g(T&);

template<class T> void h(const T&);
template<class T> void h(A<T>&);

void m() {
    const int* p;
    f(p); // f(const T*) is more specialized than f(T) or f(T*)
    float x;
    g(x); // ambiguous: g(T) or g(T&)
    A<int> z;
    h(z); // overload resolution selects h(A<T>&)
    const A<int> z2;
    h(z2); // h(const T&) is called because h(A<T>&) is not callable
}

— end example

[Note: Since partial ordering in a call context considers only parameters for which there are explicit call arguments, some parameters are ignored (namely, function parameter packs, parameters with default arguments, and ellipsis parameters).]

Example:

```cpp
template<class T> void f(T);  // #1
template<class T> void f(T*, int=1);  // #2
template<class T> void g(T);  // #3
template<class T> void g(T*, ...);  // #4

int main() {
    int* ip;
    f(ip); // calls #2
    g(ip); // calls #4
}

— end example

Example:

template<class T, class U> struct A { };  

template<class T, class U> void f(U, A<T, U>* p = 0);  // #1
template<class U> void f(U, A<U, U>* p = 0);  // #2
template<class T> void g(T, T = T());  // #3
template<class T, class... U> void g(T, U...);  // #4

void h() {
    f<int>(42, (A<int, int>*0);  // calls #2
    f<int>(42);  // error: ambiguous
    g(42);  // error: ambiguous
}

— end example

Example:

template<class T, class... U> void f(T, U...);  // #1
 template<class T> void f(T);  // #2
 template<class T, class... U> void g(T*, U...);  // #3

§ 17.5.6.2
17.5.7 Alias templates

A template-declaration in which the declaration is an alias-declaration (Clause 10) declares the identifier to be an alias template. An alias template is a name for a family of types. The name of the alias template is a template-name.

When a template-id refers to the specialization of an alias template, it is equivalent to the associated type obtained by substitution of its template-arguments for the template-parameters in the type-id of the alias template. [Note: An alias template name is never deduced. —end note] [Example:

```cpp
template<class T> struct Alloc { /* ... */ };  // #4

template<class T> using Vec = vector<T, Alloc<T>>;
Vec<int> v;  // same as vector<int, Alloc<int>> v;

void process(Vec<T>& v) {
    // error: ambiguous
    g(&i);  // OK: calls #3
}
```

—end example] —end note]

The type-id in an alias template declaration shall not refer to the alias template being declared. The type produced by an alias template specialization shall not directly or indirectly make use of that specialization. [Example:

```cpp
template <class T> struct A;
template <class T> using B = typename A<T>::U;
```
Three kinds of names can be used within a template definition:

(1.1) — The name of the template itself, and names declared within the template itself.
(1.2) — Names dependent on a template-parameter (17.6.2).
(1.3) — Names from scopes which are visible within the template definition.

A name used in a template declaration or definition and that is dependent on a template-parameter is assumed not to name a type unless the applicable name lookup finds a type name or the name is qualified by the keyword typename. [Example:

```cpp
// no B declared here
class X;

template<class T> class Y {
    class Z; // forward declaration of member class

    void f() {
        X* a1; // declare pointer to X
        T* a2; // declare pointer to T
        Y* a3; // declare pointer to Y<T>
        Z* a4; // declare pointer to Z
        typedef typename T::A TA;
        TA* a5; // declare pointer to T's A
        typename T::A* a6; // declare pointer to T's A
        T::A* a7; // T::A is not a type name:
                   // multiplication of T::A by a7; ill-formed, no visible declaration of a7
        B* a8; // B is not a type name:
                 // multiplication of B by a8; ill-formed, no visible declarations of B and a8
    }
};
```

— end example]

When a qualified-id is intended to refer to a type that is not a member of the current instantiation (17.6.2.1) and its nested-name-specifier refers to a dependent type, it shall be prefixed by the keyword typename, forming a typename-specifier. If the qualified-id in a typename-specifier does not denote a type or a class template, the program is ill-formed.

```
typename-specifier:
    typename nested-name-specifier identifier
typename nested-name-specifier template_opt simple-template-id
```

If a specialization of a template is instantiated for a set of template-arguments such that the qualified-id prefixed by typename does not denote a type or a class template, the specialization is ill-formed. The usual qualified name lookup (6.4.3) is used to find the qualified-id even in the presence of typename. [Example:

```cpp
struct A {
    struct X { }; // error: instantiation of B<short> uses own type via A<short>::U
};
```

§ 17.6
template<class T> void f(T t) {
    typename T::X x;
}
void foo() {
    A a;
    B b;
    f(b);         // OK: T::X refers to B::X
    f(a);         // error: T::X refers to the data member A::X not the struct A::X
}

—end example

A qualified name used as the name in a class-or-decltype (Clause 13) or an elaborated-type-specifier is implicitly assumed to name a type, without the use of the typename keyword. In a nested-name-specifier that immediately contains a nested-name-specifier that depends on a template parameter, the identifier or simple-template-id is implicitly assumed to name a type, without the use of the typename keyword. [Note: The typename keyword is not permitted by the syntax of these constructs. —end note]

If, for a given set of template arguments, a specialization of a template is instantiated that refers to a qualified-id that denotes a type or a class template, and the qualified-id refers to a member of an unknown specialization, the qualified-id shall either be prefixed by typename or shall be used in a context in which it implicitly names a type as described above. [Example:

```cpp
template <class T> void f(int i) {
    T::x * i;        // T::x must not be a type
}
struct Foo {
    typedef int x;
};
struct Bar {
    static int const x = 5;
};
int main() {
    f<Bar>(1);    // OK
    f<Foo>(1);    // error: Foo::x is a type
}
—end example
```

Within the definition of a class template or within the definition of a member of a class template following the declarator-id, the keyword typename is not required when referring to the name of a previously declared member of the class template that declares a type or a class template. [Note: Such names can be found using unqualified name lookup (6.4.1), class member lookup (6.4.3.1) into the current instantiation (17.6.2.1), or class member access expression lookup (6.4.5) when the type of the object expression is the current instantiation (17.6.2.2). —end note] [Example:

```cpp
template<class T> struct A {
    typedef int B;
    B b;                // OK, no typename required
};
—end example
```

Knowing which names are type names allows the syntax of every template to be checked. The program is ill-formed, no diagnostic required, if:

§ 17.6
(8.1) — no valid specialization can be generated for a template or a substatement of a constexpr if statement (9.4.1) within a template and the template is not instantiated, or

(8.2) — every valid specialization of a variadic template requires an empty template parameter pack, or

(8.3) — a hypothetical instantiation of a template immediately following its definition would be ill-formed due to a construct that does not depend on a template parameter, or

(8.4) — the interpretation of such a construct in the hypothetical instantiation is different from the interpretation of the corresponding construct in any actual instantiation of the template. [Note: This can happen in situations including the following:

(8.4.1) — a type used in a non-dependent name is incomplete at the point at which a template is defined but is complete at the point at which an instantiation is performed, or

(8.4.2) — lookup for a name in the template definition found a using-declaration, but the lookup in the corresponding scope in the instantiation does not find any declarations because the using-declaration was a pack expansion and the corresponding pack is empty, or

(8.4.3) — an instantiation uses a default argument or default template argument that had not been defined at the point at which the template was defined, or

(8.4.4) — constant expression evaluation (8.20) within the template instantiation uses

(8.4.4.1) — the value of a const object of integral or unscoped enumeration type or

(8.4.4.2) — the value of a constexpr object or

(8.4.4.3) — the value of a reference or

(8.4.4.4) — the definition of a constexpr function,

and that entity was not defined when the template was defined, or

(8.4.5) — a class template specialization or variable template specialization that is specified by a non-dependent simple-template-id is used by the template, and either it is instantiated from a partial specialization that was not defined when the template was defined or it names an explicit specialization that was not declared when the template was defined.

— end note]

Otherwise, no diagnostic shall be issued for a template for which a valid specialization can be generated. [Note: If a template is instantiated, errors will be diagnosed according to the other rules in this International Standard. Exactly when these errors are diagnosed is a quality of implementation issue. — end note]

[Example:

```cpp
int j;
template<class T> class X {
    void f(T t, int i, char* p) {
        t = i; // diagnosed if X::f is instantiated, and the assignment to t is an error
        p = i; // may be diagnosed even if X::f is not instantiated
        p = j; // may be diagnosed even if X::f is not instantiated
    }
    void g(T t) {
        *; // may be diagnosed even if X::g is not instantiated
    }
};

template<class... T> struct A {
    void operator++(int, T... t); // error: too many parameters
};
template<class... T> union X : T... { }; // error: union with base class
```
When looking for the declaration of a name used in a template definition, the usual lookup rules (6.4.1, 6.4.2) are used for non-dependent names. The lookup of names dependent on the template parameters is postponed until the actual template argument is known (17.6.2). [Example:

```cpp
#include <iostream>
using namespace std;

template<class T> class Set {
    T* p;
    int cnt;
public:
    Set();
    Set<T>(const Set<T>&);
    void printall() {
        for (int i = 0; i<cnt; i++)
            cout << p[i] << ' \n';
    }
};
```

in the example, i is the local variable declared in `printall`, cnt is the member declared in `Set`, and cout is the standard output stream declared in `iostream`. However, not every declaration can be found this way; the resolution of some names must be postponed until the actual template-arguments are known. For example, even though the name operator<< is known within the definition of `printall()` and a declaration of it can be found in `<iostream>`, the actual declaration of `operator<<` needed to print `p[i]` cannot be known until it is known what type T is (17.6.2). —end example]

If a name does not depend on a template-parameter (as defined in 17.6.2), a declaration (or set of declarations) for that name shall be in scope at the point where the name appears in the template definition; the name is bound to the declaration (or declarations) found at that point and this binding is not affected by declarations that are visible at the point of instantiation. [Example:

```cpp
void f(char);

template<class T> void g(T t) {
    f(1); // f(char)
    f(T(1)); // dependent
    f(t); // dependent
    dd++; // not dependent; error: declaration for dd not found
}
```

```cpp
enum E { e };
void f(E);

double dd;
void h() {
    g(e); // will cause one call of f(char) followed by two calls of f(E)
    g('a'); // will cause three calls of f(char)
}
```

—end example]

[Note: For purposes of name lookup, default arguments and noexcept-specifiers of function templates and default arguments and noexcept-specifiers of member functions of class templates are considered definitions (17.5). —end note]
17.6.1 Locally declared names

Like normal (non-template) classes, class templates have an injected-class-name (Clause 12). The injected-class-name can be used as a template-name or a type-name. When it is used with a template-argument-list, as a template-argument for a template template-parameter, or as the final identifier in the elaborated-type-specifier of a friend class template declaration, it refers to the class template itself. Otherwise, it is equivalent to the template-name followed by the template-parameters of the class template enclosed in <>. 

Within the scope of a class template specialization or partial specialization, when the injected-class-name is used as a type-name, it is equivalent to the template-name followed by the template-arguments of the class template specialization or partial specialization enclosed in <>. [Example:

```
template<template<class> class T> class A { }
template<class T> class Y;
template<> class Y<int> {
    Y* p; // meaning Y<int>
    Y<char>* q; // meaning Y<char>
    A<T>* a; // meaning A<:Y
    class B {
        template<class> friend class Y; // meaning ::Y
    }
};
```
—end example]

The injected-class-name of a class template or class template specialization can be used either as a template-name or a type-name wherever it is in scope. [Example:

```
template <class T> struct Base {
    Base* p;
};

template <class T> struct Derived: public Base<T> {
    typename Derived::Base* p; // meaning Derived::<Base<T>
};

template<class T, template<class> class U = T::template Base> struct Third { }
Third<Base<int> > t; // OK: default argument uses injected-class-name as a template
```
—end example]

A lookup that finds an injected-class-name (13.2) can result in an ambiguity in certain cases (for example, if it is found in more than one base class). If all of the injected-class-names that are found refer to specializations of the same class template, and if the name is used as a template-name, the reference refers to the class template itself and not a specialization thereof, and is not ambiguous. [Example:

```
template <class T> struct Base { }
template <class T> struct Derived: Base<int>, Base<char> {
    typename Derived::Base b; // error: ambiguous
    typename Derived::Base<double> d; // OK
};
```
—end example]

When the normal name of the template (i.e., the name from the enclosing scope, not the injected-class-name) is used, it always refers to the class template itself and not a specialization of the template. [Example:

```
template<class T> class X {
    X* p; // meaning X<T>
    X<T>* p2;
    X<int>* p3;
```
A `template-parameter` shall not be redeclared within its scope (including nested scopes). A `template-parameter` shall not have the same name as the template name. [Example:

```cpp
template<class T, int i> class Y {
    int T; // error: template-parameter redeclared
    void f() {
        char T; // error: template-parameter redeclared
    }
};

template<class X> class X; // error: template-parameter redeclared
```
— end example ]

In the definition of a member of a class template that appears outside of the class template definition, the name of a member of the class template hides the name of a `template-parameter` of any enclosing class templates (but not a `template-parameter` of the member if the member is a class or function template). [Example:

```cpp
template<class T> struct A {
    struct B { /* ... */ }; // A's B, not the template parameter
    typedef void C;
    void f();
    template<class U> void g(U);
};

template<class B> void A<B>::f() {
    B b; // A's B, not the template parameter
}

template<class B> template<class C> void A<B>::g(C) {
    B b; // A's B, not the template parameter
    C c; // the template parameter C, not A's C
}
— end example ]

In the definition of a member of a class template that appears outside of the namespace containing the class template definition, the name of a `template-parameter` hides the name of a member of this namespace. [Example:

```cpp
namespace N {
    class C { }
    template<class T> class B {
        void f(T);
    }
};

template<class C> void N::B<C>::f(C) {
    C b; // C is the template parameter, not N::C
}
— end example ]

In the definition of a class template or in the definition of a member of such a template that appears outside

§ 17.6.1
of the template definition, for each non-dependent base class (17.6.2.1), if the name of the base class or the
name of a member of the base class is the same as the name of a template-parameter, the base class name or
member name hides the template-parameter name (6.3.10).  

Example:

```cpp
struct A {
    struct B { /* ... */ };  // A's B
    int a;
    int Y;
};

template<class B, class a> struct X : A {
    B b;  // A's B
    a b;  // error: A's a isn't a type name
};
```

—end example—

17.6.2 Dependent names

Inside a template, some constructs have semantics which may differ from one instantiation to another. Such
a construct depends on the template parameters. In particular, types and expressions may depend on the
type and/or value of template parameters (as determined by the template arguments) and this determines
the context for name lookup for certain names. An expressions may be type-dependent (that is, its type
may depend on a template parameter) or value-dependent (that is, its value when evaluated as a constant
expression (8.20) may depend on a template parameter) as described in this subclause. In an expression of
the form:

```
postfix-expression ( expression-list_opt )
```

where the postfix-expression is an unqualified-id, the unqualified-id denotes a dependent name if

1. any of the expressions in the expression-list is a pack expansion (17.5.3),
2. any of the expressions or braced-init-lists in the expression-list is type-dependent (17.6.2.2), or
3. the unqualified-id is a template-id in which any of the template arguments depends on a template
parameter.

If an operand of an operator is a type-dependent expression, the operator also denotes a dependent name.
Such names are unbound and are looked up at the point of the template instantiation (17.6.4.1) in both the
context of the template definition and the context of the point of instantiation.

Example:

```cpp
template<class T> struct X : B<T> {
    typename T::A* pa;
    void f(B<T>* pb) {
        static int i = B<T>::i;
        pb->j++;
    }
};
```

the base class name B<T>, the type name T::A, the names B<T>::i and pb->j explicitly depend on the
template-parameter. —end example—

In the definition of a class or class template, the scope of a dependent base class (17.6.2.1) is not examined
during unqualified name lookup either at the point of definition of the class template or member or during
an instantiation of the class template or member.  [Example:

```cpp
typedef double A;
template<class T> class B {
    typedef int A;
};
```

§ 17.6.2

---

© ISO/IEC

ISO/IEC N4659

---

© ISO/IEC

ISO/IEC N4659

---
template<class T> struct X : B<T> {
    A a; // a has type double
};

The type name A in the definition of X<T> binds to the typedef name defined in the global namespace scope, not to the typedef name defined in the base class B<T>. — end example [Example:

```cpp
struct A {
    struct B { /* ... */ }; // The B defined in X
    int a;
    int Y;
};

int a;

template<class T> struct Y : T {
    struct B { /* ... */ }; // The B defined in Y
    B b; // The B defined in Y
    void f(int i) { a = i; } // ::a
    Y* p; // Y<T>
};

Y<A> ya;
```

The members A::B, A::a, and A::Y of the template argument A do not affect the binding of names in Y<A>. — end example]

17.6.2.1 Dependent types [temp.dep.type]

1 A name refers to the current instantiation if it is

(1.1) — in the definition of a class template, a nested class of a class template, a member of a class template, or a member of a nested class of a class template, the injected-class-name (Clause 12) of the class template or nested class,

(1.2) — in the definition of a primary class template or a member of a primary class template, the name of the class template followed by the template argument list of the primary template (as described below) enclosed in <> (or an equivalent template alias specialization),

(1.3) — in the definition of a nested class of a class template, the name of the nested class referenced as a member of the current instantiation, or

(1.4) — in the definition of a partial specialization or a member of a partial specialization, the name of the class template followed by the template argument list of the partial specialization enclosed in <> (or an equivalent template alias specialization). If the n-th template parameter is a parameter pack, the n-th template argument is a pack expansion (17.5.3) whose pattern is the name of the parameter pack.

2 The template argument list of a primary template is a template argument list in which the n-th template argument has the value of the n-th template parameter of the class template. If the n-th template parameter is a template parameter pack (17.5.3), the n-th template argument is a pack expansion (17.5.3) whose pattern is the name of the template parameter pack.

3 A template argument that is equivalent to a template parameter (i.e., has the same constant value or the same type as the template parameter) can be used in place of that template parameter in a reference to the current instantiation. In the case of a non-type template argument, the argument must have been given the value of the template parameter and not an expression in which the template parameter appears as a subexpression. [Example:

```cpp
template <class T> class A {
```
A* p1;  // A is the current instantiation
A<T>* p2;  // A<T> is the current instantiation
A<T*> p3;  // A<T*> is not the current instantiation
::A<T>* p4;  // ::A<T> is the current instantiation

class B {
    B* p1;  // B is the current instantiation
    A<T>* p2;  // A<T> is the current instantiation
    typename A<T>::B* p3;  // A<T>::B is not the current instantiation
};

template <class T> class A<T*> {
    A<T*>* p1;  // A<T*> is the current instantiation
    A<T>* p2;  // A<T> is not the current instantiation
};

template <class T1, class T2, int I> struct B {
    B<T1, T2, I>* b1;  // refers to the current instantiation
    B<T2, T1, I>* b2;  // not the current instantiation
typedef T1 my_T1;
    static const int my_I = I;
    static const int my_I2 = I+0;
    static const int my_I3 = my_I;
    B<my_T1, T2, my_I>* b3;  // refers to the current instantiation
    B<my_T1, T2, my_I2>* b4;  // not the current instantiation
    B<my_T1, T2, my_I3>* b5;  // refers to the current instantiation
};

A dependent base class is a base class that is a dependent type and is not the current instantiation. [Note: A base class can be the current instantiation in the case of a nested class naming an enclosing class as a base.

Example:

    template<class T> struct A {
        typedef int M;
        struct B {
            typedef void M;
            struct C;
        };
    };

    template<class T> struct A<T>::B::C : A<T> {
        M m;  // OK, A<T>::M
    };

— end example]  — end note]

A name is a member of the current instantiation if it is

(5.1) — An unqualified name that, when looked up, refers to at least one member of a class that is the current instantiation or a non-dependent base class thereof. [Note: This can only occur when looking up a name in a scope enclosed by the definition of a class template. — end note]

(5.2) — A qualified-id in which the nested-name-specifier refers to the current instantiation and that, when looked up, refers to at least one member of a class that is the current instantiation or a non-dependent base class thereof. [Note: If no such member is found, and the current instantiation has any dependent base classes, then the qualified-id is a member of an unknown specialization; see below. — end note]
An id-expression denoting the member in a class member access expression (8.2.5) for which the type of the object expression is the current instantiation, and the id-expression, when looked up (6.4.5), refers to at least one member of a class that is the current instantiation or a non-dependent base class thereof. [Note: If no such member is found, and the current instantiation has any dependent base classes, then the id-expression is a member of an unknown specialization; see below. — end note]

Example:

```cpp
template <class T> class A {
  static const int i = 5;
  int n1[i];    // i refers to a member of the current instantiation
  int n2[A::*i]; // A::*i refers to a member of the current instantiation
  int n3[A<T>::*i]; // A<T>::*i refers to a member of the current instantiation
  int f();
};

template <class T> int A<T>::f() {
  return i;    // i refers to a member of the current instantiation
}

— end example
```

A name is a member of the current instantiation if it is a member of the current instantiation that, when looked up, refers to at least one member of a class that is the current instantiation.

6 A name is a member of an unknown specialization if it is

(6.1) A qualified-id in which the nested-name-specifier names a dependent type that is not the current instantiation.

(6.2) A qualified-id in which the nested-name-specifier refers to the current instantiation, the current instantiation has at least one dependent base class, and name lookup of the qualified-id does not find any member of a class that is the current instantiation or a non-dependent base class thereof.

(6.3) An id-expression denoting the member in a class member access expression (8.2.5) in which either

(6.3.1) the type of the object expression is the current instantiation, the current instantiation has at least one dependent base class, and name lookup of the id-expression does not find a member of a class that is the current instantiation or a non-dependent base class thereof; or

(6.3.2) the type of the object expression is dependent and is not the current instantiation.

7 If a qualified-id in which the nested-name-specifier refers to the current instantiation is not a member of the current instantiation or a member of an unknown specialization, the program is ill-formed even if the template containing the qualified-id is not instantiated; no diagnostic required. Similarly, if the id-expression in a class member access expression for which the type of the object expression is the current instantiation does not refer to a member of the current instantiation or a member of an unknown specialization, the program is ill-formed even if the template containing the member access expression is not instantiated; no diagnostic required. [Example:

```cpp
template<class T> class A {
  typedef int type;
  void f() {
    A<T>::type i;    // OK: refers to a member of the current instantiation
    typename A<T>::other j; // error: neither a member of the current instantiation nor a member of an unknown specialization
  }
};

— end example
```
If, for a given set of template arguments, a specialization of a template is instantiated that refers to a member of the current instantiation with a qualified-id or class member access expression, the name in the qualified-id or class member access expression is looked up in the template instantiation context. If the result of this lookup differs from the result of name lookup in the template definition context, name lookup is ambiguous.

Example:

```cpp
struct A {
    int m;
};

struct B {
    int m;
};

template<typename T>
struct C : A, T {
    int f() { return this->m; }  // finds A::m in the template definition context
    int g() { return m; }       // finds A::m in the template definition context
};

template int C<B>::f();        // error: finds both A::m and B::m
template int C<B>::g();        // OK: transformation to class member access syntax
```

end example

A type is dependent if it is

1. a template parameter,
2. a member of an unknown specialization,
3. a nested class or enumeration that is a dependent member of the current instantiation,
4. a cv-qualified type where the cv-unqualified type is dependent,
5. a compound type constructed from any dependent type,
6. an array type whose element type is dependent or whose bound (if any) is value-dependent,
7. a function type whose exception specification is value-dependent,
8. a simple-template-id in which either the template name is a template parameter or any of the template arguments is a dependent type or an expression that is type-dependent or value-dependent or is a pack expansion [Note: This includes an injected-class-name (Clause 12) of a class template used without a template-argument-list. —end note], or
denoted by decltype(expression), where expression is type-dependent (17.6.2.2).

[Note: Because typedefs do not introduce new types, but instead simply refer to other types, a name that refers to a typedef that is a member of the current instantiation is dependent only if the type referred to is dependent. —end note]

17.6.2.2 Type-dependent expressions

Except as described below, an expression is type-dependent if any subexpression is type-dependent.

1. this is type-dependent if the class type of the enclosing member function is dependent (17.6.2.1).
2. An id-expression is type-dependent if it contains

1. an identifier associated by name lookup with one or more declarations declared with a dependent type,
2. an identifier associated by name lookup with a non-type template-parameter declared with a type that
contains a placeholder type (10.1.7.4),

(3.3) — an identifier associated by name lookup with one or more declarations of member functions of the
current instantiation declared with a return type that contains a placeholder type,

(3.4) — an identifier associated by name lookup with a structured binding declaration (11.5) whose brace-or-
equal-initializer is type-dependent,

(3.5) — the identifier __func__ (11.4.1), where any enclosing function is a template, a member of a class
template, or a generic lambda,

(3.6) — a template-id that is dependent,

(3.7) — a conversion-function-id that specifies a dependent type, or

(3.8) — a nested-name-specifier or a qualified-id that names a member of an unknown specialization;

or if it names a dependent member of the current instantiation that is a static data member of type “array of
unknown bound of T” for some T (17.5.1.3). Expressions of the following forms are type-dependent only if
the type specified by the type-id, simple-type-specifier or new-type-id is dependent, even if any subexpression
is type-dependent:

simple-type-specifier ( expression-list_opt )
::opt new new-placement_opt new-type-id new-initializer_opt
::opt new new-placement_opt ( type-id ) new-initializer_opt
dynamic_cast < type-id > ( expression )
static_cast < type-id > ( expression )
const_cast < type-id > ( expression )
reinterpret_cast < type-id > ( type-id ) cast-expression

Expressions of the following forms are never type-dependent (because the type of the expression cannot be
dependent):

literal
postfix-expression . pseudo-destructor-name
postfix-expression -> pseudo-destructor-name
sizeof unary-expression
sizeof ( type-id )
sizeof ... ( identifier )
alignof ( type-id )
typeid ( expression )
typeid ( type-id )
::opt delete cast-expression
::opt delete [ ] cast-expression
throw assignment-expression_opt
noexcept ( expression )

[Note: For the standard library macro offsetof, see 21.2. — end note]

5 A class member access expression (8.2.5) is type-dependent if the expression refers to a member of the current
instantiation and the type of the referenced member is dependent, or the class member access expression
refers to a member of an unknown specialization. [Note: In an expression of the form x.y or xp->y the
type of the expression is usually the type of the member y of the class of x (or the class pointed to by xp).
However, if x or xp refers to a dependent type that is not the current instantiation, the type of y is always
dependent. If x or xp refers to a non-dependent type or refers to the current instantiation, the type of y is
the type of the class member access expression. — end note]

6 A braced-init-list is type-dependent if any element is type-dependent or is a pack expansion.

7 A fold-expression is type-dependent.
17.6.2.3 Value-dependent expressions

Except as described below, an expression used in a context where a constant expression is required is value-dependent if any subexpression is value-dependent.

An id-expression is value-dependent if:

1. it is type-dependent,
2. it is the name of a non-type template parameter,
3. it names a static data member that is a dependent member of the current instantiation and is not initialized in a member-declarator,
4. it names a static member function that is a dependent member of the current instantiation, or
5. it is a constant with literal type and is initialized with an expression that is value-dependent.

Expressions of the following form are value-dependent if the unary-expression or expression is type-dependent or the type-id is dependent:

- sizeof unary-expression
- sizeof (type-id)
- typeid (expression)
- typeid (type-id)
- alignof (type-id)
- noexcept (expression)

[Note: For the standard library macro offsetof, see §21.2. — end note]

Expressions of the following form are value-dependent if either the type-id or simple-type-specifier is dependent or the expression or cast-expression is value-dependent:

- simple-type-specifier (expression-list<opt>)
- static_cast <type-id> (expression)
- const_cast <type-id> (expression)
- reinterpret_cast <type-id> (expression)
- (type-id) cast-expression

Expressions of the following form are value-dependent:

- sizeof ... (identifier)
- fold-expression

An expression of the form &qualified-id where the qualified-id names a dependent member of the current instantiation is value-dependent. An expression of the form &cast-expression is also value-dependent if evaluating cast-expression as a core constant expression (§8.20) succeeds and the result of the evaluation refers to a templated entity that is an object with static or thread storage duration or a member function.

17.6.2.4 Dependent template arguments

1. A type template-argument is dependent if the type it specifies is dependent.
2. A non-type template-argument is dependent if its type is dependent or the constant expression it specifies is value-dependent.
3. Furthermore, a non-type template-argument is dependent if the corresponding non-type template-parameter is of reference or pointer type and the template-argument designates or points to a member of the current instantiation or a member of a dependent type.
4. A template template-argument is dependent if it names a template-parameter or is a qualified-id that refers to a member of an unknown specialization.
17.6.3 Non-dependent names

Non-dependent names used in a template definition are found using the usual name lookup and bound at the point they are used. [Example:

```cpp
void g(double);
void h();

template<class T> class Z {
public:
  void f() {
    g(1);  // calls g(double)
    h++;  // ill-formed: cannot increment function; this could be diagnosed
           // either here or at the point of instantiation
  }
};

void g(int);  // not in scope at the point of the template definition, not considered for the call g(1)
— end example]

17.6.4 Dependent name resolution

In resolving dependent names, names from the following sources are considered:

1. Declarations that are visible at the point of definition of the template.
2. Declarations from namespaces associated with the types of the function arguments both from the instantiation context (17.6.4.1) and from the definition context.

17.6.4.1 Point of instantiation

For a function template specialization, a member function template specialization, or a specialization for a member function or static data member of a class template, if the specialization is implicitly instantiated because it is referenced from within another template specialization and the context from which it is referenced depends on a template parameter, the point of instantiation of the specialization is the point of instantiation of the enclosing specialization. Otherwise, the point of instantiation for such a specialization immediately follows the namespace scope declaration or definition that refers to the specialization.

2. If a function template or member function of a class template is called in a way which uses the definition of a default argument of that function template or member function, the point of instantiation of the default argument is the point of instantiation of the function template or member function specialization.

3. For a `noexcept-specifier` of a function template specialization or specialization of a member function of a class template, if the `noexcept-specifier` is implicitly instantiated because it is needed by another template specialization and the context that requires it depends on a template parameter, the point of instantiation of the `noexcept-specifier` is the point of instantiation of the specialization that requires it. Otherwise, the point of instantiation for such a `noexcept-specifier` immediately follows the namespace scope declaration or definition that requires the `noexcept-specifier`.

4. For a class template specialization, a class member template specialization, or a specialization for a class member of a class template, if the specialization is implicitly instantiated because it is referenced from within another template specialization, if the context from which the specialization is referenced depends on a template parameter, and if the specialization is not instantiated previous to the instantiation of the enclosing template, the point of instantiation is immediately before the point of instantiation of the enclosing template. Otherwise, the point of instantiation for such a specialization immediately precedes the namespace scope declaration or definition that refers to the specialization.

5. If a virtual function is implicitly instantiated, its point of instantiation is immediately following the point of
instantiation of its enclosing class template specialization.

6 An explicit instantiation definition is an instantiation point for the specialization or specializations specified by the explicit instantiation.

7 The instantiation context of an expression that depends on the template arguments is the set of declarations with external linkage declared prior to the point of instantiation of the template specialization in the same translation unit.

8 A specialization for a function template, a member function template, or of a member function or static data member of a class template may have multiple points of instantiations within a translation unit, and in addition to the points of instantiation described above, for any such specialization that has a point of instantiation within the translation unit, the end of the translation unit is also considered a point of instantiation. A specialization for a class template has at most one point of instantiation within a translation unit. A specialization for any template may have points of instantiation in multiple translation units. If two different points of instantiation give a template specialization different meanings according to the one-definition rule (6.2), the program is ill-formed, no diagnostic required.

17.6.4.2 Candidate functions

For a function call where the postfix-expression is a dependent name, the candidate functions are found using the usual lookup rules (6.4.1, 6.4.2) except that:

(1.1) For the part of the lookup using unqualified name lookup (6.4.1), only function declarations from the template definition context are found.

(1.2) For the part of the lookup using associated namespaces (6.4.2), only function declarations found in either the template definition context or the template instantiation context are found.

If the call would be ill-formed or would find a better match had the lookup within the associated namespaces considered all the function declarations with external linkage introduced in those namespaces in all translation units, not just considering those declarations found in the template definition and template instantiation contexts, then the program has undefined behavior.

17.6.5 Friend names declared within a class template

Friend classes or functions can be declared within a class template. When a template is instantiated, the names of its friends are treated as if the specialization had been explicitly declared at its point of instantiation.

As with non-template classes, the names of namespace-scope friend functions of a class template specialization are not visible during an ordinary lookup unless explicitly declared at namespace scope (14.3). Such names may be found under the rules for associated classes (6.4.2).140 [Example:

```cpp
template<typename T> struct number {
    number(int);
    friend number gcd(number x, number y) { return 0; };
};

void g() {
    number<double> a(3), b(4);
    a = gcd(a,b); // finds gcd because number<double> is an associated class,
                 // making gcd visible in its namespace (global scope)
    b = gcd(3,4); // ill-formed; gcd is not visible
}
```

--- end example ---

140) Friend declarations do not introduce new names into any scope, either when the template is declared or when it is instantiated.

§ 17.6.5
Template instantiation and specialization

The act of instantiating a function, a class, a member of a class template or a member template is referred to as template instantiation.

A function instantiated from a function template is called an instantiated function. A class instantiated from a class template is called an instantiated class. A member function, a member class, a member enumeration, or a static data member of a class template instantiated from the member definition of the class template is called, respectively, an instantiated member function, member class, member enumeration, or static data member. A member function instantiated from a member function template is called an instantiated member function. A member class instantiated from a member class template is called an instantiated member class.

An explicit specialization may be declared for a function template, a class template, a member of a class template or a member template. An explicit specialization declaration is introduced by \texttt{template<}. In an explicit specialization declaration for a class template, a member of a class template or a class member template, the name of the class that is explicitly specialized shall be a \texttt{simple-template-id}. In the explicit specialization declaration for a function template or a member function template, the name of the function or member function explicitly specialized may be a \texttt{template-id}. \[ \text{Example:} \]

```cpp
template<class T = int> struct A {
    static int x;
};
template<class U> void g(U) { }

template<> struct A<double> { }; // specialize for T == double
template<> struct A<>() { }; // specialize for T == int
template<> void g(char) { } // specialize for U == char

// U is deduced from the parameter type
template<> void g<>()(int) { } // specialize for U == int

template<> int A<>::x = 0; // specialize for T == char

template<class T = int> struct B {
    static int x;
};
template<> int B<>::x = 1; // specialize for T == int
```

— end example |

An instantiated template specialization can be either implicitly instantiated (17.7.1) for a given argument list or be explicitly instantiated (17.7.2). A specialization is a class, function, or class member that is either instantiated or explicitly specialized (17.7.3).

For a given template and a given set of template-arguments,

- an explicit instantiation definition shall appear at most once in a program,
- an explicit specialization shall be defined at most once in a program (according to 6.2), and
- both an explicit instantiation and a declaration of an explicit specialization shall not appear in a program unless the explicit instantiation follows a declaration of the explicit specialization.

An implementation is not required to diagnose a violation of this rule.

Each class template specialization instantiated from a template has its own copy of any static members. \[ \text{Example:} \]

```cpp
template<class T> class X {
    static T s;
};
template<class T> class X<T>::x = 0;
X<int> aa;
```

§ 17.7
X<char*> bb;

X<int> has a static member s of type int and X<char*> has a static member s of type char*. — end example

7 If a function declaration acquired its function type through a dependent type (17.6.2.1) without using the syntactic form of a function declarator, the program is ill-formed. [Example:

```c
template<class T> struct A {
    static T t;
};
typedef int function();
A<function> a;  // ill-formed: would declare A<function>::t as a static member function
```
— end example]

17.7.1 Implicit instantiation [temp.inst]

1 Unless a class template specialization has been explicitly instantiated (17.7.2) or explicitly specialized (17.7.3), the class template specialization is implicitly instantiated when the specialization is referenced in a context that requires a completely-defined object type or when the completeness of the class type affects the semantics of the program. [Note: In particular, if the semantics of an expression depend on the member or base class lists of a class template specialization, the class template specialization is implicitly generated. For instance, deleting a pointer to class type depends on whether or not the class declares a destructor, and a conversion between pointers to class type depends on the inheritance relationship between the two classes involved. — end note] [Example:

```c
template<class T> class B { /* ... */ }
template<class T> class D : public B<T> { /* ... */ }
void f(void*);
void f(B<int>*);
void g(D<int>* p, D<char>* pp, D<double>* ppp) {
    f(p);  // instantiation of D<int> required: call f(B<int>*)
    B<char>* q = pp;  // instantiation of D<char> required: convert D<char>* to B<char>*
    delete ppp;  // instantiation of D<double> required
}
```
— end example] If a class template has been declared, but not defined, at the point of instantiation (17.6.4.1), the instantiation yields an incomplete class type (6.9). [Example:

```c
template<class T> class X;
X<char> ch;  // error: incomplete type X<char>
```
— end example] [Note: Within a template declaration, a local class (12.4) or enumeration and the members of a local class are never considered to be entities that can be separately instantiated (this includes their default arguments, noexcept-specifiers, and non-static data member initializers, if any). As a result, the dependent names are looked up, the semantic constraints are checked, and any templates used are instantiated as part of the instantiation of the entity within which the local class or enumeration is declared. — end note]

2 The implicit instantiation of a class template specialization causes the implicit instantiation of the declarations, but not of the definitions, default arguments, or noexcept-specifiers of the class member functions, member classes, scoped member enumerations, static data members, member templates, and friends; and it causes the implicit instantiation of the definitions of unscoped member enumerations and member anonymous unions. However, for the purpose of determining whether an instantiated redeclaration is valid according to 6.2 and 12.2, a declaration that corresponds to a definition in the template is considered to be a definition. [Example:

§ 17.7.1
template<class T, class U>
struct Outer {
    template<class X, class Y> struct Inner;   // #1a
    template<class Y> struct Inner<T, Y>;       // #1b; OK: valid redeclaration of #1a
    template<class Y> struct Inner<U, Y> { };   // #2
};

Outer<int, int> outer;               // error at #2
Outer<int, int>::Inner<int, Y> is redeclared at #1b. (It is not defined but noted as being associated with a definition in Outer<T, U>.) #2 is also a redeclaration of #1a. It is noted as associated with a definition, so it is an invalid redeclaration of the same partial specialization.

template<typename T> struct Friendly {
    template<typename U> friend int f(U) { return sizeof(T); }
};

Friendly<char> fc;
Friendly<float> ff;               // ill-formed: produces second definition of f(U)
— end example]

3 Unless a member of a class template or a member template has been explicitly instantiated or explicitly specialized, the specialization of the member is implicitly instantiated when the specialization is referenced in a context that requires the member definition to exist; in particular, the initialization (and any associated side effects) of a static data member does not occur unless the static data member is itself used in a way that requires the definition of the static data member to exist.

4 Unless a function template specialization has been explicitly instantiated or explicitly specialized, the function template specialization is implicitly instantiated when the specialization is referenced in a context that requires a function definition to exist. A function whose declaration was instantiated from a friend function definition is implicitly instantiated when it is referenced in a context that requires a function definition to exist. Unless a call is to a function template explicit specialization or to a member function of an explicitly specialized class template, a default argument for a function template or a member function of a class template is implicitly instantiated when the function is called in a context that requires the value of the default argument.

5 [ Example:
    template<class T> struct Z {
        void f();
        void g();
    };

    void h() {
        Z<int> a;       // instantiation of class Z<int> required
        Z<char>* p;     // instantiation of class Z<char> not required
        Z<double> q;    // instantiation of class Z<double> not required

        a.f();          // instantiation of Z<int>::f() required
        p->g();         // instantiation of class Z<char>:g() required, and
                        // instantiation of Z<char>::g() required
    }

    Nothing in this example requires class Z<double>, Z<int>::g(), or Z<char>::f() to be implicitly instantiated. — end example ]

6 Unless a variable template specialization has been explicitly instantiated or explicitly specialized, the variable template specialization is implicitly instantiated when the specialization is used. A default template argument...
for a variable template is implicitly instantiated when the variable template is referenced in a context that requires the value of the default argument.

7 If the function selected by overload resolution (16.3) can be determined without instantiating a class template definition, it is unspecified whether that instantiation actually takes place. [Example:

```cpp
    template <class T> struct S {
        operator int();
    };
    void f();
    void f(S<int>&);
    void f(S<float>);
    void g(S<int>& sr) {
        f(sr);
        // instantiation of S<int> allowed but not required
        // instantiation of S<float> allowed but not required
    }
    — end example]
```

8 If a function template or a member function template specialization is used in a way that involves overload resolution, a declaration of the specialization is implicitly instantiated (17.8.3).

9 An implementation shall not implicitly instantiate a function template, a variable template, a member template, a non-virtual member function, a member class, a static data member of a class template, or a substatement of a constexpr if statement (9.4.1), unless such instantiation is required. It is unspecified whether or not an implementation implicitly instantiates a virtual member function of a class template if the virtual member function would not otherwise be instantiated. The use of a template specialization in a default argument shall not cause the template to be implicitly instantiated except that a class template may be instantiated where its complete type is needed to determine the correctness of the default argument. The use of a default argument in a function call causes specializations in the default argument to be implicitly instantiated.

10 Implicitly instantiated class, function, and variable template specializations are placed in the namespace where the template is defined. Implicitly instantiated specializations for members of a class template are placed in the namespace where the enclosing class template is defined. Implicitly instantiated member templates are placed in the namespace where the enclosing class or class template is defined. [Example:

```cpp
    namespace N {
        template<class T> class List {
            public:
                T* get();
            private:
        };
    }
    template<class K, class V> class Map {
    public:
        N::List<V> lt;
        V get(K);
    private:
    };
    void g(Map<const char*,int>& m) {
        int i = m.get("Nicholas");
    }
    a call of lt.get() from Map<const char*,int>::get() would place List<int>::get() in the namespace N rather than in the global namespace. — end example]
```
If a function template $f$ is called in a way that requires a default argument to be used, the dependent names are looked up, the semantics constraints are checked, and the instantiation of any template used in the default argument is done as if the default argument had been an initializer used in a function template specialization with the same scope, the same template parameters and the same access as that of the function template $f$ used at that point, except that the scope in which a closure type is declared (8.1.5.1) – and therefore its associated namespaces – remain as determined from the context of the definition for the default argument. This analysis is called default argument instantiation. The instantiated default argument is then used as the argument of $f$.

Each default argument is instantiated independently. [Example:

```cpp
template<class T> void f(T x, T y = ydef(T()), T z = zdef(T()));

class A { }
A zdef(A);

void g(A a, A b, A c) {
    f(a, b, c); // no default argument instantiation
    f(a, b); // default argument z = zdef(T()) instantiated
    f(a); // ill-formed; ydef is not declared
}
```

end example]

The `noexcept-specifier` of a function template specialization is not instantiated along with the function declaration; it is instantiated when needed (18.4). If such an `noexcept-specifier` is needed but has not yet been instantiated, the dependent names are looked up, the semantics constraints are checked, and the instantiation of any template used in the `noexcept-specifier` is done as if it were being done as part of instantiating the declaration of the specialization at that point.

[Note: 17.6.4.1 defines the point of instantiation of a template specialization. — end note]

There is an implementation-defined quantity that specifies the limit on the total depth of recursive instantiations (B), which could involve more than one template. The result of an infinite recursion in instantiation is undefined. [Example:

```cpp
template<class T> class X {

    X<T>* p; // OK
    X<T**> a; // implicit generation of X<T> requires
               // the implicit instantiation of X<T*> which requires
               // the implicit instantiation of X<T**> which ...
};
```

end example]

### 17.7.2 Explicit instantiation [temp.explicit]

A class, function, variable, or member template specialization can be explicitly instantiated from its template. A member function, member class or static data member of a class template can be explicitly instantiated from the member definition associated with its class template. An explicit instantiation of a function template or member function of a class template shall not use the `inline` or `constexpr` specifiers.

The syntax for explicit instantiation is:

```cpp
explicit-instantiation:
    extern opt template declaration
```

There are two forms of explicit instantiation: an explicit instantiation definition and an explicit instantiation declaration. An explicit instantiation declaration begins with the `extern` keyword.
If the explicit instantiation is for a class or member class, the *elaborated-type-specifier* in the *declaration* shall include a *simple-template-id*. If the explicit instantiation is for a function or member function, the *unqualified-id* in the *declaration* shall be either a *template-id* or, where all template arguments can be deduced, a *template-name* or *operator-function-id*. [Note: The declaration may declare a *qualified-id*, in which case the *unqualified-id* of the *qualified-id* must be a *template-id*. —end note] If the explicit instantiation is for a member function, a member class or a static data member of a class template specialization, the name of the class template specialization in the *qualified-id* for the member name shall be a *simple-template-id*. If the explicit instantiation is for a variable, the *unqualified-id* in the *declaration* shall be a *template-id*. An explicit instantiation shall appear in an enclosing namespace of its template. If the name declared in the explicit instantiation is an unqualified name, the explicit instantiation shall appear in the namespace where its template is declared or, if that namespace is inline (10.3.1), any namespace from its enclosing namespace set. [Note: Regarding qualified names in declarators, see 11.3. —end note] [Example:

```c
template<class T> class Array { void mf(); }
template class Array<char>;
template void Array<int>::mf();

template<class T> void sort(Array<T>& v) { /* ... */ }
template void sort(Array<char>&);  // argument is deduced here

namespace N {
  template<class T> void f(T&) { }
}
template void N::f<int>(int&);
}  // end example]
```

§ 17.7.2 395
A trailing template-argument can be left unspecified in an explicit instantiation of a function template specialization or of a member function template specialization provided it can be deduced from the type of a function parameter (17.8.2). [Example:

```cpp
template<class T> class Array { /* ... */ };
template<class T> void sort(Array<T>& v) { /* ... */ }

// instantiate sort(Array<int>&) – template-argument deduced
template void sort<>(Array<int>&);
```
—end example]

An explicit instantiation that names a class template specialization is also an explicit instantiation of the same kind (declaration or definition) of each of its members (not including members inherited from base classes and members that are templates) that has not been previously explicitly specialized in the translation unit containing the explicit instantiation, except as described below. [Note: In addition, it will typically be an explicit instantiation of certain implementation-dependent data about the class. —end note]

An explicit instantiation definition that names a class template specialization explicitly instantiates the class template specialization and is an explicit instantiation definition of only those members that have been defined at the point of instantiation.

Except for inline functions and variables, declarations with types deduced from their initializer or return value (10.1.7.4), const variables of literal types, variables of reference types, and class template specializations, explicit instantiation declarations have the effect of suppressing the implicit instantiation of the entity to which they refer. [Note: The intent is that an inline function that is the subject of an explicit instantiation declaration will still be implicitly instantiated when odr-used (6.2) so that the body can be considered for inlining, but that no out-of-line copy of the inline function would be generated in the translation unit. —end note]

If an entity is the subject of both an explicit instantiation declaration and an explicit instantiation definition in the same translation unit, the definition shall follow the declaration. An entity that is the subject of an explicit instantiation declaration and that is also used in a way that would otherwise cause an implicit instantiation (17.7.1) in the translation unit shall be the subject of an explicit instantiation definition somewhere in the program; otherwise the program is ill-formed, no diagnostic required. [Note: This rule does apply to inline functions even though an explicit instantiation declaration of such an entity has no other normative effect. This is needed to ensure that if the address of an inline function is taken in a translation unit in which the implementation chose to suppress the out-of-line body, another translation unit will supply the body. —end note] An explicit instantiation declaration shall not name a specialization of a template with internal linkage.

The usual access checking rules do not apply to names used to specify explicit instantiations. [Note: In particular, the template arguments and names used in the function declarator (including parameter types, return types and exception specifications) may be private types or objects which would normally not be accessible and the template may be a member template or member function which would not normally be accessible. —end note]

An explicit instantiation does not constitute a use of a default argument, so default argument instantiation is not done. [Example:

```cpp
char* p = 0;
template<class T> T g(T x = &p) { return x; }
template int g<int>(int);

// OK even though &p isn’t an int.
```
—end example]
17.7.3 Explicit specialization

An explicit specialization of any of the following:

- (1.1) function template
- (1.2) class template
- (1.3) variable template
- (1.4) member function of a class template
- (1.5) static data member of a class template
- (1.6) member class of a class template
- (1.7) member enumeration of a class template
- (1.8) member class template of a class or class template
- (1.9) member function template of a class or class template

...can be declared by a declaration introduced by `template<>`; that is:

```
explicit-specialization:
  template <> declaration
```

**Example:**

```cpp
template<class T> class stream;
```

```cpp
template<> class stream<char> { /* ... */ };
```

```cpp
template<class T> class Array { /* ... */ };
```

```cpp
template<class T> void sort(Array<T>& v) { /* ... */ }
```

```cpp
template<> void sort<char*>(Array<char*>&);
```

Given these declarations, `stream<char>` will be used as the definition of streams of `char`; other streams will be handled by class template specializations instantiated from the class template. Similarly, `sort<char*>` will be used as the sort function for arguments of type `Array<char*>`; other `Array` types will be sorted by functions generated from the template. —end example

2 An explicit specialization may be declared in any scope in which the corresponding primary template may be defined (10.3.1.2, 12.2, 17.5.2).

3 A declaration of a function template, class template, or variable template being explicitly specialized shall precede the declaration of the explicit specialization. [Note: A declaration, but not a definition of the template is required. —end note] The definition of a class or class template shall precede the declaration of an explicit specialization for a member template of the class or class template. [Example:

```
template<> class X<int> { /* ... */ }; // error: X not a template
```

```cpp
template<class T> class X;
```

```cpp
template<> class X<char*> { /* ... */ }; // OK: X is a template
```

—end example]

4 A member function, a member function template, a member class, a member enumeration, a member class template, a static data member, or a static data member template of a class template may be explicitly specialized for a class specialization that is implicitly instantiated; in this case, the definition of the class template shall precede the explicit specialization for the member of the class template. If such an explicit specialization for the member of a class template names an implicitly-declared special member function (Clause 15), the program is ill-formed.
A member of an explicitly specialized class is not implicitly instantiated from the member declaration of the class template; instead, the member of the class template specialization shall itself be explicitly defined if its definition is required. In this case, the definition of the class template explicit specialization shall be in scope at the point at which the member is defined. The definition of an explicitly specialized class is unrelated to the definition of a generated specialization. That is, its members need not have the same names, types, etc. as the members of a generated specialization. Members of an explicitly specialized class template are defined in the same manner as members of normal classes, and not using the template<> syntax. The same is true when defining a member of an explicitly specialized member class. However, template<> is used in defining a member of an explicitly specialized member class template that is specialized as a class template. [Example:

```cpp
template<class T> struct A {
  struct B { };
  template<class U> struct C { };
};

template<> struct A<int> {
  void f(int);
};

void h() {
  A<int> a;
  a.f(16); // A<int>::f must be defined somewhere
}
```

// template<> not used for a member of an explicitly specialized class template
void A<int>::f(int) { /* ... */ }

```cpp
template<> struct A<char>::B {
  void f();
}; // template<> also not used when defining a member of an explicitly specialized member class
void A<char>::B::f() { /* ... */ }

template<> template<class U> struct A<char>::C {
  void f();
}; // template<> is used when defining a member of an explicitly specialized member class template
// specialized as a class template
template<class U> void A<char>::C<U>::f() { /* ... */ }

template<> struct A<short>::B {
  void f();
};

template<>
void A<short>::B::f() { /* ... */ } // error: template<> not permitted

template<> template<class U> struct A<short>::C {
  void f();
};

template<class U> void A<short>::C<U>::f() { /* ... */ } // error: template<> required
```

—end example]

If a template, a member template or a member of a class template is explicitly specialized then that specialization shall be declared before the first use of that specialization that would cause an implicit instantiation to take place, in every translation unit in which such a use occurs; no diagnostic is required. If
the program does not provide a definition for an explicit specialization and either the specialization is used in
a way that would cause an implicit instantiation to take place or the member is a virtual member function,
the program is ill-formed, no diagnostic required. An implicit instantiation is never generated for an explicit
specialization that is declared but not defined. [Example:

```cpp
class String { };
template<class T> class Array { /* ... */ };
template<class T> void sort(Array<T>& v) { /* ... */ }

void f(Array<String>& v) {
    sort(v); // use primary template sort(Array<T>&), T is String
}

template<> void sort<String>(Array<String>& v);  // error: specialization after use of primary template
template<> void sort<>(Array<char*>& v);  // OK: sort<char*> not yet used

template<class T> struct A {
    enum E : T;
    enum class S : T;
};
template<> enum A<int>::E : int { eint }; // OK
template<> enum class A<int>::S : int { sint }; // OK

template<class T> enum A<T>::E : T { eT };
template<class T> enum class A<T>::S : T { sT };
template<> enum A<char>::E : char { echar }; // ill-formed, A<char>::E was instantiated
    // when A<char> was instantiated

Framework example]

--- end example

7 The placement of explicit specialization declarations for function templates, class templates, variable templates,
member functions of class templates, static data members of class templates, member classes of class templates,
member enumerations of class templates, member class templates of class templates, member function
templates of class templates, static data member templates of class templates, member functions of member
templates of class templates, member functions of member templates of non-template classes, static data
member templates of non-template classes, member function templates of non-template classes, etc., and the
placement of partial specialization declarations of class templates, variable templates, member
class templates of non-template classes, static data member templates of non-template classes, member class
templates of class templates, etc., can affect whether a program is well-formed according to the relative
positioning of the explicit specialization declarations and their points of instantiation in the translation unit
as specified above and below. When writing a specialization, be careful about its location; or to make it
compile will be such a trial as to kindle its self-immolation.

8 A template explicit specialization is in the scope of the namespace in which the template was defined.
[Example:

```cpp
namespace N {
    template<class T> class X { /* ... */ };
template<class T> class Y { /* ... */ };

    template<class X<int> { /* ... */ }; // OK: specialization in same namespace
    template<class Y<double>;
        // forward-declare intent to specialize for double

    template<> class N::Y<double> { /* ... */ }; // OK: specialization in enclosing namespace
    template<> class N::Y<short> { /* ... */ }; // OK: specialization in enclosing namespace

    --- end example
```

§ 17.7.3
A simple-template-id that names a class template explicit specialization that has been declared but not defined can be used exactly like the names of other incompletely-defined classes (6.9). [Example:

```
template<class T> class X; // X is a class template
template<> class X<int>;

X<int>* p; // OK: pointer to declared class X<int>
X<int> x; // error: object of incomplete class X<int>
```
—end example]

A trailing template-argument can be left unspecified in the template-id naming an explicit function template specialization provided it can be deduced from the function argument type. [Example:

```
template<class T> class Array { /* ... */ }

template<class T> void sort(Array<T>& v);

// explicit specialization for sort(Array<int>&)
// with deduced template-argument of type int
template<> void sort(Array<int>&);
```
—end example]

A function with the same name as a template and a type that exactly matches that of a template specialization is not an explicit specialization (17.5.6).

An explicit specialization of a function or variable template is inline only if it is declared with the inline specifier or defined as deleted, and independently of whether its function or variable template is inline. [Example:

```
template<class T> void f(T) { /* ... */ }
template<class T> inline T g(T) { /* ... */ }

template<> inline void f<>(int) { /* ... */ } // OK: inline
template<> int g<>(int) { /* ... */ } // OK: not inline
```
—end example]

An explicit specialization of a static data member of a template or an explicit specialization of a static data member template is a definition if the declaration includes an initializer; otherwise, it is a declaration. [Note: The definition of a static data member of a template that requires default-initialization must use a braced-init-list:

```
template<> X Q<int>::x; // declaration
template<> X Q<int>::x (); // error: declares a function
template<> X Q<int>::x {} ; // definition
```
—end note]

A member or a member template of a class template may be explicitly specialized for a given implicit instantiation of the class template, even if the member or member template is defined in the class template definition. An explicit specialization of a member or member template is specified using the syntax for explicit specialization. [Example:

```
template<class T> struct A {
    void f(T);
    template<class X1> void g1(T, X1);
    template<class X2> void g2(T, X2);
    void h(T) { }
};
```

// specialization

§ 17.7.3
template<> void A<int>::f(int);

// out of class member template definition
template<class T> template<class X1> void A<T>::g1(T, X1) { }

// member template specialization
template<> template<class X1> void A<int>::g1(int, X1);

// member template specialization
template<> template<class X1> void A<int>::g1(int, char);

// X1 deduced as char

// member specialization even if defined in class definition
template<> template<> class A<int>::B<double>;

— end example

A member or a member template may be nested within many enclosing class templates. In an explicit specialization for such a member, the member declaration shall be preceded by a template<> for each enclosing class template that is explicitly specialized. [Example:

```
template<class T1> class A {
    template<class T2> class B {
        void mf();
    };
};
template<> template<> class A<int>::B<double>;
template<> template<> void A<char>::B<char>::mf();
— end example
```

In an explicit specialization declaration for a member of a class template or a member template that appears in namespace scope, the member template and some of its enclosing class templates may remain unspecialized, except that the declaration shall not explicitly specialize a class member template if its enclosing class templates are not explicitly specialized as well. In such explicit specialization declaration, the keyword template followed by a template-parameter-list shall be provided instead of the template<> preceding the explicit specialization declaration of the member. The types of the template-parameters in the template-parameter-list shall be the same as those specified in the primary template definition. [Example:

```
template <class T1> class A {
    template<class T2> class B {
        template<class T3> void mf1(T3);
        void mf2();
    };
};
template <> template <class X>
class A<int>::B {
    template <class T> void mf1(T);
};
template <> template <> template<class T>
void A<int>::B<double>::mf1(T t) { } // ill-formed; B<double> is specialized but
// its enclosing class template A is not
```

— end example]
A specialization of a member function template, member class template, or static data member template of a non-specialized class template is itself a template.

An explicit specialization declaration shall not be a friend declaration.

Default function arguments shall not be specified in a declaration or a definition for one of the following explicit specializations:

(19.1) the explicit specialization of a function template;
(19.2) the explicit specialization of a member function template;
(19.3) the explicit specialization of a member function of a class template where the class template specialization to which the member function specialization belongs is implicitly instantiated. [Note: Default function arguments may be specified in the declaration or definition of a member function of a class template specialization that is explicitly specialized. — end note]

17.8 Function template specializations

A function instantiated from a function template is called a function template specialization; so is an explicit specialization of a function template. Template arguments can be explicitly specified when naming the function template specialization, deduced from the context (e.g., deduced from the function arguments in a call to the function template specialization, see 17.8.2), or obtained from default template arguments.

Each function template specialization instantiated from a template has its own copy of any static variable. [Example:

```cpp
template<class T> void f(T* p) {
  static T s;
};

void g(int a, char* b) {
  f(&a); // calls f<int>(int*)
  f(&b); // calls f<char*>(char**)
}
```

Here `f<int>(int*)` has a static variable `s` of type `int` and `f<char*>(char**)` has a static variable `s` of type `char*`. — end example]

17.8.1 Explicit template argument specification

Template arguments can be specified when referring to a function template specialization by qualifying the function template name with the list of template-arguments in the same way as template-arguments are specified in uses of a class template specialization. [Example:

```cpp
template<class T> void sort(Array<T>& v);

void f(Array<dcomplex>& cv, Array<int>& ci) {
  sort<dcomplex>(cv); // sort(Array<dcomplex>&)
  sort<int>(ci); // sort(Array<int>&)
}
```

and

```cpp
template<class U, class V> U convert(V v);

void g(double d) {
  int i = convert<int,double>(d); // int convert(double)
  char c = convert<char,double>(d); // char convert(double)
}
```

— end example]
A template argument list may be specified when referring to a specialization of a function template

(2.1) — when a function is called,
(2.2) — when the address of a function is taken, when a function initializes a reference to function, or when a pointer to member function is formed,
(2.3) — in an explicit specialization,
(2.4) — in an explicit instantiation, or
(2.5) — in a friend declaration.

Trailing template arguments that can be deduced (17.8.2) or obtained from default template-arguments may be omitted from the list of explicit template-arguments. A trailing template parameter pack (17.5.3) not otherwise deduced will be deduced to an empty sequence of template arguments. If all of the template arguments can be deduced, they may all be omitted; in this case, the empty template argument list <> itself may also be omitted. In contexts where deduction is done and fails, or in contexts where deduction is not done, if a template argument list is specified and it, along with any default template arguments, identifies a single function template specialization, then the template-id is an lvalue for the function template specialization. [Example:

```
template<class X, class Y> X f(Y);
template<class X, class Y, class ... Z> X g(Y);
void h() {
    int i = f<int>(5.6); // Y is deduced to be double
    int j = f(5.6); // ill-formed: X cannot be deduced
    f<void>(f<int, bool>); // Y for outer f deduced to be int (*)(bool)
    f<void>(f<int>); // ill-formed: f<int> does not denote a single function template specialization
    int k = g<int>(5.6); // Y is deduced to be double, Z is deduced to an empty sequence
    f<void>(g<int, bool>); // Y for outer f is deduced to be int (*)(bool), Z is deduced to an empty sequence
}
```

— end example]

Note: An empty template argument list can be used to indicate that a given use refers to a specialization of a function template even when a non-template function (11.3.5) is visible that would otherwise be used. For example:

```
template <class T> int f(T); // #1
int f(int); // #2
int k = f1(); // uses #2
int l = f<>1(); // uses #1
```

— end note]

Template arguments that are present shall be specified in the declaration order of their corresponding template-parameters. The template argument list shall not specify more template-arguments than there are corresponding template-parameters unless one of the template-parameters is a template parameter pack. [Example:

```
template<class X, class Y, class Z> X f(Y,Z);
template<class ... Args> void f2();
void g() {
    f<int, const char*, double*>("aa",3.0);
    f<int, const char*>("aa",3.0); // Z is deduced to be double
    f<"aa",3.0>; // Y is deduced to be const char*, and Z is deduced to be double
    f("aa",3.0); // error: X cannot be deduced
    f2<char, short, int, long>(); // OK
}
```

§ 17.8.1
Implicit conversions (Clause 7) will be performed on a function argument to convert it to the type of the corresponding function parameter if the parameter type contains no template-parameters that participate in template argument deduction. [Note: Template parameters do not participate in template argument deduction if they are explicitly specified. For example,

```cpp
template<class T> void f(T);

class Complex {
    Complex(double);
};

void g() {
    f<Complex>(1); // OK, means f<Complex>(Complex(1))
}
```

— end note —

Note: Because the explicit template argument list follows the function template name, and because conversion member function templates and constructor member function templates are called without using a function name, there is no way to provide an explicit template argument list for these function templates. — end note —

Note: For simple function names, argument dependent lookup (6.4.2) applies even when the function name is not visible within the scope of the call. This is because the call still has the syntactic form of a function call (6.4.1). But when a function template with explicit template arguments is used, the call does not have the correct syntactic form unless there is a function template with that name visible at the point of the call. If no such name is visible, the call is not syntactically well-formed and argument-dependent lookup does not apply. If some such name is visible, argument dependent lookup applies and additional function templates may be found in other namespaces. [Example:

```cpp
namespace A {
    struct B { }
    template<int X> void f(B);
}
namespace C {
    template<class T> void f(T t);
}
void g(A::B b) {
    f<3>(b); // ill-formed: not a function call
    A::f<3>(b); // well-formed
    C::f<3>(b); // ill-formed; argument dependent lookup applies only to unqualified names
    using C::f;
    f<3>(b); // well-formed because C::f is visible; then A::f is found by argument dependent lookup
}
```

— end example — end note —

Template argument deduction can extend the sequence of template arguments corresponding to a template parameter pack, even when the sequence contains explicitly specified template arguments. [Example:

```cpp
template<class ... Types> void f(Types ... values);

void g() {
    f<int*, float*>(0, 0, 0); // Types is deduced to the sequence int*, float*, int
}
```

— end example —
17.8.2 Template argument deduction [temp.deduct]

1 When a function template specialization is referenced, all of the template arguments shall have values. The values can be explicitly specified or, in some cases, be deduced from the use or obtained from default template-arguments. [Example:

```c
void f(Array<dcomplex>& cv, Array<int>& ci) {
    sort(cv);       // calls sort(Array<dcomplex>&)
    sort(ci);       // calls sort(Array<int>&)
}
```

and

```c
void g(double d) {
    int i = convert<int>(d);     // calls convert<int,double>(double)
    int c = convert<char>(d);    // calls convert<char,double>(double)
}
```

—end example]

2 When an explicit template argument list is specified, the template arguments must be compatible with the template parameter list and must result in a valid function type as described below; otherwise type deduction fails. Specifically, the following steps are performed when evaluating an explicitly specified template argument list with respect to a given function template:

1. The specified template arguments must match the template parameters in kind (i.e., type, non-type, template). There must not be more arguments than there are parameters unless at least one parameter is a template parameter pack, and there shall be an argument for each non-pack parameter. Otherwise, type deduction fails.
2. Non-type arguments must match the types of the corresponding non-type template parameters, or must be convertible to the types of the corresponding non-type parameters as specified in 17.3.2, otherwise type deduction fails.
3. The specified template argument values are substituted for the corresponding template parameters as specified below.

3 After this substitution is performed, the function parameter type adjustments described in 11.3.5 are performed. [Example: A parameter type of “void (const int, int[5])" becomes “void(*)(int,int*)”. —end example] [Note: A top-level qualifier in a function parameter declaration does not affect the function type but still affects the type of the function parameter variable within the function. —end note] [Example:

```c
template <class T> void f(T t);
template <class X> void g(const X x);
template <class Z> void h(Z, Z*);
```

```c
int main() {
    // #1: function type is f(int), t is non const
    f<int>(1);

    // #2: function type is f(int), t is const
    f<const int>(1);

    // #3: function type is g(int), x is const
    g<int>(1);

    // #4: function type is g(int), x is const
    g<const int>(1);

    // #5: function type is h(int, const int*)

    § 17.8.2
4 [Note: \textit{f<int>(1) and f<const int>(1)} call distinct functions even though both of the functions called have the same function type. — end note]

5 The resulting substituted and adjusted function type is used as the type of the function template for template argument deduction. If a template argument has not been deduced and its corresponding template parameter has a default argument, the template argument is determined by substituting the template arguments determined for preceding template parameters into the default argument. If the substitution results in an invalid type, as described above, type deduction fails. [Example:

```c
template <class T, class U = double>
void f(T t = 0, U u = 0);

void g() {
    f(1, 'c'); // f<int, char>(1, 'c')
    f(1);     // f<int, double>(1, 0)
    f();      // error: T cannot be deduced
    f<int>(); // f<int, double>(0, 0)
    f<int,char>();// f<int,char>(0, 0)
}
```
— end example]

When all template arguments have been deduced or obtained from default template arguments, all uses of template parameters in the template parameter list of the template and the function type are replaced with the corresponding deduced or default argument values. If the substitution results in an invalid type, as described above, type deduction fails.

6 At certain points in the template argument deduction process it is necessary to take a function type that makes use of template parameters and replace those template parameters with the corresponding template arguments. This is done at the beginning of template argument deduction when any explicitly specified template arguments are substituted into the function type, and again at the end of template argument deduction when any template arguments that were deduced or obtained from default arguments are substituted.

7 The substitution occurs in all types and expressions that are used in the function type and in template parameter declarations. The expressions include not only constant expressions such as those that appear in array bounds or as nontype template arguments but also general expressions (i.e., non-constant expressions) inside \texttt{sizeof}, \texttt{decltype}, and other contexts that allow non-constant expressions. The substitution proceeds in lexical order and stops when a condition that causes deduction to fail is encountered. [Note: The equivalent substitution in exception specifications is done only when the \textit{noexcept-specifier} is instantiated, at which point a program is ill-formed if the substitution results in an invalid type or expression. — end note]

[Example:

```c
template <class T> struct A { using X = typename T::X; };  
template <class T> typename T::X f(typename A<T>::X);  
template <class T> void f(...) { }  
template <class T> auto g(typename A<T>::X) -> typename T::X;  
template <class T> void g(...) { }

void h() {  
f<int>();   // OK, substituting return type causes deduction to fail  
g<int>();   // error, substituting parameter type instantiates A<int>
}
```
]
If a substitution results in an invalid type or expression, type deduction fails. An invalid type or expression is one that would be ill-formed, with a diagnostic required, if written using the substituted arguments. [Note: If no diagnostic is required, the program is still ill-formed. Access checking is done as part of the substitution process. — end note] Only invalid types and expressions in the immediate context of the function type and its template parameter types can result in a deduction failure. [Note: The substitution into types and expressions can result in effects such as the instantiation of class template specializations and/or function template specializations, the generation of implicitly-defined functions, etc. Such effects are not in the “immediate context” and can result in the program being ill-formed. — end note]

[Example:

```cpp
struct X {}
struct Y {
    Y(X){}
};

template <class T> auto f(T t1, T t2) -> decltype(t1 + t2); // #1
X f(Y, Y); // #2
X x1, x2;
X x3 = f(x1, x2); // deduction fails on #1 (cannot add X+X), calls #2
```

— end example]

[Note: Type deduction may fail for the following reasons:

8.1 — Attempting to instantiate a pack expansion containing multiple parameter packs of differing lengths.

8.2 — Attempting to create an array with an element type that is void, a function type, a reference type, or an abstract class type, or attempting to create an array with a size that is zero or negative. [Example:

```cpp
template <class T> int f(T[5]);
int I = f<int>(0);
int j = f<void>(0); // invalid array
```

— end example]

8.3 — Attempting to use a type that is not a class or enumeration type in a qualified name. [Example:

```cpp
template <class T> int f(typename T::B*);
int i = f<int>(0);
```

— end example]

8.4 — Attempting to use a type in a nested-name-specifier of a qualified-id when that type does not contain the specified member, or

8.4.1 — the specified member is not a type where a type is required, or

8.4.2 — the specified member is not a template where a template is required, or

8.4.3 — the specified member is not a non-type where a non-type is required.

[Example:

```cpp
template <int I> struct X {}
template <template <class T> class> struct Z {}
template <class T> void f(typename T::Y*){}
template <class T> void g(X<T::N>*){}
template <class T> void h(Z<T::template TT>*){}
struct A {};
struct B { int Y; };
struct C {
    typedef int N;
};
struct D {
    typedef int TT;
};

int main() {
    // Deduction fails in each of these cases:
    f<A>(0);    // A does not contain a member Y
    f<B>(0);    // The Y member of B is not a type
    g<C>(0);    // The N member of C is not a non-type
    h<D>(0);    // The TT member of D is not a template
}

— end example

— Attempting to create a pointer to reference type.

— Attempting to create a reference to void.

— Attempting to create “pointer to member of T” when T is not a class type. [Example:
    template <class T> int f(int T::*);
    int i = f<int>(0);
    — end example]

— Attempting to give an invalid type to a non-type template parameter. [Example:
    template <class T, T*> struct S {};
    template <class T> int f(<T, T()>*);
    struct X {};
    int i0 = f<X>(0);
    — end example]

— Attempting to perform an invalid conversion in either a template argument expression, or an expression
    used in the function declaration. [Example:
    template <class T, T*> int f(int);
    int i2 = f<int,1>(0);    // can't conv 1 to int*
    — end example]

— Attempting to create a function type in which a parameter has a type of void, or in which the return
type is a function type or array type.

— Attempting to create a function type in which a parameter type or the return type is an abstract class
type (13.4).

— end note]

[Example: In the following example, assuming a signed char cannot represent the value 1000, a narrowing
conversion (11.6.4) would be required to convert the template-argument of type int to signed char, therefore
substitution fails for the second template (17.3.2).

    template <int> int f(int);
    template <signed char> int f(int);
    int i1 = f<1000>(0);    // OK
    int i2 = f<1>(0);       // ambiguous; not narrowing
    — end example]
17.8.2.1 Deducing template arguments from a function call

Template argument deduction is done by comparing each function template parameter type (call it P) that contains *template-parameters* that participate in template argument deduction with the type of the corresponding argument of the call (call it A) as described below. If removing references and cv-qualifiers from P gives std::initializer_list<P> or P[N] for some P and N and the argument is a non-empty initializer list (11.6.4), then deduction is performed instead for each element of the initializer list, taking P as a function template parameter type and the initializer element as its argument, and in the P[N] case, if N is a non-type template parameter, N is deduced from the length of the initializer list. Otherwise, an initializer list argument causes the parameter to be considered a non-deduced context (17.8.2.5). [Example:

```
template<class T> void f(std::initializer_list<T>);  
f({1,2,3});  // T deduced to int  
f({1,"asdf"});  // error: T deduced to both int and const char*  

template<class T> void g(T);  
g({1,2,3});  // error: no argument deduced for T  

template<class T, int N> void h(T const(&)[N]);  
h({1,2,3});  // T deduced to int, N deduced to 3  

template<class T> void j(T const(&)[3]);  
j({42});  // T deduced to int, array bound not considered  

struct Aggr { int i; int j; };  
template<int N> void k(Aggr const(&)[N]);  
k({1,2,3});  // error: deduction fails, no conversion from int to Aggr  
k({{1},{2},{3}});  // OK, N deduced to 3  

template<int M, int N> void m(int const(&)[M][N]);  
m({{1,2},{3,4}});  // M and N both deduced to 2  

template<class T, int N> void n(T const(&)[N], T);  
n({{1},{2},{3}},Aggr());  // OK, T is Aggr, N is 3  
```

—end example] For a function parameter pack that occurs at the end of the *parameter-declaration-list*, deduction is performed for each remaining argument of the call, taking the type P of the *declarator-id* of the function parameter pack as the corresponding function template parameter type. Each deduction deduces template arguments for subsequent positions in the template parameter packs expanded by the function parameter pack. When a function parameter pack appears in a non-deduced context (17.8.2.5), the type of that parameter pack is never deduced. [Example:

```
template<class ... Types> void f(Types& ...);  
template<class T1, class ... Types> void g(T1, Types ...);  
template<class T1, class ... Types> void g1(Types ..., T1);  

void h(int x, float& y) {  
    const int z = x;  
    f(x, y, z);  // Types is deduced to int, float, const int  
    g(x, y, z);  // T1 is deduced to int, Types is deduced to float, int  
    g1(x, y, z);  // error: Types is not deduced  
    g1<int, int, int>(x, y, z);  // OK, no deduction occurs  
}  
```

—end example]

2 If P is not a reference type:
(2.1) If A is an array type, the pointer type produced by the array-to-pointer standard conversion (7.2) is used in place of A for type deduction; otherwise,

(2.2) If A is a function type, the pointer type produced by the function-to-pointer standard conversion (7.3) is used in place of A for type deduction; otherwise,

(2.3) If A is a cv-qualified type, the top-level cv-qualifiers of A’s type are ignored for type deduction.

3 If P is a cv-qualified type, the top-level cv-qualifiers of P’s type are ignored for type deduction. If P is a reference type, the type referred to by P is used for type deduction. [Example:

```cpp
template<class T> int f(const T&);
int n1 = f(5); // calls f<int>(const int&)
const int i = 0;
int n2 = f(i); // calls f<int>(const int&)
template <class T> int g(volatile T&);
int n3 = g(i); // calls g<const int>(const volatile int&)
```
—end example] A forwarding reference is an rvalue reference to a cv-unqualified template parameter that does not represent a template parameter of a class template (during class template argument deduction (16.3.1.8)).

If P is a forwarding reference and the argument is an lvalue, the type “lvalue reference to A” is used in place of A for type deduction. [Example:

```cpp
template <class T> int f(T&& heisenreference);
template <class T> int g(const T&&);
int i;
int n1 = f(i); // calls f<int&>(int&)
int n2 = f(0); // calls f<int>(int&&)
int n3 = g(i); // error: would call g<int>(const int&), which
// would bind an rvalue reference to an lvalue

template <class T> struct A {
  template <class U>
  A(T&&, U&&, int*); // #1: T&& is not a forwarding reference.
  A(T&&, int*); // #2
};
template <class T> A(T&&, int*) -> A<T>; // #3: T&& is a forwarding reference.

int *ip;
A a1{i, 0, ip}; // error: cannot deduce from #1
A a0{0, 0, ip}; // uses #1 to deduce A<int> and #1 to initialize
A a2{i, ip}; // uses #3 to deduce A<int&> and #2 to initialize
—end example]

4 In general, the deduction process attempts to find template argument values that will make the deduced A identical to A (after the type A is transformed as described above). However, there are three cases that allow a difference:

(4.1) If the original P is a reference type, the deduced A (i.e., the type referred to by the reference) can be more cv-qualified than the transformed A.

(4.2) The transformed A can be another pointer or pointer to member type that can be converted to the deduced A via a function pointer conversion (7.13) and/or qualification conversion (7.5).

(4.3) If P is a class and P has the form simple-template-id, then the transformed A can be a derived class of the deduced A. Likewise, if P is a pointer to a class of the form simple-template-id, the transformed A can be a pointer to a derived class pointed to by the deduced A.
These alternatives are considered only if type deduction would otherwise fail. If they yield more than one possible deduced A, the type deduction fails. [Note: If a template-parameter is not used in any of the function parameters of a function template, or is used only in a non-deduced context, its corresponding template-argument cannot be deduced from a function call and the template-argument must be explicitly specified. — end note]

When P is a function type, function pointer type, or pointer to member function type:

(6.1) — If the argument is an overload set containing one or more function templates, the parameter is treated as a non-deduced context.

(6.2) — If the argument is an overload set (not containing function templates), trial argument deduction is attempted using each of the members of the set. If deduction succeeds for only one of the overload set members, that member is used as the argument value for the deduction. If deduction succeeds for more than one member of the overload set the parameter is treated as a non-deduced context.

[Example:

// Only one function of an overload set matches the call so the function parameter is a deduced context.

template <class T> int f(T (*p)(T));
int g(int);
int g(char);
int i = f(g);    // calls f(int (*)(int))
— end example]

[Example:

// Ambiguous deduction causes the second function parameter to be a non-deduced context.

template <class T> int f(T, T (*p)(T));
int g(int);
char g(char);
int i = f(1, g);    // calls f(int, int (*)(int))
— end example]

[Example:

// The overload set contains a template, causing the second function parameter to be a non-deduced context.

template <class T> int f(T, T (*p)(T));
char g(char);
template <class T> T g(T);
int i = f(1, g);    // calls f(int, int (*)(int))
— end example]

If deduction succeeds for all parameters that contain template-parameters that participate in template argument deduction, and all template arguments are explicitly specified, deduced, or obtained from default template arguments, remaining parameters are then compared with the corresponding arguments. For each remaining parameter P with a type that was non-dependent before substitution of any explicitly-specified template arguments, if the corresponding argument A cannot be implicitly converted to P, deduction fails. [Note: Parameters with dependent types in which no template-parameters participate in template argument deduction, and parameters that became non-dependent due to substitution of explicitly-specified template arguments, will be checked during overload resolution. — end note] [Example:

    template <class T> struct Z {
    typedef typename T::x xx;
    };
    template <class T> typename Z<T>::xx f(void *, T);    // #1
    template <class T> void f(int, T);      // #2
    struct A {} a;
int main() {
    f(1, a);  // OK, deduction fails for #1 because there is no conversion from int to void*
}

— end example —

17.8.2.2 Deducing template arguments taking the address of a function template
[temp.deduct.funcaddr]

1 Template arguments can be deduced from the type specified when taking the address of an overloaded
function (16.4). The function template’s function type and the specified type are used as the types of \( P \)
and \( A \), and the deduction is done as described in 17.8.2.5.

2 A placeholder type (10.1.7.4) in the return type of a function template is a non-deduced context. If template
argument deduction succeeds for such a function, the return type is determined from instantiation of the
function body.

17.8.2.3 Deducing conversion function template arguments [temp.deduct.conv]

1 Template argument deduction is done by comparing the return type of the conversion function template (call
it \( P \)) with the type that is required as the result of the conversion (call it \( A \); see 11.6, 16.3.1.5, and 16.3.1.6
for the determination of that type) as described in 17.8.2.5.

2 If \( P \) is a reference type, the type referred to by \( P \) is used in place of \( P \) for type deduction and for any further
references to or transformations of \( P \) in the remainder of this section.

3 If \( A \) is not a reference type:
   
   - If \( P \) is an array type, the pointer type produced by the array-to-pointer standard conversion (7.2) is
     used in place of \( P \) for type deduction; otherwise,
   
   - If \( P \) is a function type, the pointer type produced by the function-to-pointer standard conversion (7.3)
     is used in place of \( P \) for type deduction; otherwise,
   
   - If \( P \) is a cv-qualified type, the top-level cv-qualifiers of \( P \)’s type are ignored for type deduction.

4 If \( A \) is a cv-qualified type, the top-level cv-qualifiers of \( A \)’s type are ignored for type deduction. If \( A \) is a
reference type, the type referred to by \( A \) is used for type deduction.

5 In general, the deduction process attempts to find template argument values that will make the deduced \( A \)
identical to \( A \). However, there are four cases that allow a difference:
   
   - If the original \( A \) is a reference type, \( A \) can be more cv-qualified than the deduced \( A \) (i.e., the type referred
to by the reference)
   
   - If the original \( A \) is a function pointer type, \( A \) can be “pointer to function” even if the deduced \( A \) is
     “pointer to noexcept function”.
   
   - If the original \( A \) is a pointer to member function type, \( A \) can be “pointer to member of type function”
even if the deduced \( A \) is “pointer to member of type noexcept function”.
   
   - The deduced \( A \) can be another pointer or pointer to member type that can be converted to \( A \) via a
     qualification conversion.

6 These alternatives are considered only if type deduction would otherwise fail. If they yield more than one
possible deduced \( A \), the type deduction fails.

7 When the deduction process requires a qualification conversion for a pointer or pointer to member type as
described above, the following process is used to determine the deduced template argument values:

   If \( A \) is a type

   \( cv_{1,0} \) “pointer to . . .” \( cv_{1,n-1} \) “pointer to” \( cv_{1,n} \) \( T1 \)
and \( P \) is a type
\[
\text{cv}_{2,0} \text{ "pointer to ..." } \text{cv}_{2,n-1} \text{ "pointer to" } \text{cv}_{2,n} \ T_2,
\]
then the cv-unqualified \( T_1 \) and \( T_2 \) are used as the types of \( A \) and \( P \) respectively for type deduction.

[Example:

```cpp
struct A {
    template <class T> operator T***();
};
A a;
const int * const * const * p1 = a; // \( T \) is deduced as int, not const int
```
— end example]

17.8.2.4 Deducing template arguments during partial ordering [temp.deduct.partial]

Template argument deduction is done by comparing certain types associated with the two function templates being compared.

Two sets of types are used to determine the partial ordering. For each of the templates involved there is the original function type and the transformed function type. [Note: The creation of the transformed function type is described in 17.5.6.2. — end note] The deduction process uses the transformed type as the argument template and the original type of the other template as the parameter template. This process is done twice for each type involved in the partial ordering comparison: once using the transformed template-1 as the argument template and template-2 as the parameter template and again using the transformed template-2 as the argument template and template-1 as the parameter template.

The types used to determine the ordering depend on the context in which the partial ordering is done:

- In the context of a function call, the types used are those function parameter types for which the function call has arguments.
- In the context of a call to a conversion function, the return types of the conversion function templates are used.
- In other contexts (17.5.6.2) the function template’s function type is used.

Each type nominated above from the parameter template and the corresponding type from the argument template are used as the types of \( P \) and \( A \). If a particular \( P \) contains no template-parameters that participate in template argument deduction, that \( P \) is not used to determine the ordering.

Before the partial ordering is done, certain transformations are performed on the types used for partial ordering:

- If \( P \) is a reference type, \( P \) is replaced by the type referred to.
- If \( A \) is a reference type, \( A \) is replaced by the type referred to.

If both \( P \) and \( A \) were reference types (before being replaced with the type referred to above), determine which of the two types (if any) is more cv-qualified than the other; otherwise the types are considered to be equally cv-qualified for partial ordering purposes. The result of this determination will be used below.

Remove any top-level cv-qualifiers:

- If \( P \) is a cv-qualified type, \( P \) is replaced by the cv-unqualified version of \( P \).
- If \( A \) is a cv-qualified type, \( A \) is replaced by the cv-unqualified version of \( A \).

Using the resulting types \( P \) and \( A \), the deduction is then done as described in 17.8.2.5. If \( P \) is a function parameter pack, the type \( A \) of each remaining parameter type of the argument template is compared with the

\(^{141}\) Default arguments are not considered to be arguments in this context; they only become arguments after a function has been selected.
type P of the *declarator-id* of the function parameter pack. Each comparison deduces template arguments for
subsequent positions in the template parameter packs expanded by the function parameter pack. Similarly,
if A was transformed from a function parameter pack, it is compared with each remaining parameter type
of the parameter template. If deduction succeeds for a given type, the type from the argument template is
considered to be at least as specialized as the type from the parameter template. [Example:

```
template<class... Args> void f(Args... args);  // #1
template<class T1, class... Args> void f(T1 a1, Args... args);  // #2
template<class T1, class T2> void f(T1 a1, T2 a2);  // #3
```

f();  // calls #1
f(1, 2, 3);  // calls #2
f(1, 2);  // calls #3; non-variadic template #3 is more specialized
          // than the variadic templates #1 and #2

— end example]

9 If, for a given type, deduction succeeds in both directions (i.e., the types are identical after the transformations
above) and both P and A were reference types (before being replaced with the type referred to above):

(9.1) — if the type from the argument template was an lvalue reference and the type from the parameter
template was not, the parameter type is not considered to be at least as specialized as the argument
type; otherwise,

(9.2) — if the type from the argument template is more cv-qualified than the type from the parameter template
(as described above), the parameter type is not considered to be at least as specialized as the argument
type.

10 Function template F is *at least as specialized as* function template G if, for each pair of types used to determine
the ordering, the type from F is at least as specialized as the type from G. F is *more specialized than* G if F is
at least as specialized as G and G is not at least as specialized as F.

11 If, after considering the above, function template F is at least as specialized as function template G and
vice-versa, and if G has a trailing parameter pack for which F does not have a corresponding parameter, and
if F does not have a trailing parameter pack, then F is more specialized than G.

12 In most cases, all template parameters must have values in order for deduction to succeed, but for partial
ordering purposes a template parameter may remain without a value provided it is not used in the types
being used for partial ordering. [Note: A template parameter used in a non-deduced context is considered
used. — end note] [Example:

```
template <class T> T f(int);  // #1
template <class T, class U> T f(U);  // #2
void g() {
    f<int>(1);  // calls #1
}
```

— end example]

13 [Note: Partial ordering of function templates containing template parameter packs is independent of the
number of deduced arguments for those template parameter packs. — end note] [Example:

```
template<class ...> struct Tuple { };  
template<class ... Types> void g(Tuple<Types ...>);  // #1
template<class T1, class ... Types> void g(Tuple<T1, Types ...>);  // #2
template<class T1, class ... Types> void g(Tuple<T1, Types& ...>);  // #3
```

g(Tuple<>());  // calls #1
g(Tuple<int, float>());  // calls #2
g(Tuple<int, float&>());  // calls #3

§ 17.8.2.4
17.8.2.5 Deducing template arguments from a type

Template arguments can be deduced in several different contexts, but in each case a type that is specified in terms of template parameters (call it \( P \)) is compared with an actual type (call it \( A \)), and an attempt is made to find template argument values (a type for a type parameter, a value for a non-type parameter, or a template for a template parameter) that will make \( P \), after substitution of the deduced values (call it the deduced \( A \)), compatible with \( A \).

In some cases, the deduction is done using a single set of types \( P \) and \( A \), in other cases, there will be a set of corresponding types \( P \) and \( A \). Type deduction is done independently for each \( P/A \) pair, and the deduced template argument values are then combined. If type deduction cannot be done for any \( P/A \) pair, or if for any pair the deduction leads to more than one possible set of deduced values, or if different pairs yield different deduced values, or if any template argument remains neither deduced nor explicitly specified, template argument deduction fails. The type of a type parameter is only deduced from an array bound if it is not otherwise deduced.

A given type \( P \) can be composed from a number of other types, templates, and non-type values:

1. A function type includes the types of each of the function parameters and the return type.
2. A pointer to member type includes the type of the class object pointed to and the type of the member pointed to.
3. A type that is a specialization of a class template (e.g., \( A<int> \)) includes the types, templates, and non-type values referenced by the template argument list of the specialization.
4. An array type includes the array element type and the value of the array bound.

In most cases, the types, templates, and non-type values that are used to compose \( P \) participate in template argument deduction. That is, they may be used to determine the value of a template argument, and the value so determined must be consistent with the values determined elsewhere. In certain contexts, however, the value does not participate in type deduction, but instead uses the values of template arguments that were either deduced elsewhere or explicitly specified. If a template parameter is used only in non-deduced contexts and is not explicitly specified, template argument deduction fails. [Note: Under 17.8.2.1 and 17.8.2.4, if \( P \) contains no template-parameters that appear in deduced contexts, no deduction is done, so \( P \) and \( A \) need not have the same form. — end note]

The non-deduced contexts are:

1. The nested-name-specifier of a type that was specified using a qualified-id.
2. The expression of a decltype-specifier.
3. A non-type template argument or an array bound in which a subexpression references a template parameter.
4. A template parameter used in the parameter type of a function parameter that has a default argument that is being used in the call for which argument deduction is being done.
5. A function parameter for which argument deduction cannot be done because the associated function argument is a function, or a set of overloaded functions (16.4), and one or more of the following apply:
   1. more than one function matches the function parameter type (resulting in an ambiguous deduction),
   2. no function matches the function parameter type, or
   3. the set of functions supplied as an argument contains one or more function templates.
A function parameter for which the associated argument is an initializer list (11.6.4) but the parameter does not have a type for which deduction from an initializer list is specified (17.8.2.1).  

```cpp
template<class T> void g(T);
g({1,2,3});    // error: no argument deduced for T
```

A function parameter pack that does not occur at the end of the parameter-declaration-list.

When a type name is specified in a way that includes a non-deduced context, all of the types that comprise that type name are also non-deduced. However, a compound type can include both deduced and non-deduced types.  

Example: If a type is specified as `A<T>::B<T2>`, both `T` and `T2` are non-deduced. Likewise, if a type is specified as `A<I+J>::X<T>`, `I`, `J`, and `T` are non-deduced. If a type is specified as `void f(typename A<T>::B, A<T>)`, the `T` in `A<T>::B` is non-deduced but the `T` in `A<T>` is deduced.  

Example: Here is an example where two template arguments are deduced from a single function parameter/argument pair. This can lead to conflicts that cause type deduction to fail:

```cpp
template<class T, class U> void f( T (*)( T, U, U ) );

int g1( int, float, float);
char g2( int, float, float);
int g3( int, char, float);

void r() {
  f(g1);    // OK: T is int and U is float
  f(g2);    // error: T could be char or int
  f(g3);    // error: U could be char or float
}
```

Here is an example where a qualification conversion applies between the argument type on the function call and the deduced template argument type:

```cpp
template<class T> void f(const T*) { }

int* p;
void s() {
  f(p);    // f(const int*)
}
```

Here is an example where the template argument is used to instantiate a derived class type of the corresponding function parameter type:

```cpp
template <class T> struct B { };  
template <class T> struct D : public B<T> {};  
struct D2 : public B<int> {};  
template <class T> void f(B<T>&){}
void t() {
```
A template type argument \( T \), a template template argument \( \text{T}T \) or a template non-type argument \( i \) can be deduced if \( P \) and \( A \) have one of the following forms:

\[
\begin{align*}
T & \\
vu\text{-list} & T \\
T* & \\
T& & \\
T[\text{integer-constant}] & \\
\text{template-name}\langle T\rangle & \text{(where template-name refers to a class template)} \\
type(T) & T() \\
T(T) & T\langle T\rangle  \\
T type::* & T\langle T::*\rangle  \\
type T::* & T\langle T::*\rangle  \\
T (type::*)() & T\langle T::*\rangle()  \\
type (T::*)() & T\langle T::*\rangle()  \\
type (type::*)(T) & T\langle T::*\rangle(T)  \\
T (type::*)(T) & T\langle T::*\rangle(T)  \\
T (T::*)(T) & T\langle T::*\rangle(T)  \\
type [i] & T\langle i\rangle  \\
\text{template-name}\langle i\rangle & \text{(where template-name refers to a class template)}  \\
TT\langle T\rangle & TT\langle i\rangle  \\
TT\langle > & TT\langle i\rangle
\end{align*}
\]

where \( (T) \) represents a parameter-type-list (11.3.5) where at least one parameter type contains a \( T \), and \( () \) represents a parameter-type-list where no parameter type contains a \( T \). Similarly, \( \langle T\rangle \) represents template argument lists where at least one argument contains a \( T \), \( \langle i\rangle \) represents template argument lists where at least one argument contains an \( i \) and \( <> \) represents template argument lists where no argument contains a \( T \) or an \( i \).

If \( P \) has a form that contains \( \langle T\rangle \) or \( \langle i\rangle \), then each argument \( P_i \) of the respective template argument list of \( P \) is compared with the corresponding argument \( A_i \) of the corresponding template argument list of \( A \). If the template argument list of \( P \) contains a pack expansion that is not the last template argument, the entire template argument list is a non-deduced context. If \( P_i \) is a pack expansion, then the pattern of \( P_i \) is compared with each remaining argument in the template argument list of \( A \). Each comparison deduces template arguments for subsequent positions in the template parameter packs expanded by \( P_i \). During partial ordering (17.8.2.4), if \( A_i \) was originally a pack expansion:

\begin{enumerate}
\item[(9.1)] — if \( P \) does not contain a template argument corresponding to \( A_i \) then \( A_i \) is ignored;
\item[(9.2)] — otherwise, if \( P_i \) is not a pack expansion, template argument deduction fails.
\end{enumerate}

Example:

\[
\begin{align*}
template<class T1, class... Z> & \text{class } S; \\
\text{template<class } T1, \text{class... Z> class } S<T1, \text{const } Z&...> & \{ \};
\end{align*}
\]
template<class T1, class T2> class S<T1, const T2&> { };  // #3
S<int, const int&> s;  // both #2 and #3 match; #3 is more specialized

template<class T, class... U> struct A { };  // #1
template<class T1, class T2, class... U> struct A<T1, T2*, U...> { };  // #2
template<class T1, class T2> struct A<T1, T2> { };  // #3
template struct A<int, int*>;  // selects #2

— end example

Similarly, if P has a form that contains (T), then each parameter type P_i of the respective parameter-type-list (11.3.5) of P is compared with the corresponding parameter type A_i of the corresponding parameter-type-list of A. If P and A are function types that originated from deduction when taking the address of a function template (17.8.2.2) or when deducing template arguments from a function declaration (17.8.2.6) and P_i and A_i are parameters of the top-level parameter-type-list of P and A, respectively, P_i is adjusted if it is a forwarding reference (17.8.2.1) and A_i is an lvalue reference, in which case the type of P_i is changed to be the template parameter type (i.e., T&& is changed to simply T). [Note: As a result, when P_i is T&& and A_i is X&, the adjusted P_i will be T, causing T to be deduced as X&. — end note] [Example:

```cpp
template <class T> void f(T&&);
```

```cpp
template <> void f(int&) { }  // #1
```

```cpp
template <> void f(int&&) { }  // #2
```

```cpp
void g(int i) {
    f(i);  // calls f<int&>(int&), i.e., #1
    f(0);  // calls f<int>(int&&), i.e., #2
}
```

— end example

If the parameter-declaration corresponding to P_i is a function parameter pack, then the type of its declarator-id is compared with each remaining parameter type in the parameter-type-list of A. Each comparison deduces template arguments for subsequent positions in the template parameter packs expanded by the function parameter pack. During partial ordering (17.8.2.4), if A_i was originally a function parameter pack:

10.1 — if P does not contain a function parameter type corresponding to A_i then A_i is ignored;

10.2 — otherwise, if P_i is not a function parameter pack, template argument deduction fails.

[Example:

```cpp
template<class T, class... U> void f(T*, U...) { }  // #1
```

```cpp
template<class T> void f(T) { }  // #2
```

```cpp
template void f(int*);  // selects #1
```

— end example

These forms can be used in the same way as T is for further composition of types. [Example:

```cpp
X<int> (*)(char[6])
```

is of the form

```cpp
template-name<T> (*)(type[i])
```

which is a variant of

```cpp
type (*)(T)
```

where type is X<int> and T is char[6]. — end example]

12 Template arguments cannot be deduced from function arguments involving constructs other than the ones specified above.

13 When the value of the argument corresponding to a non-type template parameter P that is declared with a
dependent type is deduced from an expression, the template parameters in the type of \( P \) are deduced from the type of the value. [Example:
\[
\begin{align*}
\text{template<long } n\text{> struct A { };} \\
\text{template<typename } T\text{> struct C;} \\
\text{template<typename } T\text{, } T \ n\text{> struct C<A<n>> {}} \\
&\quad \text{using } Q = T; \\
&\}; \\
\text{using } R = long; \\
\text{using } R = C<A<2>>::Q; &\quad \text{// OK; } T \text{ was deduced to long from the} \\
&\quad \text{// template argument value in the type } A<2> \\
\end{align*}
\]
—end example] The type of \( N \) in the type \( T[N] \) is \texttt{std::size\_t}. [Example:
\[
\begin{align*}
\text{template<typename } T\text{> struct S;} \\
\text{template<typename } T\text{, } T \ n\text{> struct S<int[n]> {}} \\
&\quad \text{using } Q = T; \\
&\}; \\
\text{using } V = decltype(sizeof 0); \\
\text{using } V = S<int[42]>::Q; &\quad \text{// OK; } T \text{ was deduced to std::size\_t from the type int[42]} \\
\end{align*}
\]
—end example]

\[\text{Example:}\]
\[
\begin{align*}
\text{template<class } T\text{, } T \ i\text{> void } f\text{(int } &a)[i]); \\
\text{int } v[10]; \\
\text{void } g() \{ \\
&\quad f(v); &\quad \text{// OK: } T \text{ is std::size\_t} \\
&\}\n\end{align*}
\]
—end example]

\[\text{Note:} \text{ Except for reference and pointer types, a major array bound is not part of a function parameter type}
\text{ and cannot be deduced from an argument:}\]
\[
\begin{align*}
\text{template<int } i\text{> void } f1\text{(int } a[10])[i]); \\
\text{template<int } i\text{> void } f2\text{(int } a[i][20]); \\
\text{template<int } i\text{> void } f3\text{(int } &a)[i][20]); \\
\text{void } g() \{ \\
&\quad \text{int } v[10][20]; \\
&\quad f1(v); &\quad \text{// OK: } i \text{ deduced to be 20} \\
&\quad f1<20>(v); &\quad \text{// OK} \\
&\quad f2(v); &\quad \text{// error: cannot deduce template-argument } i \\
&\quad f2<10>(v); &\quad \text{// OK} \\
&\quad f3(v); &\quad \text{// OK: } i \text{ deduced to be 10} \\
&\}\n\end{align*}
\]
—end note]

\[\text{Note:} \text{ If, in the declaration of a function template with a non-type template parameter, the non-type}
\text{ template parameter is used in a subexpression in the function parameter list, the expression is a non-deduced}
\text{ context as specified above.} \text{ [Example:}\]
\[
\begin{align*}
\text{template <int } i\text{> class A \{ /* ... */ \};} \\
\text{template <int } i\text{> void } g(A<i+i>); \\
\text{template <int } i\text{> void } f(A<i>, A<i+1>); \\
\end{align*}
\]

\[\text{§ 17.8.2.5} \]
void k() {
    A<1> a1;
    A<2> a2;
    g(a1); // error: deduction fails for expression i+1
    g<0>(a1); // OK
    f(a1, a2); // OK
}

—end example] —end note] 17

[Note: Template parameters do not participate in template argument deduction if they are used only in non-deduced contexts. For example,

```cpp
template<int i, typename T>
T deduce(typename A<T>::X x, // T is not deduced here
          T t, // but T is deduced here
typename B<i>::Y y); // i is not deduced here

A<int> a;
B<77> b;

int x = deduce<77>(a.xm, 62, b.ym); // T is deduced to be int, a.xm must be convertible to A<int>::X // i is explicitly specified to be 77, b.ym must be convertible to B<77>::Y

—end note] 18

If \(P\) has a form that contains \(<i>\), and if the type of \(i\) differs from the type of the corresponding template parameter of the template named by the enclosing simple-template-id, deduction fails. If \(P\) has a form that contains \([i]\), and if the type of \(i\) is not an integral type, deduction fails.\[142\] [Example:

```cpp
template<int i> class A { /* ... */ };
template<short s> void f(A<s>);
void k1() {
    A<1> a;
    f(a); // error: deduction fails for conversion from int to short
    f<1>(a); // OK
}

template<const short cs> class B { };
template<short s> void g(B<s>);
void k2() {
    B<1> b;
    g(b); // OK: cv-qualifiers are ignored on template parameter types
}

—end example]

19 A template-argument can be deduced from a function, pointer to function, or pointer to member function type.

[Example:

```cpp
template<class T> void f(void(*)(T,int));
template<class T> void foo(T,int);
void g(int,int);
void g(char,int);

void h(int,int,int);
```

\[142\] Although the template-argument corresponding to a template-parameter of type bool may be deduced from an array bound, the resulting value will always be true because the array bound will be nonzero.

§ 17.8.2.5
void h(char, int);

int m() {
    f(&g);       // error: ambiguous
    f(&h);       // OK: void h(char, int) is a unique match
    f(&foo);     // error: type deduction fails because foo is a template
}

—end example

20 A template type-parameter cannot be deduced from the type of a function default argument. [Example:

    template <class T> void f(T = 5, T = 7);
    void g() {
        f(1);           // OK: call f<int>(1,7)
        f();            // error: cannot deduce T
        f<int>();       // OK: call f<int>(5,7)
    }

—end example

21 The template-argument corresponding to a template template-parameter is deduced from the type of the template-argument of a class template specialization used in the argument list of a function call. [Example:

    template <template <class T> class X> struct A { };  
    template <template <class T> class X> void f(A<X>) { }
    template<class T> struct B { };
    A<B> ab;
    f(ab);     // calls f(A<B>)

—end example

[Note: Template argument deduction involving parameter packs (17.5.3) can deduce zero or more arguments for each parameter pack. —end note] [Example:

    template<class> struct X { };  
    template<class R, class ... ArgTypes> struct X<R(int, ArgTypes ...)>{ };  
    template<class ... Types> struct Y { };  
    template<class T, class ... Types> struct Y<T, Types& ...>{ }; 

    template<class ... Types> int f(void (*)(Types ...));
    void g(int, float);

    X<int> x1;         // uses primary template
    X<int(int, float, double)> x2;   // uses partial specialization; ArgTypes contains float, double
    X<int(float, int)> x3;          // uses primary template
    Y<1> y1;          // uses primary template; Types is empty
    Y<int, float&, double&> y2;    // uses partial specialization; T is int&, Types contains float, double
    Y<int, float, double> y3;      // uses primary template; Types contains int, float, double
    int fv = f(g);     // OK; Types contains int, float

—end example

17.8.2.6 Deducing template arguments from a function declaration [temp.deduct.decl]

1 In a declaration whose declarator-id refers to a specialization of a function template, template argument deduction is performed to identify the specialization to which the declaration refers. Specifically, this is done for explicit instantiations (17.7.2), explicit specializations (17.7.3), and certain friend declarations (17.5.4). This is also done to determine whether a deallocation function template specialization matches a placement operator new (6.7.4.2, 8.3.4). In all these cases, P is the type of the function template being considered as a potential match and A is either the function type from the declaration or the type of the deallocation function that would match the placement operator new as described in 8.3.4. The deduction is done as
described in 17.8.2.5.

If, for the set of function templates so considered, there is either no match or more than one match after partial ordering has been considered (17.5.6.2), deduction fails and, in the declaration cases, the program is ill-formed.

17.8.3 Overload resolution

A function template can be overloaded either by (non-template) functions of its name or by (other) function templates of the same name. When a call to that name is written (explicitly, or implicitly using the operator notation), template argument deduction (17.8.2) and checking of any explicit template arguments (17.3) are performed for each function template to find the template argument values (if any) that can be used with that function template to instantiate a function template specialization that can be invoked with the call arguments. For each function template, if the argument deduction and checking succeeds, the template-arguments (deduced and/or explicit) are used to synthesize the declaration of a single function template specialization which is added to the candidate functions set to be used in overload resolution. If, for a given function template, argument deduction fails or the synthesized function template specialization would be ill-formed, no such function is added to the set of candidate functions for that template. The complete set of candidate functions includes all the synthesized declarations and all of the non-template overloaded functions of the same name. The synthesized declarations are treated like any other functions in the remainder of overload resolution, except as explicitly noted in 16.3.3.143

[Example:

```cpp
template<class T> T max(T a, T b) { return a>b?a:b; }

void f(int a, int b, char c, char d) {
    int m1 = max(a,b); // max(int a, int b)
    char m2 = max(c,d); // max(char a, char b)
    int m3 = max(a,c); // error: cannot generate max(int,char)
}
```

Adding the non-template function

```cpp
int max(int,int);
```

to the example above would resolve the third call, by providing a function that could be called for `max(a,c)` after using the standard conversion of `char` to `int` for `c`. —end example]

[Example: Here is an example involving conversions on a function argument involved in template-argument deduction:

```cpp
template<class T> struct B { /* ... */ };  
template<class T> struct D : public B<T> { /* ... */ };  
template<class T> void f(B<T>&);

g(B<int>& bi, D<int>& di) {
    f(bi); // f(bi)  
    f(di); // f((B<int>&)di)
}
```

—end example]
template<class T> void f(T*, int);  // #1
template<class T> void f(T, char);   // #2

void h(int* pi, int i, char c) {
    f(pi, i);  // #1: f<int>(pi, i)
    f(pi, c);  // #2: f<int*>(pi, c)
    f(i, c);   // #2: f<int>(i, c);
    f(i, i);   // #2: f<int>(i, char(i))
}

—end example]

5 Only the signature of a function template specialization is needed to enter the specialization in a set of candidate functions. Therefore only the function template declaration is needed to resolve a call for which a template specialization is a candidate. [Example:
    template<class T> void f(T);  // declaration
    void g() {
        f("Annemarie");  // call of f<const char*>}
    ]

The call of f is well-formed even if the template f is only declared and not defined at the point of the call. The program will be ill-formed unless a specialization for f<const char*>, either implicitly or explicitly generated, is present in some translation unit. —end example]

17.9 Deduction guides [temp.deduct.guide]

Deduction guides are used when a template-name appears as a type specifier for a deduced class type (10.1.7.5). Deduction guides are not found by name lookup. Instead, when performing class template argument deduction (16.3.1.8), any deduction guides declared for the class template are considered.

deduction-guide:
    explicit_opt template-name ( parameter-declaration-clause ) -> simple-template-id ;

[Example:
    template<class T, class D = int>
    struct S {
        T data;
    };
    template<class U>
    S(U) -> S<typename U::type> ;
    ]

struct A {
    using type = short;
    operator type();
};
S x{A()} ;  // x is of type S<short, int>
—end example]

The same restrictions apply to the parameter-declaration-clause of a deduction guide as in a function declaration (11.3.5). The simple-template-id shall name a class template specialization. The template-name shall be the same identifier as the template-name of the simple-template-id. A deduction-guide shall be declared in the same scope as the corresponding class template and, for a member class template, with the same access. Two deduction guide declarations in the same translation unit for the same class template shall not have equivalent parameter-declaration-clauses.

§ 17.9 423
18 Exception handling

1 Exception handling provides a way of transferring control and information from a point in the execution of a thread to an exception handler associated with a point previously passed by the execution. A handler will be invoked only by throwing an exception in code executed in the handler's try block or in functions called from the handler’s try block.

```plaintext
try-block:
  try compound-statement handler-seq
function-try-block:
  try ctor-initializer_opt compound-statement handler-seq
handler-seq:
  handler handler-seq_opt
handler:
  catch ( exception-declaration ) compound-statement
exception-declaration:
  attribute-specifier-seq_opt type-specifier-seq declarator
  attribute-specifier-seq_opt type-specifier-seq abstract-declarator_opt
  ...
```

The optional attribute-specifier-seq in an exception-declaration appertains to the parameter of the catch clause (18.3).

2 A try-block is a statement (Clause 9). [Note: Within this Clause “try block” is taken to mean both try-block and function-try-block. — end note]

3 A goto or switch statement shall not be used to transfer control into a try block or into a handler. [Example:

```plaintext
void f() {
  goto l1; // ill-formed
  goto l2; // ill-formed
  try {
    goto l1; // OK
    goto l2; // ill-formed
    l1: ;
  } catch (...) {
    l2: ;
    goto l1; // ill-formed
    goto l2; // OK
  }
}
```
— end example] A goto, break, return, or continue statement can be used to transfer control out of a try block or handler. When this happens, each variable declared in the try block will be destroyed in the context that directly contains its declaration. [Example:

```plaintext
lab: try {
  T1 t1;
  try {
    T2 t2;
    if (condition)
      goto lab;
```

Exception handling
Here, executing `goto lab;` will destroy first `t2`, then `t1`, assuming the `condition` does not declare a variable. Any exception thrown while destroying `t2` will result in executing `handler 2`; any exception thrown while destroying `t1` will result in executing `handler 1`. —end example]

4 A `function-try-block` associates a `handler-seq` with the `ctor-initializer`, if present, and the `compound-statement`. An exception thrown during the execution of the `compound-statement` or, for constructors and destructors, during the initialization or destruction, respectively, of the class’s subobjects, transfers control to a handler in a `function-try-block` in the same way as an exception thrown during the execution of a `try-block` transfers control to other handlers. [Example:

```c
int f(int);
class C {
  int i;
  double d;
public:
  C(int, double);
};
C::C(int ii, double id)
try : i(f(ii)), d(id) {
  // constructor statements
} catch (...) {
  // handles exceptions thrown from the ctor-initializer and from the constructor statements
}
—end example]

5 In this section, “before” and “after” refer to the “sequenced before” relation (4.6).

18.1 Throwing an exception [except.throw]

1 Throwing an exception transfers control to a handler. [Note: An exception can be thrown from one of the following contexts: `throw-expressions` (8.17), allocation functions (6.7.4.1), `dynamic_cast` (8.2.7), `typeid` (8.2.8), `new-expressions` (8.3.4), and standard library functions (20.4.1.4). —end note] An object is passed and the type of that object determines which handlers can catch it. [Example:

```c
throw "Help!";
```

can be caught by a `handler` of `const char*` type:

```c
try {
  // ...
} catch(const char* p) {
  // handle character string exceptions here
}
```

and

```c
class Overflow {
public:
  Overflow(char, double, double);
};

void f(double x) {
  throw Overflow('+', x, 3.45e107);
}
```

can be caught by a handler for exceptions of type `Overflow`:

§ 18.1
try {
    f(1.2);
} catch(Overflow & oo) {
    // handle exceptions of type Overflow here
}

—end example

2 When an exception is thrown, control is transferred to the nearest handler with a matching type (18.3); “nearest” means the handler for which the compound-statement or ctor-initializer following the try keyword was most recently entered by the thread of control and not yet exited.

3 Throwing an exception copy-initializes (11.6, 15.8) a temporary object, called the exception object. An lvalue denoting the temporary is used to initialize the variable declared in the matching handler (18.3). If the type of the exception object would be an incomplete type or a pointer to an incomplete type other than cv void the program is ill-formed.

4 The memory for the exception object is allocated in an unspecified way, except as noted in 6.7.4.1. If a handler exits by rethrowing, control is passed to another handler for the same exception object. The points of potential destruction for the exception object are:

   (4.1) — when an active handler for the exception exits by any means other than rethrowing, immediately after the destruction of the object (if any) declared in the exception-declaration in the handler;

   (4.2) — when an object of type std::exception_ptr (21.8.6) that refers to the exception object is destroyed, before the destructor of std::exception_ptr returns.

Among all points of potential destruction for the exception object, there is an unspecified last one where the exception object is destroyed. All other points happen before that last one (4.7.1). [Note: No other thread synchronization is implied in exception handling. — end note] The implementation may then deallocate the memory for the exception object; any such deallocation is done in an unspecified way. [Note: A thrown exception does not propagate to other threads unless caught, stored, and rethrown using appropriate library functions; see 21.8.6 and 33.6. — end note]

5 When the thrown object is a class object, the constructor selected for the copy-initialization as well as the constructor selected for a copy-initialization considering the thrown object as an lvalue shall be non-deleted and accessible, even if the copy/move operation is elided (15.8). The destructor is potentially invoked (15.4).

6 An exception is considered caught when a handler for that exception becomes active (18.3). [Note: An exception can have active handlers and still be considered uncaught if it is rethrown. — end note]

7 If the exception handling mechanism handling an uncaught exception (18.5.2) directly invokes a function that exits via an exception, std::terminate is called (18.5.1). [Example:
18.2 Constructors and destructors

As control passes from the point where an exception is thrown to a handler, destructors are invoked by a process, specified in this section, called stack unwinding.

The destructor is invoked for each automatic object of class type constructed, but not yet destroyed, since the try block was entered. If an exception is thrown during the destruction of temporaries or local variables for a return statement (9.6.3), the destructor for the returned object (if any) is also invoked. The objects are destroyed in the reverse order of the completion of their construction. [Example:

```c
struct A { };
struct Y { ~Y() noexcept(false) { throw 0; } };

A f() {
    try {
        A a;
        Y y;
        A b;
        return {}; // #1
    } catch (...) {
    }
    return {}; // #2
}
```

At #1, the returned object of type `A` is constructed. Then, the local variable `b` is destroyed (9.6). Next, the local variable `y` is destroyed, causing stack unwinding, resulting in the destruction of the returned object, followed by the destruction of the local variable `a`. Finally, the returned object is constructed again at #2. — end example]

If the initialization or destruction of an object other than by delegating constructor is terminated by an exception, the destructor is invoked for each of the object’s direct subobjects and, for a complete object, virtual base class subobjects, whose initialization has completed (11.6) and whose destructor has not yet begun execution, except that in the case of destruction, the variant members of a union-like class are not destroyed. The subobjects are destroyed in the reverse order of the completion of their construction. Such destruction is sequenced before entering a handler of the function-try-block of the constructor or destructor, if any.

If the compound-statement of the function-body of a delegating constructor for an object exits via an exception, the object’s destructor is invoked. Such destruction is sequenced before entering a handler of the function-try-block of a delegating constructor for that object, if any.

If the object was allocated by a new-expression (8.3.4), the matching deallocation function (6.7.4.2), if any, is called to free the storage occupied by the object. — end note]

18.3 Handling an exception

The exception-declaration in a handler describes the type(s) of exceptions that can cause that handler to be entered. The exception-declaration shall not denote an incomplete type, an abstract class type, or an rvalue reference type. The exception-declaration shall not denote a pointer or reference to an incomplete type, other than void*, const void*, volatile void*, or const volatile void*.

A handler of type “array of T” or function type T is adjusted to be of type “pointer to T”.

A handler is a match for an exception object of type E if

---

— end example] [Note: Consequently, destructors should generally catch exceptions and not let them propagate. — end note]
The handler is of type \( cv\ T \) or \( cv\ T& \) and \( E \) and \( T \) are the same type (ignoring the top-level \( cv \)-qualifiers), or

the handler is of type \( cv\ T \) or \( cv\ T& \) and \( T \) is an unambiguous public base class of \( E \), or

the handler is of type \( cv\ T \) or \( const\ T& \) where \( T \) is a pointer or pointer to member type and \( E \) is a pointer or pointer to member type that can be converted to \( T \) by one or more of

a standard pointer conversion (7.11) not involving conversions to pointers to private or protected or ambiguous classes

a function pointer conversion (7.13)

a qualification conversion (7.5), or

the handler is of type \( cv\ T \) or \( const\ T& \) where \( T \) is a pointer or pointer to member type and \( E \) is \( std::nullptr_t \).

[A throw-expression whose operand is an integer literal with value zero does not match a handler of pointer or pointer to member type. A handler of reference to array or function type is never a match for any exception object (8.17). —end note]

Example:

class Matherr { /* ... */ virtual void vf();
};
class Overflow: public Matherr { /* ... */ }
; class Underflow: public Matherr { /* ... */ }
; class Zerodivide: public Matherr { /* ... */ }
;

global void f() {
    try {
        g();
    } catch (Overflow oo) {
        // ...
    } catch (Matherr mm) {
        // ...
    }
}

Here, the Overflow handler will catch exceptions of type Overflow and the Matherr handler will catch exceptions of type Matherr and of all types publicly derived from Matherr including exceptions of type Underflow and Zerodivide. —end example]

The handlers for a try block are tried in order of appearance. [Note: This makes it possible to write handlers that can never be executed, for example by placing a handler for a final derived class after a handler for a corresponding unambiguous public base class. —end note]

A ... in a handler’s exception-declaration functions similarly to ... in a function parameter declaration; it specifies a match for any exception. If present, a ... handler shall be the last handler for its try block.

If no match is found among the handlers for a try block, the search for a matching handler continues in a dynamically surrounding try block of the same thread.

A handler is considered active when initialization is complete for the parameter (if any) of the catch clause. [Note: The stack will have been unwound at that point. —end note] Also, an implicit handler is considered active when \( std::terminate() \) is entered due to a throw. A handler is no longer considered active when the catch clause exits.

The exception with the most recently activated handler that is still active is called the currently handled exception.

If no matching handler is found, the function \( std::terminate() \) is called; whether or not the stack is
unwound before this call to \texttt{std::terminate()} is implementation-defined (18.5.1).

10 Referring to any non-static member or base class of an object in the handler for a \textit{function-try-block} of a constructor or destructor for that object results in undefined behavior.

11 The scope and lifetime of the parameters of a function or constructor extend into the handlers of a \textit{function-try-block}.

12 Exceptions thrown in destructors of objects with static storage duration or in constructors of namespace-scope objects with static storage duration are not caught by a \textit{function-try-block} on the \texttt{main} function (6.6.1). Exceptions thrown in destructors of objects with thread storage duration or in constructors of namespace-scope objects with thread storage duration are not caught by a \textit{function-try-block} on the initial function of the thread.

13 If a return statement appears in a handler of the \textit{function-try-block} of a constructor, the program is ill-formed.

14 The currently handled exception is rethrown if control reaches the end of a handler of the \textit{function-try-block} of a constructor or destructor. Otherwise, flowing off the end of the \textit{compound-statement} of a \textit{handler} of a \textit{function-try-block} is equivalent to flowing off the end of the \textit{compound-statement} of that function (see 9.6.3).

15 The variable declared by the \textit{exception-declaration}, of type \texttt{cv T} or \texttt{cv T&}, is initialized from the exception object, of type \texttt{E}, as follows:

\begin{enumerate}
\item if \texttt{T} is a base class of \texttt{E}, the variable is copy-initialized (11.6) from the corresponding base class subobject of the exception object;
\item otherwise, the variable is copy-initialized (11.6) from the exception object.
\end{enumerate}

The lifetime of the variable ends when the handler exits, after the destruction of any automatic objects initialized within the handler.

16 When the handler declares an object, any changes to that object will not affect the exception object. When the handler declares a reference to an object, any changes to the referenced object are changes to the exception object and will have effect should that object be rethrown.

### 18.4 Exception specifications \[except.spec\]

1 The predicate indicating whether a function cannot exit via an exception is called the \textit{exception specification} of the function. If the predicate is false, the function has a \textit{potentially-throwing exception specification}, otherwise it has a \textit{non-throwing exception specification}. The exception specification is either defined implicitly, or defined explicitly by using a \textit{noexcept-specifier} as a suffix of a function declarator (11.3.5).

\begin{verbatim}
noexcept-specifier:
  noexcept ( constant-expression )
  noexcept
  throw ( )
\end{verbatim}

2 In a \texttt{noexcept-specifier}, the \textit{constant-expression}, if supplied, shall be a contextually converted constant expression of type \texttt{bool} (8.20); that constant expression is the exception specification of the function type in which the \texttt{noexcept-specifier} appears. A ( token that follows \texttt{noexcept} is part of the \texttt{noexcept-specifier} and does not commence an initializer (11.6). The \texttt{noexcept-specifier} \texttt{noexcept} without a \textit{constant-expression} is equivalent to the \texttt{noexcept-specifier} \texttt{noexcept(true)}. The \texttt{noexcept-specifier} \texttt{throw()} is deprecated (D.3), and equivalent to the \texttt{noexcept-specifier} \texttt{noexcept(true)}.

3 If a declaration of a function does not have a \texttt{noexcept-specifier}, the declaration has a potentially throwing exception specification unless it is a destructor or a deallocation function or is defaulted on its first declaration, in which cases the exception specification is as specified below and no other declaration for that function shall have a \texttt{noexcept-specifier}. In an explicit instantiation (17.7.2) a \texttt{noexcept-specifier} may be specified, but is not required. If a \texttt{noexcept-specifier} is specified in an explicit instantiation directive, the exception specification shall be the same as the exception specification of all other declarations of that function. A diagnostic is
required only if the exception specifications are not the same within a single translation unit.

4 If a virtual function has a non-throwing exception specification, all declarations, including the definition, of any function that overrides that virtual function in any derived class shall have a non-throwing exception specification, unless the overriding function is defined as deleted. [Example:

```c
struct B {
    virtual void f() noexcept;
    virtual void g();
    virtual void h() noexcept = delete;
};

struct D: B {
    void f();             // ill-formed
    void g() noexcept;   // OK
    void h() = delete;   // OK
};
```

The declaration of `D::f` is ill-formed because it has a potentially-throwing exception specification, whereas `B::f` has a non-throwing exception specification. —end example]

5 Whenever an exception is thrown and the search for a handler (18.3) encounters the outermost block of a function with a non-throwing exception specification, the function `std::terminate()` is called (18.5.1). [Note: An implementation shall not reject an expression merely because, when executed, it throws or might throw an exception from a function with a non-throwing exception specification. —end note] [Example:

```c
extern void f();         // potentially-throwing

void g() noexcept {
    f();              // valid, even if f throws
    throw 42;         // valid, effectively a call to std::terminate
}
```

The call to `f` is well-formed even though, when called, `f` might throw an exception. —end example]

6 An expression `e` is potentially-throwing if

(6.1) — `e` is a function call (8.2.2) whose postfix-expression has a function type, or a pointer-to-function type, with a potentially-throwing exception specification, or

(6.2) — `e` implicitly invokes a function (such as an overloaded operator, an allocation function in a `new-expression`, a constructor for a function argument, or a deconstructor if `e` is a full-expression (4.6)) that is potentially-throwing, or

(6.3) — `e` is a throw-expression (8.17), or

(6.4) — `e` is a dynamic_cast expression that casts to a reference type and requires a runtime check (8.2.7), or

(6.5) — `e` is a typeid expression applied to a (possibly parenthesized) built-in unary `*` operator applied to a pointer to a polymorphic class type (8.2.8), or

(6.6) — any of the immediate subexpressions (4.6) of `e` is potentially-throwing.

7 An implicitly-declared constructor for a class `X`, or a constructor without a noexcept-specifier that is defaulted on its first declaration, has a potentially-throwing exception specification if and only if any of the following constructs is potentially-throwing:

(7.1) — a constructor selected by overload resolution in the implicit definition of the constructor for class `X` to initialize a potentially constructed subobject, or

(7.2) — a subexpression of such an initialization, such as a default argument expression, or,

(7.3) — for a default constructor, a default member initializer.
[Note: Even though destructors for fully-constructed subobjects are invoked when an exception is thrown during the execution of a constructor (18.2), their exception specifications do not contribute to the exception specification of the constructor, because an exception thrown from such a destructor would call \texttt{std::terminate} rather than escape the constructor (18.1, 18.5.1). — end note]

8 The exception specification for an implicitly-declared destructor, or a destructor without a \texttt{noexcept-specifier}, is potentially-throwing if and only if any of the destructors for any of its potentially constructed subobjects is potentially throwing.

9 The exception specification for an implicitly-declared assignment operator, or an assignment-operator without a \texttt{noexcept-specifier} that is defaulted on its first declaration, is potentially-throwing if and only if the invocation of any assignment operator in the implicit definition is potentially-throwing.

10 A deallocation function (6.7.4.2) with no explicit \texttt{noexcept-specifier} has a non-throwing exception specification.

[Example:

```cpp
struct A {
    A(int = (A(5), 0)) noexcept;
    A(const A&) noexcept;
    A(A&&) noexcept;
    ~A();
};
struct B {
    B() throw();
    B(const B&) = default;  // implicit exception specification is noexcept(true)
    B(B&&, int = (throw Y(), 0)) noexcept;
    ~B() noexcept(false);
};
struct D : public A, public B {
    int * p = new int[n];
    // D::D() potentially-throwing, as the new operator may throw bad_alloc or bad_array_new_length
    // D::D(const D&) non-throwing
    // D::D(D&&) potentially-throwing, as the default argument for B’s constructor may throw
    // D::D() potentially-throwing
};
```

Furthermore, if \texttt{A::~A()} were virtual, the program would be ill-formed since a function that overrides a virtual function from a base class shall not have a potentially-throwing exception specification if the base class function has a non-throwing exception specification. — end example]

12 An exception specification is considered to be \texttt{needed} when:

(12.1) — in an expression, the function is the unique lookup result or the selected member of a set of overloaded functions (6.4, 16.3, 16.4);

(12.2) — the function is odr-used (6.2) or, if it appears in an unevaluated operand, would be odr-used if the expression were potentially-evaluated;

(12.3) — the exception specification is compared to that of another declaration (e.g., an explicit specialization or an overriding virtual function);

(12.4) — the function is defined; or

(12.5) — the exception specification is needed for a defaulted special member function that calls the function. [Note: A defaulted declaration does not require the exception specification of a base member function to be evaluated until the implicit exception specification of the derived function is needed, but an explicit \texttt{noexcept-specifier} needs the implicit exception specification to compare against. — end note]

§ 18.4
The exception specification of a defaulted special member function is evaluated as described above only when needed; similarly, the `noexcept-specifier` of a specialization of a function template or member function of a class template is instantiated only when needed.

18.5 Special functions

The function `std::terminate()` (18.5.1) is used by the exception handling mechanism for coping with errors related to the exception handling mechanism itself. The function `std::current_exception()` (21.8.6) and the class `std::nested_exception` (21.8.7) can be used by a program to capture the currently handled exception.

18.5.1 The `std::terminate()` function

In some situations exception handling must be abandoned for less subtle error handling techniques. [Note: These situations are:

1. when the exception handling mechanism, after completing the initialization of the exception object but before activation of a handler for the exception (18.1), calls a function that exits via an exception, or
2. when the exception handling mechanism cannot find a handler for a thrown exception (18.3), or
3. when the search for a handler (18.3) encounters the outermost block of a function with a non-throwing exception specification (18.4), or
4. when the destruction of an object during stack unwinding (18.2) terminates by throwing an exception, or
5. when initialization of a non-local variable with static or thread storage duration (6.6.3) exits via an exception, or
6. when destruction of an object with static or thread storage duration exits via an exception (6.6.4), or
7. when execution of a function registered with `std::atexit` or `std::at_quick_exit` exits via an exception (21.5), or
8. when a `throw-expression` (8.17) with no operand attempts to rethrow an exception and no exception is being handled (18.1), or
9. when the function `std::nested_exception::rethrow_nested` is called for an object that has captured no exception (21.8.7), or
10. when execution of the initial function of a thread exits via an exception (33.3.2.2), or
11. for a parallel algorithm whose `ExecutionPolicy` specifies such behavior (23.19.4, 23.19.5, 23.19.6), when execution of an element access function (28.4.1) of the parallel algorithm exits via an exception (28.4.4), or
12. when the destructor or the copy assignment operator is invoked on an object of type `std::thread` that refers to a joinable thread (33.3.2.3, 33.3.2.4), or
13. when a call to a `wait()`, `wait_until()`, or `wait_for()` function on a condition variable (33.5.3, 33.5.4) fails to meet a postcondition.]

In such cases, `std::terminate()` is called (21.8.4). In the situation where no matching handler is found, it is implementation-defined whether or not the stack is unwound before `std::terminate()` is called. In the situation where the search for a handler (18.3) encounters the outermost block of a function with a non-throwing exception specification (18.4), it is implementation-defined whether the stack is unwound, unwound partially, or not unwound at all before `std::terminate()` is called. In all other situations, the stack shall not be unwound before `std::terminate()` is called. An implementation is not permitted to finish
stack unwinding prematurely based on a determination that the unwind process will eventually cause a call to `std::terminate()`.

### 18.5.2 The `std::uncaught_exceptions()` function

An exception is considered uncaught after completing the initialization of the exception object (18.1) until completing the activation of a handler for the exception (18.3). This includes stack unwinding. If an exception is rethrown (8.17, 21.8.6), it is considered uncaught from the point of rethrow until the rethrown exception is caught. The function `std::uncaught_exceptions()` (21.8.5) returns the number of uncaught exceptions in the current thread.
19 Preprocessing directives

A preprocessing directive consists of a sequence of preprocessing tokens that satisfies the following constraints: The first token in the sequence is a # preprocessing token that (at the start of translation phase 4) is either the first character in the source file (optionally after white space containing no new-line characters) or that follows white space containing at least one new-line character. The last token in the sequence is the first new-line character that follows the first token in the sequence. A new-line character ends the preprocessing directive even if it occurs within what would otherwise be an invocation of a function-like macro.

preprocessing-file:
  group_{opt}

  group:  
  group-part
    group
    group-part

  group-part:
    control-line
    if-section
    text-line
    # conditionally-supported-directive

control-line:
  # include pp-tokens new-line
  # define identifier replacement-list new-line
  # define identifier (paren identifier-list_{opt}) replacement-list new-line
  # define identifier (paren ... ) replacement-list new-line
  # define identifier (paren identifier-list, ... ) replacement-list new-line
  # undef identifier new-line
  # line pp-tokens new-line
  # error pp-tokens_{opt} new-line
  # pragma pp-tokens_{opt} new-line
  # new-line

if-section:
  if-group elif-groups_{opt} else-group_{opt} endif-line

if-group:
  # if constant-expression new-line group_{opt}
  # ifdef identifier new-line group_{opt}
  # ifndef identifier new-line group_{opt}

elif-groups:
  elif-group
  elif-groups elif-group

elif-group:
  # elif constant-expression new-line group_{opt}

else-group:
  # else new-line group_{opt}

144) Thus, preprocessing directives are commonly called “lines”. These “lines” have no other syntactic significance, as all white space is equivalent except in certain situations during preprocessing (see the # character string literal creation operator in 19.3.2, for example).
A text line shall not begin with a # preprocessing token. A conditionally-supported-directive shall not begin with any of the directive names appearing in the syntax. A conditionally-supported-directive is conditionally-supported with implementation-defined semantics.

When in a group that is skipped (19.1), the directive syntax is relaxed to allow any sequence of preprocessing tokens to occur between the directive name and the following new-line character.

The only white-space characters that shall appear between preprocessing tokens within a preprocessing directive (from just after the introducing # preprocessing token through just before the terminating new-line character) are space and horizontal-tab (including spaces that have replaced comments or possibly other white-space characters in translation phase 3).

The implementation can process and skip sections of source files conditionally, include other source files, and replace macros. These capabilities are called preprocessing, because conceptually they occur before translation of the resulting translation unit.

The preprocessing tokens within a preprocessing directive are not subject to macro expansion unless otherwise stated.

[Example: In:
```c
#define EMPTY
EMPTY # include <file.h>
```
the sequence of preprocessing tokens on the second line is not a preprocessing directive, because it does not begin with a # at the start of translation phase 4, even though it will do so after the macro EMPTY has been replaced. —end example]

19.1 Conditional inclusion

defined-macro-expression:
defined identifier
defined ( identifier )

h-preprocessing-token:
any preprocessing-token other than >
h-pp-tokens:
  h-preprocessing-token
h-pp-tokens h-preprocessing-token

has-include-expression:
  __has_include ( < h-char-sequence > )
  __has_include ( " q-char-sequence " )
  __has_include ( string-literal )
  __has_include ( < h-pp-tokens > )

1 The expression that controls conditional inclusion shall be an integral constant expression except that identifiers (including those lexically identical to keywords) are interpreted as described below and it may contain zero or more defined-macro-expressions and/or has-include-expressions as unary operator expressions.

2 A defined-macro-expression evaluates to 1 if the identifier is currently defined as a macro name (that is, if it is predefined or if it has been the subject of a #define preprocessing directive without an intervening #undef directive with the same subject identifier), 0 if it is not.

3 The third and fourth forms of has-include-expression are considered only if neither of the first or second forms matches, in which case the preprocessing tokens are processed just as in normal text.

4 The header or source file identified by the parenthesized preprocessing token sequence in each contained has-include-expression is searched for as if that preprocessing token sequence were the pp-tokens in a #include directive, except that no further macro expansion is performed. If such a directive would not satisfy the syntactic requirements of a #include directive, the program is ill-formed. The has-include-expression evaluates to 1 if the search for the source file succeeds, and to 0 if the search fails.

5 The #ifdef and ifndef directives, and the defined conditional inclusion operator, shall treat __has_include as if it were the name of a defined macro. The identifier __has_include shall not appear in any context not mentioned in this section.

6 Each preprocessing token that remains (in the list of preprocessing tokens that will become the controlling expression) after all macro replacements have occurred shall be in the lexical form of a token (5.6).

7 Preprocessing directives of the forms

   # if     constant-expression new-line groupopt
   # elif   constant-expression new-line groupopt

check whether the controlling constant expression evaluates to nonzero.

8 Prior to evaluation, macro invocations in the list of preprocessing tokens that will become the controlling constant expression are replaced (except for those macro names modified by the defined unary operator), just as in normal text. If the token defined is generated as a result of this replacement process or use of the defined unary operator does not match one of the two specified forms prior to macro replacement, the behavior is undefined.

9 After all replacements due to macro expansion and evaluations of defined-macro-expressions and has-include-expressions have been performed, all remaining identifiers and keywords, except for true and false, are replaced with the pp-number 0, and then each preprocessing token is converted into a token. [Note: An alternative token (5.5) is not an identifier, even when its spelling consists entirely of letters and underscores. Therefore it is not subject to this replacement. — end note]

10 The resulting tokens comprise the controlling constant expression which is evaluated according to the rules of 8.20 using arithmetic that has at least the ranges specified in 21.3. For the purposes of this token conversion and evaluation all signed and unsigned integer types act as if they have the same representation as, respectively, intmax_t or uintmax_t (21.4). [Note: Thus on an implementation where std::numeric_
limits<int>::max() is 0x7FFF and std::numeric_limits<unsigned int>::max() is 0xFFFF, the integer literal 0x8000 is signed and positive within a #if expression even though it is unsigned in translation phase 7 (5.2). —end note] This includes interpreting character literals, which may involve converting escape sequences into execution character set members. Whether the numeric value for these character literals matches the value obtained when an identical character literal occurs in an expression (other than within a #if or #elif directive) is implementation-defined. [Note: Thus, the constant expression in the following #if directive and if statement is not guaranteed to evaluate to the same value in these two contexts:

```c
#if 'z' - 'a' == 25
if ('z' - 'a' == 25)
```

—end note] Also, whether a single-character character literal may have a negative value is implementation-defined. Each subexpression with type bool is subjected to integral promotion before processing continues.

11 Preprocessing directives of the forms

```
#define ifdef   identifier new-line group_opt
#define ifndef  identifier new-line group_opt
```

check whether the identifier is or is not currently defined as a macro name. Their conditions are equivalent to #if defined identifier and #if !defined identifier respectively.

12 Each directive’s condition is checked in order. If it evaluates to false (zero), the group that it controls is skipped: directives are processed only through the name that determines the directive in order to keep track of the level of nested conditionals; the rest of the directives’ preprocessing tokens are ignored, as are the other preprocessing tokens in the group. Only the first group whose control condition evaluates to true (nonzero) is processed; any following groups are skipped and their controlling directives are processed as if they were in a group that is skipped. If none of the conditions evaluates to true, and there is a #else directive, the group controlled by the #else is processed; lacking a #else directive, all the groups until the #endif are skipped.¹⁴⁶

[Example: This demonstrates a way to include a library optional facility only if it is available:

```
#include <optional>
#include <experimental/optional>
```

—end example]

19.2 Source file inclusion [cpp.include]

1 A #include directive shall identify a header or source file that can be processed by the implementation.

2 A preprocessing directive of the form

```
#include <h-char-sequence> new-line
```

searches a sequence of implementation-defined places for a header identified uniquely by the specified sequence between the < and > delimiters, and causes the replacement of that directive by the entire contents of the header. How the places are specified or the header identified is implementation-defined.

3 A preprocessing directive of the form

¹⁴⁶ As indicated by the syntax, a preprocessing token shall not follow a #else or #endif directive before the terminating new-line character. However, comments may appear anywhere in a source file, including within a preprocessing directive.
# include "q-char-sequence " new-line
causes the replacement of that directive by the entire contents of the source file identified by the specified sequence between the " delimiters. The named source file is searched for in an implementation-defined manner. If this search is not supported, or if the search fails, the directive is reprocessed as if it read

# include < h-char-sequence > new-line
with the identical contained sequence (including > characters, if any) from the original directive.

4 A preprocessing directive of the form

# include pp-tokens new-line
(that does not match one of the two previous forms) is permitted. The preprocessing tokens after include in the directive are processed just as in normal text (i.e., each identifier currently defined as a macro name is replaced by its replacement list of preprocessing tokens). If the directive resulting after all replacements does not match one of the two previous forms, the behavior is undefined.147 The method by which a sequence of preprocessing tokens between a < and a > preprocessing token pair or a pair of " characters is combined into a single header name preprocessing token is implementation-defined.

5 The implementation shall provide unique mappings for sequences consisting of one or more nondigits or digits (5.10) followed by a period (.) and a single nondigit. The first character shall not be a digit. The implementation may ignore distinctions of alphabetical case.

6 A #include preprocessing directive may appear in a source file that has been read because of a #include directive in another file, up to an implementation-defined nesting limit.

7 [Note: Although an implementation may provide a mechanism for making arbitrary source files available to the < > search, in general programmers should use the < > form for headers provided with the implementation, and the " " form for sources outside the control of the implementation. For instance:

```c
#include <stdio.h>
#include <unistd.h>
#include "usefullib.h"
#include "myprog.h"
```
—end note]

8 [Example: This illustrates macro-replaced #include directives:

```c
#if VERSION == 1
  #define INCFILE "vers1.h"
#elif VERSION == 2
  #define INCFILE "vers2.h"  // and so on
#else
  #define INCFILE "versN.h"
#endif
#include INCFILE
— end example]
```

19.3 Macro replacement [cpp.replace]

1 Two replacement lists are identical if and only if the preprocessing tokens in both have the same number, ordering, spelling, and white-space separation, where all white-space separations are considered identical.

2 An identifier currently defined as an object-like macro (see below) may be redefined by another #define preprocessing directive provided that the second definition is an object-like macro definition and the two replacement lists are identical, otherwise the program is ill-formed. Likewise, an identifier currently defined as

147) Note that adjacent string literals are not concatenated into a single string literal (see the translation phases in 5.2); thus, an expansion that results in two string literals is an invalid directive.
a function-like macro (see below) may be redefined by another \texttt{#define} preprocessing directive provided that the second definition is a function-like macro definition that has the same number and spelling of parameters, and the two replacement lists are identical, otherwise the program is ill-formed.

3 There shall be white-space between the identifier and the replacement list in the definition of an object-like macro.

4 If the \texttt{identifier-list} in the macro definition does not end with an ellipsis, the number of arguments (including those arguments consisting of no preprocessing tokens) in an invocation of a function-like macro shall equal the number of parameters in the macro definition. Otherwise, there shall be more arguments in the invocation than there are parameters in the macro definition (excluding the \ldots). There shall exist a \texttt{)} preprocessing token that terminates the invocation.

5 The identifier \texttt{\_\_VA_ARGS\_\_} shall occur only in the \texttt{replacement-list} of a function-like macro that uses the ellipsis notation in the parameters.

6 A parameter identifier in a function-like macro shall be uniquely declared within its scope.

7 The identifier immediately following the \texttt{define} is called the \texttt{macro name}. There is one name space for macro names. Any white-space characters preceding or following the replacement list of preprocessing tokens are not considered part of the replacement list for either form of macro.

8 If a \texttt{#} preprocessing token, followed by an identifier, occurs lexically at the point at which a preprocessing directive could begin, the identifier is not subject to macro replacement.

9 A preprocessing directive of the form

\begin{verbatim}
# define identifier replacement-list new-line
\end{verbatim}

defines an \texttt{object-like macro} that causes each subsequent instance of the macro name\textsuperscript{148} to be replaced by the replacement list of preprocessing tokens that constitute the remainder of the directive.\textsuperscript{149} The replacement list is then rescanned for more macro names as specified below.

10 A preprocessing directive of the form

\begin{verbatim}
# define identifier lparen identifier-list opt ) replacement-list new-line
# define identifier lparen ... ) replacement-list new-line
# define identifier lparen identifier-list , ... ) replacement-list new-line
\end{verbatim}

defines a \texttt{function-like macro} with parameters, whose use is similar syntactically to a function call. The parameters are specified by the optional list of identifiers, whose scope extends from their declaration in the identifier list until the new-line character that terminates the \texttt{#define} preprocessing directive. Each subsequent instance of the function-like macro name followed by a \texttt{(} as the next preprocessing token introduces the sequence of preprocessing tokens that is replaced by the replacement list in the definition (an invocation of the macro). The replaced sequence of preprocessing tokens is terminated by the matching \texttt{)} preprocessing token, skipping intervening matched pairs of left and right parenthesis preprocessing tokens. Within the sequence of preprocessing tokens making up an invocation of a function-like macro, new-line is considered a normal white-space character.

The sequence of preprocessing tokens bounded by the outside-most matching parentheses forms the list of arguments for the function-like macro. The individual arguments within the list are separated by comma preprocessing tokens, but comma preprocessing tokens between matching inner parentheses do not separate arguments. If there are sequences of preprocessing tokens within the list of arguments that would otherwise act as preprocessing directives,\textsuperscript{150} the behavior is undefined.

\textsuperscript{148) Since, by macro-replacement time, all character literals and string literals are preprocessing tokens, not sequences possibly containing identifier-like subsequences (see 5.2, translation phases), they are never scanned for macro names or parameters.}
\textsuperscript{149) An alternative token (5.5) is not an identifier, even when its spelling consists entirely of letters and underscores. Therefore it is not possible to define a macro whose name is the same as that of an alternative token.}
\textsuperscript{150) A \texttt{conditionally-supported-directive} is a preprocessing directive regardless of whether the implementation supports it.}
If there is a . . . immediately preceding the ) in the function-like macro definition, then the trailing arguments, including any separating comma preprocessor tokens, are merged to form a single item: the variable arguments. The number of arguments so combined is such that, following merger, the number of arguments is one more than the number of parameters in the macro definition (excluding the . . .).

19.3.1 Argument substitution

After the arguments for the invocation of a function-like macro have been identified, argument substitution takes place. A parameter in the replacement list, unless preceded by a # or ## preprocessor token or followed by a ## preprocessor token (see below), is replaced by the corresponding argument after all macros contained therein have been expanded. Before being substituted, each argument’s preprocessor tokens are completely macro replaced as if they formed the rest of the preprocessor file; no other preprocessor tokens are available.

An identifier __VA_ARGS__ that occurs in the replacement list shall be treated as if it were a parameter, and the variable arguments shall form the preprocessor tokens used to replace it.

19.3.2 The # operator

Each # preprocessor token in the replacement list for a function-like macro shall be followed by a parameter as the next preprocessor token in the replacement list.

A character string literal is a string-literal with no prefix. If, in the replacement list, a parameter is immediately preceded by a # preprocessor token, both are replaced by a single character string literal preprocessing token that contains the spelling of the preprocessor token sequence for the corresponding argument. Each occurrence of white space between the argument’s preprocessor tokens becomes a single space character in the character string literal. White space before the first preprocessor token and after the last preprocessor token comprising the argument is deleted. Otherwise, the original spelling of each preprocessor token in the argument is retained in the character string literal, except for special handling for producing the spelling of string literals and character literals: a \ character is inserted before each " and \ character of a character literal or string literal (including the delimiting " characters). If the replacement that results is not a valid character string literal, the behavior is undefined. The character string literal corresponding to an empty argument is "". The order of evaluation of # and ## operators is unspecified.

19.3.3 The ## operator

A ## preprocessor token shall not occur at the beginning or at the end of a replacement list for either form of macro definition.

If, in the replacement list of a function-like macro, a parameter is immediately preceded or followed by a ## preprocessor token, the parameter is replaced by the corresponding argument’s preprocessor token sequence; however, if an argument consists of no preprocessor tokens, the parameter is replaced by a placemarker preprocessor token instead.\[151\]

For both object-like and function-like macro invocations, before the replacement list is reexamined for more macro names to replace, each instance of a ## preprocessor token in the replacement list (not from an argument) is deleted and the preceding preprocessor token is concatenated with the following preprocessor token. Placemarker preprocessor tokens are handled specially: concatenation of two placemarkers results in a single placemarker preprocessing token, and concatenation of a placemarker with a non-placemarker preprocessing token results in the non-placemarker preprocessor token. If the result is not a valid preprocessor token, the behavior is undefined. The resulting token is available for further macro replacement. The order of evaluation of ## operators is unspecified.

[Example: In the following fragment:

#define hash_hash # ## #

\[151\] Placemarker preprocessor tokens do not appear in the syntax because they are temporary entities that exist only within translation phase 4.

§ 19.3.3
### 19.3.4 Rescanning and further replacement

After all parameters in the replacement list have been substituted and # and ## processing has taken place, all placemarker preprocessing tokens are removed. Then the resulting preprocessing token sequence is rescanned, along with all subsequent preprocessing tokens of the source file, for more macro names to replace.

If the name of the macro being replaced is found during this scan of the replacement list (not including the rest of the source file's preprocessing tokens), it is not replaced. Furthermore, if any nested replacements encounter the name of the macro being replaced, it is not replaced. These nonreplaced macro name preprocessing tokens are no longer available for further replacement even if they are later (re)examined in contexts in which that macro name preprocessing token would otherwise have been replaced.

The resulting completely macro-replaced preprocessing token sequence is not processed as a preprocessing directive even if it resembles one, but all pragma unary operator expressions within it are then processed as specified in 19.9 below.

### 19.3.5 Scope of macro definitions

A macro definition lasts (independent of block structure) until a corresponding `#undef` directive is encountered or (if none is encountered) until the end of the translation unit. Macro definitions have no significance after translation phase 4.

A preprocessing directive of the form

```plaintext
#define mkstr(a) # a
#define in_between(a) mkstr(a)
#define join(c, d) in_between(c hash_hash d)
char p[] = join(x, y); // equivalent to char p[] = "x ## y";
```

The expansion produces, at various stages:

```plaintext
join(x, y)
in_between(x hash_hash y)
in_between(x ## y)
mkstr(x ## y)
"x ## y"
```

In other words, expanding `hash_hash` produces a new token, consisting of two adjacent sharp signs, but this new token is not the `##` operator. — end example]
# define x 3
#define f(a) f(x * (a))
#undef x
#define x 2
#define g f
#define z z[0]
#define h g(\~
#define m(a) a(w)
#define w 0,1
#define t(a) a
#define p() int
#define q(x) x
#define r(x,y) x ## y
#define str(x) # x

f(y+1) + f(f(z)) % t(t(g)(0) + t)(1);
g(x+(3,4)-w) | h 5) & m
(f)^m(m);
p() i[q()] = { q(1), r(2,3), r(4,), r(5), r(,) }
char c[2][6] = { str(hello), str() };
results in
f(2 * (y+1)) + f(2 * (f(2 * (z[0])))) % f(2 * (0)) + t(1);
f(2 * (2+(3,4)-0,1)) | f(2 * (\~ 5)) & f(2 * (0,1))\~m(0,1);
int i[] = { 1, 23, 4, 5, };
char c[2][6] = { "hello", "" };
— end example]

Example: To illustrate the rules for creating character string literals and concatenating tokens, the sequence
#define str(s) # s
#define xstr(s) str(s)
#define debug(s, t) printf("x" # s "= %d, x" # t "= %s", \n x ## s, x ## t)
#define INCFILE(n) vers ## n
#define glue(a, b) a ## b
#define xglue(a, b) glue(a, b)
#define HIGHLOW "hello"
#define LOW LOW ", world"

debu(1, 2);
fputs(str(strncmp("abc\0d", "abc", '\4') == 0) str: (\0\n), s);  // this goes away
#include xstr(INCFILE(2).h)
glue(HIGH, LOW);  
xglue(HIGH, LOW)

results in
printf("x" "1" "= %d, x" "2" "= %s", x1, x2);
fputs("strncpy("abc\0d", "abc", '\4') == 0" ": \0\n", s);
#include "vers2.h"  (after macro replacement, before file access)
"hello";
"hello" ", world"
or, after concatenation of the character string literals,
printf("x1= %d, x2= %s", x1, x2);
7 [Example: To illustrate the rules for placemarker preprocessing tokens, the sequence

```
#define t(x,y,z) x ## y ## z
int j[] = { t(1,2,3), t(4,5), t(6,7), t(8,9),
           t(10,), t(11,), t(,,12), t(,) );
```

results in

```
int j[] = { 123, 45, 67, 89,
          10, 11, 12, };
```

—end example]

8 [Example: To demonstrate the redefinition rules, the following sequence is valid.

```
#define OBJ_LIKE (1-1)
#define OBJ_LIKE /* white space */ (1-1) /* other */
#define FUNC_LIKE(a) ( a )
#define FUNC_LIKE(a)( /* note the white space */
                       a /* other stuff on this line */
                      )
```

But the following redefinitions are invalid:

```
#define OBJ_LIKE (0)                     // different token sequence
#define OBJ_LIKE (1 - 1)                 // different white space
#define FUNC_LIKE(b) ( a )               // different parameter usage
#define FUNC_LIKE(b) ( b )                // different parameter spelling
```

—end example]

9 [Example: Finally, to show the variable argument list macro facilities:

```
#define debug(...) fprintf(stderr, __VA_ARGS__)
#define showlist(...) puts(#__VA_ARGS__)
#define report(test, ...) ((test) ? puts(#test) : printf(__VA_ARGS__))
debug("Flag");
showlist(The first, second, and third items.);
report(x>y, "x is %d but y is %d", x, y);
```

results in

```
fprintf(stderr, "Flag");
puts("The first, second, and third items.");
(x>y) ? puts("x>y") : printf("x is %d but y is %d", x, y));
```

—end example]

19.4 Line control

The string literal of a #line directive, if present, shall be a character string literal.

The line number of the current source line is one greater than the number of new-line characters read or
introduced in translation phase 1 (5.2) while processing the source file to the current token.

A preprocessing directive of the form
# line digit-sequence new-line
causes the implementation to behave as if the following sequence of source lines begins with a source line that
has a line number as specified by the digit sequence (interpreted as a decimal integer). If the digit sequence
specifies zero or a number greater than 2147483647, the behavior is undefined.

4 A preprocessing directive of the form

    # line digit-sequence " s-char-sequence opt " new-line

sets the presumed line number similarly and changes the presumed name of the source file to be the contents
of the character string literal.

5 A preprocessing directive of the form

    # line pp-tokens new-line

(that does not match one of the two previous forms) is permitted. The preprocessing tokens after line on the
directive are processed just as in normal text (each identifier currently defined as a macro name is replaced by
its replacement list of preprocessing tokens). If the directive resulting after all replacements does not match
one of the two previous forms, the behavior is undefined; otherwise, the result is processed as appropriate.

19.5 Error directive

1 A preprocessing directive of the form

    # error pp-tokens opt new-line

causes the implementation to produce a diagnostic message that includes the specified sequence of preprocessing
tokens, and renders the program ill-formed.

19.6 Pragma directive

1 A preprocessing directive of the form

    # pragma pp-tokens opt new-line

causes the implementation to behave in an implementation-defined manner. The behavior might cause
translation to fail or cause the translator or the resulting program to behave in a non-conforming manner.
Any pragma that is not recognized by the implementation is ignored.

19.7 Null directive

1 A preprocessing directive of the form

    # new-line

has no effect.

19.8 Predefined macro names

1 The following macro names shall be defined by the implementation:

    __cplusplus
    The integer literal 201703L.\textsuperscript{152}

    __DATE__
    The date of translation of the source file: a character string literal of the form "Mmm dd yyyy", where
    the names of the months are the same as those generated by the \texttt{asctime} function, and the first
    character of \texttt{dd} is a space character if the value is less than 10. If the date of translation is not available,
    an implementation-defined valid date shall be supplied.

\textsuperscript{152} It is intended that future versions of this International Standard will replace the value of this macro with a greater value.
Non-conforming compilers should use a value with at most five decimal digits.

§ 19.8
__FILE__
The presumed name of the current source file (a character string literal).\footnote{The presumed source file name can be changed by the \texttt{#line} directive.}

__LINE__
The presumed line number (within the current source file) of the current source line (an integer literal).\footnote{The presumed line number can be changed by the \texttt{#line} directive.}

__STDC_HOSTED__
The integer literal 1 if the implementation is a hosted implementation or the integer literal 0 if it is not.

__STDCPP_DEFAULT_NEW_ALIGNMENT__
An integer literal of type \texttt{std::size\_t} whose value is the alignment guaranteed by a call to \texttt{operator new(std::size\_t)\texttt{or operator new[]} (std::size\_t)}. [Note: Larger alignments will be passed to \texttt{operator new(std::size\_t, std::align\_val\_t)}, etc. (8.3.4). — end note]

__TIME__
The time of translation of the source file: a character string literal of the form "hh:mm:ss" as in the time generated by the \texttt{asctime} function. If the time of translation is not available, an implementation-defined valid time shall be supplied.

The following macro names are conditionally defined by the implementation:

__STDC__
Whether \texttt{__STDC__} is predefined and if so, what its value is, are implementation-defined.

__STDC_MB_MIGHT_NEQ_WC__
The integer literal 1, intended to indicate that, in the encoding for \texttt{wchar\_t}, a member of the basic character set need not have a code value equal to its value when used as the lone character in an ordinary character literal.

__STDC_VERSION__
Whether \texttt{__STDC_VERSION__} is predefined and if so, what its value is, are implementation-defined.

__STDC_ISO_10646__
An integer literal of the form \texttt{yyyymmL} (for example, \texttt{199712L}). If this symbol is defined, then every character in the Unicode required set, when stored in an object of type \texttt{wchar\_t}, has the same value as the short identifier of that character. The \textit{Unicode required set} consists of all the characters that are defined by ISO/IEC 10646, along with all amendments and technical corrigenda as of the specified year and month.

__STDCPP_STRICT_POINTER_SAFETY__
Defined, and has the value integer literal 1, if and only if the implementation has strict pointer safety (6.7.4.3).

__STDCPP_THREADS__
Defined, and has the value integer literal 1, if and only if a program can have more than one thread of execution (4.7).

The values of the predefined macros (except for \texttt{__FILE__} and \texttt{__LINE__}) remain constant throughout the translation unit.

If any of the pre-defined macro names in this subclause, or the identifier \texttt{defined}, is the subject of a \texttt{#define} or a \texttt{#undef} preprocessing directive, the behavior is undefined. Any other predefined macro names shall begin with a leading underscore followed by an uppercase letter or a second underscore.
Pragma operator

A unary operator expression of the form:

```
Pragma ( string-literal )
```

is processed as follows: The string literal is *destringized* by deleting the `L` prefix, if present, deleting the leading and trailing double-quotes, replacing each escape sequence `\"` by a double-quote, and replacing each escape sequence `\` by a single backslash. The resulting sequence of characters is processed through translation phase 3 to produce preprocessing tokens that are executed as if they were the *pp-tokens* in a pragma directive. The original four preprocessing tokens in the unary operator expression are removed.

### Example:

```
#pragma listing on "..\listing.dir"
```

can also be expressed as:

```
Pragma ( "listing on \"..\listing.dir\"" )
```

The latter form is processed in the same way whether it appears literally as shown, or results from macro replacement, as in:

```
#define LISTING(x) PRAGMA(listing on #x)
#define PRAGMA(x) _Pragma(#x)

LISTING( ..\listing.dir )
```

— *end example*}
Chapter 20

Library introduction

20.1 General

This Clause describes the contents of the C++ standard library, how a well-formed C++ program makes use of the library, and how a conforming implementation may provide the entities in the library.

The following subclauses describe the definitions (20.3), method of description (20.4), and organization (20.5.1) of the library. Clause 20.5, Clauses 21 through 33, and Annex D specify the contents of the library, as well as library requirements and constraints on both well-formed C++ programs and conforming implementations.

Detailed specifications for each of the components in the library are in Clauses 21–33, as shown in Table 15.

Table 15 — Library categories

<table>
<thead>
<tr>
<th>Clause</th>
<th>Category</th>

</tr>
</tbody>
</table>

The language support library (Clause 21) provides components that are required by certain parts of the C++ language, such as memory allocation (8.3.4, 8.3.5) and exception processing (Clause 18).

The diagnostics library (Clause 22) provides a consistent framework for reporting errors in a C++ program, including predefined exception classes.

The general utilities library (Clause 23) includes components used by other library elements, such as a predefined storage allocator for dynamic storage management (6.7.4), and components used as infrastructure in C++ programs, such as tuples, function wrappers, and time facilities.

The strings library (Clause 24) provides support for manipulating text represented as sequences of type char, sequences of type char16_t, sequences of type char32_t, sequences of type wchar_t, and sequences of any other character-like type.

The localization library (Clause 25) provides extended internationalization support for text processing.

The containers (Clause 26), iterators (Clause 27), and algorithms (Clause 28) libraries provide a C++ program with access to a subset of the most widely used algorithms and data structures.

The numerics library (Clause 29) provides numeric algorithms and complex number components that extend support for numeric processing. The valarray component provides support for n-at-a-time processing, potentially implemented as parallel operations on platforms that support such processing.

The random
number component provides facilities for generating pseudo-random numbers.

11 The input/output library (Clause 30) provides the `iostream` components that are the primary mechanism for C++ program input and output. They can be used with other elements of the library, particularly strings, locales, and iterators.

12 The regular expressions library (Clause 31) provides regular expression matching and searching.

13 The atomic operations library (Clause 32) allows more fine-grained concurrent access to shared data than is possible with locks.

14 The thread support library (Clause 33) provides components to create and manage threads, including mutual exclusion and interthread communication.

### 20.2 The C standard library

The C++ standard library also makes available the facilities of the C standard library, suitably adjusted to ensure static type safety.

1 The descriptions of many library functions rely on the C standard library for the semantics of those functions. In some cases, the signatures specified in this International Standard may be different from the signatures in the C standard library, and additional overloads may be declared in this International Standard, but the behavior and the preconditions (including any preconditions implied by the use of an ISO C `restrict` qualifier) are the same unless otherwise stated.

### 20.3 Definitions

[Note: Clause 3 defines additional terms used elsewhere in this International Standard. — end note]

#### 20.3.1 arbitrary-positional stream

a stream (described in Clause 30) that can seek to any integral position within the length of the stream

[Note: Every arbitrary-positional stream is also a repositional stream. — end note]

#### 20.3.2 character

(Clauses 24, 25, 30, and 31) any object which, when treated sequentially, can represent text

[Note: The term does not mean only `char`, `char16_t`, `char32_t`, and `wchar_t` objects, but any value that can be represented by a type that provides the definitions specified in these Clauses. — end note]

#### 20.3.3 character container type

a class or a type used to represent a `character`

[Note: It is used for one of the template parameters of the string, `iostream`, and regular expression class templates. A character container type is a POD (6.9) type. — end note]

#### 20.3.4 comparison function

an operator function (16.5) for any of the equality (8.10) or relational (8.9) operators

#### 20.3.5 component

a group of library entities directly related as members, parameters, or return types

[Note: For example, the class template `basic_string` and the non-member function templates that operate on strings are referred to as the `string component`. — end note]
20.3.6  
constant subexpression  
an expression whose evaluation as subexpression of a conditional-expression CE (8.16) would not prevent CE from being a core constant expression (8.20)

20.3.7  
deadlock  
one or more threads are unable to continue execution because each is blocked waiting for one or more of the others to satisfy some condition

20.3.8  
default behavior  
⟨implementation⟩ any specific behavior provided by the implementation, within the scope of the required behavior

20.3.9  
default behavior  
⟨specification⟩ a description of replacement function and handler function semantics

20.3.10  
direct-non-list-initialization  
a direct-initialization (11.6) that is not list-initialization (11.6.4)

20.3.11  
handler function  
a non-reserved function whose definition may be provided by a C++ program  
[ Note: A C++ program may designate a handler function at various points in its execution by supplying a pointer to the function when calling any of the library functions that install handler functions (Clause 21). — end note ]

20.3.12  
iostream class templates  
templates, defined in Clause 30, that take two template arguments  
[ Note: The arguments are named charT and traits. The argument charT is a character container class, and the argument traits is a class which defines additional characteristics and functions of the character type represented by charT necessary to implement the iostream class templates. — end note ]

20.3.13  
modifier function  
a class member function (12.2.1) other than a constructor, assignment operator, or destructor that alters the state of an object of the class

20.3.14  
move assignment  
assignment of an rvalue of some object type to a modifiable lvalue of the same type

20.3.15  
move construction  
direct-initialization of an object of some type with an rvalue of the same type

20.3.16  
NTCTS  
a sequence of values that have character type that precede the terminating null character type value charT()
20.3.17  observer function  

A class member function (12.2.1) that accesses the state of an object of the class but does not alter that state.  

[Note: Observer functions are specified as const member functions (12.2.2.1). — end note]

20.3.18  referenceable type  

An object type, a function type that does not have cv-qualifiers or a ref-qualifier, or a reference type.  

[Note: The term describes a type to which a reference can be created, including reference types. — end note]

20.3.19  replacement function  

A non-reserved function whose definition is provided by a C++ program.  

[Note: Only one definition for such a function is in effect for the duration of the program’s execution, as the result of creating the program (5.2) and resolving the definitions of all translation units (6.5). — end note]

20.3.20  repositional stream  

A stream (described in Clause 30) that can seek to a position that was previously encountered.

20.3.21  required behavior  

A description of replacement function and handler function semantics applicable to both the behavior provided by the implementation and the behavior of any such function definition in the program.  

[Note: If such a function defined in a C++ program fails to meet the required behavior when it executes, the behavior is undefined. — end note]

20.3.22  reserved function  

A function, specified as part of the C++ standard library, that must be defined by the implementation.  

[Note: If a C++ program provides a definition for any reserved function, the results are undefined. — end note]

20.3.23  stable algorithm  

An algorithm that preserves, as appropriate to the particular algorithm, the order of elements.  

[Note: Requirements for stable algorithms are given in 20.5.5.7. — end note]

20.3.24  traits class  

A class that encapsulates a set of types and functions necessary for class templates and function templates to manipulate objects of types for which they are instantiated.

20.3.25  valid but unspecified state  

A value of an object that is not specified except that the object’s invariants are met and operations on the object behave as specified for its type.  

[Example: If an object x of type std::vector<int> is in a valid but unspecified state, x.empty() can be called unconditionally, and x.front() can be called only if x.empty() returns false. — end example]
20.4 Method of description (Informative) [description]

This subclause describes the conventions used to specify the C++ standard library. 20.4.1 describes the structure of the normative Clauses 21 through 33 and Annex D. 20.4.2 describes other editorial conventions.

20.4.1 Structure of each clause [structure]

20.4.1.1 Elements [structure.elements]

Each library clause contains the following elements, as applicable: 155

1. Summary
2. Requirements
3. Detailed specifications
4. References to the C standard library

20.4.1.2 Summary [structure.summary]

The Summary provides a synopsis of the category, and introduces the first-level subclauses. Each subclause also provides a summary, listing the headers specified in the subclause and the library entities provided in each header.

1. Paragraphs labeled “Note(s):” or “Example(s):” are informative, other paragraphs are normative.

2. The contents of the summary and the detailed specifications include:

1. macros
2. values
3. types
4. classes and class templates
5. functions and function templates
6. objects

20.4.1.3 Requirements [structure.requirements]

Requirements describe constraints that shall be met by a C++ program that extends the standard library. Such extensions are generally one of the following:

1. Template arguments
2. Derived classes
3. Containers, iterators, and algorithms that meet an interface convention

2. The string and iostream components use an explicit representation of operations required of template arguments. They use a class template char_traits to define these constraints.

3. Interface convention requirements are stated as generally as possible. Instead of stating “class X has to define a member function operator++()”, the interface requires “for any object x of class X, ++x is defined”. That is, whether the operator is a member is unspecified.

4. Requirements are stated in terms of well-defined expressions that define valid terms of the types that satisfy the requirements. For every set of well-defined expression requirements there is a table that specifies an initial set of the valid expressions and their semantics. Any generic algorithm (Clause 28) that uses the well-defined expression requirements is described in terms of the valid expressions for its template type parameters.

5. Template argument requirements are sometimes referenced by name. See 20.4.2.1.

155) To save space, items that do not apply to a Clause are omitted. For example, if a Clause does not specify any requirements, there will be no “Requirements” subclause.
In some cases the semantic requirements are presented as C++ code. Such code is intended as a specification of equivalence of a construct to another construct, not necessarily as the way the construct must be implemented.\textsuperscript{156}

\section*{20.4.1.4 Detailed specifications \textsuperscript{[structure.specifications]}}

The detailed specifications each contain the following elements:

1. name and brief description
2. synopsis (class definition or function declaration, as appropriate)
3. restrictions on template arguments, if any
4. description of class invariants
5. description of function semantics

Descriptions of class member functions follow the order (as appropriate):\textsuperscript{157}

1. constructor(s) and destructor
2. copying, moving & assignment functions
3. comparison functions
4. modifier functions
5. observer functions
6. operators and other non-member functions

Descriptions of function semantics contain the following elements (as appropriate):\textsuperscript{158}

1. Requires: the preconditions for calling the function
2. Effects: the actions performed by the function
3. Synchronization: the synchronization operations (4.7) applicable to the function
4. Postconditions: the observable results established by the function
5. Returns: a description of the value(s) returned by the function
6. Throws: any exceptions thrown by the function, and the conditions that would cause the exception
7. Complexity: the time and/or space complexity of the function
8. Remarks: additional semantic constraints on the function
9. Error conditions: the error conditions for error codes reported by the function

Whenever the Effects: element specifies that the semantics of some function \( F \) are Equivalent to some code sequence, then the various elements are interpreted as follows. If \( F \)'s semantics specifies a Requires: element, then that requirement is logically imposed prior to the equivalent-to semantics. Next, the semantics of the code sequence are determined by the Requires:, Effects:, Synchronization:, Postconditions:, Returns:, Throws:, Complexity:, Remarks:, and Error conditions: specified for the function invocations contained in the code sequence. The value returned from \( F \) is specified by \( F \)'s Returns: element, or if \( F \) has no Returns: element, a non-void return from \( F \) is specified by the return statements in the code sequence. If \( F \)'s semantics contains a Throws:, Postconditions:, or Complexity: element, then that supersedes any occurrences of that element in the code sequence.

\textsuperscript{156) Although in some cases the code given is unambiguously the optimum implementation.}

\textsuperscript{157) To save space, items that do not apply to a class are omitted. For example, if a class does not specify any comparison functions, there will be no “Comparison functions” subclause.}

\textsuperscript{158) To save space, items that do not apply to a function are omitted. For example, if a function does not specify any further preconditions, there will be no Requires: paragraph.}
For non-reserved replacement and handler functions, Clause 21 specifies two behaviors for the functions in question: their required and default behavior. The default behavior describes a function definition provided by the implementation. The required behavior describes the semantics of a function definition provided by either the implementation or a C++ program. Where no distinction is explicitly made in the description, the behavior described is the required behavior.

If the formulation of a complexity requirement calls for a negative number of operations, the actual requirement is zero operations. 159

Complexity requirements specified in the library clauses are upper bounds, and implementations that provide better complexity guarantees satisfy the requirements.

Error conditions specify conditions where a function may fail. The conditions are listed, together with a suitable explanation, as the enum class errc constants (22.5).

20.4.1.5 C library

Paragraphs labeled “See also:” contain cross-references to the relevant portions of this International Standard and the ISO C standard.

20.4.2 Other conventions

This subclause describes several editorial conventions used to describe the contents of the C++ standard library. These conventions are for describing implementation-defined types (20.4.2.1), and member functions (20.4.2.2).

20.4.2.1 Type descriptions

20.4.2.1.1 General

The Requirements subclauses may describe names that are used to specify constraints on template arguments. 160 These names are used in library Clauses to describe the types that may be supplied as arguments by a C++ program when instantiating template components from the library.

Certain types defined in Clause 30 are used to describe implementation-defined types. They are based on other types, but with added constraints.

20.4.2.1.2 Exposition-only types

Several types defined in Clauses 21 through 33 and Annex D that are used as function parameter or return types are defined for the purpose of exposition only in order to capture their language linkage. The declarations of such types are followed by a comment ending in exposition only. [Example:

```cpp
namespace std {
    extern "C" using some-handler = int(int, void*, double);  // exposition only
}
```

The type placeholder some-handler can now be used to specify a function that takes a callback parameter with C language linkage. —end example]

20.4.2.1.3 Enumerated types

Several types defined in Clause 30 are enumerated types. Each enumerated type may be implemented as an enumeration or as a synonym for an enumeration. 161

The enumerated type enumerated can be written:

```cpp
enum enumerated { V_0, V_1, V_2, V_3, ...... };
```

159) This simplifies the presentation of complexity requirements in some cases.
160) Examples from 20.5.3 include: EqualityComparable, LessThanComparable, CopyConstructible. Examples from 27.2 include: InputIterator, ForwardIterator.
161) Such as an integer type, with constant integer values (6.9.1).
inline constexpr bitmask C0(V0);
inline constexpr bitmask C1(V1);
inline constexpr bitmask C2(V2);
inline constexpr bitmask C3(V3);
.....

Here, the names C0, C1, etc. represent enumerated elements for this particular enumerated type. All such elements have distinct values.

20.4.2.1.4 Bitmask types

Several types defined in Clauses 21 through 33 and Annex D are bitmask types. Each bitmask type can be implemented as an enumerated type that overloads certain operators, as an integer type, or as a bitset (23.9.2).

The bitmask type bitmask can be written:

```
// For exposition only.
// int_type is an integral type capable of representing all values of the bitmask type.
enum bitmask : int_type {
    V0 = 1 << 0, V1 = 1 << 1, V2 = 1 << 2, V3 = 1 << 3, ......
};
```

```
inline constexpr bitmask C0(V0);
inline constexpr bitmask C1(V1);
inline constexpr bitmask C2(V2);
inline constexpr bitmask C3(V3);
.....
```

```
constexpr bitmask operator&(bitmask X, bitmask Y) {
    return static_cast<bitmask>(
        static_cast<int_type>(X) & static_cast<int_type>(Y));
}
```

```
constexpr bitmask operator|(bitmask X, bitmask Y) {
    return static_cast<bitmask>(
        static_cast<int_type>(X) | static_cast<int_type>(Y));
}
```

```
constexpr bitmask operator^(bitmask X, bitmask Y) {
    return static_cast<bitmask>(
        static_cast<int_type>(X) ^ static_cast<int_type>(Y));
}
```

```
constexpr bitmask operator~(bitmask X) {
    return static_cast<bitmask>(~static_cast<int_type>(X));
}
```

```
bitmask& operator&=(bitmask& X, bitmask Y) {
    X = X & Y; return X;
}
```

```
bitmask& operator|=(bitmask& X, bitmask Y) {
    X = X | Y; return X;
}
```

```
bitmask& operator^=(bitmask& X, bitmask Y) {
    X = X ^ Y; return X;
}
```

Here, the names C0, C1, etc. represent bitmask elements for this particular bitmask type. All such elements have distinct, nonzero values such that, for any pair Ci and Cj where i ≠ j, Ci & Cj is nonzero and Ci & Cj is zero. Additionally, the value 0 is used to represent an empty bitmask, in which no bitmask elements are set.
The following terms apply to objects and values of bitmask types:

(4.1) To set a value \( Y \) in an object \( X \) is to evaluate the expression \( X = Y \).

(4.2) To clear a value \( Y \) in an object \( X \) is to evaluate the expression \( X &= \neg Y \).

(4.3) The value \( Y \) is set in the object \( X \) if the expression \( X & Y \) is nonzero.

20.4.2.1.5 Character sequences

The C standard library makes widespread use of characters and character sequences that follow a few uniform conventions:

(1.1) A letter is any of the 26 lowercase or 26 uppercase letters in the basic execution character set.

(1.2) The decimal-point character is the (single-byte) character used by functions that convert between a (single-byte) character sequence and a value of one of the floating-point types. It is used in the character sequence to denote the beginning of a fractional part. It is represented in Clauses 21 through 33 and Annex D by a period, \('.'\), which is also its value in the "C" locale, but may change during program execution by a call to \( \text{setlocale}(\text{int}, \text{const char}*) \),\(^{162}\) or by a change to a locale object, as described in Clauses 25.3 and 30.

(1.3) A character sequence is an array object \((11.3.4) A\) that can be declared as \( TA[N] \), where \( T \) is any of the types \( \text{char, unsigned char, or signed char} \) \((6.9.1)\), optionally qualified by any combination of \( \text{const or volatile} \). The initial elements of the array have defined contents up to and including an element determined by some predicate. A character sequence can be designated by a pointer value \( S \) that points to its first element.

20.4.2.1.5.1 Byte strings

A null-terminated byte string, or NTBS, is a character sequence whose highest-addressed element with defined content has the value zero (the terminating null character); no other element in the sequence has the value zero.\(^{163}\)

The length of an NTBS is the number of elements that precede the terminating null character. An empty NTBS has a length of zero.

The value of an NTBS is the sequence of values of the elements up to and including the terminating null character.

A static NTBS is an NTBS with static storage duration.\(^{164}\)

20.4.2.1.5.2 Multibyte strings

A null-terminated multibyte string, or NTMBS, is an NTBS that constitutes a sequence of valid multibyte characters, beginning and ending in the initial shift state.\(^{165}\)

A static NTMBS is an NTMBS with static storage duration.

20.4.2 Functions within classes

For the sake of exposition, Clauses 21 through 33 and Annex D do not describe copy/move constructors, assignment operators, or (non-virtual) destructors with the same apparent semantics as those that can be generated by default \((15.1, 15.4, 15.8)\). It is unspecified whether the implementation provides explicit definitions for such member function signatures, or for virtual destructors that can be generated by default.

---

\(^{162}\) declared in \( <\text{locale}> \) \((25.5)\).

\(^{163}\) Many of the objects manipulated by function signatures declared in \( <\text{cstring}> \) \((24.5)\) are character sequences or NTBSs. The size of some of these character sequences is limited by a length value, maintained separately from the character sequence.

\(^{164}\) A string literal, such as "abc", is a static NTBS.

\(^{165}\) An NTBS that contains characters only from the basic execution character set is also an NTMBS. Each multibyte character then consists of a single byte.
For the sake of exposition, the library clauses sometimes annotate constructors with *EXPLICIT*: Such a constructor is conditionally declared as either explicit or non-explicit (15.3.1). [Note: This is typically implemented by declaring two such constructors, of which at most one participates in overload resolution. —end note]

### 20.4.2.3 Private members

Clauses 21 through 33 and Annex D do not specify the representation of classes, and intentionally omit specification of class members (12.2). An implementation may define static or non-static class members, or both, as needed to implement the semantics of the member functions specified in Clauses 21 through 33 and Annex D.

For the sake of exposition, some subclauses provide representative declarations, and semantic requirements, for private members of classes that meet the external specifications of the classes. The declarations for such members are followed by a comment that ends with *exposition only*, as in:

```cpp
streambuf* sb;  // exposition only
```

An implementation may use any technique that provides equivalent observable behavior.

### 20.5 Library-wide requirements

This subclause specifies requirements that apply to the entire C++ standard library. Clauses 21 through 33 and Annex D specify the requirements of individual entities within the library.

Requirements specified in terms of interactions between threads do not apply to programs having only a single thread of execution.

Within this subclause, 20.5.1 describes the library's contents and organization, 20.5.2 describes how well-formed C++ programs gain access to library entities, 20.5.3 describes constraints on types and functions used with the C++ standard library, 20.5.4 describes constraints on well-formed C++ programs, and 20.5.5 describes constraints on conforming implementations.

#### 20.5.1 Library contents and organization

20.5.1.1 describes the entities and macros defined in the C++ standard library. 20.5.1.2 lists the standard library headers and some constraints on those headers. 20.5.1.3 lists requirements for a freestanding implementation of the C++ standard library.

#### 20.5.1.1 Library contents

The C++ standard library provides definitions for the entities and macros described in the synopses of the C++ standard library headers (20.5.1.2).

All library entities except *operator new* and *operator delete* are defined within the namespace `std` or namespaces nested within namespace `std`. It is unspecified whether names declared in a specific namespace are declared directly in that namespace or in an inline namespace inside that namespace.

Whenever a name `x` defined in the standard library is mentioned, the name `x` is assumed to be fully qualified as `::std::x`, unless explicitly described otherwise. For example, if the *Effects: section* for library function `F` is described as calling library function `G`, the function `::std::G` is meant.

#### 20.5.1.2 Headers

Each element of the C++ standard library is declared or defined (as appropriate) in a *header*. The C standard library headers (Annex D.5) also define names within the global namespace, while the C++ headers for C library facilities (20.5.1.2) may also define names within the global namespace.

This gives implementers freedom to use inline namespaces to support multiple configurations of the library.

A header is not necessarily a source file, nor are the sequences delimited by `<` and `>` in header names necessarily valid source file names (19.2).

§ 20.5.1.2
The C++ standard library provides the \textit{C++ library headers}, shown in Table 16.

Table 16 — C++ library headers

| <algorithm> | <future> | <numeric> | <stringstream> |
| <any> | <initializer_list> | <optional> | <system_error> |
| <array> | <iosmanip> | <ostream> | <thread> |
| <atomic> | <queue> | <tuple> |
| <bitset> | <random> | <type_traits> |
| <chrono> | <iostream> | <ratio> | <typeinfo> |
| <codecvt> | <istream> | <regex> | <unordered_map> |
| <complex> | <iterator> | <scoped_allocator> | <unordered_set> |
| <condition_variable> | <limits> | <set> | <utility> |
| <deque> | <list> | <shared_mutex> | <valarray> |
| <exception> | <locale> | <sstream> | <variant> |
| <execution> | <map> | <stack> | <vector> |
| <filesystem> | <memory> | <stack> | |
| <forward_list> | <memory_resource> | <streambuf> | |
| <fstream> | <mutex> | <string> | |
| <functional> | <new> | <string_view> | |

The facilities of the C standard library are provided in the additional headers shown in Table 17.\textsuperscript{169}

Table 17 — C++ headers for C library facilities

| <cassert> | <cinttypes> | <csignal> | <cstdio> | <wchar.h> |
| <complex> | <ciso646> | <cstdalign> | <cstdlib> | <cwctype> |
| <cstdlib> | <climits> | <cstdarg> | <cstring> | |
| <cerrno> | <clocale> | <cstdio> | <cwctype> |
| <cfenv> | <cmath> | <ctgmath> | |
| <cfloat> | <csetjmp> | <cassert> | |
| <cstdint> | <cassert> | | |

Except as noted in Clauses 20 through 33 and Annex D, the contents of each header \texttt{name} is the same as that of the corresponding header \texttt{name.h} as specified in the C standard library (Clause 2). In the C++ standard library, however, the declarations (except for names which are defined as macros in C) are within namespace scope (6.3.6) of the namespace \texttt{std}. It is unspecified whether these names (including any overloads added in Clauses 21 through 33 and Annex D) are first declared within the global namespace scope and are then injected into namespace \texttt{std} by explicit \texttt{using-declarations} (10.3.3).

Names which are defined as macros in C shall be defined as macros in the C++ standard library, even if C grants license for implementation as functions. [\textit{Note:} The names defined as macros in C include the following: \texttt{assert}, \texttt{offsetof}, \texttt{setjmp}, \texttt{va_arg}, \texttt{va_end}, and \texttt{va_start}. — end note]

Names that are defined as functions in C shall be defined as functions in the C++ standard library.\textsuperscript{170}

Identifiers that are keywords or operators in C++ shall not be defined as macros in C++ standard library headers.\textsuperscript{171}

\textsuperscript{169} It is intentional that there is no C++ header for any of these C headers: \texttt{<stdatomic.h>}, \texttt{<stdnoreturn.h>}, \texttt{<threads.h>}.\textsuperscript{170} This disallows the practice, allowed in C, of providing a masking macro in addition to the function prototype. The only way to achieve equivalent inline behavior in C++ is to provide a definition as an extern inline function.

\textsuperscript{171} In particular, including the standard header \texttt{<iso646.h>} or \texttt{<ciso646>} has no effect.
8 D.5, C standard library headers, describes the effects of using the name.h (C header) form in a C++ program. Annex K of the C standard describes a large number of functions, with associated types and macros, which “promote safer, more secure programming” than many of the traditional C library functions. The names of the functions have a suffix of _s; most of them provide the same service as the C library function with the unsuffixed name, but generally take an additional argument whose value is the size of the result array. If any C++ header is included, it is implementation-defined whether any of these names is declared in the global namespace. (None of them is declared in namespace std.) Table 18 lists the Annex K names that may be declared in some header. These names are also subject to the restrictions of 20.5.4.3.2.

Table 18 — C standard Annex K names

20.5.1.3 Freestanding implementations [compliance]
1 Two kinds of implementations are defined: hosted and freestanding (4.1). For a hosted implementation, this International Standard describes the set of available headers.
2 A freestanding implementation has an implementation-defined set of headers. This set shall include at least the headers shown in Table 19.
3 The supplied version of the header <cstdlib> shall declare at least the functions abort, atexit, at_quick_exit, exit, and quick_exit (21.5). The other headers listed in this table shall meet the same requirements as for a hosted implementation.

20.5.2 Using the library [using]
20.5.2.1 Overview [using.overview]
1 This section describes how a C++ program gains access to the facilities of the C++ standard library. 20.5.2.2 describes effects during translation phase 4, while 20.5.2.3 describes effects during phase 8 (5.2).

172) The ".h" headers dump all their names into the global namespace, whereas the newer forms keep their names in namespace std. Therefore, the newer forms are the preferred forms for all uses except for C++ programs which are intended to be strictly compatible with C.

### 20.5.2.2 Headers

1. The entities in the C++ standard library are defined in headers, whose contents are made available to a translation unit when it contains the appropriate #include preprocessing directive (19.2).

2. A translation unit may include library headers in any order (Clause 5). Each may be included more than once, with no effect different from being included exactly once, except that the effect of including either `<cassert>` or `<assert.h>` depends each time on the lexically current definition of `NDEBUG`.

3. A translation unit shall include a header only outside of any declaration or definition, and shall include the header lexically before the first reference in that translation unit to any of the entities declared in that header. No diagnostic is required.

### 20.5.2.3 Linkage

1. Entities in the C++ standard library have external linkage (6.5). Unless otherwise specified, objects and functions have the default `extern "C++"` linkage (10.5).

2. Whether a name from the C standard library declared with external linkage has `extern "C"` or `extern "C++"` linkage is implementation-defined. It is recommended that an implementation use `extern "C++"` linkage for this purpose.

3. Objects and functions defined in the library and required by a C++ program are included in the program prior to program startup.

4. See also replacement functions (20.5.4.6), runtime changes (20.5.4.7).

### 20.5.3 Requirements on types and expressions

1. 20.5.3.1 describes requirements on types and expressions used to instantiate templates defined in the C++ standard library. 20.5.3.2 describes the requirements on swappable types and swappable expressions. 20.5.3.3 describes the requirements on pointer-like types that support null values. 20.5.3.4 describes the requirements on hash function objects. 20.5.3.5 describes the requirements on storage allocators.

---

173) This is the same as the C standard library.

174) The only reliable way to declare an object or function signature from the C standard library is by including the header that declares it, notwithstanding the latitude granted in 7.1.4 of the C Standard.
20.5.3.1 Template argument requirements

The template definitions in the C++ standard library refer to various named requirements whose details are set out in Tables 20–27. In these tables, T is an object or reference type to be supplied by a C++ program instantiating a template; a, b, and c are values of type (possibly const) T; s and t are modifiable lvalues of type T; u denotes an identifier; rv is an rvalue of type T; and v is an lvalue of type (possibly const) T or an rvalue of type const T.

In general, a default constructor is not required. Certain container class member function signatures specify T() as a default argument. T() shall be a well-defined expression (11.6) if one of those signatures is called using the default argument (11.3.6).

Table 20 — EqualityComparable requirements

### 20.5.3.2 Swappable requirements [swappablerequirements]

1. This subclause provides definitions for swappable types and expressions. In these definitions, let t denote an expression of type T, and let u denote an expression of type U.

2. An object t is *swappable with* an object u if and only if:

   (2.1) the expressions `swap(t, u)` and `swap(u, t)` are valid when evaluated in the context described below, and

   (2.2) these expressions have the following effects:

   (2.2.1) the object referred to by t has the value originally held by u and

   (2.2.2) the object referred to by u has the value originally held by t.

3. The context in which `swap(t, u)` and `swap(u, t)` are evaluated shall ensure that a binary non-member function named “swap” is selected via overload resolution (16.3) on a candidate set that includes:

   (3.1) the two swap function templates defined in `<utility>` (23.2) and

   (3.2) the lookup set produced by argument-dependent lookup (6.4.2).

   | Note: If T and U are both fundamental types or arrays of fundamental types and the declarations from the

---
header `<utility>` are in scope, the overall lookup set described above is equivalent to that of the qualified name lookup applied to the expression `std::swap(t, u)` or `std::swap(u, t)` as appropriate. —end note]

[Note: It is unspecified whether a library component that has a swappable requirement includes the header `<utility>` to ensure an appropriate evaluation context. —end note]

An rvalue or lvalue t is swappable if and only if t is swappable with any rvalue or lvalue, respectively, of type T.

5 A type X satisfying any of the iterator requirements (27.2) satisfies the requirements of ValueSwappable if, for any dereferenceable object x of type X, *x is swappable.

[Example: User code can ensure that the evaluation of `swap` calls is performed in an appropriate context under the various conditions as follows:

```cpp
#include <utility>

// Requires: std::forward<T>(t) shall be swappable with std::forward<U>(u).
template <class T, class U>
void value_swap(T&& t, U&& u) {
    using std::swap;
    swap(std::forward<T>(t), std::forward<U>(u)); // OK: uses “swappable with” conditions
    // for rvalues and lvalues
}

// Requires: lvalues of T shall be swappable.
template <class T>
void lv_swap(T& t1, T& t2) {
    using std::swap;
    swap(t1, t2); // OK: uses swappable conditions for
    // lvalues of type T
}

namespace N {
    struct A { int m; };
    struct Proxy { A* a; };
    Proxy proxy(A& a) { return Proxy{ &a }; }
    void swap(A& x, Proxy p) {
        std::swap(x.m, p.a->m); // OK: uses context equivalent to swappable
        // conditions for fundamental types
    }
    void swap(Proxy p, A& x) { swap(x, p); } // satisfy symmetry constraint
}

int main() {
    int i = 1, j = 2;
    lv_swap(i, j);
    assert(i == 2 && j == 1);

    N::A a1 = { 5 }, a2 = { -5 };
    value_swap(a1, proxy(a2));
    assert(a1.m == -5 && a2.m == 5);
}
—end example]
20.5.3.3 NullablePointer requirements

1 A NullablePointer type is a pointer-like type that supports null values. A type \( P \) meets the requirements of NullablePointer if:

1.1 \( P \) satisfies the requirements of EqualityComparable, DefaultConstructible, CopyConstructible, CopyAssignable, and Destructible.

1.2 lvalues of type \( P \) are swappable (20.5.3.2),

1.3 the expressions shown in Table 28 are valid and have the indicated semantics, and

1.4 \( P \) satisfies all the other requirements of this subclause.

2 A value-initialized object of type \( P \) produces the null value of the type. The null value shall be equivalent only to itself. A default-initialized object of type \( P \) may have an indeterminate value. [Note: Operations involving indeterminate values may cause undefined behavior. —end note]

3 An object \( p \) of type \( P \) can be contextually converted to \( \text{bool} \) (Clause 7). The effect shall be as if \( p \neq \text{nullptr} \) had been evaluated in place of \( p \).

4 No operation which is part of the NullablePointer requirements shall exit via an exception.

5 In Table 28, \( u \) denotes an identifier, \( t \) denotes a non-\( \text{const} \) lvalue of type \( P \), \( a \) and \( b \) denote values of type (possibly \( \text{const} \)) \( P \), and \( np \) denotes a value of type (possibly \( \text{const} \)) \( \text{std::nullptr_t} \).

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
</tr>
</thead>
<tbody>
<tr>
<td>( P u(np); )</td>
<td>( P u = np; )</td>
<td>( \text{Postconditions: } u == \text{nullptr} )</td>
</tr>
<tr>
<td>( P(np) )</td>
<td>( \text{Postconditions: } P(np) == \text{nullptr} )</td>
<td></td>
</tr>
<tr>
<td>( t = np )</td>
<td>( P&amp; )</td>
<td>( \text{Postconditions: } t == \text{nullptr} )</td>
</tr>
<tr>
<td>( a \neq b )</td>
<td>contextually convertible to ( \text{bool} )</td>
<td>( !(a == b) )</td>
</tr>
<tr>
<td>( a == np )</td>
<td>contextually convertible to ( \text{bool} )</td>
<td>( a == P() )</td>
</tr>
<tr>
<td>( np == a )</td>
<td>contextually convertible to ( \text{bool} )</td>
<td>( a == np )</td>
</tr>
<tr>
<td>( np \neq a )</td>
<td>contextually convertible to ( \text{bool} )</td>
<td>( !(a == np) )</td>
</tr>
</tbody>
</table>

20.5.3.4 Hash requirements

1 A type \( H \) meets the Hash requirements if:

1.1 it is a function object type (23.14),

1.2 it satisfies the requirements of CopyConstructible and Destructible (20.5.3.1), and

1.3 the expressions shown in Table 29 are valid and have the indicated semantics.

2 Given \( \text{Key} \) is an argument type for function objects of type \( H \), in Table 29 \( h \) is a value of type (possibly \( \text{const} \)) \( H \), \( u \) is an lvalue of type \( \text{Key} \), and \( k \) is a value of a type convertible to (possibly \( \text{const} \)) \( \text{Key} \).

20.5.3.5 Allocator requirements

1 The library describes a standard set of requirements for allocators, which are class-type objects that encapsulate the information about an allocation model. This information includes the knowledge of pointer types, the type of their difference, the type of the size of objects in this allocation model, as well as the memory allocation and deallocation primitives for it. All of the string types (Clause 24), containers (Clause 26) (except array), string buffers and string streams (Clause 30), and \texttt{match_results} (Clause 31) are parameterized in terms of allocators.

§ 20.5.3.5
Table 29 — Hash requirements [hash]

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>h(k)</td>
<td>size_t</td>
<td>The value returned shall depend only on the argument k for the duration of the program. [Note: Thus all evaluations of the expression h(k) with the same value for k yield the same result for a given execution of the program. —end note] [Note: For two different values t1 and t2, the probability that h(t1) and h(t2) compare equal should be very small, approaching 1.0 / numeric_limits&lt;size_t&gt;::max(). —end note]</td>
</tr>
<tr>
<td>h(u)</td>
<td>size_t</td>
<td>Shall not modify u.</td>
</tr>
</tbody>
</table>

2 The class template allocator_traits (23.10.8) supplies a uniform interface to all allocator types. Table 30 describes the types manipulated through allocators. Table 31 describes the requirements on allocator types and thus on types used to instantiate allocator_traits. A requirement is optional if the last column of Table 31 specifies a default for a given expression. Within the standard library allocator_traits template, an optional requirement that is not supplied by an allocator is replaced by the specified default expression. A user specialization of allocator_traits may provide different defaults and may provide defaults for different requirements than the primary template. Within Tables 30 and 31, the use of move and forward always refers to std::move and std::forward, respectively.

<td>is_empty&lt;X&gt;::type</td>
</tr>
</tbody>
</table>

3 Note A: The member class template `rebind` in the table above is effectively a typedef template. [Note: In general, if the name `Allocator` is bound to `SomeAllocator<T>`, then `Allocator::rebind<U>::other` is the same type as `SomeAllocator<T>::value_type` is T and `SomeAllocator<U>::value_type` is U. — end note] If `Allocator` is a class template instantiation of the form `SomeAllocator<T, Args>`, where `Args` is zero or more type arguments, and `Allocator` does not supply a `rebind` member template, the standard `allocator_traits` template uses `SomeAllocator<U, Args>` in place of `Allocator::rebind<U>::other` by default. For allocator types that are not template instantiations of the above form, no default is provided.

4 Note B: If `X::propagate_on_container_copy_assignment::value` is true, `X` shall satisfy the `CopyAssignable` requirements (Table 26) and the copy operation shall not throw exceptions. If `X::propagate_on_container_move_assignment::value` is true, `X` shall satisfy the `MoveAssignable` requirements (Table 25)

175) It is intended that `a.allocate` be an efficient means of allocating a single object of type `T`, even when `sizeof(T)` is small. That is, there is no need for a container to maintain its own free list.

§ 20.5.3.5
and the move operation shall not throw exceptions. If \(X::\text{propagate\_on\_container\_swap}\cdot\text{value}\) is \text{true},
values of type \(X\) shall be swappable (20.5.3.2) and the \text{swap} operation shall not throw exceptions.

5 An allocator type \(X\) shall satisfy the requirements of \text{CopyConstructible} (20.5.3.1). The \(X::\text{pointer}, X::\text{const\_pointer}, X::\text{void\_pointer},\) and \(X::\text{const\_void\_pointer}\) types shall satisfy the requirements of \text{NullablePointer} (20.5.3.3). No constructor, comparison function, copy operation, move operation, or swap operation on these pointer types shall exit via an exception. \(X::\text{pointer}\) and \(X::\text{const\_pointer}\) shall also satisfy the requirements for a random access iterator (27.2.7) and of a contiguous iterator (27.2.1).

6 Let \(x_1\) and \(x_2\) denote objects of (possibly different) types \(X::\text{void\_pointer}, X::\text{const\_void\_pointer},\) \(X::\text{pointer},\) or \(X::\text{const\_pointer}.\) Then, \(x_1\) and \(x_2\) are \emph{equivalently-valued} pointer values, if and only if both \(x_1\) and \(x_2\) can be explicitly converted to the two corresponding objects \(px_1\) and \(px_2\) of type \(X::\text{const\_pointer},\) using a sequence of \text{static\_casts} using only these four types, and the expression \(px_1 == px_2\) evaluates to \text{true}.

7 Let \(w_1\) and \(w_2\) denote objects of type \(X::\text{void\_pointer}.\) Then for the expressions

\[
\begin{align*}
\text{w1} &= \text{w2} \\
\text{w1} &\neq \text{w2}
\end{align*}
\]

either or both objects may be replaced by an equivalently-valued object of type \(X::\text{const\_void\_pointer}\) with no change in semantics.

8 Let \(p_1\) and \(p_2\) denote objects of type \(X::\text{pointer}\.\) Then for the expressions

\[
\begin{align*}
\text{p1} &= \text{p2} \\
\text{p1} &\neq \text{p2} \\
\text{p1} &< \text{p2} \\
\text{p1} &\leq \text{p2} \\
\text{p1} &> \text{p2} \\
\text{p1} &\geq \text{p2} \\
\text{p1} &- \text{p2}
\end{align*}
\]

either or both objects may be replaced by an equivalently-valued object of type \(X::\text{const\_pointer}\) with no change in semantics.

9 An allocator may constrain the types on which it can be instantiated and the arguments for which its \text{construct} or \text{destroy} members may be called. If a type cannot be used with a particular allocator, the allocator class or the call to \text{construct} or \text{destroy} may fail to instantiate.

[Example: The following is an allocator class template supporting the minimal interface that satisfies the requirements of Table 31:

\[
\begin{align*}
\text{template } \langle \text{class } T \rangle &
\text{struct SimpleAllocator } \\
&\{
\text{typedef } T \text{ value\_type;} \\
\text{SimpleAllocator}(\text{ctor } \text{args});
\}
\end{align*}
\]

\[
\begin{align*}
\text{template } \langle \text{class } T \rangle &\text{ SimpleAllocator}(\text{const SimpleAllocator}<T>& \text{other}); \\
&\text{Tp* allocate(std::size\_t } n\text{);} \\
&\text{void deallocate(Tp* } p, \text{ std::size\_t } n\text{);} \\
\}
\end{align*}
\]

\[
\begin{align*}
\text{template } \langle \text{class } T, \text{ class } U \rangle &\text{ bool operator==(const SimpleAllocator}<T>&, \text{ const SimpleAllocator}<U>&); \\
\text{template } \langle \text{class } T, \text{ class } U \rangle &\text{ bool operator!=(const SimpleAllocator}<T>&, \text{ const Simple Allocator}<U>&); \\
\end{align*}
\]

—end example—

§ 20.5.3.5
If the alignment associated with a specific over-aligned type is not supported by an allocator, instantiation of the allocator for that type may fail. The allocator also may silently ignore the requested alignment.  

\[ \text{Note: Additionally, the member function } \text{allocate} \text{ for that type may fail by throwing an object of type } \text{bad_alloc}. \] \[-end note\]

### 20.5.3.5.1 Allocator completeness requirements  

If \( X \) is an allocator class for type \( T \), \( X \) additionally satisfies the allocator completeness requirements if, whether or not \( T \) is a complete type:

1. \( X \) is a complete type, and
2. all the member types of \( \text{allocator_traits}<X> \) (23.10.8) other than \( \text{value_type} \) are complete types.

### 20.5.4 Constraints on programs

#### 20.5.4.1 Overview

This section describes restrictions on C++ programs that use the facilities of the C++ standard library. The following subclauses specify constraints on the program’s use of namespaces (20.5.4.2.1), its use of various reserved names (20.5.4.3), its use of headers (20.5.4.4), its use of standard library classes as base classes (20.5.4.5), its definitions of replacement functions (20.5.4.6), and its installation of handler functions during execution (20.5.4.7).

#### 20.5.4.2 Namespace use

**Namespace std**

The behavior of a C++ program is undefined if it adds declarations or definitions to namespace \( \text{std} \) or to a namespace within namespace \( \text{std} \) unless otherwise specified. A program may add a template specialization for any standard library template to namespace \( \text{std} \) only if the declaration depends on a user-defined type and the specialization meets the standard library requirements for the original template and is not explicitly prohibited.\(^{176}\)

The behavior of a C++ program is undefined if it declares

1. an explicit specialization of any member function of a standard library class template, or
2. an explicit specialization of any member function template of a standard library class or class template, or
3. an explicit or partial specialization of any member class template of a standard library class or class template, or
4. a deduction guide for any standard library class template.

A program may explicitly instantiate a template defined in the standard library only if the declaration depends on the name of a user-defined type and the instantiation meets the standard library requirements for the original template.

A translation unit shall not declare namespace \( \text{std} \) to be an inline namespace (10.3.1).

**Namespace posix**

The behavior of a C++ program is undefined if it adds declarations or definitions to namespace \( \text{posix} \) or to a namespace within namespace \( \text{posix} \) unless otherwise specified. The namespace \( \text{posix} \) is reserved for use by ISO/IEC 9945 and other POSIX standards.

\(^{176}\) Any library code that instantiates other library templates must be prepared to work adequately with any user-supplied specialization that meets the minimum requirements of this International Standard.
20.5.4.2.3 Namespaces for future standardization [namespace.future]

Top level namespaces with a name starting with `std` and followed by a non-empty sequence of digits are reserved for future standardization. The behavior of a C++ program is undefined if it adds declarations or definitions to such a namespace. [Example: The top level namespace `std2` is reserved for use by future revisions of this International Standard. — end example]

20.5.4.3 Reserved names [reserved.names]

The C++ standard library reserves the following kinds of names:

1. macros
2. global names
3. names with external linkage

If a program declares or defines a name in a context where it is reserved, other than as explicitly allowed by this Clause, its behavior is undefined.

20.5.4.3.1 Zombie names [zombie.names]

In namespace `std`, the following names are reserved for previous standardization:

1. `auto_ptr`,
2. `binary_function`,
3. `bind1st`,
4. `bind2nd`,
5. `binder1st`,
6. `binder2nd`,
7. `const_mem_fun1_ref_t`,
8. `const_mem_fun1_t`,
9. `const_mem_fun_ref_t`,
10. `const_mem_fun_t`,
11. `get_unexpected`,
12. `mem_fun1_ref_t`,
13. `mem_fun1_t`,
14. `mem_fun_ref_t`,
15. `mem_fun_ref`,
16. `mem_fun_t`,
17. `mem_fun`,
18. `pointer_to_binary_function`,
19. `pointer_to_unary_function`,
20. `ptr_fun`,
21. `random_shuffle`,
22. `set_unexpected`,
23. `unary_function`,
24. `unexpected`, and
20.5.4.3.2 Macro names

1 A translation unit that includes a standard library header shall not \#define or \#undef names declared in any standard library header.

2 A translation unit shall not \#define or \#undef names lexically identical to keywords, to the identifiers listed in Table 4, or to the attribute-tokens described in 10.6.

20.5.4.3.3 External linkage

1 Each name declared as an object with external linkage in a header is reserved to the implementation to designate that library object with external linkage, both in namespace std and in the global namespace.

2 Each global function signature declared with external linkage in a header is reserved to the implementation to designate that function signature with external linkage.

3 Each name from the C standard library declared with external linkage is reserved to the implementation for use as a name with extern "C" linkage, both in namespace std and in the global namespace.

4 Each function signature from the C standard library declared with external linkage is reserved to the implementation for use as a function signature with both extern "C" and extern "C++" linkage, or as a name of namespace scope in the global namespace.

20.5.4.3.4 Types

1 For each type T from the C standard library, the types ::T and std::T are reserved to the implementation and, when defined, ::T shall be identical to std::T.

20.5.4.3.5 User-defined literal suffixes

1 Literal suffix identifiers (16.5.8) that do not start with an underscore are reserved for future standardization.

20.5.4.4 Headers

1 If a file with a name equivalent to the derived file name for one of the C++ standard library headers is not provided as part of the implementation, and a file with that name is placed in any of the standard places for a source file to be included (19.2), the behavior is undefined.

20.5.4.5 Derived classes

1 Virtual member function signatures defined for a base class in the C++ standard library may be overridden in a derived class defined in the program (13.3).

20.5.4.6 Replacement functions

1 Clauses 21 through 33 and Annex D describe the behavior of numerous functions defined by the C++ standard library. Under some circumstances, however, certain of these function descriptions also apply to replacement functions defined in the program (20.3).

2 A C++ program may provide the definition for any of the following dynamic memory allocation function signatures declared in header <new> (6.7.4, 21.6):

177) The list of such reserved names includes errno, declared or defined in <cerrno>.

178) The list of such reserved function signatures with external linkage includes setjmp(jmp_buf), declared or defined in <csetjmp>, and va_end(va_list), declared or defined in <cstdarg>.

179) The function signatures declared in <cuchar>, <cwchar>, and <cwctype> are always reserved, notwithstanding the restrictions imposed in subclause 4.5.1 of Amendment 1 to the C Standard for these headers.

180) These types are clock_t, div_t, FILE, fpos_t, lconv, ldiv_t, mbstate_t, ptdiff_t, sig_atomic_t, size_t, time_t, tm, va_list, wctrans_t, wctype_t, and wint_t.
The program’s definitions are used instead of the default versions supplied by the implementation (21.6). Such replacement occurs prior to program startup (6.2, 6.6). The program’s declarations shall not be specified as inline. No diagnostic is required.

20.5.4.7 Handler functions

The C++ standard library provides a default version of the following handler function (Clause 21):

(1.1) — terminate_handler

(1.2) — set_new_handler

(1.3) — set_terminate

See also subclauses 21.6.3, Storage allocation errors, and 21.8, Exception handling.

3 A C++ program can get a pointer to the current handler function by calling the following functions:

(3.1) — get_new_handler

(3.2) — get_terminate

4 Calling the set_* and get_* functions shall not incur a data race. A call to any of the set_* functions shall synchronize with subsequent calls to the same set_* function and to the corresponding get_* function.

20.5.4.8 Other functions

1 In certain cases (replacement functions, handler functions, operations on types used to instantiate standard library template components), the C++ standard library depends on components supplied by a C++ program. If these components do not meet their requirements, this International Standard places no requirements on the implementation.

2 In particular, the effects are undefined in the following cases:

(2.1) — for replacement functions (21.6.2), if the installed replacement function does not implement the semantics of the applicable Required behavior: paragraph.
for handler functions (21.6.3.3, 21.8.4.1), if the installed handler function does not implement the semantics of the applicable Required behavior: paragraph

for types used as template arguments when instantiating a template component, if the operations on the type do not implement the semantics of the applicable Requirements subclause (20.5.3.5, 26.2, 27.2, 28.3, 29.3). Operations on such types can report a failure by throwing an exception unless otherwise specified.

if any replacement function or handler function or destructor operation exits via an exception, unless specifically allowed in the applicable Required behavior: paragraph.

if an incomplete type (6.9) is used as a template argument when instantiating a template component, unless specifically allowed for that component.

20.5.4.9 Function arguments

1 Each of the following applies to all arguments to functions defined in the C++ standard library, unless explicitly stated otherwise.

(1.1) If an argument to a function has an invalid value (such as a value outside the domain of the function or a pointer invalid for its intended use), the behavior is undefined.

(1.2) If a function argument is described as being an array, the pointer actually passed to the function shall have a value such that all address computations and accesses to objects (that would be valid if the pointer did point to the first element of such an array) are in fact valid.

(1.3) If a function argument binds to an rvalue reference parameter, the implementation may assume that this parameter is a unique reference to this argument. [Note: If the parameter is a generic parameter of the form `T&&` and an lvalue of type `A` is bound, the argument binds to an lvalue reference (17.8.2.1) and thus is not covered by the previous sentence. — end note] [Note: If a program casts an lvalue to an xvalue while passing that lvalue to a library function (e.g. by calling the function with the argument `std::move(x)`), the program is effectively asking that function to treat that lvalue as a temporary. The implementation is free to optimize away aliasing checks which might be needed if the argument was an lvalue. — end note]

20.5.4.10 Library object access

1 The behavior of a program is undefined if calls to standard library functions from different threads may introduce a data race. The conditions under which this may occur are specified in 20.5.5.9. [Note: Modifying an object of a standard library type that is shared between threads risks undefined behavior unless objects of that type are explicitly specified as being sharable without data races or the user supplies a locking mechanism. — end note]

2 If an object of a standard library type is accessed, and the beginning of the object’s lifetime (6.8) does not happen before the access, or the access does not happen before the end of the object’s lifetime, the behavior is undefined unless otherwise specified. [Note: This applies even to objects such as mutexes intended for thread synchronization. — end note]

20.5.4.11 Requires paragraph

1 Violation of the preconditions specified in a function’s Requires: paragraph results in undefined behavior unless the function’s Throws: paragraph specifies throwing an exception when the precondition is violated.

20.5.5 Conforming implementations

20.5.5.1 Overview

1 This section describes the constraints upon, and latitude of, implementations of the C++ standard library.
An implementation’s use of headers is discussed in 20.5.5.2, its use of macros in 20.5.5.3, non-member functions in 20.5.5.4, member functions in 20.5.5.5, data race avoidance in 20.5.5.9, access specifiers in 20.5.5.10, class derivation in 20.5.5.11, and exceptions in 20.5.5.12.

### 20.5.5.2 Headers

1. A C++ header may include other C++ headers. A C++ header shall provide the declarations and definitions that appear in its synopsis. A C++ header shown in its synopsis as including other C++ headers shall provide the declarations and definitions that appear in the synopses of those other headers.

2. Certain types and macros are defined in more than one header. Every such entity shall be defined such that any header that defines it may be included after any other header that also defines it (6.2).

3. The C standard library headers (D.5) shall include only their corresponding C++ standard library header, as described in 20.5.1.2.

### 20.5.5.3 Restrictions on macro definitions

1. The names and global function signatures described in 20.5.1.1 are reserved to the implementation.

2. All object-like macros defined by the C standard library and described in this Clause as expanding to integral constant expressions are also suitable for use in #if preprocessing directives, unless explicitly stated otherwise.

### 20.5.5.4 Non-member functions

1. It is unspecified whether any non-member functions in the C++ standard library are defined as inline (10.1.6).

2. A call to a non-member function signature described in Clauses 21 through 33 and Annex D shall behave as if the implementation declared no additional non-member function signatures.

3. An implementation shall not declare a non-member function signature with additional default arguments.

4. Unless otherwise specified, calls made by functions in the standard library to non-operator, non-member functions do not use functions from another namespace which are found through argument-dependent name lookup (6.4.2). [Note: The phrase “unless otherwise specified” applies to cases such as the swappable with requirements (20.5.3.2). The exception for overloaded operators allows argument-dependent lookup in cases like that of \texttt{ostream\_iterator::operator\_} (27.6.2.2):]

   Effects:
   
   \begin{verbatim}
   *out\_stream << value;
   if (delim != 0)
       *out\_stream << delim;
   return *this;
   \end{verbatim}

   — end note

### 20.5.5.5 Member functions

1. It is unspecified whether any member functions in the C++ standard library are defined as inline (10.1.6).

2. For a non-virtual member function described in the C++ standard library, an implementation may declare a different set of member function signatures, provided that any call to the member function that would select an overload from the set of declarations described in this International Standard behaves as if that overload were selected. [Note: For instance, an implementation may add parameters with default values, or replace a member function with default arguments with two or more member functions with equivalent behavior, or add additional signatures for a member function name. — end note]

181) A valid C++ program always calls the expected library non-member function. An implementation may also define additional non-member functions that would otherwise not be called by a valid C++ program.
20.5.5.6 **Constexpr functions and constructors**  
This International Standard explicitly requires that certain standard library functions are **constexpr** (10.1.5). An implementation shall not declare any standard library function signature as **constexpr** except for those where it is explicitly required. Within any header that provides any non-defining declarations of constexpr functions or constructors an implementation shall provide corresponding definitions.

20.5.5.7 **Requirements for stable algorithms**  
When the requirements for an algorithm state that it is “stable” without further elaboration, it means:

1. For the **sort** algorithms the relative order of equivalent elements is preserved.
2. For the **remove** and **copy** algorithms the relative order of the elements that are not removed is preserved.
3. For the **merge** algorithms, for equivalent elements in the original two ranges, the elements from the first range (preserving their original order) precede the elements from the second range (preserving their original order).

20.5.5.8 **Reentrancy**  
Except where explicitly specified in this International Standard, it is implementation-defined which functions in the C++ standard library may be recursively reentered.

20.5.5.9 **Data race avoidance**  
This section specifies requirements that implementations shall meet to prevent data races (4.7). Every standard library function shall meet each requirement unless otherwise specified. Implementations may prevent data races in cases other than those specified below.

1. A C++ standard library function shall not directly or indirectly access objects (4.7) accessible by threads other than the current thread unless the objects are accessed directly or indirectly via the function’s arguments, including **this**.
2. A C++ standard library function shall not directly or indirectly modify objects (4.7) accessible by threads other than the current thread unless the objects are accessed directly or indirectly via the function’s non-const arguments, including **this**.
3. [Note: This means, for example, that implementations can’t use a static object for internal purposes without synchronization because it could cause a data race even in programs that do not explicitly share objects between threads. — end note]
4. A C++ standard library function shall not access objects indirectly accessible via its arguments or via elements of its container arguments except by invoking functions required by its specification on those container elements.
5. Operations on iterators obtained by calling a standard library container or string member function may access the underlying container, but shall not modify it. [Note: In particular, container operations that invalidate iterators conflict with operations on iterators associated with that container. — end note]
6. Implementations may share their own internal objects between threads if the objects are not visible to users and are protected against data races.
7. Unless otherwise specified, C++ standard library functions shall perform all operations solely within the current thread if those operations have effects that are visible (4.7) to users.
8. [Note: This allows implementations to parallelize operations if there are no visible side effects. — end note]

20.5.5.10 **Protection within classes**  
It is unspecified whether any function signature or class described in Clauses 21 through 33 and Annex D is a **friend** of another class in the C++ standard library.
20.5.5.11 Derived classes

1. An implementation may derive any class in the C++ standard library from a class with a name reserved to the implementation.

2. Certain classes defined in the C++ standard library are required to be derived from other classes in the C++ standard library. An implementation may derive such a class directly from the required base or indirectly through a hierarchy of base classes with names reserved to the implementation.

3. In any case:
   
   (3.1) Every base class described as virtual shall be virtual;
   
   (3.2) Every base class not specified as virtual shall not be virtual;
   
   (3.3) Unless explicitly stated otherwise, types with distinct names shall be distinct types.\(^{182}\)

4. All types specified in the C++ standard library shall be non-final types unless otherwise specified.

20.5.5.12 Restrictions on exception handling

1. Any of the functions defined in the C++ standard library can report a failure by throwing an exception of a type described in its Throws: paragraph, or of a type derived from a type named in the Throws: paragraph that would be caught by an exception handler for the base type.

2. Functions from the C standard library shall not throw exceptions\(^{183}\) except when such a function calls a program-supplied function that throws an exception.\(^{184}\)

3. Destructor operations defined in the C++ standard library shall not throw exceptions. Every destructor in the C++ standard library shall behave as if it had a non-throwing exception specification.

4. Functions defined in the C++ standard library that do not have a Throws: paragraph but do have a potentially-throwing exception specification may throw implementation-defined exceptions.\(^{185}\) Implementations should report errors by throwing exceptions of or derived from the standard exception classes (21.6.3.1, 21.8, 22.2).

5. An implementation may strengthen the exception specification for a non-virtual function by adding a non-throwing exception specification.

20.5.5.13 Restrictions on storage of pointers

1. Objects constructed by the standard library that may hold a user-supplied pointer value or an integer of type std::intptr_t shall store such values in a traceable pointer location (6.7.4.3). [Note: Other libraries are strongly encouraged to do the same, since not doing so may result in accidental use of pointers that are not safely derived. Libraries that store pointers outside the user’s address space should make it appear that they are stored and retrieved from a traceable pointer location. —end note]

20.5.5.14 Value of error codes

1. Certain functions in the C++ standard library report errors via a std::error_code (22.5.3.1) object. That object’s category() member shall return std::system_category() for errors originating from the operating system, or a reference to an implementation-defined error_category object for errors originating elsewhere. The implementation shall define the possible values of value() for each of these error categories. [Example: For operating systems that are based on POSIX, implementations are encouraged to define the std::system_category() values as identical to the POSIX errno values, with additional values as defined by the operating

\(^{182}\) There is an implicit exception to this rule for types that are described as synonyms for basic integral types, such as size_t (21.2) and streamoff (30.5.2).

\(^{183}\) That is, the C library functions can all be treated as if they are marked noexcept. This allows implementations to make performance optimizations based on the absence of exceptions at runtime.

\(^{184}\) The functions qsort() and bsearch() (28.8) meet this condition.

\(^{185}\) In particular, they can report a failure to allocate storage by throwing an exception of type bad_alloc, or a class derived from bad_alloc (21.6.3.1).
system’s documentation. Implementations for operating systems that are not based on POSIX are encouraged
to define values identical to the operating system’s values. For errors that do not originate from the operating system, the implementation may provide enums for the associated values. — end example]

20.5.5.15 Moved-from state of library types

Objects of types defined in the C++ standard library may be moved from (15.8). Move operations may be
explicitly specified or implicitly generated. Unless otherwise specified, such moved-from objects shall be
placed in a valid but unspecified state.
21  Language support library [language.support]

21.1  General [support.general]

1 This Clause describes the function signatures that are called implicitly, and the types of objects generated implicitly, during the execution of some C++ programs. It also describes the headers that declare these function signatures and define any related types.

2 The following subclauses describe common type definitions used throughout the library, characteristics of the predefined types, functions supporting start and termination of a C++ program, support for dynamic memory management, support for dynamic type identification, support for exception processing, support for initializer lists, and other runtime support, as summarized in Table 32.

Table 32 — Language support library summary

size_t wcstombs(const char* s, const wchar_t* pwcs, size_t n);

// 28.8, C standard library algorithms
void* bsearch(const void* key, const void* base, size_t nmemb, size_t size, compare-pred* compar);
void* qsort(void* base, size_t nmemb, size_t size, compare-pred* compar);

// 29.6.9, low-quality random number generation
int rand();
void srand(unsigned int seed);

// 29.9.2, absolute values
int abs(int j);
long int abs(long int j);
long long int abs(long long int j);
float abs(float j);
double abs(double j);
long double abs(long double j);

long int labs(long int j);
long long int llabs(long long int j);

div_t div(int numer, int denom);
dl div_t div(long int numer, long int denom);  // see 20.2
```c
lldiv_t div(long long int numer, long long int denom); // see 20.2
lldiv_t ldiv(long int numer, long int denom);
lldiv_t lldiv(long long int numer, long long int denom);
}
```

The contents and meaning of the header `<stdlib.h>` are the same as the C standard library header `<stdlib.h>`, except that it does not declare the type `wchar_t`, and except as noted in 21.2.3, 21.2.4, 21.5, 23.10.11, 24.5.6, 28.8, 29.6.9, and 29.9.2. [Note: Several functions have additional overloads in this International Standard, but they have the same behavior as in the C standard library (20.2). — end note]

See also: ISO C 7.22

### 21.2.3 Null pointers

The type `nullptr_t` is a synonym for the type of a `nullptr` expression, and it has the characteristics described in 6.9.1 and 7.11. [Note: Although `nullptr`'s address cannot be taken, the address of another `nullptr_t` object that is an lvalue can be taken. — end note]

The macro `NULL` is an implementation-defined null pointer constant.\(^{186}\)

### 21.2.4 Sizes, alignments, and offsets

The macro `offsetof(type, member-designator)` has the same semantics as the corresponding macro in the C standard library header `<stddef.h>`, but accepts a restricted set of `type` arguments in this International Standard. Use of the `offsetof` macro with a `type` other than a standard-layout class (Clause 12) is conditionally-supported.\(^{187}\) The expression `offsetof(type, member-designator)` is never type-dependent (17.6.2.2) and it is value-dependent (17.6.2.3) if and only if `type` is dependent. The result of applying the `offsetof` macro to a static data member or a function member is undefined. No operation invoked by the `offsetof` macro shall throw an exception and `noexcept(offsetof(type, member-designator))` shall be `true`.

The type `ptrdiff_t` is an implementation-defined signed integer type that can hold the difference of two subscripts in an array object, as described in 8.7.

The type `size_t` is an implementation-defined unsigned integer type that is large enough to contain the size in bytes of any object.

[Note: It is recommended that implementations choose types for `ptrdiff_t` and `size_t` whose integer conversion ranks (7.15) are no greater than that of `signed long int` unless a larger size is necessary to contain all the possible values. — end note]

The type `max_align_t` is a POD type whose alignment requirement is at least as great as that of every scalar type, and whose alignment requirement is supported in every context.

See also: Alignment (6.11), `sizeof` (8.3.3), Additive operators (8.7), Free store (15.5), and ISO C 7.19.

### 21.2.5 byte type operations

```c
template <class IntType>
constexpr byte& operator<<=(byte& b, IntType shift) noexcept;

Remarks: This function shall not participate in overload resolution unless `is_integral_v<IntType>` is true.

Effects: Equivalent to: `return b = byte(static_cast<unsigned char>(b) << shift);`
```

```c
template <class IntType>
constexpr byte operator<<=(byte b, IntType shift) noexcept;
```

\(^{186}\) Possible definitions include 0 and 0L, but not `(void*)0`.

\(^{187}\) Note that `offsetof` is required to work as specified even if unary `operator&` is overloaded for any of the types involved.

Remarks: This function shall not participate in overload resolution unless `is_integral_v<IntType>` is true.

Effects: Equivalent to: `return byte(static_cast<unsigned char>(b) << shift);`

```cpp
template <class IntType>
constexpr byte& operator>>(byte& b, IntType shift) noexcept;
```

Remarks: This function shall not participate in overload resolution unless `is_integral_v<IntType>` is true.

Effects: Equivalent to: `return b = byte(static_cast<unsigned char>(b) >> shift);`

```cpp
template <class IntType>
constexpr byte operator>>(byte b, IntType shift) noexcept;
```

Remarks: This function shall not participate in overload resolution unless `is_integral_v<IntType>` is true.

Effects: Equivalent to: `return byte(static_cast<unsigned char>(b) >> shift);`

```cpp
constexpr byte& operator|=(byte& l, byte r) noexcept;
```

Effects: Equivalent to: `return l = byte(static_cast<unsigned char>(l) | static_cast<unsigned char>(r));`

```cpp
constexpr byte operator|(byte l, byte r) noexcept;
```

Effects: Equivalent to: `return byte(static_cast<unsigned char>(l) | static_cast<unsigned char>(r));`

```cpp
constexpr byte& operator&=(byte& l, byte r) noexcept;
```

Effects: Equivalent to: `return l = byte(static_cast<unsigned char>(l) & static_cast<unsigned char>(r));`

```cpp
constexpr byte operator&(byte l, byte r) noexcept;
```

Effects: Equivalent to: `return byte(static_cast<unsigned char>(l) & static_cast<unsigned char>(r));`

```cpp
constexpr byte& operator^=(byte& l, byte r) noexcept;
```

Effects: Equivalent to: `return l = byte(static_cast<unsigned char>(l) ^ static_cast<unsigned char>(r));`

```cpp
constexpr byte operator^(byte l, byte r) noexcept;
```

Effects: Equivalent to: `return byte(static_cast<unsigned char>(l) ^ static_cast<unsigned char>(r));`

```cpp
constexpr byte operator~(byte b) noexcept;
```

Effects: Equivalent to: `return byte(~static_cast<unsigned char>(b));`

```cpp
template <class IntType>
constexpr IntType to_integer(byte b) noexcept;
```

Remarks: This function shall not participate in overload resolution unless `is_integral_v<IntType>` is true.

Effects: Equivalent to: `return IntType(b);`
21.3 Implementation properties
21.3.1 General

The headers `<limits>` (21.3.2), `<climits>` (21.3.5), and `<cfloat>` (21.3.6) supply characteristics of implementation-dependent arithmetic types (6.9.1).

21.3.2 Header `<limits>` synopsis

```cpp
namespace std {
    // 21.3.3, floating-point type properties
    enum float_round_style;
    enum float_denorm_style;

    // 21.3.4, class template numeric_limits
    template<class T> class numeric_limits;
    template<> class numeric_limits<bool>;
    template<> class numeric_limits<char>;
    template<> class numeric_limits<signed char>;
    template<> class numeric_limits<unsigned char>;
    template<> class numeric_limits<short);
    template<> class numeric_limits<int>;
    template<> class numeric_limits<long>;
    template<> class numeric_limits<long long>;
    template<> class numeric_limits<unsigned short>;
    template<> class numeric_limits<unsigned int>;
    template<> class numeric_limits<unsigned long>;
    template<> class numeric_limits<unsigned long long>;
    template<> class numeric_limits<float>;
    template<> class numeric_limits<double>;
    template<> class numeric_limits<long double>;
}
```

21.3.3 Floating-point type properties

21.3.3.1 Type `float_round_style`

```cpp
namespace std {
    enum float_round_style {
        round_indeterminate = -1,
        round_toward_zero = 0,
        round_to_nearest = 1,
        round_toward_infinity = 2,
        round_toward_neg_infinity = 3
    };
}
```

The rounding mode for floating-point arithmetic is characterized by the values:

(1.1) — `round_indeterminate` if the rounding style is indeterminable
(1.2) — `round_toward_zero` if the rounding style is toward zero
(1.3) — `round_to_nearest` if the rounding style is to the nearest representable value
round_toward_infinity if the rounding style is toward infinity

round_toward_neg_infinity if the rounding style is toward negative infinity

21.3.3.2 Type float_denorm_style

namespace std {
enum float_denorm_style {
    denorm_indeterminate = -1,
    denorm_absent = 0,
    denorm_present = 1
};
}

The presence or absence of subnormal numbers (variable number of exponent bits) is characterized by the values:

— denorm_indeterminate if it cannot be determined whether or not the type allows subnormal values
— denorm_absent if the type does not allow subnormal values
— denorm_present if the type does allow subnormal values

21.3.4 Class template numeric_limits

The numeric_limits class template provides a C++ program with information about various properties of the implementation's representation of the arithmetic types.

namespace std {
    template<class T> class numeric_limits {
public:
    static constexpr bool is_specialized = false;
    static constexpr T min() noexcept { return T(); }
    static constexpr T max() noexcept { return T(); }
    static constexpr T lowest() noexcept { return T(); }
    static constexpr int digits = 0;
    static constexpr int digits10 = 0;
    static constexpr int max_digits10 = 0;
    static constexpr bool is_signed = false;
    static constexpr bool is_integer = false;
    static constexpr bool is_exact = false;
    static constexpr int radix = 0;
    static constexpr T epsilon() noexcept { return T(); }
    static constexpr T round_error() noexcept { return T(); }
    static constexpr int min_exponent = 0;
    static constexpr int min_exponent10 = 0;

§ 21.3.4
static constexpr bool is_iec559 = false;
static constexpr bool is_bounded = false;
static constexpr bool is_modulo = false;
static constexpr bool traps = false;
static constexpr bool tinyness_before = false;
static constexpr float_round_style round_style = round_toward_zero;
};

template<class T> class numeric_limits<const T>;
template<class T> class numeric_limits<volatile T>;
template<class T> class numeric_limits<const volatile T>;

2 For all members declared static constexpr in the numeric_limits template, specializations shall define these values in such a way that they are usable as constant expressions.

3 The default numeric_limits<T> template shall have all members, but with 0 or false values.

4 Specializations shall be provided for each arithmetic type, both floating-point and integer, including bool. The member is_specialized shall be true for all such specializations of numeric_limits.

5 The value of each member of a specialization of numeric_limits on a cv-qualified type cv T shall be equal to the value of the corresponding member of the specialization on the unqualified type T.

6 Non-arithmetic standard types, such as complex<T> (29.5.2), shall not have specializations.

21.3.4.1 numeric_limits members

Each member function defined in this subclause is signal-safe (21.10.3).

static constexpr T min() noexcept;

2 Minimum finite value.\(^{188}\)

3 For floating types with subnormal numbers, returns the minimum positive normalized value.

4 Meaningful for all specializations in which is_bounded != false, or is_bounded == false && is_signed == false.

static constexpr T max() noexcept;

5 Maximum finite value.\(^{189}\)

6 Meaningful for all specializations in which is_bounded != false.

static constexpr T lowest() noexcept;

7 A finite value x such that there is no other finite value y where y < x.\(^{190}\)

8 Meaningful for all specializations in which is_bounded != false.

static constexpr int digits;

9 Number of radix digits that can be represented without change.

10 For integer types, the number of non-sign bits in the representation.

\(^{188}\) Equivalent to CHAR_MIN, SHRT_MIN, FLT_MIN, DBL_MIN, etc.
\(^{189}\) Equivalent to CHAR_MAX, SHRT_MAX, FLT_MAX, DBL_MAX, etc.
\(^{190}\) lowest() is necessary because not all floating-point representations have a smallest (most negative) value that is the negative of the largest (most positive) finite value.
For floating-point types, the number of \texttt{radix} digits in the mantissa.\footnote{Equivalent to \texttt{FLT\_MANT\_DIG}, \texttt{DBL\_MANT\_DIG}, \texttt{LDBL\_MANT\_DIG}.}

```cpp
static constexpr int digits10;
```

Number of base 10 digits that can be represented without change.\footnote{Equivalent to \texttt{FLT\_DIG}, \texttt{DBL\_DIG}, \texttt{LDBL\_DIG}.}

```cpp
static constexpr int max_digits10;
```

Number of base 10 digits required to ensure that values which differ are always differentiated.\footnote{Equivalent to \texttt{FLT\_RADIX}.}

```
static constexpr bool is_signed;
```

\texttt{true} if the type is signed.\footnote{Distinguishes types with bases other than 2 (e.g. BCD).}

```
static constexpr bool is_integer;
```

\texttt{true} if the type is integer.\footnote{Equivalent to \texttt{FLT\_EPSILON}, \texttt{DBL\_EPSILON}, \texttt{LDBL\_EPSILON}.}

```
static constexpr bool is_exact;
```

\texttt{true} if the type uses an exact representation. All integer types are exact, but not all exact types are integer.\footnote{Rounding error is described in LIA-1 Section 5.2.4 and Annex C Rationale Section C.5.2.4 — Rounding and rounding constants.}

```
static constexpr int radix;
```

For floating types, specifies the base or radix of the exponent representation (often 2).\footnote{Equivalent to \texttt{FLT\_MIN\_EXP}, \texttt{DBL\_MIN\_EXP}, \texttt{LDBL\_MIN\_EXP}.}

```
static constexpr T epsilon() noexcept;
```

Machine epsilon: the difference between 1 and the least value greater than 1 that is representable.\footnote{Equivalent to \texttt{FLT\_MIN\_EXP}, \texttt{DBL\_MIN\_EXP}, \texttt{LDBL\_MIN\_EXP}.}

```
static constexpr T round_error() noexcept;
```

Measure of the maximum rounding error.\footnote{Equivalent to \texttt{FLT\_MIN\_EXP}, \texttt{DBL\_MIN\_EXP}, \texttt{LDBL\_MIN\_EXP}.}

```
static constexpr int min_exponent;
```

Minimum negative integer such that \texttt{radix} raised to the power of one less than that integer is a normalized floating-point number.\footnote{Equivalent to \texttt{FLT\_MIN\_EXP}, \texttt{DBL\_MIN\_EXP}, \texttt{LDBL\_MIN\_EXP}.}
Minimum negative integer such that 10 raised to that power is in the range of normalized floating-point numbers.\(^{198}\)

Meaningful for all floating-point types.

```cpp
static constexpr int max_exponent;
```

Maximum positive integer such that \(\text{radix}\) raised to the power one less than that integer is a representable finite floating-point number.\(^{199}\)

Meaningful for all floating-point types.

```cpp
static constexpr int max_exponent10;
```

Maximum positive integer such that 10 raised to that power is in the range of representable finite floating-point numbers.\(^{200}\)

Meaningful for all floating-point types.

```cpp
static constexpr bool has_infinity;
```

\(\text{true}\) if the type has a representation for positive infinity.

Meaningful for all floating-point types.

Shall be \(\text{true}\) for all specializations in which \text{is_iec559} != \text{false}.

```cpp
static constexpr bool has_quiet_NaN;
```

\(\text{true}\) if the type has a representation for a quiet (non-signaling) “Not a Number”.\(^{201}\)

Meaningful for all floating-point types.

Shall be \(\text{true}\) for all specializations in which \text{is_iec559} != \text{false}.

```cpp
static constexpr bool has_signaling_NaN;
```

\(\text{true}\) if the type has a representation for a signaling “Not a Number”.\(^{202}\)

Meaningful for all floating-point types.

Shall be \(\text{true}\) for all specializations in which \text{is_iec559} != \text{false}.

```cpp
static constexpr float_denorm_style has_denorm;
```

\text{denorm_present} if the type allows subnormal values (variable number of exponent bits)\(^{203}\), \text{denorm_absent} if the type does not allow subnormal values, and \text{denorm_indeterminate} if it is indeterminate at compile time whether the type allows subnormal values.

Meaningful for all floating-point types.

```cpp
static constexpr bool has_denorm_loss;
```

\(\text{true}\) if loss of accuracy is detected as a denormalization loss, rather than as an inexact result.\(^{204}\)

```cpp
static constexpr T infinity() noexcept;
```

Representation of positive infinity, if available.\(^{205}\)

\(^{198}\) Equivalent to \text{FLT_MIN_10_EXP}, \text{DBL_MIN_10_EXP}, \text{LDBL_MIN_10_EXP}.

\(^{199}\) Equivalent to \text{FLT_MAX_EXP}, \text{DBL_MAX_EXP}, \text{LDBL_MAX_EXP}.

\(^{200}\) Equivalent to \text{FLT_MAX_10_EXP}, \text{DBL_MAX_10_EXP}, \text{LDBL_MAX_10_EXP}.

\(^{201}\) Required by LIA-1.

\(^{202}\) Required by LIA-1.

\(^{203}\) Required by LIA-1.

\(^{204}\) See ISO/IEC/IEEE 60559.

\(^{205}\) Required by LIA-1.
Meaningful for all specializations for which \texttt{has\_infinity} $\neq \texttt{false}$. Required in specializations for which \texttt{is\_iec559} $\neq \texttt{false}$.

\begin{verbatim}
static constexpr T quiet_NaN() noexcept;
\end{verbatim}

Representation of a quiet “Not a Number”, if available.\(^{206}\)

Meaningful for all specializations for which \texttt{has\_quiet\_NaN} $\neq \texttt{false}$. Required in specializations for which \texttt{is\_iec559} $\neq \texttt{false}$.

\begin{verbatim}
static constexpr T signaling_NaN() noexcept;
\end{verbatim}

Representation of a signaling “Not a Number”, if available.\(^{207}\)

Meaningful for all specializations for which \texttt{has\_signaling\_NaN} $\neq \texttt{false}$. Required in specializations for which \texttt{is\_iec559} $\neq \texttt{false}$.

\begin{verbatim}
static constexpr T denorm_min() noexcept;
\end{verbatim}

Minimum positive subnormal value.\(^{208}\)

Meaningful for all floating-point types.

In specializations for which \texttt{has\_denorm} $= \texttt{false}$, returns the minimum positive normalized value.

\begin{verbatim}
static constexpr bool is_iec559;
\end{verbatim}

\texttt{true} if and only if the type adheres to ISO/IEC/IEEE 60559.\(^{209}\)

Meaningful for all floating-point types.

\begin{verbatim}
static constexpr bool is_bounded;
\end{verbatim}

\texttt{true} if the set of values representable by the type is finite.\(^{210}\) [\textit{Note:} All fundamental types (6.9.1) are bounded. This member would be \texttt{false} for arbitrary precision types. — end note]" 

Meaningful for all floating-point types.

\begin{verbatim}
static constexpr bool is_modulo;
\end{verbatim}

\texttt{true} if the type is modulo.\(^{211}\) A type is modulo if, for any operation involving $+, -, \text{ or } \ast$ on values of that type whose result would fall outside the range $[\text{min}(\texttt{}, \texttt{}), \text{max}(\texttt{}, \texttt{})]$, the value returned differs from the true value by an integer multiple of $\text{max}(\texttt{}, \texttt{}) - \text{min}(\texttt{}, \texttt{}) + 1$.

[\textit{Example:} \texttt{is\_modulo} is \texttt{false} for signed integer types (6.9.1) unless an implementation, as an extension to this International Standard, defines signed integer overflow to wrap. — end example]

Meaningful for all specializations.

\begin{verbatim}
static constexpr bool traps;
\end{verbatim}

\texttt{true} if, at program startup, there exists a value of the type that would cause an arithmetic operation using that value to trap.\(^{212}\)

Meaningful for all specializations.

\begin{verbatim}
static constexpr bool tinyness_before;
\end{verbatim}

\(\text{§ 21.3.4.1}\)
true if tinyness is detected before rounding.\footnote{Refer to ISO/IEC/IEEE 60559. Required by LIA-1.}

Meaningful for all floating-point types.

```c
static constexpr float_round_style round_style;
```

The rounding style for the type.\footnote{Equivalent to \texttt{FLT_ROUNDS}. Required by LIA-1.}

Meaningful for all floating-point types. Specializations for integer types shall return \texttt{round_toward-_zero}.

### 21.3.4.2 numeric_limits specializations

[numeric.special]

All members shall be provided for all specializations. However, many values are only required to be meaningful under certain conditions (for example, \texttt{epsilon()} is only meaningful if \texttt{is_integer} is \texttt{false}). Any value that is not “meaningful” shall be set to 0 or \texttt{false}.

Example:
```c
namespace std {
    template<> class numeric_limits<float> {
        public:
            static constexpr bool is_specialized = true;

            static constexpr float min() noexcept { return 1.17549435E-38F; }
            static constexpr float max() noexcept { return 3.40282347E+38F; }
            static constexpr float lowest() noexcept { return -3.40282347E+38F; }

            static constexpr int digits = 24;
            static constexpr int digits10 = 6;
            static constexpr int max_digits10 = 9;

            static constexpr bool is_signed = true;
            static constexpr bool is_integer = false;
            static constexpr bool is_exact = false;

            static constexpr int radix = 2;

            static constexpr float epsilon() noexcept { return 1.19209290E-07F; }
            static constexpr float round_error() noexcept { return 0.5F; }

            static constexpr int min_exponent = -125;
            static constexpr int min_exponent10 = -37;
            static constexpr int max_exponent = +128;
            static constexpr int max_exponent10 = +38;

            static constexpr bool has_infinity = true;
            static constexpr bool has_quiet_NaN = true;
            static constexpr bool has_signaling_NaN = true;
            static constexpr float_denorm_style has_denorm = denorm_absent;
            static constexpr bool has_denorm_loss = false;

            static constexpr float infinity() noexcept { return value; }
            static constexpr float quiet_NaN() noexcept { return value; }
            static constexpr float signaling_NaN() noexcept { return value; }
            static constexpr float denorm_min() noexcept { return min(); }
```

\footnote{213) Refer to ISO/IEC/IEEE 60559. Required by LIA-1.}
\footnote{214) Equivalent to \texttt{FLT_ROUNDS}. Required by LIA-1.}

§ 21.3.4.2
The specialization for `bool` shall be provided as follows:

```cpp
namespace std {
    template<> class numeric_limits<bool> {
        public:
            static constexpr bool is_specialized = true;
            static constexpr bool min() noexcept { return false; }
            static constexpr bool max() noexcept { return true; }
            static constexpr bool lowest() noexcept { return false; }
            static constexpr int digits = 1;
            static constexpr int digits10 = 0;
            static constexpr int max_digits10 = 0;
            static constexpr bool is_signed = false;
            static constexpr bool is_integer = true;
            static constexpr bool is_exact = true;
            static constexpr int radix = 2;
            static constexpr bool epsilon() noexcept { return 0; }
            static constexpr bool round_error() noexcept { return 0; }
            static constexpr int min_exponent = 0;
            static constexpr int min_exponent10 = 0;
            static constexpr int max_exponent = 0;
            static constexpr int max_exponent10 = 0;
            static constexpr bool has_infinity = false;
            static constexpr bool has_quiet_NaN = false;
            static constexpr bool has_signaling_NaN = false;
            static constexpr float_denorm_style has_denorm = denorm_absent;
            static constexpr bool has_denorm_loss = false;
            static constexpr bool infinity() noexcept { return 0; }
            static constexpr bool quiet_NaN() noexcept { return 0; }
            static constexpr bool signaling_NaN() noexcept { return 0; }
            static constexpr bool denorm_min() noexcept { return 0; }
            static constexpr bool is_iec559 = false;
            static constexpr bool is_bounded = true;
            static constexpr bool is_modulo = false;
            static constexpr bool traps = false;
            static constexpr bool tinyness_before = false;
            static constexpr float_round_style round_style = round_toward_zero;
    }
}
```

§ 21.3.6
The header `<cfloat>` defines all macros the same as the C standard library header `<float.h>`. 

See also: ISO C 5.2.4.2.2

21.4 Integer types

21.4.1 Header `<cstdint>` synopsis

```cpp
namespace std {
  using int8_t = signed integer type; // optional
  using int16_t = signed integer type; // optional
  using int32_t = signed integer type; // optional
  using int64_t = signed integer type; // optional

  using int_fast8_t = signed integer type;
  using int_fast16_t = signed integer type;
  using int_fast32_t = signed integer type;
  using int_fast64_t = signed integer type;

  using int_least8_t = signed integer type;
  using int_least16_t = signed integer type;
  using int_least32_t = signed integer type;
  using int_least64_t = signed integer type;

  using intmax_t = signed integer type;
  using intptr_t = signed integer type; // optional

  using uint8_t = unsigned integer type; // optional
  using uint16_t = unsigned integer type; // optional
  using uint32_t = unsigned integer type; // optional
  using uint64_t = unsigned integer type; // optional

  using uint_fast8_t = unsigned integer type;
  using uint_fast16_t = unsigned integer type;
  using uint_fast32_t = unsigned integer type;
  using uint_fast64_t = unsigned integer type;

  using uint_least8_t = unsigned integer type;
  using uint_least16_t = unsigned integer type;
  using uint_least32_t = unsigned integer type;
  using uint_least64_t = unsigned integer type;

  using uintmax_t = unsigned integer type;
  using uintptr_t = unsigned integer type; // optional
}
```
The header also defines numerous macros of the form:

\[
\begin{align*}
\text{INT} & \{8 \ 16 \ 32 \ 64\}_\text{MIN} \\
\text{[U]INT} & \{8 \ 16 \ 32 \ 64\}_\text{MAX} \\
\text{INT} & \{\text{MAX PTR}\}_\text{MIN} \\
\text{[U]INT} & \{\text{MAX PTR}\}_\text{MAX} \\
\text{[PTRLONG] SIG_ATOMIC WCHAR WINT} & \{\_\text{MAX} \ \_\text{MIN}\} \\
\text{SIZE}_\text{MAX}
\end{align*}
\]

plus function macros of the form:

\[
\text{[U]INT}\{8 \ 16 \ 32 \ 64 \ \text{MAX}\}_\text{CAP}
\]

The header defines all types and macros the same as the C standard library header \texttt{<stdlib.h>}

\textbf{See also: ISO C 7.20.}

21.5 Start and termination

\[\text{[support.start.term]}\]

\[\text{[Note: The header \texttt{<cstdlib>} (21.2.2) declares the functions described in this subclause. — end note]}\]

\[[\text{noreturn}]] \text{void } _\text{Exit}(\text{int status}) \text{ noexcept};

\textbf{Effects:} This function has the semantics specified in the C standard library.

\[[\text{noreturn}]] \text{void } abort() \text{ noexcept};

\textbf{Effects:} This function has the semantics specified in the C standard library.

\textbf{Remarks:} The program is terminated without executing destructors for objects of automatic, thread, or static storage duration and without calling functions passed to \texttt{atexit()} (6.6.4). The function \texttt{_Exit} is signal-safe (21.10.3).

\begin{verbatim}
int atexit(\text{c-atexit-handler* f}) \text{ noexcept;}
\end{verbatim}

\textbf{Effects:} The \texttt{atexit()} functions register the function pointed to by \texttt{f} to be called without arguments at normal program termination. It is unspecified whether a call to \texttt{atexit()} that does not happen before (4.7) a call to \texttt{exit()} will succeed. \[\text{[Note: The \texttt{atexit()} functions do not introduce a data race (20.5.5.9). — end note]}\]

\textbf{Implementation limits:} The implementation shall support the registration of at least 32 functions.

\textbf{Returns:} The \texttt{atexit()} function returns zero if the registration succeeds, nonzero if it fails.

\[[\text{noreturn}]] \text{void } \texttt{exit}(\text{int status});

\textbf{Effects:}

(9.1) First, objects with thread storage duration and associated with the current thread are destroyed. Next, objects with static storage duration are destroyed and functions registered by calling \texttt{atexit} are called.\footnote{A function is called for every time it is registered.}

See 6.6.4 for the order of destructions and calls. (Automatic objects are not destroyed as a result of calling \texttt{exit}().)\footnote{Objects with automatic storage duration are all destroyed in a program whose \texttt{main} function (6.6.1) contains no automatic objects and executes the call to \texttt{exit}(). Control can be transferred directly to such a \texttt{main} function by throwing an exception that is caught in \texttt{main}.}

If control leaves a registered function called by \texttt{exit} because the function does not provide a handler for a thrown exception, \texttt{std::terminate()} shall be called (18.5.1).
Next, all open C streams (as mediated by the function signatures declared in `<cstdio>`) with unwritten buffered data are flushed, all open C streams are closed, and all files created by calling `tmpfile()` are removed.

Finally, control is returned to the host environment. If `status` is zero or `EXIT_SUCCESS`, an implementation-defined form of the status `successful termination` is returned. If `status` is `EXIT_FAILURE`, an implementation-defined form of the status `unsuccessful termination` is returned. Otherwise the status returned is implementation-defined.\(^{217}\)

```cpp
int at_quick_exit(c_atexit_handler* f) noexcept;
```

**Effects:** The `at_quick_exit()` functions register the function pointed to by `f` to be called without arguments when `quick_exit` is called. It is unspecified whether a call to `at_quick_exit()` that does not happen before (4.7) all calls to `quick_exit` will succeed. [Note: The `at_quick_exit()` functions do not introduce a data race (20.5.5.9). — end note] [Note: The order of registration may be indeterminate if `at_quick_exit` was called from more than one thread. — end note] [Note: The `at_quick_exit` registrations are distinct from the `atexit` registrations, and applications may need to call both registration functions with the same argument. — end note]

**Implementation limits:** The implementation shall support the registration of at least 32 functions.

**Returns:** Zero if the registration succeeds, nonzero if it fails.

```cpp
[[noreturn]] void quick_exit(int status) noexcept;
```

**Effects:** Functions registered by calls to `at_quick_exit` are called in the reverse order of their registration, except that a function shall be called after any previously registered functions that had already been called at the time it was registered. Objects shall not be destroyed as a result of calling `quick_exit`. If control leaves a registered function called by `quick_exit` because the function does not provide a handler for a thrown exception, `std::terminate()` shall be called. [Note: A function registered via `at_quick_exit` is invoked by the thread that calls `quick_exit`, which can be a different thread than the one that registered it, so registered functions should not rely on the identity of objects with thread storage duration. — end note] After calling registered functions, `quick_exit` shall call `_Exit(status)`. [Note: The standard file buffers are not flushed. — end note]

**Remarks:** The function `quick_exit` is signal-safe (21.10.3) when the functions registered with `at_quick_exit` are.

See also: 6.6, 6.6.4, ISO C 7.22.4.

### 21.6 Dynamic memory management

The header `<new>` defines several functions that manage the allocation of dynamic storage in a program. It also defines components for reporting storage management errors.

#### 21.6.1 Header `<new>` synopsis

```cpp
namespace std {
    class bad_alloc;
    class bad_array_new_length;
    enum class align_val_t : size_t {};
    struct nothrow_t { explicit nothrow_t() = default; };
    extern const nothrow_t nothrow;
    using new_handler = void (*)();
    new_handler get_new_handler() noexcept;
    new_handler set_new_handler(new_handler new_p) noexcept;
}
```

\(^{217}\) The macros `EXIT_FAILURE` and `EXIT_SUCCESS` are defined in `<cstdlib>`.

§ 21.6.1 494
template <class T> constexpr T* launder(T* p) noexcept;

inline constexpr size_t hardware_destructive_interference_size = implementation-defined;
inline constexpr size_t hardware_constructive_interference_size = implementation-defined;

}  

void* operator new(std::size_t size);
void* operator new(std::size_t size, std::align_val_t alignment);
void* operator new(std::size_t size, const std::nothrow_t&) noexcept;
void* operator new(std::size_t size, std::align_val_t alignment, const std::nothrow_t&) noexcept;
void operator delete(void* ptr) noexcept;
void operator delete(void* ptr, std::size_t size) noexcept;
void operator delete(void* ptr, std::align_val_t alignment) noexcept;
void operator delete(void* ptr, std::size_t size, std::align_val_t alignment) noexcept;
void operator delete(void* ptr, const std::nothrow_t&) noexcept;

See also: 4.4, 6.7.4, 8.3.4, 8.3.5, 15.5, 23.10.

21.6.2 Storage allocation and deallocation

Except where otherwise specified, the provisions of 6.7.4 apply to the library versions of operator new and operator delete. If the value of an alignment argument passed to any of these functions is not a valid alignment value, the behavior is undefined.

21.6.2.1 Single-object forms

Effects: The allocation functions (6.7.4.1) called by a new-expression (8.3.4) to allocate size bytes of storage. The second form is called for a type with new-extended alignment, and allocates storage with the specified alignment. The first form is called otherwise, and allocates storage suitably aligned to represent any object of that size provided the object’s type does not have new-extended alignment.

Replaceable: A C++ program may define functions with either of these function signatures, and thereby
displace the default versions defined by the C++ standard library.

3

**Required behavior:** Return a non-null pointer to suitably aligned storage (6.7.4), or else throw a `bad_alloc` exception. This requirement is binding on any replacement versions of these functions.

4

**Default behavior:**

(4.1) — Executes a loop: Within the loop, the function first attempts to allocate the requested storage. Whether the attempt involves a call to the C standard library functions `malloc` or `aligned_alloc` is unspecified.

(4.2) — Returns a pointer to the allocated storage if the attempt is successful. Otherwise, if the current `new_handler` (21.6.3.5) is a null pointer value, throws `bad_alloc`.

(4.3) — Otherwise, the function calls the current `new_handler` function (21.6.3.3). If the called function returns, the loop repeats.

(4.4) — The loop terminates when an attempt to allocate the requested storage is successful or when a called `new_handler` function does not return.

```cpp
void* operator new(std::size_t size, const std::nothrow_t&) noexcept;
void* operator new(std::size_t size, std::align_val_t alignment, const std::nothrow_t&) noexcept;
```

5

**Effects:** Same as above, except that these are called by a placement version of a *new-expression* when a C++ program prefers a null pointer result as an error indication, instead of a `bad_alloc` exception.

6

**Replaceable:** A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.

7

**Required behavior:** Return a non-null pointer to suitably aligned storage (6.7.4), or else return a null pointer. Each of these nothrow versions of `operator new` returns a pointer obtained as if acquired from the (possibly replaced) corresponding non-placement function. This requirement is binding on any replacement versions of these functions.

8

**Default behavior:** Calls `operator new(size)` or `operator new(size, alignment)`, respectively. If the call returns normally, returns the result of that call. Otherwise, returns a null pointer.

9

[Example:

```cpp
T* p1 = new T; // throws bad_alloc if it fails
T* p2 = new(nothrow) T; // returns nullptr if it fails
```

—end example]

```cpp
void operator delete(void* ptr) noexcept;
void operator delete(void* ptr, std::size_t size) noexcept;
void operator delete(void* ptr, std::align_val_t alignment) noexcept;
void operator delete(void* ptr, std::size_t size, std::align_val_t alignment) noexcept;
```

10

**Effects:** The deallocation functions (6.7.4.2) called by a *delete-expression* to render the value of ptr invalid.

11

**Replaceable:** A C++ program may define functions with any of these function signatures, and thereby displace the default versions defined by the C++ standard library. If a function without a `size` parameter is defined, the program should also define the corresponding function with a `size` parameter. If a function with a `size` parameter is defined, the program shall also define the corresponding version without the `size` parameter. [Note: The default behavior below may change in the future, which will require replacing both deallocation functions when replacing the allocation function. —end note]

12

**Requires:** ptr shall be a null pointer or its value shall represent the address of a block of memory allocated by an earlier call to a (possibly replaced) `operator new(std::size_t)` or `operator new(std::size_t, std::align_val_t)` which has not been invalidated by an intervening call to `operator delete`.

§ 21.6.2.1
Requires: If an implementation has strict pointer safety (6.7.4.3) then `ptr` shall be a safely-derived pointer.

Requires: If the `alignment` parameter is not present, `ptr` shall have been returned by an allocation function without an `alignment` parameter. If present, the `alignment` argument shall equal the `alignment` argument passed to the allocation function that returned `ptr`. If present, the `size` argument shall equal the `size` argument passed to the allocation function that returned `ptr`.

Required behavior: A call to an `operator delete` with a `size` parameter may be changed to a call to the corresponding `operator delete` without a `size` parameter, without affecting memory allocation. [Note: A conforming implementation is for `operator delete(void* ptr, std::size_t size)` to simply call `operator delete(ptr)`. — end note]

Default behavior: The functions that have a `size` parameter forward their other parameters to the corresponding function without a `size` parameter. [Note: See the note in the above Replaceable: paragraph. — end note]

Default behavior: If `ptr` is null, does nothing. Otherwise, reclaims the storage allocated by the earlier call to `operator new`.

Remarks: It is unspecified under what conditions part or all of such reclaimed storage will be allocated by subsequent calls to `operator new` or any of `aligned_alloc`, `calloc`, `malloc`, or `realloc`, declared in `<cstdlib>`.

```cpp
void operator delete(void* ptr, const std::nothrow_t&) noexcept;
void operator delete(void* ptr, std::align_val_t alignment, const std::nothrow_t&) noexcept;
```

Effects: The deallocation functions (6.7.4.2) called by the implementation to render the value of `ptr` invalid when the constructor invoked from a nothrow placement version of the `new-expression` throws an exception.

Replaceable: A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.

Requires: `ptr` shall be a null pointer or its value shall represent the address of a block of memory allocated by an earlier call to a (possibly replaced) `operator new(std::size_t)` or `operator new(std::size_t, std::align_val_t)` which has not been invalidated by an intervening call to `operator delete`.

Requires: If an implementation has strict pointer safety (6.7.4.3) then `ptr` shall be a safely-derived pointer.

Requires: If the `alignment` parameter is not present, `ptr` shall have been returned by an allocation function without an `alignment` parameter. If present, the `alignment` argument shall equal the `alignment` argument passed to the allocation function that returned `ptr`.

Default behavior: Calls `operator delete(ptr)`, or `operator delete(ptr, alignment)`, respectively.

21.6.2.2 Array forms

```cpp
void* operator new[](std::size_t size);
void* operator new[](std::size_t size, std::align_val_t alignment);
```

Effects: The allocation functions (6.7.4.1) called by the array form of a `new-expression` (8.3.4) to allocate `size` bytes of storage. The second form is called for a type with new-extended alignment, and allocates storage with the specified alignment. The first form is called otherwise, and allocates storage suitably aligned to represent any array object of that size or smaller, provided the object’s type does not have new-extended alignment.\(^{218}\)

\(^{218}\) It is not the direct responsibility of `operator new[]` or `operator delete[]` to note the repetition count or element size of the array. Those operations are performed elsewhere in the array `new` and `delete` expressions. The array `new` expression, may,
Replaceable: A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.

Required behavior: Same as for the corresponding single-object forms. This requirement is binding on any replacement versions of these functions.

Default behavior: Returns \( \text{operator new}(\text{size}) \), or \( \text{operator new}(\text{size}, \text{alignment}) \), respectively.

\[
\begin{align*}
\text{void* operator new[]} & (\text{std::size_t size}, \text{const std::nothrow_t&}) \text{ noexcept; } \\
\text{void* operator new[]} & (\text{std::size_t size}, \text{std::align_val_t alignment}, \text{const std::nothrow_t&}) \text{ noexcept; }
\end{align*}
\]

Effects: Same as above, except that these are called by a placement version of a new-expression when a C++ program prefers a null pointer result as an error indication, instead of a bad_alloc exception.

Replaceable: A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.

Required behavior: Return a non-null pointer to suitably aligned storage (6.7.4), or else return a null pointer. Each of these nothrow versions of operator new[] returns a pointer obtained as if acquired from the (possibly replaced) corresponding non-placement function. This requirement is binding on any replacement versions of these functions.

Default behavior: Calls \( \text{operator new[]} (\text{size}) \), or \( \text{operator new[]} (\text{size}, \text{alignment}) \), respectively. If the call returns normally, returns the result of that call. Otherwise, returns a null pointer.

\[
\begin{align*}
\text{void operator delete[]} & (\text{void* ptr}) \text{ noexcept; } \\
\text{void operator delete[]} & (\text{void* ptr, std::size_t size}) \text{ noexcept; } \\
\text{void operator delete[]} & (\text{void* ptr, std::align_val_t alignment}) \text{ noexcept; } \\
\text{void operator delete[]} & (\text{void* ptr, std::size_t size, std::align_val_t alignment}) \text{ noexcept; }
\end{align*}
\]

Effects: The deallocation functions (6.7.4.2) called by the array form of a delete-expression to render the value of ptr invalid.

Replaceable: A C++ program may define functions with any of these function signatures, and thereby displace the default versions defined by the C++ standard library. If a function without a size parameter is defined, the program should also define the corresponding function with a size parameter. If a function with a size parameter is defined, the program shall also define the corresponding version without the size parameter. [Note: The default behavior below may change in the future, which will require replacing both deallocation functions when replacing the allocation function. —end note]

Requires: ptr shall be a null pointer or its value shall represent the address of a block of memory allocated by an earlier call to a (possibly replaced) operator new[](std::size_t) or operator new[](std::size_t, std::align_val_t) which has not been invalidated by an intervening call to operator delete[].

Requires: If an implementation has strict pointer safety (6.7.4.3) then ptr shall be a safely-derived pointer.

Requires: If the alignment parameter is not present, ptr shall have been returned by an allocation function without an alignment parameter. If present, the alignment argument shall equal the alignment argument passed to the allocation function that returned ptr. If present, the size argument shall equal the size argument passed to the allocation function that returned ptr.

Required behavior: A call to an operator delete[] with a size parameter may be changed to a call to the corresponding operator delete[] without a size parameter, without affecting memory allocation. [Note: A conforming implementation is for operator delete[](void* ptr, std::size_t size) to simply call operator delete[](ptr). —end note]

however, increase the size argument to operator new[] to obtain space to store supplemental information.
Default behavior: The functions that have a size parameter forward their other parameters to the corresponding function without a size parameter. The functions that do not have a size parameter forward their parameters to the corresponding operator delete (single-object) function.

void operator delete[](void* ptr, const std::nothrow_t&) noexcept;
void operator delete[](void* ptr, std::align_val_t alignment, const std::nothrow_t&) noexcept;

Effects: The deallocation functions (6.7.4.2) called by the implementation to render the value of ptr invalid when the constructor invoked from a nothrow placement version of the array new-expression throws an exception.

Replaceable: A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.

Requires: ptr shall be a null pointer or its value shall represent the address of a block of memory allocated by an earlier call to a (possibly replaced) operator new[](std::size_t) or operator new[](std::size_t, std::align_val_t) which has not been invalidated by an intervening call to operator delete[].

Requires: If an implementation has strict pointer safety (6.7.4.3) then ptr shall be a safely-derived pointer.

Requires: If the alignment parameter is not present, ptr shall have been returned by an allocation function without an alignment parameter. If present, the alignment argument shall equal the alignment argument passed to the allocation function that returned ptr.

Default behavior: Calls operator delete[](ptr), or operator delete[](ptr, alignment), respectively.

21.6.2.3 Non-allocating forms

These functions are reserved; a C++ program may not define functions that displace the versions in the C++ standard library (20.5.4). The provisions of 6.7.4 do not apply to these reserved placement forms of operator new and operator delete.

void* operator new(std::size_t size, void* ptr) noexcept;

Returns: ptr.

Remarks: Intentionally performs no other action.

[Example: This can be useful for constructing an object at a known address:
  void* place = operator new(sizeof(Something));
  Something* p = new (place) Something();
  —end example]

void* operator new[](std::size_t size, void* ptr) noexcept;

Returns: ptr.

Remarks: Intentionally performs no other action.

void operator delete(void* ptr, void*) noexcept;

Effects: Intentionally performs no action.

Requires: If an implementation has strict pointer safety (6.7.4.3) then ptr shall be a safely-derived pointer.

Remarks: Default function called when any part of the initialization in a placement new-expression that invokes the library’s non-array placement operator new terminates by throwing an exception (8.3.4).
```c
void operator delete[](void* ptr, void*) noexcept;
```

**Effects:** Intentionally performs no action.

**Requires:** If an implementation has strict pointer safety (6.7.4.3) then `ptr` shall be a safely-derived pointer.

**Remarks:** Default function called when any part of the initialization in a placement `new-expression` that invokes the library’s array placement operator `new` terminates by throwing an exception (8.3.4).

### 21.6.2.4 Data races

For purposes of determining the existence of data races, the library versions of `operator new`, user replacement versions of global `operator new`, the C standard library functions `aligned_alloc`, `calloc`, and `malloc`, the library versions of `operator delete`, user replacement versions of `operator delete`, the C standard library function `free`, and the C standard library function `realloc` shall not introduce a data race (20.5.5.9). Calls to these functions that allocate or deallocate a particular unit of storage shall occur in a single total order, and each such deallocation call shall happen before (4.7) the next allocation (if any) in this order.

### 21.6.3 Storage allocation errors

#### 21.6.3.1 Class `bad_alloc`

```c
namespace std {
    class bad_alloc : public exception {
        public:
            bad_alloc() noexcept;
            bad_alloc(const bad_alloc&) noexcept;
            bad_alloc& operator=(const bad_alloc&) noexcept;
            const char* what() const noexcept override;
    };
}
```

1. The class `bad_alloc` defines the type of objects thrown as exceptions by the implementation to report a failure to allocate storage.

```c
bad_alloc() noexcept;
```

**Effects:** Constructs an object of class `bad_alloc`.

```c
bad_alloc(const bad_alloc&) noexcept;
bad_alloc& operator=(const bad_alloc&) noexcept;
```

**Effects:** Copies an object of class `bad_alloc`.

```c
const char* what() const noexcept override;
```

**Returns:** An implementation-defined NTBS.

**Remarks:** The message may be a null-terminated multibyte string (20.4.2.1.5.2), suitable for conversion and display as a `wstring` (24.3, 25.4.1.4).

#### 21.6.3.2 Class `bad_array_new_length`

```c
namespace std {
    class bad_array_new_length : public bad_alloc {
        public:
            bad_array_new_length() noexcept;
            const char* what() const noexcept override;
    };
}
```

§ 21.6.3.2
The class **bad_array_new_length** defines the type of objects thrown as exceptions by the implementation to report an attempt to allocate an array of size less than zero or greater than an implementation-defined limit (8.3.4).

```cpp
bad_array_new_length() noexcept;
```

**Effects:** constructs an object of class **bad_array_new_length**.

```cpp
const char* what() const noexcept override;
```

**Returns:** An implementation-defined NTBS.

**Remarks:** The message may be a null-terminated multibyte string (20.4.2.1.5.2), suitable for conversion and display as a wstring (24.3, 25.4.1.4).

### 21.6.3.3 Type new_handler

```cpp
using new_handler = void (*)();
```

1. **The type of a handler function** to be called by operator new() or operator new[] () (21.6.2) when they cannot satisfy a request for additional storage.

2. **Required behavior:** A new_handler shall perform one of the following:

   (2.1) — make more storage available for allocation and then return;
   
   (2.2) — throw an exception of type bad_alloc or a class derived from bad_alloc;
   
   (2.3) — terminate execution of the program without returning to the caller.

### 21.6.3.4 set_new_handler

```cpp
new_handler set_new_handler(new_handler new_p) noexcept;
```

1. **Effects:** Establishes the function designated by new_p as the current new_handler.

2. **Returns:** The previous new_handler.

3. **Remarks:** The initial new_handler is a null pointer.

### 21.6.3.5 get_new_handler

```cpp
new_handler get_new_handler() noexcept;
```

1. **Returns:** The current new_handler. [Note: This may be a null pointer value. — end note]

### 21.6.4 Pointer optimization barrier

```cpp
template <class T> constexpr T* launder(T* p) noexcept;
```

1. **Requires:** p represents the address A of a byte in memory. An object X that is within its lifetime (6.8) and whose type is similar (7.5) to T is located at the address A. All bytes of storage that would be reachable through the result are reachable through p (see below).

2. **Returns:** A value of type T * that points to X.

3. **Remarks:** An invocation of this function may be used in a core constant expression whenever the value of its argument may be used in a core constant expression. A byte of storage is reachable through a pointer value that points to an object Y if it is within the storage occupied by Y, an object that is pointer-interconvertible with Y, or the immediately-enclosing array object if Y is an array element. The program is ill-formed if T is a function type or cv void.

4. [Note: If a new object is created in storage occupied by an existing object of the same type, a pointer to the original object can be used to refer to the new object unless the type contains const or reference]
members; in the latter cases, this function can be used to obtain a usable pointer to the new object. See 6.8. — end note]

[Example:

```c
struct X { const int n; };  
X *p = new X{3};  
const int a = p->n;  
new (p) X{5};  // p does not point to new object (6.8) because X::n is const
const int b = p->n;  // undefined behavior
const int c = std::launder(p)->n;  // OK
```
—end example]

21.6.5 Hardware interference size
[hardware.interference]

```c
inline constexpr size_t hardware_destructive_interference_size = implementation-defined;
```

1 This number is the minimum recommended offset between two concurrently-accessed objects to avoid additional performance degradation due to contention introduced by the implementation. It shall be at least alignof(max_align_t).

[Example:

```c
struct keep_apart {
    alignas(hardware_destructive_interference_size) atomic<int> cat;
    alignas(hardware_destructive_interference_size) atomic<int> dog;
};
```
—end example]

```c
inline constexpr size_t hardware_constructive_interference_size = implementation-defined;
```

2 This number is the maximum recommended size of contiguous memory occupied by two objects accessed with temporal locality by concurrent threads. It shall be at least alignof(max_align_t).

[Example:

```c
struct together {
    atomic<int> dog;
    int puppy;
};
```
```c
struct kennel {
    // Other data members...
    alignas(sizeof(together)) together pack;
    // Other data members...
};
```
```c
static_assert(sizeof(together) <= hardware_constructive_interference_size);
```
—end example]

21.7 Type identification
[support.rtti]

1 The header `<typeinfo>` defines a type associated with type information generated by the implementation. It also defines two types for reporting dynamic type identification errors.

21.7.1 Header `<typeinfo>` synopsis
[typeinfo.syn]

```c
namespace std {
    class type_info;
    class bad_cast;
    class bad_typeid;
}
```

§ 21.7.1
See also: 8.2.7, 8.2.8.

21.7.2 Class type_info

namespace std {
    class type_info {
        public:
            virtual ~type_info();
            bool operator==(const type_info& rhs) const noexcept;
            bool operator!=(const type_info& rhs) const noexcept;
            bool before(const type_info& rhs) const noexcept;
            size_t hash_code() const noexcept;
            const char* name() const noexcept;
            type_info(const type_info& rhs) = delete;       // cannot be copied
            type_info& operator=(const type_info& rhs) = delete; // cannot be copied
    };
}

1 The class type_info describes type information generated by the implementation. Objects of this class effectively store a pointer to a name for the type, and an encoded value suitable for comparing two types for equality or collating order. The names, encoding rule, and collating sequence for types are all unspecified and may differ between programs.

bool operator==(const type_info& rhs) const noexcept;
2 Effects: Compares the current object with rhs.
3 Returns: true if the two values describe the same type.

bool operator!=(const type_info& rhs) const noexcept;
4 Returns: !(*this == rhs).

bool before(const type_info& rhs) const noexcept;
5 Effects: Compares the current object with rhs.
6 Returns: true if *this precedes rhs in the implementation’s collation order.

size_t hash_code() const noexcept;
7 Returns: An unspecified value, except that within a single execution of the program, it shall return the same value for any two type_info objects which compare equal.
8 Remarks: An implementation should return different values for two type_info objects which do not compare equal.

const char* name() const noexcept;
9 Returns: An implementation-defined ntbs.
10 Remarks: The message may be a null-terminated multibyte string (20.4.2.1.5.2), suitable for conversion and display as a wstring (24.3, 25.4.1.4)

21.7.3 Class bad_cast

namespace std {
    class bad_cast : public exception {
        public:
            bad_cast() noexcept;
            bad_cast(const bad_cast&) noexcept;
            bad_cast& operator=(const bad_cast&) noexcept;
    };
}

§ 21.7.3
The class `bad_cast` defines the type of objects thrown as exceptions by the implementation to report the execution of an invalid `dynamic_cast` expression (8.2.7).

```cpp
bad_cast() noexcept;
```

**Effects:** Constructs an object of class `bad_cast`.

```cpp
bad_cast(const bad_cast&) noexcept;
bad_cast& operator=(const bad_cast&) noexcept;
```

**Effects:** Copies an object of class `bad_cast`.

```cpp
const char* what() const noexcept override;
```

**Returns:** An implementation-defined NTBS.

**Remarks:** The message may be a null-terminated multibyte string (20.4.2.1.5.2), suitable for conversion and display as a `wstring` (24.3, 25.4.1.4)

### 21.7.4 Class bad_typeid

```cpp
namespace std {
    class bad_typeid : public exception {
        public:
            bad_typeid() noexcept;
            bad_typeid(const bad_typeid&) noexcept;
            bad_typeid& operator=(const bad_typeid&) noexcept;
            const char* what() const noexcept override;
        }
    }
```

The class `bad_typeid` defines the type of objects thrown as exceptions by the implementation to report a null pointer in a `typeid` expression (8.2.8).

```cpp
bad_typeid() noexcept;
```

**Effects:** Constructs an object of class `bad_typeid`.

```cpp
bad_typeid(const bad_typeid&) noexcept;
bad_typeid& operator=(const bad_typeid&) noexcept;
```

**Effects:** Copies an object of class `bad_typeid`.

```cpp
const char* what() const noexcept override;
```

**Returns:** An implementation-defined NTBS.

**Remarks:** The message may be a null-terminated multibyte string (20.4.2.1.5.2), suitable for conversion and display as a `wstring` (24.3, 25.4.1.4)

### 21.8 Exception handling

The header `<exception>` defines several types and functions related to the handling of exceptions in a C++ program.

#### 21.8.1 Header `<exception>` synopsis

```cpp
namespace std {
    class exception {
```

§ 21.8.1
class bad_exception;
class nested_exception;

using terminate_handler = void (*)(void);
terminate_handler get_terminate() noexcept;
terminate_handler set_terminate(terminate_handler f) noexcept;
[[noreturn]] void terminate() noexcept;

int uncaught_exceptions() noexcept;

using exception_ptr = unspecified;
exception_ptr current_exception() noexcept;
[[noreturn]] void rethrow_exception(exception_ptr p);
template<class E> exception_ptr make_exception_ptr(E e) noexcept;

template <class T> [[noreturn]] void throw_with_nested(T& t);
template <class E> void rethrow_if_nested(const E& e);
}

See also: 18.5.

21.8.2 Class exception

namespace std {
  class exception {
    public:
      exception() noexcept;
      exception(const exception&) noexcept;
      exception& operator=(const exception&) noexcept;
      virtual ~exception();
      virtual const char* what() const noexcept;
    }
  }

1 The class exception defines the base class for the types of objects thrown as exceptions by C++ standard library components, and certain expressions, to report errors detected during program execution.

2 Each standard library class T that derives from class exception shall have a publicly accessible copy constructor and a publicly accessible copy assignment operator that do not exit with an exception. These member functions shall meet the following postcondition: If two objects lhs and rhs both have dynamic type T and lhs is a copy of rhs, then strcmp(lhs.what(), rhs.what()) shall equal 0.

exception() noexcept;

Effects: Constructs an object of class exception.

exception(const exception& rhs) noexcept;
exception& operator=(const exception& rhs) noexcept;

Effects: Copies an exception object.

Postconditions: If *this and rhs both have dynamic type exception then the value of the expression strcmp(what(), rhs.what()) shall equal 0.

virtual ~exception();

Effects: Destroys an object of class exception.

virtual const char* what() const noexcept;

§ 21.8.2
Returns: An implementation-defined NTBS.

Remarks: The message may be a null-terminated multibyte string (20.4.2.1.5.2), suitable for conversion and display as a wstring (24.3, 25.4.1.4). The return value remains valid until the exception object from which it is obtained is destroyed or a non-const member function of the exception object is called.

### 21.8.3 Class bad_exception

```cpp
namespace std {
    class bad_exception : public exception {
    public:
        bad_exception() noexcept;
        bad_exception(const bad_exception&) noexcept;
        bad_exception& operator=(const bad_exception&) noexcept;
        const char* what() const noexcept override;
    }
}
```

1 The class bad_exception defines the type of the object referenced by the exception_ptr returned from a call to current_exception (21.8.6) when the currently active exception object fails to copy.

```cpp
bad_exception() noexcept;
```

2 Effects: Constructs an object of class bad_exception.

```cpp
bad_exception(const bad_exception&) noexcept;
bad_exception& operator=(const bad_exception&) noexcept;
```

3 Effects: Copies an object of class bad_exception.

```cpp
const char* what() const noexcept override;
```

4 Returns: An implementation-defined NTBS.

5 Remarks: The message may be a null-terminated multibyte string (20.4.2.1.5.2), suitable for conversion and display as a wstring (24.3, 25.4.1.4).

### 21.8.4 Abnormal termination

#### 21.8.4.1 Type terminate_handler

```cpp
using terminate_handler = void (*)();
```

1 The type of a handler function to be called by std::terminate() when terminating exception processing.

2 Required behavior: A terminate_handler shall terminate execution of the program without returning to the caller.

3 Default behavior: The implementation’s default terminate_handler calls abort().

#### 21.8.4.2 set_terminate

```cpp
terminate_handler set_terminate(terminate_handler f) noexcept;
```

1 Effects: Establishes the function designated by f as the current handler function for terminating exception processing.

2 Remarks: It is unspecified whether a null pointer value designates the default terminate_handler.

3 Returns: The previous terminate_handler.

#### 21.8.4.3 get_terminate

§ 21.8.4.3
terminate_handler get_terminate() noexcept;

Returns: The current terminate_handler. [Note: This may be a null pointer value. — end note]

21.8.4.4 terminate

[[noreturn]] void terminate() noexcept;

Remarks: Called by the implementation when exception handling must be abandoned for any of several reasons (18.5.1). May also be called directly by the program.

Effects: Calls a terminate_handler function. It is unspecified which terminate_handler function will be called if an exception is active during a call to set_terminate. Otherwise calls the current terminate_handler function. [Note: A default terminate_handler is always considered a callable handler in this context. — end note]

21.8.5 uncaught_exceptions

int uncaught_exceptions() noexcept;

Returns: The number of uncaught exceptions (18.5.2).

Remarks: When uncaught_exceptions() > 0, throwing an exception can result in a call of std::terminate() (18.5.1).

21.8.6 Exception propagation

using exception_ptr = unspecified;

The type exception_ptr can be used to refer to an exception object.

exception_ptr shall satisfy the requirements of NullablePointer (20.5.3.3).

Two non-null values of type exception_ptr are equivalent and compare equal if and only if they refer to the same exception.

The default constructor of exception_ptr produces the null value of the type.

exception_ptr shall not be implicitly convertible to any arithmetic, enumeration, or pointer type.

[Note: An implementation might use a reference-counted smart pointer as exception_ptr. — end note]

For purposes of determining the presence of a data race, operations on exception_ptr objects shall access and modify only the exception_ptr objects themselves and not the exceptions they refer to. Use of rethrow_exception on exception_ptr objects that refer to the same exception object shall not introduce a data race. [Note: If rethrow_exception rethrows the same exception object (rather than a copy), concurrent access to that rethrown exception object may introduce a data race. Changes in the number of exception_ptr objects that refer to a particular exception do not introduce a data race. — end note]

exception_ptr current_exception() noexcept;

Returns: An exception_ptr object that refers to the currently handled exception (18.3) or a copy of the currently handled exception, or a null exception_ptr object if no exception is being handled. The referenced object shall remain valid at least as long as there is an exception_ptr object that refers to it. If the function needs to allocate memory and the attempt fails, it returns an exception_ptr object that refers to an instance of bad_alloc. It is unspecified whether the return values of two successive calls to current_exception refer to the same exception object. [Note: That is, it is unspecified whether current_exception creates a new copy each time it is called. — end note] If the attempt to copy the current exception object throws an exception, the function returns an exception_ptr object that
refers to the thrown exception or, if this is not possible, to an instance of `bad_exception`. [Note: The copy constructor of the thrown exception may also fail, so the implementation is allowed to substitute a `bad_exception` object to avoid infinite recursion. — end note]

```cpp
[[noreturn]] void rethrow_exception(exception_ptr p);
```

**Requires:** p shall not be a null pointer.

**Throws:** The exception object to which p refers.

```cpp
template<class E> exception_ptr make_exception_ptr(E e) noexcept;
```

**Effects:** Creates an `exception_ptr` object that refers to a copy of e, as if:

```cpp
try {
    throw e;
} catch(...) {
    return current_exception();
}
```

[Note: This function is provided for convenience and efficiency reasons. — end note]

### 21.8.7 `nested_exception`

```cpp
namespace std {
    class nested_exception {
        public:
            nested_exception() noexcept;
            nested_exception(const nested_exception&) noexcept = default;
            nested_exception& operator=(const nested_exception&) noexcept = default;
            virtual ~nested_exception() = default;

            // access functions
            [[noreturn]] void rethrow_nested() const;
            exception_ptr nested_ptr() const noexcept;
        }
    template<class T> [[noreturn]] void throw_with_nested(T&& t);
    template <class E> void rethrow_if_nested(const E& e);
};
```

1. The class `nested_exception` is designed for use as a mixin through multiple inheritance. It captures the currently handled exception and stores it for later use.

2. [Note: `nested_exception` has a virtual destructor to make it a polymorphic class. Its presence can be tested for with `dynamic_cast`. — end note]

```cpp
nested_exception() noexcept;
```

**Effects:** The constructor calls `current_exception()` and stores the returned value.

```cpp
[[noreturn]] void rethrow_nested() const;
```

**Effects:** If `nested_ptr()` returns a null pointer, the function calls `std::terminate()`. Otherwise, it throws the stored exception captured by `*this`.

```cpp
exception_ptr nested_ptr() const noexcept;
```

**Returns:** The stored exception captured by this `nested_exception` object.

```cpp
template <class T> [[noreturn]] void throw_with_nested(T&& t);
```

§ 21.8.7
Let \( U \) be \( \text{decay}_t<T> \).

**Requires:** \( U \) shall be \fontfamily{linux Libertine}

\fontfamily{times}

CopyConstructible.

**Throws:** If \( \text{is_class}_v<U> \&\& \text{is_final}_v<U> \&\& \text{is_base_of}_v<\text{nested_exception}, U> \) is \textit{true}, an exception of unspecified type that is publicly derived from both \( U \) and \( \text{nested_exception} \) and constructed from \( \text{std::forward}<T>(t) \), otherwise \( \text{std::forward}<T>(t) \).

\( \text{template <class } E \text{> void rethrow_if_nested(const } E \& e); \)

**Effects:** If \( E \) is not a polymorphic class type, or if \( \text{nested_exception} \) is an inaccessible or ambiguous base class of \( E \), there is no effect. Otherwise, performs:

\[
\text{if (auto } p = \text{dynamic_cast<const } \text{nested_exception* >}(\text{addressof}(e)))}
\]

\[
p->\text{rethrow_nested}();
\]

21.9 Initializer lists

The header \langle initializer_list \rangle defines a class template and several support functions related to list-initialization (see 11.6.4). All functions specified in this subclause are signal-safe (21.10.3).

21.9.1 Header \langle initializer_list \rangle synopsis

```
namespace std {
  template<class E> class initializer_list {
    public:
      using value_type = E;
      using reference = const E&;
      using const_reference = const E&;
      using size_type = size_t;
      using iterator = const E*;
      using const_iterator = const E*;

      constexpr initializer_list() noexcept;
      constexpr size_t size() const noexcept; // number of elements
      constexpr const E* begin() const noexcept; // first element
      constexpr const E* end() const noexcept; // one past the last element
  };

  // 21.9.4, initializer list range access
  template<class E> constexpr const E* begin(initializer_list<E> il) noexcept;
  template<class E> constexpr const E* end(initializer_list<E> il) noexcept;
}
```

1 An object of type \( \text{initializer_list}<E> \) provides access to an array of objects of type \( \text{const } E \). [Note: A pair of pointers or a pointer plus a length would be obvious representations for \( \text{initializer_list} \). \( \text{initializer_list} \) is used to implement initializer lists as specified in 11.6.4. Copying an initializer list does not copy the underlying elements. — end note ]

2 If an explicit specialization or partial specialization of \( \text{initializer_list} \) is declared, the program is ill-formed.

21.9.2 Initializer list constructors

```
constexpr initializer_list() noexcept;
```

**Effects:** Constructs an empty \( \text{initializer_list} \) object.

**Postconditions:** \( \text{size}() == 0. \)
21.9.3 Initializer list access

constexpr const E* begin() const noexcept;

Returns: A pointer to the beginning of the array. If size() == 0 the values of begin() and end() are unspecified but they shall be identical.

constexpr const E* end() const noexcept;

Returns: begin() + size().

constexpr size_t size() const noexcept;

Returns: The number of elements in the array.

Complexity: Constant time.

21.9.4 Initializer list range access

template<class E> constexpr const E* begin(initializer_list<E> il) noexcept;

Returns: il.begin().

template<class E> constexpr const E* end(initializer_list<E> il) noexcept;

Returns: il.end().

21.10 Other runtime support

Headers <csetjmp> (nonlocal jumps), <csignal> (signal handling), <cstdarg> (variable arguments), and <cstdlib> (runtime environment getenv, system), provide further compatibility with C code.

Calls to the function getenv (21.2.2) shall not introduce a data race (20.5.5.9) provided that nothing modifies the environment. [Note: Calls to the POSIX functions setenv and putenv modify the environment. — end note]

A call to the setlocale function (25.5) may introduce a data race with other calls to the setlocale function or with calls to functions that are affected by the current C locale. The implementation shall behave as if no library function other than locale::global calls the setlocale function.

21.10.1 Header <cstdarg> synopsis

namespace std {
    using va_list = see below;
}

#define va_arg(V, P) see below
#define va_copy(VDST, VSRC) see below
#define va_end(V) see below
#define va_start(V, P) see below

The contents of the header <cstdarg> are the same as the C standard library header <stdarg.h>, with the following changes: The restrictions that ISO C places on the second parameter to the va_start macro in header <stdarg.h> are different in this International Standard. The parameter parmN is the rightmost parameter in the variable parameter list of the function definition (the one just before the ...).\(^{219}\) If the parameter parmN is a pack expansion (17.5.3) or an entity resulting from a lambda capture (8.1.5), the program is ill-formed, no diagnostic required. If the parameter parmN is of a reference type, or of a type that is not compatible with the type that results when passing an argument for which there is no parameter, the behavior is undefined.

\(^{219}\) Note that va_start is required to work as specified even if unary operator& is overloaded for the type of parmN.

§ 21.10.1
See also: ISO C 7.16.1.1.

21.10.2 Header `<csetjmp>` synopsis [csetjmp.syn]

```cpp
namespace std {
  using jmp_buf = see below;
  [[noreturn]] void longjmp(jmp_buf env, int val);
}
```

#define setjmp(env) see below

1 The contents of the header `<csetjmp>` are the same as the C standard library header `<setjmp.h>`.

2 The function signature `longjmp(jmp_buf jbuf, int val)` has more restricted behavior in this International Standard. A `setjmp/longjmp` call pair has undefined behavior if replacing the `setjmp` and `longjmp` by `catch` and `throw` would invoke any non-trivial destructors for any automatic objects.

See also: ISO C 7.13.

21.10.3 Header `<csignal>` synopsis [csignal.syn]

```cpp
namespace std {
  using sig_atomic_t = see below;

  // 21.10.4, signal handlers
  extern "C" using signal-handler = void(int); // exposition only
  signal-handler* signal(int sig, signal-handler* func);

  int raise(int sig);
}
```

#define SIG_DFL see below
#define SIG_ERR see below
#define SIG_IGN see below
#define SIGABRT see below
#define SIGFPE see below
#define SIGILL see below
#define SIGINT see below
#define SIGSEGV see below
#define SIGTERM see below

1 The contents of the header `<csignal>` are the same as the C standard library header `<signal.h>`.

21.10.4 Signal handlers [support.signal]

1 A call to the function `signal` synchronizes with any resulting invocation of the signal handler so installed.

2 A plain lock-free atomic operation is an invocation of a function `f` from Clause 32, such that:

(2.1) — `f` is the function `atomic_is_lock_free()`, or
(2.2) — `f` is the member function `is_lock_free()`, or
(2.3) — `f` is a non-static member function invoked on an object `A`, such that `A.is_lock_free()` yields `true`, or
(2.4) — `f` is a non-member function, and for every pointer-to-atomic argument `A` passed to `f`, `atomic_is_lock_free(A)` yields `true`.

3 An evaluation is signal-safe unless it includes one of the following:

(3.1) — a call to any standard library function, except for plain lock-free atomic operations and functions explicitly identified as signal-safe. [Note: This implicitly excludes the use of `new` and `delete` expressions that rely on a library-provided memory allocator. — end note]

§ 21.10.4
An access to an object with thread storage duration;

— a `dynamic_cast` expression;

— throwing of an exception;

— control entering a `try-block` or `function-try-block`;

— initialization of a variable with static storage duration requiring dynamic initialization (6.6.3, 9.7)\(^{220}\); or

— waiting for the completion of the initialization of a variable with static storage duration (9.7).

A signal handler invocation has undefined behavior if it includes an evaluation that is not signal-safe.

\(^4\) The function `signal` is signal-safe if it is invoked with the first argument equal to the signal number corresponding to the signal that caused the invocation of the handler.

**See also:** ISO C 7.14.

\(^{220}\) Such initialization might occur because it is the first odr-use (6.2) of that variable.
# Diagnostics library

## General

This Clause describes components that C++ programs may use to detect and report error conditions. The following subclauses describe components for reporting several kinds of exceptional conditions, documenting program assertions, and a global variable for error number codes, as summarized in Table 33.

<table>
<thead>
<tr>
<th>Subclause</th>
<th>Header(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>22.2 Exception classes</td>
<td>&lt;stdexcept&gt;</td>
</tr>
<tr>

<td>22.4 Error numbers</td>
<td>&lt;cerrno&gt;</td>
</tr>
<tr>
<td>22.5 System error support</td>
<td>&lt;system_error&gt;</td>
</tr>
</tbody>
</table>

## Exception classes

The C++ standard library provides classes to be used to report certain errors (20.5.5.12) in C++ programs. In the error model reflected in these classes, errors are divided into two broad categories: logic errors and runtime errors.

1. The distinguishing characteristic of logic errors is that they are due to errors in the internal logic of the program. In theory, they are preventable.
2. By contrast, runtime errors are due to events beyond the scope of the program. They cannot be easily predicted in advance. The header `<stdexcept>` defines several types of predefined exceptions for reporting errors in a C++ program. These exceptions are related by inheritance.

### Class `logic_error`

```cpp
namespace std {
    class logic_error : public exception {
        public:
            explicit logic_error(const string& what_arg);
            explicit logic_error(const char* what_arg);
    };
}
```
The class **logic_error** defines the type of objects thrown as exceptions to report errors presumably detectable before the program executes, such as violations of logical preconditions or class invariants.

```cpp
logic_error(const string& what_arg);
```

*Effects: Constructs an object of class logic_error.*

*Postconditions: strcmp(what(), what_arg.c_str()) == 0.*

```cpp
logic_error(const char* what_arg);
```

*Effects: Constructs an object of class logic_error.*

*Postconditions: strcmp(what(), what_arg) == 0.*

### 22.2.3 Class **domain_error**

```cpp
namespace std {
    class domain_error : public logic_error {
        public:
            explicit domain_error(const string& what_arg);
            explicit domain_error(const char* what_arg);
    };
}
```

The class **domain_error** defines the type of objects thrown as exceptions by the implementation to report domain errors.

```cpp
domain_error(const string& what_arg);
```

*Effects: Constructs an object of class domain_error.*

*Postconditions: strcmp(what(), what_arg.c_str()) == 0.*

```cpp
domain_error(const char* what_arg);
```

*Effects: Constructs an object of class domain_error.*

*Postconditions: strcmp(what(), what_arg) == 0.*

### 22.2.4 Class **invalid_argument**

```cpp
namespace std {
    class invalid_argument : public logic_error {
        public:
            explicit invalid_argument(const string& what_arg);
            explicit invalid_argument(const char* what_arg);
    };
}
```

The class **invalid_argument** defines the type of objects thrown as exceptions to report an invalid argument.

```cpp
invalid_argument(const string& what_arg);
```

*Effects: Constructs an object of class invalid_argument.*

*Postconditions: strcmp(what(), what_arg.c_str()) == 0.*

```cpp
invalid_argument(const char* what_arg);
```

*Effects: Constructs an object of class invalid_argument.*

*Postconditions: strcmp(what(), what_arg) == 0.*

### 22.2.5 Class **length_error**

§ 22.2.5
namespace std {
    class length_error : public logic_error {
    public:
        explicit length_error(const string& what_arg);
        explicit length_error(const char* what_arg);
    };
}

1 The class length_error defines the type of objects thrown as exceptions to report an attempt to produce an object whose length exceeds its maximum allowable size.

length_error(const string& what_arg);
2 Effects: Constructs an object of class length_error.
3 Postconditions: strcmp(what(), what_arg.c_str()) == 0.

length_error(const char* what_arg);
4 Effects: Constructs an object of class length_error.
5 Postconditions: strcmp(what(), what_arg) == 0.

22.2.6 Class out_of_range

namespace std {
    class out_of_range : public logic_error {
    public:
        explicit out_of_range(const string& what_arg);
        explicit out_of_range(const char* what_arg);
    };
}

1 The class out_of_range defines the type of objects thrown as exceptions to report an argument value not in its expected range.

out_of_range(const string& what_arg);
2 Effects: Constructs an object of class out_of_range.
3 Postconditions: strcmp(what(), what_arg.c_str()) == 0.

out_of_range(const char* what_arg);
4 Effects: Constructs an object of class out_of_range.
5 Postconditions: strcmp(what(), what_arg) == 0.

22.2.7 Class runtime_error

namespace std {
    class runtime_error : public exception {
    public:
        explicit runtime_error(const string& what_arg);
        explicit runtime_error(const char* what_arg);
    };
}

1 The class runtime_error defines the type of objects thrown as exceptions to report errors presumably detectable only when the program executes.

runtime_error(const string& what_arg);
2 Effects: Constructs an object of class runtime_error.
Postconditions: strcmp(what(), what_arg.c_str()) == 0.

runtime_error(const char* what_arg);

Effects: Constructs an object of class runtime_error.

Postconditions: strcmp(what(), what_arg) == 0.

### 22.2.8 Class `range_error`

```cpp
namespace std {
    class range_error : public runtime_error {
        public:
            explicit range_error(const string& what_arg);
            explicit range_error(const char* what_arg);
    };
}
```

The class `range_error` defines the type of objects thrown as exceptions to report range errors in internal computations.

range_error(const string& what_arg);

Effects: Constructs an object of class `range_error`.

Postconditions: strcmp(what(), what_arg.c_str()) == 0.

range_error(const char* what_arg);

Effects: Constructs an object of class `range_error`.

Postconditions: strcmp(what(), what_arg) == 0.

### 22.2.9 Class `overflow_error`

```cpp
namespace std {
    class overflow_error : public runtime_error {
        public:
            explicit overflow_error(const string& what_arg);
            explicit overflow_error(const char* what_arg);
    };
}
```

The class `overflow_error` defines the type of objects thrown as exceptions to report an arithmetic overflow error.

overflow_error(const string& what_arg);

Effects: Constructs an object of class `overflow_error`.

Postconditions: strcmp(what(), what_arg.c_str()) == 0.

overflow_error(const char* what_arg);

Effects: Constructs an object of class `overflow_error`.

Postconditions: strcmp(what(), what_arg) == 0.

### 22.2.10 Class `underflow_error`

```cpp
namespace std {
    class underflow_error : public runtime_error {
        public:
            explicit underflow_error(const string& what_arg);
    };
}
```
The class `underflow_error` defines the type of objects thrown as exceptions to report an arithmetic underflow error.

```cpp
explicit underflow_error(const char* what_arg);
};
```

1. The class `underflow_error` defines the type of objects thrown as exceptions to report an arithmetic underflow error.

```cpp
underflow_error(const string& what_arg);
```

2. Effects: Constructs an object of class `underflow_error`.

```cpp
Effects: Constructs an object of class `underflow_error`.
```

```cpp
Postconditions: strcmp(what(), what_arg.c_str()) == 0.
```

3. Postconditions: `strcmp(what(), what_arg.c_str()) == 0`.

```cpp
underflow_error(const char* what_arg);
```

4. Effects: Constructs an object of class `underflow_error`.

```cpp
Effects: Constructs an object of class `underflow_error`.
```

```cpp
Postconditions: strcmp(what(), what_arg) == 0.
```

5. Postconditions: `strcmp(what(), what_arg) == 0`.

### 22.3 Assertions

The header `<cassert>` provides a macro for documenting C++ program assertions and a mechanism for disabling the assertion checks.

#### 22.3.1 Header `<cassert>` synopsis

```cpp
#define assert(E) see below
```

1. The contents are the same as the C standard library header `<assert.h>`, except that a macro named `static_assert` is not defined.

See also: ISO C 7.2.

#### 22.3.2 The `assert` macro

1. An expression `assert(E)` is a constant subexpression (20.3.6), if

   (1.1) — `NDEBUG` is defined at the point where `assert` is last defined or redefined, or

   (1.2) — `E` contextually converted to `bool` (Clause 7) is a constant subexpression that evaluates to the value `true`.

### 22.4 Error numbers

The contents of the header `<cerrno>` are the same as the POSIX header `<errno.h>`, except that `errno` shall be defined as a macro. [Note: The intent is to remain in close alignment with the POSIX standard. — end note] A separate `errno` value shall be provided for each thread.

#### 22.4.1 Header `<cerrno>` synopsis

```cpp
#define errno see below
```

```cpp
#define E2BIG see below
#define EACCES see below
#define EADDRINUSE see below
#define EADDRNOTAVAIL see below
#define EAFNOSUPPORT see below
#define EAGAIN see below
#define EALREADY see below
#define EBADF see below
#define EBADMSG see below
#define EBUSY see below
#define ECANCELED see below
```
#define ECHILD see below
#define ECONNABORTED see below
#define ECONNREFUSED see below
#define ECONNRESET see below
#define EDEADLK see below
#define EDESTADDRREQ see below
#define EDOM see below
#define EXIST see below
#defineEFAULT see below
#define EFBIG see below
#define EHOSTUNREACH see below
#define EIDRM see below
#define EILSEQ see below
#define EINPROGRESS see below
#define EINTR see below
#define EINVAL see below
#define EIO see below
#define EISCONN see below
#define EISDIR see below
#define ELOOP see below
#define EMFILE see below
#define EMLINK see below
#define EMSGSIZE see below
#define ENAMETOOLONG see below
#define ENETDOWN see below
#define ENETRESET see below
#define ENETUNREACH see below
#define ENFILE see below
#define ENOBUFS see below
#define ENODATA see below
#define ENODEV see below
#define ENOENT see below
#define ENOEXEC see below
#define ENOLCK see below
#define ENOLINK see below
#defineENOMEM see below
#define ENOMSG see below
#define ENOPROTOOPT see below
#define ENOSPC see below
#define ENOSR see below
#define ENOSTR see below
#define ENOSYS see below
#define ENOTCONN see below
#define ENOTDIR see below
#define ENOTEMPTY see below
#define ENOTRECOVERABLE see below
#define ENOTSOCK see below
#define ENOTSUP see below
#define ENOTTY see below
#define ENXIO see below
#define EOPNOTSUPP see below
#define EOVERFLOW see below
#define EOWNERDEAD see below
#define EPERM see below
#define EPIPE see below
The meaning of the macros in this header is defined by the POSIX standard.

See also: ISO C 7.5.

22.5 System error support

This subclause describes components that the standard library and C++ programs may use to report error conditions originating from the operating system or other low-level application program interfaces.

Components described in this subclause shall not change the value of `errno` (22.4). Implementations should leave the error states provided by other libraries unchanged.

22.5.1 Header `<system_error>` synopsis

```cpp
namespace std {
    class error_category;
    const error_category& generic_category() noexcept;
    const error_category& system_category() noexcept;

    class error_code;
    class error_condition;
    class system_error;

    template <class T>
    struct is_error_code_enum : public false_type {};

    template <class T>
    struct is_error_condition_enum : public false_type {};

    enum class errc {
        address_family_not_supported,  // EAFNSUPPORT
        address_in_use,               // EADDRINUSE
        address_not_available,        // EADDRNOTAVAIL
        already_connected,            // EISCONN

};

template <> struct is_error_condition_enum<errc> : true_type {};

// 22.5.3.5, non-member functions
error_code make_error_code(errc e) noexcept;

template <class charT, class traits>
basic_ostream<charT, traits>&
    operator<<(basic_ostream<charT, traits>& os, const error_code& ec);

// 22.5.4.5, non-member functions
error_condition make_error_condition(errc e) noexcept;

// 22.5.5, comparison functions
bool operator<(const error_code& lhs, const error_code& rhs) noexcept;
bool operator<(const error_condition& lhs, const error_condition& rhs) noexcept;
bool operator==(const error_code& lhs, const error_code& rhs) noexcept;
bool operator==(const error_condition& lhs, const error_condition& rhs) noexcept;
bool operator!=(const error_code& lhs, const error_code& rhs) noexcept;
bool operator!=(const error_condition& lhs, const error_condition& rhs) noexcept;

// 22.5.6, hash support
template <class T> struct hash;
template <> struct hash<error_code>;
template <> struct hash<error_condition>;

// 22.5, system error support
template <class T> inline constexpr bool is_error_code_enum_v
    = is_error_code_enum<T>::value;
template <class T> inline constexpr bool is_error_condition_enum_v
    = is_error_condition_enum<T>::value;
}

1 The value of each enum errc constant shall be the same as the value of the <cerrno> macro shown in
the above synopsis. Whether or not the <system_error> implementation exposes the <cerrno> macros is
unspecified.

2 The is_error_code_enum and is_error_condition_enum may be specialized for user-defined types to indicate
that such types are eligible for class error_code and class error_condition automatic conversions,
respectively.

### 22.5.2 Class error_category

#### 22.5.2.1 Class error_category overview

The class `error_category` serves as a base class for types used to identify the source and encoding of a particular category of error code. Classes may be derived from `error_category` to support categories of errors in addition to those defined in this International Standard. Such classes shall behave as specified in this subclause. [Note: `error_category` objects are passed by reference, and two such objects are equal if they have the same address. This means that applications using custom `error_category` types should create a single object of each such type. — end note]

```cpp
namespace std {
  class error_category {
    public:
      constexpr error_category() noexcept;
      virtual ~error_category();
      error_category(const error_category&) = delete;
      error_category& operator=(const error_category&) = delete;
      virtual const char* name() const noexcept = 0;
      virtual error_condition default_error_condition(int ev) const noexcept;
      virtual bool equivalent(int code, const error_condition& condition) const noexcept;
      virtual bool equivalent(const error_code& code, int condition) const noexcept;
      virtual string message(int ev) const = 0;
      bool operator==(const error_category& rhs) const noexcept;
      bool operator!=(const error_category& rhs) const noexcept;
      bool operator<(const error_category& rhs) const noexcept;
    }

    const error_category& generic_category() noexcept;
    const error_category& system_category() noexcept;
  }
```

#### 22.5.2.2 Class error_category virtual members

1.virtual ~error_category();
   
   **Effects**: Destroys an object of class `error_category`.

2. virtual const char* name() const noexcept = 0;
   
   **Returns**: A string naming the error category.

3. virtual error_condition default_error_condition(int ev) const noexcept;
   
   **Returns**: `error_condition(ev, *this)`.

4. virtual bool equivalent(int code, const error_condition& condition) const noexcept;
   
   **Returns**: `default_error_condition(code) == condition`.

5. virtual bool equivalent(const error_code& code, int condition) const noexcept;
   
   **Returns**: `*this == code.category() && code.value() == condition`.

6. virtual string message(int ev) const = 0;
   
   **Returns**: A string that describes the error condition denoted by `ev`.

#### 22.5.2.3 Class error_category non-virtual members

§ 22.5.2.3
constexpr error_category() noexcept;

Effects: Constructs an object of class error_category.

bool operator==(const error_category& rhs) const noexcept;

Returns: this == &rhs.

bool operator!=(const error_category& rhs) const noexcept;

Returns: !(this == rhs).

bool operator<(const error_category& rhs) const noexcept;

Returns: less<const error_category*>(this, &rhs).

[Note: less (23.14.7) provides a total ordering for pointers. —end note]

22.5.2.4 Program defined classes derived from error_category

virtual const char* name() const noexcept = 0;

Returns: A string naming the error category.

virtual error_condition default_error_condition(int ev) const noexcept;

Returns: An object of type error_condition that corresponds to ev.

virtual bool equivalent(int code, const error_condition& condition) const noexcept;

Returns: true if, for the category of error represented by *this, code is considered equivalent to condition; otherwise, false.

virtual bool equivalent(const error_code& code, int condition) const noexcept;

Returns: true if, for the category of error represented by *this, code is considered equivalent to condition; otherwise, false.

22.5.2.5 Error category objects

const error_category& generic_category() noexcept;

Returns: A reference to an object of a type derived from class error_category. All calls to this function shall return references to the same object.

Remarks: The object’s default_error_condition and equivalent virtual functions shall behave as specified for the class error_category. The object’s name virtual function shall return a pointer to the string "generic".

const error_category& system_category() noexcept;

Returns: A reference to an object of a type derived from class error_category. All calls to this function shall return references to the same object.

Remarks: The object’s equivalent virtual functions shall behave as specified for class error_category. The object’s name virtual function shall return a pointer to the string "system". The object’s default_error_condition virtual function shall behave as follows:

If the argument ev corresponds to a POSIX errno value posv, the function shall return error_condition(posv, generic_category()). Otherwise, the function shall return error_condition(ev, system_category()). What constitutes correspondence for any given operating system is unspecified.

[Note: The number of potential system error codes is large and unbounded, and some may not correspond to any POSIX errno value. Thus implementations are given latitude in determining correspondence. —end note]
22.5.3 Class error_code
22.5.3.1 Class error_code overview

The class `error_code` describes an object used to hold error code values, such as those originating from the operating system or other low-level application program interfaces. [Note: Class `error_code` is an adjunct to error reporting by exception. — end note]

```cpp
namespace std {
    class error_code {
        public:
            // 22.5.3.2, constructors
            error_code() noexcept;
            error_code(int val, const error_category& cat) noexcept;
            template <class ErrorCodeEnum>
                error_code(ErrorCodeEnum e) noexcept;

            // 22.5.3.3, modifiers
            void assign(int val, const error_category& cat) noexcept;
            template <class ErrorCodeEnum>
                error_code& operator=(ErrorCodeEnum e) noexcept;
            void clear() noexcept;

            // 22.5.3.4, observers
            int value() const noexcept;
            const error_category& category() const noexcept;
            error_condition default_error_condition() const noexcept;
            string message() const;
            explicit operator bool() const noexcept;
        private:
            int val_;     // exposition only
            const error_category* cat_; // exposition only
    };

    // 22.5.3.5, non-member functions
    error_code make_error_code(errc e) noexcept;

    template <class charT, class traits>
        basic_ostream<charT, traits>&
            operator<<(basic_ostream<charT, traits>& os, const error_code& ec);
}
```

22.5.3.2 Class error_code constructors

```
error_code() noexcept;

Effects: Constructs an object of type `error_code`.
Postconditions: `val_ == 0` and `cat_ == &system_category()`.
```

```
error_code(int val, const error_category& cat) noexcept;

Effects: Constructs an object of type `error_code`.
Postconditions: `val_ == val` and `cat_ == &cat`.
```

```
template <class ErrorCodeEnum>
    error_code(ErrorCodeEnum e) noexcept;
```

§ 22.5.3.2
Effects: Constructs an object of type error_code.

Postconditions: *this == make_error_code(e).

Remarks: This constructor shall not participate in overload resolution unless
is_error_code_enum_v<ErrorCodeEnum> is true.

### 22.5.3.3 Class error_code modifiers

```cpp
void assign(int val, const error_category& cat) noexcept;
```

Postconditions: val_ == val and cat_ == &cat.

```cpp
template <class ErrorCodeEnum>
error_code& operator=(ErrorCodeEnum e) noexcept;
```

Postconditions: *this == make_error_code(e).

Returns: *this.

Remarks: This operator shall not participate in overload resolution unless
is_error_code_enum_v<ErrorCodeEnum> is true.

```cpp
void clear() noexcept;
```

Postconditions: value() == 0 and category() == system_category().

### 22.5.3.4 Class error_code observers

```cpp
int value() const noexcept;
```

Returns: val_.

```cpp
const error_category& category() const noexcept;
```

Returns: *cat_.

error_condition default_error_condition() const noexcept;

Returns: category().default_error_condition(value()).

```cpp
string message() const;
```

Returns: category().message(value()).

```cpp
explicit operator bool() const noexcept;
```

Returns: value() != 0.

### 22.5.3.5 Class error_code non-member functions

```cpp
error_code make_error_code(errc e) noexcept;
```

Returns: error_code(static_cast<int>(e), generic_category()).

```cpp
template <class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const error_code& ec);
```

Effects: As if by: os << ec.category().name() << ':' << ec.value();

§ 22.5.3.5
22.5.4 Class error_condition

22.5.4.1 Class error_condition overview

The class error_condition describes an object used to hold values identifying error conditions. [Note: error_condition values are portable abstractions, while error_code values (22.5.3) are implementation specific. —end note]

```cpp
namespace std {
    class error_condition {
        public:
            // 22.5.4.2, constructors
            error_condition() noexcept;
            error_condition(int val, const error_category& cat) noexcept;
            template <class ErrorConditionEnum>
                error_condition(ErrorConditionEnum e) noexcept;

            // 22.5.4.3, modifiers
            void assign(int val, const error_category& cat) noexcept;
            template <class ErrorConditionEnum>
                error_condition& operator=(ErrorConditionEnum e) noexcept;
            void clear() noexcept;

            // 22.5.4.4, observers
            int value() const noexcept;
            const error_category& category() const noexcept;
            string message() const;
            explicit operator bool() const noexcept;
        private:
            int val_; // exposition only
            const error_category* cat_; // exposition only
    };
}
```

22.5.4.2 Class error_condition constructors

```cpp
error_condition() noexcept;
```

1 Effects: Constructs an object of type error_condition.

2 Postconditions: val_ == 0 and cat_ == &generic_category().

```cpp
error_condition(int val, const error_category& cat) noexcept;
```

3 Effects: Constructs an object of type error_condition.

4 Postconditions: val_ == val and cat_ == &cat.

```cpp
template <class ErrorConditionEnum>
    error_condition(ErrorConditionEnum e) noexcept;
```

5 Effects: Constructs an object of type error_condition.

6 Postconditions: *this == make_error_condition(e).

7 Remarks: This constructor shall not participate in overload resolution unless is_error_condition_enum_v<ErrorConditionEnum> is true.

22.5.4.3 Class error_condition modifiers

```cpp
void assign(int val, const error_category& cat) noexcept;
```

§ 22.5.4.3
Postconditions: \( \text{val}_\text{e} = \text{val} \) and \( \text{cat}_\text{e} = \&\text{cat} \).

\[\text{template <class ErrorConditionEnum>}
\text{error_condition& operator=(ErrorConditionEnum e) noexcept;}\]

Postconditions: \( \ast\text{this} = \text{make_error_condition(e)} \).

Returns: \( \ast\text{this} \).

Remarks: This operator shall not participate in overload resolution unless \( \text{is_error_condition_enum_v<ErrorConditionEnum>} \) is true.

\[\text{void clear() noexcept;}\]

Postconditions: \( \text{value()} = 0 \) and \( \text{category()} = \text{generic\_category()} \).

\[\text{22.5.4.4 Class error\_condition observers} \quad [\text{syserr.errcondition.observers}]\]

int value() const noexcept;

Returns: \( \text{val}_\text{e} \).

const error\_category& category() const noexcept;

Returns: \( \ast\text{cat}_\text{e} \).

string message() const;

Returns: \( \text{category().message(value())} \).

explicit operator bool() const noexcept;

Returns: \( \text{value()} \neq 0 \).

\[\text{22.5.4.5 Class error\_condition non-member functions} \quad [\text{syserr.errcondition.nonmembers}]\]

error\_condition make_error\_condition(errc e) noexcept;

Returns: \( \text{error\_condition(static\_cast<int>(e), \text{generic\_category()})} \).

\[\text{22.5.5 Comparison functions} \quad [\text{syserr.compare}]\]

bool operator<(const error\_code& lhs, const error\_code& rhs) noexcept;

Returns:

\( \text{lhs.category()} < \text{rhs.category()} \) ||
\( (\text{lhs.category()} == \text{rhs.category()} \&\& \text{lhs.value()} < \text{rhs.value()}) \);

bool operator<(const error\_condition& lhs, const error\_condition& rhs) noexcept;

Returns: \( \text{lhs.category()} < \text{rhs.category()} \) || \( \text{lhs.category()} == \text{rhs.category()} \&\& \text{lhs.value()} < \text{rhs.value()} \).

bool operator==(const error\_code& lhs, const error\_code& rhs) noexcept;

Returns: \( \text{lhs.category()} == \text{rhs.category()} \&\& \text{lhs.value()} == \text{rhs.value()} \).

bool operator==(const error\_condition& lhs, const error\_condition& rhs) noexcept;

Returns: \( \text{lhs.category().equivalent(lhs.value(), rhs)} \) || \( \text{rhs.category().equivalent(lhs, rhs.value())} \).

bool operator==(const error\_condition& lhs, const error\_code& rhs) noexcept;

\[\text{§ 22.5.5} \quad 527\]
Returns: rhs.category().equivalent(rhs.value(), lhs) || lhs.category().equivalent(rhs, lhs.value()).

bool operator==(const error_condition& lhs, const error_condition& rhs) noexcept;

Returns: lhs.category() == rhs.category() && lhs.value() == rhs.value().

bool operator!=(const error_code& lhs, const error_condition& rhs) noexcept;
bool operator!=(const error_code& lhs, const error_condition& rhs) noexcept;
bool operator!=(const error_condition& lhs, const error_condition& rhs) noexcept;
bool operator!=(const error_condition& lhs, const error_condition& rhs) noexcept;

Returns: !(lhs == rhs).

22.5.6 System error hash support

template <> struct hash<error_code>;
template <> struct hash<error_condition>;

The specializations are enabled (23.14.15).

22.5.7 Class system_error

22.5.7.1 Class system_error overview

The class system_error describes an exception object used to report error conditions that have an associated error code. Such error conditions typically originate from the operating system or other low-level application program interfaces.

[Note: If an error represents an out-of-memory condition, implementations are encouraged to throw an exception object of type bad_alloc (21.6.3.1) rather than system_error. — end note]

namespace std {
    class system_error : public runtime_error {
        public:
            system_error(error_code ec, const string& what_arg);
            system_error(error_code ec, const char* what_arg);
            system_error(error_code ec);
            system_error(int ev, const error_category& ecat, const string& what_arg);
            system_error(int ev, const error_category& ecat, const char* what_arg);
            system_error(int ev, const error_category& ecat);
            const error_code& code() const noexcept;
            const char* what() const noexcept override;
    };
}

22.5.7.2 Class system_error members

system_error(error_code ec, const string& what_arg);

Effects: Constructs an object of class system_error.

Postconditions: code() == ec.

string(what()).find(what_arg) != string::npos.

system_error(error_code ec, const char* what_arg);

Effects: Constructs an object of class system_error.

Postconditions: code() == ec.

string(what()).find(what_arg) != string::npos.
system_error(error_code ec);

   Effects: Constructs an object of class system_error.

   Postconditions: code() == ec.

system_error(int ev, const error_category& ecat, const string& what_arg);

   Effects: Constructs an object of class system_error.

   Postconditions: code() == error_code(ev, ecat).

   string(what()).find(what_arg) != string::npos.

system_error(int ev, const error_category& ecat, const char* what_arg);

   Effects: Constructs an object of class system_error.

   Postconditions: code() == error_code(ev, ecat).

   string(what()).find(what_arg) != string::npos.

system_error(int ev, const error_category& ecat);

   Effects: Constructs an object of class system_error.

   Postconditions: code() == error_code(ev, ecat).

const error_code& code() const noexcept;

   Returns: ec or error_code(ev, ecat), from the constructor, as appropriate.

const char* what() const noexcept override;

   Returns: An NTBS incorporating the arguments supplied in the constructor.

   [ Note: The returned NTBS might be the contents of what_arg + ": " + code.message(). — end note ]
23 General utilities library

23.1 General

This Clause describes utilities that are generally useful in C++ programs; some of these utilities are used by other elements of the C++ standard library. These utilities are summarized in Table 34.

Table 34 — General utilities library summary

23.2 Utility components

This subclause contains some basic function and class templates that are used throughout the rest of the library.

23.2.1 Header <utility> synopsis

```cpp
#include <initializer_list> // see 21.9.1

namespace std {
    // 23.2.2, operators
    namespace rel_ops {
        template<class T> bool operator!=(const T&, const T&);
        template<class T> bool operator> (const T&, const T&);
        template<class T> bool operator<=(const T&, const T&);
        template<class T> bool operator>=(const T&, const T&);
    }
}
```

§ 23.2.1
// 23.2.3, swap
template <class T>
  void swap(T& a, T& b) noexcept(see below);

};
template <size_t I> inline constexpr in_place_index_t<I> in_place_index{};

// floating-point format for primitive numerical conversion
enum class chars_format {
    scientific = unspecified,
    fixed = unspecified,
    hex = unspecified,
    general = fixed | scientific
};

// 23.2.8, primitive numerical output conversion
struct to_chars_result {
    char* ptr;
    error_code ec;
};
to_chars_result to_chars(char* first, char* last, see below value, int base = 10);
to_chars_result to_chars(char* first, char* last, float value);
to_chars_result to_chars(char* first, char* last, double value);
to_chars_result to_chars(char* first, char* last, long double value);
to_chars_result to_chars(char* first, char* last, float value, chars_format fmt);
to_chars_result to_chars(char* first, char* last, double value, chars_format fmt);
to_chars_result to_chars(char* first, char* last, long double value, chars_format fmt);
to_chars_result to_chars(char* first, char* last, float value, chars_format fmt, int precision);
to_chars_result to_chars(char* first, char* last, double value, chars_format fmt, int precision);
to_chars_result to_chars(char* first, char* last, long double value, chars_format fmt, int precision);

// 23.2.9, primitive numerical input conversion
struct from_chars_result {
    const char* ptr;
    error_code ec;
};
from_chars_result from_chars(const char* first, const char* last, 
    see below& value, int base = 10);

from_chars_result from_chars(const char* first, const char* last, float& value, 
    chars_format fmt = chars_format::general);
from_chars_result from_chars(const char* first, const char* last, double& value, 
    chars_format fmt = chars_format::general);
from_chars_result from_chars(const char* first, const char* last, long double& value, 
    chars_format fmt = chars_format::general);

1 The header <utility> defines several types and function templates that are described in this Clause. It also defines the template pair and various function templates that operate on pair objects.
2 The type chars_format is a bitmask type (20.4.2.1.4) with elements scientific, fixed, and hex.

### 23.2.2 Operators

1 To avoid redundant definitions of operator!= out of operator== and operators >, <=, and >= out of operator<, the library provides the following:

    template <class T> bool operator!=(const T& x, const T& y);

    Requires: Type T is EqualityComparable (Table 20).

2 Returns: !(x == y).

3 template <class T> bool operator>(const T& x, const T& y);

    Requires: Type T is LessThanComparable (Table 21).

4 Returns: y < x.

5 template <class T> bool operator<=(const T& x, const T& y);

    Requires: Type T is LessThanComparable (Table 21).

6 Returns: !(y < x).

7 template <class T> bool operator>=(const T& x, const T& y);

    Requires: Type T is LessThanComparable (Table 21).

8 Returns: !(x < y).

9 In this library, whenever a declaration is provided for an operator!=, operator>, operator>=, or operator<, and requirements and semantics are not explicitly provided, the requirements and semantics are as specified in this Clause.

### 23.2.3 swap

1 template <class T>
void swap(T& a, T& b) noexcept(see below);

Remarks: This function shall not participate in overload resolution unless is_move_constructible_v<T> is true and is_move_assignable_v<T> is true. The expression inside noexcept is equivalent to:

    is_nothrow_move_constructible_v<T> && is_nothrow_move_assignable_v<T>

2 Requires: Type T shall be MoveConstructible (Table 23) and MoveAssignable (Table 25).

3 Effects: Exchanges values stored in two locations.

§ 23.2.3 534
template <class T, size_t N>
    void swap(T (&a)[N], T (&b)[N]) noexcept(is_nothrow_swappable_v<T>);

Remarks: This function shall not participate in overload resolution unless is_swappable_v<T> is true.

Requires: a[i] shall be swappable with (20.5.3.2) b[i] for all i in the range [0, N).

Effects: As if by swap_ranges(a, a + N, b).

23.2.4 exchange

[utility.exchange]

template <class T, class U = T> T exchange(T& obj, U&& new_val);

Effects: Equivalent to:
    T old_val = std::move(obj);
    obj = std::forward<U>(new_val);
    return old_val;

23.2.5 Forward/move helpers

[forward]
The library provides templated helper functions to simplify applying move semantics to an lvalue and to
simplify the implementation of forwarding functions. All functions specified in this subclause are signal-
safe (21.10.3).

template <class T> constexpr T&& forward(remove_reference_t<T>& t) noexcept;

template <class T> constexpr T&& forward(remove_reference_t<T>&& t) noexcept;

Returns: static_cast<T&&>(t).

Remarks: If the second form is instantiated with an lvalue reference type, the program is ill-formed.

[Example:
    template <class T, class A1, class A2>
    shared_ptr<T> factory(A1&& a1, A2&& a2) {
        return shared_ptr<T>(new T(std::forward<A1>(a1), std::forward<A2>(a2)));
    }

    struct A {
        A(int&, const double&);
    };

    void g() {
        shared_ptr<A> sp1 = factory<A>(2, 1.414); // error: 2 will not bind to int
        int i = 2;
        shared_ptr<A> sp2 = factory<A>(i, 1.414); // OK
    }
]

In the first call to factory, A1 is deduced as int, so 2 is forwarded to A's constructor as an rvalue. In
the second call to factory, A1 is deduced as int&, so i is forwarded to A's constructor as an lvalue.
In both cases, A2 is deduced as double, so 1.414 is forwarded to A's constructor as an rvalue. — end example]

template <class T> constexpr remove_reference_t<T>&& move(T&& t) noexcept;

Returns: static_cast<remove_reference_t<T>&&>(t).

[Example:
    template <class T, class A1>
    shared_ptr<T> factory(A1&& a1) {
        return shared_ptr<T>(new T(std::forward<A1>(a1)));
    }
]

§ 23.2.5
struct A {
    A();
    A(const A&);  // copies from lvalues
    A(A&&);      // moves from rvalues
};

void g() {
    A a;
    shared_ptr<A> sp1 = factory<A>(a);  // “a” binds to A(const A&)
    shared_ptr<A> sp1 = factory<A>(std::move(a)); // “a” binds to A(A&&)
}

In the first call to factory, A1 is deduced as A&, so a is forwarded as a non-const lvalue. This binds to the constructor A(const A&), which copies the value from a. In the second call to factory, because of the call std::move(a), A1 is deduced as A, so a is forwarded as an rvalue. This binds to the constructor A(A&&), which moves the value from a. — end example

template <class T> constexpr conditional_t<!is_nothrow_move_constructible_v<T> && is_copy_constructible_v<T>, const T&, T&&>
mov_if_noexcept(T& x) noexcept;

Returns: std::move(x).

23.2.6 Function template as_const

template <class T> constexpr add_const_t<T>& as_const(T& t) noexcept;

Returns: t.

23.2.7 Function template declval

The library provides the function template declval to simplify the definition of expressions which occur as unevaluated operands (Clause 8).

template <class T> add_rvalue_reference_t<T> declval() noexcept;  // as unevaluated operand

Remarks: If this function is odr-used (6.2), the program is ill-formed.

Remarks: The template parameter T of declval may be an incomplete type.

[Example:
    template <class To, class From> decltype(static_cast<To>(declval<From>())) convert(From&&);

declares a function template convert which only participates in overloading if the type From can be explicitly converted to type To. For another example see class template common_type (23.15.7.6). — end example]

23.2.8 Primitive numeric output conversion

All functions named to_chars convert value into a character string by successively filling the range [first, last), where [first, last) is required to be a valid range. If the member ec of the return value is such that the value, when converted to bool, is false, the conversion was successful and the member ptr is the one-past-the-end pointer of the characters written. Otherwise, the member ec has the value errc::value too large, the member ptr has the value last, and the contents of the range [first, last) are unspecified.

The functions that take a floating-point value but not a precision parameter ensure that the string representation consists of the smallest number of characters such that there is at least one digit before the radix point (if present) and parsing the representation using the corresponding from_chars function recovers
value exactly. [Note: This guarantee applies only if to_chars and from_chars are executed on the same implementation. — end note]

3 The functions taking a chars_format parameter determine the conversion specifier for printf as follows: The conversion specifier is f if fmt is chars_format::fixed, e if fmt is chars_format::scientific, a (without leading "0x" in the result) if fmt is chars_format::hex, and g if fmt is chars_format::general.

```cpp
3 to_chars_result to_chars(char* first, char* last, see below value, int base = 10);
```

4 Requires: base has a value between 2 and 36 (inclusive).

5 Effects: The value of value is converted to a string of digits in the given base (with no redundant leading zeroes). Digits in the range 10..35 (inclusive) are represented as lowercase characters a..z. If value is less than zero, the representation starts with a minus sign.

6 Throws: Nothing.

7 Remarks: The implementation shall provide overloads for all signed and unsigned integer types and char as the type of the parameter value.

```cpp
4 to_chars_result to_chars(char* first, char* last, float value);
5 to_chars_result to_chars(char* first, char* last, double value);
6 to_chars_result to_chars(char* first, char* last, long double value);
```

8 Effects: value is converted to a string in the style of printf in the "C" locale. The conversion specifier is f or e, chosen according to the requirement for a shortest representation (see above); a tie is resolved in favor of f.

9 Throws: Nothing.

```cpp
7 to_chars_result to_chars(char* first, char* last, float value, chars_format fmt);
8 to_chars_result to_chars(char* first, char* last, double value, chars_format fmt);
9 to_chars_result to_chars(char* first, char* last, long double value, chars_format fmt);
```

10 Requires: fmt has the value of one of the enumerators of chars_format.

11 Effects: value is converted to a string in the style of printf in the "C" locale.

12 Throws: Nothing.

```cpp
10 to_chars_result to_chars(char* first, char* last, float value,
11     chars_format fmt, int precision);
12 to_chars_result to_chars(char* first, char* last, double value,
13     chars_format fmt, int precision);
14 to_chars_result to_chars(char* first, char* last, long double value,
15     chars_format fmt, int precision);
```

13 Requires: fmt has the value of one of the enumerators of chars_format.

14 Effects: value is converted to a string in the style of printf in the "C" locale with the given precision.

15 Throws: Nothing.

See also: ISO C 7.21.6.1.

### 23.2.9 Primitive numeric input conversion

1 All functions named from_chars analyze the string [first, last) for a pattern, where [first, last) is required to be a valid range. If no characters match the pattern, value is unmodified, the member ptr of the return value is first and the member ec is equal to errc::invalid_argument. Otherwise, the characters matching the pattern are interpreted as a representation of a value of the type of value. The member ptr of the return value points to the first character not matching the pattern, or has the value last if all characters match. If the parsed value is not in the range representable by the type of value, value is unmodified and
the member \texttt{ec} of the return value is equal to \texttt{errc::result\_out\_of\_range}. Otherwise, \texttt{value} is set to the parsed value and the member \texttt{ec} is set such that the conversion to \texttt{bool} yields \texttt{false}.

\begin{verbatim}
from_chars_result from_chars(const char* first, const char* last,
    see below & value, int base = 10);
\end{verbatim}

\textbf{Requires}: \texttt{base} has a value between 2 and 36 (inclusive).

\textbf{Effects}: The pattern is the expected form of the subject sequence in the "C" locale for the given nonzero base, as described for \texttt{strtol}, except that no "0x" or "0X" prefix shall appear if the value of \texttt{base} is 16, and except that a minus sign is the only sign that may appear, and only if \texttt{value} has a signed type.

\textbf{Throws}: Nothing.

\textbf{Remarks}: The implementation shall provide overloads for all signed and unsigned integer types and \texttt{char} as the referenced type of the parameter \texttt{value}.

\begin{verbatim}
from_chars_result from_chars(const char* first, const char* last, float& value,
    chars_format fmt = chars_format::general);
from_chars_result from_chars(const char* first, const char* last, double& value,
    chars_format fmt = chars_format::general);
from_chars_result from_chars(const char* first, const char* last, long double& value,
    chars_format fmt = chars_format::general);
\end{verbatim}

\textbf{Requires}: \texttt{fmt} has the value of one of the enumerators of \texttt{chars\_format}.

\textbf{Effects}: The pattern is the expected form of the subject sequence in the "C" locale, as described for \texttt{strtod}, except that

\begin{itemize}
  \item [7.1] the only sign that may appear is a minus sign;
  \item [7.2] if \texttt{fmt} has \texttt{chars\_format::scientific} set but not \texttt{chars\_format::fixed}, the otherwise optional exponent part shall appear;
  \item [7.3] if \texttt{fmt} has \texttt{chars\_format::fixed} set but not \texttt{chars\_format::scientific}, the optional exponent part shall not appear; and
  \item [7.4] if \texttt{fmt} is \texttt{chars\_format::hex}, the prefix "0x" or "0X" is assumed. [Example: The string \texttt{0x123} is parsed to have the value 0 with remaining characters \texttt{x123}. \textit{— end example}]
\end{itemize}

In any case, the resulting \texttt{value} is one of at most two floating-point values closest to the value of the string matching the pattern.

\textbf{Throws}: Nothing.

\textbf{See also}: ISO C 7.22.1.3, ISO C 7.22.1.4.

\section*{23.3 Compile-time integer sequences \[intseq\]}

\subsection*{23.3.1 In general \[intseq.general\]}

The library provides a class template that can represent an integer sequence. When used as an argument to a function template the parameter pack defining the sequence can be deduced and used in a pack expansion. [\textbf{Note}: The \texttt{index\_sequence} alias template is provided for the common case of an integer sequence of type \texttt{size\_t}; see also 23.5.3.5. \textit{— end note}]

\subsection*{23.3.2 Class template \texttt{integer\_sequence} \[intseq.intseq\]}

\begin{verbatim}
namespace std {
    template<class T, T... I>
    struct integer_sequence {
        using value_type = T;
        static constexpr size_t size() noexcept { return sizeof...(I); }
    }
\end{verbatim}
T shall be an integer type.

### 23.3.3 Alias template make_integer_sequence

```cpp
template<class T, T N>
using make_integer_sequence = integer_sequence<T, see below>;
```

1 If N is negative the program is ill-formed. The alias template `make_integer_sequence` denotes a specialization of `integer_sequence` with N template non-type arguments. The type `make_integer_sequence<T, N>` denotes the type `integer_sequence<T, 0, 1, ..., N-1>`. [Note: `make_integer_sequence<int, 0>` denotes the type `integer_sequence<int>` — end note]

### 23.4 Pairs

#### 23.4.1 In general

The library provides a template for heterogeneous pairs of values. The library also provides a matching function template to simplify their construction and several templates that provide access to `pair` objects as if they were `tuple` objects (see 23.5.3.6 and 23.5.3.7).

#### 23.4.2 Class template pair

```cpp
namespace std {
  template <class T1, class T2>
  struct pair {
    using first_type = T1;
    using second_type = T2;

    T1 first;
    T2 second;
    ...

    pair(const pair&) = default;
    pair(pair&&) = default;
    EXPLICIT constexpr pair();
    EXPLICIT constexpr pair(const T1& x, const T2& y);
    template<class U1, class U2> EXPLICIT constexpr pair(U1&& x, U2&& y);
    template<class U1, class U2> EXPLICIT constexpr pair(pair<U1, U2>& p);
    template<class U1, class U2> EXPLICIT constexpr pair(pair<U1, U2>&& p);
    template <class... Args1, class... Args2>
    pair(piecewise_construct_t, tuple<Args1...> first_args, tuple<Args2...> second_args);
    ...

    pair& operator=(const pair& p);
    template<class U1, class U2> pair& operator=(const pair<U1, U2>& p);
    pair& operator=(pair&& p) noexcept(see below);
    template<class U1, class U2> pair& operator=(pair<U1, U2>&& p);
    ...

    void swap(pair& p) noexcept(see below);
  };

  template<class T1, class T2>
  pair(T1, T2) -> pair<T1, T2>;
}
```

1 Constructors and member functions of `pair` shall not throw exceptions unless one of the element-wise operations specified to be called for that operation throws an exception.
The defaulted move and copy constructor, respectively, of `pair` shall be a constexpr function if and only if all required element-wise initializations for copy and move, respectively, would satisfy the requirements for a constexpr function. The destructor of `pair` shall be a trivial destructor if `(is_trivially_destructible_v<T1> && is_trivially_destructible_v<T2>)` is true.

*EXPLICIT constexpr pair();*

**Effects:** Value-initializes `first` and `second`.

**Remarks:** This constructor shall not participate in overload resolution unless `is_default_constructible_v<first_type>` is true and `is_default_constructible_v<second_type>` is true. [Note: This behavior can be implemented by a constructor template with default template arguments. —end note] The constructor is explicit if and only if either `first_type` or `second_type` is not implicitly default-constructible. [Note: This behavior can be implemented with a trait that checks whether a `const first_type&` or a `const second_type&` can be initialized with `{}`. —end note]

*EXPLICIT constexpr pair(const T1& x, const T2& y);*

**Effects:** Initializes `first` with `x` and `second` with `y`.

**Remarks:** This constructor shall not participate in overload resolution unless `is_copy_constructible_v<first_type>` is true and `is_copy_constructible_v<second_type>` is true. The constructor is explicit if and only if `is_convertible_v<const first_type&, first_type>` is false or `is_convertible_v<const second_type&, second_type>` is false.

*template<class U1, class U2> EXPLICIT constexpr pair(U1&& x, U2&& y);*

**Effects:** Initializes `first` with `std::forward<U1>(x)` and `second` with `std::forward<U2>(y)`.

**Remarks:** This constructor shall not participate in overload resolution unless `is_constructible_v<first_type, U1&&>` is true and `is_constructible_v<second_type, U2&&>` is true. The constructor is explicit if and only if `is_convertible_v<const first_type&, first_type>` is false or `is_convertible_v<const second_type&, second_type>` is false.

*template<class U1, class U2> EXPLICIT constexpr pair(const pair<U1, U2>& p);*

**Effects:** Initializes members from the corresponding members of the argument.

**Remarks:** This constructor shall not participate in overload resolution unless `is_constructible_v<first_type, const U1&>` is true and `is_constructible_v<second_type, const U2&>` is true. The constructor is explicit if and only if `is_convertible_v<const U1&, first_type>` is false or `is_convertible_v<const U2&, second_type>` is false.

*template<class U1, class U2> EXPLICIT constexpr pair(pair<U1, U2>&& p);*

**Effects:** Initializes `first` with `std::forward<U1>(p.first)` and `second` with `std::forward<U2>(p.second)`.

**Remarks:** This constructor shall not participate in overload resolution unless `is_constructible_v<first_type, U1&&>` is true and `is_constructible_v<second_type, U2&&>` is true. The constructor is explicit if and only if `is_convertible_v<const U1&, first_type>` is false or `is_convertible_v<const U2&, second_type>` is false.

*template<class... Args1, class... Args2> pair(piecewise_construct_t, tuple<Args1...> first_args, tuple<Args2...> second_args)*

**Requires:** `is_constructible_v<first_type, Args1&&...>` is true and `is_constructible_v<second_type, Args2&&...>` is true.

**Effects:** Initializes `first` with arguments of types `Args1...` obtained by forwarding the elements of
first_args and initializes second with arguments of types Args2... obtained by forwarding the
elements of second_args. (Here, forwarding an element x of type U within a tuple object means
calling std::forward<U>(x).) This form of construction, whereby constructor arguments for first
and second are each provided in a separate tuple object, is called piecewise construction.

pair& operator=(const pair& p);
    Effects: Assigns p.first to first and p.second to second.
    Remarks: This operator shall be defined as deleted unless is_copy_assignable_v<first_type> is
true and is_copy_assignable_v<second_type> is true.
    Returns: *this.

template<class U1, class U2> pair& operator=(const pair<U1, U2>& p);
    Effects: Assigns p.first to first and p.second to second.
    Remarks: This operator shall not participate in overload resolution unless is_assignable_v<first_type&,
const U1&> is true and is_assignable_v<second_type&, const U2&> is true.
    Returns: *this.

pair& operator=(pair&& p) noexcept(see below);
    Effects: Assigns to first with std::forward<first_type>(p.first) and to second with
std::forward<second_type>(p.second).
    Remarks: This operator shall be defined as deleted unless is_move_assignable_v<first_type> is
true and is_move_assignable_v<second_type> is true.
    Remarks: The expression inside noexcept is equivalent to:
        is_nothrow_moveAssignable_v<T1> && is_nothrow_moveAssignable_v<T2>
    Returns: *this.

template<class U1, class U2> pair& operator=(pair<U1, U2>&& p);
    Effects: Assigns to first with std::forward<U1>(p.first) and to second with
std::forward<V>(p.second).
    Remarks: This operator shall not participate in overload resolution unless is_assignable_v<first_type&,
U1&&> is true and is_assignable_v<second_type&, U2&&> is true.
    Returns: *this.

void swap(pair& p) noexcept(see below);
    Requires: first shall be swappable with (20.5.3.2) p.first and second shall be swappable with
p.second.
    Effects: Swaps first with p.first and second with p.second.
    Remarks: The expression inside noexcept is equivalent to:
        is_nothrow_swappable_v<first_type> && is_nothrow_swappable_v<second_type>

23.4.3 Specialized algorithms
    [pairs.spec]

template <class T1, class T2>
constexpr bool operator==(const pair<T1, T2>& x, const pair<T1, T2>& y);
    Returns: x.first == y.first && x.second == y.second.

template <class T1, class T2>
constexpr bool operator<(const pair<T1, T2>& x, const pair<T1, T2>& y);

Returns: \( x\.first < y\.first \) || (!\( y\.first < x\.first \) && \( x\.second < y\.second \))

template <class T1, class T2>
constexpr bool operator!=(const pair<T1, T2>& x, const pair<T1, T2>& y);

Returns: \( !\( x == y \) \)

template <class T1, class T2>
constexpr bool operator>=(const pair<T1, T2>& x, const pair<T1, T2>& y);

Returns: \( !\( x < y \) \)

template <class T1, class T2>
constexpr bool operator<=(const pair<T1, T2>& x, const pair<T1, T2>& y);

Returns: \( !\( y < x \) \)

template <class T1, class T2> void swap(pair<T1, T2>& x, pair<T1, T2>& y);

Effects: As if by \( x\.swap(y) \)

Remarks: This function shall not participate in overload resolution unless is_swappable_v<T1> is true and is_swappable_v<T2> is true.

template <class T1, class T2>
constexpr pair<V1, V2> make_pair(T1&& x, T2&& y);

Returns: \( \text{pair<V1, V2>(std::forward<T1>(x), std::forward<T2>(y))} \)

[Example: In place of:

\[
\text{return pair<int, double>(5, 3.1415926);} \quad // \text{explicit types}
\]
a C++ program may contain:

\[
\text{return make_pair(5, 3.1415926);} \quad // \text{types are deduced}
\]

— end example]

23.4.4 Tuple-like access to pair

template <class T1, class T2>
struct tuple_size<pair<T1, T2>> : integral_constant<size_t, 2> { }

tuple_element<0, pair<T1, T2>>::type

Value: The type T1.

tuple_element<1, pair<T1, T2>>::type

Value: The type T2.

template<
size_t I, class T1, class T2>
constexpr tuple_element_t<I, pair<T1, T2>>& get(pair<T1, T2>& p) noexcept;

template<
size_t I, class T1, class T2>
§ 23.4.4
constexpr const tuple_element_t<I, pair<T1, T2>>& get(const pair<T1, T2>& p) noexcept;

template<size_t I, class T1, class T2>
constexpr tuple_element_t<I, pair<T1, T2>>&& get(pair<T1, T2>&& p) noexcept;

Returns: If $I == 0$ returns a reference to $p$.first; if $I == 1$ returns a reference to $p$.second; otherwise the program is ill-formed.

template <class T1, class T2>
constexpr T1& get(pair<T1, T2>& p) noexcept;

Returns: A reference to $p$.first.

template <class T2, class T1>
constexpr T2& get(pair<T1, T2>& p) noexcept;

Requires: $T1$ and $T2$ are distinct types. Otherwise, the program is ill-formed.

23.4.5 Piecewise construction [pair.piecewise]

struct piecewise_construct_t {
  explicit piecewise_construct_t() = default;
};

inline constexpr piecewise_construct_t piecewise_construct();

The struct piecewise_construct_t is an empty structure type used as a unique type to disambiguate constructor and function overloading. Specifically, pair has a constructor with piecewise_construct_t as the first argument, immediately followed by two tuple (23.5) arguments used for piecewise construction of the elements of the pair object.

23.5 Tuples [tuple]

23.5.1 In general [tuple.general]

This subclause describes the tuple library that provides a tuple type as the class template tuple that can be instantiated with any number of arguments. Each template argument specifies the type of an element in the tuple. Consequently, tuples are heterogeneous, fixed-size collections of values. An instantiation of tuple with two arguments is similar to an instantiation of pair with the same two arguments. See 23.4.

23.5.2 Header <tuple> synopsis [tuple.syn]

namespace std {

// 23.5.3, class template tuple

tuple& operator=(pair<U1, U2>&&);

// 23.5.3.3, tuple swap
void swap(tuple&) noexcept;
```

23.5.3.1 Construction

For each `tuple` constructor, an exception is thrown only if the construction of one of the types in `Types` throws an exception.

§ 23.5.3.1 546
The defaulted move and copy constructor, respectively, of \texttt{tuple} shall be a \texttt{constexpr} function if and only if all required element-wise initializations for copy and move, respectively, would satisfy the requirements for a \texttt{constexpr} function. The defaulted move and copy constructor of \texttt{tuple<>} shall be \texttt{constexpr} functions.

The destructor of \texttt{tuple} shall be a \texttt{trivial} destructor if $(\texttt{is\_trivially\_destructible\_v<Types> \&\& ...})$ is \texttt{true}.

In the constructor descriptions that follow, let $i$ be in the range $[0, \texttt{sizeof...(Types)}$ in order, $T_i$ be the $i^{\text{th}}$ type in $\texttt{Types}$, and $U_i$ be the $i^{\text{th}}$ type in a template parameter pack named $\texttt{UTypes}$, where indexing is zero-based.

**EXPLICIT** \texttt{constexpr} \texttt{tuple();}

\textbf{Effects:} Value-initializes each element.

\textbf{Remarks:} This constructor shall not participate in overload resolution unless \texttt{is\_default\_constructible\_v<T,T_i>} is \texttt{true} for all $i$. [\textit{Note:} This behavior can be implemented by a constructor template with default template arguments. — end note] The constructor is explicit if and only if $T_i$ is not implicitly default-constructible for at least one $i$. [\textit{Note:} This behavior can be implemented with a trait that checks whether a \texttt{const T_i} can be initialized with \texttt{\{}. — end note]

**EXPLICIT** \texttt{constexpr} \texttt{tuple(const Types&...);}

\textbf{Effects:} Initializes each element with the value of the corresponding parameter.

\textbf{Remarks:} This constructor shall not participate in overload resolution unless \texttt{sizeof...(Types)} $\geq$ 1 and \texttt{is\_copy\_constructible\_v<T,T_i>} is \texttt{true} for all $i$. The constructor is explicit if and only if \texttt{is\_convertible\_v<const T,T_i>} is \texttt{false} for at least one $i$.

**template <class... UTypes> EXPLICIT** \texttt{constexpr} \texttt{tuple(UTypes&&... u);}  

\textbf{Effects:} Initializes the elements in the tuple with the corresponding value in \texttt{std::forward<UTypes>(u)}.  

\textbf{Remarks:} This constructor shall not participate in overload resolution unless \texttt{sizeof...(UTypes)} $=$ \texttt{sizeof...(Types)} and $\texttt{is\_constructible\_v<T,T_i, U_i&&>}$ is \texttt{true} for all $i$. The constructor is explicit if and only if \texttt{is\_convertible\_v<const U_i&&, T_i>} is \texttt{false} for at least one $i$.

\texttt{tuple(const tuple& u) = default;}

\textbf{Requires:} $\texttt{is\_copy\_constructible\_v<T,T_i>}$ is \texttt{true} for all $i$.

\textbf{Effects:} Initializes each element of \texttt{*this} with the corresponding element of $u$.

\texttt{tuple(tuple& u) = default;}

\textbf{Requires:} $\texttt{is\_move\_constructible\_v<T,T_i>}$ is \texttt{true} for all $i$.

\textbf{Effects:} For all $i$, initializes the $i^{\text{th}}$ element of \texttt{*this} with \texttt{std::forward<T,T_i>(get<i>(u))}.  

**template <class... UTypes> EXPLICIT** \texttt{constexpr} \texttt{tuple(const tuple<UTypes...>& u);}  

\textbf{Effects:} Initializes each element of \texttt{*this} with the corresponding element of $u$.

\textbf{Remarks:} This constructor shall not participate in overload resolution unless

\begin{itemize}
  \item $\texttt{sizeof...(Types)} =$ \texttt{sizeof...(UTypes)} and
  \item $\texttt{is\_constructible\_v<T,T_i, const U_i&&} =$ \texttt{true} for all $i$, and
  \item $\texttt{sizeof...(Types)} != 1$, or (when \texttt{Types...} expands to $T$ and \texttt{UTypes...} expands to $U$) $\texttt{!is\_convertible\_v<const tuple<U&&, T> \&\& !is\_constructible\_v<T, const tuple<U&&> \&\& !is\_same\_v<T, U>}$ is \texttt{true}.
\end{itemize}

The constructor is explicit if and only if \texttt{is\_convertible\_v<const U_i&&, T_i>} is \texttt{false} for at least one
template <class... UTypes> EXPLICIT constexpr tuple(tuple<UTypes...>&& u);

Effects: For all \( i \), initializes the \( i \)th element of \(*this\) with `std::forward<U_i>(get<i>(u))`.

Remarks: This constructor shall not participate in overload resolution unless

\[(18.1)\] sizeof...(Types) == sizeof...(UTypes), and

\[(18.2)\] is_constructible_v<T_i, U_i&&> is true for all \( i \), and

\[(18.3)\] sizeof...(Types) != 1, or (when Types... expands to \( T \) and UTypes... expands to \( U \))

```cpp
!is_convertible_v<tuple<U>, T> && !is_constructible_v<T, tuple<U>> &&
!is_same_v<T, U> is true.
```

The constructor is explicit if and only if `is_convertible_v<\( U_i \), \( T \)j>` is false for at least one \( i \).

template <class U1, class U2> EXPLICIT constexpr tuple(const pair<U1, U2>& u);

Effects: Initializes the first element with \( u.first \) and the second element with \( u.second \).

Remarks: This constructor shall not participate in overload resolution unless `sizeof...(Types) == 2`, `is_constructible_v<T_0, const U1&>` is true and `is_constructible_v<T_1, const U2&>` is true.

The constructor is explicit if and only if `is_convertible_v<const U1&, T_0> is false or is_convertible_v<const U2&, T_1> is false.`

template <class U1, class U2> EXPLICIT constexpr tuple(pair<U1, U2>&& u);

Effects: Initializes the first element with `std::forward<U1>(u.first)` and the second element with `std::forward<U2>(u.second)`.

Remarks: This constructor shall not participate in overload resolution unless `sizeof...(Types) == 2`, `is_constructible_v<T_0, U1&&>` is true and `is_constructible_v<T_1, U2&&>` is true.

The constructor is explicit if and only if `is_convertible_v<U1&&, T_0> is false or is_convertible_v<U2&&, T_1> is false.`

- Requires: Alloc shall meet the requirements for an Allocator (20.5.3.5).

Effects: Equivalent to the preceding constructors except that each element is constructed with uses-allocator construction (23.10.7.2).
23.5.3.2 Assignment

For each tuple assignment operator, an exception is thrown only if the assignment of one of the types in Types throws an exception. In the function descriptions that follow, let \( i \) be in the range \([0, \text{sizeof}...\text{(Types)})\) in order, \( T_i \) be the \( i^{\text{th}} \) type in Types, and \( U_i \) be the \( i^{\text{th}} \) type in a template parameter pack named UTypes, where indexing is zero-based.

\[
tuple& \operatorname{operator=} (\text{const} \ tuple& u);
\]

**Effects:** Assigns each element of \( u \) to the corresponding element of \(*\text{this}\).  
**Remarks:** This operator shall be defined as deleted unless \( \text{is\_copy\_assignable\_v}\langle T_i \rangle \) is true for all \( i \).  
**Returns:** \(*\text{this}\).

\[
tuple& \operatorname{operator=} (\text{tuple}\&\& u) \ \text{noexcept(see below)};
\]

**Effects:** For all \( i \), assigns \( \text{std}\::\text{forward}\langle T_i \rangle (\text{get}\langle i \rangle (u)) \) to \( \text{get}\langle i \rangle (*\text{this}) \).  
**Remarks:** This operator shall be defined as deleted unless \( \text{is\_move\_assignable\_v}\langle T_i \rangle \) is true for all \( i \).  
**Remarks:** The expression inside noexcept is equivalent to the logical AND of the following expressions:  
\[
\text{is\_nothrow\_move\_assignable\_v}\langle T_i \rangle
\]
where \( T_i \) is the \( i^{\text{th}} \) type in Types.  
**Returns:** \(*\text{this}\).

\[
\text{template } <\text{class...}\ U\text{Types}> \ tuple& \operatorname{operator=} (\text{const} \ tuple<\text{UTypes}...>& u);
\]

**Effects:** Assigns each element of \( u \) to the corresponding element of \(*\text{this}\).  
**Remarks:** This operator shall not participate in overload resolution unless \( \text{sizeof}...\text{(Types)} = \text{sizeof}...\text{(UTypes)} \) and \( \text{is\_assignable\_v}\langle T_i&, \text{const} \ U_i&\rangle \) is true for all \( i \).  
**Returns:** \(*\text{this}\).

\[
\text{template } <\text{class...}\ U\text{Types}> \ tuple& \operatorname{operator=} (\text{tuple}<\text{UTypes}...>&& u);
\]

**Effects:** For all \( i \), assigns \( \text{std}\::\text{forward}\langle U_i\rangle (\text{get}\langle i \rangle (u)) \) to \( \text{get}\langle i \rangle (*\text{this}) \).  
**Remarks:** This operator shall not participate in overload resolution unless \( \text{is\_assignable\_v}\langle T_i&, \ U_i&&\rangle \) is true for all \( i \) and \( \text{sizeof}...\text{(Types)} = \text{sizeof}...\text{(UTypes)} \).  
**Returns:** \(*\text{this}\).

\[
\text{template } <\text{class} \ U_1, \ \text{class} \ U_2> \ tuple& \operatorname{operator=} (\text{const} \ \text{pair}\langle U_1, \ U_2\rangle& u);
\]

**Effects:** Assigns \( u\text{.first} \) to the first element of \(*\text{this}\) and \( u\text{.second} \) to the second element of \(*\text{this}\).  
**Remarks:** This operator shall not participate in overload resolution unless \( \text{sizeof}...\text{(Types)} = 2 \) and \( \text{is\_assignable\_v}\langle T_0&, \ \text{const} \ U_1&\rangle \) is true for the first type \( T_0 \) in Types and \( \text{is\_assignable\_v}\langle T_1&, \ \text{const} \ U_2&\rangle \) is true for the second type \( T_1 \) in Types.  
**Returns:** \(*\text{this}\).

\[
\text{template } <\text{class} \ U_1, \ \text{class} \ U_2> \ tuple& \operatorname{operator=} (\text{pair}\langle U_1, \ U_2\rangle&& u);
\]

**Effects:** Assigns \( \text{std}\::\text{forward}\langle U_1\rangle (u\text{.first}) \) to the first element of \(*\text{this}\) and \( \text{std}\::\text{forward}\langle U_2\rangle (u\text{.second}) \) to the second element of \(*\text{this}\).  
**Remarks:** This operator shall not participate in overload resolution unless \( \text{sizeof}...\text{(Types)} = 2 \) and \( \text{is\_assignable\_v}\langle T_0&, \ U_1&&\rangle \) is true for the first type \( T_0 \) in Types and \( \text{is\_assignable\_v}\langle T_1&, \ U_2&&\rangle \) is true for the second type \( T_1 \) in Types.  
**Returns:** \(*\text{this}\).
23.5.3.3 swap

void swap(tuple& rhs) noexcept(see below);

1 Requires: Each element in *this shall be swappable with (20.5.3.2) the corresponding element in rhs.

2 Effects: Calls swap for each element in *this and its corresponding element in rhs.

3 Remarks: The expression inside noexcept is equivalent to the logical AND of the following expressions:
   
is_nothrow_swappable_v<T_i>
   
   where T_i is the i^th type in Types.

4 Throws: Nothing unless one of the element-wise swap calls throws an exception.

23.5.3.4 Tuple creation functions

In the function descriptions that follow, the members of a parameter pack XTypes are denoted by X_i for i in [0, sizeof...(XTypes)) in order, where indexing is zero-based.

template<class... TTypes>
constexpr tuple<VTypes...> make_tuple(TTypes&&... t);

2 The pack VTypes is defined as follows. Let Ui be decay_t<T_i> for each T_i in TTypes. If Ui is a specialization of reference_wrapper, then Vi in VTypes is Ui::type&, otherwise Vi is Ui.

3 Returns: tuple<VTypes...>(std::forward<TTypes>(t) ...).

4 Example:
   int i; float j;
   make_tuple(i, ref(i), cref(j))

   creates a tuple of type tuple<int, int&, const float&>. — end example

template<class... TTypes>
constexpr tuple<TTypes&&...> forward_as_tuple(TTypes&&... t) noexcept;

5 Effects: Constructs a tuple of references to the arguments in t suitable for forwarding as arguments to a function. Because the result may contain references to temporary variables, a program shall ensure that the return value of this function does not outlive any of its arguments (e.g., the program should typically not store the result in a named variable).

6 Returns: tuple<TTypes&&...>(std::forward<TTypes>(t) ...).

template<class... TTypes>
constexpr tuple<TTypes&...> tie(TTypes&... t) noexcept;

7 Returns: tuple<TTypes&...>(t ...). When an argument in t is ignore, assigning any value to the corresponding tuple element has no effect.

8 Example: tie functions allow one to create tuples that unpack tuples into variables. ignore can be used for elements that are not needed:
   int i; std::string s;
   tie(i, ignore, s) = make_tuple(42, 3.14, "C++");
   // i == 42, s == "C++"
   — end example

template <class... Tuples>
constexpr tuple<CTypes...> tuple_cat(Tuples&&... tpls);

9 In the following paragraphs, let T_i be the i^th type in Tuples, U_i be remove_reference_t<T_i>, and tp_i be the i^th parameter in the function parameter pack tpls, where all indexing is zero-based.
 Requires: For all \( i \), \( U_i \) shall be the type \( \mathrm{cv} \) \( \langle \mathrm{Args}_i \ldots \rangle \), where \( \mathrm{cv} \) is the (possibly empty) \( i^{\text{th}} \) \( \mathrm{cv} \)-\( \text{qualifier-seq} \) and \( \mathrm{Args}_i \) is the parameter pack representing the element types in \( U_i \). Let \( A_{ik} \) be the \( k^{\text{th}} \) type in \( \mathrm{Args}_i \). For all \( A_{ik} \) the following requirements shall be satisfied:

\( (10.1) \)

— If \( T_i \) is deduced as an lvalue reference type, then \( \text{is_constructible}_v\langle A_{ik}, \ \mathrm{cv} A_{ik} &\rangle == \text{true} \), otherwise

\( (10.2) \)

— \( \text{is_constructible}_v\langle A_{ik}, \ \mathrm{cv} A_{ik} &&\rangle == \text{true} \).

Remarks: The types in \( \mathrm{CTypes} \) shall be equal to the ordered sequence of the extended types \( \mathrm{Args}_0 \ldots, \ \mathrm{Args}_1 \ldots, \ldots, \ \mathrm{Args}_{n-1} \ldots \), where \( n \) is equal to \( \text{sizeof} \ldots (\mathrm{Tuples}) \). Let \( e_0 \ldots \) be the \( i^{\text{th}} \) ordered sequence of tuple elements of the resulting \( \text{tuple} \) object corresponding to the type sequence \( \mathrm{Args}_i \).

Returns: A \( \text{tuple} \) object constructed by initializing the \( k_i^{\text{th}} \) type element \( e_{ik} \) in \( e_i \ldots \) with

\[ \text{get}<k_i>\!(\text{std::forward}<T_i>(\text{tp}_i)) \]

for each valid \( k_i \) and each group \( e_i \) in order.

[ Note: An implementation may support additional types in the parameter pack \( \mathrm{Tuples} \) that support the \( \text{tuple} \)-like protocol, such as \( \text{pair} \) and \( \text{array} \). — end note ]

### 23.5.3.5 Calling a function with a \textit{tuple} of arguments [tuple.apply]

```cpp
template <class F, class Tuple>
constexpr decltype(auto) apply(F&& f, Tuple&& t);
```

**Effects:** Given the exposition-only function:

```cpp
template <class F, class Tuple, size_t... I>
constexpr decltype(auto) apply_impl(F&& f, Tuple&& t, index_sequence<I...>) {
  // exposition only
  return INVOKE(std::forward<F>(f), std::get<I>(std::forward<Tuple>(t))...);
}
```

Equivalently to:

```cpp
return apply_impl(std::forward<F>(f), std::forward<Tuple>(t),
                 make_index_sequence<tuple_size_v<decay_t<Tuple>>>{});
```

### 23.5.3.6 \textit{Tuple} helper classes [tuple.helper]

```cpp
template <class T> struct tuple_size;
```

**Remarks:** All specializations of \( \text{tuple}_\text{size} \) shall meet the \text{UnaryTypeTrait} requirements (23.15.1) with a base characteristic of \( \text{integral_constant}_\langle \text{size_t}, N \rangle \) for some \( N \).

§ 23.5.3.6 551
template <class... Types>
  class tuple_size<tuple<Types...>> : public integral_constant<size_t, sizeof...(Types)> { }

template <size_t I, class... Types>
  class tuple_element<I, tuple<Types...>> {
public:
  using type = TI;
};

2 Requires: I < sizeof...(Types). The program is ill-formed if I is out of bounds.

3 Type: TI is the type of the Ith element of Types, where indexing is zero-based.

Let TS denote tuple_size<T> of the cv-unqualified type T. If the expression TS::value is well-formed when treated as an unevaluated operand, then each of the three templates shall meet the UnaryTypeTrait requirements (23.15.1) with a base characteristic of

  integral_constant<size_t, TS::value>

Otherwise, they shall have no member value.

Access checking is performed as if in a context unrelated to TS and T. Only the validity of the immediate context of the expression is considered. [ Note: The compilation of the expression can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the “immediate context” and can result in the program being ill-formed. —end note]

In addition to being available via inclusion of the <tuple> header, the three templates are available when either of the headers <array> or <utility> are included.

Let TE denote tuple_element_t<I, T> of the cv-unqualified type T. Then each of the three templates shall meet the TransformationTrait requirements (23.15.1) with a member typedef type that names the following type:

  — (7.1) for the first specialization, add_const_t<TE>,
  — (7.2) for the second specialization, add_volatile_t<TE>, and
  — (7.3) for the third specialization, add_cv_t<TE>.

In addition to being available via inclusion of the <tuple> header, the three templates are available when either of the headers <array> or <utility> are included.

23.5.3.7 Element access [tuple.elem]

template <size_t I, class... Types>
  constexpr tuple_element_t<I, tuple<Types...>>&
    get(tuple<Types...>&& t) noexcept;

template <size_t I, class... Types>
  constexpr tuple_element_t<I, tuple<Types...>>&&
    get(tuple<Types...>&& t) noexcept;  // Note A

template <size_t I, class... Types>
  constexpr const tuple_element_t<I, tuple<Types...>>&
    get(const tuple<Types...>&& t) noexcept;  // Note B
template <size_t I, class... Types>
constexpr const tuple_element_t<I, tuple<Types...>>&& get(const tuple<Types...>&& t) noexcept;

1 Requires: I < sizeof...(Types). The program is ill-formed if I is out of bounds.

2 Returns: A reference to the Ith element of t, where indexing is zero-based.

3 [Note A: If a T in Types is some reference type X&, the return type is X&, not X&&. However, if the element type is a non-reference type T, the return type is T&&. —end note]

4 [Note B: Constness is shallow. If a T in Types is some reference type X&, the return type is const X&, not const X&&. However, if the element type is a non-reference type T, the return type is const T&. This is consistent with how constness is defined to work for member variables of reference type. —end note]

template <class T, class... Types>
constexpr T& get(tuple<Types...>& t) noexcept;
template <class T, class... Types>
constexpr T&& get(tuple<Types...>&& t) noexcept;
template <class T, class... Types>
constexpr const T& get(const tuple<Types...>& t) noexcept;
template <class T, class... Types>
constexpr const T&& get(const tuple<Types...>&& t) noexcept;

5 Requires: The type T occurs exactly once in Types.... Otherwise, the program is ill-formed.

6 Returns: A reference to the element of t corresponding to the type T in Types....

7 [Example:

const tuple<int, const int, double, double> t(1, 2, 3.4, 5.6);
const int& i1 = get<int>(t); // OK. Not ambiguous. i1 == 1
const int& i2 = get<const int>(t); // OK. Not ambiguous. i2 == 2
const double& d = get<double>(t); // ERROR. ill-formed

—end example]

8 [Note: The reason get is a non-member function is that if this functionality had been provided as a member function, code where the type depended on a template parameter would have required using the template keyword. —end note]

23.5.3.8 Relational operators [tuple.rel]

template<class... TTypes, class... UTypes>
constexpr bool operator==(const tuple<TTypes...>& t, const tuple<UTypes...>& u);

1 Requires: For all i, where 0 <= i and i < sizeof...(TTypes), get<i>(t) == get<i>(u) is a valid expression returning a type that is convertible to bool. sizeof...(TTypes) == sizeof...(UTypes).

2 Returns: true if get<i>(t) == get<i>(u) for all i, otherwise false. For any two zero-length tuples e and f, e == f returns true.

3 Effects: The elementary comparisons are performed in order from the zeroth index upwards. No comparisons or element accesses are performed after the first equality comparison that evaluates to false.

template<class... TTypes, class... UTypes>
constexpr bool operator<(const tuple<TTypes...>& t, const tuple<UTypes...>& u);

4 Requires: For all i, where 0 <= i and i < sizeof...(TTypes), both get<i>(t) < get<i>(u) and get<i>(u) < get<i>(t) are valid expressions returning types that are convertible to bool. sizeof...(TTypes) == sizeof...(UTypes).

5 Returns: The result of a lexicographical comparison between t and u. The result is defined as:
(bool)(get<0>(t) < get<0>(u)) || (!(bool)(get<0>(u) < get<0>(t)) && t_tail < u_tail), where

$t_{\text{tail}}$ for some tuple $r$ is a tuple containing all but the first element of $r$. For any two zero-length tuples $e$ and $f$, $e < f$ returns false.

template<class... TTypes, class... UTypes>
constexpr bool operator!=(const tuple<TTypes...>& t, const tuple<UTypes...>& u);
Returns: !(t == u).

template<class... TTypes, class... UTypes>
constexpr bool operator<(const tuple<TTypes...>& t, const tuple<UTypes...>& u);
Returns: u < t.

template<class... TTypes, class... UTypes>
constexpr bool operator<=(const tuple<TTypes...>& t, const tuple<UTypes...>& u);
Returns: !(u < t).

template<class... TTypes, class... UTypes>
constexpr bool operator>=(const tuple<TTypes...>& t, const tuple<UTypes...>& u);
Returns: !(t < u).

[Note: The above definitions for comparison functions do not require $t_{\text{tail}}$ (or $u_{\text{tail}}$) to be constructed. It may not even be possible, as $t$ and $u$ are not required to be copy constructible. Also, all comparison functions are short circuited; they do not perform element accesses beyond what is required to determine the result of the comparison. —end note]

23.5.3.9 Tuple traits [tuple.traits]

template <class... Types, class Alloc>
struct uses_allocator<tuple<Types...>, Alloc> : true_type { };
Requires: Alloc shall be an Allocator (20.5.3.5).

[Note: Specialization of this trait informs other library components that tuple can be constructed with an allocator, even though it does not have a nested allocator_type. —end note]

23.5.3.10 Tuple specialized algorithms [tuple.special]

template <class... Types>
void swap(tuple<Types...>& x, tuple<Types...>& y) noexcept(see below);
Remarks: This function shall not participate in overload resolution unless is_swappable_v<T_i> is true for all $i$, where $0 \leq i < \text{sizeof...}(\text{Types})$. The expression inside noexcept is equivalent to:

noexcept(x.swap(y))

Effects: As if by x.swap(y).

23.6 Optional objects [optional]

23.6.1 In general [optional.general]

This subclause describes class template optional that represents optional objects. An optional object is an object that contains the storage for another object and manages the lifetime of this contained object, if any. The contained object may be initialized after the optional object has been initialized, and may be destroyed before the optional object has been destroyed. The initialization state of the contained object is tracked by the optional object.

23.6.2 Header <optional> synopsis [optional.syn]

§ 23.6.2
namespace std {

// 23.6.3, class template optional
  template <class T>
  class optional;

// 23.6.4, no-value state indicator
struct nullopt_t { see below };
inline constexpr nullopt_t nullopt(unspecified);

// 23.6.5, class bad_optional_access
class bad_optional_access;

// 23.6.6, relational operators
  template <class T, class U>
  constexpr bool operator==(const optional<T>&, const optional<U>&);
  template <class T, class U>
  constexpr bool operator!=(const optional<T>&, const optional<U>&);
  template <class T, class U>
  constexpr bool operator<(const optional<T>&, const optional<U>&);
  template <class T, class U>
  constexpr bool operator>(const optional<T>&, const optional<U>&);
  template <class T, class U>
  constexpr bool operator<=(const optional<T>&, const optional<U>&);
  template <class T, class U>
  constexpr bool operator>=(const optional<T>&, const optional<U>&);

// 23.6.7, comparison with nullopt
  template <class T> constexpr bool operator==(const optional<T>&, nullopt_t) noexcept;
  template <class T> constexpr bool operator==(nullopt_t, const optional<T>&) noexcept;
  template <class T> constexpr bool operator!=(const optional<T>&, nullopt_t) noexcept;
  template <class T> constexpr bool operator!=(nullopt_t, const optional<T>&) noexcept;
  template <class T> constexpr bool operator<(const optional<T>&, nullopt_t) noexcept;
  template <class T> constexpr bool operator<(nullopt_t, const optional<T>&) noexcept;
  template <class T> constexpr bool operator<=(const optional<T>&, nullopt_t) noexcept;
  template <class T> constexpr bool operator<=(nullopt_t, const optional<T>&) noexcept;
  template <class T> constexpr bool operator>(const optional<T>&, nullopt_t) noexcept;
  template <class T> constexpr bool operator>(nullopt_t, const optional<T>&) noexcept;
  template <class T> constexpr bool operator>=(const optional<T>&, nullopt_t) noexcept;
  template <class T> constexpr bool operator>=(nullopt_t, const optional<T>&) noexcept;

// 23.6.8, comparison with T
  template <class T, class U> constexpr bool operator==(const optional<T>&, const U&);
  template <class T, class U> constexpr bool operator==(const U&, const optional<T>&);
  template <class T, class U> constexpr bool operator!=(const optional<T>&, const U&);
  template <class T, class U> constexpr bool operator!=(const U&, const optional<T>&);
  template <class T, class U> constexpr bool operator<(const optional<T>&, const U&);
  template <class T, class U> constexpr bool operator<(const U&, const optional<T>&);
  template <class T, class U> constexpr bool operator<=(const optional<T>&, const U&);
  template <class T, class U> constexpr bool operator<=(const U&, const optional<T>&);
  template <class T, class U> constexpr bool operator>(const optional<T>&, const U&);
  template <class T, class U> constexpr bool operator>(const U&, const optional<T>&);
  template <class T, class U> constexpr bool operator>=(const optional<T>&, const U&);
  template <class T, class U> constexpr bool operator>=(const U&, const optional<T>&);

// 23.6.9, specialized algorithms

§ 23.6.2
template <class T>
void swap(optional<T>&, optional<T>&) noexcept;

template <class T>
constexpr optional<T> make_optional(T&&);

template <class T, class... Args>
constexpr optional<T> make_optional(Args&&... args);

template <class T, class U, class... Args>
constexpr optional<T> make_optional(initializer_list<U> il, Args&&... args);

// 23.6.10, hash support
template <class T> struct hash;

1 A program that necessitates the instantiation of template optional for a reference type, or for possibly cv-qualified types in_place_t or nullopt_t is ill-formed.

23.6.3 Class template optional

template <class T>
class optional {
  public:
    using value_type = T;

    // 23.6.3.1, constructors
    constexpr optional() noexcept;
    constexpr optional(nullopt_t) noexcept;
    constexpr optional(const optional&);
    constexpr optional(optional&&) noexcept;
    template <class... Args>
        constexpr explicit optional(in_place_t, Args&&...);
    template <class U, class... Args>
        constexpr explicit optional(in_place_t, initializer_list<U>, Args&&...);
    template <class U = T>
        EXPLICIT constexpr optional(U&&);
    template <class U>
        EXPLICIT optional(const optional<U>&);
    template <class U>
        EXPLICIT optional(optional<U>&&);

    // 23.6.3.2, destructor
    ~optional();

    // 23.6.3.3, assignment
    optional& operator=(nullopt_t) noexcept;
    optional& operator=(const optional&);
    optional& operator=(optional&&) noexcept;
    template <class U = T> optional& operator=(U&&);
    template <class U> optional& operator=(const optional<U>&);
    template <class U> optional& operator=(optional<U>&&);
    template <class... Args> T& emplace(Args&&...);
    template <class U, class... Args> T& emplace(initializer_list<U>, Args&&...);

    // 23.6.3.4, swap
    void swap(optional&) noexcept;
// 23.6.3.5, observers
constexpr const T* operator->() const;
constexpr T* operator->();
constexpr const T& operator*() const&;
constexpr T& operator*() &;
constexpr T&& operator*() &&;
constexpr const T&& operator*() const&&;
constexpr explicit operator bool() const noexcept;
constexpr bool has_value() const noexcept;
constexpr const T& value() const&;
constexpr T& value() &;
constexpr T&& value() &&;
constexpr const T&& value() const&&;
template <class U> constexpr T value_or(U&&) const&;
template <class U> constexpr T value_or(U&&) &&;

// 23.6.3.6, modifiers
void reset() noexcept;

private:
    T *val; // exposition only
};

template<class T> optional(T) -> optional<T>;

1 Any instance of optional<T> at any given time either contains a value or does not contain a value. When an instance of optional<T> contains a value, it means that an object of type T, referred to as the optional object’s contained value, is allocated within the storage of the optional object. Implementations are not permitted to use additional storage, such as dynamic memory, to allocate its contained value. The contained value shall be allocated in a region of the optional<T> storage suitably aligned for the type T. When an object of type optional<T> is contextually converted to bool, the conversion returns true if the object contains a value; otherwise the conversion returns false.

2 Member val is provided for exposition only. When an optional<T> object contains a value, val points to the contained value.

3 T shall be an object type and shall satisfy the requirements of Destructible (Table 27).

23.6.3.1 Constructors [optional.ctor]
constexpr optional() noexcept;
constexpr optional(nullopt_t) noexcept;
1 Postconditions: *this does not contain a value.
2 Remarks: No contained value is initialized. For every object type T these constructors shall be constexpr constructors (10.1.5).

constexpr optional(const optional& rhs);
1 Effects: If rhs contains a value, initializes the contained value as if direct-non-list-initializing an object of type T with the expression *rhs.
2 Postconditions: bool(rhs) == bool(*this).
3 Throws: Any exception thrown by the selected constructor of T.
4 Remarks: This constructor shall be defined as deleted unless is_copy_constructible_v<T> is true. If is_trivially_copy_constructible_v<T> is true, this constructor shall be a constexpr constructor.
constexpr optional(optional&& rhs) noexcept(see below);

Effects: If rhs contains a value, initializes the contained value as if direct-non-list-initializing an object of type T with the expression `std::move(*rhs)`. bool(rhs) is unchanged.

Postconditions: bool(rhs) == bool(*this).

Throws: Any exception thrown by the selected constructor of T.

Remarks: The expression inside noexcept is equivalent to `is_nothrow_move_constructible_v<T>`. This constructor shall not participate in overload resolution unless `is_move_constructible_v<T>` is true. If `is_trivially_move_constructible_v<T>` is true, this constructor shall be a constexpr constructor.

template <class... Args> constexpr explicit optional(in_place_t, Args&&... args);

Effects: Initializes the contained value as if direct-non-list-initializing an object of type T with the arguments `std::forward<Args>(args)`.

Postconditions: *this contains a value.

Throws: Any exception thrown by the selected constructor of T.

Remarks: If T's constructor selected for the initialization is a constexpr constructor, this constructor shall be a constexpr constructor. This constructor shall not participate in overload resolution unless `is_constructible_v<T, Args...>` is true.

template <class U, class... Args>
constexpr explicit optional(in_place_t, initializer_list<U> il, Args&&... args);

Effects: Initializes the contained value as if direct-non-list-initializing an object of type T with the arguments `il, std::forward<Args>(args)`.

Postconditions: *this contains a value.

Throws: Any exception thrown by the selected constructor of T.

Remarks: This constructor shall not participate in overload resolution unless `is_constructible_v<T, initializer_list<U>&, Args&&...>` is true. If T's constructor selected for the initialization is a constexpr constructor, this constructor shall be a constexpr constructor.

[Note: The following constructors are conditionally specified as explicit. This is typically implemented by declaring two such constructors, of which at most one participates in overload resolution. —end note]

template <class U = T> EXPLICIT constexpr optional(U&& v);

Effects: Initializes the contained value as if direct-non-list-initializing an object of type T with the expression `std::forward<U>(v)`.

Postconditions: *this contains a value.

Throws: Any exception thrown by the selected constructor of T.

Remarks: If T's selected constructor is a constexpr constructor, this constructor shall be a constexpr constructor. This constructor shall not participate in overload resolution unless `is_constructible_v<T, U&&>` is true, `is_same_v<decay_t<U>, in_place_t>` is false, and `is_same_v<optional<T>, decay_t<U>>` is false. The constructor is explicit if and only if `is_convertible_v<U&&, T>` is false.

template <class U> EXPLICIT optional(const optional<U>& rhs);

Effects: If rhs contains a value, initializes the contained value as if direct-non-list-initializing an object of type T with the expression *rhs.

Postconditions: bool(rhs) == bool(*this).

§ 23.6.3.1
26. Throws: Any exception thrown by the selected constructor of T.

Remarks: This constructor shall not participate in overload resolution unless

(27.1) \( \text{is\_constructible\_v<T, \text{const } U&> is true,} \)
(27.2) \( \text{is\_constructible\_v<T, \text{optional } U&> is false,} \)
(27.3) \( \text{is\_constructible\_v<T, \text{optional } U&&> is false,} \)
(27.4) \( \text{is\_constructible\_v<T, \text{const optional } U&> is false,} \)
(27.5) \( \text{is\_constructible\_v<T, \text{const optional } U&&> is false,} \)
(27.6) \( \text{is\_convertible\_v<optional } U&, T \text{ is false,} \)
(27.7) \( \text{is\_convertible\_v<optional } U&&, T \text{ is false,} \)
(27.8) \( \text{is\_convertible\_v<optional } U&, T \text{ is false, and} \)
(27.9) \( \text{is\_convertible\_v<optional } U&&, T \text{ is false.} \)

The constructor is explicit if and only if \( \text{is\_convertible\_v<\text{const } U&, T \text{ is false.} } \)

\[
\text{template <class U> EXPLICIT optional(optional<U>&& rhs);}\]

28. Effects: If \( \text{rhs} \) contains a value, initializes the contained value as if direct-non-list-initializing an object of type \( T \) with the expression \( \text{std::move(*rhs)} \). \text{bool(rhs)} \text{ is unchanged.} \)

Postconditions: \( \text{bool(rhs)} == \text{bool(*this).} \)

29. Throws: Any exception thrown by the selected constructor of T.

Remarks: This constructor shall not participate in overload resolution unless

(31.1) \( \text{is\_constructible\_v<T, U&> is true,} \)
(31.2) \( \text{is\_constructible\_v<T, \text{optional } U&> is false,} \)
(31.3) \( \text{is\_constructible\_v<T, \text{optional } U&&> is false,} \)
(31.4) \( \text{is\_constructible\_v<T, \text{const optional } U&> is false,} \)
(31.5) \( \text{is\_constructible\_v<T, \text{const optional } U&&> is false,} \)
(31.6) \( \text{is\_convertible\_v<optional } U&, T \text{ is false,} \)
(31.7) \( \text{is\_convertible\_v<optional } U&&, T \text{ is false,} \)
(31.8) \( \text{is\_convertible\_v<optional } U&, T \text{ is false, and} \)
(31.9) \( \text{is\_convertible\_v<optional } U&&, T \text{ is false.} \)

The constructor is explicit if and only if \( \text{is\_convertible\_v<U&&, T \text{ is false.} } \)

### 23.6.3.2 Destructor

\[\text{=optional();}\]

Effects: If \( \text{is\_trivially\_destructible\_v<T> != true} \) and \( \text{*this} \) contains a value, calls \( \text{val->T::~T()} \)

Remarks: If \( \text{is\_trivially\_destructible\_v<T> == true} \) then this destructor shall be a trivial destructor.

### 23.6.3.3 Assignment

\[\text{optional<T>& operator=(nullopt_t) noexcept;}\]
Effects: If \*this contains a value, calls val->T::\~T() to destroy the contained value; otherwise no effect.

Returns: \*this.

Postconditions: \*this does not contain a value.

optional&lt;T&gt;& operator=(const optional&lt;T&gt; & rhs);

Effects: See Table 35.

### Table 35 — optional::operator=(const optional&lt;T&gt;) effects

<table>
<thead>
<tr>
<th></th>
<th>*this contains a value</th>
<th>*this does not contain a value</th>
</tr>
</thead>
<tbody>
<tr>
<td>rhs contains a value</td>
<td>assigns *rhs to the contained value</td>
<td>initializes the contained value as if direct-non-list-initializing an object of type T with *rhs</td>
</tr>
<tr>
<td>rhs does not contain a value</td>
<td>destroys the contained value by calling val-&gt;T::~T()</td>
<td>no effect</td>
</tr>
</tbody>
</table>

Returns: \*this.

Postconditions: bool(rhs) == bool(*this).

Remarks: If any exception is thrown, the result of the expression bool(*this) remains unchanged. If an exception is thrown during the call to T's copy constructor, no effect. If an exception is thrown during the call to T's copy assignment, the state of its contained value is as defined by the exception safety guarantee of T's copy assignment. This operator shall be defined as deleted unless is_copy_constructible_v&lt;T&gt; is true and is_copyAssignable_v&lt;T&gt; is true.

optional&lt;T&gt;& operator=(optional&lt;T&gt;&& rhs) noexcept(see below);

Effects: See Table 36. The result of the expression bool(rhs) remains unchanged.

### Table 36 — optional::operator=(optional&lt;T&gt;&&) effects

<table>
<thead>
<tr>
<th></th>
<th>*this contains a value</th>
<th>*this does not contain a value</th>
</tr>
</thead>
<tbody>
<tr>
<td>rhs contains a value</td>
<td>assigns std::move(*rhs) to the contained value</td>
<td>initializes the contained value as if direct-non-list-initializing an object of type T with std::move(*rhs)</td>
</tr>
<tr>
<td>rhs does not contain a value</td>
<td>destroys the contained value by calling val-&gt;T::~T()</td>
<td>no effect</td>
</tr>
</tbody>
</table>

Returns: \*this.

Postconditions: bool(rhs) == bool(*this).

Remarks: The expression inside noexcept is equivalent to:

\[
\text{is_nothrow_move_assignable_v&lt;T&gt; & \& is_nothrow_move_constructible_v&lt;T&gt;}
\]

If any exception is thrown, the result of the expression bool(*this) remains unchanged. If an exception is thrown during the call to T's move constructor, the state of *rhs.val is determined

§ 23.6.3.3
by the exception safety guarantee of T's move constructor. If an exception is thrown during the
call to T's move assignment, the state of *val and *rhs.val is determined by the exception safety
guarantee of T's move assignment. This operator shall not participate in overload resolution unless
is_move_constructible_v<T> is true and is_move_assignable_v<T> is true.

```cpp
template <class U = T> optional<T>& operator=(U&& v);
```

**Effects:** If *this contains a value, assigns std::forward<U>(v) to the contained value; otherwise
initializes the contained value as if direct-non-list-initializing object of type T with std::forward<U>(v).

**Returns:** *this.

**Postconditions:** *this contains a value.

**Remarks:** If any exception is thrown, the result of the expression bool(*this) remains unchanged. If
an exception is thrown during the call to T's constructor, the state of v is determined by the exception
safety guarantee of T's constructor. If an exception is thrown during the call to T's assignment, the
state of *val and v is determined by the exception safety guarantee of T's assignment. This function
shall not participate in overload resolution unless

- is_same_v<optional<T>, decay_t<U>> is false,
- conjunction_v<is_scalar<T>, is_same<T, decay_t<U>> is false, is_constructible_v<T, U> is true, and is_assignable_v<T&, U> is true.

```cpp
template <class U> optional<T>& operator=(const optional<U>& rhs);
```

**Effects:** See Table 37.

**Table 37 — optional::operator=(const optional<U>&) effects**

<table>
<thead>
<tr>
<th>rhs contains a value</th>
<th>*this contains a value</th>
<th>*this does not contain a value</th>
</tr>
</thead>
<tbody>
<tr>
<td>assigns *rhs to the contained value</td>
<td>initializes the contained value as if direct-non-list-initializing an object of type T with *rhs</td>
<td></td>
</tr>
<tr>
<td>rhs does not contain a value</td>
<td>destroys the contained value by calling val-&gt;T::~T()</td>
<td>no effect</td>
</tr>
</tbody>
</table>

**Returns:** *this.

**Postconditions:** bool(rhs) == bool(*this).

**Remarks:** If any exception is thrown, the result of the expression bool(*this) remains unchanged. If
an exception is thrown during the call to T's constructor, the state of *rhs.val is determined by the
exception safety guarantee of T's constructor. If an exception is thrown during the call to T's
assignment, the state of *val and *rhs.val is determined by the exception safety guarantee of T's
assignment. This function shall not participate in overload resolution unless

- is_constructible_v<T, const U&> is true,
- is_assignable_v<T&, const U&> is true,
- is_constructible_v<T, optional<U>&> is false,
- is_constructible_v<T, optional<U>&&> is false,
- is_constructible_v<T, const optional<U>&> is false,
- is_constructible_v<T, const optional<U>&&> is false,
- is_convertible_v<optional<U>&, T> is false,

§ 23.6.3.3
— is_convertible_v<optional<U>&&, T> is false,
— is_convertible_v<const optional<U>&, T> is false,
— is_convertible_v<const optional<U>&&, T> is false,
— is_assignable_v<T&, optional<U>&> is false,
— is_assignable_v<T&, optional<U>&&> is false,
— is_assignable_v<T&, const optional<U>&> is false, and
— is_assignable_v<T&, const optional<U>&&> is false.

template <class U> optional<T>& operator=(optional<U>&& rhs);

Effects: See Table 38. The result of the expression bool(rhs) remains unchanged.

Table 38 — optional::operator=(optional<U>&&) effects

<table>
<thead>
<tr>
<th>rhs contains a value</th>
<th>*this contains a value</th>
<th>*this does not contain a value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>assigns std::move(*rhs) to the contained value</td>
<td>initializes the contained value as if direct-non-list-initializing an object of type T with std::move(*rhs)</td>
</tr>
<tr>
<td>rhs does not contain a value</td>
<td>destroys the contained value by calling val-&gt;T::~T()</td>
<td>no effect</td>
</tr>
</tbody>
</table>

Returns: *this.

Postconditions: bool(rhs) == bool(*this).

Remarks: If any exception is thrown, the result of the expression bool(*this) remains unchanged. If an exception is thrown during the call to T’s constructor, the state of *rhs.val is determined by the exception safety guarantee of T’s constructor. If an exception is thrown during the call to T’s assignment, the state of *val and *rhs.val is determined by the exception safety guarantee of T’s assignment. This function shall not participate in overload resolution unless

— is_constructible_v<T, U> is true,
— is_assignable_v<T&, U> is true,
— is_constructible_v<T, optional<U>&> is false,
— is_constructible_v<T, optional<U>&&> is false,
— is_constructible_v<T, const optional<U>&> is false,
— is_constructible_v<T, const optional<U>&&> is false,
— is_convertible_v<optional<U>&, T> is false,
— is_convertible_v<optional<U>&&, T> is false,
— is_convertible_v<optional<U>&, T> is false,
— is assignable_v<T&, const optional<U>&&> is false.

template <class... Args> T& emplace(Args&&... args);

Requires: is constructible_v<T, Args&&...> is true.

Effects: Calls *this = nullopt. Then initializes the contained value as if direct-non-list-initializing an object of type T with the arguments std::forward<Args>(args)....

Postconditions: *this contains a value.

Returns: A reference to the new contained value.

Throws: Any exception thrown by the selected constructor of T.

Remarks: If an exception is thrown during the call to T’s constructor, *this does not contain a value, and the previous *val (if any) has been destroyed.

template <class U, class... Args> T& emplace(initializer_list<U> il, Args&&... args);

Effects: Calls *this = nullopt. Then initializes the contained value as if direct-non-list-initializing an object of type T with the arguments il, std::forward<Args>(args)....

Postconditions: *this contains a value.

Returns: A reference to the new contained value.

Throws: Any exception thrown by the selected constructor of T.

Remarks: If an exception is thrown during the call to T’s constructor, *this does not contain a value, and the previous *val (if any) has been destroyed. This function shall not participate in overload resolution unless is constructible_v<T, initializer_list<U>&, Args&&...> is true.

23.6.3.4 Swap [optional.swap]

void swap(optional& rhs) noexcept(see below);

Requires: Lvalues of type T shall be swappable and is move constructible_v<T> is true.

Effects: See Table 39.

Throws: Any exceptions thrown by the operations in the relevant part of Table 39.

Remarks: The expression inside noexcept is equivalent to:

is noexcept move constructible_v<T> && is noexcept swappable_v<T>

If any exception is thrown, the results of the expressions bool(*this) and bool(rhs) remain unchanged. If an exception is thrown during the call to function swap, the state of *val and *rhs.val is determined by the exception safety guarantee of swap for lvalues of T. If an exception is thrown during the call to T’s move constructor, the state of *val and *rhs.val is determined by the exception safety guarantee of T’s move constructor.

23.6.3.5 Observers [optional.observe]

constexpr const T* operator->() const;
constexpr T* operator->();

Requires: *this contains a value.

Returns: val.

Throws: Nothing.

Remarks: These functions shall be constexpr functions.

constexpr const T& operator*() const&;

§ 23.6.3.5
Table 39 — `optional::swap(optional&)` effects

<table>
<thead>
<tr>
<th>*this contains a value</th>
<th>*this does not contain a value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>rhs contains a value</strong></td>
<td><strong>calls <code>swap(*(*this), *rhs)</code></strong></td>
</tr>
<tr>
<td></td>
<td>initializes the contained value of *this as if direct-non-list-initializing an object of type T with the expression <code>std::move(*rhs)</code>, followed by <code>rhs.val-&gt;T::~T()</code>; postcondition is that *this contains a value and rhs does not contain a value</td>
</tr>
<tr>
<td><strong>rhs does not contain a value</strong></td>
<td>initializes the contained value of rhs as if direct-non-list-initializing an object of type T with the expression <code>std::move(*(*this))</code>, followed by <code>val-&gt;T::~T()</code>; postcondition is that *this does not contain a value and rhs contains a value</td>
</tr>
</tbody>
</table>

```cpp
constexpr T& operator*() &;

5  Requires: *this contains a value.
6  Returns: *val.
7  Throws: Nothing.
8  Remarks: These functions shall be constexpr functions.

constexpr T&& operator*() &&;
constexpr const T&& operator*() const&&;

9  Requires: *this contains a value.
10 Effects: Equivalent to: return std::move(*val);

constexpr explicit operator bool() const noexcept;

11 Returns: true if and only if *this contains a value.
12 Remarks: This function shall be a constexpr function.

constexpr bool has_value() const noexcept;

13 Returns: true if and only if *this contains a value.
14 Remarks: This function shall be a constexpr function.

constexpr const T& value() const&;
constexpr T& value() &;

15 Effects: Equivalent to:
   return bool(*this) ? *val : throw bad_optional_access();
```

§ 23.6.3.5
constexpr T&& value() &&;
constexpr const T&& value() const&&;

16 Effects: Equivalent to:
\[\text{return bool(*this) ? std::move(*val) : throw bad_optional_access();}\]

template <class U> constexpr T value_or(U&& v) const&;

17 Effects: Equivalent to:
\[\text{return bool(*this) ? **this : static_cast<T>(std::forward<U>(v));}\]

18 Remarks: If \(\text{is\_copy\_constructible\_v<T> && is\_convertible\_v<U&&, T>}\) is false, the program is ill-formed.

template <class U> constexpr T value_or(U&& v) &&;

19 Effects: Equivalent to:
\[\text{return bool(*this) ? std::move(**this) : static_cast<T>(std::forward<U>(v));}\]

20 Remarks: If \(\text{is\_move\_constructible\_v<T> && is\_convertible\_v<U&&, T>}\) is false, the program is ill-formed.

23.6.3.6 Modifiers

void reset() noexcept;

1 Effects: If \*this contains a value, calls \text{val->T::\_T()} to destroy the contained value; otherwise no effect.

2 Postconditions: \*this does not contain a value.

23.6.4 No-value state indicator

struct nullopt_t { see below; }
inline constexpr nullopt_t nullopt(unspecified);

1 The struct \text{nullopt\_t} is an empty structure type used as a unique type to indicate the state of not containing a value for \text{optional} objects. In particular, \text{optional<T>} has a constructor with \text{nullopt\_t} as a single argument; this indicates that an optional object not containing a value shall be constructed.

2 Type \text{nullopt\_t} shall not have a default constructor or an initializer-list constructor, and shall not be an aggregate.

23.6.5 Class \text{bad\_optional\_access}

class bad_optional_access : public exception {
public:
    bad_optional_access();
};

1 The class \text{bad\_optional\_access} defines the type of objects thrown as exceptions to report the situation where an attempt is made to access the value of an optional object that does not contain a value.

bad_optional_access();

2 Effects: Constructs an object of class \text{bad\_optional\_access}.

3 Postconditions: \text{what()} returns an implementation-defined \text{ntbs}.

23.6.6 Relational operators

template <class T, class U> constexpr bool operator==(const optional<T>& x, const optional<U>& y);

§ 23.6.6
Requires: The expression \(*x == *y\) shall be well-formed and its result shall be convertible to \(\text{bool}\).

[Note: \(T\) need not be \(\text{EqualityComparable}\). — end note]

Returns: If \(\text{bool}(x) \neq \text{bool}(y)\), \(false\); otherwise if \(\text{bool}(x) == \text{false}\), \(true\); otherwise \(*x == *y\).

Remarks: Specializations of this function template for which \(*x == *y\) is a core constant expression shall be constexpr functions.

```cpp
template <class T, class U> constexpr bool operator!=(const optional<T>& x, const optional<U>& y);
```

Requires: The expression \(*x != *y\) shall be well-formed and its result shall be convertible to \(\text{bool}\).

Returns: If \(\text{bool}(x) \neq \text{bool}(y)\), \(true\); otherwise, if \(\text{bool}(x) == \text{false}\), \(false\); otherwise \(*x != *y\).

Remarks: Specializations of this function template for which \(*x != *y\) is a core constant expression shall be constexpr functions.

```cpp
template <class T, class U> constexpr bool operator<(const optional<T>& x, const optional<U>& y);
```

Requires: \(*x < *y\) shall be well-formed and its result shall be convertible to \(\text{bool}\).

Returns: If \(!y\), \(false\); otherwise, if \(!x\), \(true\); otherwise \(*x < *y\).

Remarks: Specializations of this function template for which \(*x < *y\) is a core constant expression shall be constexpr functions.

```cpp
template <class T, class U> constexpr bool operator<=(const optional<T>& x, const optional<U>& y);
```

Requires: The expression \(*x <= *y\) shall be well-formed and its result shall be convertible to \(\text{bool}\).

Returns: If \(!x\), \(true\); otherwise, if \(!y\), \(false\); otherwise \(*x <= *y\).

Remarks: Specializations of this function template for which \(*x <= *y\) is a core constant expression shall be constexpr functions.

```cpp
template <class T, class U> constexpr bool operator>(const optional<T>& x, const optional<U>& y);
```

Requires: The expression \(*x > *y\) shall be well-formed and its result shall be convertible to \(\text{bool}\).

Returns: If \(!y\), \(false\); otherwise, if \(!x\), \(true\); otherwise \(*x > *y\).

Remarks: Specializations of this function template for which \(*x > *y\) is a core constant expression shall be constexpr functions.

```cpp
template <class T, class U> constexpr bool operator>=(const optional<T>& x, const optional<U>& y);
```

Requires: The expression \(*x >= *y\) shall be well-formed and its result shall be convertible to \(\text{bool}\).

Returns: If \(!y\), \(true\); otherwise, if \(!x\), \(false\); otherwise \(*x >= *y\).

Remarks: Specializations of this function template for which \(*x >= *y\) is a core constant expression shall be constexpr functions.

### 23.6.7 Comparison with `nullopt`

```cpp
template <class T> constexpr bool operator==(const optional<T>& x, nullopt_t) noexcept;
```

Returns: \(!x\).

```cpp
template <class T> constexpr bool operator!=(nullopt_t, const optional<T>& x) noexcept;
```

Returns: \(\text{bool}(x)\).

```cpp
template <class T> constexpr bool operator!=(const optional<T>& x, nullopt_t) noexcept;
```

Returns: \(!x\).

```cpp
template <class T> constexpr bool operator==(nullopt_t, const optional<T>& x) noexcept;
```

Returns: \(\text{bool}(x)\).

```cpp
template <class T> constexpr bool operator==(const optional<T>& x, nullopt_t) noexcept;
```

Returns: \(!x\).

```cpp
template <class T> constexpr bool operator!=(nullopt_t, const optional<T>& x) noexcept;
```

Returns: \(\text{bool}(x)\).

```cpp
template <class T> constexpr bool operator!=(const optional<T>& x, nullopt_t) noexcept;
```

Returns: \(!x\).
template <class T> constexpr bool operator<(nullopt_t, const optional<T>& x) noexcept;
  Returns: false.

template <class T> constexpr bool operator<=(const optional<T>& x, nullopt_t) noexcept;
  Returns: !x.

template <class T> constexpr bool operator<=(nullopt_t, const optional<T>& x) noexcept;
  Returns: true.

template <class T> constexpr bool operator>(const optional<T>& x, nullopt_t) noexcept;
  Returns: true.

template <class T> constexpr bool operator>(nullopt_t, const optional<T>& x) noexcept;
  Returns: false.

template <class T> constexpr bool operator>=(const optional<T>& x, nullopt_t) noexcept;
  Returns: true.

Returns: !x.

23.6.8 Comparison with T

[optional.comp_with_t]

template <class T, class U> constexpr bool operator==(const optional<T>& x, const U& v);
  Requires: The expression *x == v shall be well-formed and its result shall be convertible to bool.
  Effects: Equivalent to: return bool(x) ? *x == v : false;

template <class T, class U> constexpr bool operator==(const U& v, const optional<T>& x);
  Requires: The expression v == *x shall be well-formed and its result shall be convertible to bool.
  Effects: Equivalent to: return bool(x) ? v == *x : false;

template <class T, class U> constexpr bool operator!=(const optional<T>& x, const U& v);
  Requires: The expression *x != v shall be well-formed and its result shall be convertible to bool.
  Effects: Equivalent to: return bool(x) ? *x != v : true;

template <class T, class U> constexpr bool operator!=(const U& v, const optional<T>& x);
  Requires: The expression v != *x shall be well-formed and its result shall be convertible to bool.
  Effects: Equivalent to: return bool(x) ? v != *x : true;

template <class T, class U> constexpr bool operator<(const optional<T>& x, const U& v);
  Requires: The expression *x < v shall be well-formed and its result shall be convertible to bool.
  Effects: Equivalent to: return bool(x) ? *x < v : true;

template <class T, class U> constexpr bool operator<(const U& v, const optional<T>& x);
  Requires: The expression v < *x shall be well-formed and its result shall be convertible to bool.
  Effects: Equivalent to: return bool(x) ? v < *x : false;
template <class T, class U> constexpr bool operator<=(const optional<T>& x, const U& v);

Requires: The expression \*x <= v shall be well-formed and its result shall be convertible to bool.
Effects: Equivalent to: return bool(x) ? \*x <= v : true;

template <class T, class U> constexpr bool operator<=(const U& v, const optional<T>& x);

Requires: The expression v <= \*x shall be well-formed and its result shall be convertible to bool.
Effects: Equivalent to: return bool(x) ? v <= \*x : false;

template <class T, class U> constexpr bool operator>(const optional<T>& x, const U& v);

Requires: The expression \*x > v shall be well-formed and its result shall be convertible to bool.
Effects: Equivalent to: return bool(x) ? \*x > v : false;

template <class T, class U> constexpr bool operator>(const U& v, const optional<T>& x);

Requires: The expression v > \*x shall be well-formed and its result shall be convertible to bool.
Effects: Equivalent to: return bool(x) ? v > \*x : true;

template <class T, class U> constexpr bool operator>=(const optional<T>& x, const U& v);

Requires: The expression \*x >= v shall be well-formed and its result shall be convertible to bool.
Effects: Equivalent to: return bool(x) ? \*x >= v : false;

template <class T, class U> constexpr bool operator>=(const U& v, const optional<T>& x);

Requires: The expression v >= \*x shall be well-formed and its result shall be convertible to bool.
Effects: Equivalent to: return bool(x) ? v >= \*x : true;

23.6.9 Specialized algorithms

[optional.specalg]

template <class T> void swap(optional<T>& x, optional<T>& y) noexcept(noexcept(x.swap(y)));
Effects: Calls x.swap(y).
Remarks: This function shall not participate in overload resolution unless is_move_constructible_<
v<T> is true and is_swappable_v<T> is true.

template <class T> constexpr optional<decay_t<T>> make_optional(T&& v);
Returns: optional<decay_t<T>>(std::forward<T>(v)).

template <class T, class... Args>
constexpr optional<T> make_optional(Args&&... args);
Effects: Equivalent to: return optional<T>(in_place, std::forward<Args>(args)...);

template <class T, class U, class... Args>
constexpr optional<T> make_optional(initializer_list<U> il, Args&&... args);
Effects: Equivalent to: return optional<T>(in_place, il, std::forward<Args>(args)...);

23.6.10 Hash support

[optional.hash]

The specialization hash<optional<T>> is enabled (23.14.15) if and only if hash<remove_const_<
t<T>> is enabled. When enabled, for an object o of type optional<T>, if bool(o) == true, then
hash<optional<T>>(o) shall evaluate to the same value as hash<remove_const_t<T>>(*(o); oth-

§ 23.6.10
erwise it evaluates to an unspecified value. The member functions are not guaranteed to be noexcept.

23.7 Variants

23.7.1 In general

A variant object holds and manages the lifetime of a value. If the variant holds a value, that value’s type has to be one of the template argument types given to variant. These template arguments are called alternatives.

23.7.2 Header <variant> synopsis

namespace std {
    // 23.7.3, class template variant
    template <class... Types>
        class variant;

    // 23.7.4, variant helper classes
    template <class T> struct variant_size;    // not defined
    template <class T> struct variant_size<const T>;
    template <class T> struct variant_size<volatile T>;
    template <class T> struct variant_size<const volatile T>;
    template <class T> inline constexpr size_t variant_size_v = variant_size<T>::value;
    template <class... Types>
        struct variant_size<variant<Types...>>;
    template <size_t I, class... Types>
        struct variant_alternative;
    template <size_t I, class... Types>
        struct variant_alternative<I, const T>;
    template <size_t I, class... Types>
        struct variant_alternative<I, volatile T>;
    template <size_t I, class... Types>
        struct variant_alternative<I, const volatile T>;
    template <size_t I, class... Types>
        using variant_alternative_t = typename variant_alternative<I, T>::type;
    template <size_t I, class... Types>
        struct variant_alternative<I, variant<Types...>>;
    inline constexpr size_t variant_npos = -1;

    // 23.7.5, value access
    template <class T, class... Types>
        constexpr bool holds_alternative(const variant<Types...>&) noexcept;
    template <size_t I, class... Types>
        constexpr variant_alternative_t<I, variant<Types...>>& get(variant<Types...>&);
    template <size_t I, class... Types>
        constexpr variant_alternative_t<I, variant<Types...>>&& get(variant<Types...>&&);
    template <size_t I, class... Types>
        constexpr const variant_alternative_t<I, variant<Types...>>& get(const variant<Types...>&);
    template <size_t I, class... Types>
        constexpr const variant_alternative_t<I, variant<Types...>>&& get(const variant<Types...>&&);
    template <class T, class... Types>
        constexpr T& get(variant<Types...>&);

23.7.3 Class template variant

namespace std {
    template <class... Types>
    class variant {
    public:
        // 23.7.3.1, constructors
        constexpr variant() noexcept;
        variant(const variant&);
        variant(variant&&) noexcept;
        template <class T>
        constexpr variant(T&&) noexcept;
        template <class T, class... Args>
        constexpr explicit variant(in_place_type_t<T>, Args&&...);
        template <class T, class U, class... Args>
        constexpr explicit variant(in_place_type_t<T>, initializer_list<U>, Args&&...);
        template <size_t I, class... Args>
        constexpr explicit variant(in_place_index_t<I>, Args&&...);
        template <size_t I, class U, class... Args>
        constexpr explicit variant(in_place_index_t<I>, initializer_list<U>, Args&&...);

        allocator-related constructors
        template <class Alloc>
        variant(allocator_arg_t, const Alloc&);
        template <class Alloc>
        variant(allocator_arg_t, const Alloc&, const variant&);
        template <class Alloc>
        variant(allocator_arg_t, const Alloc&, variant&&);
        template <class Alloc, class T>
        variant(allocator_arg_t, const Alloc&, T&&);
        template <class Alloc, class T, class... Args>
        variant(allocator_arg_t, const Alloc&, in_place_type_t<T>, Args&&...);
        template <class Alloc, class T, class U, class... Args>
        variant(allocator_arg_t, const Alloc&, in_place_type_t<T>, initializer_list<U>, Args&&...);
        template <class Alloc, size_t I, class... Args>
        variant(allocator_arg_t, const Alloc&, in_place_index_t<I>, Args&&...);
        template <class Alloc, size_t I, class U, class... Args>
        variant(allocator_arg_t, const Alloc&, in_place_index_t<I>, initializer_list<U>, Args&&...);

        // 23.7.3.2, destructor
        ~variant();
ISO/IEC N4659

// 23.7.3.3, assignment
variant& operator=(const variant&);
variant& operator=(variant&&) noexcept(see below);

// 23.7.3.4, modifiers
template <class T> variant& operator=(T&&) noexcept(see below);

// 23.7.3.5, value status
constexpr bool valueless_by_exception() const noexcept;
constexpr size_t index() const noexcept;

// 23.7.3.6, swap
void swap(variant&) noexcept(see below);

1 Any instance of `variant` at any given time either holds a value of one of its alternative types, or it holds no value. When an instance of `variant` holds a value of alternative type `T`, it means that a value of type `T`, referred to as the `variant` object’s contained value, is allocated within the storage of the `variant` object. Implementations are not permitted to use additional storage, such as dynamic memory, to allocate the contained value. The contained value shall be allocated in a region of the `variant` storage suitably aligned for all types in `Types...`. It is implementation-defined whether over-aligned types are supported.

2 All types in `Types...` shall be (possibly cv-qualified) object types that are not arrays.

3 A program that instantiates the definition of `variant` with no template arguments is ill-formed.

23.7.3.1 Constructors [variant.ctor]

1 In the descriptions that follow, let `i` be in the range `[0, sizeof...(Types))`, and `T_i` be the `i`th type in `Types...`.

constexpr variant() noexcept(see below);

2 Effects: Constructs a `variant` holding a value-initialized value of type `T_0`.

3 Postconditions: `valueless_by_exception()` is false and `index()` is 0.

4 Throws: Any exception thrown by the value-initialization of `T_0`.

5 Remarks: This function shall be `constexpr` if and only if the value-initialization of the alternative type `T_0` would satisfy the requirements for a `constexpr` function. The expression inside `noexcept` is equivalent to `is_nothrow_default_constructible_v<T_0>`. This function shall not participate in overload resolution unless `is_default_constructible_v<T_0>` is true. [Note: See also class `monostate`. —end note]

variant(const variant& w);

6 Effects: If `w` holds a value, initializes the `variant` to hold the same alternative as `w` and direct-initializes the contained value with `get<j>(w)`, where `j` is `w.index()`. Otherwise, initializes the `variant` to not hold a value.
7  Throws: Any exception thrown by direct-initializing any T_i for all i.

8  Remarks: This function shall not participate in overload resolution unless is_copy_constructible_v<T_i> is true for all i.

variant(variant&& w) noexcept(see below);

9  Effects: If w holds a value, initializes the variant to hold the same alternative as w and direct-initializes the contained value with get<j>(std::move(w)), where j is w.index(). Otherwise, initializes the variant to not hold a value.

10 Throws: Any exception thrown by move-constructing any T_i for all i.

11 Remarks: The expression inside noexcept is equivalent to the logical AND of is_nothrow_move_constructible_v<T_i> for all i. This function shall not participate in overload resolution unless is_move_constructible_v<T_i> is true for all i.

template <class T> constexpr variant(T&& t) noexcept(see below);

12 Let T_j be a type that is determined as follows: build an imaginary function FUN(T_i) for each alternative type T_i. The overload FUN(T_j) selected by overload resolution for the expression FUN(std::forward<T>(t)) defines the alternative T_j which is the type of the contained value after construction.

13 Effects: Initializes *this to hold the alternative type T_j and direct-initializes the contained value as if direct-non-list-initializing it with std::forward<T>(t).

14 Postconditions: holds_alternative<T_j>(*this) is true.

15 Throws: Any exception thrown by the initialization of the selected alternative T_j.

16 Remarks: This function shall not participate in overload resolution unless is_same_v<decay_t<T>, variant> is false, unless decay_t<T> is neither a specialization of in_place_type_t nor a specialization of in_place_index_t, unless is_constructible_v<T_j, T> is true, and unless the expression FUN(std::forward<T>(t)) (with FUN being the above-mentioned set of imaginary functions) is well formed.

[ Note:

   variant<string, string> v("abc");

is ill-formed, as both alternative types have an equally viable constructor for the argument. —end note]

17 The expression inside noexcept is equivalent to is_nothrow_constructible_v<T_j, T>. If T_j’s selected constructor is a constexpr constructor, this constructor shall be a constexpr constructor.

template <class T, class... Args> constexpr explicit variant(in_place_type_t<T>, Args&&... args);

19 Effects: Initializes the contained value as if direct-non-list-initializing an object of type T with the arguments std::forward<Args>(args)....

20 Postconditions: holds_alternative<T>(*this) is true.

21 Throws: Any exception thrown by calling the selected constructor of T.

22 Remarks: This function shall not participate in overload resolution unless there is exactly one occurrence of T in Types... and is_constructible_v<T, Args...> is true. If T’s selected constructor is a constexpr constructor, this constructor shall be a constexpr constructor.

template <class T, class U, class... Args>
constexpr explicit variant(in_place_type_t<T>, initializer_list<U> il, Args&&... args);

23 Effects: Initializes the contained value as if direct-non-list-initializing an object of type T with the arguments il, std::forward<Args>(args)....
Postconditions: \texttt{holds_alternative<T>(*this)} is true.

Throws: Any exception thrown by calling the selected constructor of \texttt{T}.

Remarks: This function shall not participate in overload resolution unless there is exactly one occurrence of \texttt{T} in \texttt{Types...} and \texttt{is_constructible_v<T, initializer_list<U>&, Args...>} is true. If \texttt{T}’s selected constructor is a constexpr constructor, this constructor shall be a constexpr constructor.

```cpp
template <size_t I, class... Args> constexpr explicit variant(in_place_index_t<I>, Args&&... args);
```

Effects: Initializes the contained value as if direct-non-list-initializing an object of type \texttt{T}<\texttt{I}> with the arguments \texttt{std::forward<Args>(args)}....

Postconditions: \texttt{index()} is \texttt{I}.

Throws: Any exception thrown by calling the selected constructor of \texttt{T}<\texttt{I}>.

Remarks: This function shall not participate in overload resolution unless

\begin{itemize}
  \item \texttt{I} is less than \texttt{sizeof...(Types)} and
  \item \texttt{is_constructible_v<T<\texttt{I}>, Args...>} is true.
\end{itemize}

If \texttt{T}<\texttt{I}>’s selected constructor is a constexpr constructor, this constructor shall be a constexpr constructor.

```cpp
template <size_t I, class U, class... Args>
constexpr explicit variant(in_place_index_t<I>, initializer_list<U> il, Args&&... args);
```

Effects: Initializes the contained value as if direct-non-list-initializing an object of type \texttt{T}<\texttt{I}> with the arguments \texttt{il, std::forward<Args>(args)}....

Postconditions: \texttt{index()} is \texttt{I}.

Remarks: This function shall not participate in overload resolution unless

\begin{itemize}
  \item \texttt{I} is less than \texttt{sizeof...(Types)} and
  \item \texttt{is_constructible_v<T<\texttt{I}>, initializer_list<U>&, Args...>} is true.
\end{itemize}

If \texttt{T}<\texttt{I}>’s selected constructor is a constexpr constructor, this constructor shall be a constexpr constructor.

// allocator-extended constructors
template <class Alloc>
variant(allocation_arg_t, const Alloc& a);
```

Effects: Equivalent to the preceding constructors except that the contained value is constructed with

\section{23.7.3.1}
uses-allocator construction (23.10.7.2).

23.7.3.2 Destructor

~variant();

1 Effects: If valueless_by_exception() is false, destroys the currently contained value.

2 Remarks: If is_trivially_destructible_v<T_i> == true for all T_i then this destructor shall be a trivial destructor.

23.7.3.3 Assignment

variant& operator=(const variant& rhs);

1 Let j be rhs.index().

2 Effects:

(2.1) — If neither *this nor rhs holds a value, there is no effect. Otherwise,

(2.2) — if *this holds a value but rhs does not, destroys the value contained in *this and sets *this to not hold a value. Otherwise,

(2.3) — if index() == j, assigns the value contained in rhs to the value contained in *this. Otherwise,

(2.4) — if either is_nothrow_copy_constructible_v<T_i> or !is_nothrow_move_constructible_v<T_i> is true, equivalent to emplace<j>(get<j>(lhs)). Otherwise,

(2.5) — equivalent to operator=(variant(rhs)).

3 Returns: *this.

4 Postconditions: index() == rhs.index().

5 Remarks: This function shall not participate in overload resolution unless is_copy_constructible_v<T_i> && is_copy_assignable_v<T_i> is true for all i.

variant& operator=(variant&& rhs) noexcept(see below);

6 Let j be rhs.index().

7 Effects:

(7.1) — If neither *this nor rhs holds a value, there is no effect. Otherwise,

(7.2) — if *this holds a value but rhs does not, destroys the value contained in *this and sets *this to not hold a value. Otherwise,

(7.3) — if index() == j, assigns get<j>(std::move(rhs)) to the value contained in *this. Otherwise,

(7.4) — equivalent to emplace<j>(get<j>(std::move(rhs))).

8 Returns: *this.

9 Remarks: This function shall not participate in overload resolution unless is_move_constructible_v<T_i> && is_move_assignable_v<T_i> is true for all i. The expression inside noexcept is equivalent to: is_nothrow_move_constructible_v<T_i> && is_nothrow_move_assignable_v<T_i> for all i.

(9.1) — If an exception is thrown during the call to T_j’s move construction (with j being rhs.index()), the variant will hold no value.

(9.2) — If an exception is thrown during the call to T_j’s move assignment, the state of the contained value is as defined by the exception safety guarantee of T_j’s move assignment; index() will be j.

template <class T> variant& operator=(T& t) noexcept(see below);
Let $T_j$ be a type that is determined as follows: build an imaginary function $FUN(T_i)$ for each alternative type $T_i$. The overload $FUN(T_j)$ selected by overload resolution for the expression $FUN(std::forward<T>(t))$ defines the alternative $T_j$ which is the type of the contained value after assignment.

**Effects:**

1. If `*this` holds a $T_j$, assigns `std::forward<T>(t)` to the value contained in `*this`. Otherwise,
2. if `is_nothrow_constructible_v<T_j, T> || !is_nothrow_move_constructible_v<T_j, T>` is true, equivalent to `emplace<T_j>(std::forward<T>(t))`. Otherwise,
3. equivalent to `operator=(variant(std::forward<T>(t)))`.

**Postconditions:** `holds_alternative<T_j>(*this)` is `true`, with $T_j$ selected by the imaginary function overload resolution described above.

**Returns:** `*this`.

**Remarks:** This function shall not participate in overload resolution unless `is_same_v<decay_t<T>, variant>` is `false`, unless `is_assignable_v<T_j&, T> && is_constructible_v<T_j, T>` is `true`, and unless the expression $FUN(std::forward<T>(t))$ (with $FUN$ being the above-mentioned set of imaginary functions) is well formed.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>variant&lt;string, string&gt; v;</td>
</tr>
<tr>
<td>v = &quot;abc&quot;;</td>
</tr>
<tr>
<td>is ill-formed, as both alternative types have an equally viable constructor for the argument. — end note</td>
</tr>
</tbody>
</table>

The expression inside `noexcept` is equivalent to:

- `is_nothrow_assignable_v<T_j&, T> && is_nothrow_constructible_v<T_j, T>`
- If an exception is thrown during the assignment of `std::forward<T>(t)` to the value contained in `*this`, the state of the contained value and `t` are as defined by the exception safety guarantee of the assignment expression; `valueless_by_exception()` will be `false`.
- If an exception is thrown during the initialization of the contained value, the `variant` object might not hold a value.

### 23.7.3.4 Modifiers

**template <class T, class... Args> T& emplace(Args&&... args);**

1. Let $I$ be the zero-based index of $T$ in `Types`.
2. **Effects:** Equivalent to: `return emplace<I>(std::forward<Args>(args)...);`
3. **Remarks:** This function shall not participate in overload resolution unless `is_constructible_v<T, Args...>` is `true`, and $T$ occurs exactly once in `Types`.

**template <class T, class U, class... Args> T& emplace(initializer_list<U> il, Args&&... args);**

4. Let $I$ be the zero-based index of $T$ in `Types`.
5. **Effects:** Equivalent to: `return emplace<I>(il, std::forward<Args>(args)...);`
6. **Remarks:** This function shall not participate in overload resolution unless `is_constructible_v<T, initializer_list<U>&, Args...>` is `true`, and $T$ occurs exactly once in `Types`.

**template <size_t I, class... Args> variant_alternative_t<I, variant<Types...>>& emplace(Args&&... args);**

7. **Requires:** $I < $sizeof...($Types$).
Effects: Destroys the currently contained value if `valueless_by_exception()` is `false`. Then initializes the contained value as if direct-non-list-initializing a value of type `T_I` with the arguments `std::forward<Args>(args)`... Then initializes the contained value as if direct-non-list-initializing a value of type `T_I` with the arguments `std::forward<Args>(args)`...

Postconditions: `index()` is I.

Returns: A reference to the new contained value.

Throws: Any exception thrown during the initialization of the contained value.

Remarks: This function shall not participate in overload resolution unless `is_constructible_v<T_I, Args...>` is `true`. If an exception is thrown during the initialization of the contained value, the `variant` might not hold a value.

```cpp
template <size_t I, class U, class... Args>
variant_alternative_t<I, variant<Types...>>& emplace(initializer_list<U> il, Args&&... args);
```

Requires: `I < sizeof...(Types)`.

Effects: Destroys the currently contained value if `valueless_by_exception()` is `false`. Then initializes the contained value as if direct-non-list-initializing a value of type `T_I` with the arguments `il, std::forward<Args>(args)`... Then initializes the contained value as if direct-non-list-initializing a value of type `T_I` with the arguments `il, std::forward<Args>(args)`...

Postconditions: `index()` is I.

Returns: A reference to the new contained value.

Throws: Any exception thrown during the initialization of the contained value.

Remarks: This function shall not participate in overload resolution unless `is_constructible_v<T_I, initializer_list<U>&, Args...>` is `true`. If an exception is thrown during the initialization of the contained value, the `variant` might not hold a value.

23.7.3.5 Value status

```cpp
constexpr bool valueless_by_exception() const noexcept;
```

Effects: Returns `false` if and only if the `variant` holds a value.

[Note: A `variant` might not hold a value if an exception is thrown during a type-changing assignment or emplacement. The latter means that even a `variant<float, int>` can become `valueless_by_exception()`, for instance by

```cpp
struct S { operator int() { throw 42; } };  
variant<float, int> v{12.f};  
v.emplace<1>(S());
```

— end note]

```cpp
constexpr size_t index() const noexcept;
```

Effects: If `valueless_by_exception()` is `true`, returns `variant_npos`. Otherwise, returns the zero-based index of the alternative of the contained value.

23.7.3.6 Swap

```cpp
void swap(variant& rhs) noexcept(see below);
```

Requires: Lvalues of type `T_i` shall be swappable (20.5.3.2) and `is_move_constructible_v<T_i>` shall be `true` for all `i`.

Effects:

1. if `valueless_by_exception()` && `rhs.valueless_by_exception()` no effect. Otherwise,
if \( \text{index}() == \text{rhs.index}() \), calls \( \text{swap}(\text{get<}\i(\ast \text{this}), \text{get<}\i(\text{rhs})) \) where \( i \) is \( \text{index}() \). Otherwise,

— exchanges values of \( \text{rhs} \) and \( \ast \text{this} \).

**Throws:** If \( \text{index}() == \text{rhs.index}() \), any exception thrown by \( \text{swap}(\text{get<}\i(\ast \text{this}), \text{get<}\i(\text{rhs})) \) with \( i \) being \( \text{index}() \). Otherwise, any exception thrown by the move constructor of \( \text{T}_i \) or \( \text{T}_j \) with \( i \) being \( \text{index}() \) and \( j \) being \( \text{rhs.index}() \).

**Remarks:** If an exception is thrown during the call to function \( \text{swap}(\text{get<}\i(\ast \text{this}), \text{get<}\i(\text{rhs})) \), the states of the contained values of \( \ast \text{this} \) and \( \text{rhs} \) are determined by the exception safety guarantee of \( \text{swap} \) for lvalues of \( \text{T}_i \) with \( i \) being \( \text{index}() \). If an exception is thrown during the exchange of the values of \( \ast \text{this} \) and \( \text{rhs} \), the states of the values of \( \ast \text{this} \) and of \( \text{rhs} \) are determined by the exception safety guarantee of \( \text{variant}'s \) move constructor. The expression inside \( \text{noexcept} \) is equivalent to the logical AND of \( \text{is_nothrow_move_constructible_v<T}_i> \& \& \text{is_nothrow_swappable_v<T}_i> \) for all \( i \).

### 23.7.4 variant helper classes

#### template <class T> struct variant_size;

*Remarks:* All specializations of \( \text{variant_size} \) shall meet the UnaryTypeTrait requirements (23.15.1) with a base characteristic of \( \text{integral_constant<size_t, N>} \) for some \( N \).

template <class T> class variant_size<const T>;
template <class T> class variant_size<volatile T>;
template <class T> class variant_size<const volatile T>;

Let \( \text{VS} \) denote \( \text{variant_size<T>} \) of the cv-unqualified type \( T \). Then each of the three templates shall meet the UnaryTypeTrait requirements (23.15.1) with a base characteristic of \( \text{integral_constant<size_t, \text{VS}.value>} \).

template <class... Types>
struct variant_size<variant<Types...>> : integral_constant<size_t, sizeof...(Types)> { };

template <size_t I, class T> class variant_alternative<I, const T>;
template <size_t I, class T> class variant_alternative<I, volatile T>;
template <size_t I, class T> class variant_alternative<I, const volatile T>;

Let \( \text{VA} \) denote \( \text{variant_alternative<I, T>} \) of the cv-unqualified type \( T \). Then each of the three templates shall meet the TransformationTrait requirements (23.15.1) with a member typedef \( \text{type} \) that names the following type:

- for the first specialization, \( \text{add_const_t}<\text{VA::type}> \),
- for the second specialization, \( \text{add_volatile_t}<\text{VA::type}> \), and
- for the third specialization, \( \text{add_cv_t}<\text{VA::type}> \).

**Requires:** \( I < \text{sizeof...(Types)} \).

**Value:** The type \( T_I \).

### 23.7.5 Value access

#### template <class T, class... Types>

```cpp
constexpr bool holds_alternative(const variant<Types...>& v) noexcept;
```

*Requires:* The type \( T \) occurs exactly once in \( \text{Types}... \). Otherwise, the program is ill-formed.

*Returns:* \( \text{true} \) if \( \text{index}() \) is equal to the zero-based index of \( T \) in \( \text{Types}... \).
template <size_t I, class... Types>
constexpr variant_alternative_t<I, variant<Types...>> get(variant<Types...>& v);

template <size_t I, class... Types>
constexpr variant_alternative_t<I, variant<Types...>> get(variant<Types...>&& v);

template <size_t I, class... Types>
constexpr const variant_alternative_t<I, variant<Types...>>& get(const variant<Types...>& v);

template <size_t I, class... Types>
constexpr const variant_alternative_t<I, variant<Types...>>&& get(const variant<Types...>&& v);

3 Requires: I < sizeof...(Types). Otherwise the program is ill-formed.

Effects: If v.index() is I, returns a reference to the object stored in the variant. Otherwise, throws an exception of type bad_variant_access.

template <class T, class... Types> constexpr T& get(variant<Types...>& v);

template <class T, class... Types> constexpr T&& get(variant<Types...>&& v);

template <class T, class... Types> constexpr const T& get(const variant<Types...>& v);

template <class T, class... Types> constexpr const T&& get(const variant<Types...>&& v);

5 Requires: The type T occurs exactly once in Types.... Otherwise, the program is ill-formed.

Effects: If v holds a value of type T, returns a reference to that value. Otherwise, throws an exception of type bad_variant_access.

template <size_t I, class... Types>
constexpr add_pointer_t<variant_alternative_t<I, variant<Types...>>> get_if(variant<Types...>* v) noexcept;

template <size_t I, class... Types>
constexpr add_pointer_t<const variant_alternative_t<I, variant<Types...>>> get_if(const variant<Types...>* v) noexcept;

7 Requires: I < sizeof...(Types). Otherwise the program is ill-formed.

Returns: A pointer to the value stored in the variant, if v != nullptr and v->index() == I. Otherwise, returns nullptr.

template <class T, class... Types>
constexpr add_pointer_t<T> get_if(variant<Types...>* v) noexcept;

template <class T, class... Types>
constexpr add_pointer_t<const T> get_if(const variant<Types...>* v) noexcept;

9 Requires: The type T occurs exactly once in Types.... Otherwise, the program is ill-formed.

Effects: Equivalent to: return get_if<i>(v); with i being the zero-based index of T in Types....

23.7.6 Relational operators [variant.relops]

template <class... Types>
constexpr bool operator==(const variant<Types...>& v, const variant<Types...>& w);

1 Requires: get<i>(v) == get<i>(w) is a valid expression returning a type that is convertible to bool, for all i.

Returns: If v.index() != w.index(), false; otherwise if v.valueless_by_exception(), true; otherwise get<i>(v) == get<i>(w) with i being v.index().

template <class... Types>
constexpr bool operator!=(const variant<Types...>& v, const variant<Types...>& w);

3 Requires: get<i>(v) != get<i>(w) is a valid expression returning a type that is convertible to bool,
for all \( i \).

**Returns:** If \( v.\text{index}() \neq w.\text{index}() \), \( v.\text{valueless\_by\_exception}() \), \( w.\text{valueless\_by\_exception}() \), otherwise get\(<i>(v) \neq \text{get<i>(w)} \) with \( i \) being \( v.\text{index}() \).

```cpp
template <class... Types>
constexpr bool operator<(const variant<Types...>& v, const variant<Types...>& w);
```

**Requires:** get\(<i>(v) < \text{get<i>(w)} \) is a valid expression returning a type that is convertible to \( \text{bool} \), for all \( i \).

**Returns:** If \( v.\text{valueless\_by\_exception}() \), \( w.\text{valueless\_by\_exception}() \), \( v.\text{valueless\_by\_exception}() \), otherwise \( \text{get<i>(v)} < \text{get<i>(w)} \) with \( i \) being \( v.\text{index}() \).

```cpp
template <class... Types>
constexpr bool operator>(const variant<Types...>& v, const variant<Types...>& w);
```

**Requires:** get\(<i>(v) > \text{get<i>(w)} \) is a valid expression returning a type that is convertible to \( \text{bool} \), for all \( i \).

**Returns:** If \( v.\text{valueless\_by\_exception}() \), \( w.\text{valueless\_by\_exception}() \), \( w.\text{valueless\_by\_exception}() \), otherwise \( \text{get<i>(v)} > \text{get<i>(w)} \) with \( i \) being \( v.\text{index}() \).

```cpp
template <class... Types>
constexpr bool operator<=(const variant<Types...>& v, const variant<Types...>& w);
```

**Requires:** get\(<i>(v) \leq \text{get<i>(w)} \) is a valid expression returning a type that is convertible to \( \text{bool} \), for all \( i \).

**Returns:** If \( v.\text{valueless\_by\_exception}() \), \( w.\text{valueless\_by\_exception}() \), \( v.\text{valueless\_by\_exception}() \), otherwise \( \text{get<i>(v)} \leq \text{get<i>(w)} \) with \( i \) being \( v.\text{index}() \).

```cpp
template <class... Types>
constexpr bool operator>=(const variant<Types...>& v, const variant<Types...>& w);
```

**Requires:** get\(<i>(v) \geq \text{get<i>(w)} \) is a valid expression returning a type that is convertible to \( \text{bool} \), for all \( i \).

**Returns:** If \( w.\text{valueless\_by\_exception}() \), \( v.\text{valueless\_by\_exception}() \), \( v.\text{valueless\_by\_exception}() \), otherwise \( \text{get<i>(v)} \geq \text{get<i>(w)} \) with \( i \) being \( v.\text{index}() \).

### 23.7.7 Visitation [variant.visit]

```cpp
template <class Visitor, class... Variants>
constexpr see below visit(Visitor&& vis, Variants&&... vars);
```

**Requires:** The expression in the *Effects* element shall be a valid expression of the same type and value category, for all combinations of alternative types of all variants. Otherwise, the program is ill-formed.  

**Effects:** Let \( \text{is... be vars.index}() \ldots \). Returns INVOK(\( \text{forward<Visitor}(vis), \text{get<is>(forward<Variants>(vars))} \ldots \));

**Remarks:** The return type is the common type of all possible INVOK expressions of the *Effects* element.

**Throws:** bad_variant_access if any variant in \( \text{vars} \) is \( \text{valueless\_by\_exception}() \).

**Complexity:** For \( \text{sizeof...(Variants)} \leq 1 \), the invocation of the callable object is implemented in constant time, i.e. it does not depend on \( \text{sizeof...(Types)} \). For \( \text{sizeof...(Variants)} \geq 1 \), the
invocation of the callable object has no complexity requirements.

23.7.8 Class monostate

```cpp
struct monostate{};
```

1 The class `monostate` can serve as a first alternative type for a `variant` to make the `variant` type default constructible.

23.7.9 monostate relational operators

```cpp
constexpr bool operator<(monostate, monostate) noexcept { return false; }
constexpr bool operator>(monostate, monostate) noexcept { return false; }
constexpr bool operator<=(monostate, monostate) noexcept { return true; }
constexpr bool operator>=(monostate, monostate) noexcept { return true; }
constexpr bool operator==(monostate, monostate) noexcept { return true; }
constexpr bool operator!=(monostate, monostate) noexcept { return false; }
```

1 [Note: `monostate` objects have only a single state; they thus always compare equal. — end note]

23.7.10 Specialized algorithms

```cpp
template <class... Types>
void swap(variant<Types...>& v, variant<Types...>& w) noexcept(see below);
```

1 Effects: Equivalent to `v.swap(w)`.

2 Remarks: This function shall not participate in overload resolution unless `is_move_constructible_v<T_i>` && `is_swappable_v<T_i>` is true for all `i`. The expression inside `noexcept` is equivalent to `noexcept(v.swap(w))`.

23.7.11 Class bad_variant_access

```cpp
class bad_variant_access : public exception {
public:
    bad_variant_access() noexcept;
    const char* what() const noexcept override;
};
```

1 Objects of type `bad_variant_access` are thrown to report invalid accesses to the value of a `variant` object.

2 Constructs a `bad_variant_access` object.

3 Returns: An implementation-defined NTBS.

23.7.12 Hash support

```cpp
template <class... Types> struct hash<variant<Types...>>;
```

1 The specialization `hash<variant<Types...>>` is enabled (23.14.15) if and only if every specialization in `hash<remove_const_t<Types>>...` is enabled. The member functions are not guaranteed to be `noexcept`.

2 The specialization is enabled (23.14.15).
23.7.13 Allocator-related traits

```cpp
template <class... Types, class Alloc>
struct uses_allocator<variant<Types...>, Alloc> : true_type {);

1 Requires: Alloc shall be an Allocator (20.5.3.5).

2 [ Note: Specialization of this trait informs other library components that variant can be constructed
with an allocator, even though it does not have a nested allocator_type. — end note ]
```

23.8 Storage for any type

1 This section describes components that C++ programs may use to perform operations on objects of a
discriminated type.

2 [ Note: The discriminated type may contain values of different types but does not attempt conversion between
them, i.e. 5 is held strictly as an int and is not implicitly convertible either to "5" or to 5.0. This indifference
to interpretation but awareness of type effectively allows safe, generic containers of single values, with no
scope for surprises from ambiguous conversions. — end note ]

23.8.1 Header <any> synopsis

```cpp
namespace std {

    // 23.8.2, class bad_any_cast
    class bad_any_cast;

    // 23.8.3, class any
    class any;

    // 23.8.4, non-member functions
    void swap(any& x, any& y) noexcept;
    template <class T, class... Args>
    any make_any(Args&& ...args);
    template <class T, class U, class... Args>
    any make_any(initializer_list<U> il, Args&& ...args);
    template<class T>
    T any_cast(const any& operand);
    template<class T>
    T any_cast(any& operand);
    template<class T>
    T any_cast(any&& operand);
    template<class T>
    const T* any_cast(const any* operand) noexcept;
    template<class T>
    T* any_cast(any* operand) noexcept;
}
```

23.8.2 Class bad_any_cast

```cpp
class bad_any_cast : public bad_cast {
    public:
        const char* what() const noexcept override;
};

1 Objects of type bad_any_cast are thrown by a failed any_cast (23.8.4).
```

const char* what() const noexcept override;
Returns: An implementation-defined NTBS.

Remarks: The message may be a null-terminated multibyte string (20.4.2.1.5.2), suitable for conversion and display as a wstring (24.3, 25.4.1.4).

### 23.8.3 Class any [any.class]

class any {
  public:
    // 23.8.3.1, construction and destruction
    constexpr any() noexcept;
    any(const any& other);
    any(any&& other) noexcept;
    template <class T> any(T&& value);
    template <class T, class... Args>
      explicit any(in_place_type_t<T>, Args&&...);
    template <class T, class U, class... Args>
      explicit any(in_place_type_t<T>, initializer_list<U>, Args&&...);
    ~any();
    // 23.8.3.2, assignments
    any& operator=(const any& rhs);
    any& operator=(any&& rhs) noexcept;
    template <class T> any& operator=(T&& rhs);
    // 23.8.3.3, modifiers
    template <class T, class... Args>
      decay_t<T>& emplace(Args&& ...);
    template <class T, class U, class... Args>
      decay_t<T>& emplace(initializer_list<U>, Args&&...);
    void reset() noexcept;
    void swap(any& rhs) noexcept;
    // 23.8.3.4, observers
    bool has_value() const noexcept;
    const type_info& type() const noexcept;
};

1 An object of class any stores an instance of any type that satisfies the constructor requirements or it has no value, and this is referred to as the state of the class any object. The stored instance is called the contained value. Two states are equivalent if either they both have no value, or both have a value and the contained values are equivalent.

2 The non-member any_cast functions provide type-safe access to the contained value.

3 Implementations should avoid the use of dynamically allocated memory for a small contained value. [Example: where the object constructed is holding only an int. — end example] Such small-object optimization shall only be applied to types T for which is_nothrow_move_constructible_v<T> is true.

### 23.8.3.1 Construction and destruction [any.cons]

constexpr any() noexcept;

1 Postconditions: has_value() is false.
any(const any& other);

Effects: If other.has_value() is false, constructs an object that has no value. Otherwise, equivalent to any(in_place<T>, any_cast<const T&>(other)) where T is the type of the contained object.

Throws: Any exceptions arising from calling the selected constructor for the contained value.

any(any&& other) noexcept;

Effects: If other.has_value() is false, constructs an object that has no value. Otherwise, constructs an object of type any that contains either the contained object of other, or contains an object of the same type constructed from the contained object of other considering that contained object as an rvalue.

Postconditions: other is left in a valid but otherwise unspecified state.

template<class T>
any(T&& value);

Let VT be decay_t<T>.

Requires: VT shall satisfy the CopyConstructible requirements.

Effects: Constructs an object of type any that contains an object of type VT direct-initialized with std::forward<T>(value).

Remarks: This constructor shall not participate in overload resolution unless VT is not the same type as any, VT is not a specialization of in_place_type_t, and is_copy_constructible_v<VT> is true.

Throws: Any exception thrown by the selected constructor of VT.

template <class T, class... Args>
explicit any(in_place_type_t<T>, Args&&... args);

Let VT be decay_t<T>.

Requires: VT shall satisfy the CopyConstructible requirements.

Effects: Initializes the contained value as if direct-non-list-initializing an object of type VT with the arguments std::forward<Args>(args)....

Postconditions: *this contains a value of type VT.

Remarks: This constructor shall not participate in overload resolution unless is_copy_constructible_v<VT> is true and is_constructible_v<VT, Args...> is true.

template <class T, class U, class... Args>
explicit any(in_place_type_t<T>, initializer_list<U> il, Args&&... args);

Let VT be decay_t<T>.

Requires: VT shall satisfy the CopyConstructible requirements.

Effects: Initializes the contained value as if direct-non-list-initializing an object of type VT with the arguments il, std::forward<Args>(args)....

Postconditions: *this contains a value.

Remarks: This constructor shall not participate in overload resolution unless is_copy_constructible_v<VT> is true and is_constructible_v<VT, initializer_list<U>&, Args...> is true.

~any();
23.8.3.2 Assignment

```cpp
any& operator=(const any& rhs);
```

**Effects:** As if by `any(rhs).swap(*this)`. No effects if an exception is thrown.

**Returns:** `*this`.

**Throws:** Any exceptions arising from the copy constructor for the contained value.

```cpp
any& operator=(any&& rhs) noexcept;
```

**Effects:** As if by `any(std::move(rhs)).swap(*this)`.

**Returns:** `*this`.

**Postconditions:** The state of `*this` is equivalent to the original state of `rhs` and `rhs` is left in a valid but otherwise unspecified state.

```cpp
template<class T>
any& operator=(T&& rhs);
```

**Let** `VT` be `decay_t<T>`.

**Requires:** `VT` shall satisfy the `CopyConstructible` requirements.

**Effects:** Constructs an object `tmp` of type `any` that contains an object of type `VT` direct-initialized with `std::forward<T>(rhs)`, and `tmp.swap(*this)`. No effects if an exception is thrown.

**Returns:** `*this`.

**Remarks:** This operator shall not participate in overload resolution unless `VT` is not the same type as `any` and `is_copy_constructible_v<VT>` is true.

**Throws:** Any exception thrown by the selected constructor of `VT`.

23.8.3.3 Modifiers

```cpp
template <class T, class... Args>
decay_t<T>& emplace(Args&&... args);
```

**Let** `VT` be `decay_t<T>`.

**Requires:** `VT` shall satisfy the `CopyConstructible` requirements.

**Effects:** Calls `reset()`. Then initializes the contained value as if direct-non-list-initializing an object of type `VT` with the arguments `std::forward<Args>(args)...`. No effects if an exception is thrown.

**Postconditions:** `*this` contains a value.

**Returns:** A reference to the new contained value.

**Throws:** Any exception thrown by the selected constructor of `VT`.

**Remarks:** If an exception is thrown during the call to `VT`'s constructor, `*this` does not contain a value, and any previously contained value has been destroyed. This function shall not participate in overload resolution unless `is_copy_constructible_v<VT>` is true and `is_constructible_v<VT, Args...>` is true.

```cpp
template <class T, class U, class... Args>
decay_t<T>& emplace(initializer_list<U> il, Args&&... args);
```

**Let** `VT` be `decay_t<T>`.

**Requires:** `VT` shall satisfy the `CopyConstructible` requirements.
Effects: Calls reset(). Then initializes the contained value as if direct-non-list-initializing an object of type VT with the arguments il, std::forward<Args>(args)....

Postconditions: *this contains a value.

Returns: A reference to the new contained value.

Throws: Any exception thrown by the selected constructor of VT.

Remarks: If an exception is thrown during the call to VT's constructor, *this does not contain a value, and any previously contained value has been destroyed. The function shall not participate in overload resolution unless is_copy_constructible_v<VT> is true and is_constructible_v<VT, initializer_list<U>&, Args...> is true.

void reset() noexcept;

Effects: If has_value() is true, destroys the contained value.

Postconditions: has_value() is false.

void swap(any& rhs) noexcept;

Effects: Exchanges the states of *this and rhs.

23.8.3.4 Observers

bool has_value() const noexcept;

Returns: true if *this contains an object, otherwise false.

const type_info& type() const noexcept;

Returns: typeid(T) if *this has a contained value of type T, otherwise typeid(void).

[Note: Useful for querying against types known either at compile time or only at runtime. —end note]

23.8.4 Non-member functions

void swap(any& x, any& y) noexcept;

Effects: As if by x.swap(y).

template <class T, class... Args>
any make_any(Args&& ...args);

Effects: Equivalent to: return any(in_place_type<T>, std::forward<Args>(args)...);

template <class T, class U, class... Args>
any make_any(initializer_list<U> il, Args&& ...args);

Effects: Equivalent to: return any(in_place_type<T>, il, std::forward<Args>(args)...);

template<class T>
T any_cast(const any& operand);
template<class T>
T any_cast(any& operand);
template<class T>
T any_cast(any&& operand);

Let U be the type remove_cv_t<remove_reference_t<ValueType>>.

Requires: For the first overload, is_constructible_v<ValueType, const U&> is true. For the second overload, is_constructible_v<ValueType, U&> is true. For the third overload, is_constructible_-

§ 23.8.4
v< ValueType, U > is true. Otherwise the program is ill-formed.

6 Returns: For the first and second overload, static_cast<ValueType>(*any_cast<U>(&operand)). For the third overload, static_cast<ValueType>(std::move(*any_cast<U>(&operand))).

7 Throws: bad_any_cast if operand.type() != typeid(remove_reference_t<T>).

[ Example:
  any x(5); // x holds int
  assert(any_cast<int>(x) == 5);
  any_cast<int&>(x) = 10; // cast to reference
  assert(any_cast<int>(x) == 10);

  x = "Meow"; // x holds const char*
  assert(strcmp(any_cast<const char*>(x), "Meow") == 0);
  any_cast<const char* &>(x) = "Harry";
  assert(strcmp(any_cast<const char*>(x), "Harry") == 0);

  x = string("Meow"); // x holds string
  string s, s2("Jane");
  s = move(any_cast<string&>(x)); // move from any
  assert(s == "Meow");
  any_cast<string&>(x) = move(s2); // move to any
  assert(any_cast<const string&>(x) == "Jane");

  string cat("Meow");
  const any y(cat); // const y holds string
  assert(any_cast<const string&>(y) == cat);

  any_cast<string&>(y); // error; cannot
  // any_cast away const
  — end example ]

template<class T>
const T* any_cast(const any* operand) noexcept;

template<class T>
T* any_cast(any* operand) noexcept;

9 Returns: If operand != nullptr & operand->type() == typeid(T), a pointer to the object contained by operand; otherwise, nullptr.

[ Example:
  bool is_string(const any& operand) {
    return any_cast<string>(&operand) != nullptr;
  }
  — end example ]

23.9 Bitsets [bitset]

23.9.1 Header <bitset> synopsis [bitset.syn]

#include <string>
#include <iosfwd> // for istream (30.7.1), ostream (30.7.2), see 30.3.1

namespace std {
  template <size_t N> class bitset;
The header `<bitset>` defines a class template and several related functions for representing and manipulating fixed-size sequences of bits.

### 23.9.2 Class template `bitset`

```cpp
namespace std {
    template<size_t N> class bitset {
        public:
            // bit reference:
            class reference {
                friend class bitset;
                reference() noexcept;
                public:
                    ~reference() noexcept;
                    reference& operator=(bool x) noexcept; // for b[i] = x;
                    reference& operator=(const reference&) noexcept; // for b[i] = b[j];
                    bool operator~() const noexcept; // flips the bit
                    operator bool() const noexcept; // for x = b[i];
                    reference& flip() noexcept; // for b[i].flip();
            };

            // 23.9.2.1, constructors
            constexpr bitset() noexcept;
            constexpr bitset(unsigned long long val) noexcept;
            template<class charT, class traits, class Allocator>
            explicit bitset(
                const basic_string<charT, traits, Allocator>& str,
                typename basic_string<charT, traits, Allocator>::size_type pos = 0,
                typename basic_string<charT, traits, Allocator>::size_type n =
                basic_string<charT, traits, Allocator>::npos,
                charT zero = charT('0'),
                charT one = charT('1'));
            template <class charT>
            explicit bitset(
                const charT* str,
                typename basic_string<charT>::size_type n = basic_string<charT>::npos,
                charT zero = charT('0'),
                charT one = charT('1'));

            // 23.9.2.2, bitset operations
            bitset<N>& operator&(const bitset<N>&, const bitset<N>&) noexcept;
            bitset<N>& operator|=(const bitset<N>&, const bitset<N>&) noexcept;
            bitset<N>& operator~(const bitset<N>&) noexcept;
    }
}
```

1 The header `<bitset>` defines a class template and several related functions for representing and manipulating fixed-size sequences of bits.
The class template `bitset<N>` describes an object that can store a sequence consisting of a fixed number of bits, N.

Each bit represents either the value zero (reset) or one (set). To `toggle` a bit is to change the value zero to one, or the value one to zero. Each bit has a non-negative position `pos`. When converting between an object of class `bitset<N>` and a value of some integral type, bit position `pos` corresponds to the bit value `1 << pos`. The integral value corresponding to two or more bits is the sum of their bit values.

The functions described in this subclause can report three kinds of errors, each associated with a distinct exception:

1. an `invalid_argument` error is associated with exceptions of type `invalid_argument` (22.2.4);
2. an `out_of_range` error is associated with exceptions of type `out_of_range` (22.2.6);
3. an `overflow` error is associated with exceptions of type `overflow_error` (22.2.9).

### 23.9.2.1 `bitset` constructors

§ 23.9.2.1
constexpr bitset() noexcept;

Effects: Constructs an object of class bitset<N>, initializing all bits to zero.

constexpr bitset(unsigned long long val) noexcept;

Effects: Constructs an object of class bitset<N>, initializing the first M bit positions to the corresponding bit values in val. M is the smaller of N and the number of bits in the value representation (6.9) of unsigned long long. If M < N, the remaining bit positions are initialized to zero.

template <class charT, class traits, class Allocator>
explicit
bitset(const basic_string<charT, traits, Allocator>& str,
     typename basic_string<charT, traits, Allocator>::size_type pos = 0,
     typename basic_string<charT, traits, Allocator>::size_type n =
     basic_string<charT, traits, Allocator>::npos,
     charT zero = charT('0'), charT one = charT('1'));

Throws: out_of_range if pos > str.size() or invalid_argument if an invalid character is found (see below).

Effects: Determines the effective length rlen of the initializing string as the smaller of n and str.size() - pos.
The function then throws invalid_argument if any of the rlen characters in str beginning at position pos is other than zero or one. The function uses traits::eq() to compare the character values.
Otherwise, the function constructs an object of class bitset<N>, initializing the first M bit positions to values determined from the corresponding characters in the string str. M is the smaller of N and rlen.
An element of the constructed object has value zero if the corresponding character in str, beginning at position pos, is zero. Otherwise, the element has the value one. Character position pos + M - 1 corresponds to bit position zero. Subsequent decreasing character positions correspond to increasing bit positions.
If M < N, remaining bit positions are initialized to zero.

template <class charT>
explicit bitset(
    const charT* str,
    typename basic_string<charT>::size_type n = basic_string<charT>::npos,
    charT zero = charT('0'), charT one = charT('1'));

Effects: Constructs an object of class bitset<N> as if by:

bitset(
    n == basic_string<charT>::npos
    ? basic_string<charT>(str)
    : basic_string<charT>(str, n),
    0, n, zero, one)

23.9.2.2 bitset members

bitset<N>& operator&=(const bitset<N>& rhs) noexcept;

Effects: Clears each bit in this for which the corresponding bit in rhs is clear, and leaves all other bits unchanged.

Returns: *this.

bitset<N>& operator|=(const bitset<N>& rhs) noexcept;
Effects: Sets each bit in \*this for which the corresponding bit in rhs is set, and leaves all other bits unchanged.

Returns: \*this.

bitset<N>& operator\^=(const bitset<N>& rhs) noexcept;
Effects: Toggles each bit in \*this for which the corresponding bit in rhs is set, and leaves all other bits unchanged.

Returns: \*this.

bitset<N>& operator<<=(size_t pos) noexcept;
Effects: Replaces each bit at position I in \*this with a value determined as follows:

\( \text{(7.1) If } I < pos, \text{ the new value is zero; } \)
\( \text{(7.2) If } I \geq pos, \text{ the new value is the previous value of the bit at position } I - pos. \)

Returns: \*this.

bitset<N>& operator>>=(size_t pos) noexcept;
Effects: Replaces each bit at position I in \*this with a value determined as follows:

\( \text{(9.1) If } pos \geq N - I, \text{ the new value is zero; } \)
\( \text{(9.2) If } pos < N - I, \text{ the new value is the previous value of the bit at position } I + pos. \)

Returns: \*this.

bitset<N>& set() noexcept;
Effects: Sets all bits in \*this.

Returns: \*this.

bitset<N>& set(size_t pos, bool val = true);
Throws: out_of_range if pos does not correspond to a valid bit position.
Effects: Stores a new value in the bit at position pos in \*this. If val is nonzero, the stored value is one, otherwise it is zero.

Returns: \*this.

bitset<N>& reset() noexcept;
Effects: Resets all bits in \*this.

Returns: \*this.

bitset<N>& reset(size_t pos);
Throws: out_of_range if pos does not correspond to a valid bit position.
Effects: Resets the bit at position pos in \*this.

Returns: \*this.

bitset<N> operator~() const noexcept;
Effects: Constructs an object x of class bitset<N> and initializes it with \*this.

Returns: x.flip().

bitset<N>& flip() noexcept;
Effects: Toggles all bits in *this.

Returns: *this.

bitset<N>& flip(size_t pos);

Throws: out_of_range if pos does not correspond to a valid bit position.
Effects: Toggles the bit at position pos in *this.
Returns: *this.

unsigned long to_ulong() const;

Throws: overflow_error if the integral value x corresponding to the bits in *this cannot be represented as type unsigned long.
Returns: x.

unsigned long long to_ullong() const;

Throws: overflow_error if the integral value x corresponding to the bits in *this cannot be represented as type unsigned long long.
Returns: x.

template <class charT = char,
    class traits = char_traits<charT>,
    class Allocator = allocator<charT>>
    basic_string<charT, traits, Allocator>
to_string(charT zero = charT('0'), charT one = charT('1')) const;

Effects: Constructs a string object of the appropriate type and initializes it to a string of length N characters. Each character is determined by the value of its corresponding bit position in *this. Character position N - 1 corresponds to bit position zero. Subsequent decreasing character positions correspond to increasing bit positions. Bit value zero becomes the character zero, bit value one becomes the character one.

Returns: The created object.

size_t count() const noexcept;

Returns: A count of the number of bits set in *this.

constexpr size_t size() const noexcept;

Returns: N.

bool operator==(const bitset<N>& rhs) const noexcept;

Returns: true if the value of each bit in *this equals the value of the corresponding bit in rhs.

bool operator!=(const bitset<N>& rhs) const noexcept;

Returns: true if !(this == rhs).

bool test(size_t pos) const;

Throws: out_of_range if pos does not correspond to a valid bit position.
Returns: true if the bit at position pos in *this has the value one.

bool all() const noexcept;

Returns: count() == size().

§ 23.9.2.2
bool any() const noexcept;
   
   Returns: count() != 0.

bool none() const noexcept;
   
   Returns: count() == 0.

bitset<N> operator<<(size_t pos) const noexcept;
   
   Returns: bitset<N>(*this) <<= pos.

bitset<N> operator>>(size_t pos) const noexcept;
   
   Returns: bitset<N>(*this) >>= pos.

castexpr bool operator[](size_t pos) const;
   
   Requires: pos shall be valid.
   
   Returns: true if the bit at position pos in *this has the value one, otherwise false.
   
   Throws: Nothing.

bitset<N>::reference operator[](size_t pos);
   
   Requires: pos shall be valid.
   
   Returns: An object of type bitset<N>::reference such that (*this)[pos] == this->test(pos),
   and such that (*this)[pos] = val is equivalent to this->set(pos, val).
   
   Throws: Nothing.

   Remarks: For the purpose of determining the presence of a data race (4.7), any access or update through
   the resulting reference potentially accesses or modifies, respectively, the entire underlying bitset.

23.9.3 bitset hash support
   
   template <size_t N> struct hash<bitset<N>>;
   
   The specialization is enabled (23.14.15).

23.9.4 bitset operators
   
   bitset<N> operator&(const bitset<N>& lhs, const bitset<N>& rhs) noexcept;
   
   Returns: bitset<N>(lhs) &= rhs.

   bitset<N> operator|(const bitset<N>& lhs, const bitset<N>& rhs) noexcept;
   
   Returns: bitset<N>(lhs) |= rhs.

   bitset<N> operator^(const bitset<N>& lhs, const bitset<N>& rhs) noexcept;
   
   Returns: bitset<N>(lhs) ^= rhs.

   template <class charT, class traits, size_t N>
   basic_istream<
   charT, traits>& operator>>(basic_istream<
   charT, traits>& is, bitset<N>& x);
   
   A formatted input function (30.7.4.2).
   
   Effects: Extracts up to N characters from is. Stores these characters in a temporary object str of type
   basic_string<charT, traits>, then evaluates the expression x = bitset<N>(str). Characters are
   extracted and stored until any of the following occurs:
(5.1) 
— N characters have been extracted and stored;
(5.2) 
— end-of-file occurs on the input sequence;
(5.3) 
— the next input character is neither \texttt{is.widen('0')} nor \texttt{is.widen('1')} (in which case the input character is not extracted).

If no characters are stored in \texttt{str}, calls \texttt{is.setstate(ios::base::failbit)} (which may throw \texttt{ios::base::failure (30.5.5.4)}).

Returns: \texttt{is}.

\begin{verbatim}
template <class charT, class traits, size_t N>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const bitset<N>& x);
\end{verbatim}

Returns:

\begin{verbatim}
os << x.template to_string<charT, traits, allocator<charT>>(
    use_facet<ctype<charT>>(os.getloc()).widen('0'),
    use_facet<ctype<charT>>(os.getloc()).widen('1'))
\end{verbatim}

(see 30.7.5.2).

23.10 Memory

23.10.1 In general

This subclause describes the contents of the header \texttt{<memory> (23.10.2)} and some of the contents of the header \texttt{<cstdlib> (21.2.2)}.

23.10.2 Header <memory> synopsis

The header \texttt{<memory>} defines several types and function templates that describe properties of pointers and pointer-like types, manage memory for containers and other template types, destroy objects, and construct multiple objects in uninitialized memory buffers (23.10.3–23.10.10). The header also defines the templates \texttt{unique_ptr}, \texttt{shared_ptr}, \texttt{weak_ptr}, and various function templates that operate on objects of these types (23.11).

\begin{verbatim}
namespace std {
// 23.10.3, pointer traits
    template <class Ptr> struct pointer_traits;
    template <class T> struct pointer_traits<T*>;

// 23.10.4, pointer safety
    enum class pointer_safety { relaxed, preferred, strict };
    void declare_reachable(void* p);
    template <class T> T* undeclare_reachable(T* p);
    void declare_no_pointers(char* p, size_t n);
    void undeclare_no_pointers(char* p, size_t n);
    pointer_safety get_pointer_safety() noexcept;

// 23.10.5, pointer alignment function
    void* align(size_t alignment, size_t size, void*& ptr, size_t& space);

// 23.10.6, allocator argument tag
    struct allocator_arg_t { explicit allocator_arg_t() = default; };
    inline constexpr allocator_arg_t allocator_arg{};

// 23.10.7, uses_allocator
    template <class T, class Alloc> struct uses_allocator;
\end{verbatim}
// allocator traits
template <class Alloc> struct allocator_traits;

// the default allocator
template <class T> class allocator;
template <class T, class U>
  bool operator==(const allocator<T>&, const allocator<U>&) noexcept;
template <class T, class U>
  bool operator!=(const allocator<T>&, const allocator<U>&) noexcept;

// specialized algorithms
template <class T> constexpr T* addressof(T& r) noexcept;
template <class T> const T* addressof(const T&&) = delete;
template <class ForwardIterator>
  void uninitialized_default_construct(ForwardIterator first, ForwardIterator last);
template <class ExecutionPolicy, class ForwardIterator>
  void uninitialized_default_construct(ExecutionPolicy&& exec, // see 28.4.5
                                    ForwardIterator first, ForwardIterator last);
template <class ForwardIterator, class Size>
  ForwardIterator uninitialized_default_construct_n(ForwardIterator first, Size n);
template <class ExecutionPolicy, class ForwardIterator, class Size>
  ForwardIterator uninitialized_default_construct_n(ExecutionPolicy&& exec, // see 28.4.5
                                                    ForwardIterator first, Size n);

template <class ForwardIterator>
  void uninitialized_value_construct(ForwardIterator first, ForwardIterator last);
template <class ExecutionPolicy, class ForwardIterator>
  void uninitialized_value_construct(ExecutionPolicy&& exec, // see 28.4.5

```

// 23.10.7.1, uses_allocator

```cpp
// 23.10.7.1, uses_allocator
template <class T, class Alloc>
  inline constexpr bool uses_allocator_v = uses_allocator<T, Alloc>::value;
}
```

23.10.3 Pointer traits

The class template `pointer_traits` supplies a uniform interface to certain attributes of pointer-like types.

namespace std {
```cpp
  template <class Ptr> struct pointer_traits {
    using pointer = Ptr;
    using element_type = see below;
    using difference_type = see below;

    template <class U> using rebind = see below;
```
static pointer pointer_to(see below r);
};

template <class T> struct pointer_traits<T*> {
    using pointer = T*;
    using element_type = T;
    using difference_type = ptrdiff_t;

    template <class U> using rebind = U*;

    static pointer pointer_to(see below r) noexcept;
};

23.10.3.1 Pointer traits member types

using element_type = see below;
1 Type: Ptr::element_type if the qualified-id Ptr::element_type is valid and denotes a type (17.8.2); otherwise, T if Ptr is a class template instantiation of the form SomePointer<T, Args>, where Args is zero or more type arguments; otherwise, the specialization is ill-formed.

using difference_type = see below;
2 Type: Ptr::difference_type if the qualified-id Ptr::difference_type is valid and denotes a type (17.8.2); otherwise, ptrdiff_t.

template <class U> using rebind = see below;
3 Alias template: Ptr::rebind<U> if the qualified-id Ptr::rebind<U> is valid and denotes a type (17.8.2); otherwise, SomePointer<U, Args> if Ptr is a class template instantiation of the form SomePointer<T, Args>, where Args is zero or more type arguments; otherwise, the instantiation of rebind is ill-formed.

23.10.3.2 Pointer traits member functions

static pointer pointer_traits::pointer_to(see below r);
static pointer pointer_traits<T*>::pointer_to(see below r) noexcept;
1 Remarks: If element_type is cv void, the type of r is unspecified; otherwise, it is element_type&.
2 Returns: The first member function returns a pointer to r obtained by calling Ptr::pointer_to(r) through which indirection is valid; an instantiation of this function is ill-formed if Ptr does not have a matching pointer_to static member function. The second member function returns addressof(r).

23.10.4 Pointer safety

A complete object is declared reachable while the number of calls to declare_reachable with an argument referencing the object exceeds the number of calls to undeclare_reachable with an argument referencing the object.

void declare_reachable(void* p);
1 Requires: p shall be a safely-derived pointer (6.7.4.3) or a null pointer value.
2 Effects: If p is not null, the complete object referenced by p is subsequently declared reachable (6.7.4.3).
3 Throws: May throw bad_alloc if the system cannot allocate additional memory that may be required to track objects declared reachable.

template <class T> T* undeclare_reachable(T* p);

§ 23.10.4
Requires: If \( p \) is not null, the complete object referenced by \( p \) shall have been previously declared reachable, and shall be live (6.8) from the time of the call until the last undeclare_reachable(\( p \)) call on the object.

Returns: A safely derived copy of \( p \) which shall compare equal to \( p \).

Throws: Nothing.

[Note: It is expected that calls to declare_reachable(\( p \)) will consume a small amount of memory in addition to that occupied by the referenced object until the matching call to undeclare_reachable(\( p \)) is encountered. Long running programs should arrange that calls are matched. —end note]

```cpp
void declare_no_pointers(char* p, size_t n);
```

Requires: No bytes in the specified range are currently registered with declare_no_pointers(). If the specified range is in an allocated object, then it must be entirely within a single allocated object. The object must be live until the corresponding undeclare_no_pointers() call. [Note: In a garbage-collecting implementation, the fact that a region in an object is registered with declare_no_pointers() should not prevent the object from being collected. —end note]

Effects: The \( n \) bytes starting at \( p \) no longer contain traceable pointer locations, independent of their type. Hence indirection through a pointer located there is undefined if the object it points to was created by global operator new and not previously declared reachable. [Note: This may be used to inform a garbage collector or leak detector that this region of memory need not be traced. —end note]

Throws: Nothing.

[Note: Under some conditions implementations may need to allocate memory. However, the request can be ignored if memory allocation fails. —end note]

```cpp
void undeclare_no_pointers(char* p, size_t n);
```

Requires: The same range must previously have been passed to declare_no_pointers().

Effects: Unregisters a range registered with declare_no_pointers() for destruction. It must be called before the lifetime of the object ends.

Throws: Nothing.

```cpp
pointer_safety get_pointer_safety() noexcept;
```

Returns: \( \text{pointer_safety::strict} \) if the implementation has strict pointer safety (6.7.4.3). It is implementation-defined whether get_pointer_safety returns \( \text{pointer_safety::relaxed} \) or \( \text{pointer_safety::preferred} \) if the implementation has relaxed pointer safety.\(^{221}\)

### 23.10.5 Align

```cpp
void* align(size_t alignment, size_t size, void*& ptr, size_t& space);
```

Effects: If it is possible to fit \( \text{size} \) bytes of storage aligned by \( \text{alignment} \) into the buffer pointed to by \( \text{ptr} \) with length \( \text{space} \), the function updates \( \text{ptr} \) to represent the first possible address of such storage and decreases \( \text{space} \) by the number of bytes used for alignment. Otherwise, the function does nothing.

Requires:

\(^{(2.1)}\) alignment shall be a power of two

\(^{(2.2)}\) ptr shall represent the address of contiguous storage of at least \( \text{space} \) bytes

\(^{221}\) pointer_safety::preferred might be returned to indicate that a leak detector is running so that the program can avoid spurious leak reports.
Returns: A null pointer if the requested aligned buffer would not fit into the available space, otherwise the adjusted value of ptr.

[Note: The function updates its ptr and space arguments so that it can be called repeatedly with possibly different alignment and size arguments for the same buffer. —end note]

23.10.6 Allocator argument tag

namespace std {
  struct allocator_arg_t { explicit allocator_arg_t() = default; };
  inline constexpr allocator_arg_t allocator_arg{};
}

The allocator_arg_t struct is an empty structure type used as a unique type to disambiguate constructor and function overloading. Specifically, several types (see tuple 23.5) have constructors with allocator_arg_t as the first argument, immediately followed by an argument of a type that satisfies the Allocator requirements (20.5.3.5).

23.10.7 uses_allocator

23.10.7.1 uses_allocator trait

template <class T, class Alloc> struct uses_allocator;

Remarks: Automatically detects whether T has a nested allocator_type that is convertible from Alloc. Meets the BinaryTypeTrait requirements (23.15.1). The implementation shall provide a definition that is derived from true_type if the qualified-id T::allocator_type is valid and denotes a type (17.8.2) and is_convertible_v<Alloc, T::allocator_type> != false, otherwise it shall be derived from false_type. A program may specialize this template to derive from true_type for a user-defined type T that does not have a nested allocator_type but nonetheless can be constructed with an allocator where either:

(1.1) — the first argument of a constructor has type allocator_arg_t and the second argument has type Alloc or

(1.2) — the last argument of a constructor has type Alloc.

23.10.7.2 Uses-allocator construction

Uses-allocator construction with allocator Alloc refers to the construction of an object obj of type T, using constructor arguments v1, v2, ..., vN of types V1, V2, ..., VN, respectively, and an allocator alloc of type Alloc, according to the following rules:

(1.1) — if uses_allocator_v<T, Alloc> is false and is_constructible_v<T, V1, V2, ..., VN> is true, then obj is initialized as obj(v1, v2, ..., vN);

(1.2) — otherwise, if uses_allocator_v<T, Alloc> is true and is_constructible_v<T, allocator_arg_t, Alloc, V1, V2, ..., VN> is true, then obj is initialized as obj(allocator_arg, alloc, v1, v2, ..., vN);

(1.3) — otherwise, if uses_allocator_v<T, Alloc> is true and is_constructible_v<T, V1, V2, ..., VN, Alloc> is true, then obj is initialized as obj(v1, v2, ..., vN, alloc);

(1.4) — otherwise, the request for uses-allocator construction is ill-formed. [Note: An error will result if uses_allocator_v<T, Alloc> is true but the specific constructor does not take an allocator. This definition prevents a silent failure to pass the allocator to an element. —end note]

23.10.8 Allocator traits

The class template allocator_traits supplies a uniform interface to all allocator types. An allocator cannot be a non-class type, however, even if allocator_traits supplies the entire required interface. [Note: Thus,
it is always possible to create a derived class from an allocator. — end note]

namespace std {
    template <class Alloc> struct allocator_traits {
        using allocator_type = Alloc;
        using value_type = typename Alloc::value_type;
        using pointer = see below;
        using const_pointer = see below;
        using void_pointer = see below;
        using const_void_pointer = see below;
        using difference_type = see below;
        using size_type = see below;
        using propagate_on_container_copy_assignment = see below;
        using propagate_on_container_move_assignment = see below;
        using propagate_on_container_swap = see below;
        using is_always_equal = see below;
        template <class T> using rebind_alloc = see below;
        template <class T> using rebind_traits = allocator_traits<rebind_alloc<T>>;
        static pointer allocate(Alloc& a, size_type n);
        static pointer allocate(Alloc& a, size_type n, const_void_pointer hint);
        static void deallocate(Alloc& a, pointer p, size_type n);
        template <class T, class... Args>
            static void construct(Alloc& a, T* p, Args&&... args);
        template <class T>
            static void destroy(Alloc& a, T* p);
        static size_type max_size(const Alloc& a) noexcept;
        static Alloc select_on_container_copy_construction(const Alloc& rhs);
    }
}

23.10.8.1 Allocator traits member types

[allocator.traits.types]

using pointer = see below;
1 Type: Alloc::pointer if the qualified-id Alloc::pointer is valid and denotes a type (17.8.2); otherwise, value_type*.

using const_pointer = see below;
2 Type: Alloc::const_pointer if the qualified-id Alloc::const_pointer is valid and denotes a type (17.8.2); otherwise, pointer_traits<pointer>::rebind<const value_type>.

using void_pointer = see below;
3 Type: Alloc::void_pointer if the qualified-id Alloc::void_pointer is valid and denotes a type (17.8.2); otherwise, pointer_traits<pointer>::rebind<void>.
using const_void_pointer = see below;

Type: Alloc::const_void_pointer if the qualified-id Alloc::const_void_pointer is valid and denotes a type (17.8.2); otherwise, pointer_traits<pointer>::rebind<const void>.

using difference_type = see below;

Type: Alloc::difference_type if the qualified-id Alloc::difference_type is valid and denotes a type (17.8.2); otherwise, pointer_traits<pointer>::difference_type.

using size_type = see below;

Type: Alloc::size_type if the qualified-id Alloc::size_type is valid and denotes a type (17.8.2); otherwise, make_unsigned_t<difference_type>.

using propagate_on_container_copy_assignment = see below;

Type: Alloc::propagate_on_container_copy_assignment if the qualified-id Alloc::propagate_on_container_copy_assignment is valid and denotes a type (17.8.2); otherwise false_type.

using propagate_on_container_move_assignment = see below;

Type: Alloc::propagate_on_container_move_assignment if the qualified-id Alloc::propagate_on_container_move_assignment is valid and denotes a type (17.8.2); otherwise false_type.

using propagate_on_container_swap = see below;

Type: Alloc::propagate_on_container_swap if the qualified-id Alloc::propagate_on_container_swap is valid and denotes a type (17.8.2); otherwise false_type.

using is_always_equal = see below;

Type: Alloc::is_always_equal if the qualified-id Alloc::is_always_equal is valid and denotes a type (17.8.2); otherwise is_empty<Alloc>::type.

template <class T> using rebind_alloc = see below;

Alias template: Alloc::rebind<T>::other if the qualified-id Alloc::rebind<T>::other is valid and denotes a type (17.8.2); otherwise Alloc<T, Args> if Alloc is a class template instantiation of the form Alloc<U, Args>, where Args is zero or more type arguments; otherwise, the instantiation of rebind_alloc is ill-formed.

23.10.8.2 Allocator traits static member functions

static pointer allocate(Alloc& a, size_type n);

Returns: a.allocate(n).

static pointer allocate(Alloc& a, size_type n, const_void_pointer hint);

Returns: a.allocate(n, hint) if that expression is well-formed; otherwise, a.allocate(n).

static void deallocate(Alloc& a, pointer p, size_type n);

Effects: Calls a.deallocate(p, n).

Throws: Nothing.

template <class T, class... Args>
static void construct(Alloc& a, T* p, Args&&... args);

Effects: Calls a.construct(p, std::forward<Args>(args)... if that call is well-formed; otherwise, invokes ::new (static_cast<void*>(p)) T(std::forward<Args>(args)...).
template <class T>
static void destroy(Alloc& a, T* p);

Effects: Calls a.destroy(p) if that call is well-formed; otherwise, invokes p->~T().

static size_type max_size(const Alloc& a) noexcept;

Returns: a.max_size() if that expression is well-formed; otherwise, numeric_limits<size_type>::
max()/sizeof(value_type).

static Alloc select_on_container_copy_construction(const Alloc& rhs);

Returns: rhs.select_on_container_copy_construction() if that expression is well-formed; other-
wise, rhs.

23.10.9 The default allocator

All specializations of the default allocator satisfy the allocator completeness requirements (20.5.3.5.1).

namespace std {
    template <class T> class allocator {
        public:
            using value_type = T;
            using propagate_on_container_move_assignment = true_type;
            using is_always_equal = true_type;

            allocator() noexcept;
            allocator(const allocator&) noexcept;
            template <class U> allocator(const allocator<U>&) noexcept;
            ~allocator();

            T* allocate(size_t n);
            void deallocate(T* p, size_t n);
    }
}

23.10.9.1 allocator members

Except for the destructor, member functions of the default allocator shall not introduce data races (4.7)
as a result of concurrent calls to those member functions from different threads. Calls to these functions
that allocate or deallocate a particular unit of storage shall occur in a single total order, and each such
deallocation call shall happen before the next allocation (if any) in this order.

T* allocate(size_t n);

Returns: A pointer to the initial element of an array of storage of size n * sizeof(T), aligned
appropriately for objects of type T.

Remarks: the storage is obtained by calling ::operator new (21.6.2), but it is unspecified when or
how often this function is called.

Throws: bad_alloc if the storage cannot be obtained.

void deallocate(T* p, size_t n);

Requires: p shall be a pointer value obtained from allocate(). n shall equal the value passed as the
first argument to the invocation of allocate which returned p.

Effects: Deallocates the storage referenced by p .

Remarks: Uses ::operator delete (21.6.2), but it is unspecified when this function is called.
§ 23.10.9.2 allocator globals

```
template <class T, class U>
bool operator==(const allocator<T>&, const allocator<U>&) noexcept;

template <class T, class U>
bool operator!=(const allocator<T>&, const allocator<U>&) noexcept;
```

1 Returns: true.

2 Returns: false.

23.10.10 Specialized algorithms

Throughout this subclause, the names of template parameters are used to express type requirements.

(1.1) If an algorithm’s template parameter is named InputIterator, the template argument shall satisfy the requirements of an input iterator (27.2.3).

(1.2) If an algorithm’s template parameter is named ForwardIterator, the template argument shall satisfy the requirements of a forward iterator (27.2.5), and is required to have the property that no exceptions are thrown from increment, assignment, comparison, or indirection through valid iterators.

Unless otherwise specified, if an exception is thrown in the following algorithms there are no effects.

23.10.10.1 addressof

```
template <class T> constexpr T* addressof(T& r) noexcept;
```

1 Returns: The actual address of the object or function referenced by r, even in the presence of an overloaded operator&.

2 Remarks: An expression addressof(E) is a constant subexpression (20.3.6) if E is an lvalue constant subexpression.

23.10.10.2 uninitialized_default_construct

```
template <class ForwardIterator>
void uninitialized_default_construct(ForwardIterator first, ForwardIterator last);
```

1 Effects: Equivalent to:
```
for (; first != last; ++first)
    ::new (static_cast<void*>(addressof(*first)))
        typename iterator_traits<ForwardIterator>::value_type;
```

```
template <class ForwardIterator, class Size>
ForwardIterator uninitialized_default_construct_n(ForwardIterator first, Size n);
```

2 Effects: Equivalent to:
```
for (; n>0; (void)++first, --n)
    ::new (static_cast<void*>(addressof(*first)))
        typename iterator_traits<ForwardIterator>::value_type;
return first;
```

23.10.10.3 uninitialized_value_construct

```
template <class ForwardIterator>
void uninitialized_value_construct(ForwardIterator first, ForwardIterator last);
```

1 Effects: Equivalent to:
```
for (; first != last; ++first)
```
template <class ForwardIterator, class Size>
ForwardIterator uninitialized_value_construct_n(ForwardIterator first, Size n);

Effects: Equivalent to:
for (; n>0; (void)++first, --n)
  ::new (static_cast<void*>(addressof(*first)))
  typename iterator_traits<ForwardIterator>::value_type();
return first;

23.10.10.4 uninitialized_copy

template <class InputIterator, class ForwardIterator>
ForwardIterator uninitialized_copy(InputIterator first, InputIterator last, 
  ForwardIterator result);
Effects: As if by:
for (; first != last; ++result, (void)++first)
  ::new (static_cast<void*>(addressof(*result)))
  typename iterator_traits<ForwardIterator>::value_type(*first);
Returns: result.

template <class InputIterator, class Size, class ForwardIterator>
ForwardIterator uninitialized_copy_n(InputIterator first, Size n, 
  ForwardIterator result);
Effects: As if by:
for ( ; n > 0; ++result, (void) ++first, --n) {
  ::new (static_cast<void*>(addressof(*result)))
  typename iterator_traits<ForwardIterator>::value_type(*first);
}
Returns: result.

23.10.10.5 uninitialized_move

template <class InputIterator, class ForwardIterator>
ForwardIterator uninitialized_move(InputIterator first, InputIterator last, 
  ForwardIterator result);
Effects: Equivalent to:
for (; first != last; (void)++result, ++first)
  ::new (static_cast<void*>(addressof(*result)))
  typename iterator_traits<ForwardIterator>::value_type(std::move(*first));
return result;
Remarks: If an exception is thrown, some objects in the range [first, last) are left in a valid but unspecified state.

template <class InputIterator, class Size, class ForwardIterator>
pair<InputIterator, ForwardIterator>
uninitialized_move_n(InputIterator first, Size n, ForwardIterator result);
Effects: Equivalent to:
for ( ; n > 0; ++result, (void) ++first, --n)
  ::new (static_cast<void*>(addressof(*result)))
typedef typename iterator_traits<ForwardIterator>::value_type(std::move(*first));
return {first, result};

Remarks: If an exception is thrown, some objects in the range [first, std::next(first, n)) are left in a valid but unspecified state.

23.10.10.6 uninitialized_fill

template <class ForwardIterator, class T>
void uninitialized_fill(ForwardIterator first, ForwardIterator last,
const T& x);

Effects: As if by:
for (; first != last; ++first)
::new (static_cast<void*>(addressof(*first)))
typename iterator_traits<ForwardIterator>::value_type(x);

template <class ForwardIterator, class Size, class T>
ForwardIterator uninitialized_fill_n(ForwardIterator first, Size n, const T& x);

Effects: As if by:
for (; n--; ++first)
::new (static_cast<void*>(addressof(*first)))
typename iterator_traits<ForwardIterator>::value_type(x);
return first;

23.10.10.7 destroy

template <class T>
void destroy_at(T* location);

Effects: Equivalent to:
location->~T();

template <class ForwardIterator>
void destroy(ForwardIterator first, ForwardIterator last);

Effects: Equivalent to:
for (; first!=last; ++first)
destroy_at(addressof(*first));

template <class ForwardIterator, class Size>
ForwardIterator destroy_n(ForwardIterator first, Size n);

Effects: Equivalent to:
for (; n > 0; (void)++first, --n)
destroy_at(addressof(*first));
return first;

23.10.11 C library memory allocation

[Note: The header <cstdlib> (21.2.2) declares the functions described in this subclause. — end note]

void* aligned_alloc(size_t alignment, size_t size);
void* calloc(size_t nmemb, size_t size);
void* malloc(size_t size);
void* realloc(void* ptr, size_t size);

Effects: These functions have the semantics specified in the C standard library.
Remarks: These functions do not attempt to allocate storage by calling `::operator new()` (21.6).

Storage allocated directly with these functions is implicitly declared reachable (see 6.7.4.3) on allocation, ceases to be declared reachable on deallocation, and need not cease to be declared reachable as the result of an `undeclare_reachable()` call. [Note: This allows existing C libraries to remain unaffected by restrictions on pointers that are not safely derived, at the expense of providing far fewer garbage collection and leak detection options for `malloc()`-allocated objects. It also allows `malloc()` to be implemented with a separate allocation arena, bypassing the normal `declare_reachable()` implementation. The above functions should never intentionally be used as a replacement for `declare_reachable()`, and newly written code is strongly encouraged to treat memory allocated with these functions as though it were allocated with `operator new`. — end note]

```c
void free(void* ptr);
```

Effects: This function has the semantics specified in the C standard library.

Remarks: This function does not attempt to deallocate storage by calling `::operator delete()`.

See also: ISO C 7.22.3.

### 23.11 Smart pointers

#### [smartptr] 23.11.1 Class template `unique_ptr`

#### [unique.ptr]

A *unique pointer* is an object that owns another object and manages that other object through a pointer. More precisely, a unique pointer is an object `u` that stores a pointer to a second object `p` and will dispose of `p` when `u` is itself destroyed (e.g., when leaving block scope (9.7)). In this context, `u` is said to own `p`.

The mechanism by which `u` disposes of `p` is known as `p`'s associated deleter, a function object whose correct invocation results in `p`'s appropriate disposition (typically its deletion).

Let the notation `u.p` denote the pointer stored by `u`, and let `u.d` denote the associated deleter. Upon request, `u` can reset (replace) `u.p` and `u.d` with another pointer and deleter, but must properly dispose of its owned object via the associated deleter before such replacement is considered completed.

Additionally, `u` can, upon request, transfer ownership to another unique pointer `u2`. Upon completion of such a transfer, the following postconditions hold:

(4.1) — `u2.p` is equal to the pre-transfer `u.p`,

(4.2) — `u.p` is equal to `nullptr`, and

(4.3) — if the pre-transfer `u.d` maintained state, such state has been transferred to `u2.d`.

As in the case of a reset, `u2` must properly dispose of its pre-transfer owned object via the pre-transfer associated deleter before the ownership transfer is considered complete. [Note: A deleter’s state need never be copied, only moved or swapped as ownership is transferred. — end note]

Each object of a type `U` instantiated from the `unique_ptr` template specified in this subclause has the strict ownership semantics, specified above, of a unique pointer. In partial satisfaction of these semantics, each such `U` is `MoveConstructible` and `MoveAssignable`, but is not `CopyConstructible` nor `CopyAssignable`. The template parameter `T` of `unique_ptr` may be an incomplete type.

[Note: The uses of `unique_ptr` include providing exception safety for dynamically allocated memory, passing ownership of dynamically allocated memory to a function, and returning dynamically allocated memory from a function. — end note]

```cpp
namespace std {
    template<class T> struct default_delete;
    template<class T> struct default_delete<T[]>>;

    template<class T, class D = default_delete<T>> class unique_ptr;
}
```
template<class T, class D> class unique_ptr<T[], D>;

template<class T, class... Args> unique_ptr<T> make_unique(Args&&... args);
template<class T> unique_ptr<T> make_unique(size_t n);

template<class T, class... Args> unspecified make_unique(Args&&...) = delete;

template<class T, class D> void swap(unique_ptr<T, D>& x, unique_ptr<T, D>& y) noexcept;

template<class T1, class D1, class T2, class D2>
bool operator==(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);  

template<class T1, class D1, class T2, class D2>
bool operator!=(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);  

template<class T1, class D1, class T2, class D2>
bool operator<(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);  

template<class T1, class D1, class T2, class D2>
bool operator>=(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);  

template <class T, class D>
bool operator==(const unique_ptr<T, D>& x, nullptr_t) noexcept;

template <class T, class D>
bool operator==(nullptr_t, const unique_ptr<T, D>& y) noexcept;

template <class T, class D>
bool operator!=(const unique_ptr<T, D>& x, nullptr_t) noexcept;

template <class T, class D>
bool operator!=(nullptr_t, const unique_ptr<T, D>& y) noexcept;

§ 23.11.1.1 Default deleters  
23.11.1.1.1 In general

The class template default_delete serves as the default deleter (destruction policy) for the class template unique_ptr.

The template parameter T of default_delete may be an incomplete type.
23.11.1.1.2 default_delete

namespace std {
    template <class T> struct default_delete {
        constexpr default_delete() noexcept = default;
        template <class U> default_delete(const default_delete<U>&) noexcept;
        void operator()(T* const) const;
    };
}

template <class U> default_delete(const default_delete<U>& other) noexcept;

1 Effects: Constructs a default_delete object from another default_delete<U> object.
2 Remarks: This constructor shall not participate in overload resolution unless U* is implicitly convertible to T*.

void operator()(T* ptr) const;

3 Effects: Calls delete on ptr.
4 Remarks: If T is an incomplete type, the program is ill-formed.

23.11.1.1.3 default_delete<T[]>

namespace std {
    template <class T> struct default_delete<T[]> {
        constexpr default_delete() noexcept = default;
        template <class U> default_delete(const default_delete<U[]>& other) noexcept;
        template <class U> void operator()(U* ptr) const;
    };
}

template <class U> default_delete(const default_delete<U[]>& other) noexcept;

1 Effects: constructs a default_delete object from another default_delete<U[]> object.
2 Remarks: This constructor shall not participate in overload resolution unless U(*)[] is convertible to T(*)[].

template <class U> void operator()(U* ptr) const;

3 Effects: Calls delete[] on ptr.
4 Remarks: If U is an incomplete type, the program is ill-formed. This function shall not participate in overload resolution unless U(*)([]) is convertible to T(*)([]).

23.11.1.2 unique_ptr for single objects

namespace std {
    template <class T, class D = default_delete<T>> class unique_ptr {
        public:
            using pointer = see below;
            using element_type = T;
            using deleter_type = D;

            // 23.11.1.2.1, constructors
            constexpr unique_ptr() noexcept;
            explicit unique_ptr(pointer p) noexcept;
            unique_ptr(pointer p, see below d1) noexcept;
            unique_ptr(pointer p, see below d2) noexcept;
            unique_ptr(unique_ptr&& u) noexcept;
    }
}

§ 23.11.1.2
constexpr unique_ptr(nullptr_t) noexcept;

template <class U, class E>
unique_ptr(unique_ptr<U, E>&& u) noexcept;

// 23.11.1.2.2, destructor
~unique_ptr();

// 23.11.1.2.3, assignment
unique_ptr& operator=(unique_ptr&& u) noexcept;

// 23.11.1.2.4, observers
add_lvalue_reference_t<T> operator*() const;
pointer operator->() const noexcept;
pointer get() const noexcept;
deleter_type& get_deleter() noexcept;
const deleter_type& get_deleter() const noexcept;
explicit operator bool() const noexcept;

// 23.11.1.2.5, modifiers
pointer release() noexcept;
void reset(pointer p = pointer()) noexcept;
void swap(unique_ptr& u) noexcept;

// disable copy from lvalue
unique_ptr(const unique_ptr&) = delete;
unique_ptr& operator=(const unique_ptr&) = delete;

1 The default type for the template parameter D is default_delete. A client-supplied template argument D shall be a function object type (23.14), lvalue reference to function, or lvalue reference to function object type for which, given a value d of type D and a value ptr of type unique_ptr<T, D>::pointer, the expression d(ptr) is valid and has the effect of disposing of the pointer as appropriate for that deleter.

2 If the deleter's type D is not a reference type, D shall satisfy the requirements of Destructible (Table 27).

3 If the qualified-id remove_reference_t<D>::pointer is valid and denotes a type (17.8.2), then unique_ptr<T, D>::pointer shall be a synonym for remove_reference_t<D>::pointer. Otherwise unique_ptr<T, D>::pointer shall be a synonym for element_type*. The type unique_ptr<T, D>::pointer shall satisfy the requirements of NullablePointer (20.5.3.3).

4 [Example: Given an allocator type X (20.5.3.5) and letting A be a synonym for allocator_traits<X>, the types A::pointer, A::const_pointer, A::void_pointer, and A::const_void_pointer may be used as unique_ptr<T, D>::pointer. —end example]

23.11.1.2.1 unique_ptr constructors

constexpr unique_ptr() noexcept;
constexpr unique_ptr(nullptr_t) noexcept;

1 Requires: D shall satisfy the requirements of DefaultConstructible (Table 22), and that construction shall not throw an exception.

2 Effects: Constructs a unique_ptr object that owns nothing, value-initializing the stored pointer and the stored deleter.

3 Postconditions: get() == nullptr. get_deleter() returns a reference to the stored deleter.
explicit unique_ptr(pointer p) noexcept;

Requires: D shall satisfy the requirements of DefaultConstructible (Table 22), and that construction shall not throw an exception.

Effects: Constructs a unique_ptr which owns p, initializing the stored pointer with p and value-initializing the stored deleter.

Postconditions: get() == p. get_deleter() returns a reference to the stored deleter.

Remarks: If is_pointer_v<deleter_type> is true or is_default_constructible_v<deleter_type> is false, this constructor shall not participate in overload resolution.

unique_ptr(pointer p, see below d1) noexcept;
unique_ptr(pointer p, see below d2) noexcept;

The signature of these constructors depends upon whether D is a reference type. If D is a non-reference type A, then the signatures are:

unique_ptr(pointer p, const A& d) noexcept;
unique_ptr(pointer p, A&& d) noexcept;

If D is an lvalue reference type A&, then the signatures are:

unique_ptr(pointer p, A& d) noexcept;
unique_ptr(pointer p, A&& d) = delete;

If D is an lvalue reference type const A&, then the signatures are:

unique_ptr(pointer p, const A& d) noexcept;
unique_ptr(pointer p, const A&& d) = delete;

Effects: Constructs a unique_ptr object which owns p, initializing the stored pointer with p and initializing the deleter from std::forward<decltype(d)>(d).

Remarks: These constructors shall not participate in overload resolution unless is_constructible_v<D, decltype(d)> is true.

Postconditions: get() == p. get_deleter() returns a reference to the stored deleter. If D is a reference type then get_deleter() returns a reference to the lvalue d.

Remarks: If class template argument deduction (16.3.1.8) would select a function template corresponding to either of these constructors, then the program is ill-formed.

[ Example:

D d;
unique_ptr<int, D> p1(new int, D()); // D must be MoveConstructible
unique_ptr<int, D> p2(new int, d); // D must be CopyConstructible
unique_ptr<int, D&> p3(new int, d); // p3 holds a reference to d
unique_ptr<int, const D&> p4(new int, D()); // error: value deleter object combined
// with reference deleter type

— end example ]

unique_ptr(unique_ptr&& u) noexcept;

Requires: If D is not a reference type, D shall satisfy the requirements of MoveConstructible (Table 23). Construction of the deleter from an rvalue of type D shall not throw an exception.
Effects: Constructs a `unique_ptr` by transferring ownership from `u` to `*this`. If `D` is a reference type, this deleter is copy constructed from `u`'s deleter; otherwise, this deleter is move constructed from `u`'s deleter. [Note: The deleter constructor can be implemented with `std::forward<D>`. — end note]

Postconditions: `get()` yields the value `u.get()` yielded before the construction. `get_deleter()` returns a reference to the stored deleter that was constructed from `u.get_deleter()`. If `D` is a reference type then `get_deleter()` and `u.get_deleter()` both reference the same lvalue deleter.

```cpp
template <class U, class E> unique_ptr(unique_ptr<U, E>&& u) noexcept;
```

Requires: If `E` is not a reference type, construction of the deleter from an rvalue of type `E` shall be well formed and shall not throw an exception. Otherwise, `E` is a reference type and construction of the deleter from an lvalue of type `E` shall be well formed and shall not throw an exception.

Remarks: This constructor shall not participate in overload resolution unless:

1. `unique_ptr<U, E>::pointer` is implicitly convertible to `pointer`,
2. `U` is not an array type, and
3. either `D` is a reference type and `E` is the same type as `D`, or `D` is not a reference type and `E` is implicitly convertible to `D`.

Effects: Constructs a `unique_ptr` by transferring ownership from `u` to `*this`. If `E` is a reference type, this deleter is copy constructed from `u`'s deleter; otherwise, this deleter is move constructed from `u`'s deleter. [Note: The deleter constructor can be implemented with `std::forward<E>`. — end note]

Postconditions: `get()` yields the value `u.get()` yielded before the construction. `get_deleter()` returns a reference to the stored deleter that was constructed from `u.get_deleter()`.

### 23.11.1.2.2 `unique_ptr` destructor

```cpp
~unique_ptr();
```

Requires: The expression `get_deleter()(get())` shall be well formed, shall have well-defined behavior, and shall not throw exceptions. [Note: The use of `default_delete` requires `T` to be a complete type. — end note]

Effects: If `get() == nullptr` there are no effects. Otherwise `get_deleter()(get())`.

### 23.11.1.2.3 `unique_ptr` assignment

```cpp
unique_ptr& operator=(unique_ptr&& u) noexcept;
```

Requires: If `D` is not a reference type, `D` shall satisfy the requirements of `MoveAssignable` (Table 25) and assignment of the deleter from an rvalue of type `D` shall not throw an exception. Otherwise, `D` is a reference type; `remove_reference_t<D>` shall satisfy the `CopyAssignable` requirements and assignment of the deleter from an lvalue of type `D` shall not throw an exception.

Effects: Transfers ownership from `u` to `*this` as if by calling `reset(u.release())` followed by `get_deleter() = std::forward<D>(u.get_deleter())`.

Returns: `*this`.

```cpp
template <class U, class E> unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;
```

Requires: If `E` is not a reference type, assignment of the deleter from an rvalue of type `E` shall be well-formed and shall not throw an exception. Otherwise, `E` is a reference type and assignment of the deleter from an lvalue of type `E` shall be well-formed and shall not throw an exception.

Remarks: This operator shall not participate in overload resolution unless:

1. `unique_ptr<U, E>::pointer` is implicitly convertible to `pointer`, and
U is not an array type, and
— is_assignable_v<D&, E&&> is true.

**Effects:** Transfers ownership from u to *this as if by calling reset(u.release()) followed by get_deleter() = std::forward<E>(u.get_deleter()).

**Returns:** *this.

unique_ptr& operator=(nullptr_t) noexcept;

**Effects:** As if by reset().

**Postconditions:** get() == nullptr.

**Returns:** *this.

### 23.11.1.2.4 unique_ptr observers

add_lvalue_reference_t<T> operator*() const;

**Requires:** get() != nullptr.

**Returns:** *get().

pointer operator->() const noexcept;

**Requires:** get() != nullptr.

**Returns:** get().

[Note: The use of this function typically requires that T be a complete type. — end note]

pointer get() const noexcept;

**Returns:** The stored pointer.

deleter_type& get_deleter() noexcept;

**Returns:** A reference to the stored deleter.

deleter_type const get_deleter() const noexcept;

explicit operator bool() const noexcept;

**Returns:** get() != nullptr.

### 23.11.1.2.5 unique_ptr modifiers

pointer release() noexcept;

**Postconditions:** get() == nullptr.

**Returns:** The value get() had at the start of the call to release.

void reset(pointer p = pointer()) noexcept;

**Requires:** The expression get_deleter()(get()) shall be well formed, shall have well-defined behavior, and shall not throw exceptions.

**Effects:** Assigns p to the stored pointer, and then if and only if the old value of the stored pointer, old_p, was not equal to nullptr, calls get_deleter()(old_p). [Note: The order of these operations is significant because the call to get_deleter() may destroy *this. — end note]

**Postconditions:** get() == p. [Note: The postcondition does not hold if the call to get_deleter() destroys *this since this->get() is no longer a valid expression. — end note]

void swap(unique_ptr& u) noexcept;
Requires: `get_deleter()` shall be swappable (20.5.3.2) and shall not throw an exception under `swap`.

Effects: Invokes `swap` on the stored pointers and on the stored deleters of `*this` and `u`.

23.11.1.3 `unique_ptr` for array objects with a runtime length

```cpp
namespace std {
  template <class T, class D> class unique_ptr<T[], D> {
    public:
      using pointer = see below;
      using element_type = T;
      using deleter_type = D;

    // 23.11.1.3.1, constructors
      constexpr unique_ptr() noexcept;
      template <class U> explicit unique_ptr(U p) noexcept;
      template <class U> unique_ptr(U p, see below d) noexcept;
      unique_ptr(unique_ptr&& u) noexcept;
      template <class U, class E>
        unique_ptr(unique_ptr<U, E>&& u) noexcept;
      constexpr unique_ptr(nullptr_t) noexcept;

    // destructor
      ~unique_ptr();

    // assignment
      unique_ptr& operator=(unique_ptr&& u) noexcept;
      template <class U, class E>
        unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;
      unique_ptr& operator=(nullptr_t) noexcept;

    // 23.11.1.3.3, observers
      T& operator[](size_t i) const;
      pointer get() const noexcept;
      deleter_type& get_deleter() noexcept;
      const deleter_type& get_deleter() const noexcept;
      explicit operator bool() const noexcept;

    // 23.11.1.3.4, modifiers
      pointer release() noexcept;
      template <class U> void reset(U p) noexcept;
      void reset(nullptr_t = nullptr) noexcept;
      void swap(unique_ptr& u) noexcept;

    // disable copy from lvalue
      unique_ptr(const unique_ptr&) = delete;
      unique_ptr& operator=(const unique_ptr&) = delete;
  };
}
```

1 A specialization for array types is provided with a slightly altered interface.

(1.1) Conversions between different types of `unique_ptr<T[], D>` that would be disallowed for the corresponding pointer-to-array types, and conversions to or from the non-array forms of `unique_ptr`, produce an ill-formed program.

(1.2) Pointers to types derived from `T` are rejected by the constructors, and by `reset`.

§ 23.11.1.3
— The observers operator* and operator-> are not provided.

— The indexing observer operator[] is provided.

— The default deleter will call delete[].

2 Descriptions are provided below only for members that differ from the primary template.

3 The template argument T shall be a complete type.

23.11.1.3.1 unique_ptr constructors

template <class U> explicit unique_ptr(U p) noexcept;

1 This constructor behaves the same as the constructor in the primary template that takes a single parameter of type pointer except that it additionally shall not participate in overload resolution unless

(1.1) — U is the same type as pointer, or

(1.2) — pointer is the same type as element_type*, U is a pointer type V*, and V(*)[] is convertible to element_type(*)[].

template <class U> unique_ptr(U p, see below d) noexcept;
template <class U> unique_ptr(U p, see below d) noexcept;

2 These constructors behave the same as the constructors in the primary template that take a parameter of type pointer and a second parameter except that they shall not participate in overload resolution unless either

(2.1) — U is the same type as pointer,

(2.2) — U is nullptr_t, or

(2.3) — pointer is the same type as element_type*, U is a pointer type V*, and V(*)[] is convertible to element_type(*)[].

template <class U, class E>
unique_ptr(unique_ptr<U, E>&& u) noexcept;

3 This constructor behaves the same as in the primary template, except that it shall not participate in overload resolution unless all of the following conditions hold, where UP is unique_ptr<U, E>:

(3.1) — U is an array type, and

(3.2) — pointer is the same type as element_type*, and

(3.3) — UP::pointer is the same type as UP::element_type*, and

(3.4) — UP::element_type(*)[] is convertible to element_type(*)[], and

(3.5) — either D is a reference type and E is the same type as D, or D is not a reference type and E is implicitly convertible to D.

[Note: This replaces the overload-resolution specification of the primary template — end note]

23.11.1.3.2 unique_ptr assignment

template <class U, class E>
unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;

1 This operator behaves the same as in the primary template, except that it shall not participate in overload resolution unless all of the following conditions hold, where UP is unique_ptr<U, E>:

(1.1) — U is an array type, and

(1.2) — pointer is the same type as element_type*, and
UP::pointer is the same type as UP::element_type*, and

UP::element_type(*)[] is convertible to element_type(*)[], and

is_assignable_v<D&, E&&> is true.

[Note: This replaces the overload-resolution specification of the primary template — end note]

23.11.1.3.3 unique_ptr observers

T& operator[](size_t i) const;

1 Requires: i < the number of elements in the array to which the stored pointer points.
2 Returns: get()[i].

23.11.1.3.4 unique_ptr modifiers

void reset(nullptr_t p = nullptr) noexcept;

1 Requires: Equivalent to reset(pointer()).
2 template <class U> void reset(U p) noexcept;

This function behaves the same as the reset member of the primary template, except that it shall not participate in overload resolution unless either

(2.1) — U is the same type as pointer, or
(2.2) — pointer is the same type as element_type*, U is a pointer type V*, and V(*)[] is convertible to element_type(*)([]).

23.11.1.4 unique_ptr creation

template <class T, class... Args> unique_ptr<T> make_unique(Args&&... args);

1 Remarks: This function shall not participate in overload resolution unless T is not an array.
2 Returns: unique_ptr<T>(new T(std::forward<Args>(args)...)).

template <class T> unique_ptr<T> make_unique(size_t n);

1 Remarks: This function shall not participate in overload resolution unless T is an array of unknown bound.
2 Returns: unique_ptr<T>(new remove_extent_t<T>[n]());

3 template <class T, class... Args> unspecified make_unique(Args&&...) = delete;

4 Remarks: This function shall not participate in overload resolution unless T is an array of known bound.

23.11.1.5 unique_ptr specialized algorithms

template <class T, class D> void swap(unique_ptr<T, D>& x, unique_ptr<T, D>& y) noexcept;

1 Remarks: This function shall not participate in overload resolution unless is_swappable_v<D> is true.
2 Effects: Calls x.swap(y).

template <class T1, class D1, class T2, class D2>
bool operator==(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);

1 Remarks: This function shall not participate in overload resolution unless D1 and D2 are
2 convertible to D.
3 Returns: x.get() == y.get().

template <class T1, class D1, class T2, class D2>
bool operator!=(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
template <class T1, class D1, class T2, class D2>
bool operator<(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);

Requires: Let CT denote
  common_type_t<
typename unique_ptr<T1, D1>::pointer,
  typename unique_ptr<T2, D2>::pointer>
Then the specialization less<CT> shall be a function object type (23.14) that induces a strict weak ordering (28.7) on the pointer values.

template <class T1, class D1, class T2, class D2>
bool operator<=(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);

Returns: !(y < x).

template <class T1, class D1, class T2, class D2>
bool operator>(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);

Returns: y < x.

template <class T1, class D1, class T2, class D2>
bool operator>=(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);

Returns: !(x < y).

template <class T, class D>
bool operator==(const unique_ptr<T, D>& x, nullptr_t) noexcept;

template <class T, class D>
bool operator==(nullptr_t, const unique_ptr<T, D>& x) noexcept;

Returns: !x.

template <class T, class D>
bool operator!=(const unique_ptr<T, D>& x, nullptr_t) noexcept;

template <class T, class D>
bool operator!=(nullptr_t, const unique_ptr<T, D>& x) noexcept;

Returns: (bool)x.

template <class T, class D>
bool operator<(const unique_ptr<T, D>& x, nullptr_t);

template <class T, class D>
bool operator<(nullptr_t, const unique_ptr<T, D>& x);

Requires: The specialization less<unique_ptr<T, D>::pointer> shall be a function object type (23.14) that induces a strict weak ordering (28.7) on the pointer values.

Returns: The first function template returns less<unique_ptr<T, D>::pointer>()(x.get(), nullptr). The second function template returns less<unique_ptr<T, D>::pointer>()(nullptr, x.get()).
Returns: The first function template returns `nullptr < x`. The second function template returns `x < nullptr`.

```cpp
template <class T, class D>
bool operator<=(const unique_ptr<T, D>& x, nullptr_t);

template <class T, class D>
bool operator<=(nullptr_t, const unique_ptr<T, D>& x);
```

Returns: The first function template returns `!(nullptr < x)`. The second function template returns `!(x < nullptr)`.

```cpp
template <class T, class D>
bool operator>=(const unique_ptr<T, D>& x, nullptr_t);

template <class T, class D>
bool operator>=(nullptr_t, const unique_ptr<T, D>& x);
```

Returns: The first function template returns `!(x < nullptr)`. The second function template returns `!(nullptr < x)`.

### 23.11.2 Shared-ownership pointers

#### 23.11.2.1 Class `bad_weak_ptr`

```cpp
namespace std {
    class bad_weak_ptr : public exception {
        public:
            bad_weak_ptr() noexcept;
        }
    }
```

1. An exception of type `bad_weak_ptr` is thrown by the `shared_ptr` constructor taking a `weak_ptr`.

```cpp
bad_weak_ptr() noexcept;
```

Postconditions: `what()` returns an implementation-defined NTBS.

#### 23.11.2.2 Class template `shared_ptr`

The `shared_ptr` class template stores a pointer, usually obtained via `new`. `shared_ptr` implements semantics of shared ownership: the last remaining owner of the pointer is responsible for destroying the object, or otherwise releasing the resources associated with the stored pointer. A `shared_ptr` is said to be empty if it does not own a pointer.

```cpp
namespace std {
    template<class T> class shared_ptr {
        public:
            using element_type = remove_extent_t<T>;
            using weak_type = weak_ptr<T>;

            // 23.11.2.2.1. constructors
            constexpr shared_ptr() noexcept;
            template<class Y> explicit shared_ptr(Y* p);
            template<class Y, class D> shared_ptr(Y* p, D d);
            template<class Y, class D, class A> shared_ptr(Y* p, D d, A a);
            template <class D> shared_ptr(nullptr_t p, D d);
            template <class D, class A> shared_ptr(nullptr_t p, D d, A a);
            template<class Y> shared_ptr(const shared_ptr<Y>& r, element_type* p) noexcept;
            shared_ptr(const shared_ptr& r) noexcept;
            template<class Y> shared_ptr(const shared_ptr<Y>& r) noexcept;
            shared_ptr(shared_ptr& r) noexcept;
    }
```
```cpp
// 23.11.2.2, destructor
~shared_ptr();

// 23.11.2.3, assignment
shared_ptr& operator=(const shared_ptr& r) noexcept;
template<class Y> shared_ptr& operator=(const shared_ptr<Y>&& r) noexcept;
template<class Y> shared_ptr& operator=(weak_ptr<Y>& r) noexcept;
template<class Y> shared_ptr& operator=(shared_ptr<Y>& r) noexcept;
template<class Y> shared_ptr& operator=(shared_ptr<Y>&& r) noexcept;
template<class Y, class D> shared_ptr& operator=(unique_ptr<Y, D>&& r);

// 23.11.2.4, modifiers
void swap(shared_ptr& r) noexcept;
void reset() noexcept;
template<class Y> void reset(Y* p);
template<class Y, class D> void reset(Y* p, D d);
template<class Y, class D, class A> void reset(Y* p, D d, A a);

// 23.11.2.5, observers
element_type* get() const noexcept;
T& operator*() const noexcept;
T* operator->() const noexcept;
element_type& operator[](ptrdiff_t i) const;
long use_count() const noexcept;
explicit operator bool() const noexcept;
template<class U> bool owner_before(const shared_ptr<U>& b) const noexcept;
template<class U> bool owner_before(const weak_ptr<U>& b) const noexcept;

// 23.11.2.6, shared_ptr creation
template<class T, class... Args>
shared_ptr<T> make_shared(Args&&... args);
template<class T, class A, class... Args>
shared_ptr<T> allocate_shared(const A& a, Args&&... args);

// 23.11.2.7, shared_ptr comparisons
template<class T, class U>
bool operator==(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;
template<class T, class U>
bool operator!=(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;
template<class T, class U>
bool operator<(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;
template<class T, class U>
bool operator<=(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;
template<class T, class U>
bool operator>(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;
template<class T, class U>
bool operator>=(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;
```
template <class T>
  bool operator==(const shared_ptr<T>& a, nullptr_t) noexcept;
template <class T>
  bool operator==(nullptr_t, const shared_ptr<T>& b) noexcept;
template <class T>
  bool operator!=(const shared_ptr<T>& a, nullptr_t) noexcept;
template <class T>
  bool operator!=(nullptr_t, const shared_ptr<T>& b) noexcept;
template <class T>
  bool operator<(const shared_ptr<T>& a, nullptr_t) noexcept;
template <class T>
  bool operator<(nullptr_t, const shared_ptr<T>& b) noexcept;
template <class T>
  bool operator<=(const shared_ptr<T>& a, nullptr_t) noexcept;
template <class T>
  bool operator<=(nullptr_t, const shared_ptr<T>& b) noexcept;
template <class T>
  bool operator>(const shared_ptr<T>& a, nullptr_t) noexcept;
template <class T>
  bool operator>(nullptr_t, const shared_ptr<T>& b) noexcept;
template <class T>
  bool operator>=(const shared_ptr<T>& a, nullptr_t) noexcept;
template <class T>
  bool operator>=(nullptr_t, const shared_ptr<T>& b) noexcept;

// 23.11.2.2.8, shared_ptr specialized algorithms
template<class T>
  void swap(shared_ptr<T>& a, shared_ptr<T>& b) noexcept;

// 23.11.2.2.9, shared_ptr casts
template<class T, class U>
  shared_ptr<T> static_pointer_cast(const shared_ptr<U>& r) noexcept;
template<class T, class U>
  shared_ptr<T> dynamic_pointer_cast(const shared_ptr<U>& r) noexcept;
template<class T, class U>
  shared_ptr<T> const_pointer_cast(const shared_ptr<U>& r) noexcept;
template<class T, class U>
  shared_ptr<T> reinterpret_pointer_cast(const shared_ptr<U>& r) noexcept;

// 23.11.2.2.10, shared_ptr get_deleter
template<class D, class T>
  D* get_deleter(const shared_ptr<T>& p) noexcept;

// 23.11.2.2.11, shared_ptr I/O
template<class E, class T, class Y>
  basic_ostream<E, T>& operator<<(basic_ostream<E, T>& os, const shared_ptr<Y>& p);
}

Specializations of shared_ptr shall be CopyConstructible, CopyAssignable, and LessThanComparable, allowing their use in standard containers. Specializations of shared_ptr shall be contextually convertible to bool, allowing their use in boolean expressions and declarations in conditions. The template parameter T of shared_ptr may be an incomplete type.

[Example:
if (shared_ptr<X> px = dynamic_pointer_cast<X>(py)) {
    // do something with px
}

— end example

4 For purposes of determining the presence of a data race, member functions shall access and modify only the
shared_ptr and weak_ptr objects themselves and not objects they refer to. Changes in use_count() do not
reflect modifications that can introduce data races.

5 For the purposes of subclause 23.11.2, a pointer type Y* is said to be compatible with a pointer type T* when
either Y* is convertible to T* or Y is U[N] and T is cv U[].

23.11.2.2.1 shared_ptr constructors

1 In the constructor definitions below, enables shared_from_this with p, for a pointer p of type Y*, means
that if Y has an unambiguous and accessible base class that is a specialization of enable_shared_from_this
(23.11.2.5), then remove_cv_t<Y*> shall be implicitly convertible to T* and the constructor evaluates
the statement:

if (p != nullptr && p->weak_this_expired())
    p->weak_this = shared_ptr<remove_cv_t<Y>>(*this, const_cast<remove_cv_t<Y>*>(p));

The assignment to the weak_this member is not atomic and conflicts with any potentially concurrent access
to the same object (4.7).

constexpr shared_ptr() noexcept;
2 Effects: Constructs an empty shared_ptr object.
3 Postconditions: use_count() == 0 && get() == nullptr.

template<class Y> explicit shared_ptr(Y* p);
4 Requires: Y shall be a complete type. The expression delete[] p, when T is an array type, or delete
p when T is not an array type, shall have well-defined behavior, and shall not throw exceptions.
5 Effects: When T is not an array type, constructs a shared_ptr object that owns the pointer p. Otherwise,
constructs a shared_ptr that owns p and a deleter of an unspecified type that calls delete[] p. When
T is not an array type, enables shared_from_this with p. If an exception is thrown, delete p is called
when T is not an array type, delete[] p otherwise.
6 Postconditions: use_count() == 1 && get() == p.
7 Throws: bad_alloc, or an implementation-defined exception when a resource other than memory could
not be obtained.
8 Remarks: When T is an array type, this constructor shall not participate in overload resolution unless
the expression delete[] p is well-formed and either T is U[N] and Y(*)[N] is convertible to T*, or T is
U[] and Y(*)[] is convertible to T*. When T is not an array type, this constructor shall not participate
in overload resolution unless the expression delete p is well-formed and Y* is convertible to T*.

template<class Y, class D> shared_ptr(Y* p, D d);
template<class Y, class D, class A> shared_ptr(Y* p, D d, A a);
template <class D> shared_ptr(nullptr_t p, D d);
template <class D, class A> shared_ptr(nullptr_t p, D d, A a);
9 Requires: Construction of d and a deleter of type D initialized with std::move(d) shall not throw
exceptions. The expression d(p) shall have well-defined behavior and shall not throw exceptions. A
shall be an allocator (20.5.3.5).
10 Effects: Constructs a shared_ptr object that owns the object p and the deleter d. When T is not an
array type, the first and second constructors enable `shared_from_this` with `p`. The second and fourth constructors shall use a copy of `a` to allocate memory for internal use. If an exception is thrown, `d(p)` is called.

*Postconditions:* `use_count() == 1 && get() == p`.

*Throws:* `bad_alloc`, or an implementation-defined exception when a resource other than memory could not be obtained.

*Remarks:* When `T` is an array type, this constructor shall not participate in overload resolution unless `is_move_constructible_v<D>` is `true`, the expression `d(p)` is well-formed, and either `T` is `U[N]` and `Y(*)[N]` is convertible to `T*`, or `T` is `U[]` and `Y(*)[]` is convertible to `T*`. When `T` is not an array type, this constructor shall not participate in overload resolution unless `is_move_constructible_v<D>` is `true`, the expression `d(p)` is well-formed, and `Y*` is convertible to `T*`.

```cpp
template<class Y> shared_ptr(const shared_ptr<Y>& r, element_type* p) noexcept;
```

*Effects:* Constructs a `shared_ptr` instance that stores `p` and shares ownership with `r`.

*Postconditions:* `get() == p && use_count() == r.use_count()`.

*Remarks:* The second constructor shall not participate in overload resolution unless `Y*` is compatible with `T*`.

*Effects:* If `r` is empty, constructs an empty `shared_ptr` object; otherwise, constructs a `shared_ptr` object that shares ownership with `r`.

*Postconditions:* `get() == r.get() && use_count() == r.use_count()`.

```cpp
template<class Y> explicit shared_ptr(const weak_ptr<Y>& r);
```

*Effects:* Constructs a `shared_ptr` object that shares ownership with `r` and stores a copy of the pointer stored in `r`. If an exception is thrown, the constructor has no effect.

*Postconditions:* `use_count() == r.use_count()`.

*Throws:* `bad_weak_ptr` when `r.expired()`.

*Remarks:* This constructor shall not participate in overload resolution unless `Y*` is compatible with `T*`.

```cpp
template <class Y, class D> shared_ptr(unique_ptr<Y, D>&& r);
```

*Remarks:* This constructor shall not participate in overload resolution unless `Y*` is compatible with `T*` and `unique_ptr<Y, D>::pointer` is convertible to `element_type*`.

*Effects:* If `r.get() == nullptr`, equivalent to `shared_ptr()`. Otherwise, if `D` is not a reference
type, equivalent to \texttt{shared\_ptr(r.release(), r.get\_deleter())}. Otherwise, equivalent to \texttt{shared\_ptr(r.release(), ref(r.get\_deleter()))}. If an exception is thrown, the constructor has no effect.

23.11.2.2 \texttt{shared\_ptr} destructor

\texttt{~shared\_ptr();}

\begin{enumerate}
\item \textit{Effects:}
\begin{enumerate}
\item If \texttt{\*this} is empty or shares ownership with another \texttt{shared\_ptr} instance (\texttt{use\_count()} > 1), there are no side effects.
\item Otherwise, if \texttt{\*this} owns an object \texttt{p} and a deleter \texttt{d}, \texttt{d(p)} is called.
\item Otherwise, \texttt{\*this} owns a pointer \texttt{p}, and \texttt{delete p} is called.
\end{enumerate}
\end{enumerate}

[\textit{Note:} Since the destruction of \texttt{\*this} decreases the number of instances that share ownership with \texttt{\*this} by one, after \texttt{\*this} has been destroyed all \texttt{shared\_ptr} instances that shared ownership with \texttt{\*this} will report a \texttt{use\_count()} that is one less than its previous value. --- end note]

23.11.2.2.3 \texttt{shared\_ptr} assignment

\begin{verbatim}
shared\_ptr\& operator=(const shared\_ptr\& r) noexcept;
template<class Y> shared\_ptr\& operator=(const shared\_ptr\<Y\>& r) noexcept;
\end{verbatim}

\begin{enumerate}
\item \textit{Effects:} Equivalent to \texttt{shared\_ptr(r).swap(*this)}.
\item \textit{Returns:} \texttt{\*this}.
\end{enumerate}

[\textit{Note:} The use count updates caused by the temporary object construction and destruction are not observable side effects, so the implementation may meet the effects (and the implied guarantees) via different means, without creating a temporary. In particular, in the example:
\begin{verbatim}
shared\_ptr\<int\> p(new int);
shared\_ptr\<void\> q(p);
p = p;
q = p;
\end{verbatim}
both assignments may be no-ops. --- end note]

\begin{verbatim}
shared\_ptr\& operator=(shared\_ptr\&& r) noexcept;
template<class Y> shared\_ptr\& operator=(shared\_ptr\<Y\>&& r) noexcept;
\end{verbatim}

\begin{enumerate}
\item \textit{Effects:} Equivalent to \texttt{shared\_ptr(std::move(r)).swap(*this)}.
\item \textit{Returns:} \texttt{\*this}.
\end{enumerate}

\begin{verbatim}
template <class Y, class D> shared\_ptr\& operator=(unique\_ptr\<Y, D\>&& r);
\end{verbatim}

\begin{enumerate}
\item \textit{Effects:} Equivalent to \texttt{shared\_ptr(std::move(r)).swap(*this)}.
\item \textit{Returns:} \texttt{\*this}.
\end{enumerate}

23.11.2.4 \texttt{shared\_ptr} modifiers

\begin{verbatim}
void swap(shared\_ptr\& r) noexcept;
\end{verbatim}

\begin{enumerate}
\item \textit{Effects:} Exchanges the contents of \texttt{\*this} and \texttt{r}.
\end{enumerate}

\begin{verbatim}
void reset() noexcept;
\end{verbatim}

\begin{enumerate}
\item \textit{Effects:} Equivalent to \texttt{shared\_ptr().swap(*this)}.
\end{enumerate}

\begin{verbatim}
template<class Y> void reset(Y* p);
\end{verbatim}

\begin{enumerate}
\item \textit{Effects:} Equivalent to \texttt{shared\_ptr(p).swap(*this)}.
\end{enumerate}
template<class Y, class D> void reset(Y* p, D d);

**Effects:** Equivalent to `shared_ptr(p, d).swap(*this)`.

template<class Y, class D, class A> void reset(Y* p, D d, A a);

**Effects:** Equivalent to `shared_ptr(p, d, a).swap(*this)`.

### 23.11.2.2.5 `shared_ptr` observers

[element_type* get() const noexcept;](util.smartptr.shared.obs)

**Returns:** The stored pointer.

T& operator*() const noexcept;

**Requires:** `get() != 0`.

**Returns:** `*get()`.

**Remarks:** When `T` is an array type or `cv void`, it is unspecified whether this member function is declared. If it is declared, it is unspecified what its return type is, except that the declaration (although not necessarily the definition) of the function shall be well formed.

T* operator->() const noexcept;

**Requires:** `get() != 0`.

**Returns:** `get()`.

**Remarks:** When `T` is an array type, it is unspecified whether this member function is declared. If it is declared, it is unspecified what its return type is, except that the declaration (although not necessarily the definition) of the function shall be well formed.

element_type& operator[](ptrdiff_t i) const;

**Requires:** `get() != 0 && i >= 0`. If `T` is `U[N]`, `i < N`.

**Returns:** `get()[i]`.

**Remarks:** When `T` is not an array type, it is unspecified whether this member function is declared. If it is declared, it is unspecified what its return type is, except that the declaration (although not necessarily the definition) of the function shall be well formed.

Throws: Nothing.

long use_count() const noexcept;

**Returns:** The number of `shared_ptr` objects, `*this` included, that share ownership with `*this`, or 0 when `*this` is empty.

Synchronization: None.

[Note: `get() == nullptr` does not imply a specific return value of `use_count()`. — end note]

[Note: `weak_ptr<T>::lock()` can affect the return value of `use_count()`. — end note]

[Note: When multiple threads can affect the return value of `use_count()`, the result should be treated as approximate. In particular, `use_count() == 1` does not imply that accesses through a previously destroyed `shared_ptr` have in any sense completed. — end note]

explicit operator bool() const noexcept;

**Returns:** `get() != 0`.

template<class U> bool owner_before(const shared_ptr<U>& b) const noexcept;
template<class U> bool owner_before(const weak_ptr<U>& b) const noexcept;

Returns: An unspecified value such that

- x.owner_before(y) defines a strict weak ordering as defined in 28.7;
- under the equivalence relation defined by owner_before, !a.owner_before(b) && !b.owner_before(a), two shared_ptr or weak_ptr instances are equivalent if and only if they share ownership or are both empty.

23.11.2.2.6 shared_ptr creation

template<class T, class... Args>
shared_ptr<T> make_shared(Args&&... args);

1 Requires: The expression ::new (pv) T(std::forward<Args>(args)...), where pv has type void* and points to storage suitable to hold an object of type T, shall be well formed. A shall be an allocator (20.5.3.5). The copy constructor and destructor of A shall not throw exceptions.

2 Effects: Allocates memory suitable for an object of type T and constructs an object in that memory via the placement new-expression ::new (pv) T(std::forward<Args>(args)...). The template allocate_shared uses a copy of a to allocate memory. If an exception is thrown, the functions have no effect.

Returns: A shared_ptr instance that stores and owns the address of the newly constructed object of type T.

Postconditions: get() != 0 && use_count() == 1.

3 Throws: bad_alloc, or an exception thrown from A::allocate or from the constructor of T.

5 Remarks: The shared_ptr constructor called by this function enables shared_from_this with the address of the newly constructed object of type T. Implementations should perform no more than one memory allocation. [Note: This provides efficiency equivalent to an intrusive smart pointer. — end note]

[Note: These functions will typically allocate more memory than sizeof(T) to allow for internal bookkeeping structures such as the reference counts. — end note]

23.11.2.2.7 shared_ptr comparison

template<class T, class U>
bool operator==(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;

1 Returns: a.get() == b.get().

template<class T, class U>
bool operator<(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;

2 Returns: less<>()(a.get(), b.get()).

3 [Note: Defining a comparison function allows shared_ptr objects to be used as keys in associative containers. — end note]

template <class T>
bool operator==(const shared_ptr<T>& a, nullptr_t) noexcept;

template <class T>
bool operator!=(const nullptr_t, const shared_ptr<T>& a) noexcept;

4 Returns: !a.

§ 23.11.2.2.7
template <class T>
bool operator!=(const shared_ptr<T>& a, nullptr_t) noexcept;

template <class T>
bool operator!=(nullptr_t, const shared_ptr<T>& a) noexcept;

Returns: (bool)a.

5

6

7

template <class T>
bool operator<(const shared_ptr<T>& a, nullptr_t) noexcept;

template <class T>
bool operator<(nullptr_t, const shared_ptr<T>& a) noexcept;

Returns: The first function template returns less<shared_ptr<T>::element_type*>(a.get(), nullptr). The second function template returns less<shared_ptr<T>::element_type*>(nullptr, a.get()).

8

9

Returns: The first function template returns nullptr < a. The second function template returns a < nullptr.

template <class T>
bool operator>=(const shared_ptr<T>& a, nullptr_t) noexcept;

template <class T>
bool operator>=(nullptr_t, const shared_ptr<T>& a) noexcept;

Returns: The first function template returns !(nullptr < a). The second function template returns !(a < nullptr).

23.11.2.2.8 shared_ptr specialized algorithms

template<class T>
void swap(shared_ptr<T>& a, shared_ptr<T>& b) noexcept;

Effects: Equivalent to a.swap(b).

23.11.2.2.9 shared_ptr casts

template<class T, class U>
shared_ptr<T> static_pointer_cast(const shared_ptr<U>& r) noexcept;

Requires: The expression static_cast<T*>(U*)0 shall be well formed.

Returns:

shared_ptr<T>(r, static_cast<typename shared_ptr<T>::element_type*>(r.get()))

[Note: The seemingly equivalent expression shared_ptr<T>(static_cast<T*>(r.get())) will eventually result in undefined behavior, attempting to delete the same object twice. — end note]
shared_ptr<T> dynamic_pointer_cast(const shared_ptr<U>& r) noexcept;

Requires: The expression dynamic_cast<T*>(U*)0 shall be well formed and shall have well defined behavior.

Returns:
(5.1) — When dynamic_cast<typename shared_ptr<T>::element_type*>(r.get()) returns a nonzero value p, shared_ptr<T>(r, p).
(5.2) — Otherwise, shared_ptr<T>().

[Note: The seemingly equivalent expression shared_ptr<T>(dynamic_cast<T*>(r.get())) will eventually result in undefined behavior, attempting to delete the same object twice. — end note]

template<class T, class U>
shared_ptr<T> const_pointer_cast(const shared_ptr<U>& r) noexcept;

Requires: The expression const_cast<T*>(U*)0 shall be well formed.

Returns:
shared_ptr<T>(r, const_cast<typename shared_ptr<T>::element_type*>(r.get()))

[Note: The seemingly equivalent expression shared_ptr<T>(const_cast<T*>(r.get())) will eventually result in unde ned behavior, attempting to delete the same object twice. — end note]

template<class T, class U>
shared_ptr<T> reinterpret_pointer_cast(const shared_ptr<U>& r) noexcept;

Requires: The expression reinterpret_cast<T*>(U*)0 shall be well formed.

Returns:
shared_ptr<T>(r, reinterpret_cast<typename shared_ptr<T>::element_type*>(r.get()))

[Note: The seemingly equivalent expression shared_ptr<T>(reinterpret_cast<T*>(r.get())) will eventually result in undefined behavior, attempting to delete the same object twice. — end note]

23.11.2.10 get_deleter

[util.smartptr.getdeleter]

template<class D, class T>
D* get_deleter(const shared_ptr<T>& p) noexcept;

Returns: If p owns a deleter d of type cv-unqualified D, returns addressof(d); otherwise returns nullptr. The returned pointer remains valid as long as there exists a shared_ptr instance that owns d. [Note: It is unspecified whether the pointer remains valid longer than that. This can happen if the implementation doesn’t destroy the deleter until all weak_ptr instances that share ownership with p have been destroyed. — end note]

23.11.2.11 shared_ptr I/O

[util.smartptr.shared.io]

template<class E, class T, class Y>
basic_ostream<E, T>& operator<<(basic_ostream<E, T>& os, const shared_ptr<Y>& p);

Effects: As if by: os << p.get();

Returns: os.

23.11.2.3 Class template weak_ptr

[util.smartptr.weak]

The weak_ptr class template stores a weak reference to an object that is already managed by a shared_ptr. To access the object, a weak_ptr can be converted to a shared_ptr using the member function lock.

namespace std {

§ 23.11.2.3
template<class T> class weak_ptr {
public:
  using element_type = T;

  // 23.11.2.3.1, constructors
  constexpr weak_ptr() noexcept;
  template<class Y> weak_ptr(const shared_ptr<Y>& r) noexcept;
  weak_ptr(const weak_ptr& r) noexcept;
  template<class Y> weak_ptr(const weak_ptr<Y>& r) noexcept;
  weak_ptr(weak_ptr&& r) noexcept;
  template<class Y> weak_ptr(weak_ptr<Y>&& r) noexcept;

  // 23.11.2.3.2, destructor
  ~weak_ptr();

  // 23.11.2.3.3, assignment
  weak_ptr& operator=(const weak_ptr& r) noexcept;
  template<class Y> weak_ptr& operator=(const weak_ptr<Y>& r) noexcept;
  template<class Y> weak_ptr& operator=(const shared_ptr<Y>& r) noexcept;
  weak_ptr& operator=(weak_ptr&& r) noexcept;
  template<class Y> weak_ptr& operator=(weak_ptr<Y>&& r) noexcept;

  // 23.11.2.3.4, modifiers
  void swap(weak_ptr& r) noexcept;
  void reset() noexcept;

  // 23.11.2.3.5, observers
  long use_count() const noexcept;
  bool expired() const noexcept;
  shared_ptr<T> lock() const noexcept;
  template<class U> bool owner_before(const shared_ptr<U>& b) const;
  template<class U> bool owner_before(const weak_ptr<U>& b) const;
};

template<class T> weak_ptr(shared_ptr<T>) -> weak_ptr<T>;

// 23.11.2.3.6, specialized algorithms
template<class T> void swap(weak_ptr<T>& a, weak_ptr<T>& b) noexcept;
}

2 Specializations of weak_ptr shall be CopyConstructible and CopyAssignable, allowing their use in standard containers. The template parameter T of weak_ptr may be an incomplete type.

23.11.2.3.1 weak_ptr constructors

constexpr weak_ptr() noexcept;

1 Effects: Constructs an empty weak_ptr object.

2 Postconditions: use_count() == 0.

weak_ptr(const weak_ptr& r) noexcept;
template<class Y> weak_ptr(const weak_ptr<Y>& r) noexcept;

3 Remarks: The second and third constructors shall not participate in overload resolution unless Y* is compatible with T*.

§ 23.11.2.3.1
**Effects:** If \( r \) is empty, constructs an empty `weak_ptr` object; otherwise, constructs a `weak_ptr` object that shares ownership with \( r \) and stores a copy of the pointer stored in \( r \).

**Postconditions:** \( \text{use\_count()} == r.\text{use\_count()} \).

```cpp
weak_ptr(weak_ptr&& r) noexcept;
template<class Y> weak_ptr(weak_ptr<Y>&& r) noexcept;
```

**Remarks:** The second constructor shall not participate in overload resolution unless \( Y* \) is compatible with \( T* \).

**Effects:** Move constructs a `weak_ptr` instance from \( r \).

**Postconditions:** \( *this \) shall contain the old value of \( r \). \( r \) shall be empty. \( r.\text{use\_count()} == 0 \).

### 23.11.2.3.2 weak_ptr destructor

[util.smartptr.weak.dest]

```cpp
~weak_ptr();
```

**Effects:** Destroys this `weak_ptr` object but has no effect on the object its stored pointer points to.

### 23.11.2.3.3 weak_ptr assignment

[util.smartptr.weak.assign]

```cpp
weak_ptr& operator=(const weak_ptr& r) noexcept;
template<class Y> weak_ptr& operator=(const weak_ptr<Y>& r) noexcept;
```

**Effects:** Equivalent to `weak_ptr(r).swap(*this)`.

**Remarks:** The implementation may meet the effects (and the implied guarantees) via different means, without creating a temporary.

**Returns:** \( *this \).

```cpp
weak_ptr& operator=(weak_ptr&& r) noexcept;
template<class Y> weak_ptr& operator=(weak_ptr<Y>&& r) noexcept;
```

**Effects:** Equivalent to `weak_ptr(std::move(r)).swap(*this)`.

**Returns:** \( *this \).

### 23.11.2.3.4 weak_ptr modifiers

[util.smartptr.weak.mod]

```cpp
void swap(weak_ptr& r) noexcept;
```

**Effects:** Exchanges the contents of \( *this \) and \( r \).

```cpp
void reset() noexcept;
```

**Effects:** Equivalent to `weak_ptr().swap(*this)`.

### 23.11.2.3.5 weak_ptr observers

[util.smartptr.weak.obs]

```cpp
long use_count() const noexcept;
```

**Returns:** \( 0 \) if \( *this \) is empty; otherwise, the number of `shared_ptr` instances that share ownership with \( *this \).

```cpp
bool expired() const noexcept;
```

**Returns:** \( \text{use\_count()} == 0 \).

```cpp
shared_ptr<T> lock() const noexcept;
```

**Returns:** \( \text{expired()} ? \text{shared\_ptr<T>() : shared\_ptr<T>(*this)} \), executed atomically.
template<class U> bool owner_before(const shared_ptr<U>& b) const;
template<class U> bool owner_before(const weak_ptr<U>& b) const;

Returns: An unspecified value such that

- x.owner_before(y) defines a strict weak ordering as defined in 28.7;
- under the equivalence relation defined by owner_before, !a.owner_before(b) && !b.owner_before(a), two shared_ptr or weak_ptr instances are equivalent if and only if they share ownership or are both empty.

23.11.2.6 weak_ptr specialized algorithms

template<class T>
void swap(weak_ptr<T>& a, weak_ptr<T>& b) noexcept;

Effects: Equivalent to a.swap(b).

23.11.2.4 Class template owner_less

The class template owner_less allows ownership-based mixed comparisons of shared and weak pointers.

namespace std {
  template<class T = void> struct owner_less;

  template<class T> struct owner_less<shared_ptr<T>> {
    bool operator()(const shared_ptr<T>&, const shared_ptr<T>&) const noexcept;
    bool operator()(const shared_ptr<T>&, const weak_ptr<T>&) const noexcept;
    bool operator()(const weak_ptr<T>&, const shared_ptr<T>&) const noexcept;
  };

  template<class T> struct owner_less<weak_ptr<T>> {
    bool operator()(const weak_ptr<T>&, const weak_ptr<T>&) const noexcept;
    bool operator()(const shared_ptr<T>&, const weak_ptr<T>&) const noexcept;
    bool operator()(const weak_ptr<T>&, const shared_ptr<T>&) const noexcept;
  };

  template<> struct owner_less<void> {
    template<class T, class U>
      bool operator()(const shared_ptr<T>&, const shared_ptr<U>&) const noexcept;
    template<class T, class U>
      bool operator()(const shared_ptr<T>&, const weak_ptr<U>&) const noexcept;
    template<class T, class U>
      bool operator()(const weak_ptr<T>&, const shared_ptr<U>&) const noexcept;
    template<class T, class U>
      bool operator()(const weak_ptr<T>&, const weak_ptr<U>&) const noexcept;
    using is_transparent = unspecified;
  };
}

operator()(x, y) shall return x.owner_before(y). [Note: Note that
- operator() defines a strict weak ordering as defined in 28.7;
- under the equivalence relation defined by operator(), !operator()(a, b) && !operator()(b, a), two shared_ptr or weak_ptr instances are equivalent if and only if they share ownership or are both empty.
- end note]
23.11.2.5 Class template enable_shared_from_this

A class \( T \) can inherit from `enable_shared_from_this<T>` to inherit the `shared_from_this` member functions that obtain a `shared_ptr` instance pointing to `*this`.

[Example:

```cpp
struct X: public enable_shared_from_this<X> { }

int main() {
  shared_ptr<X> p(new X);
  shared_ptr<X> q = p->shared_from_this();
  assert(p == q);
  assert(!p.owner_before(q) && !q.owner_before(p)); // p and q share ownership
}
```
— end example]

namespace std {
  template<class T> class enable_shared_from_this {
  protected:
    constexpr enable_shared_from_this() noexcept;
    enable_shared_from_this(const enable_shared_from_this<T>&) noexcept;
    enable_shared_from_this& operator=(const enable_shared_from_this<T>&) noexcept;
    ~enable_shared_from_this();
  public:
    shared_ptr<T> shared_from_this();
    shared_ptr<T const> shared_from_this() const;
    weak_ptr<T> weak_from_this() noexcept;
    weak_ptr<T const> weak_from_this() const noexcept;
  private:
    mutable weak_ptr<T> weak_this; // exposition only
  }
}

The template parameter \( T \) of `enable_shared_from_this` may be an incomplete type.

```cpp
constexpr enable_shared_from_this() noexcept;
enable_shared_from_this(const enable_shared_from_this<T>&) noexcept;
```

**Effects:** Value-initializes `weak_this`.

```cpp
enable_shared_from_this<T>& operator=(const enable_shared_from_this<T>&) noexcept;
```

**Returns:** `*this`.

[Note: `weak_this` is not changed. — end note]

```cpp
shared_ptr<T> shared_from_this();
shared_ptr<T const> shared_from_this() const;
```

**Returns:** `shared_ptr<T>(weak_this)`.

```cpp
weak_ptr<T> weak_from_this() noexcept;
weak_ptr<T const> weak_from_this() const noexcept;
```

**Returns:** `weak_this`.

23.11.2.6 shared_ptr atomic access

Concurrent access to a `shared_ptr` object from multiple threads does not introduce a data race if the access is done exclusively via the functions in this section and the instance is passed as their first argument.
The meaning of the arguments of type `memory_order` is explained in 32.4.

```
template<class T>
bool atomic_is_lock_free(const shared_ptr<T>* p);

Requires: p shall not be null.
Returns: true if atomic access to *p is lock-free, false otherwise.
Throws: Nothing.
```

```
template<class T>
shared_ptr<T> atomic_load(const shared_ptr<T>* p);

Requires: p shall not be null.
Returns: atomic_load_explicit(p, memory_order_seq_cst).
Throws: Nothing.
```

```
template<class T>
shared_ptr<T> atomic_load_explicit(const shared_ptr<T>* p, memory_order mo);

Requires: p shall not be null.
Requires: mo shall not be memory_order_release or memory_order_acq_rel.
Returns: *p.
Throws: Nothing.
```

```
template<class T>
void atomic_store(shared_ptr<T>* p, shared_ptr<T> r);

Requires: p shall not be null.
Effects: As if by atomic_store_explicit(p, r, memory_order_seq_cst).
Throws: Nothing.
```

```
template<class T>
void atomic_store_explicit(shared_ptr<T>* p, shared_ptr<T> r, memory_order mo);

Requires: p shall not be null.
Requires: mo shall not be memory_order_acquire or memory_order_acq_rel.
Effects: As if by p->swap(r).
Throws: Nothing.
```

```
template<class T>
shared_ptr<T> atomic_exchange(shared_ptr<T>* p, shared_ptr<T> r);

Requires: p shall not be null.
Returns: atomic_exchange_explicit(p, r, memory_order_seq_cst).
Throws: Nothing.
```

```
template<class T>
shared_ptr<T> atomic_exchange_explicit(shared_ptr<T>* p, shared_ptr<T> r, memory_order mo);

Requires: p shall not be null.
Effects: As if by p->swap(r).
Returns: The previous value of *p.
```
template<class T>
bool atomic_compare_exchange_weak(shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w);

Requires: p shall not be null and v shall not be null.
Returns:
atomic_compare_exchange_weak_explicit(p, v, w, memory_order_seq_cst, memory_order_seq_cst)
Throws: Nothing.

template<class T>
bool atomic_compare_exchange_strong(shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w);

Returns:
atomic_compare_exchange_strong_explicit(p, v, w, memory_order_seq_cst, memory_order_seq_cst)

template<class T>
bool atomic_compare_exchange_weak_explicit(
    shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w,
    memory_order success, memory_order failure);

Requires: p shall not be null and v shall not be null. The failure argument shall not be memory_order_release nor memory_order_acq_rel.
Effects: If *p is equivalent to *v, assigns w to *p and has synchronization semantics corresponding to the value of success, otherwise assigns *p to *v and has synchronization semantics corresponding to the value of failure.
Returns: true if *p was equivalent to *v, false otherwise.
Throws: Nothing.
Remarks: Two shared_ptr objects are equivalent if they store the same pointer value and share ownership. The weak form may fail spuriously. See 32.6.1.

23.11.2.7 Smart pointer hash support [util.smartptr.hash]

template <class T, class D> struct hash<unique_ptr<T, D>>;

Letting UP be unique_ptr<T,D>, the specialization hash<UP> is enabled (23.14.15) if and only if hash<typename UP::pointer> is enabled. When enabled, for an object p of type UP, hash<UP>()(p) shall evaluate to the same value as hash<typename UP::pointer>()(p.get()). The member functions are not guaranteed to be noexcept.

template <class T> struct hash<shared_ptr<T>>;

For an object p of type shared_ptr<T>, hash<shared_ptr<T>>()(p) shall evaluate to the same value as hash<typename shared_ptr<T>::element_type*>()(p.get()).

23.12 Memory resources [mem.res]
23.12.1 Header <memory_resource> synopsis [mem.res.syn]

namespace std::pmr {
    // 23.12.2, class memory_resource
    class memory_resource;
bool operator==(const memory_resource& a, const memory_resource& b) noexcept;
bool operator!=(const memory_resource& a, const memory_resource& b) noexcept;

// 23.12.3, class template polymorphic_allocator
template <class Tp> class polymorphic_allocator;

template <class T1, class T2>
bool operator==(const polymorphic_allocator<T1>& a,
               const polymorphic_allocator<T2>& b) noexcept;

template <class T1, class T2>
bool operator!=(const polymorphic_allocator<T1>& a,
               const polymorphic_allocator<T2>& b) noexcept;

// 23.12.4, global memory resources
memory_resource* new_delete_resource() noexcept;
memory_resource* null_memory_resource() noexcept;
memory_resource* set_default_resource(memory_resource* r) noexcept;
memory_resource* get_default_resource() noexcept;

// 23.12.5, pool resource classes
struct pool_options;
class synchronized_pool_resource;
class unsynchronized_pool_resource;
class monotonic_buffer_resource;
}

23.12.2 Class memory_resource [mem.res.class]

The memory_resource class is an abstract interface to an unbounded set of classes encapsulating memory resources.

class memory_resource {
    static constexpr size_t max_align = alignof(max_align_t); // exposition only

public:
    virtual ~memory_resource();

    void* allocate(size_t bytes, size_t alignment = max_align);
    void deallocate(void* p, size_t bytes, size_t alignment = max_align);

    bool is_equal(const memory_resource& other) const noexcept;

private:
    virtual void* do_allocate(size_t bytes, size_t alignment) = 0;
    virtual void do_deallocate(void* p, size_t bytes, size_t alignment) = 0;

    virtual bool do_is_equal(const memory_resource& other) const noexcept = 0;
};

23.12.2.1 memory_resource public member functions [mem.res.public]

~memory_resource();

Effects: Destroys this memory_resource.

void* allocate(size_t bytes, size_t alignment = max_align);
2 Effects: Equivalent to: return do_allocate(bytes, alignment);

deallocate(void* p, size_t bytes, size_t alignment = max_align);
3 Effects: Equivalent to: do_deallocate(p, bytes, alignment);

bool is_equal(const memory_resource& other) const noexcept;
4 Effects: Equivalent to: return do_is_equal(other);

23.12.2.2 memory_resource private virtual member functions

virtual void do_allocate(size_t bytes, size_t alignment) = 0;
1 Requires: alignment shall be a power of two.
2 Returns: A derived class shall implement this function to return a pointer to allocated storage (6.7.4.2) with a size of at least bytes. The returned storage is aligned to the specified alignment, if such alignment is supported (6.11); otherwise it is aligned to max_align.
3 Throws: A derived class implementation shall throw an appropriate exception if it is unable to allocate memory with the requested size and alignment.

virtual void do_deallocate(void* p, size_t bytes, size_t alignment) = 0;
4 Requires: p shall have been returned from a prior call to allocate(bytes, alignment) on a memory resource equal to *this, and the storage at p shall not yet have been deallocated.
5 Effects: A derived class shall implement this function to dispose of allocated storage.
6 Throws: Nothing.

virtual bool do_is_equal(const memory_resource& other) const noexcept = 0;
7 Returns: A derived class shall implement this function to return true if memory allocated from this can be deallocated from other and vice-versa, otherwise false. [Note: The most-derived type of other might not match the type of this. For a derived class D, a typical implementation of this function will immediately return false if dynamic_cast<const D*>(&other) == nullptr. —end note]

23.12.2.3 memory_resource equality

bool operator==(const memory_resource& a, const memory_resource& b) noexcept;
1 Returns: &a == &b || a.is_equal(b).

bool operator!=(const memory_resource& a, const memory_resource& b) noexcept;
2 Returns: !(a == b).

23.12.3 Class template polymorphic_allocator

A specialization of class template pmr::polymorphic_allocator conforms to the Allocator requirements (20.5.3.5). Constructed with different memory resources, different instances of the same specialization of pmr::polymorphic_allocator can exhibit entirely different allocation behavior. This runtime polymorphism allows objects that use polymorphic_allocator to behave as if they used different allocator types at run time even though they use the same static allocator type.

template <class Tp>
class polymorphic_allocator {

    memory_resource* memory_rsrc; // exposition only

d_lb: using value_type = Tp;

§ 23.12.3
// 23.12.3.1, constructors
polymorphic_allocator() noexcept;
polymorphic_allocator(memory_resource* r);

polymorphic_allocator(const polymorphic_allocator& other) = default;

template <class U>
polymorphic_allocator(const polymorphic_allocator<U>& other) noexcept;

polymorphic_allocator&
operator=(const polymorphic_allocator& rhs) = delete;

// 23.12.3.2, member functions
Tp* allocate(size_t n);
void deallocate(Tp* p, size_t n);

template <class T, class... Args>
void construct(T* p, Args&&... args);

template <class T1, class T2, class... Args1, class... Args2>
void construct(pair<T1,T2>* p, piecewise_construct_t,
tuple<Args1...> x, tuple<Args2...> y);

template <class T1, class T2>
void construct(pair<T1,T2>* p);

template <class T1, class T2, class U, class V>
void construct(pair<T1,T2>* p, U&& x, V&& y);

template <class T1, class T2, class U, const pair<U, V>& pr>
void construct(pair<T1,T2>* p, const pair<U, V>& pr);

template <class T1, class T2, class U, V&& pr>
void construct(pair<T1,T2>* p, pair<U, V>&& pr);

template <class T>
void destroy(T* p);

polymorphic_allocator select_on_container_copy_construction() const;

memory_resource* resource() const;
};

23.12.3.1 polymorphic_allocator constructors

polymorphic_allocator() noexcept;

Effects: Sets memory_rs to get_default_resource().

polymorphic_allocator(memory_resource* r);

Requires: r is non-null.

Effects: Sets memory_rs to r.

Throws: Nothing.

[ Note: This constructor provides an implicit conversion from memory_resource*. — end note ]

template <class U>
polymorphic_allocator(const polymorphic_allocator<U>& other) noexcept;
Effects: Sets `memory_rsrc` to `other.resource()`.

### 23.12.3.2 polymorphic_allocator member functions

```cpp
Tp* allocate(size_t n);
```

**Returns:** Equivalent to:

```cpp
return static_cast<Tp*>(memory_rsrc->allocate(n * sizeof(Tp), alignof(Tp)));
```

```cpp
void deallocate(Tp* p, size_t n);
```

**Requires:** `p` was allocated from a memory resource `x`, equal to `*memory_rsrc`, using `x.allocate(n * sizeof(Tp), alignof(Tp))`.

**Effects:** Equivalent to `memory_rsrc->deallocate(p, n * sizeof(Tp), alignof(Tp))`.

**Throws:** Nothing.

```cpp
template <class T, class... Args>
void construct(T* p, Args&&... args);
```

**Requires:** Uses-allocator construction of `T` with allocator `resource()` (see 23.10.7.2) and constructor arguments `std::forward<Args>(args)...` is well-formed.  

[Note: Uses-allocator construction is always well formed for types that do not use allocators. — end note]

**Effects:** Construct a `T` object in the storage whose address is represented by `p` by uses-allocator construction with allocator `resource()` and constructor arguments `std::forward<Args>(args)...`.

**Throws:** Nothing unless the constructor for `T` throws.

```cpp
template <class T1, class T2, class... Args1, class... Args2>
void construct(pair<T1,T2>* p, piecewise_construct_t,
tuple<Args1...> x, tuple<Args2...> y);
```

[Note: This method and the `construct` methods that follow are overloads for piecewise construction of pairs (23.4.2). — end note]

**Effects:** Let `xprime` be a `tuple` constructed from `x` according to the appropriate rule from the following list.  

[Note: The following description can be summarized as constructing a `pair<T1, T2>` object in the storage whose address is represented by `p`, as if by separate uses-allocator construction with allocator `resource()` (23.10.7.2) of `p->first` using the elements of `x` and `p->second` using the elements of `y`. — end note]

1. If `uses_allocator_v<T1,memory_resource*>>` is false and `is_constructible_v<T1,Args1...>` is true, then `xprime` is `x`.
2. Otherwise, if `uses_allocator_v<T1,memory_resource*>` is true and `is_constructible_v<T1,allocator_arg_t,memory_resource*,Args1...>` is true, then `xprime` is `tuple_cat(make_tuple(allocator_arg, resource()), std::move(x))`.
3. Otherwise, if `uses_allocator_v<T1,memory_resource*>>` is true and `is_constructible_v<T1,Args1...,memory_resource*>>` is true, then `xprime` is `tuple_cat(std::move(x), make_tuple(resource()))`.
4. Otherwise the program is ill formed.

Let `yprime` be a tuple constructed from `y` according to the appropriate rule from the following list:

1. If `uses_allocator_v<T2,memory_resource*>>` is false and `is_constructible_v<T2,Args2...>` is true, then `yprime` is `y`.

§ 23.12.3.2
Otherwise, if \( \text{uses_allocator_v<T2, memory_resource*} \) is true
and \( \text{is_constructible_v<T2, allocator_arg_t, memory_resource*, Args2...> is true} \),
then \( y' \) is \( \text{tuple_cat(make_tuple(allocator_arg, resource()), std::move(y))} \).

Otherwise, if \( \text{uses_allocator_v<T2, memory_resource*} \) is true
and \( \text{is_constructible_v<T2, Args2..., memory_resource*> is true} \),
then \( y' \) is \( \text{tuple_cat(std::move(y), make_tuple(resource()))} \).

Otherwise the program is ill formed.

Then, using \( \text{piecewise_construct} \), \( x' \), and \( y' \) as the constructor arguments, this function
constructs a \( \text{pair<T1, T2>} \) object in the storage whose address is represented by \( p \).

\[ \]
\text{template <class T1, class T2>}
\text{void construct(pair<T1,T2>* p);}
\text{Effects: Equivalent to:}
\text{construct(p, piecewise_construct, tuple<>(), tuple<>());}
\text{template <class T1, class T2, class U, class V>}
\text{void construct(pair<T1,T2>* p, U&& x, V&& y);}

\text{construct(p, piecewise_construct,}
\text{ forward_as_tuple(std::forward<U>(pr.first)),}
\text{ forward_as_tuple(std::forward<V>(pr.second));}
\text{template <class T>}
\text{void destroy(T* p);}  
\text{Effects: As if by p->~T().}

polymorphic_allocator \text{select_on_container_copy_construction() const;}
\text{Returns: polymorphic_allocator().}
\text{[Note: The memory resource is not propagated. — end note]}

memory_resource* \text{resource() const;}
\text{Returns: memory_rsrs.}

\text{23.12.3.3 polymorphic_allocator equality [mem.polyallocator.eq]}
\text{template <class T1, class T2>}
\text{§ 23.12.3.3}
bool operator==(const polymorphic_allocator<T1>& a,
    const polymorphic_allocator<T2>& b) noexcept;

Returns: \(*a\).resource() == \(*b\).resource().

template <class T1, class T2>
bool operator!=(const polymorphic_allocator<T1>& a,
    const polymorphic_allocator<T2>& b) noexcept;

Returns: !\((a == b)\).

### 23.12.4 Access to program-wide memory_resource objects

memory_resource* new_delete_resource() noexcept;

Returns: A pointer to a static-duration object of a type derived from memory_resource that can serve as a resource for allocating memory using ::operator new and ::operator delete. The same value is returned every time this function is called. For a return value \(p\) and a memory resource \(r\), \(p->is_equal(r)\) returns \&r == \(p\).

memory_resource* null_memory_resource() noexcept;

Returns: A pointer to a static-duration object of a type derived from memory_resource for which allocate() always throws bad_alloc and for which deallocate() has no effect. The same value is returned every time this function is called. For a return value \(p\) and a memory resource \(r\), \(p->is_equal(r)\) returns \&r == \(p\).

The default memory resource pointer is a pointer to a memory resource that is used by certain facilities when an explicit memory resource is not supplied through the interface. Its initial value is the return value of new_delete_resource().

memory_resource* set_default_resource(memory_resource* r) noexcept;

Effects: If \(r\) is non-null, sets the value of the default memory resource pointer to \(r\), otherwise sets the default memory resource pointer to new_delete_resource().

Postconditions: get_default_resource() == \(r\).

Returns: The previous value of the default memory resource pointer.

Remarks: Calling the set_default_resource and get_default_resource functions shall not incur a data race. A call to the set_default_resource function shall synchronize with subsequent calls to the set_default_resource and get_default_resource functions.

memory_resource* get_default_resource() noexcept;

Returns: The current value of the default memory resource pointer.

### 23.12.5 Pool resource classes

#### 23.12.5.1 Classes synchronized_pool_resource and unsynchronized_pool_resource

The synchronized_pool_resource and unsynchronized_pool_resource classes (collectively called pool resource classes) are general-purpose memory resources having the following qualities:

1. Each resource frees its allocated memory on destruction, even if deallocate has not been called for some of the allocated blocks.

2. A pool resource consists of a collection of pools, serving requests for different block sizes. Each individual pool manages a collection of chunks that are in turn divided into blocks of uniform size, returned via
calls to \texttt{do\_allocate}. Each call to \texttt{do\_allocate(size, alignment)} is dispatched to the pool serving the smallest blocks accommodating at least \texttt{size} bytes.

— When a particular pool is exhausted, allocating a block from that pool results in the allocation of an additional chunk of memory from the \textit{upstream allocator} (supplied at construction), thus replenishing the pool. With each successive replenishment, the chunk size obtained increases geometrically. \[\text{Note: By allocating memory in chunks, the pooling strategy increases the chance that consecutive allocations will be close together in memory. \textit{— end note}}\]

— Allocation requests that exceed the largest block size of any pool are fulfilled directly from the upstream allocator.

— A \texttt{pool\_options} struct may be passed to the pool resource constructors to tune the largest block size and the maximum chunk size.

A \texttt{synchronized\_pool\_resource} may be accessed from multiple threads without external synchronization and may have thread-specific pools to reduce synchronization costs. An \texttt{unsynchronized\_pool\_resource} class may not be accessed from multiple threads simultaneously and thus avoids the cost of synchronization entirely in single-threaded applications.

```cpp
struct pool_options {
    size_t max_blocks_per_chunk = 0;
    size_t largest_required_pool_block = 0;
};

class synchronized_pool_resource : public memory_resource {
public:
    synchronized_pool_resource(const pool_options& opts,
                                memory_resource* upstream);

    synchronized_pool_resource() :
        synchronized_pool_resource(pool_options(), get_default_resource()) {} 
explicit synchronized_pool_resource(memory_resource* upstream) :
        synchronized_pool_resource(pool_options(), upstream) {} 
explicit synchronized_pool_resource(const pool_options& opts) :
        synchronized_pool_resource(opts, get_default_resource()) {} 

    synchronized_pool_resource(const synchronized_pool_resource&) = delete;
    virtual ~synchronized_pool_resource();

    synchronized_pool_resource&
        operator=(const synchronized_pool_resource&) = delete;

    void release();
    memory_resource* upstream_resource() const;
    pool_options options() const;

protected:
    void *do_allocate(size_t bytes, size_t alignment) override;
    void do_deallocate(void *p, size_t bytes, size_t alignment) override;

    bool do_is_equal(const memory_resource& other) const noexcept override;
};

class unsynchronized_pool_resource : public memory_resource {
public:
    unsynchronized_pool_resource(const pool_options& opts,
                                memory_resource* upstream)
```
memory_resource* upstream);

unsynchronized_pool_resource()
    : unsynchronized_pool_resource(pool_options(), get_default_resource()) {}
explicit unsynchronized_pool_resource(memory_resource* upstream)
    : unsynchronized_pool_resource(pool_options(), upstream) {}
explicit unsynchronized_pool_resource(const pool_options& opts)
    : unsynchronized_pool_resource(opts, get_default_resource()) {}

unsynchronized_pool_resource(const unsynchronized_pool_resource&) = delete;
virtual ~unsynchronized_pool_resource();

unsynchronized_pool_resource&
    operator=(const unsynchronized_pool_resource&) = delete;

void release();
memory_resource *upstream_resource() const;
pool_options options() const;

protected:
    void* do_allocate(size_t bytes, size_t alignment) override;
    void do_deallocate(void* p, size_t bytes, size_t alignment) override;
    
    bool do_is_equal(const memory_resource& other) const noexcept override;
};

23.12.5.2 pool_options data members

The members of pool_options comprise a set of constructor options for pool resources. The effect of each option on the pool resource behavior is described below:

size_t max_blocks_per_chunk;

The maximum number of blocks that will be allocated at once from the upstream memory resource (23.12.6) to replenish a pool. If the value of max_blocks_per_chunk is zero or is greater than an implementation-defined limit, that limit is used instead. The implementation may choose to use a smaller value than is specified in this field and may use different values for different pools.

size_t largest_required_pool_block;

The largest allocation size that is required to be fulfilled using the pooling mechanism. Attempts to allocate a single block larger than this threshold will be allocated directly from the upstream memory resource. If largest_required_pool_block is zero or is greater than an implementation-defined limit, that limit is used instead. The implementation may choose a pass-through threshold larger than specified in this field.

23.12.5.3 Pool resource constructors and destructors

synchronized_pool_resource(const pool_options& opts, memory_resource* upstream);
unsynchronized_pool_resource(const pool_options& opts, memory_resource* upstream);

Requires: upstream is the address of a valid memory resource.

Effects: Constructs a pool resource object that will obtain memory from upstream whenever the pool resource is unable to satisfy a memory request from its own internal data structures. The resulting object will hold a copy of upstream, but will not own the resource to which upstream points.

[Note: The intention is that calls to upstream->allocate() will be substantially fewer than calls

§ 23.12.5.3 643
The behavior of the pooling mechanism is tuned according to the value of the opts argument. — end note

Throws: Nothing unless upstream->allocate() throws. It is unspecified if, or under what conditions, this constructor calls upstream->allocate().

virtual ~synchronized_pool_resource();
virtual ~unsynchronized_pool_resource();

Effects: Calls release().

### 23.12.5.4 Pool resource members

void release();

Effects: Calls upstream_resource() -> deallocate() as necessary to release all allocated memory.

[Note: The memory is released back to upstream_resource() even if deallocate has not been called for some of the allocated blocks. — end note]

memory_resource* upstream_resource() const;

Returns: The value of the upstream argument provided to the constructor of this object.

pool_options options() const;

Returns: The options that control the pooling behavior of this resource. The values in the returned struct may differ from those supplied to the pool resource constructor in that values of zero will be replaced with implementation-defined defaults, and sizes may be rounded to unspecified granularity.

void* do_allocate(size_t bytes, size_t alignment) override;

Returns: A pointer to allocated storage (6.7.4.2) with a size of at least bytes. The size and alignment of the allocated memory shall meet the requirements for a class derived from memory_resource (23.12).

Effects: If the pool selected for a block of size bytes is unable to satisfy the memory request from its own internal data structures, it will call upstream_resource() -> allocate() to obtain more memory. If bytes is larger than that which the largest pool can handle, then memory will be allocated using upstream_resource() -> allocate().

Throws: Nothing unless upstream_resource() -> allocate() throws.

void do_deallocate(void* p, size_t bytes, size_t alignment) override;

Effects: Returns the memory at p to the pool. It is unspecified if, or under what circumstances, this operation will result in a call to upstream_resource() -> deallocate().

Throws: Nothing.

bool synchronized_pool_resource::do_is_equal(
    const memory_resource& other) const noexcept override;

Returns: this == dynamic_cast<const synchronized_pool_resource*>(&other).

bool unsynchronized_pool_resource::do_is_equal(
    const memory_resource& other) const noexcept override;

Returns: this == dynamic_cast<const unsynchronized_pool_resource*>(&other).

### 23.12.6 Class monotonic_buffer_resource

A monotonic_buffer_resource is a special-purpose memory resource intended for very fast memory allocations in situations where memory is used to build up a few objects and then is released all at once when the memory resource object is destroyed. It has the following qualities:

§ 23.12.6
— A call to `deallocate` has no effect, thus the amount of memory consumed increases monotonically until the resource is destroyed.

— The program can supply an initial buffer, which the allocator uses to satisfy memory requests.

— When the initial buffer (if any) is exhausted, it obtains additional buffers from an `upstream` memory resource supplied at construction. Each additional buffer is larger than the previous one, following a geometric progression.

— It is intended for access from one thread of control at a time. Specifically, calls to `allocate` and `deallocate` do not synchronize with one another.

— It frees the allocated memory on destruction, even if `deallocate` has not been called for some of the allocated blocks.

class monotonic_buffer_resource : public memory_resource {

memory_resource *upstream_rsrc; // exposition only
void *current_buffer; // exposition only
size_t next_buffer_size; // exposition only

public:
    explicit monotonic_buffer_resource(memory_resource *upstream);
    monotonic_buffer_resource(size_t initial_size, memory_resource *upstream);
    monotonic_buffer_resource(void *buffer, size_t buffer_size,
                              memory_resource *upstream);

    monotonic_buffer_resource() :
        monotonic_buffer_resource(get_default_resource()) {}             
    explicit monotonic_buffer_resource(size_t initial_size) :
        monotonic_buffer_resource(initial_size, get_default_resource()) {}       
    monotonic_buffer_resource(void *buffer, size_t buffer_size) :
        monotonic_buffer_resource(buffer, buffer_size, get_default_resource()) {}      

    monotonic_buffer_resource(const monotonic_buffer_resource&) = delete;

    virtual ~monotonic_buffer_resource();

    monotonic_buffer_resource
    operator=(const monotonic_buffer_resource&) = delete;

    void release();

    memory_resource* upstream_resource() const;

protected:
    void* do_allocate(size_t bytes, size_t alignment) override;
    void do_deallocate(void* p, size_t bytes, size_t alignment) override;

    bool do_is_equal(const memory_resource& other) const noexcept override;
};

23.12.6.1 monotonic_buffer_resource constructor and destructor

[mem.res.monotonic.buffer ctor]

explicit monotonic_buffer_resource(memory_resource* upstream);
monotonic_buffer_resource(size_t initial_size, memory_resource* upstream);

Requires: `upstream` shall be the address of a valid memory resource. `initial_size`, if specified, shall be greater than zero.
2. **Effects:** Sets `upstream_rsrc` to `upstream` and `current_buffer` to `nullptr`. If `initial_size` is specified, sets `next_buffer_size` to at least `initial_size`; otherwise sets `next_buffer_size` to an implementation-defined size.

```cpp
monotonic_buffer_resource(void* buffer, size_t buffer_size, memory_resource* upstream);
```

3. **Requires:** `upstream` shall be the address of a valid memory resource. `buffer_size` shall be no larger than the number of bytes in `buffer`.

4. **Effects:** Sets `upstream_rsrc` to `upstream`, `current_buffer` to `buffer`, and `next_buffer_size` to `buffer_size` (but not less than 1), then increases `next_buffer_size` by an implementation-defined growth factor (which need not be integral).

```cpp
~monotonic_buffer_resource();
```

5. **Effects:** Calls `release()`.

### 23.12.6.2 monotonic_buffer_resource members

```cpp
void release();
```

1. **Effects:** Calls `upstream_rsrc->deallocate()` as necessary to release all allocated memory.

2. **[Note:** The memory is released back to `upstream_rsrc` even if some blocks that were allocated from this have not been deallocated from this. — end note**]

```cpp
memory_resource* upstream_resource() const;
```

3. **Returns:** The value of `upstream_rsrc`.

```cpp
void* do_allocate(size_t bytes, size_t alignment) override;
```

4. **Returns:** A pointer to allocated storage (6.7.4.2) with a size of at least `bytes`. The size and alignment of the allocated memory shall meet the requirements for a class derived from `memory_resource` (23.12).

5. **Effects:** If the unused space in `current_buffer` can fit a block with the specified `bytes` and `alignment`, then allocate the return block from `current_buffer`; otherwise set `current_buffer` to `upstream_rsrc->allocate(n, m)`, where `n` is not less than `max(bytes, next_buffer_size)` and `m` is not less than `alignment`, and increase `next_buffer_size` by an implementation-defined growth factor (which need not be integral), then allocate the return block from the newly-allocated `current_buffer`.

6. **Throws:** Nothing unless `upstream_rsrc->allocate()` throws.

```cpp
void do_deallocate(void* p, size_t bytes, size_t alignment) override;
```

7. **Effects:** None.

8. **Throws:** Nothing.

9. **Remarks:** Memory used by this resource increases monotonically until its destruction.

```cpp
bool do_is_equal(const memory_resource& other) const noexcept override;
```

10. **Returns:** `true` if `other` is a `monotonic_buffer_resource` object.

### 23.13 Class template scoped_allocator_adaptor

#### 23.13.1 Header <scoped_allocator> synopsis

```cpp
template <class OuterAlloc, class... InnerAllocs>
class scoped_allocator_adaptor;
```

```cpp
template <class OuterA1, class OuterA2, class... InnerAllocs>
bool operator==(const scoped_allocator_adaptor<OuterA1, InnerAllocs...>& a,
```
The class template `scoped_allocator_adaptor` is an allocator template that specifies the memory resource (the outer allocator) to be used by a container (as any other allocator does) and also specifies an inner allocator resource to be passed to the constructor of every element within the container. This adaptor is instantiated with one outer and zero or more inner allocator types. If instantiated with only one allocator type, the inner allocator becomes the `scoped_allocator_adaptor` itself, thus using the same allocator resource for the container and every element within the container and, if the elements themselves are containers, each of their elements recursively. If instantiated with more than one allocator, the first allocator is the outer allocator for use by the container, the second allocator is passed to the constructors of the container’s elements, and, if the elements themselves are containers, the third allocator is passed to the elements’ elements, and so on. If containers are nested to a depth greater than the number of allocators, the last allocator is used repeatedly, as in the single-allocator case, for any remaining recursions. [Note: The `scoped_allocator_adaptor` is derived from the outer allocator type so it can be substituted for the outer allocator type in most expressions. —end note]

```cpp
namespace std {
    template <class OuterAlloc, class... InnerAllocs>
    class scoped_allocator_adaptor : public OuterAlloc {

    private:
        using OuterTraits = allocator_traits<OuterAlloc>; // exposition only
        scoped_allocator_adaptor<InnerAllocs...> inner; // exposition only

    public:
        using outer_allocator_type = OuterAlloc;
        using inner_allocator_type = see below;

        using value_type = typename OuterTraits::value_type;
        using size_type = typename OuterTraits::size_type;
        using difference_type = typename OuterTraits::difference_type;
        using pointer = typename OuterTraits::pointer;
        using const_pointer = typename OuterTraits::const_pointer;
        using void_pointer = typename OuterTraits::void_pointer;
        using const_void_pointer = typename OuterTraits::const_void_pointer;

        using propagate_on_container_copy_assignment = see below;
        using propagate_on_container_move_assignment = see below;
        using propagate_on_container_swap = see below;
        using is_always_equal = see below;

    template <class Tp>
    struct rebind {
        using other = scoped_allocator_adaptor<
            OuterTraits::template rebind_alloc<Tp>, InnerAllocs...>;
    };

    scoped_allocator_adaptor();
    template <class OuterA2>
    scoped_allocator_adaptor(OuterA2&& outerAlloc,
        const InnerAllocs&&... innerAllocs) noexcept;

    scoped_allocator_adaptor(const scoped_allocator_adaptor& other) noexcept;
    scoped_allocator_adaptor(scoped_allocator_adaptor&& other) noexcept;
}

}
23.13.2 Scoped allocator adaptor member types

using inner_allocator_type = see below;

Type: scoped_allocator_adaptor<OuterAlloc> if sizeof...(InnerAllocs) is zero; otherwise,
scoped_allocator_adaptor<InnerAllocs...>.

using propagate_on_container_copy_assignment = see below;

Type: true_type if allocator_traits<A>::propagate_on_container_copy_assignment::value is
true for any A in the set of OuterAlloc and InnerAllocs...; otherwise, false_type.

using propagate_on_container_move_assignment = see below;

Type: true_type if allocator_traits<A>::propagate_on_container_move_assignment::value is
true for any A in the set of OuterAlloc and InnerAllocs...; otherwise, false_type.

using propagate_on_container_swap = see below;

Type: true_type if allocator_traits<A>::propagate_on_container_swap::value is true for any
A in the set of OuterAlloc and InnerAllocs...; otherwise, false_type.

using is_always_equal = see below;

Type: true_type if allocator_traits<A>::is_always_equal::value is true for every A in the set
of OuterAlloc and InnerAllocs...; otherwise, false_type.

23.13.3 Scoped allocator adaptor constructors

scoped_allocator_adaptor();

Effects: Value-initializes the OuterAlloc base class and the inner allocator object.

template <class OuterA2>
scoped_allocator_adaptor(OuterA2&& outerAlloc,
  const InnerAllocs&... innerAllocs) noexcept;

Effects: Initializes the OuterAlloc base class with std::forward<OuterA2>(outerAlloc) and inner
with innerAllocs... (hence recursively initializing each allocator within the adaptor with the
corresponding allocator from the argument list).

Remarks: This constructor shall not participate in overload resolution unless
is_constructible_<v<OuterAlloc, OuterA2> is true.

scoped_allocator_adaptor(const scoped_allocator_adaptor& other) noexcept;

Effects: Initializes each allocator within the adaptor with the corresponding allocator from other.

scoped_allocator_adaptor(scoped_allocator_adaptor&& other) noexcept;

Effects: Move constructs each allocator within the adaptor with the corresponding allocator from other.

template <class OuterA2>
scoped_allocator_adaptor(const scoped_allocator_adaptor<OuterA2,
  InnerAllocs...>& other) noexcept;

Effects: Initializes each allocator within the adaptor with the corresponding allocator from other.

Remarks: This constructor shall not participate in overload resolution unless
is_constructible_<v<OuterAlloc, const OuterA2&> is true.

template <class OuterA2>

§ 23.13.3
scoped_allocator_adaptor(scoped_allocator_adaptor<OuterA2, InnerAllocs...>&& other) noexcept;

Effects: Initializes each allocator within the adaptor with the corresponding allocator rvalue from other.

Remarks: This constructor shall not participate in overload resolution unless is_constructible_v<OuterAlloc, OuterA2> is true.

### 23.13.4 Scoped allocator adaptor members

In the construct member functions, OUTERMOST(x) is x if x does not have an outer_allocator() member function and OUTERMOST(x.outer_allocator()) otherwise; OUTERMOST_ALLOC_TRAITS(x) is allocator_traits<decIdxtype(OUTERMOST(x))>. [Note: OUTERMOST(x) and OUTERMOST_ALLOC_TRAITS(x) are recursive operations. It is incumbent upon the definition of outer_allocator() to ensure that the recursion terminates. It will terminate for all instantiations of scoped_allocator_adaptor. —end note]

inner_allocator_type& inner_allocator() noexcept;
const inner_allocator_type& inner_allocator() const noexcept;

Returns: *this if sizeof...(InnerAllocs) is zero; otherwise, inner.

outer_allocator_type& outer_allocator() noexcept;
const outer_allocator_type& outer_allocator() const noexcept;

Returns: static_cast<OuterAlloc&>(*this).

pointer allocate(size_type n);

Returns: allocator_traits<OuterAlloc>::allocate(outer_allocator(), n).

pointer allocate(size_type n, const_void_pointer hint);

Returns: allocator_traits<OuterAlloc>::allocate(outer_allocator(), n, hint).

void deallocate(pointer p, size_type n) noexcept;

Effects: As if by: allocator_traits<OuterAlloc>::deallocate(outer_allocator(), p, n);

size_type max_size() const;

Returns: allocator_traits<OuterAlloc>::max_size(outer_allocator()).

template <class T, class... Args>
void construct(T* p, Args&&... args);

Effects:

(9.1) If uses_allocator_v<T, inner_allocator_type> is false and is_constructible_v<T, Args...> is true, calls:

OUTERMOST_ALLOC_TRAITS(*this)::construct(
OUTERMOST(*this), p, std::forward<Args>(args)....)

(9.2) Otherwise, if uses_allocator_v<T, inner_allocator_type> is true and is_constructible_v<T, allocator_arg_t, inner_allocator_type&, Args...> is true, calls:

OUTERMOST_ALLOC_TRAITS(*this)::construct(
OUTERMOST(*this), p, allocator_arg, inner_allocator(), std::forward<Args>(args)...)

(9.3) Otherwise, if uses_allocator_v<T, inner_allocator_type> is true and is_constructible_v<T, Args..., inner_allocator_type&> is true, calls:
OUTERMOST_ALLOC_TRAITS(*this)::construct(
    OUTERMOST(*this), p, std::forward<Args>(args)..., inner_allocator())

— Otherwise, the program is ill-formed. [Note: An error will result if uses_allocator evaluates
to true but the specific constructor does not take an allocator. This definition prevents a silent
failure to pass an inner allocator to a contained element. — end note]
13 Effects: Equivalent to:

```cpp
construct(p, piecewise_construct,
    forward_as_tuple(std::forward<U>(x)),
    forward_as_tuple(std::forward<V>(y)));
```

```cpp
template <class T1, class T2, class U, class V>
void construct(pair<T1, T2>* p, const pair<U, V>& x);
```

14 Effects: Equivalent to:

```cpp
construct(p, piecewise_construct,
    forward_as_tuple(x.first),
    forward_as_tuple(x.second));
```

```cpp
template <class T1, class T2, class U, class V>
void construct(pair<T1, T2>* p, pair<U, V>&& x);
```

15 Effects: Equivalent to:

```cpp
construct(p, piecewise_construct,
    forward_as_tuple(std::forward<U>(x.first)),
    forward_as_tuple(std::forward<V>(x.second)));
```

```cpp
template <class T>
void destroy(T* p);
```

16 Effects: Calls `OUTERMOST_ALLOC_TRAITS(*this)::destroy(OUTERMOST(*this), p)`.

```cpp
scoped_allocator_adaptor select_on_container_copy_construction() const;
```

17 Returns: A new `scoped_allocator_adaptor` object where each allocator A in the adaptor is initialized from the result of calling `allocator_traits<A>::select_on_container_copy_construction()` on the corresponding allocator in `*this`.

### 23.13.5 Scoped allocator operators

```cpp
template <class OuterA1, class OuterA2, class... InnerAllocs>
bool operator==(const scoped_allocator_adaptor<OuterA1, InnerAllocs...>& a,
    const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& b) noexcept;
```

1 Returns: If `sizeof...(InnerAllocs)` is zero,

```cpp
    a.outer_allocator() == b.outer_allocator()
```

otherwise

```cpp
    a.outer_allocator() == b.outer_allocator() && a.inner_allocator() == b.inner_allocator()
```

```cpp
template <class OuterA1, class OuterA2, class... InnerAllocs>
bool operator!=(const scoped_allocator_adaptor<OuterA1, InnerAllocs...>& a,
    const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& b) noexcept;
```

2 Returns: `(a != b)`.

### 23.14 Function objects

A *function object type* is an object type (6.9) that can be the type of the *postfix-expression* in a function call (8.2.2, 16.3.1.1). A *function object* is an object of a function object type. In the places where one would expect to pass a pointer to a function to an algorithmic template (Clause 28), the interface is specified to

222) Such a type is a function pointer or a class type which has a member `operator()` or a class type which has a conversion to a pointer to function.
accept a function object. This not only makes algorithmic templates work with pointers to functions, but also enables them to work with arbitrary function objects.

### 23.14.1 Header `<functional>` synopsis

```cpp
namespace std {
    // 23.14.4. invoke
    template <class F, class... Args>
    invoke_result_t<F, Args...> invoke(F&& f, Args&&... args)
        noexcept(is_nothrow_invocable_v<F, Args...>);

    // 23.14.5. reference_wrapper
    template <class T> class reference_wrapper;

    template <class T> reference_wrapper<T> ref(T&) noexcept;
    template <class T> reference_wrapper<const T> cref(const T&) noexcept;
    template <class T> void ref(const T&) = delete;
    template <class T> void cref(const T&) = delete;

    template <class T> reference_wrapper<T> ref(reference_wrapper<T>) noexcept;
    template <class T> reference_wrapper<const T> cref(reference_wrapper<T>) noexcept;

    // 23.14.6. arithmetic operations
    template <class T = void> struct plus;
    template <class T = void> struct minus;

// 23.14.15, hash function primary template
template <class T>
struct hash;

// 23.14.11, function object binders
template <class T>
inline constexpr bool is_bind_expression_v = is_bind_expression<T>::value;

template <class T>
inline constexpr int is_placeholder_v = is_placeholder<T>::value;
}

1 [ Example: If a C++ program wants to have a by-element addition of two vectors \(a\) and \(b\) containing \texttt{double}\ and put the result into \(a\), it can do:

\[
\text{transform}(a.begin(), a.end(), b.begin(), a.begin(), plus<double>())
\]

— end example ]

2 [ Example: To negate every element of \(a\):

\[
\text{transform}(a.begin(), a.end(), a.begin(), negate<double>())
\]

— end example ]

23.14.2 Definitions [func.def]

1 The following definitions apply to this Clause:

2 A \textit{call signature} is the name of a return type followed by a parenthesized comma-separated list of zero or more argument types.

3 A \textit{callable type} is a function object type (23.14) or a pointer to member.

4 A \textit{callable object} is an object of a callable type.

5 A \textit{call wrapper type} is a type that holds a callable object and supports a call operation that forwards to that object.

6 A \textit{call wrapper} is an object of a call wrapper type.

7 A \textit{target object} is the callable object held by a call wrapper.

23.14.3 Requirements [func.require]

1 Define \texttt{INVOKE(f, t1, t2, ..., tN)} as follows:

\[(t1.*f)(t2, ..., tN)\] when \(f\) is a pointer to a member function of a class \(T\) and \texttt{is_base_of_v<T,}
decay_t<decltype(t1)>::is true;

— (t1.get().*f)(t2, ..., tN) when f is a pointer to a member function of a class T and decay_t<decltype(t1)>::is a specialization of reference_wrapper;

— (t1.*f)(t2, ..., tN) when f is a pointer to a member function of a class T and t1 does not satisfy the previous two items;

— t1.*f when N == 1 and f is a pointer to data member of a class T and is_base_of_v<T, decay_t<decltype(t1)>> is true;

— t1.get().*f when N == 1 and f is a pointer to data member of a class T and decay_t<decltype(t1)>::is a specialization of reference_wrapper;

— (t1).*f when N == 1 and f is a pointer to data member of a class T and t1 does not satisfy the previous two items;

(1.7) f(t1, t2, ..., tN) in all other cases.

Define INVOKE_R>(f, t1, t2, ..., tN) as static_cast<void>(INVOKE(f, t1, t2, ..., tN)) if R is cv void, otherwise INVOKE(f, t1, t2, ..., tN) implicitly converted to R.

Every call wrapper (23.14.2) shall be MoveConstructible. A forwarding call wrapper is a call wrapper that can be called with an arbitrary argument list and delivers the arguments to the wrapped callable object as references. This forwarding step shall ensure that rvalue arguments are delivered as rvalue references and lvalue arguments are delivered as lvalue references. A simple call wrapper is a forwarding call wrapper that is CopyConstructible and CopyAssignable and whose copy constructor, move constructor, and assignment operator do not throw exceptions. [Note: In a typical implementation forwarding call wrappers have an overloaded function call operator of the form

```
    template<class... UnBoundArgs>
    R operator()(UnBoundArgs&&... unbound_args) cv-qual;
```

— end note]

23.14.4 Function template invoke

```
template <class F, class... Args>
invoke_result_t<F, Args...> invoke(F&& f, Args&&... args)
    noexcept(is_nothrow_invocable_v<F, Args...>);
```

1 Returns: INVOKE(std::forward<F>(f), std::forward<Args>(args)...) (23.14.3).

23.14.5 Class template reference_wrapper

```
namespace std {
    template <class T> class reference_wrapper {
        public :
            // types
            using type = T;

            // construct/copy/destroy
            reference_wrapper(T&) noexcept;
            reference_wrapper(T&&) = delete; // do not bind to temporary objects
            reference_wrapper(const reference_wrapper& x) noexcept;

            // assignment
            reference_wrapper& operator=(const reference_wrapper& x) noexcept;

            // access
            operator T& () const noexcept;

```
T& get() const noexcept;

// invocation
template <class... ArgTypes>
    invoke_result_t<T&, ArgTypes...>
        operator() (ArgTypes&&...) const;
};

template<class T>
    reference_wrapper(reference_wrapper<T>) -> reference_wrapper<T>;
}

1 reference_wrapper<T> is a CopyConstructible and CopyAssignable wrapper around a reference to an object or function of type T.

2 reference_wrapper<T> shall be a trivially copyable type (6.9).

23.14.5.1 reference_wrapper construct/copy/destroy [refwrap.const]

reference_wrapper(T& t) noexcept;
1 Effects: Constructs a reference_wrapper object that stores a reference to t.

reference_wrapper(const reference_wrapper& x) noexcept;
2 Effects: Constructs a reference_wrapper object that stores a reference to x.get().

23.14.5.2 reference_wrapper assignment [refwrap.assign]

reference_wrapper& operator=(const reference_wrapper& x) noexcept;
1 Postconditions: *this stores a reference to x.get().

23.14.5.3 reference_wrapper access [refwrap.access]

operator T& () const noexcept;
1 Returns: The stored reference.

T& get() const noexcept;
2

Returns: The stored reference.

23.14.5.4 reference_wrapper invocation [refwrap.invoke]

template <class... ArgTypes>
    invoke_result_t<T&, ArgTypes...>
        operator() (ArgTypes&&... args) const;
1 Returns: INVOKE(get(), std::forward<ArgTypes>(args)...). (23.14.3)

23.14.5.5 reference_wrapper helper functions [refwrap.helpers]

template <class T> reference_wrapper<T> ref(T& t) noexcept;
1 Returns: reference_wrapper<T>(t).

template <class T> reference_wrapper<T> ref(reference_wrapper<T> t) noexcept;
2 Returns: ref(t.get()).

template <class T> reference_wrapper<const T> cref(const T& t) noexcept;
3 Returns: reference_wrapper< const T>(t).
template <class T> reference_wrapper<const T> cref(reference_wrapper<T> t) noexcept;

Returns: cref(t.get()).

23.14.6 Arithmetic operations [arithmetic.operations]

The library provides basic function object classes for all of the arithmetic operators in the language (8.6, 8.7).

23.14.6.1 Class template plus [arithmetic.operations.plus]

template <class T = void> struct plus {
    constexpr T operator()(const T& x, const T& y) const;
    constexpr T operator()(const T& x, const T& y) const;

Returns: x + y.

template <> struct plus<void> {
    template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) + std::forward<U>(u));

using is_transparent = unspecified;
};

template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) + std::forward<U>(u));

23.14.6.2 Class template minus [arithmetic.operations.minus]

template <class T = void> struct minus {
    constexpr T operator()(const T& x, const T& y) const;
    constexpr T operator()(const T& x, const T& y) const;

Returns: x - y.

template <> struct minus<void> {
    template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) - std::forward<U>(u));

using is_transparent = unspecified;
};

template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) - std::forward<U>(u));

23.14.6.3 Class template multiplies [arithmetic.operations.multiplies]

template <class T = void> struct multiplies {
    constexpr T operator()(const T& x, const T& y) const;
    constexpr T operator()(const T& x, const T& y) const;

Returns: x * y.
template <> struct multiplies<void> {
  template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) * std::forward<U>(u));

  using is_transparent = unspecified;
};

template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) * std::forward<U>(u));

2 Returns: std::forward<T>(t) * std::forward<U>(u).

23.14.6.4 Class template divides [arithmetic.operations.divides]

template <class T = void> struct divides {
  constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;
1 Returns: x / y.

template <> struct divides<void> {
  template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) / std::forward<U>(u));

  using is_transparent = unspecified;
};

template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) / std::forward<U>(u));
2 Returns: std::forward<T>(t) / std::forward<U>(u).

23.14.6.5 Class template modulus [arithmetic.operations.modulus]

template <class T = void> struct modulus {
  constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;
1 Returns: x % y.

template <> struct modulus<void> {
  template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) % std::forward<U>(u));

  using is_transparent = unspecified;
};

template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) % std::forward<U>(u));
2 Returns: std::forward<T>(t) % std::forward<U>(u).

23.14.6.6 Class template negate [arithmetic.operations.negate]

template <class T = void> struct negate {
  constexpr T operator()(const T& x) const;
};

§ 23.14.6.6
constexpr T operator()(const T& x) const;

Returns: \(-x\).

template <> struct negate<void> {
    template <class T> constexpr auto operator()(T&& t) const
        -> decltype(-std::forward<T>(t));

    using is_transparent = unspecified;
};

template <class T> constexpr auto operator()(T&& t) const
    -> decltype(-std::forward<T>(t));

Returns: \(-\text{std::forward}(t)\).

23.14.7 Comparisons

The library provides basic function object classes for all of the comparison operators in the language (8.9, 8.10).

For templates `less`, `greater`, `less_equal`, and `greater_equal`, the specializations for any pointer type yield a strict total order that is consistent among those specializations and is also consistent with the partial order imposed by the built-in operators `<`, `>`, `<=`, `>=`. [Note: When `a < b` is well-defined for pointers `a` and `b` of type `P`, this implies `(a < b) == \text{less}<P>(a, b)`, `(a > b) == \text{greater}<P>(a, b)`, and so forth. —end note] For template specializations `less<void>`, `greater<void>`, `less_equal<void>`, and `greater_equal<void>`, if the call operator calls a built-in operator comparing pointers, the call operator yields a strict total order that is consistent among those specializations and is also consistent with the partial order imposed by those built-in operators.

23.14.7.1 Class template equal_to

```
template <class T = void> struct equal_to {
    constexpr bool operator()(const T& x, const T& y) const;
};
```

```
constexpr bool operator()(const T& x, const T& y) const;
```

Returns: `x == y`.

```
template <> struct equal_to<void> {
    template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) == std::forward<U>(u));

    using is_transparent = unspecified;
};
```

```
template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) == std::forward<U>(u));
```

Returns: `\text{std::forward}(t) == \text{std::forward}(u)`.

23.14.7.2 Class template not_equal_to

```
template <class T = void> struct not_equal_to {
    constexpr bool operator()(const T& x, const T& y) const;
};
```

```
constexpr bool operator()(const T& x, const T& y) const;
```

§ 23.14.7.2
Returns: \( x \neq y \).

```cpp
template <> struct not_equal_to<void> {
    template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) != std::forward<U>(u));
    using is_transparent = unspecified;
};
```  

Returns: \( \text{std::forward<T>(t)} \neq \text{std::forward<U>(u)} \).

### 23.14.7.3 Class template greater

returns: \( x > y \).

```cpp
template <> struct greater<void> {
    template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) > std::forward<U>(u));
    using is_transparent = unspecified;
};
```  

Returns: \( \text{std::forward<T>(t)} > \text{std::forward<U>(u)} \).

### 23.14.7.4 Class template less

returns: \( x < y \).

```cpp
template <> struct less<void> {
    template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) < std::forward<U>(u));
    using is_transparent = unspecified;
};
```  

Returns: \( \text{std::forward<T>(t)} < \text{std::forward<U>(u)} \).

### 23.14.7.5 Class template greater_equal

returns: \( x \geq y \).

```cpp
template <> struct greater_equal<void> {
    template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) \geq std::forward<U>(u));
    using is_transparent = unspecified;
};
```  

Returns: \( \text{std::forward<T>(t)} \geq \text{std::forward<U>(u)} \).
constexpr bool operator()(const T& x, const T& y) const;
1

Returns: x >= y.

template <> struct greater_equal<void> {
    template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) >= std::forward<U>(u));

    using is_transparent = unspecified;
};

template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) >= std::forward<U>(u));
2

Returns: std::forward<T>(t) >= std::forward<U>(u).

23.14.7.6 Class template less_equal

template <class T = void> struct less_equal {
    constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;
1

Returns: x <= y.

template <> struct less_equal<void> {
    template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) <= std::forward<U>(u));

    using is_transparent = unspecified;
};

template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) <= std::forward<U>(u));
2

Returns: std::forward<T>(t) <= std::forward<U>(u).

23.14.8 Logical operations

The library provides basic function object classes for all of the logical operators in the language (8.14, 8.15, 8.3.1).

23.14.8.1 Class template logical_and

template <class T = void> struct logical_and {
    constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;
1

Returns: x && y.

template <> struct logical_and<void> {
    template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) && std::forward<U>(u));

    using is_transparent = unspecified;
};

§ 23.14.8.1 662
template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) && std::forward<U>(u));

    Returns: std::forward<T>(t) && std::forward<U>(u).

23.14.8.2 Class template logical_or

template <class T = void> struct logical_or {
    constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;

1 Returns: x || y.

2 template <> struct logical_or<void> {
    template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) || std::forward<U>(u));

    using is_transparent = unspecified;
};

template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) || std::forward<U>(u));

2 Returns: std::forward<T>(t) || std::forward<U>(u).

23.14.8.3 Class template logical_not

template <class T = void> struct logical_not {
    constexpr bool operator()(const T& x) const;
};

constexpr bool operator()(const T& x) const;

1 Returns: !x.

2 template <> struct logical_not<void> {
    template <class T> constexpr auto operator()(T&& t) const
        -> decltype(!std::forward<T>(t));

    using is_transparent = unspecified;
};

template <class T> constexpr auto operator()(T&& t) const
    -> decltype(!std::forward<T>(t));

2 Returns: !std::forward<T>(t).

23.14.9 Bitwise operations

The library provides basic function object classes for all of the bitwise operators in the language (8.11, 8.13, 8.12, 8.3.1).

23.14.9.1 Class template bit_and

template <class T = void> struct bit_and {
    constexpr T operator()(const T& x, const T& y) const;
};
constexpr T operator()(const T& x, const T& y) const;

Returns: x & y.

template <> struct bit_and<void> {
    template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) & std::forward<U>(u));

    using is_transparent = unspecified;
};

template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) & std::forward<U>(u));

Returns: std::forward<T>(t) & std::forward<U>(u).

23.14.9.2 Class template bit_or

template <class T = void> struct bit_or {
    constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

Returns: x | y.

template <> struct bit_or<void> {
    template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) | std::forward<U>(u));

    using is_transparent = unspecified;
};

template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) | std::forward<U>(u));

Returns: std::forward<T>(t) | std::forward<U>(u).

23.14.9.3 Class template bit_xor

template <class T = void> struct bit_xor {
    constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

Returns: x ^ y.

template <> struct bit_xor<void> {
    template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) ^ std::forward<U>(u));

    using is_transparent = unspecified;
};

template <class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) ^ std::forward<U>(u));

Returns: std::forward<T>(t) ^ std::forward<U>(u).

23.14.9.4 Class template bit_not

§ 23.14.9.4
template <class T = void> struct bit_not {
    constexpr T operator()(const T& x) const;
};

constexpr T operator()(const T& x) const;

Returns: ~x.

template <> struct bit_not<void> {
    template <class T> constexpr auto operator()(T&& t) const
    -> decltype(~std::forward<T>(t));
};

using is_transparent = unspecified;

template <class T> constexpr auto operator()(T&&) const
-> decltype(~std::forward<T>(t));

Returns: ~std::forward<T>(t).

§ 23.14.10 Function template not_fn [func.not_fn]

template <class F> unspecified not_fn(F&& f);

Effects: Equivalent to return call_wrapper(std::forward<F>(f)); where call_wrapper is an exposition only class defined as follows:

class call_wrapper {
    using FD = decay_t<F>
    FD fd;

    explicit call_wrapper(F&& f);

    public:
        call_wrapper(call_wrapper&&) = default;
        call_wrapper(const call_wrapper&) = default;

        template<class... Args>
        auto operator()(Args&&...) &
        -> decltype(!declval<invoke_result_t<FD&, Args...>>());

        template<class... Args>
        auto operator()(Args&&...) const&
        -> decltype(!declval<invoke_result_t<const FD&, Args...>>());

        template<class... Args>
        auto operator()(Args&&...) &&
        -> decltype(!declval<invoke_result_t<FD, Args...>>());

        template<class... Args>
        auto operator()(Args&&...) const&&
        -> decltype(!declval<invoke_result_t<const FD, Args...>>());

    explicit call_wrapper(F&& f);

Requires: FD shall satisfy the requirements of MoveConstructible. is_constructible_v<FD, F> shall be true. fd shall be a callable object (23.14.2).
Effects: Initializes \( \text{fd} \) from \( \text{std::forward}<\text{F}>(\text{f}) \).

Throws: Any exception thrown by construction of \( \text{fd} \).

```
template<class... Args>
auto operator() (Args&&... args) &
-> decltype(!declval<invoke_result_t<FD&, Args...>>());
template<class... Args>
auto operator() (Args&&... args) const&
-> decltype(!declval<invoke_result_t<const FD&, Args...>>());
```

Effects: Equivalent to:
```
return !INVOKE(fd, std::forward<Args>(args)...); // see 23.14.3
```

```
template<class... Args>
auto operator() (Args&&... args) &&
-> decltype(!declval<invoke_result_t<FD, Args...>>());
template<class... Args>
auto operator() (Args&&... args) const&&
-> decltype(!declval<invoke_result_t<const FD, Args...>>());
```

Effects: Equivalent to:
```
return !INVOKE(std::move(fd), std::forward<Args>(args)...); // see 23.14.3
```

### 23.14.11 Function object binders

This subclause describes a uniform mechanism for binding arguments of callable objects.

#### 23.14.11.1 Class template is bind expression

```
namespace std {
    template<class T> struct is_bind_expression; // see below
}
```

The class template `is_bind_expression` can be used to detect function objects generated by `bind`. The function template `bind` uses `is_bind_expression` to detect subexpressions.

Instantiations of the `is_bind_expression` template shall meet the `UnaryTypeTrait` requirements (23.15.1). The implementation shall provide a definition that has a base characteristic of `true_type` if \( T \) is a type returned from `bind`, otherwise it shall have a base characteristic of `false_type`. A program may specialize this template for a user-defined type \( T \) to have a base characteristic of `true_type` to indicate that \( T \) should be treated as a subexpression in a `bind` call.

#### 23.14.11.2 Class template is placeholder

```
namespace std {
    template<class T> struct is_placeholder; // see below
}
```

The class template `is_placeholder` can be used to detect the standard placeholders \(_1, _2\), and so on. The function template `bind` uses `is_placeholder` to detect placeholders.

Instantiations of the `is_placeholder` template shall meet the `UnaryTypeTrait` requirements (23.15.1). The implementation shall provide a definition that has the base characteristic of `integral_constant<int, J>` if \( T \) is the type of \( \text{std::placeholders::_J} \), otherwise it shall have a base characteristic of `integral_constant<int, 0>`. A program may specialize this template for a user-defined type \( T \) to have a base characteristic of `integral_constant<int, N>` with \( N > 0 \) to indicate that \( T \) should be treated as a place-
holder type.

23.14.11.3 Function template bind [func.bind.bind]

1 In the text that follows:

(1.1) — FD is the type decay_t<F>.
(1.2) — fd is an lvalue of type FD constructed from std::forward<F>(f),
(1.3) — Ti is the ith type in the template parameter pack BoundArgs,
(1.4) — TDi is the type decay_t<Ti>,
(1.5) — ti is the ith argument in the function parameter pack bound_args,
(1.6) — td is an lvalue of type TDi constructed from std::forward<Ti>(ti),
(1.7) — Uj is the jth deduced type of the UnBoundArgs&&... parameter of the forwarding call wrapper, and
(1.8) — uj is the jth argument associated with Uj.

```cpp
template<class F, class... BoundArgs>
unspecified bind(F&& f, BoundArgs&&... bound_args);
```

2 Requires: is_constructible_v<FD, F> shall be true. For each Ti in BoundArgs, is_constructible_v<TDi, Ti> shall be true. INVOKE(fd, w1, w2, ..., wN) (23.14.3) shall be a valid expression for some values w1, w2, ..., wN, where N has the value sizeof...(bound_args). The cv-qualifiers cv of the call wrapper g, as specified below, shall be neither volatile nor const volatile.

3 Returns: A forwarding call wrapper g (23.14.3). The effect of g(u1, u2, ..., uM) shall be

```
INVOKE(fd, std::forward<V1>(v1), std::forward<V2>(v2), ..., std::forward<VN>(vN))
```

where the values and types of the bound arguments v1, v2, ..., vN are determined as specified below. The copy constructor and move constructor of the forwarding call wrapper shall throw an exception if and only if the corresponding constructor of FD or of any of the types TDi throws an exception.

4 Throws: Nothing unless the construction of fd or of one of the values td, throws an exception.

5 Remarks: The return type shall satisfy the requirements of MoveConstructible. If all of FD and TDi satisfy the requirements of CopyConstructible, then the return type shall satisfy the requirements of CopyConstructible. [Note: This implies that all of FD and TDi are MoveConstructible. — end note]

```cpp
template<class R, class F, class... BoundArgs>
unspecified bind(F&& f, BoundArgs&&... bound_args);
```

6 Requires: is_constructible_v<FD, F> shall be true. For each Ti in BoundArgs, is_constructible_v<TDi, Ti> shall be true. INVOKE(fd, w1, w2, ..., wN) shall be a valid expression for some values w1, w2, ..., wN, where N has the value sizeof...(bound_args). The cv-qualifiers cv of the call wrapper g, as specified below, shall be neither volatile nor const volatile.

7 Returns: A forwarding call wrapper g (23.14.3). The effect of g(u1, u2, ..., uM) shall be

```
INVOKE<R>(fd, std::forward<V1>(v1), std::forward<V2>(v2), ..., std::forward<VN>(vN))
```

where the values and types of the bound arguments v1, v2, ..., vN are determined as specified below. The copy constructor and move constructor of the forwarding call wrapper shall throw an exception if and only if the corresponding constructor of FD or of any of the types TDi throws an exception.

8 Throws: Nothing unless the construction of fd or of one of the values td, throws an exception.

9 Remarks: The return type shall satisfy the requirements of MoveConstructible. If all of FD and TDi satisfy the requirements of CopyConstructible, then the return type shall satisfy the requirements of CopyConstructible. [Note: This implies that all of FD and TDi are MoveConstructible. — end
The values of the *bound arguments* $v_1, v_2, \ldots, v_N$ and their corresponding types $V_1, V_2, \ldots, V_N$ depend on the types $TD_i$ derived from the call to `bind` and the cv-qualifiers $cv$ of the call wrapper $g$ as follows:

1. if $TD_i$ is `reference_wrapper<T>`, the argument is $td_i().$ and its type $V_i$ is $T&$;
2. if the value of `is_bind_expression_v<TD_i>` is true, the argument is $td_i(std::forward<U_j>(u_j)\ldots)$ and its type $V_i$ is $invoke_result_t<TD_i, cv&, U_j\ldots>&&$;
3. if the value $j$ of `is_placeholder_v<TD_i>` is not zero, the argument is $std::forward<U_j>(u_j)$ and its type $V_i$ is $U_j&&$;
4. otherwise, the value is $td_i$ and its type $V_i$ is $TD_i, cv&.$

### 23.14.11.4 Placeholders

```cpp
define std::placeholders { // M is the implementation-defined number of placeholders 
  see below _1;
  see below _2;
  ...
  see below _M;
}
```

All placeholder types shall be `DefaultConstructible` and `CopyConstructible`, and their default constructors and copy/move constructors shall not throw exceptions. It is implementation-defined whether placeholder types are `CopyAssignable`. `CopyAssignable` placeholders’ copy assignment operators shall not throw exceptions.

Placeholders should be defined as:

```cpp
inline constexpr unspecified _1{};
```

If they are not, they shall be declared as:

```cpp
extern unspecified _1;
```

### 23.14.12 Function template `mem_fn`

```cpp
template<class R, class T> unspecified mem_fn(R T::* pm) noexcept;
```

1. Returns: A simple call wrapper (23.14.2) $fn$ such that the expression $fn(t, a2, \ldots, aN)$ is equivalent to $INVOKE(pm, t, a2, \ldots, aN)$ (23.14.3).

### 23.14.13 Polymorphic function wrappers

1. This subclause describes a polymorphic wrapper class that encapsulates arbitrary callable objects.

#### 23.14.13.1 Class `bad_function_call`

```cpp
namespace std {
  class bad_function_call : public exception {
    public:
      // 23.14.13.1.1, constructor
      bad_function_call() noexcept;
  }
}
```

An exception of type `bad_function_call` is thrown by `function::operator()` (23.14.13.2.4) when the function wrapper object has no target.
23.14.13.1.1 bad_function_call constructor

bad_function_call() noexcept;

1 Effects: Constructs a bad_function_call object.

2 Postconditions: what() returns an implementation-defined NTBS.

23.14.13.2 Class template function

namespace std {
    template<class> class function; // not defined

template<class R, class... ArgTypes>
    class function<R(ArgTypes...)>:: { 
        public:
            using result_type = R;

            // 23.14.13.2.1, construct/copy/destroy
            function() noexcept;
            function(nullptr_t) noexcept;
            function(const function&);
            function(function&&);
            template<class F> function(F);

            function& operator=(const function&);
            function& operator=(function&&);
            function& operator=(nullptr_t) noexcept;
            template<class F> function& operator=(F&&);
            template<class F> function& operator=(reference_wrapper<F>) noexcept;

            ~function();

            // 23.14.13.2.2, function modifiers
            void swap(function&) noexcept;

            // 23.14.13.2.3, function capacity
            explicit operator bool() const noexcept;

            // 23.14.13.2.4, function invocation
            R operator()(ArgTypes...) const;

            // 23.14.13.2.5, function target access
            const type_info& target_type() const noexcept;
            template<class T> T* target() noexcept;
            template<class T> const T* target() const noexcept;
    };

    template<class R, class... ArgTypes>
        function(R(*)(ArgTypes...)) -> function<R(ArgTypes...)>

    template<class F> function(F) -> function<see below>

    // 23.14.13.2.6, Null pointer comparisons
    template <class R, class... ArgTypes>
        bool operator==(const function<R(ArgTypes...)>&, nullptr_t) noexcept;

§ 23.14.13.2
template <class R, class... ArgTypes>
    bool operator==(nullptr_t, const function<R(ArgTypes...)>&) noexcept;

template <class R, class... ArgTypes>
    bool operator!=(const function<R(ArgTypes...)>&, nullptr_t) noexcept;

template <class R, class... ArgTypes>
    bool operator!=(nullptr_t, const function<R(ArgTypes...)>&) noexcept;

// 23.14.13.2.7, specialized algorithms
template <class R, class... ArgTypes>
    void swap(function<R(ArgTypes...)>&, function<R(ArgTypes...)>&) noexcept;

1 The function class template provides polymorphic wrappers that generalize the notion of a function pointer. Wrappers can store, copy, and call arbitrary callable objects (23.14.2), given a call signature (23.14.2), allowing functions to be first-class objects.

2 A callable type (23.14.2) \( F \) is \texttt{Lvalue-Callable} for argument types \( \texttt{ArgTypes} \) and return type \( \texttt{R} \) if the expression \( \texttt{INVOKE} < \texttt{R} > (\texttt{declval<\texttt{F}@>()}, \texttt{declval<\texttt{ArgTypes}@>()}) \), considered as an unevaluated operand (Clause 8), is well formed (23.14.3).

3 The function class template is a call wrapper (23.14.2) whose call signature (23.14.2) is \( \texttt{R(ArgTypes...)} \).

4 [Note: The types deduced by the deduction guides for function may change in future versions of this International Standard. —end note]

\textbf{23.14.13.2.1 function construct/copy/destroy} \hspace{1em} \hspace{1em} [func.wrap.func.con]

function() noexcept;
1 \hspace{1em} \textit{Postconditions:} \!*\texttt{this}.

function(nullptr_t) noexcept;
2 \hspace{1em} \textit{Postconditions:} \!*\texttt{this}.

function(const function& f);
3 \hspace{1em} \textit{Postconditions:} \!*\texttt{this} if \(!f\); otherwise, \texttt{\!*this} targets a copy of \texttt{f.target()}.

\textit{Throws:} shall not throw exceptions if \( f \)’s target is a specialization of reference\_wrapper or a function pointer. Otherwise, may throw \texttt{bad_alloc} or any exception thrown by the copy constructor of the stored callable object. [Note: Implementations are encouraged to avoid the use of dynamically allocated memory for small callable objects, for example, where \( f \)’s target is an object holding only a pointer or reference to an object and a member function pointer. —end note]

function(function&& f);
4 \hspace{1em} \textit{Postconditions:} If \(!f\), \texttt{\!*this} has no target; otherwise, the target of \texttt{\!*this} is equivalent to the target of \( f \) before the construction, and \( f \) is in a valid state with an unspecified value.

\textit{Throws:} shall not throw exceptions if \( f \)’s target is a specialization of reference\_wrapper or a function pointer. Otherwise, may throw \texttt{bad_alloc} or any exception thrown by the copy or move constructor of the stored callable object. [Note: Implementations are encouraged to avoid the use of dynamically allocated memory for small callable objects, for example, where \( f \)’s target is an object holding only a pointer or reference to an object and a member function pointer. —end note]

\textbf{template<class F> function(F f);} 
5 \hspace{1em} \textit{Requires:} \( F \) shall be CopyConstructible.
Remarks: This constructor template shall not participate in overload resolution unless \( F \) is Lvalue-Callable (23.14.13.2) for argument types ArgTypes... and return type R.

Postconditions: \(!\this\) if any of the following hold:

(9.1) \( f \) is a null function pointer value.
(9.2) \( f \) is a null member pointer value.
(9.3) \( F \) is an instance of the function class template, and \(!f\).

Otherwise, \(*\this\) targets a copy of \( f \) initialized with std::move(\( f \)). [Note: Implementations are encouraged to avoid the use of dynamically allocated memory for small callable objects, for example, where \( f \) is an object holding only a pointer or reference to an object and a member function pointer. —end note]

Throws: shall not throw exceptions when \( f \) is a function pointer or a reference_wrapper\(<\text{T}>\) for some \text{T}. Otherwise, may throw bad_alloc or any exception thrown by \( F \)’s copy or move constructor.

\[
\text{template<class F> function(F) -> function<see below>;} \]

Remarks: This deduction guide participates in overload resolution only if \&\&\( F :: \text{operator}() \) is well-formed when treated as an unevaluated operand. In that case, if decltype(\&\&\( F :: \text{operator}() \)) is of the form \( R(\text{G}::*)(\text{A}...)\) cv \&\ opt noexcept\_opt for a class type \text{G}, then the deduced type is function\(<\text{R}(\text{A}...)>\).

[Example:

\[
\begin{align*}
\text{void f() \{} \\
\text{int i(5);} \\
\text{function g = [&](double) { return i; };} \quad // \text{deduces function<int(double)>} \\
\text{\} } \\
\end{align*}
\]

—end example]

\[
\text{function\& operator=(const function\& f);} \]

Effects: As if by function(\( f \)).swap(\(*\this\));

Returns: \(*\this\).

\[
\text{function\& operator=(function\&\& f);} \]

Effects: Replaces the target of \(*\this\) with the target of \( f \).

Returns: \(*\this\).

\[
\text{function\& operator=(nullptr_t) noexcept;} \]

Effects: If \(*\this\) != nullptr, destroys the target of this.

Postconditions: !(*\this\).

Returns: \(*\this\).

\[
\text{template<class F> function\& operator=(F\&\& f);} \]

Effects: As if by: function(std::forward\(<\text{F}>\)(\( f \))).swap(\(*\this\));

Returns: \(*\this\).

Remarks: This assignment operator shall not participate in overload resolution unless decay_t<\text{F}> is Lvalue-Callable (23.14.13.2) for argument types ArgTypes... and return type R.

\[
\text{template<class F> function\& operator=(reference_wrapper<\text{F}> f) noexcept;} \]

Effects: As if by: function(\( f \)).swap(\(*\this\));
Returns: *this.

~function();

Effects: If *this != nullptr, destroys the target of this.

23.14.13.2.2 function modifiers

void swap(function& other) noexcept;

Effects: interchanges the targets of *this and other.

23.14.13.2.3 function capacity

explicit operator bool() const noexcept;

Returns: true if *this has a target, otherwise false.

23.14.13.2.4 function invocation

R operator()(ArgTypes... args) const;

Returns: INVOKE<R>(f, std::forward<ArgTypes>(args)...) (23.14.3), where f is the target object (23.14.2) of *this.

Throws: bad_function_call if !*this; otherwise, any exception thrown by the wrapped callable object.

23.14.13.2.5 function target access

const type_info& target_type() const noexcept;

Returns: If *this has a target of type T, typeid(T); otherwise, typeid(void).

template<class T> T* target() noexcept;
template<class T> const T* target() const noexcept;

Returns: If target_type() == typeid(T) a pointer to the stored function target; otherwise a null pointer.

23.14.13.2.6 null pointer comparison functions

template <class R, class... ArgTypes>
bool operator==(const function<R(ArgTypes...)>& f, nullptr_t) noexcept;

template <class R, class... ArgTypes>
bool operator!=(nullptr_t, const function<R(ArgTypes...)>& f) noexcept;

Returns: !f.

template <class R, class... ArgTypes>
bool operator!=(nullptr_t, const function<R(ArgTypes...)>& f) noexcept;

Returns: (bool)f.

23.14.13.2.7 specialized algorithms

template<class R, class... ArgTypes>
void swap(function<R(ArgTypes...)>& f1, function<R(ArgTypes...)>& f2) noexcept;

Effects: As if by: f1.swap(f2);
23.14.14 Searchers

This subclause provides function object types (23.14) for operations that search for a sequence \((\text{pat}\_\text{first}, \text{pat}\_\text{last})\) in another sequence \((\text{first}, \text{last})\) that is provided to the object’s function call operator. The first sequence (the pattern to be searched for) is provided to the object’s constructor, and the second (the sequence to be searched) is provided to the function call operator.

Each specialization of a class template specified in this subclause 23.14.14 shall meet the \texttt{CopyConstructible} and \texttt{CopyAssignable} requirements. Template parameters named

\begin{itemize}
  \item (2.1) ForwardIterator,
  \item (2.2) ForwardIterator1,
  \item (2.3) ForwardIterator2,
  \item (2.4) RandomAccessIterator,
  \item (2.5) RandomAccessIterator1,
  \item (2.6) RandomAccessIterator2, and
  \item (2.7) BinaryPredicate
\end{itemize}

of templates specified in this subclause 23.14.14 shall meet the same requirements and semantics as specified in 28.1. Template parameters named \texttt{Hash} shall meet the requirements as specified in 20.5.3.4.

The Boyer-Moore searcher implements the Boyer-Moore search algorithm. The Boyer-Moore-Horspool searcher implements the Boyer-Moore-Horspool search algorithm. In general, the Boyer-Moore searcher will use more memory and give better runtime performance than Boyer-Moore-Horspool.

23.14.14.1 Class template \texttt{default_searcher}

\begin{verbatim}
template <class ForwardIterator1, class BinaryPredicate = equal_to<>>
class default_searcher {
public:
  default_searcher(ForwardIterator1 pat_first, ForwardIterator1 pat_last,
                   BinaryPredicate pred = BinaryPredicate());

  template <class ForwardIterator2>
  pair<ForwardIterator2, ForwardIterator2>
    operator()(ForwardIterator2 first, ForwardIterator2 last) const;

private:
  ForwardIterator1 pat_first_; // exposition only
  ForwardIterator1 pat_last_; // exposition only
  BinaryPredicate pred_; // exposition only
};
\end{verbatim}

\begin{verbatim}
default_searcher(ForwardIterator pat_first, ForwardIterator pat_last,
                 BinaryPredicate pred = BinaryPredicate());
\end{verbatim}

\begin{itemize}
  \item (1) \texttt{Effects}: Constructs a \texttt{default_searcher} object, initializing \texttt{pat}\_\texttt{first} with \texttt{pat}\_\texttt{first}, \texttt{pat}\_\texttt{last} with \texttt{pat}\_\texttt{last}, and \texttt{pred} with \texttt{pred}.
  \item (2) \texttt{Throws}: Any exception thrown by the copy constructor of \texttt{BinaryPredicate} or \texttt{ForwardIterator1}.
\end{itemize}

\begin{verbatim}
template<class ForwardIterator2>
pair<ForwardIterator2, ForwardIterator2>
  operator()(ForwardIterator2 first, ForwardIterator2 last) const;
\end{verbatim}

\begin{itemize}
  \item (1) \texttt{Effects}: Returns a pair of iterators \texttt{i} and \texttt{j} such that
\end{itemize}
— if $i == \text{last}$, then $j == \text{last}$, otherwise $j == \text{next}(i, \text{distance}(\text{pat\_first}_, \text{pat\_last}_))$.

### 23.14.14.2 Class template boyer_moore_searcher

```cpp
template <class RandomAccessIterator1, 
          class Hash = hash<typename iterator_traits<RandomAccessIterator1>::value_type>, 
          class BinaryPredicate = equal_to<>>
class boyer_moore_searcher {
public:
    boyer_moore_searcher(RandomAccessIterator1 pat_first,
                          RandomAccessIterator1 pat_last,
                          Hash hf = Hash(),
                          BinaryPredicate pred = BinaryPredicate());

template <class RandomAccessIterator2>
pair<RandomAccessIterator2, RandomAccessIterator2>
    operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;

private:
    RandomAccessIterator1 pat_first_; // exposition only
    RandomAccessIterator1 pat_last_;   // exposition only
    Hash hash_;                      // exposition only
    BinaryPredicate pred_;           // exposition only
};
```

boyer_moore_searcher(RandomAccessIterator1 pat_first,
                      RandomAccessIterator1 pat_last,
                      Hash hf = Hash(),
                      BinaryPredicate pred = BinaryPredicate());

1 Requires: The value type of `RandomAccessIterator1` shall meet the `DefaultConstructible` requirements, the `CopyConstructible` requirements, and the `CopyAssignable` requirements.

2 Requires: For any two values $A$ and $B$ of the type `iterator_traits<RandomAccessIterator1>::value_type`, if $\text{pred}(A, B) == \text{true}$, then $\text{hf}(A) == \text{hf}(B)$ shall be `true`.

3 Effects: Constructs a `boyer_moore_searcher` object, initializing `pat_first_` with `pat_first`, `pat_last_` with `pat_last`, `hash_` with `hf`, and `pred_` with `pred`.

4 Throws: Any exception thrown by the copy constructor of `RandomAccessIterator1`, or by the default constructor, copy constructor, or the copy assignment operator of the value type of `RandomAccessIterator1`, or the copy constructor or `operator()` of `BinaryPredicate` or `Hash`. May throw `bad_alloc` if additional memory needed for internal data structures cannot be allocated.

```cpp
template <class RandomAccessIterator2>
pair<RandomAccessIterator2, RandomAccessIterator2>
    operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;
```

5 Requires: `RandomAccessIterator1` and `RandomAccessIterator2` shall have the same value type.

6 Effects: Finds a subsequence of equal values in a sequence.

7 Returns: A pair of iterators $i$ and $j$ such that

1. $i$ is the first iterator in the range `[first, last - (\text{pat\_last}_ - \text{pat\_first}_))` such that for every non-negative integer $n$ less than `\text{pat\_last}_ - \text{pat\_first}_` the following condition holds: $\text{pred}(*(i + n), *(\text{pat\_first}_ + n)) != \text{false}$, and
2. $j == \text{next}(i, \text{distance}(\text{pat\_first}_, \text{pat\_last}_))$.

Returns `make_pair(first, first)` if `\text{pat\_first}_, \text{pat\_last}_` is empty, otherwise returns `make_pair`...
pair(last, last) if no such iterator is found.

8  Complexity: At most \((last - first) \times (pat_last_ - pat_first_\)) applications of the predicate.

23.14.14.3  Class template boyer_moore_horspool_searcher

Template

template <class RandomAccessIterator1,
   class Hash = hash<typename iterator_traits<RandomAccessIterator1>::value_type>,
   class BinaryPredicate = equal_to<>>
class boyer_moore_horspool_searcher {
public:
   boyer_moore_horspool_searcher(RandomAccessIterator1 pat_first,
                                  RandomAccessIterator1 pat_last,
                                  Hash hf = Hash(),
                                  BinaryPredicate pred = BinaryPredicate());

   template <class RandomAccessIterator2>
   pair<RandomAccessIterator2, RandomAccessIterator2>
   operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;

private:
   RandomAccessIterator1 pat_first_;  // exposition only
   RandomAccessIterator1 pat_last_;   // exposition only
   Hash hash_;                       // exposition only
   BinaryPredicate pred_;            // exposition only
};

boyer_moore_horspool_searcher(RandomAccessIterator1 pat_first,
                               RandomAccessIterator1 pat_last,
                               Hash hf = Hash(),
                               BinaryPredicate pred = BinaryPredicate());

1  Requires: The value type of RandomAccessIterator1 shall meet the DefaultConstructible, CopyConstructible, and CopyAssignable requirements.

2  Requires: For any two values \(A\) and \(B\) of the type iterator_traits<RandomAccessIterator1>::value_type, if \(\text{pred}(A, B) == true\), then \(hf(A) == hf(B)\) shall be true.

3  Effects: Constructs a boyer_moore_horspool_searcher object, initializing \(\text{pat_first}_\) with \(\text{pat_first}\), \(\text{pat_last}_\) with \(\text{pat_last}\), \(\text{hash}_\) with \(\text{hf}\), and \(\text{pred}_\) with \(\text{pred}\).

4  Throws: Any exception thrown by the copy constructor of RandomAccessIterator1, or by the default constructor, copy constructor, or the copy assignment operator of the value type of RandomAccessIterator1 or the copy constructor or \(\text{operator}()\) of BinaryPredicate or Hash. May throw bad_alloc if additional memory needed for internal data structures cannot be allocated.

Template

template <class RandomAccessIterator2>
pair<RandomAccessIterator2, RandomAccessIterator2>
operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;

5  Requires: RandomAccessIterator1 and RandomAccessIterator2 shall have the same value type.

6  Effects: Finds a subsequence of equal values in a sequence.

7  Returns: A pair of iterators \(i\) and \(j\) such that

\[
\begin{align*}
\text{(7.1)} & \quad i \text{ is the first iterator } i \text{ in the range } [\text{first}, \text{last} - (\text{pat_last}_ - \text{pat_first}_)] \text{ such that for every non-negative integer } n \text{ less than } \text{pat_last}_ - \text{pat_first}_ \text{ the following condition holds: } \\
& \quad \text{pred}(*(i + n), *(\text{pat_first}_ + n)) != false, \text{ and} \\
\text{(7.2)} & \quad j = \text{next}(i, \text{distance}(\text{pat_first}_, \text{pat_last}_)).
\end{align*}
\]
Returns make_pair(first, first) if [pat_first_, pat_last_) is empty, otherwise returns make_pair(last, last) if no such iterator is found.

Complexity: At most (last - first) * (pat_last_ - pat_first_) applications of the predicate.

23.14.15 Class template hash [unord.hash]

The unordered associative containers defined in 26.5 use specializations of the class template hash (23.14.1) as the default hash function.

Each specialization of hash is either enabled or disabled, as described below. [Note: Enabled specializations meet the requirements of Hash, and disabled specializations do not. — end note] Each header that declares the template hash provides enabled specializations of hash for nullptr_t and all cv-unqualified arithmetic, enumeration, and pointer types. For any type Key for which neither the library nor the user provides an explicit or partial specialization of the class template hash, hash<Key> is disabled.

If the library provides an explicit or partial specialization of hash<Key>, that specialization is enabled except as noted otherwise, and its member functions are noexcept except as noted otherwise.

If H is a disabled specialization of hash, these values are false: is_default_constructible_v<H>, is_copy_constructible_v<H>, is_move_constructible_v<H>, is_copy_assignable_v<H>, and is_move_assignable_v<H>. Disabled specializations of hash are not function object types (23.14). [Note: This means that the specialization of hash exists, but any attempts to use it as a Hash will be ill-formed. — end note]

An enabled specialization hash<Key> will:

---

5.1 satisfy the Hash requirements (20.5.3.4), with Key as the function call argument type, the DefaultConstructible requirements (Table 22), the CopyAssignable requirements (Table 26),

5.2 be swappable (20.5.3.2) for lvalues,

5.3 satisfy the requirement that if k1 == k2 is true, h(k1) == h(k2) is also true, where h is an object of type hash<Key> and k1 and k2 are objects of type Key;

5.4 satisfy the requirement that the expression h(k), where h is an object of type hash<Key> and k is an object of type Key, shall not throw an exception unless hash<Key> is a user-defined specialization that depends on at least one user-defined type.

23.15 Metaprogramming and type traits [meta]

This subclause describes components used by C++ programs, particularly in templates, to support the widest possible range of types, optimise template code usage, detect type related user errors, and perform type inference and transformation at compile time. It includes type classification traits, type property inspection traits, and type transformations. The type classification traits describe a complete taxonomy of all possible C++ types, and state where in that taxonomy a given type belongs. The type property inspection traits allow important characteristics of types or of combinations of types to be inspected. The type transformations allow certain properties of types to be manipulated.

All functions specified in this subclause are signal-safe (21.10.3).

23.15.1 Requirements [meta.rqmts]

A UnaryTypeTrait describes a property of a type. It shall be a class template that takes one template type argument and, optionally, additional arguments that help define the property being described. It shall be DefaultConstructible, CopyConstructible, and publicly and unambiguously derived, directly or indirectly, from its base characteristic, which is a specialization of the template integral_constant (23.15.3), with the arguments to the template integral_constant determined by the requirements for the particular property being described. The member names of the base characteristic shall not be hidden and shall be unambiguously available in the UnaryTypeTrait.
A `BinaryTypeTrait` describes a relationship between two types. It shall be a class template that takes two template type arguments and, optionally, additional arguments that help define the relationship being described. It shall be `DefaultConstructible`, `CopyConstructible`, and publicly and unambiguously derived, directly or indirectly, from its `base characteristic`, which is a specialization of the template `integral_constant (23.15.3)`, with the arguments to the template `integral_constant` determined by the requirements for the particular relationship being described. The member names of the base characteristic shall not be hidden and shall be unambiguously available in the `BinaryTypeTrait`.

A `TransformationTrait` modifies a property of a type. It shall be a class template that takes one template type argument and, optionally, additional arguments that help define the modification. It shall define a publicly accessible nested type named `type`, which shall be a synonym for the modified type.

### 23.15.2 Header `<type_traits>` synopsis

```cpp
namespace std {
    // 23.15.3, helper class

    = is_convertible<From, To>::value;
template <class Fn, class... ArgTypes> inline constexpr bool is_invocable_v
    = is_invocable<Fn, ArgTypes...>::value;
template <class R, class Fn, class... ArgTypes> inline constexpr bool is_invocable_r_v
    = is_invocable_r<R, Fn, ArgTypes...>::value;
template <class R, class Fn, class... ArgTypes> inline constexpr bool is_nothrow_invocable_v
    = is_nothrow_invocable<R, Fn, ArgTypes...>::value;

// 23.15.8, logical operator traits
template<class... B> inline constexpr bool conjunction_v = conjunction<B...>::value;
template<class... B> inline constexpr bool disjunction_v = disjunction<B...>::value;
template<class B> inline constexpr bool negation_v = negation<B>::value;
\end{verbatim}

1 The behavior of a program that adds specializations for any of the templates defined in this subclause is undefined unless otherwise specified.
Unless otherwise specified, an incomplete type may be used to instantiate a template in this subclause.

23.15.3 Helper classes

```
namespace std {
    template <class T, T v>
    struct integral_constant {
        static constexpr T value = v;
        using value_type = T;
        using type = integral_constant<T, v>;
        constexpr operator value_type() const noexcept { return value; }
        constexpr value_type operator()() const noexcept { return value; }
    };
}
```

The class template `integral_constant`, alias template `bool_constant`, and its associated typedef-names `true_type` and `false_type` are used as base classes to define the interface for various type traits.

23.15.4 Unary type traits

This subclause contains templates that may be used to query the properties of a type at compile time.

Each of these templates shall be a `UnaryTypeTrait` (23.15.1) with a base characteristic of `true_type` if the corresponding condition is `true`, otherwise `false_type`.

23.15.4.1 Primary type categories

The primary type categories correspond to the descriptions given in section 6.9 of the C++ standard.

For any given type `T`, the result of applying one of these templates to `T` and to `cv T` shall yield the same result.

[Note: For any given type `T`, exactly one of the primary type categories has a `value` member that evaluates to `true`. — end note]

23.15.4.2 Composite type traits

1 These templates provide convenient compositions of the primary type categories, corresponding to the descriptions given in section 6.9.

2 For any given type T, the result of applying one of these templates to T and to cv T shall yield the same result.

Table 41 — Composite type category predicates

</tr>
</tbody>
</table>

23.15.4.3 Type properties

1 These templates provide access to some of the more important properties of types.

2 It is unspecified whether the library defines any full or partial specializations of any of these templates.

3 For all of the class templates X declared in this subclause, instantiating that template with a template-argument that is a class template specialization may result in the implicit instantiation of the template argument if and only if the semantics of X require that the argument must be a complete type.
For the purpose of defining the templates in this subclause, a function call expression `declval<T>()` for any type `T` is considered to be a trivial (6.9, 15) function call that is not an odr-use (6.2) of `declval` in the context of the corresponding definition notwithstanding the restrictions of 23.2.7.

</tr>
</tbody>
</table>

5 [Example:

```cpp
is_const_v<const volatile int>  // true
is_const_v<const int*>      // false
is_const_v<const int&>       // false
is_const_v<int[3]>            // false
is_const_v<const int[3]>      // true

— end example]
```

6 [Example:

```cpp
remove_const_t<const volatile int>  // volatile int
remove_const_t<const int* const>   // const int*
remove_const_t<const int&>         // const int&

— end example]
```

7 [Example:

```cpp
// Given:
struct P final { };
union U1 { };
union U2 final { };

// the following assertions hold:
static_assert(!is_final_v<int>);
static_assert(is_final_v<P>);
static_assert(!is_final_v<U1>);
static_assert(is_final_v<U2>);

— end example]
```

8 The predicate condition for a template specialization is_constructible<T, Args...> shall be satisfied if and only if the following variable definition would be well-formed for some invented variable t:

```cpp
T t(declval<Args>()...);
```

[Note: These tokens are never interpreted as a function declaration. — end note] Access checking is
performed as if in a context unrelated to \( T \) and any of the \textit{Args}. Only the validity of the immediate context of the variable initialization is considered. \textit{[Note: The evaluation of the initialization can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the “immediate context” and can result in the program being ill-formed. — end note]}

9 The predicate condition for a template specialization \texttt{has_unique_object_representations<T>} shall be satisfied if and only if:

\begin{align*}
(9.1) & \quad T \text{ is trivially copyable, and} \\
(9.2) & \quad \text{any two objects of type } T \text{ with the same value have the same object representation, where two objects of array or non-union class type are considered to have the same value if their respective sequences of direct subobjects have the same values, and two objects of union type are considered to have the same value if they have the same active member and the corresponding members have the same value.}
\end{align*}

The set of scalar types for which this condition holds is implementation-defined. \textit{[Note: If a type has padding bits, the condition does not hold; otherwise, the condition holds true for unsigned integral types. — end note]}

23.15.5 Type property queries \[\text{[meta.unary.prop.query]}\]

This subclause contains templates that may be used to query properties of types at compile time.

Table 43 — Type property queries

<table>
<thead>
<tr>
<th>Template</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>template &lt;class T&gt; struct alignment_of;</td>
<td>\texttt{alignof(T)}. \textit{Requires:} \texttt{alignof(T)} shall be a valid expression (8.3.6)</td>
</tr>
<tr>
<td>template &lt;class T&gt; struct rank;</td>
<td>If ( T ) names an array type, an integer value representing the number of dimensions of ( T ); otherwise, 0.</td>
</tr>
<tr>
<td>template &lt;class T, unsigned I = 0&gt; struct extent;</td>
<td>If ( T ) is not an array type, or if it has rank less than or equal to ( I ), or if ( I ) is 0 and ( T ) has type “array of unknown bound of ( U )”, then 0; otherwise, the bound (11.3.4) of the ( I )’th dimension of ( T ), where indexing of ( I ) is zero-based</td>
</tr>
</tbody>
</table>

2 Each of these templates shall be a \texttt{UnaryTypeTrait} (23.15.1) with a base characteristic of \texttt{integral_constant<size_t, Value>}.

3 \texttt{[Example:}

\begin{verbatim}
// the following assertions hold:
assert(rank_v<int> == 0);
assert(rank_v<int[2]> == 1);
assert(rank_v<int[][4]> == 2);
\end{verbatim}

\texttt{— end example]}

4 \texttt{[Example:}

\begin{verbatim}
// the following assertions hold:
assert(extent_v<int> == 0);
assert(extent_v<int[2]> == 2);
assert(extent_v<int[2][4]> == 2);
assert(extent_v<int[][4]> == 2);
assert((extent_v<int[, 1]) == 0);
assert((extent_v<int[2], 1>) == 0);
assert((extent_v<int[2][4], 1>) == 4);
\end{verbatim}

\texttt{§ 23.15.5}
assert((extent_v<int[4][4][4], 1>) == 4);
—end example]

**23.15.6 Relationships between types**

1 This subclause contains templates that may be used to query relationships between types at compile time.

2 Each of these templates shall be a BinaryTypeTrait (23.15.1) with a base characteristic of `true_type` if the corresponding condition is true, otherwise `false_type`.

<table>
<thead>
<tr>
<th>Template</th>
<th>Condition</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>template &lt;class T, class U&gt;</td>
<td>T and U name the same type with the same cv-qualifications</td>
<td></td>
</tr>
<tr>
<td>struct is_same;</td>
<td></td>
<td></td>
</tr>
<tr>
<td>template &lt;class Base, class Derived&gt;</td>
<td>Base is a base class of Derived (Clause 13) without regard to cv-qualifiers or Base and Derived are not unions and name the same class type without regard to cv-qualifiers</td>
<td>If Base and Derived are non-union class types and are not possibly cv-qualified versions of the same type, Derived shall be a complete type. [Note: Base classes that are private, protected, or ambiguous are, nonetheless, base classes. —end note]</td>
</tr>
<tr>
<td>struct is_base_of;</td>
<td></td>
<td></td>
</tr>
<tr>
<td>template &lt;class From, class To&gt;</td>
<td>see below</td>
<td>From and To shall be complete types, arrays of unknown bound, or cv void types.</td>
</tr>
<tr>
<td>struct is_convertible;</td>
<td></td>
<td></td>
</tr>
<tr>
<td>template &lt;class Fn, class... ArgTypes&gt;</td>
<td>The expression <code>INVOKE(declval&lt;Fn&gt;(), declval&lt;ArgTypes&gt;()...)</code> is well formed when treated as an unevaluated operand</td>
<td>Fn and all types in the parameter pack ArgTypes shall be complete types, cv void, or arrays of unknown bound.</td>
</tr>
<tr>
<td>struct is_invocable;</td>
<td></td>
<td></td>
</tr>
<tr>
<td>template &lt;class R, class Fn, class... ArgTypes&gt;</td>
<td>The expression <code>INVOKE&lt;R&gt;(declval&lt;Fn&gt;(), declval&lt;ArgTypes&gt;()...)</code> is well formed when treated as an unevaluated operand</td>
<td>Fn, R, and all types in the parameter pack ArgTypes shall be complete types, cv void, or arrays of unknown bound.</td>
</tr>
<tr>
<td>struct is_invocable_r;</td>
<td></td>
<td></td>
</tr>
<tr>
<td>template &lt;class Fn, class... ArgTypes&gt;</td>
<td><code>is_invocable_v&lt;Fn, ArgTypes...&gt;</code> is true and the expression <code>INVOKE(declval&lt;Fn&gt;(), declval&lt;ArgTypes&gt;()...)</code> is known not to throw any exceptions</td>
<td>Fn and all types in the parameter pack ArgTypes shall be complete types, cv void, or arrays of unknown bound.</td>
</tr>
<tr>
<td>struct is_nothrow_invocable;</td>
<td></td>
<td></td>
</tr>
<tr>
<td>template &lt;class R, class Fn, class... ArgTypes&gt;</td>
<td><code>is_invocable_r_v&lt;R, Fn, ArgTypes...&gt;</code> is true and the expression <code>INVOKE&lt;R&gt;(declval&lt;Fn&gt;(), declval&lt;ArgTypes&gt;()...)</code> is known not to throw any exceptions</td>
<td>Fn, R, and all types in the parameter pack ArgTypes shall be complete types, cv void, or arrays of unknown bound.</td>
</tr>
<tr>
<td>struct is_nothrow_invocable_r;</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
For the purpose of defining the templates in this subclause, a function call expression `declval<T>()` for any type `T` is considered to be a trivial (6.9, 15) function call that is not an odr-use (6.2) of `declval` in the context of the corresponding definition notwithstanding the restrictions of 23.2.7.

```
Example:

struct B {};  
struct B1 : B {};  
struct B2 : B {};  
struct D : private B1, private B2 {};  

is_base_of_v<B, D>  // true  
is_base_of_v<const B, D>  // true  
is_base_of_v<B, const D>  // true  
is_base_of_v<B, const B>  // true  
is_base_of_v<D, B>  // false  
is_base_of_v<B&, D&>  // false  
is_base_of_v<B[3], D[3]>  // false  
is_base_of_v<int, int>  // false  
```

—end example

The predicate condition for a template specialization `is_convertible<From, To>` shall be satisfied if and only if the return expression in the following code would be well-formed, including any implicit conversions to the return type of the function:

```c
To test() {
    return declval<From>();
}
```

[Note: This requirement gives well defined results for reference types, void types, array types, and function types. — end note] Access checking is performed in a context unrelated to `To` and `From`. Only the validity of the immediate context of the expression of the return statement (including initialization of the returned object or reference) is considered. [Note: The initialization can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the “immediate context” and can result in the program being ill-formed. — end note]

### 23.15.7 Transformations between types

This subclause contains templates that may be used to transform one type to another following some predefined rule.

Each of the templates in this subclause shall be a `TransformationTrait` (23.15.1).

#### 23.15.7.1 Const-volatile modifications

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>template &lt;class T&gt;</td>
<td>The member typedef type names the same type as <code>T</code> except that any top-level const-qualifier has been removed. [Example: <code>remove_const_t&lt;const volatile int&gt;</code> evaluates to <code>volatile int</code>, whereas <code>remove_const_t&lt;const int*&gt;</code> evaluates to <code>const int*</code>. — end example]</td>
</tr>
<tr>
<td>struct remove_const;</td>
<td></td>
</tr>
</tbody>
</table>
Table 45 — Const-volatile modifications (continued)

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>template &lt;class T&gt; struct remove_volatile;</td>
<td>The member typedef type names the same type as T except that any top-level volatile-qualifier has been removed. [Example: remove_volatile_t&lt;const volatile int&gt; evaluates to const int, whereas remove_volatile_t&lt;volatile int*&gt; evaluates to volatile int*. — end example]</td>
</tr>
<tr>
<td>template &lt;class T&gt; struct remove_cv;</td>
<td>The member typedef type shall be the same as T except that any top-level cv-qualifier has been removed. [Example: remove_cv_t&lt;const volatile int&gt; evaluates to int, whereas remove_cv_t&lt;const volatile int*&gt; evaluates to const volatile int*. — end example]</td>
</tr>
<tr>
<td>template &lt;class T&gt; struct add_const;</td>
<td>If T is a reference, function, or top-level const-qualified type, then type names the same type as T, otherwise T const.</td>
</tr>
<tr>
<td>template &lt;class T&gt; struct add_volatile;</td>
<td>If T is a reference, function, or top-level volatile-qualified type, then type names the same type as T, otherwise T volatile.</td>
</tr>
<tr>
<td>template &lt;class T&gt; struct add_cv;</td>
<td>The member typedef type names the same type as add_const_t&lt;add_volatile_t&lt;T&gt;&gt;.</td>
</tr>
</tbody>
</table>

23.15.7.2 Reference modifications

Table 46 — Reference modifications

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>template &lt;class T&gt; struct remove_reference;</td>
<td>If T has type “reference to T1” then the member typedef type names T1; otherwise, type names T.</td>
</tr>
<tr>
<td>template &lt;class T&gt; struct add_lvalue_reference;</td>
<td>If T names a referenceable type (20.3.18) then the member typedef type names T&amp;; otherwise, type names T. [Note: This rule reflects the semantics of reference collapsing (11.3.2). — end note]</td>
</tr>
<tr>
<td>template &lt;class T&gt; struct add_rvalue_reference;</td>
<td>If T names a referenceable type then the member typedef type names T&amp;&amp;; otherwise, type names T. [Note: This rule reflects the semantics of reference collapsing (11.3.2). For example, when a type T names a type T1&amp;, the type add_rvalue_reference_t&lt;T&gt; is not an rvalue reference. — end note]</td>
</tr>
</tbody>
</table>

23.15.7.3 Sign modifications

§ 23.15.7.3
Table 47 — Sign modifications

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>template &lt;class T&gt;</td>
<td>If T names a (possibly cv-qualified) signed integer type (6.9.1) then the member typedef type names the type T; otherwise, if T names a (possibly cv-qualified) unsigned integer type then type names the corresponding signed integer type, with the same cv-qualifiers as T; otherwise, type names the signed integer type with smallest rank (7.15) for which sizeof(T) == sizeof(type), with the same cv-qualifiers as T. Requires: T shall be a (possibly cv-qualified) integral type or enumeration but not a bool type.</td>
</tr>
<tr>
<td>struct make_signed;</td>
<td></td>
</tr>
<tr>
<td>template &lt;class T&gt;</td>
<td>If T names a (possibly cv-qualified) unsigned integer type (6.9.1) then the member typedef type names the type T; otherwise, if T names a (possibly cv-qualified) signed integer type then type names the corresponding unsigned integer type, with the same cv-qualifiers as T; otherwise, type names the unsigned integer type with smallest rank (7.15) for which sizeof(T) == sizeof(type), with the same cv-qualifiers as T. Requires: T shall be a (possibly cv-qualified) integral type or enumeration but not a bool type.</td>
</tr>
<tr>
<td>struct make_unsigned;</td>
<td></td>
</tr>
</tbody>
</table>
23.15.7.4  Array modifications

Table 48 — Array modifications

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>template &lt;class T&gt;</td>
<td>If T names a type “array of U”, the member typedef type shall be U, otherwise T.  [Note: For multidimensional arrays, only the first array dimension is removed. For a type “array of const U”, the resulting type is const U. —end note]</td>
</tr>
<tr>
<td>struct remove_extent;</td>
<td></td>
</tr>
<tr>
<td>template &lt;class T&gt;</td>
<td>If T is “multi-dimensional array of U”, the resulting member typedef type is U, otherwise T.</td>
</tr>
<tr>
<td>struct remove_all_extents;</td>
<td></td>
</tr>
</tbody>
</table>

1 [Example:]

// the following assertions hold:
assert((is_same_v<remove_extent_t<int>, int>));
assert((is_same_v<remove_extent_t<int[2]>, int>));
assert((is_same_v<remove_extent_t<int[2][3], int[3]>));
assert((is_same_v<remove_extent_t<int[][3], int[3]>));
—end example]

2 [Example:]

// the following assertions hold:
assert((is_same_v<remove_all_extents_t<int>, int>));
assert((is_same_v<remove_all_extents_t<int[2]>, int>));
assert((is_same_v<remove_all_extents_t<int[2][3], int[]>));
assert((is_same_v<remove_all_extents_t<int [[]][3], int[]>));
—end example]

23.15.7.5  Pointer modifications

Table 49 — Pointer modifications

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>template &lt;class T&gt;</td>
<td>If T has type “(possibly cv-qualified) pointer to T1” then the member typedef type names T1; otherwise, it names T.</td>
</tr>
<tr>
<td>struct remove_pointer;</td>
<td></td>
</tr>
<tr>
<td>template &lt;class T&gt;</td>
<td>If T names a referenceable type (20.3.18) or a cv void type then the member typedef type names the same type as remove_reference_t&lt;T&gt;*; otherwise, type names T.</td>
</tr>
<tr>
<td>struct add_pointer;</td>
<td></td>
</tr>
</tbody>
</table>

§ 23.15.7.5 698
### 23.15.7.6 Other transformations

Table 50 — Other transformations

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
</table>
| template <size_t Len, size_t Align = default-alignment> struct aligned_storage; | The value of default-alignment shall be the most stringent alignment requirement for any C++ object type whose size is no greater than Len (6.9). The member typedef type shall be a POD type suitable for use as uninitialized storage for any object whose size is at most Len and whose alignment is a divisor of Align. 
Requires: Len shall not be zero. Align shall be equal to alignof(T) for some type T or to default-alignment. |
| template <size_t Len, class... Types> struct aligned_union; | The member typedef type shall be a POD type suitable for use as uninitialized storage for any object whose type is listed in Types; its size shall be at least Len. The static member alignment_value shall be an integral constant of type size_t whose value is the strictest alignment of all types listed in Types. 
Requires: At least one type is provided. |
| template <class T> struct decay; | Let U be remove_reference_t<T>. If is_array_v<U> is true, the member typedef type shall equal remove_extent_t<U>*. If is_function_v<U> is true, the member typedef type shall equal add_pointer_t<U>. Otherwise the member typedef type equals remove_cv_t<U>. [Note: This behavior is similar to the lvalue-to-rvalue (7.1), array-to-pointer (7.2), and function-to-pointer (7.3) conversions applied when an lvalue expression is used as an rvalue, but also strips cv-qualifiers from class types in order to more closely model by-value argument passing. — end note] |
| template <bool B, class T = void> struct enable_if; | If B is true, the member typedef type shall equal T; otherwise, there shall be no member type. |
| template <bool B, class T, class F> struct conditional; | If B is true, the member typedef type shall equal T. If B is false, the member typedef type shall equal F. |
| template <class... T> struct common_type; | Unless this trait is specialized (as specified in Note B, below), the member type shall be defined or omitted as specified in Note A, below. If it is omitted, there shall be no member type. Each type in the parameter pack T shall be complete, cv void, or an array of unknown bound. |
| template <class T> struct underlying_type; | The member typedef type names the underlying type of T. 
Requires: T shall be a complete enumeration type (10.2) |
Table 50 — Other transformations (continued)

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>template &lt;class Fn, class... ArgTypes&gt; struct invoke_result;</td>
<td>If the expression <code>INVOKE(declval&lt;Fn&gt;(), declval&lt;ArgTypes&gt;()...)</code> is well formed when treated as an unevaluated operand (Clause 8), the member typedef <code>type</code> names the type <code>decltype(INVOKE(declval&lt;Fn&gt;(), declval&lt;ArgTypes&gt;()...))</code>; otherwise, there shall be no member <code>type</code>. Access checking is performed as if in a context unrelated to <code>Fn</code> and <code>ArgTypes</code>. Only the validity of the immediate context of the expression is considered. [Note: The compilation of the expression can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the “immediate context” and can result in the program being ill-formed. —end note] Requires: <code>Fn</code> and all types in the parameter pack <code>ArgTypes</code> shall be complete types, <code>cv void</code>, or arrays of unknown bound.</td>
</tr>
</tbody>
</table>

1 [Note: A typical implementation would define `aligned_storage` as:
   ```cpp
   template <size_t Len, size_t Alignment>
   struct aligned_storage {
       typedef struct {
           alignas(Alignment) unsigned char __data[Len];
       } type;
   };
   —end note]

2 It is implementation-defined whether any extended alignment is supported (6.11).

3 Note A: For the `common_type` trait applied to a parameter pack `T` of types, the member `type` shall be either defined or not present as follows:
   (3.1) If `sizeof...(T)` is zero, there shall be no member `type`.
   (3.2) If `sizeof...(T)` is one, let `T0` denote the sole type constituting the pack `T`. The member `typedef-name type` shall denote the same type, if any, as `common_type_t<T0, T0>`; otherwise there shall be no member `type`.
   (3.3) If `sizeof...(T)` is two, let the first and second types constituting `T` be denoted by `T1` and `T2`, respectively, and let `D1` and `D2` denote the same types as `decay_t<T1>` and `decay_t<T2>`, respectively.
   (3.3.1) If `is_same_v<T1, D1>` is `false` or `is_same_v<T2, D2>` is `false`, let `C` denote the same type, if any, as `common_type_t<D1, D2>`.
   (3.3.2) Otherwise, let `C` denote the same type, if any, as `decay_t<decayt(false ? declval<D1>() : declval<D2>())>`  
   [Note: This will not apply if there is a specialization `common_type_t<D1, D2>`. —end note] In either case, the member `typedef-name type` shall denote the same type, if any, as `C`. Otherwise, there shall be no member `type`.
   (3.4) If `sizeof...(T)` is greater than two, let `T1`, `T2`, and `R`, respectively, denote the first, second, and (pack of) remaining types constituting `T`. Let `C` denote the same type, if any, as `common_type_t<T1, T2>`. If there is such a type `C`, the member `typedef-name type` shall denote the same type, if any, as
common_type_t<C, R...>. Otherwise, there shall be no member type.

4 Note B: Notwithstanding the provisions of 23.15.2, and pursuant to 20.5.4.2.1, a program may specialize common_type<T1, T2> for types T1 and T2 such that is_same_v<T1, decay_t<T1>> and is_same_v<T2, decay_t<T2>> are each true. [Note: Such specializations are needed when only explicit conversions are desired between the template arguments. — end note] Such a specialization need not have a member named type, but if it does, that member shall be a typedef-name for an accessible and unambiguous cv-unqualified non-reference type C to which each of the types T1 and T2 is explicitly convertible. Moreover, common_type_t<T1, T2> shall denote the same type, if any, as does common_type_t<T2, T1>. No diagnostic is required for a violation of this Note’s rules.

5 [ Example: Given these definitions:
    using PF1 = bool (&)();
    using PF2 = short (*)(long);
    struct S {
      operator PF2() const;
      double operator()(char, int&);
      void fn(long) const;
      char data;
    };
    using PMF = void (S::*)(long) const;
    using PMD = char S::*;
    the following assertions will hold:
    static_assert(is_same_v<invoke_result_t<S, int>, short>);
    static_assert(is_same_v<invoke_result_t<S&, unsigned char, int&>, double>);
    static_assert(is_same_v<invoke_result_t<PF1>, bool>);
    static_assert(is_same_v<invoke_result_t<PMF, unique_ptr<S>, int, void>);
    static_assert(is_same_v<invoke_result_t<PMF, S, char&>);
    static_assert(is_same_v<invoke_result_t<PMF, const S*, const char&>);
    — end example ]

23.15.8 Logical operator traits

1 This subclause describes type traits for applying logical operators to other type traits.

template<class... B> struct conjunction : see below { };

2 The class template conjunction forms the logical conjunction of its template type arguments.

3 For a specialization conjunction<B1, ..., BN>, if there is a template type argument Bi for which bool(Bi::value) is false, then instantiating conjunction<B1, ..., BN>::value does not require the instantiation of Bj::value for j > i. [Note: This is analogous to the short-circuiting behavior of the built-in operator &&. — end note]

4 Every template type argument for which Bi::value is instantiated shall be usable as a base class and shall have a member value which is convertible to bool, is not hidden, and is unambiguously available in the type.

5 The specialization conjunction<B1, ..., BN> has a public and unambiguous base that is either

(5.1) — the first type Bi in the list true_type, B1, ..., BN for which bool(Bi::value) is false, or

(5.2) — if there is no such Bi, the last type in the list.

[Note: This means a specialization of conjunction does not necessarily inherit from either true_type or false_type. — end note]
The member names of the base class, other than `conjunction` and `operator=`, shall not be hidden and shall be unambiguously available in `conjunction`.

```cpp
template<class... B> struct disjunction : see below { };                         
```

The class template `disjunction` forms the logical disjunction of its template type arguments.

For a specialization `disjunction<B1, ..., BN>`, if there is a template type argument `Bi` for which `bool(Bi::value)` is `true`, then instantiating `disjunction<B1, ..., BN>::value` does not require the instantiation of `Bj::value` for `j > i`. [Note: This is analogous to the short-circuiting behavior of the built-in operator `||`. — end note]

Every template type argument for which `B::value` is instantiated shall be usable as a base class and shall have a member `value` which is convertible to `bool`, is not hidden, and is unambiguously available in the type.

The specialization `disjunction<B1, ..., BN>` has a public and unambiguous base that is either

- the first type `Bi` in the list `false_type, B1, ..., BN` for which `bool(Bi::value)` is `true`, or
- if there is no such `Bi`, the last type in the list.

[Note: This means a specialization of `disjunction` does not necessarily inherit from either `true_type` or `false_type`. — end note]

The member names of the base class, other than `disjunction` and `operator=`, shall not be hidden and shall be unambiguously available in `disjunction`.

```cpp
template<class B> struct negation : see below { };                               
```

The class template `negation` forms the logical negation of its template type argument. The type `negation<B>` is a `UnaryTypeTrait` with a base characteristic of `bool_constant<!bool(B::value)>`.

### 23.16 Compile-time rational arithmetic [ratio]

#### 23.16.1 In general [ratio.general]

This subclause describes the ratio library. It provides a class template `ratio` which exactly represents any finite rational number with a numerator and denominator representable by compile-time constants of type `intmax_t`.

Throughout this subclause, the names of template parameters are used to express type requirements. If a template parameter is named `R1` or `R2`, and the template argument is not a specialization of the `ratio` template, the program is ill-formed.

#### 23.16.2 Header `<ratio>` synopsis [ratio.syn]

```cpp
namespace std {
    // 23.16.3, class template ratio
    template <intmax_t N, intmax_t D = 1> class ratio;

    // 23.16.4, ratio arithmetic
    template <class R1, class R2> using ratio_add = see below;
    template <class R1, class R2> using ratio_subtract = see below;
    template <class R1, class R2> using ratio_multiply = see below;
    template <class R1, class R2> using ratio_divide = see below;

    // 23.16.5, ratio comparison
    template <class R1, class R2> struct ratio_equal;
    template <class R1, class R2> struct ratio_not_equal;
    template <class R1, class R2> struct ratio_less;

} // namespace std
```

§ 23.16.2
template <class R1, class R2> struct ratio_less_equal;
template <class R1, class R2> struct ratio_greater;
template <class R1, class R2> struct ratio_greater_equal;

// 23.16.6, convenience SI typedefs
using yocto = ratio<1, 1'000'000'000'000'000'000'000'000'>; // see below
using zepto = ratio<1, 1'000'000'000'000'000'000'000'>; // see below
using atto = ratio<1, 1'000'000'000'000'000'000'>;   
using femto = ratio<1, 1'000'000'>;                   
using pico = ratio<1, 1'000'>;                        
using nano = ratio<1, 1'>;                           
using micro = ratio<1, 100>;                         
using milli = ratio<1, 10>;                          
using centi = ratio<1, 10>;                          
using deca = ratio<1, 10>;                           
using hecto = ratio<1, 100>;                         
using kilo = ratio<1, 1000>;                         
using mega = ratio<1, 1'000'>;                       
using giga = ratio<1, 1'000'000'>;                  
using tera = ratio<1, 1'000'000'000'>;              
using peta = ratio<1, 1'000'000'000'000'>;          
using exa = ratio<1, 1'000'000'000'000'000'>;       
using zetta = ratio<1, 1'000'000'000'000'000'000'>; // see below
using yotta = ratio<1, 1'000'000'000'000'000'000'000'>; // see below

23.16.3 Class template ratio

namespace std {
    template <intmax_t N, intmax_t D = 1>
    class ratio {
        public:
            static constexpr intmax_t num;
            static constexpr intmax_t den;
            using type = ratio<num, den>;
    };
}

1 If the template argument D is zero or the absolute values of either of the template arguments N and D is not representable by type intmax_t, the program is ill-formed. [Note: These rules ensure that infinite ratios are avoided and that for any negative input, there exists a representable value of its absolute value which is positive. In a two’s complement representation, this excludes the most negative value. — end note]
The static data members \texttt{num} and \texttt{den} shall have the following values, where \texttt{gcd} represents the greatest common divisor of the absolute values of \(N\) and \(D\):

\[\text{num} \quad \text{shall have the value} \quad \text{sign}(N) \times \text{sign}(D) \times \abs(N) / \text{gcd}.\]

\[\text{den} \quad \text{shall have the value} \quad \abs(D) / \text{gcd}.\]

### 23.16.4 Arithmetic on ratios

Each of the alias templates \texttt{ratio\_add}, \texttt{ratio\_subtract}, \texttt{ratio\_multiply}, and \texttt{ratio\_divide} denotes the result of an arithmetic computation on two \texttt{ratio}s \texttt{R1} and \texttt{R2}. With \(X\) and \(Y\) computed (in the absence of arithmetic overflow) as specified by Table 51, each alias denotes a \texttt{ratio}\(\langle\text{U}, \text{V}\rangle\) such that \texttt{U} is the same as \texttt{ratio}\(\langle\text{X}, \text{Y}\rangle::\text{num}\) and \texttt{V} is the same as \texttt{ratio}\(\langle\text{X}, \text{Y}\rangle::\text{den}\).

If it is not possible to represent \texttt{U} or \texttt{V} with \texttt{intmax\_t}, the program is ill-formed. Otherwise, an implementation should yield correct values of \texttt{U} and \texttt{V}. If it is not possible to represent \texttt{X} or \texttt{Y} with \texttt{intmax\_t}, the program is ill-formed unless the implementation yields correct values of \texttt{U} and \texttt{V}.

<table>
<thead>
<tr>
<th>Type</th>
<th>Value of X</th>
<th>Value of Y</th>
</tr>
</thead>
<tbody>
<tr>
<td>ratio_add\langle R1, R2 \rangle</td>
<td>R1::num \times R2::den + R1::den \times R2::den</td>
<td>R2::num \times R1::den</td>
</tr>
<tr>
<td>ratio_subtract\langle R1, R2 \rangle</td>
<td>R1::num \times R2::den - R1::den \times R2::den</td>
<td>R2::num \times R1::den</td>
</tr>
<tr>
<td>ratio_multiply\langle R1, R2 \rangle</td>
<td>R1::num \times R2::num</td>
<td>R1::den \times R2::den</td>
</tr>
<tr>
<td>ratio_divide\langle R1, R2 \rangle</td>
<td>R1::num \times R2::den</td>
<td>R1::den \times R2::num</td>
</tr>
</tbody>
</table>

3  

[Example:

\begin{verbatim}
static_assert(ratio\_add\langle ratio\langle 1, 3 \rangle, ratio\langle 1, 6 \rangle \rangle::num == 1, "1/3+1/6 == 1/2");
static_assert(ratio\_add\langle ratio\langle 1, 3 \rangle, ratio\langle 1, 6 \rangle \rangle::den == 2, "1/3+1/6 == 1/2");
static_assert(ratio\_multiply\langle ratio\langle 1, 3 \rangle, ratio\langle 1, 3 \rangle \rangle::num == 1, "1/3*1/3 == 1/9");
static_assert(ratio\_multiply\langle ratio\langle 1, 3 \rangle, ratio\langle 1, 3 \rangle \rangle::den == 2, "1/3*1/3 == 1/9");

// The following cases may cause the program to be ill-formed under some implementations
static_assert(ratio\_add\langle ratio\langle 1, INT\_MAX \rangle, ratio\langle 1, INT\_MAX \rangle \rangle::num == 2, "1/INT\_MAX+1/INT\_MAX == 2/INT\_MAX");
static_assert(ratio\_add\langle ratio\langle 1, INT\_MAX \rangle, ratio\langle 1, INT\_MAX \rangle \rangle::den == INT\_MAX, "1/INT\_MAX+1/INT\_MAX == 2/INT\_MAX");
static_assert(ratio\_multiply\langle ratio\langle 1, INT\_MAX \rangle, ratio\langle 1, INT\_MAX \rangle \rangle::num == 1, "1/INT\_MAX*1/INT\_MAX == 1/INT\_MAX");
static_assert(ratio\_multiply\langle ratio\langle 1, INT\_MAX \rangle, ratio\langle 1, INT\_MAX \rangle \rangle::den == 2, "1/INT\_MAX*1/INT\_MAX == 1/INT\_MAX");
\end{verbatim}

— end example]

### 23.16.5 Comparison of ratios

\begin{verbatim}
template <class R1, class R2>
struct ratio\_equal : bool\_constant<R1::num == R2::num && R1::den == R2::den> { };

template <class R1, class R2>
struct ratio\_not\_equal : bool\_constant<!ratio\_equal\_v\langle R1, R2 \rangle> { }; 

template <class R1, class R2>
struct ratio\_less : bool\_constant<see below> { }; 
\end{verbatim}
If $R1::num \times R2::den$ is less than $R2::num \times R1::den$, $\text{ratio_less}<R1, R2>$ shall be derived from $\text{bool_constant}<\text{true}>$; otherwise it shall be derived from $\text{bool_constant}<\text{false}>$. Implementations may use other algorithms to compute this relationship to avoid overflow. If overflow occurs, the program is ill-formed.

```cpp
template <class R1, class R2>
struct ratio_less_equal : bool_constant<!ratio_less_v<R2, R1>> { };

template <class R1, class R2>
struct ratio_greater : bool_constant<ratio_less_v<R2, R1>> { };

template <class R1, class R2>
struct ratio_greater_equal : bool_constant<!ratio_less_v<R1, R2>> { };
```

23.16.6 SI types for ratio

For each of the typedef-names yocto, zepto, zetta, and yotta, if both of the constants used in its specification are representable by $\text{intmax_t}$, the typedef shall be defined; if either of the constants is not representable by $\text{intmax_t}$, the typedef shall not be defined.

23.17 Time utilities

23.17.1 In general

This subclause describes the chrono library (23.17.2) and various C functions (23.17.8) that provide generally useful time utilities.

23.17.2 Header <chrono> synopsis

```cpp
namespace std {
    namespace chrono {
        namespace {
            // 23.17.5, class template duration
            template <class Rep, class Period = ratio<1>> class duration;
        }
        // 23.17.6, class template time_point
        template <class Clock, class Duration = typename Clock::duration> class time_point;
    }
    // 23.17.4.3, common_type specializations
    template <class Rep1, class Period1, class Rep2, class Period2>
    struct common_type<chrono::duration<Rep1, Period1>,
        chrono::duration<Rep2, Period2>>;
    template <class Clock, class Duration1, class Duration2>
    struct common_type<chrono::time_point<Clock, Duration1>,
        chrono::time_point<Clock, Duration2>>;
}

namespace chrono {
    // 23.17.4, customization traits
    template <class Rep> struct treat_as_floating_point;
    template <class Rep> struct duration_values;
    template <class Rep> inline constexpr bool treat_as_floating_point_v
        = treat_as_floating_point<Rep>::value;
    // 23.17.5.5, duration arithmetic
    template <class Rep1, class Period1, class Rep2, class Period2>
    constexpr operator+(const duration<Rep1, Period1>& lhs,
        const duration<Rep2, Period2>& rhs,
        const duration<Rep1, Period1>& rhs) { }
```
const duration<Rep2, Period2>& rhs);
template <class Rep1, class Period1, class Rep2, class Period2>
    constexpr common_type_t<duration<Rep1, Period1>, duration<Rep2, Period2>>& operator-(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

23.17.3 Clock requirements

A clock is a bundle consisting of a duration, a time_point, and a function now() to get the current time_point. The origin of the clock’s time_point is referred to as the clock’s epoch. A clock shall meet the requirements in Table 52.

In Table 52 C1 and C2 denote clock types. t1 and t2 are values returned by C1::now() where the call returning t1 happens before (4.7) the call returning t2 and both of these calls occur before C1::time_point::max(). [Note: This means C1 did not wrap around between t1 and t2. — end note]

Table 52 — Clock requirements

<table>

<td>The <code>time_point</code> type of the clock. C1 and C2 shall refer to the same epoch.</td>
</tr>
<tr>
<td>C1::is_steady</td>
<td><code>const bool</code></td>
<td><code>true</code> if <code>t1 &lt;= t2</code> is always <code>true</code> and the time between clock ticks is constant, otherwise <code>false</code>.</td>
</tr>
<tr>
<td>C1::now()</td>
<td>C1::time_point</td>
<td>Returns a <code>time_point</code> object representing the current point in time.</td>
</tr>
</tbody>
</table>

3 [Note: The relative difference in durations between those reported by a given clock and the SI definition is a measure of the quality of implementation. — end note]

4 A type TC meets the `TrivialClock` requirements if:

(4.1) — TC satisfies the `Clock` requirements (23.17.3),

(4.2) — the types TC::rep, TC::duration, and TC::time_point satisfy the requirements of `EqualityComparable` (Table 20), `LessThanComparable` (Table 21), `DefaultConstructible` (Table 22), `CopyConstructible` (Table 24), `CopyAssignable` (Table 26), `Destructible` (Table 27), and the requirements of numeric types (29.3). [Note: This means, in particular, that operations on these types will not throw exceptions. — end note]

(4.3) — lvalues of the types TC::rep, TC::duration, and TC::time_point are swappable (20.5.3.2),

(4.4) — the function TC::now() does not throw exceptions, and

(4.5) — the type TC::time_point::clock meets the `TrivialClock` requirements, recursively.

23.17.4 Time-related traits

23.17.4.1 `treat_as_floating_point` [time.traits.is_fp]

```cpp
template <class Rep> struct treat_as_floating_point
  : is_floating_point<Rep> { };
```

1 The `duration` template uses the `treat_as_floating_point` trait to help determine if a `duration` object can be converted to another `duration` with a different tick period. If `treat_as_floating_point_v<Rep>` is `true`, then implicit conversions are allowed among `durations`. Otherwise, the implicit convertibility depends on the tick periods of the `durations`. [Note: The intention of this trait is to indicate whether a given class behaves like a floating-point type, and thus allows division of one value by another with acceptable loss of precision. If `treat_as_floating_point_v<Rep>` is `false`, Rep will be treated as if it behaved like an integral type for the purpose of these conversions. — end note]

23.17.4.2 `duration_values` [time.traits.duration_values]

```cpp
template <class Rep>
struct duration_values {
  public:
```
The `duration` template uses the `duration_values` trait to construct special values of the durations representation (`Rep`). This is done because the representation might be a class type with behavior which requires some other implementation to return these special values. In that case, the author of that class type should specialize `duration_values` to return the indicated values.

```cpp
static constexpr Rep zero();
static constexpr Rep min();
static constexpr Rep max();
```

1. **Returns:** `Rep(0)`.
   - **Note:** `Rep(0)` is specified instead of `Rep()` because `Rep()` may have some other meaning, such as an uninitialized value. —end note

2. **Remarks:** The value returned shall be the additive identity.

```cpp
static constexpr Rep min();
static constexpr Rep max();
```

3. **Returns:** `numeric_limits<Rep>::lowest()`.
4. **Remarks:** The value returned shall compare less than or equal to `zero()`.
5. **Remarks:** The value returned shall compare greater than `zero()`.

### 23.17.4.3 Specializations of `common_type` [time.traits.specializations]

```cpp
template <class Rep1, class Period1, class Rep2, class Period2>
struct common_type<chrono::duration<Rep1, Period1>, chrono::duration<Rep2, Period2>> {
    using type = chrono::duration<common_type_t<Rep1, Rep2>, see below>;
};
```

1. **Notes:** The typedef name `type` is a synonym for the `duration` with the largest tick period possible where both `duration` arguments will convert to it without requiring a division operation. The representation of this type is intended to be able to hold any value resulting from this conversion with no truncation error, although floating-point durations may have round-off errors. —end note

```cpp
template <class Clock, class Duration1, class Duration2>
struct common_type<chrono::time_point<Clock, Duration1>, chrono::time_point<Clock, Duration2>> {
    using type = chrono::time_point<Clock, common_type_t<Duration1, Duration2>>;
};
```

3. The common type of two `time_point` types is a `time_point` with the same clock as the two types and the common type of their two `durations`.

### 23.17.5 Class template `duration` [time.duration]

1. A `duration` type measures time between two points in `time` (`time_points`). A `duration` has a representation which holds a count of ticks and a tick period. The tick period is the amount of time which occurs from one tick to the next, in units of seconds. It is expressed as a rational constant using the template `ratio`.

```cpp
template <class Rep, class Period = ratio<1>>
class duration {
```
public:
    using rep = Rep;
    using period = typename Period::type;
private:
    rep rep_;  // exposition only
public:
    // 23.17.5.1, construct/copy/destroy
    constexpr duration() = default;
    template <class Rep2>
        constexpr explicit duration(const Rep2& r);
    template <class Rep2, class Period2>
        constexpr duration(const duration<Rep2, Period2>& d);
    ~duration() = default;
    duration(const duration&) = default;
    duration& operator=(const duration&) = default;
    // 23.17.5.2, observer
    constexpr rep count() const;
    // 23.17.5.3, arithmetic
    constexpr common_type_t<duration> operator+() const;
    constexpr common_type_t<duration> operator-() const;
    constexpr duration& operator++();
    constexpr duration operator++(int);
    constexpr duration& operator--();
    constexpr duration operator--(int);
    constexpr duration& operator+=(const duration& d);
    constexpr duration& operator-=(const duration& d);
    constexpr duration& operator*=(const rep& rhs);
    constexpr duration& operator/=(const rep& rhs);
    constexpr duration& operator%=(const rep& rhs);
    constexpr duration& operator%=(const duration& rhs);
    // 23.17.5.4, special values
    static constexpr duration zero();
    static constexpr duration min();
    static constexpr duration max();
};

2 Rep shall be an arithmetic type or a class emulating an arithmetic type. If duration is instantiated with a duration type as the argument for the template parameter Rep, the program is ill-formed.

3 If Period is not a specialization of ratio, the program is ill-formed. If Period::num is not positive, the program is ill-formed.

4 Members of duration shall not throw exceptions other than those thrown by the indicated operations on their representations.

5 The defaulted copy constructor of duration shall be a constexpr function if and only if the required initialization of the member rep_ for copy and move, respectively, would satisfy the requirements for a constexpr function.

6 [ Example:
    
    duration<long, ratio<60>> d0;  // holds a count of minutes using a long
    duration<long, long, milli> d1;  // holds a count of milliseconds using a long long
    duration<double, ratio<1, 30>> d2;  // holds a count with a tick period of \frac{1}{30} of a second

§ 23.17.5
template <class Rep2>
constexpr explicit duration(const Rep2& r);

Remarks: This constructor shall not participate in overload resolution unless Rep2 is implicitly
convertible to rep and

(1.1) 
— treat_as_floating_point_v<rep> is true or

(1.2) 
— treat_as_floating_point_v<Rep2> is false.

[Example:
  duration<int, milli> d(3); // OK
  duration<int, milli> d(3.5); // error
  — end example]

Effects: Constructs an object of type duration.
Postconditions: count() == static_cast<rep>(r).

template <class Rep2, class Period2>
constexpr duration(const duration<Rep2, Period2>& d);

Remarks: This constructor shall not participate in overload resolution unless no overflow is induced
in the conversion and treat_as_floating_point_v<rep> is true or both ratio_divide<Period2,
period>::den is 1 and treat_as_floating_point_v<Rep2> is false. [Note: This requirement
prevents implicit truncation error when converting between integral-based duration types. Such a con-
struction could easily lead to confusion about the value of the duration. — end note] [Example:
  duration<int, milli> ms(3);
  duration<int, micro> us = ms; // OK
  duration<int, milli> ms2 = us; // error
  — end example]

Effects: Constructs an object of type duration, constructing rep_ from
duration_cast<duration>(d).count().

23.17.5.2 duration observer

constexpr rep count() const;

Returns: rep_.

23.17.5.3 duration arithmetic

constexpr common_type_t<duration> operator+() const;

Returns: common_type_t<duration>(*this).

constexpr common_type_t<duration> operator-() const;

Returns: common_type_t<duration>(-rep_).

constexpr duration& operator++();

Effects: As if by ++rep_.

Returns: *this.

§ 23.17.5.3
constexpr duration operator++(int);
   
   Returns: duration(rep_++).

constexpr duration& operator--();
   
   Effects: As if by --rep_.
   
   Returns: *this.

constexpr duration operator--(int);
   
   Returns: duration(rep_--).

constexpr duration& operator+=(const duration& d);
   
   Effects: As if by: rep_ += d.count();
   
   Returns: *this.

constexpr duration& operator-=(const duration& d);
   
   Effects: As if by: rep_ -= d.count();
   
   Returns: *this.

constexpr duration& operator*=(const rep& rhs);
   
   Effects: As if by: rep_ *= rhs;
   
   Returns: *this.

constexpr duration& operator/=(const rep& rhs);
   
   Effects: As if by: rep_ /= rhs;
   
   Returns: *this.

constexpr duration& operator%=(const rep& rhs);
   
   Effects: As if by: rep_ %= rhs;
   
   Returns: *this.

constexpr duration& operator%=(const duration& rhs);
   
   Effects: As if by: rep_ %= rhs.count();
   
   Returns: *this.

static constexpr duration zero();
   
   Returns: duration(duration_values<rep>::zero()).

static constexpr duration min();
   
   Returns: duration(duration_values<rep>::min()).

static constexpr duration max();
   
   Returns: duration(duration_values<rep>::max()).

23.17.5.4  duration special values  

23.17.5.5  duration non-member arithmetic  

In the function descriptions that follow, CD represents the return type of the function. CR(A, B) represents common_type_t<A, B>.
template <class Rep1, class Period1, class Rep2, class Period2>
    constexpr common_type_t<duration<Rep1, Period1>, duration<Rep2, Period2>>
    operator+(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

2 Returns: CD(CD(lhs).count() + CD(rhs).count()).

template <class Rep1, class Period1, class Rep2, class Period2>
    constexpr common_type_t<duration<Rep1, Period1>, duration<Rep2, Period2>>
    operator-(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

3 Returns: CD(CD(lhs).count() - CD(rhs).count()).

template <class Rep1, class Period, class Rep2>
    constexpr duration<common_type_t<Rep1, Rep2>, Period>
    operator*(const duration<Rep1, Period>& d, const Rep2& s);

4 Remarks: This operator shall not participate in overload resolution unless Rep2 is implicitly convertible to CR(Rep1, Rep2).

5 Returns: CD(CD(d).count() * s).

template <class Rep1, class Rep2, class Period>
    constexpr duration<common_type_t<Rep1, Rep2>, Period>
    operator*(const Rep1& s, const duration<Rep2, Period>& d);

6 Remarks: This operator shall not participate in overload resolution unless Rep1 is implicitly convertible to CR(Rep1, Rep2).

7 Returns: d * s.

template <class Rep1, class Period, class Rep2>
    constexpr duration<common_type_t<Rep1, Rep2>, Period>
    operator%(const duration<Rep1, Period>& d, const Rep2& s);

8 Remarks: This operator shall not participate in overload resolution unless Rep2 is implicitly convertible to CR(Rep1, Rep2) and Rep2 is not a specialization of duration.

9 Returns: CD(CD(d).count() / s).

template <class Rep1, class Period1, class Rep2, class Period2>
    constexpr common_type_t<duration<Rep1, Period1>, duration<Rep2, Period2>>
    operator%(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

10 Returns: CD(CD(lhs).count() % CD(rhs).count()).
23.17.5.6 duration comparisons

In the function descriptions that follow, $CT$ represents $\text{common\_type\_t}<A, B>$, where $A$ and $B$ are the types of the two arguments to the function.

```cpp
template <class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator==(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

Returns: $CT(lhs).\text{count}() == CT(rhs).\text{count}()$.
```

```cpp
template <class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator!=(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

Returns: !(lhs == rhs).
```

```cpp
template <class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator<(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

Returns: $CT(lhs).\text{count}() < CT(rhs).\text{count}()$.
```

```cpp
template <class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator<=(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

Returns: !(rhs < lhs).
```

```cpp
template <class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator>(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

Returns: rhs < lhs.
```

```cpp
template <class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator>=(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

Returns: !(lhs < rhs).
```

23.17.5.7 duration_cast

```cpp
template <class ToDuration, class Rep, class Period>
constexpr ToDuration duration_cast(const duration<Rep, Period>& d);

Remarks: This function shall not participate in overload resolution unless ToDuration is a specialization of duration.

Returns: Let $CF$ be $\text{ratio\_divide}\langle\text{Period}, \text{typename ToDuration::period}\rangle$, and $CR$ be $\text{common\_type}\langle\text{typename ToDuration::rep, Rep, intmax_t::type}\rangle$.

(2.1) If $\text{CF::num} == 1$ and $\text{CF::den} == 1$, returns

$\text{ToDuration}(\text{static\_cast}\langle\text{typename ToDuration::rep}\rangle(d.\text{count}()))$

(2.2) Otherwise, if $\text{CF::num} != 1$ and $\text{CF::den} == 1$, returns

$\text{ToDuration}(\text{static\_cast}\langle\text{typename ToDuration::rep}\rangle(\text{static\_cast}\langle\text{CR}\rangle(d.\text{count}()) * \text{static\_cast}\langle\text{CR}\rangle(\text{CF::num})))$

(2.3) Otherwise, if $\text{CF::num} == 1$ and $\text{CF::den} != 1$, returns

$\text{ToDuration}(\text{static\_cast}\langle\text{typename ToDuration::rep}\rangle(\text{static\_cast}\langle\text{CR}\rangle(d.\text{count}()) / \text{static\_cast}\langle\text{CR}\rangle(\text{CF::den}))))$

§ 23.17.5.7
— otherwise, returns

\[
\text{ToDuration}(\text{static\_cast<\text{typename ToDuration::rep}>(}
\text{static\_cast<\text{CR}}(\text{d\_count()}) \times \text{static\_cast<\text{CR}}(\text{CF\_num}) / \text{static\_cast<\text{CR}}(\text{CF\_den}))\text{)}
\]

[Note: This function does not use any implicit conversions; all conversions are done with \text{static\_cast}. It avoids multiplications and divisions when it is known at compile time that one or more arguments is 1. Intermediate computations are carried out in the widest representation and only converted to the destination representation at the final step. —end note]

\[
\text{template <class ToDuration, class Rep, class Period>}
\]
\[
\text{constexpr ToDuration floor(const duration<Rep, Period>& d);}
\]

Remarks: This function shall not participate in overload resolution unless \text{ToDuration} is a specialization of \text{duration}.

Returns: The greatest result \( t \) representable in \text{ToDuration} for which \( t \leq d \).

\[
\text{template <class ToDuration, class Rep, class Period>}
\]
\[
\text{constexpr ToDuration ceil(const duration<Rep, Period>& d);}
\]

Remarks: This function shall not participate in overload resolution unless \text{ToDuration} is a specialization of \text{duration}.

Returns: The least result \( t \) representable in \text{ToDuration} for which \( t \geq d \).

\[
\text{template <class ToDuration, class Rep, class Period>}
\]
\[
\text{constexpr ToDuration round(const duration<Rep, Period>& d);}
\]

Remarks: This function shall not participate in overload resolution unless \text{ToDuration} is a specialization of \text{duration}, and \text{treat\_as\_floating\_point\_v<\text{typename ToDuration::rep>}} is \text{false}.

Returns: The value of \text{ToDuration} that is closest to \( d \). If there are two closest values, then return the value \( t \) for which \( t \% 2 == 0 \).

23.17.5.8 Suffixes for duration literals

[time.duration.literals]

1 This section describes literal suffixes for constructing duration literals. The suffixes \text{h}, \text{min}, \text{s}, \text{ms}, \text{us}, \text{ns} denote duration values of the corresponding types \text{hours}, \text{minutes}, \text{seconds}, \text{milliseconds}, \text{microseconds}, and \text{nanoseconds} respectively if they are applied to integral literals.

2 If any of these suffixes are applied to a floating-point literal the result is a \text{chrono::duration} literal with an unspecified floating-point representation.

3 If any of these suffixes are applied to an integer literal and the resulting \text{chrono::duration} value cannot be represented in the result type because of overflow, the program is ill-formed.

[Example: The following code shows some duration literals.

\[
\text{using namespace std::chrono_literals;}
\text{auto constexpr aday=24h;}
\text{auto constexpr lesson=45min;}
\text{auto constexpr halfanhour=0.5h;}
\text{—end example}]
\]

\[
\text{constexpr chrono::hours operator"h(unsigned long long hours);}
\text{constexpr chrono::duration<unspecified, ratio<3600, 1>> operator"h(long double hours);}\]

5 Returns: A duration literal representing hours hours.

\[
\text{constexpr chrono::minutes operator"min(unsigned long long minutes);}
\text{constexpr chrono::duration<unspecified, ratio<60, 1>> operator"min(long double minutes);}\]
Returns: A duration literal representing minutes.

constexpr chrono::seconds operator""s(unsigned long long sec);
constexpr chrono::duration<unspecified> operator""s(long double sec);

Returns: A duration literal representing sec seconds.

[Note: The same suffix s is used for basic_string but there is no conflict, since duration suffixes apply to numbers and string literal suffixes apply to character array literals. — end note]

constexpr chrono::milliseconds operator""ms(unsigned long long msec);
constexpr chrono::duration<unspecified, milli> operator""ms(long double msec);

Returns: A duration literal representing msec milliseconds.

constexpr chrono::microseconds operator""us(unsigned long long usec);
constexpr chrono::duration<unspecified, micro> operator""us(long double usec);

Returns: A duration literal representing usec microseconds.

constexpr chrono::nanoseconds operator""ns(unsigned long long nsec);
constexpr chrono::duration<unspecified, nano> operator""ns(long double nsec);

Returns: A duration literal representing nsec nanoseconds.

23.17.5.9 duration algorithms

template <class Rep, class Period>
constexpr duration<Rep, Period> abs(duration<Rep, Period> d);

Remarks: This function shall not participate in overload resolution unless numeric_limits<Rep>::is_signed is true.

Returns: If d >= d.zero(), return d, otherwise return -d.

23.17.6 Class template time_point

template <class Clock, class Duration = typename Clock::duration>
class time_point {
public:
  using clock = Clock;
  using duration = Duration;
  using rep = typename duration::rep;
  using period = typename duration::period;
private:
  duration d_; // exposition only

public:
  // 23.17.6.1, construct
  constexpr time_point(); // has value epoch
  constexpr explicit time_point(const duration& d); // same as time_point() + d
  template <class Duration2>
  constexpr time_point(const time_point<clock, Duration2>& t);
  // 23.17.6.2, observer
  constexpr duration time_since_epoch() const;
  // 23.17.6.3, arithmetic
  constexpr time_point& operator+=(const duration& d);
  constexpr time_point& operator-=(const duration& d);

§ 23.17.6
// 23.17.6.4, special values
static constexpr time_point min();
static constexpr time_point max();

1 Clock shall meet the Clock requirements (23.17.3).
2 If Duration is not an instance of duration, the program is ill-formed.

23.17.6.1 time_point constructors

constexpr time_point();
1 Effects: Constructs an object of type time_point, initializing d_ with duration::zero(). Such a time_point object represents the epoch.

constexpr explicit time_point(const duration& d);
2 Effects: Constructs an object of type time_point, initializing d_ with d. Such a time_point object represents the epoch + d.

template <class Duration2>
constexpr time_point(const time_point<clock, Duration2>& t);
3 Remarks: This constructor shall not participate in overload resolution unless Duration2 is implicitly convertible to duration.
4 Effects: Constructs an object of type time_point, initializing d_ with t.time_since_epoch().

23.17.6.2 time_point observer

constexpr duration time_since_epoch() const;
1 Returns: d_.

23.17.6.3 time_point arithmetic

constexpr time_point& operator+=(const duration& d);
1 Effects: As if by: d_ += d;
2 Returns: *this.

constexpr time_point& operator-=(const duration& d);
3 Effects: As if by: d_ -= d;
4 Returns: *this.

23.17.6.4 time_point special values

static constexpr time_point min();
1 Returns: time_point(duration::min()).

static constexpr time_point max();
2 Returns: time_point(duration::max()).

23.17.6.5 time_point non-member arithmetic

template <class Clock, class Duration1, class Rep2, class Period2>
constexpr time_point<Clock, common_type_t<Duration1, duration<Rep2, Period2>>> operator+(const time_point<Clock, Duration1>& lhs, const duration<Rep2, Period2>& rhs);
1 Returns: CT(lhs.time_since_epoch() + rhs), where CT is the type of the return value.
template <class Rep1, class Period1, class Clock, class Duration2>
constexpr time_point<Clock, common_type_t<duration<Rep1, Period1>, Duration2>>
operator+(const duration<Rep1, Period1>& lhs, const time_point<Clock, Duration2>& rhs);

Returns: rhs + lhs.

template <class Clock, class Duration1, class Rep2, class Period2>
constexpr time_point<Clock, common_type_t<Duration1, duration<Rep2, Period2>>>
operator-(const time_point<Clock, Duration1>& lhs, const duration<Rep2, Period2>& rhs);

Returns: CT(lhs.time_since_epoch() - rhs), where CT is the type of the return value.

template <class Clock, class Duration1, class Duration2>
constexpr common_type_t<Duration1, Duration2>
operator-(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);

Returns: lhs.time_since_epoch() - rhs.time_since_epoch().

23.17.6.6 time_point comparisons

template <class Clock, class Duration1, class Duration2>
constexpr bool operator==(const time_point<Clock, Duration1>& lhs,
const time_point<Clock, Duration2>& rhs);

Returns: lhs.time_since_epoch() == rhs.time_since_epoch().

template <class Clock, class Duration1, class Duration2>
constexpr bool operator!=(const time_point<Clock, Duration1>& lhs,
const time_point<Clock, Duration2>& rhs);

Returns: !(lhs == rhs).

template <class Clock, class Duration1, class Duration2>
constexpr bool operator<(const time_point<Clock, Duration1>& lhs,
const time_point<Clock, Duration2>& rhs);

Returns: lhs.time_since_epoch() < rhs.time_since_epoch().

template <class Clock, class Duration1, class Duration2>
constexpr bool operator<=(const time_point<Clock, Duration1>& lhs,
const time_point<Clock, Duration2>& rhs);

Returns: !(rhs < lhs).

template <class Clock, class Duration1, class Duration2>
constexpr bool operator>(const time_point<Clock, Duration1>& lhs,
const time_point<Clock, Duration2>& rhs);

Returns: rhs < lhs.

template <class Clock, class Duration1, class Duration2>
constexpr bool operator>=(const time_point<Clock, Duration1>& lhs,
const time_point<Clock, Duration2>& rhs);

Returns: !(lhs < rhs).

23.17.6.7 time_point_cast

template <class ToDuration, class Clock, class Duration>
constexpr time_point<Clock, ToDuration>
time_point_cast(const time_point<Clock, Duration>& t);

§ 23.17.6.7
Remarks: This function shall not participate in overload resolution unless `ToDuration` is a specialization of `duration`.

Returns:

```cpp
time_point<Clock, ToDuration>(duration_cast<ToDuration>(t.time_since_epoch()))
```

```cpp
template <class ToDuration, class Clock, class Duration>
constexpr time_point<Clock, ToDuration>
floor(const time_point<Clock, Duration>& tp);
```

Remarks: This function shall not participate in overload resolution unless `ToDuration` is a specialization of `duration`.

Returns: `time_point<Clock, ToDuration>(floor<ToDuration>(tp.time_since_epoch()))`.

```cpp
template <class ToDuration, class Clock, class Duration>
constexpr time_point<Clock, ToDuration>
ceil(const time_point<Clock, Duration>& tp);
```

Remarks: This function shall not participate in overload resolution unless `ToDuration` is a specialization of `duration`.

Returns: `time_point<Clock, ToDuration>(ceil<ToDuration>(tp.time_since_epoch()))`.

```cpp
template <class ToDuration, class Clock, class Duration>
constexpr time_point<Clock, ToDuration>
round(const time_point<Clock, Duration>& tp);
```

Remarks: This function shall not participate in overload resolution unless `ToDuration` is a specialization of `duration`, and `treat_as_floating_point_v<typename ToDuration::rep>` is `false`.

Returns: `time_point<Clock, ToDuration>(round<ToDuration>(tp.time_since_epoch()))`.

### 23.17.7 Clocks

The types defined in this subclause shall satisfy the TrivialClock requirements (23.17.3).

#### 23.17.7.1 Class `system_clock`

Objects of class `system_clock` represent wall clock time from the system-wide realtime clock.

```cpp
class system_clock {
public:
    using rep = unspecified;
    using period = ratio<unspecified, unspecified>;
    using duration = chrono::duration<rep, period>;
    using time_point = chrono::time_point<system_clock>;
    static constexpr bool is_steady = unspecified;

    static time_point now() noexcept;
    // Map to C API
    static time_t to_time_t (const time_point& t) noexcept;
    static time_point from_time_t(time_t t) noexcept;
};
```

using `system_clock::rep = unspecified`;

Requires: `system_clock::duration::min() < system_clock::duration::zero()` shall be `true`.

[Note: This implies that `rep` is a signed type. — end note]

```cpp
static time_t to_time_t(const time_point& t) noexcept;
```

§ 23.17.7.1
3  Returns: A `time_t` object that represents the same point in time as `t` when both values are restricted to the coarser of the precisions of `time_t` and `time_point`. It is implementation-defined whether values are rounded or truncated to the required precision.

    static time_point from_time_t(time_t t) noexcept;

4  Returns: A `time_point` object that represents the same point in time as `t` when both values are restricted to the coarser of the precisions of `time_t` and `time_point`. It is implementation-defined whether values are rounded or truncated to the required precision.

23.17.7.2 Class `steady_clock` [time.clock.steady]

Objects of class `steady_clock` represent clocks for which values of `time_point` never decrease as physical time advances and for which values of `time_point` advance at a steady rate relative to real time. That is, the clock may not be adjusted.

    class steady_clock {
    public:
        using rep = unspecified;
        using period = ratio<unspecified, unspecified>;
        using duration = chrono::duration<rep, period>;
        using time_point = chrono::time_point<unspecified, duration>;
        static constexpr bool is_steady = true;

        static time_point now() noexcept;
    };

23.17.7.3 Class `high_resolution_clock` [time.clock.hires]

Objects of class `high_resolution_clock` represent clocks with the shortest tick period. `high_resolution_clock` may be a synonym for `system_clock` or `steady_clock`.

    class high_resolution_clock {
    public:
        using rep = unspecified;
        using period = ratio<unspecified, unspecified>;
        using duration = chrono::duration<rep, period>;
        using time_point = chrono::time_point<unspecified, duration>;
        static constexpr bool is_steady = unspecified;

        static time_point now() noexcept;
    };

23.17.8 Header `<ctime>` synopsis [ctime.syn]

    #define NULL see 21.2.3
    #define CLOCKS_PER_SEC see below
    #define TIME_UTC see below

    namespace std {
        using size_t = see 21.2.4;
        using clock_t = see below;
        using time_t = see below;

        struct timespec;
        struct tm;

        clock_t clock();
        double difftime(time_t time1, time_t time0);
time_t mktime(struct tm* timeptr);
#include "time.h"

int timespec_get(timespec* ts, int base);

char* asctime(const struct tm* timeptr);

char* ctime(const time_t* timer);

struct tm* gmtime(const time_t* timer);

struct tm* localtime(const time_t* timer);

size_t strftime(char* s, size_t maxsize, const char* format, const struct tm* timeptr);

1 The contents of the header <ctime> are the same as the C standard library header <time.h>.

2 The functions asctime, ctime, gmtime, and localtime are not required to avoid data races (20.5.5.9).

See also: ISO C 7.27.

23.18 Class type_index

23.18.1 Header <typeindex> synopsis
namespace std {
    class type_index;
    template <class T> struct hash;
    template<> struct hash<type_index>;
}

23.18.2 type_index overview

namespace std {
    class type_index {
        public:
            type_index(const type_info& rhs) noexcept;
            bool operator==(const type_index& rhs) const noexcept;
            bool operator!=(const type_index& rhs) const noexcept;
            bool operator< (const type_index& rhs) const noexcept;
            bool operator<= (const type_index& rhs) const noexcept;
            bool operator> (const type_index& rhs) const noexcept;
            bool operator>= (const type_index& rhs) const noexcept;
            size_t hash_code() const noexcept;
            const char* name() const noexcept;
        private:
            const type_info* target;   // exposition only
            // Note that the use of a pointer here, rather than a reference,
            // means that the default copy/move constructor and assignment
            // operators will be provided and work as expected.
    };
}

1 The class type_index provides a simple wrapper for type_info which can be used as an index type in
associative containers (26.4) and in unordered associative containers (26.5).

23.18.3 type_index members

        type_index(const type_info& rhs) noexcept;

1 Effects: Constructs a type_index object, the equivalent of target = &rhs.

bool operator==(const type_index& rhs) const noexcept;

2 Returns: *target == *rhs.target.

23.18.3 722

§ 23.18.3
bool operator!=(const type_index& rhs) const noexcept;

Returns: *target != *rhs.target.

bool operator<(const type_index& rhs) const noexcept;

Returns: target->before(*rhs.target).

bool operator<=(const type_index& rhs) const noexcept;

Returns: !rhs.target->before(*target).

bool operator>=(const type_index& rhs) const noexcept;

Returns: !target->before(*rhs.target).

bool operator>=(const type_index& rhs) const noexcept;

Returns: target->hash_code().

const char* name() const noexcept;

Returns: target->name().

23.18.4 Hash support

For an object index of type type_index, hash<type_index>()(index) shall evaluate to the same result as index.hash_code().

23.19 Execution policies

23.19.1 In general

This subclause describes classes that are execution policy types. An object of an execution policy type indicates the kinds of parallelism allowed in the execution of an algorithm and expresses the consequent requirements on the element access functions. [Example:

using namespace std;
vector<int> v = /* ... */;

// standard sequential sort
sort(v.begin(), v.end());

// explicitly sequential sort
sort(execution::seq, v.begin(), v.end());

// permitting parallel execution
sort(execution::par, v.begin(), v.end());

// permitting vectorization as well
sort(execution::par_unseq, v.begin(), v.end());

—end example] [Note: Because different parallel architectures may require idiosyncratic parameters for efficient execution, implementations may provide additional execution policies to those described in this standard as extensions. —end note]

23.19.2 Header <execution> synopsis

§ 23.19.2
namespace std {
    // 23.19.3, execution policy type trait
    template<class T> struct is_execution_policy;
    template<class T> inline constexpr bool is_execution_policy_v = is_execution_policy<T>::value;
}

namespace std::execution {
    // 23.19.4, sequenced execution policy
    class sequenced_policy;
    // 23.19.5, parallel execution policy
    class parallel_policy;
    // 23.19.6, parallel and unsequenced execution policy
    class parallel_unsequenced_policy;
    // 23.19.7, execution policy objects
    inline constexpr sequenced_policy seq{ unspecified };
    inline constexpr parallel_policy par{ unspecified };
    inline constexpr parallel_unsequenced_policy par_unseq{ unspecified };
}

23.19.3 Execution policy type trait

    template<class T> struct is_execution_policy { see below };

    1 is_execution_policy can be used to detect execution policies for the purpose of excluding function
        signatures from otherwise ambiguous overload resolution participation.

    2 is_execution_policy<T> shall be a UnaryTypeTrait with a base characteristic of true_type if T is
        the type of a standard or implementation-defined execution policy, otherwise false_type.

        [ Note: This provision reserves the privilege of creating non-standard execution policies to the library
            implementation. — end note ]

    3 The behavior of a program that adds specializations for is_execution_policy is undefined.

23.19.4 Sequenced execution policy

    class execution::sequenced_policy { unspecified };

    1 The class execution::sequenced_policy is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and require that a parallel algorithm’s execution may not be parallelized.

    2 During the execution of a parallel algorithm with the execution::sequenced_policy policy, if the invocation of an element access function exits via an uncaught exception, terminate() shall be called.

23.19.5 Parallel execution policy

    class execution::parallel_policy { unspecified };

    1 The class execution::parallel_policy is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm’s execution may be parallelized.

    2 During the execution of a parallel algorithm with the execution::parallel_policy policy, if the invocation of an element access function exits via an uncaught exception, terminate() shall be called.

23.19.6 Parallel and unsequenced execution policy

    § 23.19.6
class execution::parallel_unsequenced_policy { unspecified; }

1 The class execution::parallel_unsequenced_policy is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm’s execution may be parallelized and vectorized.

2 During the execution of a parallel algorithm with the execution::parallel_unsequenced_policy policy, if the invocation of an element access function exits via an uncaught exception, terminate() shall be called.

23.19.7 Execution policy objects [execpol.objects]

inline constexpr execution::sequenced_policy execution::seq{ unspecified; }
inline constexpr execution::parallel_policy execution::par{ unspecified; }
inline constexpr execution::parallel_unsequenced_policy execution::par_unseq{ unspecified; }

1 The header <execution> declares global objects associated with each type of execution policy.
24 Strings library

24.1 General

This Clause describes components for manipulating sequences of any non-array POD (6.9) type. Such types are called char-like types, and objects of char-like types are called char-like objects or simply characters.

The following subclauses describe a character traits class, a string class, and null-terminated sequence utilities, as summarized in Table 53.

Table 53 — Strings library summary

<table>
<thead>
<tr>
<th>Subclause</th>
<th>Header(s)</th>
</tr>
</thead>
<tbody>
<tr>

24.2 Character traits

This subclause defines requirements on classes representing character traits, and defines a class template char_traits<charT>, along with four specializations, char_traits<char>, char_traits<char16_t>, char_traits<char32_t>, and char_traits<wchar_t>, that satisfy those requirements.

Most classes specified in Clauses 24.3 and 30 need a set of related types and functions to complete the definition of their semantics. These types and functions are provided as a set of member typedef-names and functions in the template parameter traits used by each such template. This subclause defines the semantics of these members.

To specialize those templates to generate a string or iostream class to handle a particular character container type CharT, that and its related character traits class Traits are passed as a pair of parameters to the string or iostream template as parameters charT and traits. Traits::char_type shall be the same as CharT.

This subclause specifies a class template, char_traits<charT>, and four explicit specializations of it, char_traits<char>, char_traits<char16_t>, char_traits<char32_t>, and char_traits<wchar_t>, all of which appear in the header <string> and satisfy the requirements below.

24.2.1 Character traits requirements

In Table 54, X denotes a Traits class defining types and functions for the character container type CharT; c and d denote values of type CharT; p and q denote values of type const CharT*; s denotes a value of type CharT; n, i and j denote values of type size_t; e and f denote values of type X::int_type; pos denotes a value of type X::pos_type; state denotes a value of type X::state_type; and r denotes an lvalue of type CharT. Operations on Traits shall not throw exceptions.

</table>

2 The class template

```cpp
template<class charT> struct char_traits;
```

shall be provided in the header `<string>` as a basis for explicit specializations.

24.2.2 Traits typedefs

```cpp
using char_type = CHAR_T;
```

1 The type `char_type` is used to refer to the character container type in the implementation of the library classes defined in 24.3 and Clause 30.

```cpp
using int_type = INT_T;
```

2 Requires: For a certain character container type `char_type`, a related container type `INT_T` shall be a type or class which can represent all of the valid characters converted from the corresponding `char_type` values, as well as an end-of-file value, `eof()`. The type `int_type` represents a character container type which can hold end-of-file to be used as a return type of the iostream class member functions.²⁴

```cpp
using off_type = implementation-defined;
using pos_type = implementation-defined;
```

3 Requires: Requirements for `off_type` and `pos_type` are described in 30.2.2 and 30.3.

```cpp
using state_type = STATE_T;
```

4 Requires: `state_type` shall meet the requirements of `CopyAssignable` (Table 26), `CopyConstructible` (Table 24), and `DefaultConstructible` (Table 22) types.

24.2.3 char_traits specializations

²⁴) If `eof()` can be held in `char_type` then some iostreams operations may give surprising results.
namespace std {
    template<> struct char_traits<char>;
    template<> struct char_traits<char16_t>;
    template<> struct char_traits<char32_t>;
    template<> struct char_traits<wchar_t>;
}

The header `<string>` shall define four specializations of the class template char_traits: char_traits<char>, char_traits<char16_t>, char_traits<char32_t>, and char_traits<wchar_t>.

The requirements for the members of these specializations are given in Clause 24.2.1.

24.2.3.1 struct char_traits<char>  

namespace std {
    template<> struct char_traits<char> {
        using char_type = char;
        using int_type = int;
        using off_type = streamoff;
        using pos_type = streampos;
        using state_type = mbstate_t;

        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;
        static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
        static constexpr size_t length(const char_type* s);
        static constexpr const char_type* find(const char_type* s, size_t n, const char_type& a);
        static char_type* move(char_type* s1, const char_type* s2, size_t n);
        static char_type* copy(char_type* s1, const char_type* s2, size_t n);
        static char_type* assign(char_type* s, size_t n, char_type a);
        static constexpr int_type not_eof(int_type c) noexcept;
        static constexpr char_type to_char_type(int_type c) noexcept;
        static constexpr int_type to_int_type(char_type c) noexcept;
        static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
        static constexpr int_type eof() noexcept;
    };
}

1 The defined types for int_type, pos_type, off_type, and state_type shall be int, streampos, streamoff, and mbstate_t respectively.

2 The type streampos shall be an implementation-defined type that satisfies the requirements for pos_type in 30.2.2 and 30.3.

3 The type streamoff shall be an implementation-defined type that satisfies the requirements for off_type in 30.2.2 and 30.3.

4 The type mbstate_t is defined in `<cwchar>` and can represent any of the conversion states that can occur in an implementation-defined set of supported multibyte character encoding rules.

5 The two-argument member assign shall be defined identically to the built-in operator =. The two-argument members eq and lt shall be defined identically to the built-in operators == and < for type unsigned char.

6 The member eof() shall return EOF.

24.2.3.2 struct char_traits<char16_t>  

[char.traits.specializations.char16_t]
namespace std {
    template<> struct char_traits<char16_t> {
        using char_type = char16_t;
        using int_type = uint_least16_t;
        using off_type = streamoff;
        using pos_type = u16streampos;
        using state_type = mbstate_t;

        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;
        static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
        static constexpr size_t length(const char_type* s);
        static constexpr const char_type* find(const char_type* s, size_t n, const char_type& a);
        static char_type* move(char_type* s1, const char_type* s2, size_t n);
        static char_type* copy(char_type* s1, const char_type* s2, size_t n);
        static char_type* assign(char_type* s, size_t n, char_type a);
        static constexpr int_type not_eof(int_type c) noexcept;
        static constexpr char_type to_char_type(int_type c) noexcept;
        static constexpr int_type to_int_type(char_type c) noexcept;
        static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
        static constexpr int_type eof() noexcept;
    };

1. The type u16streampos shall be an implementation-defined type that satisfies the requirements for pos_type in 30.2.2 and 30.3.

2. The two-argument members assign, eq, and lt shall be defined identically to the built-in operators =, ==, and < respectively.

3. The member eof() shall return an implementation-defined constant that cannot appear as a valid UTF-16 code unit.

24.2.3.3 struct char_traits<char32_t> [char.traits.specializations.char32_t]

namespace std {
    template<> struct char_traits<char32_t> {
        using char_type = char32_t;
        using int_type = uint_least32_t;
        using off_type = streamoff;
        using pos_type = u32streampos;
        using state_type = mbstate_t;

        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;
        static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
        static constexpr size_t length(const char_type* s);
        static constexpr const char_type* find(const char_type* s, size_t n, const char_type& a);
        static char_type* move(char_type* s1, const char_type* s2, size_t n);
        static char_type* copy(char_type* s1, const char_type* s2, size_t n);
        static char_type* assign(char_type* s, size_t n, char_type a);
        static constexpr int_type not_eof(int_type c) noexcept;
        static constexpr char_type to_char_type(int_type c) noexcept;
        static constexpr int_type to_int_type(char_type c) noexcept;
        static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
    };

§ 24.2.3.3
static constexpr int_type not_eof(int_type c) noexcept;
static constexpr char_type to_char_type(int_type c) noexcept;
static constexpr int_type to_int_type(char_type c) noexcept;
static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
static constexpr int_type eof() noexcept;
};
}

1 The type u32streampos shall be an implementation-defined type that satisfies the requirements for pos_type in 30.2.2 and 30.3.

2 The two-argument members assign, eq, and lt shall be defined identically to the built-in operators ==, and < respectively.

3 The member eof() shall return an implementation-defined constant that cannot appear as a Unicode code point.

4 The defined types for int_type, pos_type, and state_type shall be wint_t, wstreampos, and mbstate_t respectively.

The two-argument members assign, eq, and lt shall be defined identically to the built-in operators ==, and < respectively.
The member `eof()` shall return `WEOF`.

24.3 String classes

The header `<string>` defines the `basic_string` class template for manipulating varying-length sequences of char-like objects and four `typedef-names`, `string`, `u16string`, `u32string`, and `wstring`, that name the specializations `basic_string<char>`, `basic_string<char16_t>`, `basic_string<char32_t>`, and `basic_string<wchar_t>`, respectively.

24.3.1 Header `<string>` synopsis

```cpp
#include <initializer_list>

namespace std {
  // 24.2, character traits
  template<class charT> struct char_traits;
  template<> struct char_traits<char>;
  template<> struct char_traits<char16_t>;
  template<> struct char_traits<char32_t>;
  template<> struct char_traits<wchar_t>;

  // 24.3.2, basic_string
  template<class charT, class traits = char_traits<charT>,
           class Allocator = allocator<charT>>
  class basic_string;

24.3.2 Class template basic_string

The class template basic_string describes objects that can store a sequence consisting of a varying number of arbitrary char-like objects with the first element of the sequence at position zero. Such a sequence is also called a “string” if the type of the char-like objects that it holds is clear from context. In the rest of this Clause, the type of the char-like objects held in a basic_string object is designated by charT.

The member functions of basic_string use an object of the Allocator class passed as a template parameter to allocate and free storage for the contained char-like objects.225

A basic_string is a contiguous container (26.2.1).

In all cases, size() <= capacity().

The functions described in this Clause can report two kinds of errors, each associated with an exception type:

(5.1) — a length error is associated with exceptions of type length_error (22.2.5);
(5.2) — an out-of-range error is associated with exceptions of type out_of_range (22.2.6).

    basic_string(InputIterator, InputIterator, Allocator = Allocator())
        -> basic_string<typename iterator_traits<InputIterator>::value_type,
            char_traits<typename iterator_traits<InputIterator>::value_type>,
            Allocator>;
    
24.3.2.1 basic_string general requirements  [string.require]

1 If any operation would cause size() to exceed max_size(), that operation shall throw an exception object of type length_error.

2 If any member function or operator of basic_string throws an exception, that function or operator shall have no other effect.

3 In every specialization basic_string<charT, traits, Allocator>, the type allocator_traits<Allocator>::value_type shall name the same type as charT. Every object of type basic_string<charT, traits, Allocator> shall use an object of type Allocator to allocate and free storage for the contained charT objects as needed. The Allocator object used shall be obtained as described in 26.2.1. In every specialization basic_string<charT, traits, Allocator>, the type traits shall satisfy the character traits requirements (24.2), and the type traits::char_type shall name the same type as charT.

4 References, pointers, and iterators referring to the elements of a basic_string sequence may be invalidated by the following uses of that basic_string object:

(4.1) — as an argument to any standard library function taking a reference to non-const basic_string as an argument.226

(4.2) — Calling non-const member functions, except operator[], at, data, front, back, begin, rbegin, end, and rend.

24.3.2.2 basic_string constructors and assignment operators  [string.cons]

explicit basic_string(const Allocator& a) noexcept;

Effects: Constructs an object of class basic_string. The postconditions of this function are indicated in Table 55.

226) For example, as an argument to non-member functions swap() (24.3.3.8), operator>>() (24.3.3.9), and getline() (24.3.3.9), or as an argument to basic_string::swap().
Table 55 — basic_string(const Allocator&) effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>data()</td>
<td>a non-null pointer that is copyable and can have 0 added to it</td>
</tr>
<tr>
<td>size()</td>
<td>0</td>
</tr>
<tr>
<td>capacity()</td>
<td>an unspecified value</td>
</tr>
</tbody>
</table>

basic_string(const basic_string& str);
basic_string(basic_string&& str) noexcept;

Effects: Constructs an object of class basic_string as indicated in Table 56. In the second form, str is left in a valid state with an unspecified value.

Table 56 — basic_string(const basic_string&) effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>data()</td>
<td>points at the first element of an allocated copy of the array whose first element is pointed at by str.data()</td>
</tr>
<tr>
<td>size()</td>
<td>str.size()</td>
</tr>
<tr>
<td>capacity()</td>
<td>a value at least as large as size()</td>
</tr>
</tbody>
</table>

basic_string(const basic_string& str, size_type pos, const Allocator& a = Allocator());

Throws: out_of_range if pos > str.size().

Effects: Constructs an object of class basic_string and determines the effective length rlen of the initial string value as str.size() - pos, as indicated in Table 57.

basic_string(const basic_string& str, size_type pos, size_type n, const Allocator& a = Allocator());

Throws: out_of_range if pos > str.size().

Effects: Constructs an object of class basic_string and determines the effective length rlen of the initial string value as the smaller of n and str.size() - pos, as indicated in Table 57.

Table 57 — basic_string(const basic_string&, size_type, const Allocator&) and basic_string(const basic_string&, size_type, size_type, const Allocator&) effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>data()</td>
<td>points at the first element of an allocated copy of rlen consecutive elements of the string controlled by str beginning at position pos</td>
</tr>
<tr>
<td>size()</td>
<td>rlen</td>
</tr>
<tr>
<td>capacity()</td>
<td>a value at least as large as size()</td>
</tr>
</tbody>
</table>

template<class T>
basic_string(const T& t, size_type pos, size_type n, const Allocator& a = Allocator());

§ 24.3.2.2
Effects: Creates a variable, \( sv \), as if by
\[
\text{basic_string_view<charT, traits> } sv = t;
\]
and then behaves the same as:
\[
\text{basic_string(sv.substr(pos, n), a);} 
\]
Remarks: This constructor shall not participate in overload resolution unless
\[
\text{is_convertible_v<const T&, basic_string_view<charT, traits>>}
\]
is true.

\[
\text{explicit basic_string(basic_string_view<charT, traits> } sv,\]
\[
\text{const Allocator& a = Allocator());}
\]
Effects: Same as \( \text{basic_string(sv.data(), sv.size(), a).} \)

\[
\text{basic_string(const charT* s, size_type n,}\]
\[
\text{const Allocator& a = Allocator());}
\]
Requires: \( s \) points to an array of at least \( n \) elements of charT.
Effects: Constructs an object of class basic_string and determines its initial string value from the
array of charT of length \( n \) whose first element is designated by \( s \), as indicated in Table 58.

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>data()</td>
<td>points at the first element of an allocated copy of the array whose first element is pointed at by ( s )</td>
</tr>
<tr>
<td>size()</td>
<td>( n )</td>
</tr>
<tr>
<td>capacity()</td>
<td>a value at least as large as size()</td>
</tr>
</tbody>
</table>

\[
\text{basic_string(const charT* s, const Allocator& a = Allocator());}
\]
Requires: \( s \) points to an array of at least \( \text{traits::length(s)} + 1 \) elements of charT.
Effects: Constructs an object of class basic_string and determines its initial string value from the
array of charT of length \( \text{traits::length(s)} \) whose first element is designated by \( s \), as indicated in Table 59.

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>data()</td>
<td>points at the first element of an allocated copy of the array whose first element is pointed at by ( s )</td>
</tr>
<tr>
<td>size()</td>
<td>( \text{traits::length(s)} )</td>
</tr>
<tr>
<td>capacity()</td>
<td>a value at least as large as size()</td>
</tr>
</tbody>
</table>

\[
\text{basic_string(size_type n, charT c, const Allocator& a = Allocator());}
\]
Requires: \( n < \text{npos} \).
Effects: Constructs an object of class basic_string and determines its initial string value by repeating the char-like object \( c \) for all \( n \) elements, as indicated in Table 60.

\[
\text{template<class InputIterator>}\]
\[
\text{basic_string(InputIterator begin, InputIterator end,}\]
\[
\text{const Allocator& a = Allocator());}
\]
Effects: If InputIterator is an integral type, equivalent to:
Table 60 — basic_string(size_t, charT, const Allocator&) effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>data()</td>
<td>points at the first element of an allocated array of n elements, each storing the initial value c</td>
</tr>
<tr>
<td>size()</td>
<td>n</td>
</tr>
<tr>
<td>capacity()</td>
<td>a value at least as large as size()</td>
</tr>
</tbody>
</table>

basic_string(static_cast<size_type>(begin), static_cast<value_type>(end), a);
Otherwise constructs a string from the values in the range [begin, end), as indicated in the Sequence Requirements table (see 26.2.3).

basic_string(initializer_list<charT> il, const Allocator& a = Allocator());
17  Effects: Same as basic_string(il.begin(), il.end(), a).

basic_string(const basic_string& str, const Allocator& alloc);
basic_string(basic_string&& str, const Allocator& alloc);
18  Effects: Constructs an object of class basic_string as indicated in Table 61. The stored allocator is constructed from alloc. In the second form, str is left in a valid state with an unspecified value.

Table 61 — basic_string(const basic_string&, const Allocator&) and basic_string(basic_string&&, const Allocator&) effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>data()</td>
<td>points at the first element of an allocated copy of the array whose first element is pointed at by the original value of str.data().</td>
</tr>
<tr>
<td>size()</td>
<td>the original value of str.size()</td>
</tr>
<tr>
<td>capacity()</td>
<td>a value at least as large as size()</td>
</tr>
<tr>
<td>get_allocator()</td>
<td>alloc</td>
</tr>
</tbody>
</table>

19  Throws: The second form throws nothing if alloc == str.get_allocator().

template<class InputIterator,
        class Allocator = allocator<typename iterator_traits<InputIterator>::value_type>>
basic_string(InputIterator, InputIterator, Allocator = Allocator())
20  -> basic_string<typename iterator_traits<InputIterator>::value_type,
        char_traits<typename iterator_traits<InputIterator>::value_type>,
        Allocator>;

Remarks: Shall not participate in overload resolution if InputIterator is a type that does not qualify as an input iterator, or if Allocator is a type that does not qualify as an allocator (26.2.1).

basic_string& operator=(const basic_string& str);
21  Effects: If *this and str are not the same object, modifies *this as shown in Table 62.
22  If *this and str are the same object, the member has no effect.
23  Returns: *this.
Table 62 — operator=(const basic_string&) effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>data()</td>
<td>points at the first element of an allocated copy of the array whose first element is pointed at by str.data()</td>
</tr>
<tr>
<td>size()</td>
<td>str.size()</td>
</tr>
<tr>
<td>capacity()</td>
<td>a value at least as large as size()</td>
</tr>
</tbody>
</table>

allocator_traits<Allocator>::is_always_equal::value);

Effects: Move assigns as a sequence container (26.2), except that iterators, pointers and references may be invalidated.

Returns: *this.

basic_string& operator=(basic_string_view<charT, traits> sv);

Effects: Equivalent to: return assign(sv);

basic_string& operator=(const charT* s);

Returns: *this = basic_string(s).

Remarks: Uses traits::length().

basic_string& operator=(charT c);

Returns: *this = basic_string(1, c).

basic_string& operator=(initializer_list<charT> il);

Effects: As if by: *this = basic_string(il);

Returns: *this.

24.3.2.3 basic_string iterator support [string.iterators]

iterator begin() noexcept;
const_iterator begin() const noexcept;
const_iterator cbegin() const noexcept;

Returns: An iterator referring to the first character in the string.

iterator end() noexcept;
const_iterator end() const noexcept;
const_iterator cend() const noexcept;

Returns: An iterator which is the past-the-end value.

reverse_iterator rbegin() noexcept;
const_reverse_iterator rbegin() const noexcept;
const_reverse_iterator crbegin() const noexcept;

Returns: An iterator which is semantically equivalent to reverse_iterator(end()).

reverse_iterator rend() noexcept;
const_reverse_iterator rend() const noexcept;
const_reverse_iterator crend() const noexcept;

Returns: An iterator which is semantically equivalent to reverse_iterator(begin()).
24.3.2.4 basic_string capacity

size_type size() const noexcept;

Returns: A count of the number of char-like objects currently in the string.
Complexity: Constant time.

size_type length() const noexcept;

Returns: size() size_type max_size() const noexcept;

Returns: The largest possible number of char-like objects that can be stored in a basic_string. Complexity: Constant time.

void resize(size_type n, charT c);

Throws: length_error if n > max_size(). Effects: Alters the length of the string designated by *this as follows:

— If n <= size(), the function replaces the string designated by *this with a string of length n whose elements are a copy of the initial elements of the original string designated by *this.

— If n > size(), the function replaces the string designated by *this with a string of length n whose first size() elements are a copy of the original string designated by *this, and whose remaining elements are all initialized to c.

void resize(size_type n);

Effects: As if by resize(n, charT()).

size_type capacity() const noexcept;

Returns: The size of the allocated storage in the string.

void reserve(size_type res_arg=0);

The member function reserve() is a directive that informs a basic_string object of a planned change in size, so that it can manage the storage allocation accordingly. Effects: After reserve(), capacity() is greater or equal to the argument of reserve. [Note: Calling reserve() with a res_arg argument less than capacity() is in effect a non-binding shrink request. A call with res_arg <= size() is in effect a non-binding shrink-to-fit request. —end note]

Throws: length_error if res_arg > max_size(). 227

void shrink_to_fit();

Effects: shrink_to_fit is a non-binding request to reduce capacity() to size(). [Note: The request is non-binding to allow latitude for implementation-specific optimizations. —end note] It does not increase capacity(), but may reduce capacity() by causing reallocation. Complexity: Linear in the size of the sequence. Remarks: Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence as well as the past-the-end iterator. If no reallocation happens, they remain valid.

void clear() noexcept;

Effects: Behaves as if the function calls:

227) reserve() uses allocator_traits<Allocator>::allocate() which may throw an appropriate exception.
erase(begin(), end());

bool empty() const noexcept;

Returns: size() == 0.

### 24.3.2.5 basic_string element access

const_reference operator[](size_type pos) const;
reference operator[](size_type pos);

1 Requires: pos <= size().
2 Returns: *(begin() + pos) if pos < size(). Otherwise, returns a reference to an object of type charT with value charT(), where modifying the object to any value other than charT() leads to undefined behavior.
3 Throws: Nothing.
4 Complexity: Constant time.

const_reference at(size_type pos) const;
reference at(size_type pos);

5 Throws: out_of_range if pos >= size().
6 Returns: operator[](pos).

const charT& front() const;
charT& front();

7 Requires: !empty().
8 Effects: Equivalent to: return operator[](0);

const charT& back() const;
charT& back();

9 Requires: !empty().
10 Effects: Equivalent to: return operator[](size() - 1);

### 24.3.2.6 basic_string modifiers

#### 24.3.2.6.1 basic_string::operator+=

basic_string&
operator+=(const basic_string& str);

1 Effects: Calls append(str).
2 Returns: *this.

basic_string& operator+=(basic_string_view<charT, traits> sv);

3 Effects: Calls append(sv).
4 Returns: *this.

basic_string& operator+=(const charT* s);

5 Effects: Calls append(s).
6 Returns: *this.

basic_string& operator+=(charT c);

§ 24.3.2.6.1
24.3.2.6.2 `basic_string::append` [string.append]

`basic_string& append(const basic_string& str);`

- **Effects:** Calls `append(str.data(), str.size());`
- **Returns:** `*this`.

`basic_string& append(const basic_string& str, size_type pos, size_type n = npos);`

- **Throws:** `out_of_range` if `pos > str.size()`.
- **Effects:** Determines the effective length `rlen` of the string to append as the smaller of `n` and `str.size() - pos` and calls `append(str.data() + pos, rlen)`.
- **Returns:** `*this`.

`basic_string& append(basic_string_view<charT, traits> sv);`

- **Effects:** Equivalent to: `return append(sv.data(), sv.size());`

`template<class T> basic_string& append(const T& t, size_type pos, size_type n = npos);`

- **Throws:** `out_of_range` if `pos > sv.size()`.
- **Effects:** Creates a variable, `sv`, as if by `basic_string_view<charT, traits> sv = t`. Determines the effective length `rlen` of the string to append as the smaller of `n` and `sv.size() - pos` and calls `append(sv.data() + pos, rlen)`.
- **Remarks:** This function shall not participate in overload resolution unless `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and `is_convertible_v<const T&, const charT*>` is false.
- **Returns:** `*this`.

`basic_string& append(const charT* s, size_type n);`

- **Requires:** `s` points to an array of at least `n` elements of `charT`.
- **Throws:** `length_error` if `size() + n > max_size()`.
- **Effects:** The function replaces the string controlled by `*this` with a string of length `size() + n` whose first `size()` elements are a copy of the original string controlled by `*this` and whose remaining elements are a copy of the initial `n` elements of `s`.
- **Returns:** `*this`.

`basic_string& append(const charT* s);`

- **Requires:** `s` points to an array of at least `traits::length(s) + 1` elements of `charT`.
- **Effects:** Calls `append(s, traits::length(s));`
Returns: *this.

basic_string& append(size_type n, charT c);
  Effects: Equivalent to append(basic_string(n, c)).
  Returns: *this.

template<class InputIterator>
  basic_string& append(InputIterator first, InputIterator last);
  Requires: [first, last) is a valid range.
  Effects: Equivalent to append(basic_string(first, last, get_allocator())).
  Returns: *this.

basic_string& append(initializer_list<charT> il);
  Effects: Calls append(il.begin(), il.size()).
  Returns: *this.

void push_back(charT c);
  Effects: Equivalent to append(static_cast<size_type>(1), c).

24.3.2.6.3 basic_string::assign
  [string.assign]

basic_string& assign(const basic_string& str);
  Effects: Equivalent to *this = str.
  Returns: *this.

basic_string& assign(basic_string&& str)
  noexcept(allocator_traits<Allocator>::propagate_on_container_move_assignment::value ||
            allocator_traits<Allocator>::is_always_equal::value);
  Effects: Equivalent to *this = std::move(str).
  Returns: *this.

basic_string&
  assign(const basic_string& str, size_type pos, size_type n = npos);
  Throws: out_of_range if pos > str.size().
  Effects: Determines the effective length rlen of the string to assign as the smaller of n and str.size() - pos and calls assign(str.data() + pos, rlen).
  Returns: *this.

basic_string&
  assign(basic_string_view<charT, traits> sv);
  Effects: Equivalent to: return assign(sv.data(), sv.size());

template<class T>
  basic_string& assign(const T& t, size_type pos, size_type n = npos);
  Throws: out_of_range if pos > sv.size().
  Effects: Creates a variable, sv, as if by basic_string_view<charT, traits> sv = t. Determines the effective length rlen of the string to assign as the smaller of n and sv.size() - pos and calls assign(sv.data() + pos, rlen).

§ 24.3.2.6.3 749
Remarks: This function shall not participate in overload resolution unless is_convertible_v<const T&, basic_string_view<charT, traits>> is true and is_convertible_v<const T&, const charT*> is false.

Returns: *this.

basic_string& assign(const charT* s, size_type n);
Requires: s points to an array of at least n elements of charT.
Throws: length_error if n > max_size().
Effects: Replaces the string controlled by *this with a string of length n whose elements are a copy of those pointed to by s.
Returns: *this.

basic_string& assign(const charT* s);
Requires: s points to an array of at least traits::length(s) + 1 elements of charT.
Effects: Calls assign(s, traits::length(s)).
Returns: *this.

basic_string& assign(initializer_list<charT> il);
Effects: Calls assign(il.begin(), il.size()).
*this.

basic_string& assign(size_type n, charT c);
Effects: Equivalent to assign(basic_string(n, c)).
Returns: *this.

template<class InputIterator>
  basic_string& assign(InputIterator first, InputIterator last);
Effects: Equivalent to assign(basic_string(first, last, get_allocator())).
Returns: *this.

24.3.2.6.4 basic_string::insert

basic_string&
  insert(size_type pos, const basic_string& str);
Effects: Equivalent to: return insert(pos, str.data(), str.size());

basic_string&
  insert(size_type pos1, const basic_string& str, size_type pos2, size_type n = npos);
Returns: *this.

24.3.2.6.4 [string.insert]

basic_string&
  insert(size_type pos, basic_string_view<charT, traits> sv);
Effects: Equivalent to: return insert(pos, sv.data(), sv.size());
template<class T>
    basic_string& insert(size_type pos1, const T& t,
        size_type pos2, size_type n = npos);

    Throws: out_of_range if pos1 > size() or pos2 > sv.size().
    Effects: Creates a variable, sv, as if by basic_string_view<charT, traits> sv = t. Determines
        the effective length rlen of the string to assign as the smaller of n and sv.size() - pos2 and calls
        insert(pos1, sv.data() + pos2, rlen).
    Remarks: This function shall not participate in overload resolution unless is_convertible_v<const T&,
        basic_string_view<charT, traits>> is true and is_convertible_v<const T&, const charT*> is false.
    Returns: *this.

basic_string&
    insert(size_type pos, const charT* s, size_type n);

    Requires: s points to an array of at least n elements of charT.
    Throws: out_of_range if pos > size() or length_error if size() + n > max_size().
    Effects: Replaces the string controlled by *this with a string of length size() + n whose first pos
        elements are a copy of the initial elements of the original string controlled by *this and whose next n
        elements are a copy of the elements in s and whose remaining elements are a copy of the remaining
        elements of the original string controlled by *this.
    Returns: *this.

basic_string&
    insert(size_type pos, const charT* s);

    Requires: s points to an array of at least traits::length(s) + 1 elements of charT.
    Effects: Equivalent to: return insert(pos, s, traits::length(s));

basic_string&
    insert(size_type pos, size_type n, charT c);

    Effects: Equivalent to insert(pos, basic_string(n, c)).
    Returns: *this.

iterator insert(const_iterator p, charT c);

    Requires: p is a valid iterator on *this.
    Effects: Inserts a copy of c before the character referred to by p.
    Returns: An iterator which refers to the copy of the inserted character.

iterator insert(const_iterator p, size_type n, charT c);

    Requires: p is a valid iterator on *this.
    Effects: Inserts n copies of c before the character referred to by p.
    Returns: An iterator which refers to the copy of the first inserted character, or p if n == 0.

template<class InputIterator>
    iterator insert(const_iterator p, InputIterator first, InputIterator last);

    Requires: p is a valid iterator on *this. [first, last) is a valid range.
    Effects: Equivalent to insert(p - begin(), basic_string(first, last, get_allocator())).
iterator insert(const_iterator p, initializer_list<charT> il);

Effects: As if by insert(p, il.begin(), il.end()).

Returns: An iterator which refers to the copy of the first inserted character, or p if il is empty.

### 24.3.2.6.5 basic_string::erase

basic_string& erase(size_type pos = 0, size_type n = npos);

1 \hspace{1em} Throws: out_of_range if pos > size().
2 \hspace{1em} Effects: Determines the effective length xlen of the string to be removed as the smaller of n and size() - pos.
3 \hspace{1em} The function then replaces the string controlled by *this with a string of length size() - xlen whose first pos elements are a copy of the initial elements of the original string controlled by *this, and whose remaining elements are a copy of the elements of the original string controlled by *this beginning at position pos + xlen.
4 \hspace{1em} Returns: *this.

iterator erase(const_iterator p);

5 \hspace{1em} Throws: Nothing.
6 \hspace{1em} Effects: Removes the character referred to by p.
7 \hspace{1em} Returns: An iterator which points to the element immediately following p prior to the element being erased. If no such element exists, end() is returned.

iterator erase(const_iterator first, const_iterator last);

8 \hspace{1em} Requires: first and last are valid iterators on *this, defining a range [first, last).
9 \hspace{1em} Throws: Nothing.
10 \hspace{1em} Effects: Removes the characters in the range [first, last).
11 \hspace{1em} Returns: An iterator which points to the element pointed to by last prior to the other elements being erased. If no such element exists, end() is returned.

void pop_back();

12 \hspace{1em} Requires: !empty().
13 \hspace{1em} Throws: Nothing.
14 \hspace{1em} Effects: Equivalent to erase(size() - 1, 1).

### 24.3.2.6.6 basic_string::replace

basic_string& replace(size_type pos1, size_type n1, const basic_string& str);

1 \hspace{1em} Effects: Equivalent to: return replace(pos1, n1, str.data(), str.size());

basic_string& replace(size_type pos1, size_type n1, const basic_string& str, size_type pos2, size_type n2 = npos);

2 \hspace{1em} Throws: out_of_range if pos1 > size() or pos2 > str.size().
Effects: Determines the effective length \( rlen \) of the string to be inserted as the smaller of \( n2 \) and \( \text{str.size()} - \text{pos2} \) and calls replace(pos1, n1, str.data() + pos2, rlen).

Returns: *this.

\[
\text{basic_string} \& \text{replace(size_type pos1, size_type n1, basic_string_view<charT, traits> sv);} 
\]

Effects: Equivalent to: return replace(pos1, n1, sv.data(), sv.size());

template<class T>
\[
\text{basic_string} \& \text{replace(size_type pos1, size_type n1, const T} \& t, 
\quad \text{size_type pos2, size_type n2 = npos);} 
\]

Throws: out_of_range if pos1 > size() or pos2 > sv.size().

Effects: Creates a variable, sv, as if by basic_string_view<charT, traits> sv = t. Determines the effective length \( rlen \) of the string to be inserted as the smaller of \( n2 \) and \( sv\text{.size()} - \text{pos2} \) and calls replace(pos1, n1, sv.data() + pos2, rlen).

Remarks: This function shall not participate in overload resolution unless is_convertible_v<const T} \&, basic_string_view<charT, traits>> is true and is_convertible_v<const T} \&, const charT*> is false.

Returns: *this.

\[
\text{basic_string} \& \text{replace(size_type pos1, size_type n1, const charT} * s, size_type n2);} 
\]

Requires: s points to an array of at least n2 elements of charT.

Throws: out_of_range if pos1 > size() or length_error if the length of the resulting string would exceed max_size() (see below).

Effects: Determines the effective length \( xlen \) of the string to be removed as the smaller of \( n1 \) and size() - pos1. If size() - xlen >= max_size() - n2 throws length_error. Otherwise, the function replaces the string controlled by *this with a string of length size() - xlen + n2 whose first \( pos1 \) elements are a copy of the initial elements of the original string controlled by *this, whose next \( n2 \) elements are a copy of the initial \( n2 \) elements of s, and whose remaining elements are a copy of the elements of the original string controlled by *this beginning at position pos + xlen.

Returns: *this.

\[
\text{basic_string} \& \text{replace(size_type pos, size_type n, const charT} * s);} 
\]

Requires: s points to an array of at least traits::length(s) + 1 elements of charT.

Effects: Equivalent to: return replace(pos, n, s, traits::length(s));

\[
\text{basic_string} \& \text{replace(size_type pos1, size_type n1, 
\quad size_type n2, charT c);} 
\]

Effects: Equivalent to replace(pos1, n1, basic_string(n2, c)).

Returns: *this.

\[
\text{basic_string} \& \text{replace(const_iterator i1, const_iterator i2, const basic_string} & str);} 
\]

Requires: [begin(), i1) and [i1, i2) are valid ranges.

Effects: Calls replace(i1 - begin(), i2 - i1, str).
© ISO/IEC

Returns: \*this.

basic_string& replace(const_iterator i1, const_iterator i2,
                      basic_string_view<CharT, traits> sv);

Requires: \[begin(), i1) and \[i1, i2) are valid ranges.

Effects: Calls replace(i1 - begin(), i2 - i1, sv).

Returns: \*this.

basic_string&
replace(const_iterator i1, const_iterator i2, const CharT* s, size_type n);

Requires: \[begin(), i1) and \[i1, i2) are valid ranges and s points to an array of at least n elements of CharT.

Effects: Calls replace(i1 - begin(), i2 - i1, s, n).

Returns: \*this.

basic_string& replace(const_iterator i1, const_iterator i2, const CharT* s);

Requires: \[begin(), i1) and \[i1, i2) are valid ranges and s points to an array of at least traits::length(s) + 1 elements of CharT.

Effects: Calls replace(i1 - begin(), i2 - i1, s, traits::length(s)).

Returns: \*this.

basic_string& replace(const_iterator i1, const_iterator i2, size_type n,
                      CharT c);

Requires: \[begin(), i1) and \[i1, i2) are valid ranges.

Effects: Calls replace(i1 - begin(), i2 - i1, basic_string(n, c)).

Returns: \*this.

template<class InputIterator>

basic_string& replace(const_iterator i1, const_iterator i2,
                      InputIterator j1, InputIterator j2);

Requires: \[begin(), i1), \[i1, i2) and \[j1, j2) are valid ranges.

Effects: Calls replace(i1 - begin(), i2 - i1, basic_string(j1, j2, get_allocator())).

Returns: \*this.

basic_string& replace(const_iterator i1, const_iterator i2,
                      initializer_list<CharT> il);

Requires: \[begin(), i1) and \[i1, i2) are valid ranges.

Effects: Calls replace(i1 - begin(), i2 - i1, il.begin(), il.size()).

Returns: \*this.

24.3.2.6.7 basic_string::copy

size_type copy(CharT* s, size_type n, size_type pos = 0) const;

Let rlen be the smaller of n and size() - pos.

Throws: out_of_range if pos > size().

Requires: \[s, s + rlen) is a valid range.
4 Effects: Equivalent to: \texttt{traits::copy(s, data() + pos, rlen)}. \textit{[Note: This does not terminate s with a null object. — end note]}  
5 Returns: \texttt{rlen}.

24.3.2.6.8 \texttt{basic_string::swap}  

\texttt{void swap(basic_string& s)}  
\texttt{noexcept(allocator_traits<Allocator>::propagate_on_container_swap::value ||}  
\texttt{allocator_traits<Allocator>::is_always_equal::value);}  
1 Postconditions: \texttt{*this} contains the same sequence of characters that was in \texttt{s}, \texttt{s} contains the same sequence of characters that was in \texttt{*this}.  
2 Throws: Nothing.  
3 Complexity: Constant time.

24.3.2.7 \texttt{basic_string string operations}  

24.3.2.7.1 \texttt{basic_string accessors}  

\texttt{const charT* c_str()} const noexcept;  
\texttt{const charT* data()} const noexcept;  
1 Returns: A pointer \( p \) such that \( p + i = \&\texttt{operator[]}\( i \) for each \( i \) in \( [0, \texttt{size()}] \).  
2 Complexity: Constant time.  
3 Requires: The program shall not alter any of the values stored in the character array.  

\texttt{charT* data()} noexcept;  
1 Returns: A pointer \( p \) such that \( p + i = \&\texttt{operator[]}\( i \) for each \( i \) in \( [0, \texttt{size()}] \).  
2 Complexity: Constant time.  
3 Requires: The program shall not alter the value stored at \( p + \texttt{size()} \).  

\texttt{operator basic_string_view<charT, traits>() const noexcept;}  
7 Effects: Equivalent to: return \texttt{basic_string_view<charT, traits>(data(), size());}  
8 \texttt{allocator_type get_allocator()} const noexcept;  
8 Returns: A copy of the \texttt{Allocator} object used to construct the string or, if that allocator has been replaced, a copy of the most recent replacement.

24.3.2.7.2 \texttt{basic_string::find}  

\texttt{size_type find(basic_string_view<charT, traits> sv, size_type pos = 0) const noexcept;}  
1 Effects: Determines the lowest position \( xpos \), if possible, such that both of the following conditions hold:  

\begin{align*}  
(1.1) & \text{ pos } \leq \text{xpos and xpos + sv.size()} \leq \text{size;} \\
(1.2) & \text{ traits::eq(at(xpos + I), sv.at(I)) for all elements I of the data referenced by sv.} 
\end{align*}  
2 Returns: \( xpos \) if the function can determine such a value for \( xpos \). Otherwise, returns \texttt{npos}.  

\texttt{size_type find(const basic_string& str, size_type pos = 0) const noexcept;}  
3 Equivalent to: return \texttt{find(basic_string_view<charT, traits>(str), pos);}  

\texttt{size_type find(const charT* s, size_type pos, size_type n) const;}
Returns: find(basic_string_view<charT, traits>(s, n), pos).

size_type find(const charT* s, size_type pos = 0) const;

Requires: s points to an array of at least traits::length(s) + 1 elements of charT.

Returns: find(basic_string_view<charT, traits>(s), pos).

size_type find(charT c, size_type pos = 0) const;

Returns: find(basic_string(1, c), pos).

24.3.2.7.3 basic_string::rfind

size_type rfind(basic_string_view<charT, traits> sv, size_type pos = npos) const noexcept;

Effects: Determines the highest position xpos, if possible, such that both of the following conditions hold:

1. xpos <= pos and xpos + sv.size() <= size();
2. traits::eq(at(xpos + I), sv.at(I)) for all elements I of the data referenced by sv.

Returns: xpos if the function can determine such a value for xpos. Otherwise, returns npos.

size_type rfind(const basic_string& str, size_type pos = npos) const noexcept;

Effects: Equivalent to: return rfind(basic_string_view<charT, traits>(str), pos);

size_type rfind(const charT* s, size_type pos, size_type n) const;

Returns: rfind(basic_string_view<charT, traits>(s, n), pos).

size_type rfind(const charT* s, size_type pos = npos) const;

Requires: s points to an array of at least traits::length(s) + 1 elements of charT.

Returns: rfind(basic_string_view<charT, traits>(s), pos).

size_type rfind(charT c, size_type pos = npos) const;

Returns: rfind(basic_string(1, c), pos).

24.3.2.7.4 basic_string::find_first_of

size_type find_first_of(basic_string_view<charT, traits> sv, size_type pos = 0) const noexcept;

Effects: Determines the lowest position xpos, if possible, such that both of the following conditions hold:

1. pos <= xpos and xpos < size();
2. traits::eq(at(xpos), sv.at(I)) for some element I of the data referenced by sv.

Returns: xpos if the function can determine such a value for xpos. Otherwise, returns npos.

size_type find_first_of(const basic_string& str, size_type pos = 0) const noexcept;

Effects: Equivalent to: return find_first_of(basic_string_view<charT, traits>(str), pos);

size_type find_first_of(const charT* s, size_type pos, size_type n) const;

Returns: find_first_of(basic_string_view<charT, traits>(s, n), pos).

size_type find_first_of(const charT* s, size_type pos = 0) const;

Requires: s points to an array of at least traits::length(s) + 1 elements of charT.
size_type find_first_of(basic_string_view<charT, traits>(s), pos);

size_type find_first_of(charT c, size_type pos = 0) const;

Returns: find_first_of(basic_string(1, c), pos).

24.3.2.7.5 basic_string::find_last_of

size_type find_last_of(basic_string_view<charT, traits> sv, size_type pos = npos) const noexcept;

Effects: Determines the highest position xpos, if possible, such that both of the following conditions hold:

(1.1) xpos <= pos and xpos < size();
(1.2) traits::eq(at(xpos), sv.at(I)) for some element I of the data referenced by sv.

Returns: xpos if the function can determine such a value for xpos. Otherwise, returns npos.

size_type find_last_of(const basic_string& str, size_type pos = npos) const noexcept;

Effects: Equivalent to: return find_last_of(basic_string_view<charT, traits>(str), pos);

size_type find_last_of(const charT* s, size_type pos, size_type n) const;

Returns: find_last_of(basic_string_view<charT, traits>(s, n), pos).

size_type find_last_of(const charT* s, size_type pos = npos) const;

Requires: s points to an array of at least traits::length(s) + 1 elements of charT.

Returns: find_last_of(basic_string_view<charT, traits>(s), pos).

size_type find_last_of(charT c, size_type pos = npos) const;

Returns: find_last_of(basic_string(1, c), pos).

24.3.2.7.6 basic_string::find_first_not_of

size_type find_first_not_of(basic_string_view<charT, traits> sv, size_type pos = 0) const noexcept;

Effects: Determines the lowest position xpos, if possible, such that both of the following conditions hold:

(1.1) pos <= xpos and xpos < size();
(1.2) traits::eq(at(xpos), sv.at(I)) for no element I of the data referenced by sv.

Returns: xpos if the function can determine such a value for xpos. Otherwise, returns npos.

size_type find_first_not_of(const basic_string& str, size_type pos = 0) const noexcept;

Effects: Equivalent to:

return find_first_not_of(basic_string_view<charT, traits>(str), pos);

size_type find_first_not_of(const charT* s, size_type pos, size_type n) const;

Returns: find_first_not_of(basic_string_view<charT, traits>(s, n), pos).

size_type find_first_not_of(const charT* s, size_type pos = 0) const;

Requires: s points to an array of at least traits::length(s) + 1 elements of charT.

Returns: find_first_not_of(basic_string_view<charT, traits>(s), pos).

size_type find_first_not_of(charT c, size_type pos = 0) const;

§ 24.3.2.7.6
Returns: `find_first_not_of(basic_string(1, c), pos)`.

### 24.3.2.7.7 basic_string::find_last_not_of

```cpp
data_type find_last_not_of(basic_string_view<charT, traits> sv, size_type pos = npos) const noexcept;
```

**Effects:** Determines the highest position `xpos`, if possible, such that both of the following conditions hold:

1. `xpos <= pos` and `xpos < size()`;
2. `traits::eq(at(xpos), sv.at(I))` for no element `I` of the data referenced by `sv`.

**Returns:** `xpos` if the function can determine such a value for `xpos`. Otherwise, returns `npos`.

```cpp
size_type find_last_not_of(const basic_string& str, size_type pos = npos) const noexcept;
```

**Effects:** Equivalent to:

```cpp
return find_last_not_of(basic_string_view<charT, traits>(str), pos);
```

```cpp
size_type find_last_not_of(const charT* s, size_type pos, size_type n) const;
```

**Returns:** `find_last_not_of(basic_string_view<charT, traits>(s), pos)`.

**Requires:** `s` points to an array of at least `traits::length(s) + 1` elements of `charT`.

```cpp
size_type find_last_not_of(charT c, size_type pos = npos) const;
```

**Returns:** `find_first_not_of(basic_string(1, c), pos)`.

### 24.3.2.7.8 basic_string::substr

```cpp
basic_string substr(size_type pos = 0, size_type n = npos) const;
```

**Throws:** `out_of_range` if `pos > size()`.

**Effects:** Determines the effective length `rlen` of the string to copy as the smaller of `n` and `size() - pos`.

**Returns:** `basic_string(data() + pos, rlen)`.

### 24.3.2.7.9 basic_string::compare

```cpp
int compare(basic_string_view<charT, traits> sv) const noexcept;
```

**Effects:** Determines the effective length `rlen` of the strings to compare as the smaller of `size()` and `sv.size()`. The function then compares the two strings by calling `traits::compare(data(), sv.data(), rlen)`.

**Returns:** The nonzero result if the result of the comparison is nonzero. Otherwise, returns a value as indicated in Table 63.

```cpp
int compare(size_type pos1, size_type n1, basic_string_view<charT, traits> sv) const;
```

**Effects:** Equivalent to:

```cpp
return basic_string_view<charT, traits>(data(), size()).substr(pos1, n1).compare(sv);
```

```cpp
template<class T>
int compare(size_type pos1, size_type n1, const T& t, // § 24.3.2.7.9
```

758
Table 63 — compare() results

<table>
<thead>
<tr>
<th>Condition</th>
<th>Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>size() &lt; sv.size()</td>
<td>&lt; 0</td>
</tr>
<tr>
<td>size() == sv.size()</td>
<td>0</td>
</tr>
<tr>
<td>size() &gt; sv.size()</td>
<td>&gt; 0</td>
</tr>
</tbody>
</table>

size_type pos2, size_type n2 = npos) const;

Effects: Equivalent to:

basic_string_view<charT, traits> sv = t;
return basic_string_view<charT, traits>(
data(), size()).substr(pos1, n1).compare(sv.substr(pos2, n2));

Remarks: This function shall not participate in overload resolution unless is_convertible_v<const T&, basic_string_view<charT, traits>> is true and is_convertible_v<const T&, const charT*> is false.

4

int compare(const basic_string& str) const noexcept;

Effects: Equivalent to: return compare(basic_string_view<charT, traits>(str));

5

int compare(size_type pos1, size_type n1, const basic_string& str) const;

Effects: Equivalent to: return compare(pos1, n1, basic_string_view<charT, traits>(str));

6

int compare(size_type pos1, size_type n1, const basic_string& str, size_type pos2, size_type n2 = npos) const;

Effects: Equivalent to:

return compare(pos1, n1, basic_string_view<charT, traits>(str), pos2, n2);

7

int compare(const charT* s) const;

Returns: compare(basic_string(s)).

8

int compare(size_type pos, size_type n1, const charT* s) const;

Returns: basic_string(*this, pos, n1).compare(basic_string(s)).

9

int compare(size_type pos, size_type n1, const charT* s, size_type n2) const;

Returns: basic_string(*this, pos, n1).compare(basic_string(s, n2)).
const basic_string<charT, traits, Allocator>& rhs);

Returns: std::move(lhs.append(rhs)).

template<class charT, class traits, class Allocator>
  basic_string<charT, traits, Allocator>
  operator+(const basic_string<charT, traits, Allocator>& lhs,
            basic_string<charT, traits, Allocator>&& rhs);

Returns: std::move(rhs.insert(0, lhs)).

Warning: Or equivalently, std::move(rhs.insert(0, lhs)).

—end note

template<class charT, class traits, class Allocator>
  basic_string<charT, traits, Allocator>
  operator+(const charT* lhs,
            const basic_string<charT, traits, Allocator>& rhs);

Returns: basic_string<charT, traits, Allocator>(lhs) + rhs.

Remarks: Uses traits::length().

template<class charT, class traits, class Allocator>
  basic_string<charT, traits, Allocator>
  operator+(const charT* lhs,
            basic_string<charT, traits, Allocator>&& rhs);

Returns: std::move(rhs.insert(0, lhs)).

Remarks: Uses traits::length().

template<class charT, class traits, class Allocator>
  basic_string<charT, traits, Allocator>
  operator+(charT lhs,
            const basic_string<charT, traits, Allocator>& rhs);

Returns: basic_string<charT, traits, Allocator>(1, lhs) + rhs.

template<class charT, class traits, class Allocator>
  basic_string<charT, traits, Allocator>
  operator+(charT lhs,
            basic_string<charT, traits, Allocator>&& rhs);

Returns: std::move(rhs.insert(0, 1, lhs)).

template<class charT, class traits, class Allocator>
  basic_string<charT, traits, Allocator>
  operator+(const basic_string<charT, traits, Allocator>& lhs,
            const charT* rhs);

Returns: lhs + basic_string<charT, traits, Allocator>(rhs).

Remarks: Uses traits::length().

template<class charT, class traits, class Allocator>
  basic_string<charT, traits, Allocator>
operator+(basic_string<charT, traits, Allocator>&& lhs,
    const charT* rhs);

Returns: std::move(lhs.append(rhs)).
Remarks: Uses traits::length().

template<class charT, class traits, class Allocator>
basic_string<charT, traits, Allocator>
    operator+(const basic_string<charT, traits, Allocator>& lhs,
    charT rhs);

Returns: lhs + basic_string<charT, traits, Allocator>(1, rhs).

24.3.3.2 operator==

template<class charT, class traits, class Allocator>
    bool operator==(const basic_string<charT, traits, Allocator>& lhs,
    const basic_string<charT, traits, Allocator>& rhs) noexcept;

Returns: lhs.compare(rhs) == 0.

24.3.3.3 operator!=

template<class charT, class traits, class Allocator>
    bool operator!=(const basic_string<charT, traits, Allocator>& lhs,
    const basic_string<charT, traits, Allocator>& rhs) noexcept;

Returns: !(lhs == rhs).

§ 24.3.3.3 761
24.3.3.4 operator<

```
template<class charT, class traits, class Allocator>
bool operator<(const basic_string<charT, traits, Allocator>& lhs,
            const basic_string<charT, traits, Allocator>& rhs) noexcept;
```

1. **Returns:** `lhs.compare(rhs) < 0`.

```
template<class charT, class traits, class Allocator>
bool operator<(const charT* lhs,
            const basic_string<charT, traits, Allocator>& rhs);
```

2. **Returns:** `rhs.compare(lhs) > 0`.

```
template<class charT, class traits, class Allocator>
bool operator<(const basic_string<charT, traits, Allocator>& lhs,
            const charT* rhs);
```

3. **Returns:** `lhs.compare(rhs) < 0`.

24.3.3.5 operator>

```
template<class charT, class traits, class Allocator>
bool operator>(const basic_string<charT, traits, Allocator>& lhs,
            const basic_string<charT, traits, Allocator>& rhs) noexcept;
```

1. **Returns:** `lhs.compare(rhs) > 0`.

```
template<class charT, class traits, class Allocator>
bool operator>(const charT* lhs,
            const basic_string<charT, traits, Allocator>& rhs);
```

2. **Returns:** `rhs.compare(lhs) < 0`.

```
template<class charT, class traits, class Allocator>
bool operator>(const basic_string<charT, traits, Allocator>& lhs,
            const charT* rhs);
```

3. **Returns:** `lhs.compare(rhs) > 0`.

24.3.3.6 operator<=

```
template<class charT, class traits, class Allocator>
bool operator<=(const basic_string<charT, traits, Allocator>& lhs,
            const basic_string<charT, traits, Allocator>& rhs) noexcept;
```

1. **Returns:** `lhs.compare(rhs) <= 0`.

```
template<class charT, class traits, class Allocator>
bool operator<=(const charT* lhs,
            const basic_string<charT, traits, Allocator>& rhs);
```

2. **Returns:** `rhs.compare(lhs) >= 0`.

```
template<class charT, class traits, class Allocator>
bool operator<=(const basic_string<charT, traits, Allocator>& lhs,
            const charT* rhs);
```

3. **Returns:** `lhs.compare(rhs) <= 0`.

24.3.3.7 operator>=

```
```

§ 24.3.3.7

762
bool operator>=(const basic_string<charT, traits, Allocator>& lhs, const basic_string<charT, traits, Allocator>& rhs) noexcept;

Returns: lhs.compare(rhs) >= 0.

template<class charT, class traits, class Allocator>
bool operator>=(const charT* lhs, const basic_string<charT, traits, Allocator>& rhs);

Returns: rhs.compare(lhs) <= 0.

template<class charT, class traits, class Allocator>
bool operator>=(const basic_string<charT, traits, Allocator>& lhs, const charT* rhs);

Returns: lhs.compare(rhs) >= 0.

24.3.3.8 swap [string.special]

template<class charT, class traits, class Allocator>
void swap(basic_string<charT, traits, Allocator>& lhs, basic_string<charT, traits, Allocator>& rhs) noexcept(noexcept(lhs.swap(rhs)));

Effects: Equivalent to: lhs.swap(rhs);

24.3.3.9 Inserters and extractors [string.io]

template<class charT, class traits, class Allocator>
basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& is, basic_string<charT, traits, Allocator>& str);

Effects: Behaves as a formatted input function (30.7.4.2.1). After constructing a sentry object, if the sentry converts to true, calls str.erase() and then extracts characters from is and appends them to str as if by calling str.append(1, c). If is.width() is greater than zero, the maximum number n of characters appended is is.width(); otherwise n is str.max_size(). Characters are extracted and appended until any of the following occurs:

1. n characters are stored;
2. end-of-file occurs on the input sequence;
3. isspace(c, is.getloc()) is true for the next available input character c.

After the last character (if any) is extracted, is.width(0) is called and the sentry object is destroyed.

Returns: is.

template<class charT, class traits, class Allocator>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const basic_string<charT, traits, Allocator>& str);

Effects: Equivalent to: return os << basic_string_view<charT, traits>(str);

template<class charT, class traits, class Allocator>
basic_istream<charT, traits>&
getline(basic_istream<charT, traits>& is, basic_string<charT, traits, Allocator>& str, § 24.3.3.9 763

Effects: Behaves as an unformatted input function (30.7.4.3), except that it does not affect the value returned by subsequent calls to `basic_istream<>::gcount()`. After constructing a sentry object, if the sentry converts to true, calls `str.erase()` and then extracts characters from `is` and appends them to `str` as if by calling `str.append(1, c)` until any of the following occurs:

- end-of-file occurs on the input sequence (in which case, the `getline` function calls `is.setstate(ios_base::eofbit)`).
- `traits::eq(c, delim)` for the next available input character `c` (in which case, `c` is extracted but not appended) (30.5.5.4)
- `str.max_size()` characters are stored (in which case, the function calls `is.setstate(ios_base::failbit)`) (30.5.5.4)

The conditions are tested in the order shown. In any case, after the last character is extracted, the sentry object is destroyed.

If the function extracts no characters, it calls `is.setstate(ios_base::failbit)` which may throw `ios_base::failure` (30.5.5.4).

Returns: `is`.

template<class charT, class traits, class Allocator>
inline basic_istream<charT, traits>&
ggetline(basic_istream<charT, traits>&& is,
        basic_string<charT, traits, Allocator>& str,
        charT delim);

Effects: the first two functions call `strtol(str.c_str(), ptr, base)`, and the last three functions call `strtoul(str.c_str(), ptr, base)`, `strtoll(str.c_str(), ptr, base)`, and `strtoull(str.c_str(), ptr, base)`, respectively. Each function returns the converted result, if any. The argument `ptr` designates a pointer to an object internal to the function that is used to determine what to store at `*idx`. If the function does not throw an exception and `idx != 0`, the function stores in `*idx` the index of the first unconverted element of `str`.

Returns: The converted result.

Throws: `invalid_argument` if `strtol`, `strtoul`, `strtoll`, or `strtoull` reports that no conversion could be performed. Throws `out_of_range` if `strtol`, `strtoul`, `strtoll` or `strtoull` sets `errno` to `ERANGE`, or if the converted value is outside the range of representable values for the return type.
float stof(const string& str, size_t* idx = 0);
double stod(const string& str, size_t* idx = 0);
long double stold(const string& str, size_t* idx = 0);

4  **Effects:** These functions call `strtof(str.c_str(), ptr), strtod(str.c_str(), ptr), and strtold(str.c_str(), ptr),` respectively. Each function returns the converted result, if any. The argument `ptr` designates a pointer to an object internal to the function that is used to determine what to store at *idx. If the function does not throw an exception and idx != 0, the function stores in *idx the index of the first unconverted element of `str`.

5  **Returns:** The converted result.

6  **Throws:** invalid_argument if `strtof`, `strtod`, or `strtold` reports that no conversion could be performed. Throws `out_of_range` if `strtof`, `strtod`, or `strtold` sets `errno` to `ERANGE` or if the converted value is outside the range of representable values for the return type.

string to_string(int val);
string to_string(unsigned val);
string to_string(long val);
string to_string(unsigned long val);
string to_string(long long val);
string to_string(float val);
string to_string(double val);
string to_string(long double val);

7  **Returns:** Each function returns a string object holding the character representation of the value of its argument that would be generated by calling `sprintf(buf, fmt, val)` with a format specifier of "%d", "%u", "%ld", "%lu", "%lld", "%llu", "%f", "%F", or "%Lf", respectively, where `buf` designates an internal character buffer of sufficient size.

int stoi(const wstring& str, size_t* idx = 0, int base = 10);
long stol(const wstring& str, size_t* idx = 0, int base = 10);
unsigned long stoul(const wstring& str, size_t* idx = 0, int base = 10);
long long stoll(const wstring& str, size_t* idx = 0, int base = 10);
unsigned long long stoull(const wstring& str, size_t* idx = 0, int base = 10);

8  **Effects:** the first two functions call `wcstol(str.c_str(), ptr, base), and the last three functions call` `wcstoul(str.c_str(), ptr, base), wcstoll(str.c_str(), ptr, base), and wcstoull(str.c_str(), ptr, base),` respectively. Each function returns the converted result, if any. The argument `ptr` designates a pointer to an object internal to the function that is used to determine what to store at *idx. If the function does not throw an exception and idx != 0, the function stores in *idx the index of the first unconverted element of `str`.

9  **Returns:** The converted result.

10  **Throws:** invalid_argument if `wcstol`, `wcstoul`, `wcstoll`, or `wcstoull` reports that no conversion could be performed. Throws `out_of_range` if the converted value is outside the range of representable values for the return type.

float stof(const wstring& str, size_t* idx = 0);
double stod(const wstring& str, size_t* idx = 0);
long double stold(const wstring& str, size_t* idx = 0);

11  **Effects:** These functions call `wcstof(str.c_str(), ptr), wcstod(str.c_str(), ptr), and wcstold(str.c_str(), ptr),` respectively. Each function returns the converted result, if any. The argument `ptr` designates a pointer to an object internal to the function that is used to determine what to store at *idx. If the function does not throw an exception and idx != 0, the function stores in *idx the
index of the first unconverted element of `str`.

**Returns:** The converted result.

**Throws:** `invalid_argument` if `wcstof`, `wcstod`, or `wcstold` reports that no conversion could be performed. Throws `out_of_range` if `wcstof`, `wcstod`, or `wcstold` sets `errno` to `ERANGE`.

```cpp
wstring to_wstring(int val);
wstring to_wstring(unsigned val);
wstring to_wstring(long val);
wstring to_wstring(unsigned long val);
wstring to_wstring(long long val);
wstring to_wstring(unsigned long long val);
```

**Returns:** Each function returns a `wstring` object holding the character representation of the value of its argument that would be generated by calling `swprintf(buf, buffsz, fmt, val)` with a format specifier of `L"%d"`, `L"%u"`, `L"%ld"`, `L"%lu"`, `L"%lld"`, `L"%llu"`, `L"%f"`, `L"%f"`, or `L"%Lf"`, respectively, where `buf` designates an internal character buffer of sufficient size `buffsz`.

### 24.3.5 Hash support

```cpp
template<> struct hash<string>;
template<> struct hash<u16string>;
template<> struct hash<u32string>;
template<> struct hash<wstring>;
```

If `S` is one of these string types, `SV` is the corresponding string view type, and `s` is an object of type `S`, then `hash<S>()(s) == hash<SV>()(SV(s))`.

### 24.3.6 Suffix for `basic_string` literals

```cpp
string operator""s(const char* str, size_t len);
u16string operator""s(const char16_t* str, size_t len);
u32string operator""s(const char32_t* str, size_t len);
wstring operator""s(const wchar_t* str, size_t len);
```

**Returns:** `string{str, len}`, `u16string{str, len}`, `u32string{str, len}`, `wstring{str, len}`.

**Note:** The same suffix `s` is used for `chrono::duration` literals denoting seconds but there is no conflict, since duration suffixes apply to numbers and string literal suffixes apply to character array literals. —end note]

### 24.4 String view classes

The class template `basic_string_view` describes an object that can refer to a constant contiguous sequence of char-like (24.1) objects with the first element of the sequence at position zero. In the rest of this section, the type of the char-like objects held in a `basic_string_view` object is designated by `charT`.

**Note:** The library provides implicit conversions from `const charT*` and `std::basic_string<charT, ...>` to `std::basic_string_view<charT, ...>` so that user code can accept just `std::basic_string_view<...>`.

§ 24.4 766
view<charT> as a non-templated parameter wherever a sequence of characters is expected. User-defined types should define their own implicit conversions to std::basic_string_view in order to interoperate with these functions. — end note]

3 The complexity of basic_string_view member functions is $O(1)$ unless otherwise specified.

24.4.1 Header <string_view> synopsis
[string.view.synop]
namespace std {

constexpr size_type find_last_not_of(charT c, size_type pos = npos) const noexcept;
constexpr size_type find_last_not_of(const charT* s, size_type pos, size_type n) const;
constexpr size_type find_last_not_of(const charT* s, size_type pos = npos) const;

private:
  const_pointer data_;  // exposition only
  size_type size_;       // exposition only
};

1 In every specialization basic_string_view<
charT, traits>, the type traits shall satisfy the character

§ 24.4.2
traits requirements (24.2), and the type traits::char_type shall name the same type as charT.

### 24.4.2.1 Construction and assignment

```cpp
constexpr basic_string_view() noexcept;
```

**Effects:** Constructs an empty basic_string_view.

**Postconditions:** size_ == 0 and data_ == nullptr.

```cpp
constexpr basic_string_view(const charT* str);
```

**Requires:** [str, str + traits::length(str)) is a valid range.

**Effects:** Constructs a basic_string_view, with the postconditions in Table 64.

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_</td>
<td>str</td>
</tr>
<tr>
<td>size_</td>
<td>traits::length(str)</td>
</tr>
</tbody>
</table>

**Complexity:** \( O(\text{traits::length(str)}) \).

```cpp
constexpr basic_string_view(const charT* str, size_type len);
```

**Requires:** [str, str + len) is a valid range.

**Effects:** Constructs a basic_string_view, with the postconditions in Table 65.

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_</td>
<td>str</td>
</tr>
<tr>
<td>size_</td>
<td>len</td>
</tr>
</tbody>
</table>

### 24.4.2.2 Iterator support

```cpp
using const_iterator = implementation-defined;
```

A type that meets the requirements of a constant random access iterator (27.2.7) and of a contiguous iterator (27.2.1) whose value_type is the template parameter charT.

For a basic_string_view str, any operation that invalidates a pointer in the range [str.data(), str.data() + str.size()) invalidates pointers, iterators, and references returned from str’s methods.

All requirements on container iterators (26.2) apply to basic_string_view::const_iterator as well.

```cpp
constexpr const_iterator begin() const noexcept;
```

**Returns:** An iterator such that

1. if !empty(), &*begin() == data_,
2. otherwise, an unspecified value such that [begin(), end()) is a valid range.

```cpp
constexpr const_iterator end() const noexcept;
```

**Returns:** begin() + size().
constexpr const_reverse_iterator rbegin() const noexcept;
constexpr const_reverse_iterator crbegin() const noexcept;

Returns: const_reverse_iterator(end()).

constexpr const_reverse_iterator rend() const noexcept;
constexpr const_reverse_iterator crend() const noexcept;

Returns: const_reverse_iterator(begin()).

24.4.2.3 Capacity

constexpr size_type size() const noexcept;
Returns: size_.

constexpr size_type length() const noexcept;
Returns: size_.

constexpr size_type max_size() const noexcept;
Returns: The largest possible number of char-like objects that can be referred to by a basic_string_view.

constexpr bool empty() const noexcept;
Returns: size_ == 0.

24.4.2.4 Element access

constexpr const_reference operator[](size_type pos) const;
Requires: pos < size().
Returns: data_[pos].
Throws: Nothing.

[Note: Unlike basic_string::operator[], basic_string_view::operator[](size()) has undefined behavior instead of returning charT(). — end note]

constexpr const_reference at(size_type pos) const;
Throws: out_of_range if pos >= size().
Returns: data_[pos].

constexpr const_reference front() const;
Requires: !empty().
Returns: data_[0].
Throws: Nothing.

constexpr const_reference back() const;
Requires: !empty().
Returns: data_[size() - 1].
Throws: Nothing.

constexpr const_pointer data() const noexcept;
Returns: data_.

§ 24.4.2.4
[Note: Unlike basic_string::data() and string literals, data() may return a pointer to a buffer that is not null-terminated. Therefore it is typically a mistake to pass data() to a function that takes just a const charT* and expects a null-terminated string. — end note]

24.4.2.5 Modifiers

```cpp
constexpr void remove_prefix(size_type n);
1  Requires: n <= size().
2  Effects: Equivalent to: data_ += n; size_ -= n;
```  
```cpp
constexpr void remove_suffix(size_type n);
3  Requires: n <= size().
4  Effects: Equivalent to: size_ -= n;
```  
```cpp
constexpr void swap(basic_string_view& s) noexcept;
5  Effects: Exchanges the values of *this and s.
```  
24.4.2.6 String operations

```cpp
size_type copy(charT* s, size_type n, size_type pos = 0) const;
1  Let rlen be the smaller of n and size() - pos.
2  Throws: out_of_range if pos > size().
3  Requires: [s, s + rlen) is a valid range.
4  Effects: Equivalent to traits::copy(s, data() + pos, rlen).
5  Returns: rlen.
6  Complexity: O(rlen).
```  
```cpp
constexpr basic_string_view substr(size_type pos = 0, size_type n = npos) const;
7  Let rlen be the smaller of n and size() - pos.
8  Throws: out_of_range if pos > size().
9  Effects: Determines rlen, the effective length of the string to reference.
10 Returns: basic_string_view(data() + pos, rlen).
```  
```cpp
constexpr int compare(basic_string_view str) const noexcept;
11  Let rlen be the smaller of size() and str.size().
12  Effects: Determines rlen, the effective length of the strings to compare. The function then compares the two strings by calling traits::compare(data(), str.data(), rlen).
13  Complexity: \(O(rlen)\).
14 Returns: The nonzero result if the result of the comparison is nonzero. Otherwise, returns a value as indicated in Table 66.
```  
```cpp
constexpr int compare(size_type pos1, size_type n1, basic_string_view str) const;
15  Effects: Equivalent to: return substr(pos1, n1).compare(str);
```  
```cpp
constexpr int compare(size_type pos1, size_type n1, basic_string_view str,
16  size_type pos2, size_type n2) const;
17  Effects: Equivalent to: return substr(pos1, n1).compare(substr(pos2, n2));
```
### Table 66 — compare() results

<table>
<thead>
<tr>
<th>Condition</th>
<th>Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>size() &lt; str.size()</td>
<td>&lt; 0</td>
</tr>
<tr>
<td>size() == str.size()</td>
<td>0</td>
</tr>
<tr>
<td>size() &gt; str.size()</td>
<td>&gt; 0</td>
</tr>
</tbody>
</table>

```cpp
constexpr int compare(const charT* s) const;
```

**Effects:**
Equivalent to: `return compare(basic_string_view(s));`

```cpp
constexpr int compare(size_type pos1, size_type n1, const charT* s) const;
```

**Effects:**
Equivalent to: `return substr(pos1, n1).compare(basic_string_view(s));`

```cpp
constexpr int compare(size_type pos1, size_type n1, const charT* s, size_type n2) const;
```

**Effects:**
Equivalent to: `return substr(pos1, n1).compare(basic_string_view(s, n2));`

#### 24.4.2.7 Searching

This section specifies the `basic_string_view` member functions named `find`, `rfind`, `find_first_of`, `find_last_of`, `find_first_not_of`, and `find_last_not_of`.

Member functions in this section have complexity $O(size() \times str.size())$ at worst, although implementations are encouraged to do better.

Each member function of the form

```cpp
constexpr return-type F(const charT* s, size_type pos);
```

is equivalent to `return F(basic_string_view(s), pos);`

Each member function of the form

```cpp
constexpr return-type F(const charT* s, size_type pos, size_type n);
```

is equivalent to `return F(basic_string_view(s, n), pos);`

Each member function of the form

```cpp
constexpr return-type F(charT c, size_type pos);
```

is equivalent to `return F(basic_string_view(&c, 1), pos);`

```cpp
constexpr size_type find(basic_string_view str, size_type pos = 0) const noexcept;
```

Let `xpos` be the lowest position, if possible, such that the following conditions hold:

1. $pos <= xpos$
2. $xpos + str.size() <= size()$
3. $traits::eq(at(xpos + I), str.at(I))$ for all elements $I$ of the string referenced by $str$.

**Effects:** Determines `xpos`.

**Returns:** `xpos` if the function can determine such a value for `xpos`. Otherwise, returns `npos`.

```cpp
constexpr size_type rfind(basic_string_view str, size_type pos = npos) const noexcept;
```

Let `xpos` be the highest position, if possible, such that the following conditions hold:

1. $xpos <= pos$
(9.2) \[ x_{pos} + \text{str}.\text{size()} \leq \text{size()} \]
(9.3) \[ \text{traits}::\text{eq}(\text{at}(x_{pos} + I), \text{str}.\text{at}(I)) \text{ for all elements } I \text{ of the string referenced by str}. \]

**Effects:** Determines \( x_{pos} \).

**Returns:** \( x_{pos} \) if the function can determine such a value for \( x_{pos} \). Otherwise, returns \( \text{npos} \).

```cpp
constexpr size_type find_first_of(basic_string_view str, size_type pos = 0) const noexcept;
```

Let \( x_{pos} \) be the lowest position, if possible, such that the following conditions hold:

- \( \text{pos} \leq x_{pos} \)
- \( x_{pos} < \text{size()} \)
- \( \text{traits}::\text{eq}(\text{at}(x_{pos}), \text{str}.\text{at}(I)) \text{ for some element } I \text{ of the string referenced by str}. \)

**Effects:** Determines \( x_{pos} \).

**Returns:** \( x_{pos} \) if the function can determine such a value for \( x_{pos} \). Otherwise, returns \( \text{npos} \).

```cpp
constexpr size_type find_last_of(basic_string_view str, size_type pos = npos) const noexcept;
```

Let \( x_{pos} \) be the highest position, if possible, such that the following conditions hold:

- \( x_{pos} \leq \text{pos} \)
- \( x_{pos} < \text{size()} \)
- \( \text{traits}::\text{eq}(\text{at}(x_{pos}), \text{str}.\text{at}(I)) \text{ for some element } I \text{ of the string referenced by str}. \)

**Effects:** Determines \( x_{pos} \).

**Returns:** \( x_{pos} \) if the function can determine such a value for \( x_{pos} \). Otherwise, returns \( \text{npos} \).

```cpp
constexpr size_type find_first_not_of(basic_string_view str, size_type pos = 0) const noexcept;
```

Let \( x_{pos} \) be the lowest position, if possible, such that the following conditions hold:

- \( \text{pos} \leq x_{pos} \)
- \( x_{pos} < \text{size()} \)
- \( \text{traits}::\text{eq}(\text{at}(x_{pos}), \text{str}.\text{at}(I)) \text{ for no element } I \text{ of the string referenced by str}. \)

**Effects:** Determines \( x_{pos} \).

**Returns:** \( x_{pos} \) if the function can determine such a value for \( x_{pos} \). Otherwise, returns \( \text{npos} \).

```cpp
constexpr size_type find_last_not_of(basic_string_view str, size_type pos = npos) const noexcept;
```

Let \( x_{pos} \) be the highest position, if possible, such that the following conditions hold:

- \( x_{pos} \leq \text{pos} \)
- \( x_{pos} < \text{size()} \)
- \( \text{traits}::\text{eq}(\text{at}(x_{pos}), \text{str}.\text{at}(I)) \text{ for no element } I \text{ of the string referenced by str}. \)

**Effects:** Determines \( x_{pos} \).

**Returns:** \( x_{pos} \) if the function can determine such a value for \( x_{pos} \). Otherwise, returns \( \text{npos} \).

### 24.4.3 Non-member comparison functions

Let \( S \) be \( \text{basic_string_view<charT, traits>} \), and \( sv \) be an instance of \( S \). Implementations shall provide sufficient additional overloaded functions marked `constexpr` and `noexcept` so that an object \( t \) with an implicit conversion to \( S \) can be compared according to Table 67.

**Example:** A sample conforming implementation for `operator==` would be:
Table 67 — Additional `basic_string_view` comparison overloads

<table>
<thead>
<tr>
<th>Expression</th>
<th>Equivalent to</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>t == sv</code></td>
<td><code>S(t) == sv</code></td>
</tr>
<tr>
<td><code>sv == t</code></td>
<td><code>sv == S(t)</code></td>
</tr>
<tr>
<td><code>t != sv</code></td>
<td><code>S(t) != sv</code></td>
</tr>
<tr>
<td><code>sv != t</code></td>
<td><code>sv != S(t)</code></td>
</tr>
<tr>
<td><code>t &lt; sv</code></td>
<td><code>S(t) &lt; sv</code></td>
</tr>
<tr>
<td><code>sv &lt; t</code></td>
<td><code>sv &lt; S(t)</code></td>
</tr>
<tr>
<td><code>t &gt; sv</code></td>
<td><code>S(t) &gt; sv</code></td>
</tr>
<tr>
<td><code>sv &gt; t</code></td>
<td><code>sv &gt; S(t)</code></td>
</tr>
<tr>
<td><code>t &lt;= sv</code></td>
<td><code>S(t) &lt;= sv</code></td>
</tr>
<tr>
<td><code>sv &lt;= t</code></td>
<td><code>sv &lt;= S(t)</code></td>
</tr>
<tr>
<td><code>t &gt;= sv</code></td>
<td><code>S(t) &gt;= sv</code></td>
</tr>
<tr>
<td><code>sv &gt;= t</code></td>
<td><code>sv &gt;= S(t)</code></td>
</tr>
</tbody>
</table>

```cpp
template<class T> using __identity = decay_t<T>;

template<class charT, class traits>
constexpr bool operator==(basic_string_view<charT, traits> lhs, __identity<basic_string_view<charT, traits>> rhs) noexcept {
    return lhs.compare(rhs) == 0;
}

template<class charT, class traits>
constexpr bool operator==(basic_string_view<charT, traits> lhs, basic_string_view<charT, traits> rhs) noexcept {
    return lhs.compare(rhs) == 0;
}

template<class charT, class traits>
constexpr bool operator==(__identity<basic_string_view<charT, traits>> lhs, basic_string_view<charT, traits> rhs) noexcept {
    return lhs.compare(rhs) == 0;
}

— end example ]
```

2 Returns: `lhs.compare(rhs) == 0`.

3 Returns: `lhs.compare(rhs) != 0`.

4 Returns: `lhs.compare(rhs) < 0`.
basic_string_view<charT, traits> rhs) noexcept;

Returns: lhs.compare(rhs) > 0.

template<class charT, class traits>
constexpr bool operator<=(basic_string_view<charT, traits> lhs,
                       basic_string_view<charT, traits> rhs) noexcept;

Returns: lhs.compare(rhs) <= 0.

template<class charT, class traits>
constexpr bool operator>=(basic_string_view<charT, traits> lhs,
                       basic_string_view<charT, traits> rhs) noexcept;

Returns: lhs.compare(rhs) >= 0.

24.4.4 Inserters and extractors

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os,
          basic_string_view<charT, traits> str);

Effects: Behaves as a formatted output function (30.7.5.2.1) of os. Forms a character sequence seq, initially consisting of the elements defined by the range [str.begin(), str.end()). Determines padding for seq as described in 30.7.5.2.1. Then inserts seq as if by calling os.rdbuf()->sputn(seq, n), where n is the larger of os.width() and str.size(); then calls os.width(0).

Returns: os

24.4.5 Hash support

template<> struct hash<string_view>;
template<> struct hash<u16string_view>;
template<> struct hash<u32string_view>;
template<> struct hash<wstring_view>;

The specialization is enabled (23.14.15). [ Note: The hash value of a string view object is equal to the hash value of the corresponding string object (24.3.5). — end note ]

24.4.6 Suffix for basic_string_view literals

constexpr string_view operator"sv(const char* str, size_t len) noexcept;

Returns: string_view{str, len}.

constexpr u16string_view operator"sv(const char16_t* str, size_t len) noexcept;

Returns: u16string_view{str, len}.

constexpr u32string_view operator"sv(const char32_t* str, size_t len) noexcept;

Returns: u32string_view{str, len}.

constexpr wstring_view operator"sv(const wchar_t* str, size_t len) noexcept;

Returns: wstring_view{str, len}.

24.5 Null-terminated sequence utilities

24.5.5 Header <cuchar> synopsis [cuchar.syn]

namespace std {
    using mbstate_t = see below;
    using size_t = see 21.2.4;

    size_t mbrtoc16(char16_t* pc16, const char* s, size_t n, mbstate_t* ps);
    size_t c16rtomb(char* s, char16_t c16, mbstate_t* ps);
    size_t mbrtoc32(char32_t* pc32, const char* s, size_t n, mbstate_t* ps);
    size_t c32rtomb(char* s, char32_t c32, mbstate_t* ps);
}

1 The contents and meaning of the header <cuchar> are the same as the C standard library header <uchar.h>, except that it does not declare types char16_t nor char32_t.

See also: ISO C 7.28

24.5.6 Multibyte / wide string and character conversion functions [c.mb.wcs]

1 [Note: The headers <cstdlib> (21.2.2) and <cwchar> (24.5.4) declare the functions described in this subclause. —end note]

int mbsinit(const mbstate_t* ps);
int mblen(const char* s, size_t n);
size_t mbstowcs(wchar_t* pwcs, const char* s, size_t n);
size_t wcstombs(char* s, const wchar_t* pwcs, size_t n);

   Effects: These functions have the semantics specified in the C standard library.

See also: ISO C 7.22.7.1, 7.22.8, 7.29.6.2.1

int mbtowc(wchar_t* pwc, const char* s, size_t n);
int wctomb(char* s, wchar_t wchar);

   Effects: These functions have the semantics specified in the C standard library.

3 Remarks: Calls to these functions may introduce a data race (20.5.5.9) with other calls to the same function.

See also: ISO C 7.22.7

size_t mrblen(const char* s, size_t n, mbstate_t* ps);
size_t mbstowc(wchar_t* pwcs, const char* s, size_t n, mbstate_t* ps);
size_t wcrtomb(char* s, wchar_t wc, mbstate_t* ps);
size_t mbstowcs(wchar_t* dst, const char** src, size_t len, mbstate_t* ps);
size_t wcsrtombs(char* dst, const wchar_t** src, size_t len, mbstate_t* ps);

§ 24.5.6
Effects: These functions have the semantics specified in the C standard library.

Remarks: Calling these functions with an mbstate_t* argument that is a null pointer value may introduce a data race (20.5.5.9) with other calls to the same function with an mbstate_t* argument that is a null pointer value.

25 Localization library

25.1 General

This Clause describes components that C++ programs may use to encapsulate (and therefore be more portable when confronting) cultural differences. The locale facility includes internationalization support for character classification and string collation, numeric, monetary, and date/time formatting and parsing, and message retrieval.

The following subclauses describe components for locales themselves, the standard facets, and facilities from the ISO C library, as summarized in Table 68.

<table>

<td>C library locales</td>
</tr>
</tbody>
</table>

25.2 Header <locale> synopsis

```cpp
namespace std {
    // 25.3.1, locale
    class locale;
    template <class Facet> const Facet& use_facet(const locale&);
    template <class Facet> bool has_facet(const locale&) noexcept;

    // 25.3.3, convenience interfaces
    template <class charT> bool isspace(charT c, const locale& loc);
    template <class charT> bool isprint(charT c, const locale& loc);
    template <class charT> bool iscntrl(charT c, const locale& loc);
    template <class charT> bool isupper(charT c, const locale& loc);
    template <class charT> bool islower(charT c, const locale& loc);
    template <class charT> bool isalpha(charT c, const locale& loc);
    template <class charT> bool isdigit(charT c, const locale& loc);
    template <class charT> bool ispunct(charT c, const locale& loc);
    template <class charT> bool isxdigit(charT c, const locale& loc);
    template <class charT> bool isalnum(charT c, const locale& loc);
    template <class charT> bool isgraph(charT c, const locale& loc);
    template <class charT> charT toupper(charT c, const locale& loc);
    template <class charT> charT tolower(charT c, const locale& loc);

    // 25.4.1, ctype
    class ctype_base;
    template <class charT> class ctype;
    template <> class ctype<char>;
    template <class charT> class ctype_byname;
    class codecvt_base;
    template <class internT, class externT, class stateT> class codecvt;
    template <class internT, class externT, class stateT> class codecvt_byname;
} /* std */
```

§ 25.2
The header `<locale>` defines classes and declares functions that encapsulate and manipulate the information peculiar to a locale.\(^\text{229}\)

\(^{229}\) In this subclause, the type name `struct tm` is an incomplete type that is defined in `<ctime>`.
25.3 Locales

25.3.1 Class locale

namespace std {
    class locale {
    public:
        // types:
        class facet;
        class id;
        using category = int;
        static const category
            none = 0,
            collate = 0x010, ctype = 0x020,
            monetary = 0x040, numeric = 0x080,
            time = 0x100, messages = 0x200,
            all = collate | ctype | monetary | numeric | time | messages;

        // construct/copy/destroy:
        locale() noexcept;
        locale(const locale& other) noexcept;
        explicit locale(const char* std_name);
        explicit locale(const string& std_name);
        locale(const locale& other, const char* std_name, category);
        locale(const locale& other, const string& std_name, category);
        template <class Facet> locale(const locale& other, Facet* f);
        locale(const locale& other, const locale& one, category);
        ~locale();
        const locale& operator=(const locale& other) noexcept;
        template <class Facet> locale combine(const locale& other) const;

        // locale operations:
        basic_string<char> name() const;
        bool operator==(const locale& other) const;
        bool operator!=(const locale& other) const;
        template <class charT, class traits, class Allocator>
        bool operator()(const basic_string<charT, traits, Allocator>& s1,
                        const basic_string<charT, traits, Allocator>& s2) const;

        // global locale objects:
        static locale global(const locale&);
        static const locale& classic();
    };
}

1 Class locale implements a type-safe polymorphic set of facets, indexed by facet type. In other words, a facet has a dual role: in one sense, it’s just a class interface; at the same time, it’s an index into a locale’s set of facets.

2 Access to the facets of a locale is via two function templates, use_facet<> and has_facet<>.

3 [ Example: An iostream operator<< might be implemented as:]

```cpp
    template <class charT, class traits>
    basic_ostream<charT, traits>&
    operator<<(basic_ostream<charT, traits>& s, const locale& l);
```

Note that in the call to put the stream is implicitly converted to an ostreambuf_iterator<charT, traits>.

§ 25.3.1
 operator<< (basic_ostream<charT, traits>& s, Date d) {
    typename basic_ostream<charT, traits>::sentry cerberos(s);
    if (cerberos) {
        ios_base::iostate err = ios_base::iostate::goodbit;
        tm tmbuf; d.extract(tmbuf);
        use_facet<time_put<charT, ostreambuf_iterator<charT, traits>>>(
          s.getloc()).put(s, s, s.fill(), err, &tmbuf, 'x');
        s.setstate(err); // might throw
    }
    return s;
}

— end example

4 In the call to use_facet<Facet>(loc), the type argument chooses a facet, making available all members
of the named type. If Facet is not present in a locale, it throws the standard exception bad_cast. A C++
program can check if a locale implements a particular facet with the function template has_facet<Facet>().
User-defined facets may be installed in a locale, and used identically as may standard facets (25.4.8).

5 [ Note: All locale semantics are accessed via use_facet<> and has_facet<>], except that:

(5.1) — A member operator template operator()(const basic_string<C, T, A>&, const basic_string<C, T, A>&) is provided so that a locale may be used as a predicate argument to the standard collections,
to collate strings.

(5.2) — Convenient global interfaces are provided for traditional ctype functions such as isdigit() and
isspace(), so that given a locale object loc a C++ program can call isspace(c, loc). (This eases
upgrading existing extractors (30.7.4.2).)

— end note ]

6 Once a facet reference is obtained from a locale object by calling use_facet<> , that reference remains usable,
and the results from member functions of it may be cached and re-used, as long as some locale object refers
to that facet.

7 In successive calls to a locale facet member function on a facet object installed in the same locale, the returned
result shall be identical.

8 A locale constructed from a name string (such as "POSIX"), or from parts of two named locales, has a name;
all others do not. Named locales may be compared for equality; an unnamed locale is equal only to (copies
of) itself. For an unnamed locale, locale::name() returns the string "*".

9 Whether there is one global locale object for the entire program or one global locale object per thread is
implementation-defined. Implementations should provide one global locale object per thread. If there is a
single global locale object for the entire program, implementations are not required to avoid data races on
it (20.5.5.9).

25.3.1.1 locale types [... locale.types]

25.3.1.1.1 Type locale::category [... locale.category]

using category = int;

1 Valid category values include the locale member bitmask elements collate, ctype, monetary, numeric,
time, and messages, each of which represents a single locale category. In addition, locale member bitmask
constant none is defined as zero and represents no category. And locale member bitmask constant all is
defined such that the expression

        (collate | ctype | monetary | numeric | time | messages | all) == all

is true, and represents the union of all categories. Further, the expression (X | Y), where X and Y each
represent a single category, represents the union of the two categories.

2 **locale** member functions expecting a **category** argument require one of the **category** values defined above, or the union of two or more such values. Such a **category** value identifies a set of **locale** categories. Each **locale** category, in turn, identifies a set of **locale** facets, including at least those shown in Table 69.

### Table 69 — **Locale** category facets

<table>
<thead>
<tr>
<th>Category</th>
<th>Includes facets</th>
</tr>
</thead>
<tbody>
<tr>
<td>collate</td>
<td>collate&lt;char&gt;, collate&lt;wchar_t&gt;</td>
</tr>

</tr>
<tr>
<td>time</td>
<td>time_get&lt;char&gt;, time_get&lt;wchar_t&gt;</td>
</tr>
<tr>
<td></td>
<td>time_put&lt;char&gt;, time_put&lt;wchar_t&gt;</td>
</tr>
<tr>
<td>messages</td>
<td>messages&lt;char&gt;, messages&lt;wchar_t&gt;</td>
</tr>
</tbody>
</table>

3 For any **locale** loc either constructed, or returned by **locale**:classic(), and any facet **Facet** shown in Table 69, has_facet<**Facet**>(loc) is true. Each **locale** member function which takes a **locale**:category argument operates on the corresponding set of facets.

4 An implementation is required to provide those specializations for facet templates identified as members of a category, and for those shown in Table 70.

5 The provided implementation of members of facets num_get<charT> and num_put<charT> calls use_facet<**F**>(1) only for facet **F** of types numpunct<charT> and ctype<charT>, and for **locale** l the value obtained by calling member getloc() on the ios_base& argument to these functions.

6 In declarations of facets, a template parameter with name **InputIterator** or **OutputIterator** indicates the set of all possible specializations on parameters that satisfy the requirements of an Input Iterator or an Output Iterator, respectively (27.2). A template parameter with name C represents the set of types containing char, wchar_t, and any other implementation-defined character types that satisfy the requirements for a character on which any of the iostream components can be instantiated. A template parameter with name **International** represents the set of all possible specializations on a bool parameter.

#### 25.3.1.1.2 Class **locale**:facet

```cpp
namespace std {
    class locale::facet {
        protected:
            explicit facet(size_t refs = 0);
            virtual -facet();
            facet(const facet&) = delete;
            void operator=(const facet&) = delete;
    };
```
### Table 70 — Required specializations

</tbody>
</table>

1. Class facet is the base class for locale feature sets. A class is a facet if it is publicly derived from another facet, or if it is a class derived from `locale::facet` and contains a publicly accessible declaration as follows:  
   ```cpp
   static ::std::locale::id id;
   ```

2. Template parameters in this Clause which are required to be facets are those named Facet in declarations. A program that passes a type that is not a facet, or a type that refers to a volatile-qualified facet, as an (explicit or deduced) template parameter to a locale function expecting a facet, is ill-formed. A const-qualified facet is a valid template argument to any locale function that expects a Facet template parameter.

3. The refs argument to the constructor is used for lifetime management. For refs == 0, the implementation performs `delete static_cast<locale::facet*>(f)` (where f is a pointer to the facet) when the last locale object containing the facet is destroyed; for refs == 1, the implementation never destroys the facet.

4. Constructors of all facets defined in this Clause take such an argument and pass it along to their facet base class constructor. All one-argument constructors defined in this Clause are explicit, preventing their participation in automatic conversions.

5. For some standard facets a standard “... _byname” class, derived from it, implements the virtual function semantics equivalent to that facet of the locale constructed by `locale(const char*)` with the same name. Each such facet provides a constructor that takes a `const char*` argument, which names the locale, and a refs argument, which is passed to the base class constructor. Each such facet also provides a constructor that takes a string argument str and a refs argument, which has the same effect as calling the first constructor with the two arguments `str.c_str()` and refs. If there is no “... _byname” version of a facet, the base class

---

231) This is a complete list of requirements; there are no other requirements. Thus, a facet class need not have a public copy constructor, assignment, default constructor, destructor, etc.

§ 25.3.1.1.2
implements named locale semantics itself by reference to other facets.

25.3.1.1.3 Class locale::id

namespace std {
    class locale::id {
    public:
    id();
    void operator=(const id&) = delete;
    id(const id&) = delete;
    }
};

1 The class locale::id provides identification of a locale facet interface, used as an index for lookup and to encapsulate initialization.

2 [Note: Because facets are used by iostreams, potentially while static constructors are running, their initialization cannot depend on programmed static initialization. One initialization strategy is for locale to initialize each facet’s id member the first time an instance of the facet is installed into a locale. This depends only on static storage being zero before constructors run (6.6.2). — end note]

25.3.1.2 locale constructors and destructor

locale() noexcept;

1 Default constructor: a snapshot of the current global locale.

2 Effects: Constructs a copy of the argument last passed to locale::global(locale&), if it has been called; else, the resulting facets have virtual function semantics identical to those of locale::classic().

[Note: This constructor is commonly used as the default value for arguments of functions that take a const locale& argument. — end note]

locale(const locale& other) noexcept;

3 Effects: Constructs a locale which is a copy of other.

explicit locale(const char* std_name);

4 Effects: Constructs a locale using standard C locale names, e.g., "POSIX". The resulting locale implements semantics defined to be associated with that name.

5 Throws: runtime_error if the argument is not valid, or is null.

6 Remarks: The set of valid string argument values is "C", "", and any implementation-defined values.

explicit locale(const string& std_name);

7 Effects: The same as locale(std_name.c_str()).

locale(const locale& other, const char* std_name, category);

8 Effects: Constructs a locale as a copy of other except for the facets identified by the category argument, which instead implement the same semantics as locale(std_name).

9 Throws: runtime_error if the argument is not valid, or is null.

10 Remarks: The locale has a name if and only if other has a name.

locale(const locale& other, const string& std_name, category cat);

11 Effects: The same as locale(other, std_name.c_str(), cat).

template <class Facet> locale(const locale& other, Facet* f);

12 Effects: Constructs a locale incorporating all facets from the first argument except that of type Facet,
and installs the second argument as the remaining facet. If \( f \) is null, the resulting object is a copy of other.

**Remarks:** The resulting locale has no name.

```
locale(const locale& other, const locale& one, category cats);
```

**Effects:** Constructs a locale incorporating all facets from the first argument except those that implement cats, which are instead incorporated from the second argument.

**Remarks:** The resulting locale has a name if and only if the first two arguments have names.

```
const locale& operator=(const locale& other) noexcept;
```

**Effects:** Creates a copy of other, replacing the current value.

**Returns:** *this.

```
~locale();
```

A non-virtual destructor that throws no exceptions.

### 25.3.1.3 locale members

```
template <class Facet> locale combine(const locale& other) const;
```

**Effects:** Constructs a locale incorporating all facets from *this except for that one facet of other that is identified by Facet.

**Returns:** The newly created locale.

**Throws:** runtime_error if has_facet<Facet>(other) is false.

**Remarks:** The resulting locale has no name.

```
basic_string<char> name() const;
```

**Returns:** The name of *this, if it has one; otherwise, the string "*".

### 25.3.1.4 locale operators

```
bool operator==(const locale& other) const;
```

**Returns:** true if both arguments are the same locale, or one is a copy of the other, or each has a name and the names are identical; false otherwise.

```
bool operator!=(const locale& other) const;
```

**Returns:** !(*this == other).

```
template <class charT, class traits, class Allocator>
bool operator()(const basic_string<charT, traits, Allocator>& s1, const basic_string<charT, traits, Allocator>& s2) const;
```

**Effects:** Compares two strings according to the collate<charT> facet.

**Remarks:** This member operator template (and therefore locale itself) satisfies requirements for a comparator predicate template argument (Clause 28) applied to strings.

**Returns:**

```
use_facet<collate<charT>>(*this).compare(s1.data(), s1.data() + s1.size(), s2.data(), s2.data() + s2.size()) < 0
```

**Example:** A vector of strings \( v \) can be collated according to collation rules in locale \( \text{loc} \) simply by (28.7.1, 26.3.11):

§ 25.3.1.4
```cpp
std::sort(v.begin(), v.end(), loc);
```

—end example]

### 25.3.1.5 locale static members

```cpp
static locale global(const locale& loc);
```

1. Sets the global locale to its argument.

2. **Effects:** Causes future calls to the constructor `locale()` to return a copy of the argument. If the argument has a name, does

   ```cpp
   setlocale(LC_ALL, loc.name().c_str());
   ```

   otherwise, the effect on the C locale, if any, is implementation-defined. No library function other than `locale::global()` shall affect the value returned by `locale()`. [Note: See 25.5 for data race considerations when `setlocale` is invoked. —end note]

3. **Returns:** The previous value of `locale()`.

```cpp
static const locale& classic();
```

4. The "C" locale.

5. **Returns:** A locale that implements the classic "C" locale semantics, equivalent to the value `locale("C")`.

6. **Remarks:** This locale, its facets, and their member functions, do not change with time.

### 25.3.2 locale globals

```cpp
template <class Facet> const Facet& use_facet(const locale& loc);
```

1. **Requires:** `Facet` is a facet class whose definition contains the public static member `id` as defined in 25.3.1.1.2.

2. **Returns:** A reference to the corresponding facet of `loc`, if present.

3. **Throws:** `bad_cast` if `has_facet<Facet>(loc)` is false.

4. **Remarks:** The reference returned remains valid at least as long as any copy of `loc` exists.

```cpp
template <class Facet> bool has_facet(const locale& loc) noexcept;
```

5. **Returns:** `true` if the facet requested is present in `loc`; otherwise `false`.

### 25.3.3 Convenience interfaces

**25.3.3.1 Character classification**

```cpp
template <class charT> bool isspace (charT c, const locale& loc);
template <class charT> bool isprint (charT c, const locale& loc);
template <class charT> bool iscntrl (charT c, const locale& loc);
template <class charT> bool isupper (charT c, const locale& loc);
template <class charT> bool islower (charT c, const locale& loc);
template <class charT> bool isalpha (charT c, const locale& loc);
template <class charT> bool isdigit (charT c, const locale& loc);
template <class charT> bool ispunct (charT c, const locale& loc);
template <class charT> bool isxdigit(charT c, const locale& loc);
template <class charT> bool isalnum (charT c, const locale& loc);
template <class charT> bool isgraph (charT c, const locale& loc);
template <class charT> bool isblank (charT c, const locale& loc);
```

1. Each of these functions is $F$ returns the result of the expression:
use_facet<ctype<charT>>(loc).is(ctype_base::F, c)

where \( F \) is the \texttt{ctype_base::mask} value corresponding to that function (25.4.1).\(^{232}\)

25.3.3.2 Conversions

25.3.3.2.1 Character conversions

template <class charT> charT toupper(charT c, const locale& loc);

1 Returns: use_facet<ctype<charT>>(loc).toupper(c).

template <class charT> charT tolower(charT c, const locale& loc);

2 Returns: use_facet<ctype<charT>>(loc).tolower(c).

25.4 Standard locale categories

1 Each of the standard categories includes a family of facets. Some of these implement formatting or parsing of a datum, for use by standard or users’ iostream operators \(<\text{and}\>\), as members \texttt{put()} and \texttt{get()}, respectively. Each such member function takes an \texttt{ios_base\&} argument whose members \texttt{flags()}, \texttt{precision()}, and \texttt{width()}, specify the format of the corresponding datum (30.5.3). Those functions which need to use other facets call its member \texttt{getloc()} to retrieve the locale imbued there. Formatting facets use the character argument \texttt{fill} to fill out the specified width where necessary.

2 The \texttt{put()} members make no provision for error reporting. (Any failures of the OutputIterator argument must be extracted from the returned iterator.) The \texttt{get()} members take an \texttt{ios_base::iostate\&} argument whose value they ignore, but set to \texttt{ios_base::failbit} in case of a parse error.

3 Within this clause it is unspecified whether one virtual function calls another virtual function.

25.4.1 The \texttt{ctype} category

namespace std {

    class ctype_base {
        public:

            using mask = T;

            // numeric values are for exposition only.
            static const mask space = 1 << 0;
            static const mask print = 1 << 1;
            static const mask cntrl = 1 << 2;
            static const mask upper = 1 << 3;
            static const mask lower = 1 << 4;
            static const mask alpha = 1 << 5;
            static const mask digit = 1 << 6;
            static const mask punct = 1 << 7;
            static const mask xdigit = 1 << 8;
            static const mask blank = 1 << 9;
            static const mask alnum = alpha | digit;
            static const mask graph = alnum | punct;
        }
    }

1 The type \texttt{mask} is a bitmask type (20.4.2.1.4).

25.4.1.1 Class template \texttt{ctype}

namespace std {

    template <class charT>

232) When used in a loop, it is faster to cache the \texttt{ctype<>} facet and use it directly, or use the vector form of \texttt{ctype::is}.
class ctype : public locale::facet, public ctype_base {
  public:
    using char_type = charT;

    explicit ctype(size_t refs = 0);

    bool is(mask m, charT c) const;
    const charT* is(const charT* low, const charT* high, mask* vec) const;
    const charT* scan_is(mask m, const charT* low, const charT* high) const;
    const charT* scan_not(mask m, const charT* low, const charT* high) const;
    charT toupper(charT c) const;
    const charT* toupper(charT* low, const charT* high) const;
    charT tolower(charT c) const;
    const charT* tolower(charT* low, const charT* high) const;

    charT widen(char c) const;
    const charT* widen(const char* low, const charT* high, charT* to) const;
    char narrow(charT c, char dfault) const;
    const charT* narrow(const charT* low, const charT* high, char dfault, char* to) const;

  protected:
    ~ctype();
    virtual bool do_is(mask m, charT c) const;
    virtual const charT* do_is(const charT* low, const charT* high, mask* vec) const;
    virtual const charT* do_scan_is(mask m, const charT* low, const charT* high) const;
    virtual const charT* do_scan_not(mask m, const charT* low, const charT* high) const;
    virtual charT do_toupper(charT) const;
    virtual const charT* do_toupper(charT* low, const charT* high) const;
    virtual charT do_tolower(charT) const;
    virtual const charT* do_tolower(charT* low, const charT* high) const;
    virtual charT do_widen(char) const;
    virtual const char* do_widen(const char* low, const char* high, charT* dest) const;
    virtual char do_narrow(charT, char dfault) const;
    virtual const charT* do_narrow(const charT* low, const charT* high, char dfault, char* dest) const;
  };

1 Class ctype encapsulates the C library <cctype> features. istream members are required to use ctype<> for character classing during input parsing.

2 The specializations required in Table 69 (25.3.1.1.1), namely ctype<char> and ctype<wchar_t>, implement character classing appropriate to the implementation’s native character set.

25.4.1.1.1 ctype members

bool is(mask m, charT c) const;
const charT* is(const charT* low, const charT* high, mask* vec) const;

1 Returns: do_is(m, c) or do_is(low, high, vec).

const charT* scan_is(mask m,
                      const charT* low, const charT* high) const;

2 Returns: do_scan_is(m, low, high).
const charT* scan_not(mask m,
    const charT* low, const charT* high) const;

    Returns: do_scan_not(m, low, high).

charT  toupper(charT c) const;
const charT* toupper(charT* low, const charT* high) const;

    Returns: do_toupper(c) or do_toupper(low, high).

ccharT tolower(charT c) const;
const charT* tolower(charT* low, const charT* high) const;

    Returns: do_tolower(c) or do_tolower(low, high).

ccharT widen(char c) const;
const char* widen(const char* low, const char* high,
    charT* to) const;

    Returns: do_widen(c) or do_widen(low, high, to).

cchar narrow(charT c, char dfault) const;
const charT* narrow(const charT* low, const charT* high,
    charT* to) const;

    Returns: do_narrow(c, dfault) or do_narrow(low, high, dfault, to).

25.4.1.1.2 ctype virtual functions [locale.ctype.virtuals]

bool      do_is(mask m, charT c) const;
const charT* do_is(const charT* low, const charT* high,
    mask* vec) const;

    Effects: Classifies a character or sequence of characters. For each argument character, identifies a value M of type ctype_base::mask. The second form identifies a value M of type ctype_base::mask for each *p where (low <= p && p < high), and places it into vec[p - low].

    Returns: The first form returns the result of the expression (M & m) != 0; i.e., true if the character has the characteristics specified. The second form returns high.

const charT* do_scan_is(mask m, const charT* low, const charT* high) const;

    Effects: Locates a character in a buffer that conforms to a classification m.

    Returns: The smallest pointer p in the range [low, high) such that is(m, *p) would return true; otherwise, returns high.

const charT* do_scan_not(mask m, const charT* low, const charT* high) const;

    Effects: Locates a character in a buffer that fails to conform to a classification m.

    Returns: The smallest pointer p, if any, in the range [low, high) such that is(m, *p) would return false; otherwise, returns high.

charT    do_toupper(charT c) const;
const charT* do_toupper(charT* low, const charT* high) const;

    Effects: Converts a character or characters to upper case. The second form replaces each character *p in the range [low, high) for which a corresponding upper-case character exists, with that character.

    Returns: The first form returns the corresponding upper-case character if it is known to exist, or its argument if not. The second form returns high.
const charT* do_tolower(charT* low, const charT* high) const;

Effects: Converts a character or characters to lower case. The second form replaces each character *p in the range [low, high] and for which a corresponding lower-case character exists, with that character.

Returns: The first form returns the corresponding lower-case character if it is known to exist, or its argument if not. The second form returns high.

charT do_widen(char c) const;
const charT* do_widen(const charT* low, const charT* high,
                     charT* dest) const;

Effects: Applies the simplest reasonable transformation from a char value or sequence of char values to the corresponding charT value or values. The only characters for which unique transformations are required are those in the basic source character set (5.3).

For any named ctype category with a ctype <charT> facet ctc and valid ctype_base::mask value M,
( ctc.is(M, c) || !is(M, do_widen(c)) ) is true.

The second form transforms each character *p in the range [low, high], placing the result in dest[p - low].

Returns: The first form returns the transformed value. The second form returns high.

char do_narrow(charT c, char dfault) const;
const charT* do_narrow(const charT* low, const charT* high,
                       charT dfault, char* dest) const;

Effects: Applies the simplest reasonable transformation from a charT value or sequence of charT values to the corresponding char value or values.

For any character c in the basic source character set (5.3) the transformation is such that
    do_widen(do_narrow(c, 0)) == c

For any named ctype category with a ctype<char> facet ctc however, and ctype_base::mask value M,
    (is(M, c) || !ctc.is(M, do_narrow(c, dfault)) ) is true (unless do_narrow returns dfault). In addition, for any digit character c, the expression (do_narrow(c, dfault) - '0') evaluates to the digit value of the character. The second form transforms each character *p in the range [low, high], placing the result (or dfault if no simple transformation is readily available) in dest[p - low].

Returns: The first form returns the transformed value; or dfault if no mapping is readily available. The second form returns high.

25.4.1.2 Class template ctype_byname

namespace std {
    template <class charT>
    class ctype_byname : public ctype<charT> {
        public:
            using mask = typename ctype<charT>::mask;
            explicit ctype_byname(const char*, size_t refs = 0);
            explicit ctype_byname(const string&, size_t refs = 0);
            protected:
                ~ctype_byname();

233) The char argument of do_widen is intended to accept values derived from character literals for conversion to the locale’s encoding.
234) In other words, the transformed character is not a member of any character classification that c is not also a member of.
25.4.1.3 ctype specializations

namespace std {
    template <>
    class ctype<char> : public locale::facet, public ctype_base {
        public:
            using char_type = char;
            explicit ctype(const mask* tab = 0, bool del = false,
                size_t refs = 0);
            bool is(mask m, char c) const;
            const char* is(const char* low, const char* high, mask* vec) const;
            const char* scan_is (mask m,
                const char* low, const char* high) const;
            const char* scan_not(mask m,
                const char* low, const char* high) const;
            char toupper(char c) const;
            const char* toupper(char* low, const char* high) const;
            char tolower(char c) const;
            const char* tolower(char* low, const char* high) const;
            char widen(char c) const;
            const char* widen(const char* low, const char* high, char* to) const;
            char narrow(char c, char dfault) const;
            const char* narrow(const char* low, const char* high, char dfault,
                char* to) const;
        static locale::id id;
        static const size_t table_size = implementation-defined;
        const mask* table() const noexcept;
        static const mask* classic_table() noexcept;
    protected:
        ~ctype();
        virtual char do_toupper(char c) const;
        virtual const char* do_toupper(char* low, const char* high) const;
        virtual char do_tolower(char c) const;
        virtual const char* do_tolower(char* low, const char* high) const;
        virtual char do_widen(char c) const;
        virtual const char* do_widen(const char* low,
            const char* high,
            char* to) const;
        virtual char do_narrow(char c, char dfault) const;
        virtual const char* do_narrow(const char* low,
            const char* high,
            char dfault, char* to) const;
    };
}

A specialization ctype<char> is provided so that the member functions on type char can be implemented.
The implementation-defined value of member `table_size` is at least 256.

### 25.4.1.3.1 `ctype<char>` destructor

```cpp
-ctype();
```

**Effects:** If the constructor’s first argument was nonzero, and its second argument was `true`, does `delete [] table();`.

### 25.4.1.3.2 `ctype<char>` members

In the following member descriptions, for `unsigned char` values `v` where `v >= table_size`, `table()[v]` is assumed to have an implementation-specific value (possibly different for each such value `v`) without performing the array lookup.

```cpp
explicit ctype(const mask* tbl = 0, bool del = false,
              size_t refs = 0);
```

**Requires:** `tbl` either 0 or an array of at least `table_size` elements.

**Effects:** Passes its `refs` argument to its base class constructor.

```cpp
bool is(mask m, char c) const;
const char* is(const char* low, const char* high,
               mask* vec) const;
```

**Effects:** The second form, for all `*p` in the range `[low, high)`, assigns into `vec[p - low]` the value `table()[(unsigned char)*p]`.

**Returns:** The first form returns `table()[(unsigned char)c] & m`; the second form returns `high`.

```cpp
const char* scan_is(mask m, 
                    const char* low, const char* high) const;
```

**Returns:** The smallest `p` in the range `[low, high)` such that `table()[(unsigned char)*p] & m` is `true`.

```cpp
const char* scan_not(mask m, 
                     const char* low, const char* high) const;
```

**Returns:** The smallest `p` in the range `[low, high)` such that `table()[(unsigned char)*p] & m` is `false`.

```cpp
char toupper(char c) const;
const char* toupper(char* low, const char* high) const;
```

**Returns:** `do_toupper(c)` or `do_toupper(low, high)`, respectively.

```cpp
char tolower(char c) const;
const char* tolower(char* low, const char* high) const;
```

**Returns:** `do_tolower(c)` or `do_tolower(low, high)`, respectively.

```cpp
char widen(char c) const;
const char* widen(const char* low, const char* high,
                 const char* to) const;
```

---

235) Only the `char` (not `unsigned char` and `signed char`) form is provided. The specialization is specified in the standard, and not left as an implementation detail, because it affects the derivation interface for `ctype<char>`. 
Returns: do_widen(c) or do_widen(low, high, to), respectively.

char narrow(char c, char dfault) const;
const char* narrow(const char* low, const char* high,
    char dfault, char* to) const;

Returns: do_narrow(c, dfault) or do_narrow(low, high, dfault, to), respectively.

const mask* table() const noexcept;

Returns: The first constructor argument, if it was nonzero, otherwise classic_table().

25.4.1.3.3 ctype<char> static members
static const mask* classic_table() noexcept;

Returns: A pointer to the initial element of an array of size table_size which represents the classifications of characters in the "C" locale.

25.4.1.3.4 ctype<char> virtual functions
char do_toupper(char) const;
const char* do_toupper(char* low, const char* high) const;
char do_tolower(char) const;
const char* do_tolower(char* low, const char* high) const;

virtual char do_widen(char c) const;
virtual const char* do_widen(const char* low,
    const char* high,
    char* to) const;

virtual char do_narrow(char c, char dfault) const;
virtual const char* do_narrow(const char* low,
    const char* high,
    char dfault, char* to) const;

These functions are described identically as those members of the same name in the ctype class template (25.4.1.1.1).

25.4.1.4 Class template codecvt
namespace std {
class codecvt_base {
    public:
        enum result { ok, partial, error, noconv }; 
};

template <class internT, class externT, class stateT>
class codecvt : public locale::facet, public codecvt_base {
    public:
        using intern_type = internT;
        using extern_type = externT;
        using state_type = stateT;

        explicit codecvt(intern_t refs = 0);

    result out(
        stateT& state,
        const internT* from, const internT* from_end, const internT*& from_next,
        externT* to, externT* to_end, externT*& to_next) const;

§ 25.4.1.4
The class `codecvt<internT, externT, stateT>` is for use when converting from one character encoding to another, such as from wide characters to multibyte characters or between wide character encodings such as Unicode and EUC.

The `stateT` argument selects the pair of character encodings being mapped between.

The specializations required in Table 69 (25.3.1.1.1) convert the implementation-defined native character set. `codecvt<char, char, mbstate_t>` implements a degenerate conversion; it does not convert at all. The specialization `codecvt<char16_t, char, mbstate_t>` converts between the UTF-16 and UTF-8 encoding forms, and the specialization `codecvt<char32_t, char, mbstate_t>` converts between the UTF-32 and UTF-8 encoding forms. `codecvt<wchar_t, char, mbstate_t>` converts between the native character sets for narrow and wide characters. Specializations on `mbstate_t` perform conversion between encodings known to the library implementer. Other encodings can be converted by specializing on a user-defined `stateT` type. Objects of type `stateT` can contain any state that is useful to communicate to or from the specialized `do_in` or `do_out` members.

### 25.4.1.4.1 codecvt members

```cpp
result out(
    stateT& state,
    externT* to, externT* to_end, externT*& to_next) const;
```

1 The class `codecvt<internT, externT, stateT>` is for use when converting from one character encoding to another, such as from wide characters to multibyte characters or between wide character encodings such as Unicode and EUC.

2 The `stateT` argument selects the pair of character encodings being mapped between.

3 The specializations required in Table 69 (25.3.1.1.1) convert the implementation-defined native character set. `codecvt<char, char, mbstate_t>` implements a degenerate conversion; it does not convert at all. The specialization `codecvt<char16_t, char, mbstate_t>` converts between the UTF-16 and UTF-8 encoding forms, and the specialization `codecvt<char32_t, char, mbstate_t>` converts between the UTF-32 and UTF-8 encoding forms. `codecvt<wchar_t, char, mbstate_t>` converts between the native character sets for narrow and wide characters. Specializations on `mbstate_t` perform conversion between encodings known to the library implementer. Other encodings can be converted by specializing on a user-defined `stateT` type. Objects of type `stateT` can contain any state that is useful to communicate to or from the specialized `do_in` or `do_out` members.

```cpp
result unshift(
    stateT& state,
    externT* to, externT* to_end, externT*& to_next) const;
```

```cpp
result in(
    stateT& state,
    const externT* from, const externT* from_end, const externT*& from_next,
    internT* to, internT* to_end, internT*& to_next) const;
```

```cpp
int encoding() const noexcept;
bool always_noconv() const noexcept;
int length(stateT&, const externT* from, const externT* end, size_t max) const;
int max_length() const noexcept;
```

```cpp
static locale::id id;
```
const internT* from, const internT* from_end, const internT*& from_next,
externT* to, externT* to_end, externT*& to_next) const;

1 Returns: do_out(state, from, from_end, from_next, to, to_end, to_next).

result unshift(stateT& state, externT* to, externT* to_end, externT*& to_next) const;

2 Returns: do_unshift(state, to, to_end, to_next).

result in(
    stateT& state,
    const externT* from, const externT* from_end, const externT*& from_next,
    internT* to, internT* to_end, internT*& to_next) const;

3 Returns: do_in(state, from, from_end, from_next, to, to_end, to_next).

int encoding() const noexcept;

4 Returns: do_encoding().

bool always_noconv() const noexcept;

5 Returns: do_always_noconv().

int length(stateT& state, const externT* from, const externT* from_end, size_t max) const;

6 Returns: do_length(state, from, from_end, max).

int max_length() const noexcept;

7 Returns: do_max_length().

25.4.1.4.2 codecvt virtual functions [locale.codecvt.virtuals]

result do_out(
    stateT& state,
    const internT* from, const internT* from_end, const internT*& from_next,
    externT* to, externT* to_end, externT*& to_next) const;

1 Requires: (from <= from_end && to <= to_end) well-defined and true; state initialized, if at the
beginning of a sequence, or else equal to the result of converting the preceding characters in the
sequence.

Effects: Translates characters in the source range [from, from_end], placing the results in sequential
positions starting at destination to. Converts no more than (from_end - from) source elements, and
stores no more than (to_end - to) destination elements.

Stops if it encounters a character it cannot convert. It always leaves the from_next and to_next pointers
pointing one beyond the last element successfully converted. If returns noconv, internT and externT
are the same type and the converted sequence is identical to the input sequence [from, from_next).

The value of to_next is set equal to to, the value of state is unchanged, and there are no changes to the values in
[to, to_end).

A codecvt facet that is used by basic_filebuf (30.9) shall have the property that if

    do_out(state, from, from_end, from_next, to, to_end, to_next)

would return ok, where from != from_end, then

§ 25.4.1.4.2
do_out(state, from, from + 1, from_next, to, to_end, to_next) shall also return ok, and that if
doin(state, from, from_end, from_next, to, to_end, to_next)
would return ok, where to != to_end, then
doin(state, from, from_end, from_next, to, to + 1, to_next)
shall also return ok.236 Note: As a result of operations on state, it can return ok or partial and set
from_next == from and to_next != to. —end note

Remarks: Its operations on state are unspecified. [Note: This argument can be used, for example, to
maintain shift state, to specify conversion options (such as count only), or to identify a cache of seek
offsets.—end note]

Returns: An enumeration value, as summarized in Table 71.

Table 71 — do_in/do_out result values

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ok</td>
<td>completed the conversion</td>
</tr>
<tr>
<td>partial</td>
<td>not all source characters converted</td>
</tr>
<tr>
<td>error</td>
<td>encountered a character in [from, from_end)</td>
</tr>
<tr>
<td></td>
<td>that it could not convert</td>
</tr>
<tr>
<td>noconv</td>
<td>internT and externT are the same type, and input</td>
</tr>
<tr>
<td></td>
<td>sequence is identical to converted sequence</td>
</tr>
</tbody>
</table>

A return value of partial, if (from_next == from_end), indicates that either the destination sequence
has not absorbed all the available destination elements, or that additional source elements are needed
before another destination element can be produced.

result do_unshift(stateT& state, externT* to, externT* to_end, externT*& to_next) const;

Requires: (to <= to_end) well defined and true; state initialized, if at the beginning of a sequence, or
else equal to the result of converting the preceding characters in the sequence.

Effects: Places characters starting at to that should be appended to terminate a sequence when the
current stateT is given by state.237 Stores no more than (to_end - to) destination elements, and
leaves the to_next pointer pointing one beyond the last element successfully stored.

Returns: An enumeration value, as summarized in Table 72.

Table 72 — do_unshift result values

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ok</td>
<td>completed the sequence</td>
</tr>
<tr>
<td>partial</td>
<td>space for more than to_end - to destination elements was needed to terminate a sequence given the value of state</td>
</tr>
<tr>
<td>error</td>
<td>an unspecified error has occurred</td>
</tr>
<tr>
<td>noconv</td>
<td>no termination is needed for this state_type</td>
</tr>
</tbody>
</table>

236) Informally, this means that basic_filebuf assumes that the mappings from internal to external characters is 1 to N: a codecvt facet that is used by basic_filebuf must be able to translate characters one internal character at a time.
237) Typically these will be characters to return the state to stateT().
int do_encoding() const noexcept;

Returns: -1 if the encoding of the externT sequence is state-dependent; else the constant number of externT characters needed to produce an internal character; or 0 if this number is not a constant.\textsuperscript{238}

bool do_always_noconv() const noexcept;

Returns: true if do_in() and do_out() return noconv for all valid argument values. codecvt<char, char, mbstate_t> returns true.

int do_length(stateT& state, const externT* from, const externT* from_end, size_t max) const;

Requires: (from <= from_end) well-defined and true; state initialized, if at the beginning of a sequence, or else equal to the result of converting the preceding characters in the sequence.

Effects: The effect on the state argument is “as if” it called do_in(state, from, from_end, from, to, to+max, to) for to pointing to a buffer of at least max elements.

Returns: (from_next-from) where from_next is the largest value in the range [from, from_end] such that the sequence of values in the range [from, from_next) represents max or fewer valid complete characters of type internT. The specialization codecvt<char, char, mbstate_t>, returns the lesser of max and (from_end-from).

int do_max_length() const noexcept;

Returns: The maximum value that do_length(state, from, from_end, 1) can return for any valid range [from, from_end] and stateT value state. The specialization codecvt<char, char, mbstate_t>::do_max_length() returns 1.

25.4.1.5 Class template codecvt_byname

namespace std {
  template <class internT, class externT, class stateT>
  class codecvt_byname : public codecvt<internT, externT, stateT> {
    public:
      explicit codecvt_byname(const char*, size_t refs = 0);
      explicit codecvt_byname(const string&, size_t refs = 0);
    protected:
      ~codecvt_byname();
  };
}

25.4.2 The numeric category

The classes num_get<> and num_put<> handle numeric formatting and parsing. Virtual functions are provided for several numeric types. Implementations may (but are not required to) delegate extraction of smaller types to extractors for larger types.\textsuperscript{239}

All specifications of member functions for num_put and num_get in the subclauses of 25.4.2 only apply to the specializations required in Tables 69 and 70 (25.3.1.1.1), namely num_get<char>, num_get<wchar_t>, num_get<C, InputIterator>, num_put<char>, num_put<wchar_t>, and num_put<C, OutputIterator>. These specializations refer to the ios_base& argument for formatting specifications (25.4), and to its imbued locale for the numpunct<> facet to identify all numeric punctuation preferences, and also for the ctype<> facet to perform character classification.

\textsuperscript{238} If encoding() yields -1, then more than max_length() externT elements may be consumed when producing a single internT character, and additional externT elements may appear at the end of a sequence after those that yield the final internT character.

\textsuperscript{239} Parsing "-1" correctly into, e.g., an unsigned short requires that the corresponding member get() at least extract the sign before delegating.
Extractor and inserter members of the standard iostreams use `num_get<>` and `num_put<>` member functions for formatting and parsing numeric values (30.7.4.2.1, 30.7.5.2.1).

### 25.4.2.1 Class template `num_get`

```cpp
namespace std {
    template <class charT, class InputIterator = istreambuf_iterator<charT>>
    class num_get : public locale::facet {
public:
    using char_type = charT;
    using iter_type = InputIterator;

    explicit num_get(size_t refs = 0);

    iter_type get(iter_type in, iter_type end, ios_base&,
                  std::ios_base::iostate&, bool& v) const;
    iter_type get(iter_type in, iter_type end, ios_base&,
                  std::ios_base::iostate&, long& v) const;
    iter_type get(iter_type in, iter_type end, ios_base&,
                  std::ios_base::iostate&, long long& v) const;
    iter_type get(iter_type in, iter_type end, ios_base&,
                  std::ios_base::iostate&, unsigned short& v) const;
    iter_type get(iter_type in, iter_type end, ios_base&,
                  std::ios_base::iostate&, unsigned int& v) const;
    iter_type get(iter_type in, iter_type end, ios_base&,
                  std::ios_base::iostate&, unsigned long& v) const;
    iter_type get(iter_type in, iter_type end, ios_base&,
                  std::ios_base::iostate&, unsigned long long& v) const;
    iter_type get(iter_type in, iter_type end, ios_base&,
                  std::ios_base::iostate&, float& v) const;
    iter_type get(iter_type in, iter_type end, ios_base&,
                  std::ios_base::iostate&, double& v) const;
    iter_type get(iter_type in, iter_type end, ios_base&,
                  std::ios_base::iostate&, long double& v) const;
    iter_type get(iter_type in, iter_type end, ios_base&,
                  std::ios_base::iostate&, void*& v) const;

    static locale::id id;
}
```
The facet `num_get` is used to parse numeric values from an input sequence such as an istream.

### 25.4.2.1.1 num_get members

- `iter_type get(iter_type in, iter_type end, ios_base& str, ios_base::iostate& err, bool& val) const;`
- `iter_type get(iter_type in, iter_type end, ios_base& str, ios_base::iostate& err, long& val) const;`
- `iter_type get(iter_type in, iter_type end, ios_base& str, ios_base::iostate& err, long long& val) const;`
- `iter_type get(iter_type in, iter_type end, ios_base& str, ios_base::iostate& err, unsigned short& val) const;`
- `iter_type get(iter_type in, iter_type end, ios_base& str, ios_base::iostate& err, unsigned int& val) const;`
- `iter_type get(iter_type in, iter_type end, ios_base& str, ios_base::iostate& err, unsigned long& val) const;`
- `iter_type get(iter_type in, iter_type end, ios_base& str, ios_base::iostate& err, unsigned long long& val) const;`
- `iter_type get(iter_type in, iter_type end, ios_base& str, ios_base::iostate& err, float& val) const;`
- `iter_type get(iter_type in, iter_type end, ios_base& str, ios_base::iostate& err, double& val) const;`

#### Returns: `do_get(in, end, str, err, val).`

### 25.4.2.1.2 num_get virtual functions

- `iter_type do_get(iter_type in, iter_type end, ios_base& str, ios_base::iostate& err, bool& v) const;`
- `iter_type do_get(iter_type in, iter_type end, ios_base& str, ios_base::iostate& err, double& v) const;`
- `iter_type do_get(iter_type in, iter_type end, ios_base& str, ios_base::iostate& err, long double& v) const;`
- `iter_type do_get(iter_type in, iter_type end, ios_base& str, ios_base::iostate& err, void*& v) const;`
**iter_type do_get(iter_type in, iter_type end, ios_base& str, ios_base::iostate& err, long double& val) const;**

**iter_type do_get(iter_type in, iter_type end, ios_base& str, ios_base::iostate& err, void*& val) const;**

1. **Effects:** Reads characters from `in`, interpreting them according to `str.flags()`, `use_facet<ctype<charT>>(loc)`, and `use_facet<numpunct<charT>>(loc)`, where `loc` is `str.getloc()`.

2. The details of this operation occur in three stages

   (2.1) — Stage 1: Determine a conversion specifier
   
   (2.2) — Stage 2: Extract characters from `in` and determine a corresponding `char` value for the format expected by the conversion specification determined in stage 1.
   
   (2.3) — Stage 3: Store results

3. The details of the stages are presented below.

**Stage 1:** The function initializes local variables via

```cpp
fmtflags flags = str.flags();
fmtflags basefield = (flags & ios_base::basefield);
fmtflags uppercase = (flags & ios_base::uppercase);
fmtflags boolalpha = (flags & ios_base::boolalpha);
```

For conversion to an integral type, the function determines the integral conversion specifier as indicated in Table 73. The table is ordered. That is, the first line whose condition is true applies.

**Table 73 — Integer conversions**

<table>
<thead>
<tr>
<th>State</th>
<th>stdio equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>basefield == oct</td>
<td>%o</td>
</tr>
<tr>
<td>basefield == hex</td>
<td>%X</td>
</tr>
<tr>
<td>basefield == 0</td>
<td>%i</td>
</tr>
<tr>
<td>signed integral type</td>
<td>%d</td>
</tr>
<tr>
<td>unsigned integral type</td>
<td>%u</td>
</tr>
</tbody>
</table>

For conversions to a floating type the specifier is %g.

For conversions to `void*` the specifier is %p.

A length modifier is added to the conversion specification, if needed, as indicated in Table 74.

**Table 74 — Length modifier**

<table>
<thead>
<tr>
<th>Type</th>
<th>Length modifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>short</td>
<td>h</td>
</tr>
<tr>
<td>unsigned short</td>
<td>h</td>
</tr>
<tr>
<td>long</td>
<td>l</td>
</tr>
<tr>
<td>unsigned long</td>
<td>l</td>
</tr>
<tr>
<td>long long</td>
<td>ll</td>
</tr>
<tr>
<td>unsigned long long</td>
<td>ll</td>
</tr>
<tr>
<td>double</td>
<td>l</td>
</tr>
<tr>
<td>long double</td>
<td>L</td>
</tr>
</tbody>
</table>

**Stage 2:** If `in == end` then stage 2 terminates. Otherwise a `charT` is taken from `in` and local variables are initialized as if by

§ 25.4.2.1.2
char_type ct = *in;
char c = src[find(atoms, atoms + sizeof(src) - 1, ct) - atoms];
if (ct == use_facet<numpunct<charT>>(loc).decimal_point())
  c = '．';
bool discard =
  ct == use_facet<numpunct<charT>>(loc).thousands_sep()
  && use_facet<numpunct<charT>>(loc).grouping().length() != 0;
where the values src and atoms are defined as if by:
  static const char src[] = "0123456789abcdefxABCDEFX+-";
  char_type atoms[sizeof(src)];
  use_facet<ctype<charT>>(loc).widen(src, src + sizeof(src), atoms);
for this value of loc.
If discard is true, then if '．' has not yet been accumulated, then the position of the character is remembered, but the character is otherwise ignored. Otherwise, if '．' has already been accumulated, the character is discarded and Stage 2 terminates. If it is not discarded, then a check is made to determine if c is allowed as the next character of an input field of the conversion specifier returned by Stage 1. If so, it is accumulated.
If the character is either discarded or accumulated then in is advanced by ++in and processing returns to the beginning of stage 2.

Stage 3: The sequence of chars accumulated in stage 2 (the field) is converted to a numeric value by the rules of one of the functions declared in the header <cstdlib>:

- For a signed integer value, the function `strtoll`.
- For an unsigned integer value, the function `strtoull`.
- For a float value, the function `strtof`.
- For a double value, the function `strtod`.
- For a long double value, the function `strtold`.
The numeric value to be stored can be one of:

- zero, if the conversion function does not convert the entire field.
- the most positive (or negative) representable value, if the field to be converted to a signed integer type represents a value too large positive (or negative) to be represented in `val`.
- the most positive representable value, if the field to be converted to an unsigned integer type represents a value that cannot be represented in `val`.
- the converted value, otherwise.
The resultant numeric value is stored in `val`. If the conversion function does not convert the entire field, or if the field represents a value outside the range of representable values, `ios_base::failbit` is assigned to `err`.

Digit grouping is checked. That is, the positions of discarded separators is examined for consistency with `use_facet<numpunct<charT>>(loc).grouping()`. If they are not consistent then `ios_base::failbit` is assigned to `err`.

In any case, if stage 2 processing was terminated by the test for `in == end` then `err |== ios_base::eofbit` is performed.

iter_type do_get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, bool& val) const;
Effects: If `(str.flags()&ios_base::boolalpha) == 0` then input proceeds as it would for a long except that if a value is being stored into `val`, the value is determined according to the following: If the value to be stored is 0 then `false` is stored. If the value is 1 then `true` is stored. Otherwise `true` is stored and `ios_base::failbit` is assigned to `err`. 

§ 25.4.2.1.2
Otherwise target sequences are determined “as if” by calling the members `falsename()` and `truename()` of the facet obtained by `use_facet<numpunct<charT>>(str.getloc())`. Successive characters in the range `[in, end)` (see 26.2.3) are obtained and matched against corresponding positions in the target sequences only as necessary to identify a unique match. The input iterator `in` is compared to `end` only when necessary to obtain a character. If a target sequence is uniquely matched, `val` is set to the corresponding value. Otherwise `false` is stored and `ios_base::failbit` is assigned to `err`.

The `in` iterator is always left pointing one position beyond the last character successfully matched. If `val` is set, then `err` is set to `str.goodbit`; or to `str.eofbit` if, when seeking another character to match, it is found that (`in == end`). If `val` is not set, then `err` is set to `str.failbit`; or to (`str.failbit|str.eofbit`) if the reason for the failure was that (`in == end`).  

Example: For targets `true`: "a" and `false`: "abb", the input sequence "a" yields `val == true` and `err == str.eofbit`; the input sequence "abc" yields `err = str.failbit`, with `in` ending at the ‘c’ element. For targets `true`: "1" and `false`: "0", the input sequence "1" yields `val == true` and `err == str.goodbit`. For empty targets (""), any input sequence yields `err == str.failbit. —end example

Returns: `in`.

25.4.2.2 Class template num_put

```cpp
namespace std {
    template <class charT, class OutputIterator = ostreambuf_iterator<charT>>
    class num_put : public locale::facet {
    public:
        using char_type = charT;
        using iter_type = OutputIterator;

        explicit num_put(size_t refs = 0);

        iter_type put(iter_type s, ios_base& f, char_type fill, bool v) const;
        iter_type put(iter_type s, ios_base& f, char_type fill, long v) const;
        iter_type put(iter_type s, ios_base& f, char_type fill, long long v) const;
        iter_type put(iter_type s, ios_base& f, char_type fill, unsigned long) const;
        iter_type put(iter_type s, ios_base& f, char_type fill, unsigned long long) const;
        iter_type put(iter_type s, ios_base& f, char_type fill, double v) const;
        iter_type put(iter_type s, ios_base& f, char_type fill, long double v) const;
        iter_type put(iter_type s, ios_base& f, char_type fill, const void* v) const;

        static locale::id id;
    protected:
        ~num_put();
        virtual iter_type do_put(iter_type, ios_base&, char_type fill, bool v) const;
        virtual iter_type do_put(iter_type, ios_base&, char_type fill, long v) const;
        virtual iter_type do_put(iter_type, ios_base&, char_type fill, long long v) const;
        virtual iter_type do_put(iter_type, ios_base&, char_type fill, unsigned long) const;
        virtual iter_type do_put(iter_type, ios_base&, char_type fill, unsigned long long) const;
        virtual iter_type do_put(iter_type, ios_base&, char_type fill, double v) const;
        virtual iter_type do_put(iter_type, ios_base&, char_type fill, long double v) const;
        virtual iter_type do_put(iter_type, ios_base&, char_type fill, const void* v) const;
    }
};
```

The facet `num_put` is used to format numeric values to a character sequence such as an ostream.

25.4.2.2.1 num_put members
iter_type put(iter_type out, ios_base& str, char_type fill, bool val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, long long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, unsigned long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, unsigned long long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, double val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, long double val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, const void* val) const;

Returns: do_put(out, str, fill, val).

25.4.2.2.2  num_put virtual functions  [facet.num.put.virtuals]

iter_type do_put(iter_type out, ios_base& str, char_type fill, long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, long long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, unsigned long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, unsigned long long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, double val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, long double val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, const void* val) const;

Effects: Writes characters to the sequence out, formatting val as desired. In the following description, a local variable initialized with:
locale loc = str.getloc();
The details of this operation occur in several stages:

(2.1) — Stage 1: Determine a printf conversion specifier spec and determine the characters that would be printed by printf (30.11) given this conversion specifier for

printf(spec, val)

assuming that the current locale is the "C" locale.

(2.2) — Stage 2: Adjust the representation by converting each char determined by stage 1 to a charT using a conversion and values returned by members of use_facet<numpunct<charT>>(str.getloc())

(2.3) — Stage 3: Determine where padding is required.

(2.4) — Stage 4: Insert the sequence into the out.

Detailed descriptions of each stage follow.

Returns: out.

Stage 1: The first action of stage 1 is to determine a conversion specifier. The tables that describe this determination use the following local variables

fmtflags flags = str.flags();
fmtflags basefield = (flags & (ios_base::basefield));
fmtflags uppercase = (flags & (ios_base::uppercase));
fmtflags floatfield = (flags & (ios_base::floatfield));
fmtflags showpos = (flags & (ios_base::showpos));
fmtflags showbase = (flags & (ios_base::showbase));
fmtflags showpoint = (flags & (ios_base::showpoint));

All tables used in describing stage 1 are ordered. That is, the first line whose condition is true applies. A line without a condition is the default behavior when none of the earlier lines apply.

For conversion from an integral type other than a character type, the function determines the integral conversion specifier as indicated in Table 75.
Table 75 — Integer conversions

<table>
<thead>
<tr>
<th>State</th>
<th>stdio equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>basefield == ios_base::oct</td>
<td>%o</td>
</tr>
<tr>
<td>(basefield == ios_base::hex) &amp;&amp; !uppercase</td>
<td>%x</td>
</tr>
<tr>
<td>(basefield == ios_base::hex)</td>
<td>%X</td>
</tr>
<tr>
<td>for a signed integral type</td>
<td>%d</td>
</tr>
<tr>
<td>for an unsigned integral type</td>
<td>%u</td>
</tr>
</tbody>
</table>

For conversion from a floating-point type, the function determines the floating-point conversion specifier as indicated in Table 76.

Table 76 — Floating-point conversions

<table>
<thead>
<tr>
<th>State</th>
<th>stdio equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>floatfield == ios_base::fixed</td>
<td>%f</td>
</tr>
<tr>
<td>floatfield == ios_base::scientific &amp;&amp; !uppercase</td>
<td>%e</td>
</tr>
<tr>
<td>floatfield == ios_base::scientific</td>
<td>%E</td>
</tr>
<tr>
<td>floatfield == (ios_base::fixed</td>
<td>ios_base::scientific) &amp;&amp; !uppercase</td>
</tr>
<tr>
<td>floatfield == (ios_base::fixed</td>
<td>ios_base::scientific)</td>
</tr>
<tr>
<td>!uppercase</td>
<td>%g</td>
</tr>
<tr>
<td>otherwise</td>
<td>%G</td>
</tr>
</tbody>
</table>

For conversions from an integral or floating-point type a length modifier is added to the conversion specifier as indicated in Table 77.

Table 77 — Length modifier

<table>
<thead>
<tr>
<th>Type</th>
<th>Length modifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>long</td>
<td>l</td>
</tr>
<tr>
<td>long long</td>
<td>ll</td>
</tr>
<tr>
<td>unsigned long</td>
<td>l</td>
</tr>
<tr>
<td>unsigned long long</td>
<td>ll</td>
</tr>
<tr>
<td>long double</td>
<td>L</td>
</tr>
<tr>
<td>otherwise</td>
<td>none</td>
</tr>
</tbody>
</table>

The conversion specifier has the following optional additional qualifiers prepended as indicated in Table 78.

Table 78 — Numeric conversions

<table>
<thead>
<tr>
<th>Type(s)</th>
<th>State</th>
<th>stdio equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>an integral type</td>
<td>showpos</td>
<td>+</td>

<td></td>
<td>showbase</td>
<td>#</td>
</tr>
<tr>
<td>a floating-point type</td>
<td>showpos</td>
<td>+</td>
</tr>
<tr>
<td></td>
<td>showpoint</td>
<td>#</td>
</tr>
</tbody>
</table>

For conversion from a floating-point type, if floatfield != (ios_base::fixed | ios_base::scientific), str.precision() is specified as precision in the conversion specification. Otherwise, no precision is specified.
For conversion from void* the specifier is %p.

The representations at the end of stage 1 consists of the char's that would be printed by a call of printf(s, val) where s is the conversion specifier determined above.

Stage 2: Any character c other than a decimal point(.) is converted to a charT via use_facet<ctype<charT>>(loc).widen( c )

A local variable punct is initialized via

    const numpunct<charT>& punct = use_facet<numpunct<charT>>(str.getloc());

For arithmetic types, punct.thousands_sep() characters are inserted into the sequence as determined by the value returned by punct.do_grouping() using the method described in 25.4.3.1.2

Decimal point characters(.) are replaced by punct.decimal_point().

Stage 3: A local variable is initialized as

    fmtflags adjustfield = (flags & (ios_base::adjustfield));

The location of any padding\textsuperscript{240} is determined according to Table 79.

Table 79 — Fill padding

<table>
<thead>
<tr>
<th>State</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>adjustfield == ios_base::left</td>
<td>pad after</td>
</tr>
<tr>
<td>adjustfield == ios_base::right</td>
<td>pad before</td>
</tr>
<tr>
<td>adjustfield == internal and a sign occurs in the representation</td>
<td>pad after the sign</td>
</tr>
<tr>
<td>adjustfield == internal and representation after stage 1 began with 0x or 0X</td>
<td>pad after x or X</td>
</tr>
<tr>
<td>otherwise</td>
<td>pad before</td>
</tr>
</tbody>
</table>

If str.width() is nonzero and the number of charT's in the sequence after stage 2 is less than str.width(), then enough fill characters are added to the sequence at the position indicated for padding to bring the length of the sequence to str.width().

str.width(0) is called.

Stage 4: The sequence of charT's at the end of stage 3 are output via

    *out++ = c

\textsuperscript{6} iter_type do_put(iter_type out, ios_base& str, char_type fill, bool val) const;

Returns: If \((\text{str.flags()} \& \text{ios_base::boolalpha}) == 0\) returns do_put(out, str, fill, (int)val), otherwise obtains a string s as if by

    string_type s =
    val ? use_facet<numpunct<charT>>(loc).truename() : use_facet<numpunct<charT>>(loc).falsename();

and then inserts each character c of s into out via *out++ = c and returns out.

25.4.3 The numeric punctuation facet

25.4.3.1 Class template numpunct

namespace std {
    template <class charT>
    class numpunct : public locale::facet {
        public:

240 The conversion specification #o generates a leading 0 which is not a padding character.
using char_type = charT;
using string_type = basic_string<charT>;

explicit numpunct(size_t refs = 0);

char_type decimal_point() const;
char_type thousands_sep() const;
string grouping() const;
string_type truename() const;
string_type falsename() const;

static locale::id id;

protected:
~numpunct();  // virtual
virtual char_type do_decimal_point() const;
virtual char_type do_thousands_sep() const;
virtual string do_grouping() const;
virtual string_type do_truename() const;  // for bool
virtual string_type do_falsename() const;  // for bool
};

1 numpunct<> specifies numeric punctuation. The specializations required in Table 69 (25.3.1.1.1), namely numpunct<wchar_t> and numpunct<char>, provide classic "C" numeric formats, i.e., they contain information equivalent to that contained in the "C" locale or their wide character counterparts as if obtained by a call to widen.

2 The syntax for number formats is as follows, where digit represents the radix set specified by the fmtflags argument value, and thousands-sep and decimal-point are the results of corresponding numpunct<charT> members. Integer values have the format:

integer ::= [sign] units
sign ::= plusminus
plusminus ::= '+' | '-'
units ::= digits [thousands-sep units]
digits ::= digit [digits]

and floating-point values have:

floatval ::= [sign] units [decimal-point [digits]] [e [sign] digits] |
[sign] decimal-point digits [e [sign] digits]
e ::= 'e' | 'E'

where the number of digits between thousands-seps is as specified by do_grouping(). For parsing, if the digits portion contains no thousands-separators, no grouping constraint is applied.

25.4.3.1.1 numpunct members

char_type decimal_point() const;
1 Returns: do_decimal_point().

char_type thousands_sep() const;
2 Returns: do_thousands_sep().

string grouping() const;
3 Returns: do_grouping().

§ 25.4.3.1.1
string_type truename() const;
string_type falsename() const;

Returns: do_truename() or do_falsename(), respectively.

25.4.3.1.2 numppunct virtual functions

char_type do_decimal_point() const;
1
Returns: A character for use as the decimal radix separator. The required specializations return \'.\' or L'.\'.

char_type do_thousands_sep() const;
2
Returns: A character for use as the digit group separator. The required specializations return \',\' or L',\'.

string do_grouping() const;
3
Returns: A basic_string<char> vec used as a vector of integer values, in which each element vec[i]
represents the number of digits\(^{241}\) in the group at position i, starting with position 0 as the rightmost

group. If vec.size() <= i, the number is the same as group (i - 1); if (i < 0 || vec[i] <= 0
|| vec[i] == CHAR_MAX), the size of the digit group is unlimited.

The required specializations return the empty string, indicating no grouping.

string_type do_truename() const;
5
Returns: A string representing the name of the boolean value true or false, respectively.

In the base class implementation these names are "true" and "false", or L"true" and L"false".

25.4.3.2 Class template numppunct_byname

namespace std {
    template <class charT>
    class numppunct_byname : public numppunct<charT> {
        // this class is specialized for char and wchar_t.
        public:
            using char_type = charT;
            using string_type = basic_string<charT>;

            explicit numppunct_byname(const char*, size_t refs = 0);
            explicit numppunct_byname(const string&, size_t refs = 0);
            protected:
                ~numppunct_byname();
        }
    }
}

25.4.4 The collate category

25.4.4.1 Class template collate

namespace std {
    template <class charT>
    class collate : public locale::facet {
        public:
            using char_type = charT;

241) Thus, the string "\003" specifies groups of 3 digits each, and "3" probably indicates groups of 51 (!) digits each, because 51
is the ASCII value of "3".

§ 25.4.4.1
using string_type = basic_string<charT>;

explicit collate(size_t refs = 0);

int compare(const charT* low1, const charT* high1,
            const charT* low2, const charT* high2) const;
string_type transform(const charT* low, const charT* high) const;
long hash(const charT* low, const charT* high) const;

static locale::id id;

protected:
    ~collate();
    virtual int do_compare(const charT* low1, const charT* high1,
                           const charT* low2, const charT* high2) const;
    virtual string_type do_transform(const charT* low, const charT* high) const;
    virtual long do_hash(const charT* low, const charT* high) const;
};

1 The class collate<charT> provides features for use in the collation (comparison) and hashing of strings. A locale member function template, operator(), uses the collate facet to allow a locale to act directly as the predicate argument for standard algorithms (Clause 28) and containers operating on strings. The specializations required in Table 69 (25.3.1.1.1), namely collate<char> and collate<wchar_t>, apply lexicographic ordering (28.7.10).

2 Each function compares a string of characters *p in the range [low, high).

25.4.4.1.1 collate members

int compare(const charT* low1, const charT* high1,
            const charT* low2, const charT* high2) const;

Returns: do_compare(low1, high1, low2, high2).

string_type transform(const charT* low, const charT* high) const;

Returns: do_transform(low, high).

long hash(const charT* low, const charT* high) const;

Returns: do_hash(low, high).

25.4.4.1.2 collate virtual functions

int do_compare(const charT* low1, const charT* high1,
               const charT* low2, const charT* high2) const;

Returns: 1 if the first string is greater than the second, -1 if less, zero otherwise. The specializations required in Table 69 (25.3.1.1.1), namely collate<char> and collate<wchar_t>, implement a lexicographical comparison (28.7.10).

string_type do_transform(const charT* low, const charT* high) const;

Returns: A basic_string<charT> value that, compared lexicographically with the result of calling transform() on another string, yields the same result as calling do_compare() on the same two strings. \(^{242}\)

long do_hash(const charT* low, const charT* high) const;

---

\(^{242}\) This function is useful when one string is being compared to many other strings.
Returns: An integer value equal to the result of calling hash() on any other string for which do_compare() returns 0 (equal) when passed the two strings. [Note: The probability that the result equals that for another string which does not compare equal should be very small, approaching (1.0/numeric_limits<unsigned long>::max()). —end note]

25.4.4.2 Class template collate_byname

namespace std {
  template <class charT>
  class collate_byname : public collate<charT> {
    public:
      using string_type = basic_string<charT>;
      explicit collate_byname(const char*, size_t refs = 0);
      explicit collate_byname(const string&, size_t refs = 0);
    protected:
      ~collate_byname();
  };
}

25.4.5 The time category

Templates time_get<charT, InputIterator> and time_put<charT, OutputIterator> provide date and time formatting and parsing. All specifications of member functions for time_put and time_get in the subclauses of 25.4.5 only apply to the specializations required in Tables 69 and 70 (25.3.1.1.1). Their members use their ios_base&, ios_base::iostate&, and fill arguments as described in 25.4, and the ctype<> facet, to determine formatting details.

25.4.5.1 Class template time_get

namespace std {
  class time_base {
    public:
      enum dateorder { no_order, dmy, mdy, ymd, ydm };
  };

  template <class charT, class InputIterator = istreambuf_iterator<charT>>
  class time_get : public locale::facet, public time_base {
    public:
      using char_type = charT;
      using iter_type = InputIterator;
      explicit time_get(size_t refs = 0);
      dateorder date_order() const { return do_date_order(); }
      iter_type get_time(iter_type s, iter_type end, ios_base& f,
          ios_base::iostate& err, tm* t) const;
      iter_type get_date(iter_type s, iter_type end, ios_base& f,
          ios_base::iostate& err, tm* t) const;
      iter_type get_weekday(iter_type s, iter_type end, ios_base& f,
          ios_base::iostate& err, tm* t) const;
      iter_type get_monthname(iter_type s, iter_type end, ios_base& f,
          ios_base::iostate& err, tm* t) const;
      iter_type get_year(iter_type s, iter_type end, ios_base& f,
          ios_base::iostate& err, tm* t) const;
      iter_type get(iter_type s, iter_type end, ios_base& f,
          ios_base::iostate& err, tm* t, char format, char modifier = 0) const;
  };
}
iter_type get(iter_type s, iter_type end, ios_base& f,  
    ios_base::iostate& err, tm* t, const char_type* fmt,  
    const char_type* fmtend) const;

static locale::id id;

protected:
    ~time_get();
    virtual dateorder do_date_order() const;
    virtual iter_type do_get_time(iter_type s, iter_type end, ios_base& f,  
        ios_base::iostate& err, tm* t) const;
    virtual iter_type do_get_date(iter_type s, iter_type end, ios_base& f,  
        ios_base::iostate& err, tm* t) const;
    virtual iter_type do_get_weekday(iter_type s, iter_type end, ios_base& f,  
        ios_base::iostate& err, tm* t) const;
    virtual iter_type do_get_monthname(iter_type s, iter_type end, ios_base& f,  
        ios_base::iostate& err, tm* t) const;
    virtual iter_type do_get_year(iter_type s, iter_type end, ios_base& f,  
        ios_base::iostate& err, tm* t) const;
    virtual iter_type do_get(iter_type s, iter_type end, ios_base& f,  
        ios_base::iostate& err, tm* t, char format, char modifier) const;
};

1 time_get is used to parse a character sequence, extracting components of a time or date into a struct tm object. Each get member parses a format as produced by a corresponding format specifier to time_put<>::put. If the sequence being parsed matches the correct format, the corresponding members of the struct tm argument are set to the values used to produce the sequence; otherwise either an error is reported or unspecified values are assigned.243

2 If the end iterator is reached during parsing by any of the get() member functions, the member sets ios_base::eofbit in err.

25.4.5.1.1 time_get members

[locale.time.get.members]

dateorder date_order() const;

1 Returns: do_date_order().

iter_type get_time(iter_type s, iter_type end, ios_base& str,  
    ios_base::iostate& err, tm* t) const;

2 Returns: do_get_time(s, end, str, err, t).

iter_type get_date(iter_type s, iter_type end, ios_base& str,  
    ios_base::iostate& err, tm* t) const;

3 Returns: do_get_date(s, end, str, err, t).

iter_type get_weekday(iter_type s, iter_type end, ios_base& str,  
    ios_base::iostate& err, tm* t) const;
    iter_type get_monthname(iter_type s, iter_type end, ios_base& str,  
        ios_base::iostate& err, tm* t) const;

4 Returns: do_get_weekday(s, end, str, err, t) or do_get_monthname(s, end, str, err, t).

iter_type get_year(iter_type s, iter_type end, ios_base& str,  

243) In other words, user confirmation is required for reliable parsing of user-entered dates and times, but machine-generated formats can be parsed reliably. This allows parsers to be aggressive about interpreting user variations on standard formats.

§ 25.4.5.1.1
Returns: do_get_year(s, end, str, err, t).

iter_type get(iter_type s, iter_type end, ios_base& f, ios_base::iostate& err, tm* t, char format, char modifier = 0) const;

Returns: do_get(s, end, f, err, t, format, modifier).

iter_type get(iter_type s, iter_type end, ios_base& f, ios_base::iostate& err, tm* t, const char_type* fmt, const char_type* fmtend) const;

Requires: [fmt, fmtend) shall be a valid range.

Effects: The function starts by evaluating err = ios_base::goodbit. It then enters a loop, reading zero or more characters from s at each iteration. Unless otherwise specified below, the loop terminates when the first of the following conditions holds:

(8.1) — The expression fmt == fmtend evaluates to true.
(8.2) — The expression err == ios_base::goodbit evaluates to false.
(8.3) — The expression s == end evaluates to true, in which case the function evaluates err = ios_base::eofbit | ios_base::failbit.
(8.4) — The next element of fmt is equal to '%', optionally followed by a modifier character, followed by a conversion specifier character, format, together forming a conversion specification valid for the ISO/IEC 9945 function strptime. If the number of elements in the range [fmt, fmtend) is not sufficient to unambiguously determine whether the conversion specification is complete and valid, the function evaluates err = ios_base::failbit. Otherwise, the function evaluates s = do_get(s, end, f, err, t, format, modifier), where the value of modifier is '\0' when the optional modifier is absent from the conversion specification. If err == ios_base::goodbit holds after the evaluation of the expression, the function increments fmt to point just past the end of the conversion specification and continues looping.
(8.5) — The expression isspace(*fmt, f.getloc()) evaluates to true, in which case the function first increments fmt until fmt == fmtend || !isspace(*fmt, f.getloc()) evaluates to true, then advances s until s == end || !isspace(*s, f.getloc()) is true, and finally resumes looping.
(8.6) — The next character read from s matches the element pointed to by fmt in a case-insensitive comparison, in which case the function evaluates ++fmt, ++s and continues looping. Otherwise, the function evaluates err = ios_base::failbit.

Note: The function uses the ctype<charT> facet installed in f’s locale to determine valid whitespace characters. It is unspecified by what means the function performs case-insensitive comparison or whether multi-character sequences are considered while doing so. — end note

Returns: s.

25.4.5.1.2 time_get virtual functions

dateorder do_date_order() const;

Returns: An enumeration value indicating the preferred order of components for those date formats that are composed of day, month, and year. Returns no_order if the date format specified by 'x' contains other variable components (e.g., Julian day, week number, week day).

iter_type do_get_time(iter_type s, iter_type end, ios_base& str, ios_base::iostate& err, tm* t) const;

244) This function is intended as a convenience only, for common formats, and may return no_order in valid locales.
Effects: Reads characters starting at \(s\) until it has extracted those \texttt{struct tm} members, and remaining
format characters, used by \texttt{time_put<>::put} to produce the format specified by \texttt{"%H:%M:%S"}, or until
it encounters an error or end of sequence.

Returns: An iterator pointing immediately beyond the last character recognized as possibly part of a
valid time.

\[
\text{iter	extunderscore type do	extunderscore get	extunderscore date(}
\text{iter	extunderscore type s, iter	extunderscore type end, ios	extunderscore base	extunderscore str,}
\text{ios	extunderscore base	extunderscore iostate	extunderscore err, tm	extunderscore t}) \text{ const;
}
\]

Effects: Reads characters starting at \(s\) until it has extracted those \texttt{struct tm} members and remaining
format characters used by \texttt{time_put<>::put} to produce one of the following formats, or until it
encounters an error. The format depends on the value returned by \texttt{date_order()} as shown in Table 80.

Table 80 — do_get_date effects

<table>
<thead>
<tr>
<th>date_order()</th>
<th>Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>no_order</td>
<td>&quot;%m%d%y&quot;</td>
</tr>
<tr>
<td>dmy</td>
<td>&quot;%d%m%y&quot;</td>
</tr>
<tr>
<td>mdy</td>
<td>&quot;%m%d%y&quot;</td>
</tr>
<tr>
<td>ymd</td>
<td>&quot;%y%m%d&quot;</td>
</tr>
<tr>
<td>ydm</td>
<td>&quot;%y%d%m&quot;</td>
</tr>
</tbody>
</table>

An implementation may also accept additional implementation-defined formats.

Returns: An iterator pointing immediately beyond the last character recognized as possibly part of a
valid date.

\[
\text{iter	extunderscore type do	extunderscore get	extunderscore weekday(}
\text{iter	extunderscore type s, iter	extunderscore type end, ios	extunderscore base	extunderscore str,}
\text{ios	extunderscore base	extunderscore iostate	extunderscore err, tm	extunderscore t}) \text{ const;
}
\]

\[
\text{iter	extunderscore type do	extunderscore get	extunderscore monthname(}
\text{iter	extunderscore type s, iter	extunderscore type end, ios	extunderscore base	extunderscore str,}
\text{ios	extunderscore base	extunderscore iostate	extunderscore err, tm	extunderscore t}) \text{ const;
}
\]

Effects: Reads characters starting at \(s\) until it has extracted the (perhaps abbreviated) name of a
weekday or month. If it finds an abbreviation that is followed by characters that could match a full
name, it continues reading until it matches the full name or fails. It sets the appropriate \texttt{struct tm}
member accordingly.

Returns: An iterator pointing immediately beyond the last character recognized as part of a valid name.

\[
\text{iter	extunderscore type do	extunderscore get	extunderscore year(}
\text{iter	extunderscore type s, iter	extunderscore type end, ios	extunderscore base	extunderscore str,}
\text{ios	extunderscore base	extunderscore iostate	extunderscore err, tm	extunderscore t}) \text{ const;
}
\]

Effects: Reads characters starting at \(s\) until it has extracted an unambiguous year identifier. It is
implementation-defined whether two-digit year numbers are accepted, and (if so) what century they
are assumed to lie in. Sets the \(t->tm\_year\) member accordingly.

Returns: An iterator pointing immediately beyond the last character recognized as part of a valid year
identifier.

\[
\text{iter	extunderscore type do	extunderscore get(}
\text{iter	extunderscore type s, iter	extunderscore type end, ios	extunderscore base	extunderscore f,}
\text{ios	extunderscore base	extunderscore iostate	extunderscore err, tm	extunderscore t, char format, char modifier}) \text{ const;
}
\]

Requires: \(t\) shall point to an object.

Effects: The function starts by evaluating \(err = \text{ios	extunderscore base	extunderscore:iostate::goodbit}\). It then reads characters starting
at \(s\) until it encounters an error, or until it has extracted and assigned those \texttt{struct tm} members, and
any remaining format characters, corresponding to a conversion directive appropriate for the ISO/IEC
9945 function `strptime`, formed by concatenating ‘%’, the modifier character, when non-NUL, and the format character. When the concatenation fails to yield a complete valid directive the function leaves the object pointed to by `t` unchanged and evaluates `err |= ios_base::failbit`. When `s == end` evaluates to `true` after reading a character the function evaluates `err |= ios_base::eofbit`. For complex conversion directives such as `%c`, `%x`, or `%X`, or directives that involve the optional modifiers E or O, when the function is unable to unambiguously determine some or all struct tm members from the input sequence `[s, end)`, it evaluates `err |= ios_base::eofbit`. In such cases the values of those struct tm members are unspecified and may be outside their valid range.

Remarks: It is unspecified whether multiple calls to `do_get()` with the address of the same struct tm object will update the current contents of the object or simply overwrite its members. Portable programs must zero out the object before invoking the function.

Returns: An iterator pointing immediately beyond the last character recognized as possibly part of a valid input sequence for the given format and modifier.

25.4.5.2 Class template `time_get_byname` [locale.time.get.byname]

namespace std {

    template <class charT, class InputIterator = istreambuf_iterator<charT>>
    class time_get_byname : public time_get<charT, InputIterator> {
        public:
            using dateorder = time_base::dateorder;
            using iter_type = InputIterator;

            explicit time_get_byname(const char*, size_t refs = 0);
            explicit time_get_byname(const string&, size_t refs = 0);
        protected:
            ~time_get_byname();
    };
}

25.4.5.3 Class template `time_put` [locale.time.put]

namespace std {

    template <class charT, class OutputIterator = ostreambuf_iterator<charT>>
    class time_put : public locale::facet {
        public:
            using char_type = charT;
            using iter_type = OutputIterator;

            explicit time_put(size_t refs = 0);

            iter_type put(iter_type s, ios_base& f, char_type fill, const tm* tmb, const charT* pattern, const charT* pat_end) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, const tm* tmb, char format, char modifier = 0) const;

            static locale::id id;
        protected:
            ~time_put();
            virtual iter_type do_put(iter_type s, ios_base& f, char_type, const tm* t, char format, char modifier) const;
    };
}

§ 25.4.5.3
25.4.5.3.1 time_put members

```cpp
type put(iter_type s, ios_base& str, char_type fill, const tm* t, const charT* pattern, const charT* pat_end) const;```

**Effects:** The first form steps through the sequence from `pattern` to `pat_end`, identifying characters that are part of a format sequence. Each character that is not part of a format sequence is written to `s` immediately, and each format sequence, as it is identified, results in a call to `do_put`; thus, format elements and other characters are interleaved in the output in the order in which they appear in the pattern. Format sequences are identified by converting each character `c` to a `char` value as if by `ct.narrow(c, 0)`, where `ct` is a reference to `ctype<charT>` obtained from `str.getloc()`. The first character of each sequence is equal to `'%'`, followed by an optional modifier character `mod` and a format specifier character `spec` as defined for the function `strftime`. If no modifier character is present, `mod` is zero. For each valid format sequence identified, calls `do_put(s, str, fill, t, spec, mod)`.

```cpp
2
```

The second form calls `do_put(s, str, fill, t, format, modifier)`.

3

| Note: The `fill` argument may be used in the implementation-defined formats or by derivations. A space character is a reasonable default for this argument. — end note |

**Returns:** An iterator pointing immediately after the last character produced.

25.4.5.3.2 time_put virtual functions

```cpp
type do_put(iter_type s, ios_base& str, char_type fill, const tm* t, char format, char modifier) const;```

1

**Effects:** Formats the contents of the parameter `t` into characters placed on the output sequence `s`. Formatting is controlled by the parameters `format` and `modifier`, interpreted identically as the format specifiers in the string argument to the standard library function `strftime()`\(^{246}\), except that the sequence of characters produced for those specifiers that are described as depending on the C locale are instead implementation-defined.\(^{247}\)

2

**Returns:** An iterator pointing immediately after the last character produced. [Note: The `fill` argument may be used in the implementation-defined formats or by derivations. A space character is a reasonable default for this argument. — end note]

25.4.5.4 Class template time_put_byname

```cpp
namespace std {
    template <class charT, class OutputIterator = ostreambuf_iterator<charT>>
    class time_put_byname : public time_put<charT, OutputIterator>
    {
        public:
            using char_type = charT;
            using iter_type = OutputIterator;

            explicit time_put_byname(const char*, size_t refs = 0);
            explicit time_put_byname(const string&, size_t refs = 0);
        protected:
            -time_put_byname();
    };```

\(^{245}\) Although the C programming language defines no modifiers, most vendors do.

\(^{246}\) Interpretation of the `modifier` argument is implementation-defined, but should follow POSIX conventions.

\(^{247}\) Implementations are encouraged to refer to other standards such as POSIX for these definitions.
25.4.6 The monetary category

These templates handle monetary formats. A template parameter indicates whether local or international monetary formats are to be used.

All specifications of member functions for `money_put` and `money_get` in the subclauses of 25.4.6 only apply to the specializations required in Tables 69 and 70 (25.3.1.1.1). Their members use their `ios_base&`, `ios_base::iostate&`, and `fill` arguments as described in 25.4, and the `moneypunct<>` and `ctype<>` facets, to determine formatting details.

25.4.6.1 Class template `money_get`

```cpp
namespace std {
    template <class charT, class InputIterator = istreambuf_iterator<charT>>
    class money_get : public locale::facet {
        public:
            using char_type = charT;
            using iter_type = InputIterator;
            using string_type = basic_string<charT>;

            explicit money_get(size_t refs = 0);

            iter_type get(iter_type s, iter_type end, bool intl,
                          ios_base& f, ios_base::iostate& err,
                          long double& units) const;
            iter_type get(iter_type s, iter_type end, bool intl,
                          ios_base& f, ios_base::iostate& err,
                          string_type& digits) const;

            static locale::id id;

            protected:
                ~money_get();
                virtual iter_type do_get(iter_type, iter_type, bool, ios_base&,
                                          ios_base::iostate& err, long double& units) const;
                virtual iter_type do_get(iter_type, iter_type, bool, ios_base&,
                                          ios_base::iostate& err, string_type& digits) const;
    };
}
```

25.4.6.1.1 `money_get` members

```cpp
iter_type get(iter_type s, iter_type end, bool intl,
              ios_base& f, ios_base::iostate& err,
              long double& units) const;

iter_type get(s, iter_type end, bool intl, ios_base&f,
              ios_base::iostate& err, string_type& quant) const;
```

Returns: `do_get(s, end, intl, f, err, quant)`.

25.4.6.1.2 `money_get` virtual functions

```cpp
iter_type do_get(iter_type s, iter_type end, bool intl,
                 ios_base& str, ios_base::iostate& err,
                 long double& units) const;

iter_type do_get(iter_type s, iter_type end, bool intl,
                 ios_base& str, ios_base::iostate& err,
                 string_type& digits) const;
```
Effects: Reads characters from \( s \) to parse and construct a monetary value according to the format specified by a \( \text{moneypunct}\langle\text{charT}, \text{Intl}\rangle \) facet reference \( mp \) and the character mapping specified by a \( \text{ctype}\langle\text{charT}\rangle \) facet reference \( ct \) obtained from the locale returned by \( \text{str.getloc()} \), and \( \text{str.flags()} \). If a valid sequence is recognized, does not change \( \text{err} \); otherwise, sets \( \text{err} \) to \( (\text{err} | \text{str.failbit}) \), or \( (\text{err} | \text{str.failbit} | \text{str.eofbit}) \) if no more characters are available, and does not change \( \text{units} \) or \( \text{digits} \). Uses the pattern returned by \( \text{mp.neg_format()} \) to parse all values. The result is returned as an integral value stored in \( \text{units} \) or as a sequence of digits possibly preceded by a minus sign (as produced by \( \text{ct.widen}(c) \) where \( c \) is \( '−' \) or in the range from \( '0' \) through \( '9' \), inclusive) stored in \( \text{digits} \). [Example: The sequence $1,056.23$ in a common United States locale would yield, for \( \text{units} \), \( 105623 \), or, for \( \text{digits} \), "105623". —end example] If \( \text{mp.grouping()} \) indicates that no thousands separators are permitted, any such characters are not read, and parsing is terminated at the point where they first appear. Otherwise, thousands separators are optional; if present, they are checked for correct placement only after all format components have been read.

Where \( \text{money_base::space} \) or \( \text{money_base::none} \) appears as the last element in the format pattern, no white space is consumed. Otherwise, where \( \text{money_base::space} \) appears in any of the initial elements of the format pattern, at least one white space character is required. Where \( \text{money_base::none} \) appears in any of the initial elements of the format pattern, white space is allowed but not required. If \((\text{str.flags()} & \text{str.showbase})\) is false, the currency symbol is optional and is consumed only if other characters are needed to complete the format; otherwise, the currency symbol is required.

If the first character (if any) in the string \( \text{pos} \) returned by \( \text{mp.positive_sign()} \) or the string \( \text{neg} \) returned by \( \text{mp.negative_sign()} \) is recognized in the position indicated by \( \text{sign} \) in the format pattern, it is consumed and any remaining characters in the string are required after all the other format components. [Example: If \( \text{showbase} \) is off, then for a \( \text{neg} \) value of "()" and a currency symbol of "L", in "(100 L)" the "L" is consumed; but if \( \text{neg} \) is "-", the "L" in "-100 L" is not consumed. —end example] If \( \text{pos} \) or \( \text{neg} \) is empty, the sign component is optional, and if no sign is detected, the result is given the sign that corresponds to the source of the empty string. Otherwise, the character in the indicated position must match the first character of \( \text{pos} \) or \( \text{neg} \), and the result is given the corresponding sign. If the first character of \( \text{pos} \) is equal to the first character of \( \text{neg} \), or if both strings are empty, the result is given a positive sign.

Digits in the numeric monetary component are extracted and placed in \( \text{digits} \), or into a character buffer \( \text{buf1} \) for conversion to produce a value for \( \text{units} \), in the order in which they appear, preceded by a minus sign if and only if the result is negative. The value \( \text{units} \) is produced as if by

\[
\text{for (int i = 0; i < n; ++i)}
\begin{align*}
&\text{buf2[i] = src[find(atoms, atoms+sizeof(src), buf1[i]) - atoms];} \\
&\text{buf2[n] = 0;} \\
&\text{sscanf(buf2, "%Lf", &units);} \\
\end{align*}
\]

where \( n \) is the number of characters placed in \( \text{buf1} \), \( \text{buf2} \) is a character buffer, and the values \( \text{src} \) and \( \text{atoms} \) are defined as if by

\[
\text{static const char src[] = "0123456789-";} \\
\text{charT atoms[sizeof(src)];} \\
\text{ct.widen(src, src + sizeof(src) - 1, atoms);} \\
\]

Returns: An iterator pointing immediately beyond the last character recognized as part of a valid monetary quantity.

25.4.6.2 Class template \text{money\_put}[locale.money.put]

\[
\text{namespace std { [locale.money.put]}
\begin{align*}
&\text{template <class charT, class OutputIterator = ostreambuf_iterator<charT> >}
\end{align*}
\]

248) The semantics here are different from \text{ct.narrow}.
class money_put : public locale::facet {
public:
    using char_type = charT;
    using iter_type = OutputIterator;
    using string_type = basic_string<charT>;

    explicit money_put(size_t refs = 0);

    iter_type put(iter_type s, bool intl, ios_base& f,
                  char_type fill, long double units) const;
    iter_type put(iter_type s, bool intl, ios_base& f,
                  char_type fill, const string_type& digits) const;

    static locale::id id;

protected:
    ~money_put();
    virtual iter_type do_put(iter_type, bool, ios_base&, char_type fill,
                             long double units) const;
    virtual iter_type do_put(iter_type, bool, ios_base&, char_type fill,
                             const string_type& digits) const;
};

25.4.6.2.1 money_put members

iter_type put(iter_type s, bool intl, ios_base& f,
              char_type fill, long double quant) const;
iter_type put(iter_type s, bool intl, ios_base& f,
              char_type fill, const string_type& quant) const;

Returns: do_put(s, intl, f, loc, quant).

25.4.6.2.2 money_put virtual functions

iter_type do_put(iter_type s, bool intl, ios_base& str,
                 char_type fill, long double units) const;
iter_type do_put(iter_type s, bool intl, ios_base& str,
                 char_type fill, const string_type& digits) const;

Effects: Writes characters to s according to the format specified by a moneypunct<charT, Intl> facet reference mp and the character mapping specified by a ctype<charT> facet reference ct obtained from the locale returned by str.getloc(), and str.flags(). The argument units is transformed into a sequence of wide characters as if by

    ct.widen(buf1, buf1 + sprintf(buf1, "%0Lf", units), buf2)

for character buffers buf1 and buf2. If the first character in digits or buf2 is equal to ct.widen('-'), then the pattern used for formatting is the result of mp.neg_format(); otherwise the pattern is the result of mp.pos_format(). Digit characters are written, interspersed with any thousands separators and decimal point specified by the format, in the order they appear (after the optional leading minus sign) in digits or buf2. In digits, only the optional leading minus sign and the immediately subsequent digit characters (as classified according to ct) are used; any trailing characters (including digits appearing after a non-digit character) are ignored. Calls str.width(0).

Remarks: The currency symbol is generated if and only if (str.flags() & str.showbase) is nonzero. If the number of characters generated for the specified format is less than the value returned by str.width() on entry to the function, then copies of fill are inserted as necessary to pad to the speci-
fied width. For the value af equal to (str.flags() & str.adjustfield), if (af == str.internal)

is true, the fill characters are placed where none or space appears in the formatting pattern; otherwise

if (af == str.left) is true, they are placed after the other characters; otherwise, they are placed

before the other characters. [Note: It is possible, with some combinations of format patterns and flag

values, to produce output that cannot be parsed using num_get<>::get. —end note]

Returns: An iterator pointing immediately after the last character produced.

§ 25.4.6.3 Class template moneypunct

namespace std {
    class money_base {
        public:
            enum part { none, space, symbol, sign, value };
            struct pattern { char field[4]; };
    };

    template <class charT, bool International = false>
    class moneypunct : public locale::facet, public money_base {
        public:
            using char_type = charT;
            using string_type = basic_string<charT>;

            explicit moneypunct(size_t refs = 0);

            charT decimal_point() const;
            charT thousands_sep() const;
            string grouping() const;
            string_type curr_symbol() const;
            string_type positive_sign() const;
            string_type negative_sign() const;
            int frac_digits() const;
            pattern pos_format() const;
            pattern neg_format() const;

            static locale::id id;
            static const bool intl = International;

        protected:
            ~moneypunct();
            virtual charT do_decimal_point() const;
            virtual charT do_thousands_sep() const;
            virtual string do_grouping() const;
            virtual string_type do_curr_symbol() const;
            virtual string_type do_positive_sign() const;
            virtual string_type do_negative_sign() const;
            virtual int do_frac_digits() const;
            virtual pattern do_pos_format() const;
            virtual pattern do_neg_format() const;
    };

1 The moneypunct<> facet defines monetary formatting parameters used by money_get<> and money_put<>. A

monetary format is a sequence of four components, specified by a pattern value p, such that the part value

static_cast<part>(p.field[i]) determines the ith component of the format. In the field member

249) An array of char, rather than an array of part, is specified for pattern::field purely for efficiency.
of a pattern object, each value symbol, sign, value, and either space or none appears exactly once. The value none, if present, is not first; the value space, if present, is neither first nor last.

2 Where none or space appears, white space is permitted in the format, except where none appears at the end, in which case no white space is permitted. The value space indicates that at least one space is required at that position. Where symbol appears, the sequence of characters returned by curr_symbol() is permitted, and can be required. Where sign appears, the first (if any) of the sequence of characters returned by positive_sign() or negative_sign() (respectively as the monetary value is non-negative or negative) is required. Any remaining characters of the sign sequence are required after all other format components. Where value appears, the absolute numeric monetary value is required.

3 The format of the numeric monetary value is a decimal number:

```
value ::= units [ decimal-point [ digits ] ]
    decimal-point digits
if frac_digits() returns a positive value, or
value ::= units
```

otherwise. The symbol decimal-point indicates the character returned by decimal_point(). The other symbols are defined as follows:

```
units ::= digits [ thousands-sep units ]
digits ::= adigit [ digits ]
```

In the syntax specification, the symbol adigit is any of the values ct.widen(c) for c in the range ‘0’ through ‘9’, inclusive, and ct is a reference of type const ctype<charT>& obtained as described in the definitions of money_get<> and money_put<>. The symbol thousands-sep is the character returned by thousands_sep(). The space character used is the value ct.widen(‘ ’). White space characters are those characters c for which ci.is(space, c) returns true. The number of digits required after the decimal point (if any) is exactly the value returned by frac_digits().

4 The placement of thousands-separator characters (if any) is determined by the value returned by grouping(), defined identically as the member numpunct<>:do_grouping().

### 25.4.6.3.1 moneypunct members

```
charT decimal_point() const;
charT thousands_sep() const;
string grouping() const;
string_type curr_symbol() const;
string_type positive_sign() const;
string_type negative_sign() const;
int frac_digits() const;
pattern pos_format() const;
pattern neg_format() const;
```

1 Each of these functions F returns the result of calling the corresponding virtual member function do_F().

### 25.4.6.3.2 moneypunct virtual functions

```
charT do_decimal_point() const;
void do_thousands_sep() const;
```

1 Returns: The radix separator to use in case do_frac_digits() is greater than zero.

2 Returns: The digit group separator to use in case do_grouping() specifies a digit grouping pattern.

---

250) In common U.S. locales this is ‘,’.
251) In common U.S. locales this is ‘,’.
string do_grouping() const;

Returns: A pattern defined identically as, but not necessarily equal to, the result of 

\[ \text{numpunct<charT>::do_grouping()}. \]

string_type do_curr_symbol() const;

Returns: A string to use as the currency identifier symbol.

string_type do_positive_sign() const;
string_type do_negative_sign() const;

Returns: \( \text{do_positive_sign()} \) returns the string to use to indicate a positive monetary value; \( \text{do_negative_sign()} \) returns the string to use to indicate a negative value.

int do_frac_digits() const;

Returns: The number of digits after the decimal radix separator, if any.

pattern do_pos_format() const;
pattern do_neg_format() const;

Returns: The specializations required in Table 70 (25.3.1.1.1), namely \( \text{moneypunct<char>}, \text{moneypunct<wchar_t>}, \text{moneypunct<char, true>}, \) and \( \text{moneypunct<wchar_t, true>} \), return an object of type \( \text{pattern} \) initialized to \( \{ \text{symbol}, \text{sign}, \text{none}, \text{value} \} \).

25.4.6.4 Class template moneypunct_byname

```cpp
namespace std {
    template <class charT, bool Intl = false>
    class moneypunct_byname : public moneypunct<charT, Intl> {
    public:
        using pattern = money_base::pattern;
        using string_type = basic_string<charT>;

        explicit moneypunct_byname(const char*, size_t refs = 0);
        explicit moneypunct_byname(const string&, size_t refs = 0);
        protected:
            ~moneypunct_byname();
    }
}
```

25.4.7 The message retrieval category

Class \( \text{messages<charT>} \) implements retrieval of strings from message catalogs.

25.4.7.1 Class template messages

```cpp
namespace std {
    class messages_base {
    public:
        using catalog = unspecified signed integer type;
    };

    template <class charT>
```

252) To specify grouping by 3s, the value is "\003" not "3".
253) For international specializations (second template parameter \text{true}) this is typically four characters long, usually three letters and a space.
254) This is usually the empty string.
255) In common U.S. locales, this is 2.
256) Note that the international symbol returned by \( \text{do_curr_sym()} \) usually contains a space, itself; for example, "USD ".

§ 25.4.7.1
class messages : public locale::facet, public messages_base {
  public:
    using char_type = charT;
    using string_type = basic_string<charT>;

    explicit messages(size_t refs = 0);

    catalog open(const basic_string<char>& fn, const locale&) const;
    string_type get(catalog c, int set, int msgid,
                    const string_type& dfault) const;
    void close(catalog c) const;

    static locale::id id;

  protected:
    ~messages();
    virtual catalog do_open(const basic_string<char>&, const locale&) const;
    virtual string_type do_get(catalog, int set, int msgid,
                               const string_type& dfault) const;
    virtual void do_close(catalog) const;
  }

1 Values of type messages_base::catalog usable as arguments to members get and close can be obtained only by calling member open.

25.4.7.1.1 messages members [locale.messages.members]

catalog open(const basic_string<char>& name, const locale& loc) const;

1 Returns: do_open(name, loc).

string_type get(catalog cat, int set, int msgid, const string_type& dfault) const;

2 Returns: do_get(cat, set, msgid, dfault).

void close(catalog cat) const;

3 Effects: Calls do_close(cat).

25.4.7.1.2 messages virtual functions [locale.messages.virtuals]

catalog do_open(const basic_string<char>& name, const locale& loc) const;

1 Returns: A value that may be passed to get() to retrieve a message from the message catalog identified by the string name according to an implementation-defined mapping. The result can be used until it is passed to close().

2 Returns a value less than 0 if no such catalog can be opened.

3 Remarks: The locale argument loc is used for character set code conversion when retrieving messages, if needed.

string_type do_get(catalog cat, int set, int msgid, const string_type& dfault) const;

4 Requires: cat shall be a catalog obtained from open() and not yet closed.

5 Returns: A message identified by arguments set, msgid, and dfault, according to an implementation-defined mapping. If no such message can be found, returns dfault.

void do_close(catalog cat) const;

§ 25.4.7.1.2 825
6  \textit{Requires:} \texttt{cat} shall be a catalog obtained from \texttt{open()} and not yet closed.

7  \textit{Effects:} Releases unspecified resources associated with \texttt{cat}.

8  \textit{Remarks:} The limit on such resources, if any, is implementation-defined.

25.4.7.2 Class template messages\_byname

\begin{verbatim}
namespace std {
    template <class charT>
    class messages_byname : public messages<charT> {
        public:
          using catalog = messages_base::catalog;
          using string_type = basic_string<charT>;

          explicit messages_byname(const char*, size_t refs = 0);
          explicit messages_byname(const string&, size_t refs = 0);
          protected:
            ~messages_byname();
    };
}
\end{verbatim}

25.4.8 Program-defined facets

1  A C++ program may define facets to be added to a locale and used identically as the built-in facets. To create a new facet interface, C++ programs simply derive from \texttt{locale::facet} a class containing a static member: \texttt{static locale::id id}.

2  [ \textit{Note:} The locale member function templates verify its type and storage class. \textit{— end note} ]

3  [ \textit{Example:} Traditional global localization is still easy: 

\begin{verbatim}
#include <iostream>
#include <locale>

int main(int argc, char** argv) {
    using namespace std;
    locale::global(locale(""); // set the global locale
                  // imbue it on all the std streams
    cin.imbue(locale());
    cout.imbue(locale());
    cerr.imbue(locale());
    wcin.imbue(locale());
    wcout.imbue(locale());
    wcerr.imbue(locale());

    return MyObject(argc, argv).doit();
}
\end{verbatim}

\textit{— end example} ]

4  [ \textit{Example:} Greater flexibility is possible: 

\begin{verbatim}
#include <iostream>
#include <locale>

int main() {
    using namespace std;
    cin.imbue(locale("")); // the user’s preferred locale
    cout.imbue(locale::classic());
    double f;
    while (cin >> f) cout << f << endl;
    return (cin.fail() != 0);
}\end{verbatim}

\section{25.4.8}
In a European locale, with input 3.456,78, output is 3456.78. —end example]

This can be important even for simple programs, which may need to write a data file in a fixed format, regardless of a user’s preference.

[Example: Here is an example of the use of locales in a library interface.

```cpp
// file: Date.h
#include <iosfwd>
#include <string>
#include <locale>

class Date {
public:
    Date(unsigned day, unsigned month, unsigned year);
    std::string asString(const std::locale& = std::locale());
};

std::istream& operator>>(std::istream& s, Date& d);
std::ostream& operator<<(std::ostream& s, Date d);
```

This example illustrates two architectural uses of class locale.

The first is as a default argument in `Date::asString()`, where the default is the global (presumably user-preferred) locale.

The second is in the operators `<<` and `>>`, where a locale “hitchhikes” on another object, in this case a stream, to the point where it is needed.

```cpp
// file: Date.C
#include "Date" // includes <ctime>
#include <sstream>
std::string Date::asString(const std::locale& l) {
    using namespace std;
    ostringstream s; s.imbue(l);
    s << *this; return s.str();
}

std::istream& operator>>(std::istream& s, Date& d) {
    using namespace std;
    istream::sentry cerberos(s);
    if (cerberos) {
        ios_base::iostate err = goodbit;
        struct tm t;
        use_facet<time_get<char>>(s.getloc()).get_date(s, 0, s, err, &t);
        if (!err) d = Date(t.tm_day, t.tm_mon + 1, t.tm_year + 1900);
        s.setstate(err);
    }
    return s;
}
```

—end example]

A locale object may be extended with a new facet simply by constructing it with an instance of a class derived from `locale::facet`. The only member a C++ program must define is the static member `id`, which identifies your class interface as a new facet.

[Example: Classifying Japanese characters:

§ 25.4.8 827
© ISO/IEC

N4659

// file: <jctype>
#include <locale>
namespace My {
using namespace std;
class JCtype : public locale::facet {
public:
static locale::id id;
// required for use as a new locale facet
bool is_kanji (wchar_t c) const;
JCtype() { }
protected:
~JCtype() { }
};
}
// file: filt.C
#include <iostream>
#include <locale>
#include "jctype"
// above
std::locale::id My::JCtype::id; // the static JCtype member declared above.
int main() {
using namespace std;
using wctype = ctype<wchar_t>;
locale loc(locale(""),
// the user’s preferred locale ...
new My::JCtype);
// and a new feature ...
wchar_t c = use_facet<wctype>(loc).widen(’!’);
if (!use_facet<My::JCtype>(loc).is_kanji(c))
cout << "no it isn’t!" << endl;
}
12

The new facet is used exactly like the built-in facets. — end example ]

13

[ Example: Replacing an existing facet is even easier. The code does not define a member id because it is
reusing the numpunct<charT> facet interface:
// file: my_bool.C
#include <iostream>
#include <locale>
#include <string>
namespace My {
using namespace std;
using cnumpunct = numpunct_byname<char>;
class BoolNames : public cnumpunct {
protected:
string do_truename() const { return "Oui Oui!"; }
string do_falsename() const { return "Mais Non!"; }
~BoolNames() { }
public:
BoolNames(const char* name) : cnumpunct(name) { }
};
}
int main(int argc, char** argv) {
using namespace std;
// make the user’s preferred locale, except for...
locale loc(locale(""), new My::BoolNames(""));
cout.imbue(loc);

§ 25.4.8

828


cout << boolalpha << "Any arguments today? " << (argc > 1) << endl;
}

— end example

25.5 C library locales

25.5.1 Header <clocale> synopsis

namespace std {
  struct lconv;

  char* setlocale(int category, const char* locale);
  lconv* localeconv();
}

#define NULL see 21.2.3
#define LC_ALL see below
#define LC_COLLATE see below
#define LC_CTYPE see below
#define LC_MONETARY see below
#define LC_NUMERIC see below
#define LC_TIME see below

1 The contents and meaning of the header <clocale> are the same as the C standard library header <locale.h>.

2 Calls to the function setlocale may introduce a data race (20.5.5.9) with other calls to setlocale or with calls to the functions listed in Table 81.

26 Containers library

26.1 General

1 This Clause describes components that C++ programs may use to organize collections of information.

2 The following subclauses describe container requirements, and components for sequence containers and associative containers, as summarized in Table 82.

Table 82 — Containers library summary

26.2 Container requirements

26.2.1 General container requirements

1 Containers are objects that store other objects. They control allocation and deallocation of these objects through constructors, destructors, insert and erase operations.

2 All of the complexity requirements in this Clause are stated solely in terms of the number of operations on the contained objects. [Example: The copy constructor of type vector<vector<int>> has linear complexity, even though the complexity of copying each contained vector<int> is itself linear. —end example]

3 For the components affected by this subclause that declare an allocator_type, objects stored in these components shall be constructed using the function allocator_traits<allocator_type>::rebind_traits<U>::construct and destroyed using the function allocator_traits<allocator_type>::rebind_traits<U>::destroy (23.10.8.2), where U is either allocator_type::value_type or an internal type used by the container. These functions are called only for the container’s element type, not for internal types used by the container. [Note: This means, for example, that a node-based container might need to construct nodes containing aligned buffers and call construct to place the element into the buffer. —end note]

4 In Tables 83, 84, and 85 X denotes a container class containing objects of type T, a and b denote values of type X, u denotes an identifier, r denotes a non-const value of type X, and rv denotes a non-const rvalue of type X.

</tr>
</tbody>
</table>

Those entries marked “(Note A)” or “(Note B)” have linear complexity for `array` and have constant complexity for all other standard containers. [Note: The algorithm `equal()` is defined in Clause 28. — end note]
The member function \texttt{size()} returns the number of elements in the container. The number of elements is defined by the rules of constructors, inserts, and erases.

\texttt{begin()} returns an iterator referring to the first element in the container. \texttt{end()} returns an iterator which is the past-the-end value for the container. If the container is empty, then \texttt{begin()} == \texttt{end()}.

In the expressions

\begin{verbatim}
i == j
i != j
i < j
i <= j
i >= j
i > j
i - j
\end{verbatim}

where \texttt{i} and \texttt{j} denote objects of a container’s \texttt{iterator} type, either or both may be replaced by an object of the container’s \texttt{const_iterator} type referring to the same element with no change in semantics.

Unless otherwise specified, all containers defined in this clause obtain memory using an allocator (see 20.5.3.5). [Note: In particular, containers and iterators do not store references to allocated elements other than through the allocator’s pointer type, i.e., as objects of type \texttt{P} or \texttt{pointer_traits<P>::template rebind<unspecified>}, where \texttt{P} is \texttt{allocator_traits<allocator_type>::pointer}. — end note] Copy constructors for these container types obtain an allocator by calling \texttt{allocator_traits<allocator_type>::select_on_container_copy_construction} on the allocator belonging to the container being copied. Move constructors obtain an allocator by move construction from the allocator belonging to the container being moved. Such move construction of the allocator shall not exit via an exception. All other constructors for these container types take a \texttt{const allocator_type&} argument. [Note: If an invocation of a constructor uses the default value of an optional allocator argument, then the \texttt{Allocator} type must support value-initialization. — end note] A copy of this allocator is used for any memory allocation and element construction performed, by these constructors and by all member functions, during the lifetime of each container object or until the allocator is replaced. The allocator may be replaced only via assignment or \texttt{swap()}. Allocator replacement is performed by copy assignment, move assignment, or swapping of the allocator only if \texttt{allocator_traits<allocator_type>::propagate_on_container_copy_assignment::value}, \texttt{allocator_traits<allocator_type>::propagate_on_container_move_assignment::value}, or \texttt{allocator_traits<allocator_type>::propagate_on_container_swap::value} is \texttt{true} within the implementation of the corresponding container operation. In all container types defined in this Clause, the member \texttt{get_allocator()} returns a copy of the allocator used to construct the container or, if that allocator has been replaced, a copy of the most recent replacement.

The expression \texttt{a.swap(b)}, for containers \texttt{a} and \texttt{b} of a standard container type other than \texttt{array}, shall exchange the values of \texttt{a} and \texttt{b} without invoking any move, copy, or swap operations on the individual container elements. Lvalues of any \texttt{Compare}, \texttt{Pred}, or \texttt{Hash} types belonging to \texttt{a} and \texttt{b} shall be swappable and shall be exchanged by calling \texttt{swap} as described in 20.5.3.2. If \texttt{allocator_traits<allocator_type>::propagate_on_container_swap::value} is \texttt{true}, then lvalues of type \texttt{allocator_type} shall be swappable and the allocators of \texttt{a} and \texttt{b} shall also be exchanged by calling \texttt{swap} as described in 20.5.3.2. Otherwise, the allocators shall not be swapped, and the behavior is undefined unless \texttt{a.get_allocator()} == \texttt{b.get_allocator()}. Every iterator referring to an element in one container before the swap shall refer to the same element in the other container after the swap. It is unspecified whether an iterator with value \texttt{a.end()} before the swap will have value \texttt{b.end()} after the swap.

If the iterator type of a container belongs to the bidirectional or random access iterator categories (27.2), the container is called \textit{reversible} and satisfies the additional requirements in Table 84.

</tbody>
</table>

11 Unless otherwise specified (see 26.2.6.1, 26.2.7.1, 26.3.8.4, and 26.3.11.5) all container types defined in this Clause meet the following additional requirements:

- (11.1) if an exception is thrown by an `insert()` or `emplace()` function while inserting a single element, that function has no effects.
- (11.2) if an exception is thrown by a `push_back()`, `push_front()`, `emplace_back()`, or `emplace_front()` function, that function has no effects.
- (11.3) no `erase()`, `clear()`, `pop_back()` or `pop_front()` function throws an exception.
- (11.4) no copy constructor or assignment operator of a returned iterator throws an exception.
- (11.5) no `swap()` function throws an exception.
- (11.6) no `swap()` function invalidates any references, pointers, or iterators referring to the elements of the containers being swapped. [Note: The `end()` iterator does not refer to any element, so it may be invalidated. — end note]

12 Unless otherwise specified (either explicitly or by defining a function in terms of other functions), invoking a container member function or passing a container as an argument to a library function shall not invalidate iterators to, or change the values of, objects within that container.

13 A **contiguous container** is a container that supports random access iterators (27.2.7) and whose member types `iterator` and `const_iterator` are contiguous iterators (27.2.1).

14 Table 85 lists operations that are provided for some types of containers but not others. Those containers for which the listed operations are provided shall implement the semantics described in Table 85 unless otherwise stated.
Table 85 — Optional container operations

</tr>
</tbody>
</table>

[Note: The algorithm lexicographical_compare() is defined in Clause 28. — end note]

All of the containers defined in this Clause and in 24.3.2 except array meet the additional requirements of an allocator-aware container, as described in Table 86.

Given an allocator type A and given a container type X having a value_type identical to T and an allocator_type identical to allocator_traits<A>::rebind_alloc<T> and given an lvalue m of type A, a pointer p of type T*, an expression v of type (possibly const) T, and an rvalue rv of type T, the following terms are defined. If X is not allocator-aware, the terms below are defined as if A were allocator<T> — no allocator object needs to be created and user specializations of allocator<T> are not instantiated:

(15.1) — T is DefaultInsertable into X means that the following expression is well-formed:
   allocator_traits<A>::construct(m, p)

(15.2) — An element of X is default-inserted if it is initialized by evaluation of the expression
   allocator_traits<A>::construct(m, p)
   where p is the address of the uninitialized storage for the element allocated within X.

(15.3) — T is MoveInsertable into X means that the following expression is well-formed:
   allocator_traits<A>::construct(m, p, rv)
   and its evaluation causes the following postcondition to hold: The value of *p is equivalent to the value of rv before the evaluation. [Note: rv remains a valid object. Its state is unspecified — end note]

(15.4) — T is CopyInsertable into X means that, in addition to T being MoveInsertable into X, the following expression is well-formed:
   allocator_traits<A>::construct(m, p, v)
   and its evaluation causes the following postcondition to hold: The value of v is unchanged and is equivalent to *p.

(15.5) — T is EmplaceConstructible into X from args, for zero or more arguments args, means that the following expression is well-formed:
   allocator_traits<A>::construct(m, p, args)

(15.6) — T is Erasable from X means that the following expression is well-formed:
   allocator_traits<A>::destroy(m, p)

§ 26.2.1
[Note: A container calls allocator_traits<A>::construct(m, p, args) to construct an element at p using args, with m == get_allocator(). The default construct in allocator will call ::new((void*)p) T(args), but specialized allocators may choose a different definition. — end note]

In Table 86, X denotes an allocator-aware container class with a value_type of T using allocator of type A, u denotes a variable, a and b denote non-const lvalues of type X, t denotes an lvalue or a const rvalue of type X, rv denotes a non-const rvalue of type X, and m is a value of type A.

17 The behavior of certain container member functions and deduction guides depends on whether types qualify as input iterators or allocators. The extent to which an implementation determines that a type cannot be an input iterator is unspecified, except that as a minimum integral types shall not qualify as input iterators. Likewise, the extent to which an implementation determines that a type cannot be an allocator is unspecified, except that as a minimum a type \( \text{A} \) shall not qualify as an allocator unless it satisfies both of the following conditions:

(17.1) The qualified-id \( \text{A}::\text{value\_type} \) is valid and denotes a type (17.8.2).

(17.2) The expression `\text{declval<A&>().allocate(size_t{})}` is well-formed when treated as an unevaluated operand.

26.2.2 Container data races [container.requirements.dataraces]

1 For purposes of avoiding data races (20.5.5.9), implementations shall consider the following functions to be const: begin, end, rbegin, rend, front, back, data, find, lower_bound, upper_bound, equal_range, at and, except in associative or unordered associative containers, operator[].

2 Notwithstanding 20.5.5.9, implementations are required to avoid data races when the contents of the contained object in different elements in the same container, excepting \text{vector<bool>}, are modified concurrently.

3 \[ \text{Note: For a vector<int> x with a size greater than one, x[1] = 5 and \&x.begin() = 10 can be executed concurrently without a data race, but x[0] = 5 and \&x.begin() = 10 executed concurrently may result in a data race. As an exception to the general rule, for a vector<bool> y, y[0] = true may race with y[1] = true. — end note} \]

26.2.3 Sequence containers [sequence.reqmts]

1 A sequence container organizes a finite set of objects, all of the same type, into a strictly linear arrangement. The library provides four basic kinds of sequence containers: vector, forward_list, list, and deque. In addition, array is provided as a sequence container which provides limited sequence operations because it has a fixed number of elements. The library also provides container adaptors that make it easy to construct abstract data types, such as stacks or queues, out of the basic sequence container kinds (or out of other kinds of sequence containers that the user might define).

2 The sequence containers offer the programmer different complexity trade-offs and should be used accordingly. vector or array is the type of sequence container that should be used by default. list or forward_list
should be used when there are frequent insertions and deletions from the middle of the sequence. `deque` is the data structure of choice when most insertions and deletions take place at the beginning or at the end of the sequence.

3 In Tables 87 and 88, `X` denotes a sequence container class, `a` denotes a value of type `X` containing elements of type `T`, `u` denotes the name of a variable being declared, `A` denotes `X::allocator_type` if the `qualified-id X::allocator_type` is valid and denotes a type (17.8.2) and `allocator<T>` if it doesn’t. `i` and `j` denote iterators satisfying input iterator requirements and refer to elements implicitly convertible to `value_type`, `[i, j)` denotes a valid range, `il` designates an object of type `initializer_list<value_type>`, `n` denotes a value of type `X::size_type`, `p` denotes a valid constant iterator to `a`, `q` denotes a valid dereferenceable constant iterator to `a`, `[q1, q2)` denotes a valid range of constant iterators in `a`, `t` denotes an lvalue or a const rvalue of `X::value_type`, and `rv` denotes a non-const rvalue of `X::value_type`. `Args` denotes a template parameter pack; `args` denotes a function parameter pack with the pattern `Args&&`.

4 The complexities of the expressions are sequence dependent.

### Table 87 — Sequence container requirements (in addition to container)

<table>

</tr>
</tbody>
</table>
Table 87 — Sequence container requirements (in addition to container) (continued)

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Assertion/note</th>
</tr>
</thead>
<tbody>
<tr>
<td>a.assign(i,j)</td>
<td>void</td>
<td>Requires: T shall be EmplaceConstructible into X from *i and assignable from *i. For vector, if the iterator does not meet the forward iterator requirements (27.2.5), T shall also be MoveInsertable into X. Each iterator in the range [i, j) shall be dereferenced exactly once. Requires: i, j are not iterators into a. Replaces elements in a with a copy of [i, j). Invalidates all references, pointers and iterators referring to the elements of a. For vector and deque, also invalidates the past-the-end iterator.</td>
</tr>
<tr>
<td>a.assign(il)</td>
<td>void</td>
<td>a.assign(il.begin(), il.end()).</td>
</tr>
<tr>
<td>a.assign(n,t)</td>
<td>void</td>
<td>Requires: T shall be CopyInsertable into X and CopyAssignable. Requires: t is not a reference into a. Replaces elements in a with n copies of t. Invalidates all references, pointers and iterators referring to the elements of a. For vector and deque, also invalidates the past-the-end iterator.</td>
</tr>
</tbody>
</table>

5 The iterator returned from a.insert(p, t) points to the copy of t inserted into a.
6 The iterator returned from a.insert(p, rv) points to the copy of rv inserted into a.
7 The iterator returned from a.insert(p, n, t) points to the copy of the first element inserted into a, or p if n == 0.
8 The iterator returned from a.insert(p, i, j) points to the copy of the first element inserted into a, or p if i == j.
9 The iterator returned from a.insert(p, il) points to the copy of the first element inserted into a, or p if il is empty.
10 The iterator returned from aemplace(p, args) points to the new element constructed from args into a.
11 The iterator returned from a.erase(q) points to the element immediately following q prior to the element being erased. If no such element exists, a.end() is returned.
12 The iterator returned by a.erase(q1, q2) points to the element pointed to by q2 prior to any elements being erased. If no such element exists, a.end() is returned.
13 For every sequence container defined in this Clause and in Clause 24:

\[\text{template <class InputIterator>}
\text{X(InputIterator first, InputIterator last,}
\text{ const allocator_type& alloc = allocator_type());}\]
is called with a type `InputIterator` that does not qualify as an input iterator, then the constructor shall not participate in overload resolution.

(13.2) — If the member functions of the forms:

```cpp
    template <class InputIterator>
    return-type F(const_iterator p,
                  InputIterator first, InputIterator last); // such as insert
```

```cpp
    template <class InputIterator>
    return-type F(InputIterator first, InputIterator last); // such as append, assign
```

```cpp
    template <class InputIterator>
    return-type F(const_iterator i1, const_iterator i2,
                  InputIterator first, InputIterator last); // such as replace
```

are called with a type `InputIterator` that does not qualify as an input iterator, then these functions shall not participate in overload resolution.

(13.3) — A deduction guide for a sequence container shall not participate in overload resolution if it has an `InputIterator` template parameter and a type that does not qualify as an input iterator is deduced for that parameter, or if it has an `Allocator` template parameter and a type that does not qualify as an allocator is deduced for that parameter.

Table 88 lists operations that are provided for some types of sequence containers but not others. An implementation shall provide these operations for all container types shown in the “container” column, and shall implement them so as to take amortized constant time.

15 The member function at() provides bounds-checked access to container elements. at() throws out_of_range if n >= a.size().

26.2.4 Node handles [container.node]

26.2.4.1 node_handle overview [container.node.overview]

1 A node handle is an object that accepts ownership of a single element from an associative container (26.2.6) or an unordered associative container (26.2.7). It may be used to transfer that ownership to another container with compatible nodes. Containers with compatible nodes have the same node handle type. Elements may be transferred in either direction between container types in the same row of Table 89.

2 If a node handle is not empty, then it contains an allocator that is equal to the allocator of the container when the element was extracted. If a node handle is empty, it contains no allocator.

3 Class node_handle is for exposition only. An implementation is permitted to provide equivalent functionality without providing a class with this name.

4 If a user-defined specialization of pair exists for pair<const Key, T> or pair<Key, T>, where Key is the container’s key_type and T is the container’s mapped_type, the behavior of operations involving node handles is undefined.

```cpp
template< unspecified >
class node_handle {
public:
  // These type declarations are described in Tables 90 and 91.
  using value_type = see below; // not present for map containers
  using key_type = see below;   // not present for set containers
  using mapped_type = see below; // not present for set containers

private:
  using container_node_type = unspecified;
  using ator_traits = allocator_traits<allocator_type>;

  typedef ator_traits::rebind_traits<container_node_type>::pointer ptr_;
  optional<allocator_type> alloc_

public:
  constexpr node_handle() noexcept : ptr_(), alloc_() {} ~node_handle();
  node_handle(node_handle&&) noexcept;
  node_handle& operator=(node_handle&&);

  value_type& value() const; // not present for map containers
  key_type& key() const;     // not present for set containers
  mapped_type& mapped() const; // not present for set containers

  allocator_type get_allocator() const;
  explicit operator bool() const noexcept;
  bool empty() const noexcept;

  void swap(node_handle&amp);
    noexcept(ator_traits::propagate_on_container_swap::value ||
             ator_traits::is_always_equal::value);

friend void swap(node_handle&amp x, node_handle&amp y) noexcept(noexcept(x.swap(y))) {
```

§ 26.2.4.1
x.swap(y); }
};

26.2.4.2 node_handle constructors, copy, and assignment

node_handle(node_handle&& nh) noexcept;

Effects: Constructs a node_handle object initializing ptr_ with nh.ptr_. Move constructs alloc_ with nh.alloc_. Assigns nullptr to nh.ptr_ and assigns nullopt to nh.alloc_.

node_handle& operator=(node_handle&& nh);

Requires: Either !alloc_, or ator_traits::propagate_on_container_move_assignment is true, or alloc_ == nh.alloc_.

Effects:
(3.1) — If ptr_ != nullptr, destroys the value_type subobject in the container_node_type object pointed to by ptr_ by calling ator_traits::destroy, then deallocates ptr_ by calling ator_traits::rebind_traits<container_node_type>::deallocate.
(3.2) — Assigns nh.ptr_ to ptr_.
(3.3) — If !alloc_ or ator_traits::propagate_on_container_move_assignment is true, move assigns nh.alloc_ to alloc_.
(3.4) — Assigns nullptr to nh.ptr_ and assigns nullopt to nh.alloc_.

Returns: *this.

Throws: Nothing.

26.2.4.3 node_handle destructor

~node_handle();

Effects: If ptr_ != nullptr, destroys the value_type subobject in the container_node_type object pointed to by ptr_ by calling ator_traits::destroy, then deallocates ptr_ by calling ator_traits::rebind_traits<container_node_type>::deallocate.

26.2.4.4 node_handle observers

value_type& value() const;

Requires: empty() == false.

Returns: A reference to the value_type subobject in the container_node_type object pointed to by ptr_.

Throws: Nothing.

key_type& key() const;

Requires: empty() == false.

Returns: A non-const reference to the key_type member of the value_type subobject in the container_node_type object pointed to by ptr_.

Throws: Nothing.

Remarks: Modifying the key through the returned reference is permitted.

mapped_type& mapped() const;

Requires: empty() == false.
Returns: A reference to the mapped_type member of the value_type subobject in the container_-node_type object pointed to by ptr_.

Throws: Nothing.

allocator_type get_allocator() const;

Requires: empty() == false.

Returns: *alloc_.

Throws: Nothing.

explicit operator bool() const noexcept;

Returns: ptr_ != nullptr.

bool empty() const noexcept;

Returns: ptr_ == nullptr.

26.2.4.5 node_handle modifiers [container.node.modifiers]

void swap(node_handle& nh)

noexcept(ator_traits::propagate_on_container_swap::value ||
ator_traits::is_always_equal::value);

Requires: !alloc_, or !nh.alloc_, or ator_traits::propagate_on_container_swap is true, or alloc_ == nh.alloc_.

Effects: Calls swap(ptr_, nh.ptr_). If !alloc_, or !nh.alloc_, or ator_traits::propagate_on_container_swap is true calls swap(alloc_, nh.alloc_).

26.2.5 Insert return type [container.insert.return]

The associative containers with unique keys and the unordered containers with unique keys have a member function insert that returns a nested type insert_return_type. That return type is a specialization of the type specified in this subclause.

template <class Iterator, class NodeType>
struct INSERT_RETURN_TYPE
{
    Iterator position;
    bool inserted;
    NodeType node;
};

The name INSERT_RETURN_TYPE is exposition only. INSERT_RETURN_TYPE has the template parameters, data members, and special members specified above. It has no base classes or members other than those specified.

26.2.6 Associative containers [associative.reqmts]

Associative containers provide fast retrieval of data based on keys. The library provides four basic kinds of associative containers: set, multiset, map and multimap.

Each associative container is parameterized on Key and an ordering relation Compare that induces a strict weak ordering (28.7) on elements of Key. In addition, map and multimap associate an arbitrary mapped type T with the Key. The object of type Compare is called the comparison object of a container.

The phrase “equivalence of keys” means the equivalence relation imposed by the comparison and not the operator== on keys. That is, two keys k1 and k2 are considered to be equivalent if for the comparison
object comp, comp(k1, k2) == false & comp(k2, k1) == false. For any two keys k1 and k2 in the
same container, calling comp(k1, k2) shall always return the same value.

An associative container supports unique keys if it may contain at most one element for each key. Otherwise, it supports equivalent keys. The set and map classes support unique keys; the multiset and multimap classes support equivalent keys. For multiset and multimap, insert, emplace, and erase preserve the relative ordering of equivalent elements.

For set and multiset the value type is the same as the key type. For map and multimap it is equal to pair<const key, T>.

The associative containers meet all the requirements of Allocator-aware containers (26.2.1), except that iterator of an associative container is of the bidirectional iterator category. For associative containers where the value type is the same as the key type, both iterator and const_iterator are constant iterators. It is unspecified whether or not iterator and const_iterator are the same type. [Note: iterator and const_iterator have identical semantics in this case, and iterator is convertible to const_iterator. Users can avoid violating the one-definition rule by always using const_iterator in their function parameter lists. —end note]

The associative containers meet all the requirements of Allocator-aware containers (26.2.1), except that for map and multimap, the requirements placed on value_type in Table 83 apply instead to key_type and mapped_type. [Note: For example, in some cases key_type and mapped_type are required to be CopyAssignable even though the associated value_type, pair<const key_type, mapped_type>, is not CopyAssignable. —end note]

In Table 90, X denotes an associative container class, a denotes a value of type X, a2 denotes a value of a type with nodes compatible with type X (Table 89), b denotes a possibly const value of type X, u denotes the name of a variable being declared, a_uniq denotes a value of type X when X supports unique keys, a_eq denotes a value of type X when X supports multiple keys, a_tran denotes a possibly const value of type X when the qualified-id X::key_compare::is_transparent is valid and denotes a type (17.8.2), i and j satisfy input iterator requirements and refer to elements implicitly convertible to value_type, [i, j] denotes a valid range, p denotes a valid constant iterator to a, q denotes a valid dereferenceable constant iterator to a, r denotes a valid dereferenceable iterator to a, [q1, q2) denotes a valid range of constant iterators in a, il designates an object of type initializer_list<value_type>, t denotes a value of type X::value_type, k denotes a value of type X::key_type and c denotes a possibly const value of type X::key_compare; kl is a value such that a is partitioned (28.7) with respect to c(r, kl), with r the key value of e and e in a; ku is a value such that a is partitioned with respect to !c(ku, r); ke is a value such that a is partitioned with respect to c(r, ke) and !c(ke, r), with c(r, ke) implying !c(ke, r). A denotes the storage allocator used by X, if any, or allocator<X::value_type> otherwise, m denotes an allocator of a type convertible to A, and nh denotes a non-const rvalue of type X::node_type.

|                     | equivalent to make_pair(a_tran.lower_bound(ke), a_tran.upper_bound(ke)). |             | logarithmic |

9 The **insert** and **emplace** members shall not affect the validity of iterators and references to the container, and the **erase** members shall invalidate only iterators and references to the erased elements.

10 The **extract** members invalidate only iterators to the removed element; pointers and references to the removed element remain valid. However, accessing the element through such pointers and references while the element is owned by a node_type is undefined behavior. References and pointers to an element obtained while it is owned by a node_type are invalidated if the element is successfully inserted.

11 The fundamental property of iterators of associative containers is that they iterate through the containers in the non-descending order of keys where non-descending is defined by the comparison that was used to construct them. For any two dereferenceable iterators \(i\) and \(j\) such that distance from \(i\) to \(j\) is positive, the following condition holds:

\[
\text{value_comp}(i, j) = \text{false}
\]

12 For associative containers with unique keys the stronger condition holds:

\[
\text{value_comp}(i, j) \neq \text{false}
\]

13 When an associative container is constructed by passing a comparison object the container shall not store a pointer or reference to the passed object, even if that object is passed by reference. When an associative container is copied, either through a copy constructor or an assignment operator, the target container shall then use the comparison object from the container being copied, as if that comparison object had been passed to the target container in its constructor.

14 The member function templates **find**, **count**, **lower_bound**, **upper_bound**, and **equal_range** shall not participate in overload resolution unless the qualified-id `Compare::is_transparent` is valid and denotes a type (17.8.2).

15 A deduction guide for an associative container shall not participate in overload resolution if any of the following are true:

(15.1) — It has an **InputIterator** template parameter and a type that does not qualify as an input iterator is
deduced for that parameter.

(15.2) — It has an Allocator template parameter and a type that does not qualify as an allocator is deduced for that parameter.

(15.3) — It has a Compare template parameter and a type that qualifies as an allocator is deduced for that parameter.

26.2.6.1 Exception safety guarantees [associative.reqmts.except]

1 For associative containers, no clear() function throws an exception. erase(k) does not throw an exception unless that exception is thrown by the container’s Compare object (if any).

2 For associative containers, if an exception is thrown by any operation from within an insert or emplace function inserting a single element, the insertion has no effect.

3 For associative containers, no swap function throws an exception unless that exception is thrown by the swap of the container’s Compare object (if any).

26.2.7 Unordered associative containers [unord.req]

1 Unordered associative containers provide an ability for fast retrieval of data based on keys. The worst-case complexity for most operations is linear, but the average case is much faster. The library provides four unordered associative containers: unordered_set, unordered_map, unordered_multiset, and unordered_multimap.

2 Unordered associative containers conform to the requirements for Containers (26.2), except that the expressions a == b and a != b have different semantics than for the other container types.

3 Each unordered associative container is parameterized by Key, by a function object type Hash that meets the Hash requirements (20.5.3.4) and acts as a hash function for argument values of type Key, and by a binary predicate Pred that induces an equivalence relation on values of type Key. Additionally, unordered_map and unordered_multimap associate an arbitrary mapped type T with the Key.

4 The container’s object of type Hash — denoted by hash — is called the hash function of the container. The container’s object of type Pred — denoted by pred — is called the key equality predicate of the container.

5 Two values k1 and k2 of type Key are considered equivalent if the container’s key equality predicate returns true when passed those values. If k1 and k2 are equivalent, the container’s hash function shall return the same value for both. [Note: Thus, when an unordered associative container is instantiated with a non-default Pred parameter it usually needs a non-default Hash parameter as well. — end note] For any two keys k1 and k2 in the same container, calling pred(k1, k2) shall always return the same value. For any key k in a container, calling hash(k) shall always return the same value.

6 An unordered associative container supports unique keys if it may contain at most one element for each key. Otherwise, it supports equivalent keys. unordered_set and unordered_map support unique keys. unordered_multiset and unordered_multimap support equivalent keys. In containers that support equivalent keys, elements with equivalent keys are adjacent to each other in the iteration order of the container. Thus, although the absolute order of elements in an unordered container is not specified, its elements are grouped into equivalent-key groups such that all elements of each group have equivalent keys. Mutating operations on unordered containers shall preserve the relative order of elements within each equivalent-key group unless otherwise specified.

7 For unordered_set and unordered_multiset the value type is the same as the key type. For unordered_map and unordered_multimap it is pair<const Key, T>.

8 For unordered containers where the value type is the same as the key type, both iterator and const_iterator are constant iterators. It is unspecified whether or not iterator and const_iterator are the same type. [Note: iterator and const_iterator have identical semantics in this case, and iterator is convertible
to const_iterator. Users can avoid violating the one-definition rule by always using const_iterator in their function parameter lists. — end note]

9 The elements of an unordered associative container are organized into buckets. Keys with the same hash code appear in the same bucket. The number of buckets is automatically increased as elements are added to an unordered associative container, so that the average number of elements per bucket is kept below a bound. Rehashing invalidates iterators, changes ordering between elements, and changes which buckets elements appear in, but does not invalidate pointers or references to elements. For unordered_multiset and unordered_multimap, rehashing preserves the relative ordering of equivalent elements.

10 The unordered associative containers meet all the requirements of Allocator-aware containers (26.2.1), except that for unordered_map and unordered_multimap, the requirements placed on value_type in Table 83 apply instead to key_type and mapped_type. [Note: For example, key_type and mapped_type are sometimes required to be CopyAssignable even though the associated value_type, pair<const key_type, mapped_type>, is not CopyAssignable. — end note]

11 In Table 91: X denotes an unordered associative container class, a denotes a value of type X, a2 denotes a value of a type with nodes compatible with type X (Table 89), b denotes a possibly const value of type X, a_uniq denotes a value of type X when X supports unique keys, a_eq denotes a value of type X when X supports equivalent keys, i and j denote input iterators that refer to value_type, [i, j) denotes a valid range, p and q2 denote valid constant iterators to a, q and q1 denote valid dereferenceable constant iterators to a, r denotes a valid dereferenceable iterator to a, [q1, q2) denotes a valid range in a, il denotes a value of type initializer_list<value_type>, t denotes a value of type X::value_type, k denotes a value of type key_type, hf denotes a possibly const value of type hasher, eq denotes a possibly const value of type key_equal, n denotes a value of type size_type, z denotes a value of type float, and nh denotes a non-const rvalue of type X::node_type.

</tr>
</tbody>
</table>
| a.rehash(n)            | void               | Postconditions: 
  a.bucket_count() \(\geq\) a.size() / a.max_load_factor() and a.bucket_count() \(\geq\) n. | Average case linear in a.size(), worst case quadratic. |
| a.reserve(n)           | void               | Same as a.rehash(ceil(n / a.max_load_factor())). | Average case linear in a.size(), worst case quadratic. |

12 Two unordered containers \(a\) and \(b\) compare equal if a.size() == b.size() and, for every equivalent-key group [Ea1, Ea2) obtained from a.equal_range(Ea1), there exists an equivalent-key group [Eb1, Eb2) obtained from b.equal_range(Ea1), such that is_permutation(Ea1, Ea2, Eb1, Eb2) returns true. For unordered_set and unordered_map, the complexity of operator== (i.e., the number of calls to the == operator of the value_type, to the predicate returned by key_eq(), and to the hasher returned by hash_function()) is proportional to \(N\) in the average case and to \(N^2\) in the worst case, where \(N\) is a.size(). For unordered_multiset and unordered_multimap, the complexity of operator== is proportional to \(\sum E_i^2\) in the average case and to \(N^2\) in the worst case, where \(N\) is a.size(), and \(E_i\) is the size of the \(i\)th equivalent-key group in \(a\). However, if the respective elements of each corresponding pair of equivalent-key groups Ea_i and Eb_i are arranged in the same order (as is commonly the case, e.g., if \(a\) and \(b\) are unmodified copies of the same container), then the average-case complexity for unordered_multiset and unordered_multimap becomes proportional to \(N\) (but worst-case complexity remains \(O(N^2)\), e.g., for a pathologically bad hash function). The behavior of a program that uses operator== or operator!= on unordered containers is undefined unless the Hash and Pred function objects respectively have the same behavior for both containers and the equality
comparison function for Key is a refinement\textsuperscript{257} of the partition into equivalent-key groups produced by Pred.

13 The iterator types iterator and const_iterator of an unordered associative container are of at least the forward iterator category. For unordered associative containers where the key type and value type are the same, both iterator and const_iterator are constant iterators.

14 The insert and emplace members shall not affect the validity of references to container elements, but may invalidate all iterators to the container. The erase members shall invalidate only iterators and references to the erased elements, and preserve the relative order of the elements that are not erased.

15 The insert and emplace members shall not affect the validity of iterators if \((N+n) \leq z \times B\), where \(N\) is the number of elements in the container prior to the insert operation, \(n\) is the number of elements inserted, \(B\) is the container’s bucket count, and \(z\) is the container’s maximum load factor.

16 The extract members invalidate only iterators to the removed element, and preserve the relative order of the elements that are not erased; pointers and references to the removed element remain valid. However, accessing the element through such pointers and references while the element is owned by a node_type is undefined behavior. References and pointers to an element obtained while it is owned by a node_type are invalidated if the element is successfully inserted.

17 A deduction guide for an unordered associative container shall not participate in overload resolution if any of the following are true:

\begin{align*}
(17.1) & \quad \text{It has an InputIterator template parameter and a type that does not qualify as an input iterator is deduced for that parameter.} \\
(17.2) & \quad \text{It has an Allocator template parameter and a type that does not qualify as an allocator is deduced for that parameter.} \\
(17.3) & \quad \text{It has a Hash template parameter and an integral type or a type that qualifies as an allocator is deduced for that parameter.} \\
(17.4) & \quad \text{It has a Pred template parameter and a type that qualifies as an allocator is deduced for that parameter.}
\end{align*}

26.2.7.1 Exception safety guarantees \[unord.req.except]\(\)

1 For unordered associative containers, no clear() function throws an exception. erase(k) does not throw an exception unless that exception is thrown by the container’s Hash or Pred object (if any).

2 For unordered associative containers, if an exception is thrown by any operation other than the container’s hash function from within an insert or emplace function inserting a single element, the insertion has no effect.

3 For unordered associative containers, no swap function throws an exception unless that exception is thrown by the swap of the container’s Hash or Pred object (if any).

4 For unordered associative containers, if an exception is thrown from within a rehash() function other than by the container’s hash function or comparison function, the rehash() function has no effect.

26.3 Sequence containers \[sequences]\(\)

26.3.1 In general \[sequences.general]\(\)

1 The headers <array>, <deque>, <forward_list>, <list>, and <vector> define class templates that meet the requirements for sequence containers.

    template <class Allocator> struct hash<vector<bool, Allocator>>;

    namespace pmr {
        template <class T>
            using vector = std::vector<T, polymorphic_allocator<T>>;
    }
}
```

### 26.3.7 Class template array

#### 26.3.7.1 Class template array overview

1. The header `<array>` defines a class template for storing fixed-size sequences of objects. An **array** is a contiguous container (26.2.1). An instance of **array<T, N>** stores N elements of type T, so that `size()` == N is an invariant.

2. An **array** is an aggregate (11.6.1) that can be list-initialized with up to N elements whose types are convertible to T.

3. An **array** satisfies all of the requirements of a container and of a reversible container (26.2), except that a default constructed **array** object is not empty and that `swap` does not have constant complexity. An **array** satisfies some of the requirements of a sequence container (26.2.3). Descriptions are provided here only for

§ 26.3.7.1 871
operations on `array` that are not described in one of these tables and for operations where there is additional
semantic information.

namespace std {
  template <class T, size_t N>
  struct array {
    // types:
    using value_type = T;
    using pointer = T*;
    using const_pointer = const T*;
    using reference = T&;
    using const_reference = const T&;
    using size_type = size_t;
    using difference_type = ptrdiff_t;
    using iterator = implementation-defined; // see 26.2
    using const_iterator = implementation-defined; // see 26.2
    using reverse_iterator = std::reverse_iterator<iterator>;
    using const_reverse_iterator = std::reverse_iterator<const_iterator>;
    // no explicit construct/copy/destroy for aggregate type
    void fill(const T& u);
    void swap(array&) noexcept(is_nothrow_swappable_v<T>);
    // iterators:
    constexpr iterator begin() noexcept;
    constexpr const_iterator begin() const noexcept;
    constexpr iterator end() noexcept;
    constexpr const_iterator end() const noexcept;
    constexpr reverse_iterator rbegin() noexcept;
    constexpr const_reverse_iterator rbegin() const noexcept;
    constexpr reverse_iterator rend() noexcept;
    constexpr const_reverse_iterator rend() const noexcept;
    constexpr const_iterator cbegin() const noexcept;
    constexpr const_iterator cend() const noexcept;
    constexpr const_reverse_iterator crbegin() const noexcept;
    constexpr const_reverse_iterator crend() const noexcept;
    // capacity:
    constexpr bool empty() const noexcept;
    constexpr size_type size() const noexcept;
    constexpr size_type max_size() const noexcept;
    // element access:
    constexpr reference operator[](size_type n);
    constexpr const_reference operator[](size_type n) const;
    constexpr reference at(size_type n);
    constexpr const_reference at(size_type n) const;
    constexpr reference front();
    constexpr const_reference front() const;
    constexpr reference back();
    constexpr const_reference back() const;
    constexpr T * data() noexcept;
  };

§ 26.3.7.1
constexpr const T * data() const noexcept;
};

template<class T, class... U>
array(T, U...) -> array<T, 1 + sizeof...(U)>;
}

26.3.7.2 array constructors, copy, and assignment

The conditions for an aggregate (11.6.1) shall be met. Class array relies on the implicitly-declared special member functions (15.1, 15.4, and 15.8) to conform to the container requirements table in 26.2. In addition to the requirements specified in the container requirements table, the implicit move constructor and move assignment operator for array require that T be MoveConstructible or MoveAssignable, respectively.

template<class T, class... U>
array(T, U...) -> array<T, 1 + sizeof...(U)>;

Requires: (is_same_v<T, U> && ...) is true. Otherwise the program is ill-formed.

26.3.7.3 array specialized algorithms

template <class T, size_t N>
void swap(array<T, N>& x, array<T, N>& y) noexcept(noexcept(x.swap(y)));

Remarks: This function shall not participate in overload resolution unless N == 0 or is_swappable_v<T> is true.

Effects: As if by x.swap(y).

Complexity: Linear in N.

26.3.7.4 array::size

template <class T, size_t N> constexpr size_type array<T, N>::size() const noexcept;

Returns: N.

26.3.7.5 array::data

constexpr T* data() noexcept;
constexpr const T* data() const noexcept;

Returns: A pointer such that data() == addressof(front()), and [data(), data() + size()) is a valid range.

26.3.7.6 array::fill

void fill(const T& u);

Effects: As if by fill_n(begin(), N, u).

26.3.7.7 array::swap

void swap(array& y) noexcept(is_nothrow_swappable_v<T>);

Effects: Equivalent to swap_ranges(begin(), end(), y.begin()).

[Note: Unlike the swap function for other containers, array::swap takes linear time, may exit via an exception, and does not cause iterators to become associated with the other container. —end note]

26.3.7.8 Zero sized arrays

array shall provide support for the special case N == 0.
In the case that \( N == 0 \), begin() == end() == unique value. The return value of data() is unspecified.

The effect of calling front() or back() for a zero-sized array is undefined.

Member function swap() shall have a non-throwing exception specification.

### 26.3.7.9 Tuple interface to class template array

```
template <class T, size_t N>
struct tuple_size<array<T, N>> : integral_constant<size_t, N> { };

tuple_element<I, array<T, N>>::type
```

1. Requires: \( I < N \). The program is ill-formed if \( I \) is out of bounds.
2. Value: The type \( T \).

```
template <size_t I, class T, size_t N>
constexpr T& get(array<T, N>& a) noexcept;
template <size_t I, class T, size_t N>
constexpr T&& get(array<T, N>&& a) noexcept;
template <size_t I, class T, size_t N>
constexpr const T& get(const array<T, N>& a) noexcept;
template <size_t I, class T, size_t N>
constexpr const T&& get(const array<T, N>&& a) noexcept;
```

1. Requires: \( I < N \). The program is ill-formed if \( I \) is out of bounds.
2. Returns: A reference to the \( I \)th element of \( a \), where indexing is zero-based.

### 26.3.8 Class template deque

#### 26.3.8.1 Class template deque overview

A deque is a sequence container that supports random access iterators (27.2.7). In addition, it supports constant time insert and erase operations at the beginning or the end; insert and erase in the middle take linear time. That is, a deque is especially optimized for pushing and popping elements at the beginning and end. Storage management is handled automatically.

A deque satisfies all of the requirements of a container, of a reversible container (given in tables in 26.2), of a sequence container, including the optional sequence container requirements (26.2.3), and of an allocator-aware container (Table 86). Descriptions are provided here only for operations on deque that are not described in one of these tables or for operations where there is additional semantic information.

```
namespace std {
    template <class T, class Allocator = allocator<T>>
    class deque {
        public:
            // types:
            using value_type = T;
            using allocator_type = Allocator;
            using pointer = typename allocator_traits<Allocator>::pointer;
            using const_pointer = typename allocator_traits<Allocator>::const_pointer;
            using reference = value_type&;
            using const_reference = const value_type&;
            using size_type = implementation-defined; // see 26.2
            using difference_type = implementation-defined; // see 26.2
            using iterator = implementation-defined; // see 26.2
            using const_iterator = implementation-defined; // see 26.2
            using reverse_iterator = std::reverse_iterator<iterator>;
            using const_reverse_iterator = std::reverse_iterator<const_iterator>;

§ 26.3.8.1
// 26.3.8.2, construct/copy/destroy
deque() : deque(Allocator()) { }
explicit deque(const Allocator&);
explicit deque(size_type n, const Allocator& = Allocator());

void push_back(const T& x);
void push_back(T&& x);

iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, size_type n, const T& x);
template <class InputIterator>
iterator insert(const_iterator position, InputIterator first, InputIterator last);
iterator insert(const_iterator position, initializer_list<T>);

void pop_front();
void pop_back();

iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);
void swap(deque&) noexcept(algorithm::is_always_equal::value);

};

template<class InputIterator,
class Allocator = allocator<typename iterator_traits<InputIterator>::value_type>>
deque<InputIterator, InputIterator, Allocator = Allocator>()
-> deque<typename iterator_traits<InputIterator>::value_type, Allocator>;

template <class T, class Allocator>
bool operator==(const deque<T, Allocator>& x, const deque<T, Allocator>& y);
template <class T, class Allocator>
bool operator<(const deque<T, Allocator>& x, const deque<T, Allocator>& y);
template <class T, class Allocator>
bool operator==(const deque<T, Allocator>& x, const deque<T, Allocator>& y);
template <class T, class Allocator>
bool operator<(const deque<T, Allocator>& x, const deque<T, Allocator>& y);
template <class T, class Allocator>
bool operator==(const deque<T, Allocator>& x, const deque<T, Allocator>& y);
template <class T, class Allocator>
bool operator<(const deque<T, Allocator>& x, const deque<T, Allocator>& y);
template <class T, class Allocator>
bool operator==(const deque<T, Allocator>& x, const deque<T, Allocator>& y);

// 26.3.8.5, specialized algorithms
template <class T, class Allocator>
void swap(deque<T, Allocator>& x, deque<T, Allocator>& y) noexcept(noexcept(x.swap(y)));
}

26.3.8.2 deque constructors, copy, and assignment [deque.cons]

§ 26.3.8.2 876
explicit deque(const Allocator&);
   Effects: Constructs an empty deque, using the specified allocator.
   Complexity: Constant.

explicit deque(size_type n, const Allocator& = Allocator());
   Effects: Constructs a deque with n default-inserted elements using the specified allocator.
   Requires: T shall be DefaultInsertable into *this.
   Complexity: Linear in n.

deque(size_type n, const T& value, const Allocator& = Allocator());
   Effects: Constructs a deque with n copies of value, using the specified allocator.
   Requires: T shall be CopyInsertable into *this.
   Complexity: Linear in n.

template <class InputIterator>
deque(InputIterator first, InputIterator last, const Allocator& = Allocator());
   Effects: Constructs a deque equal to the range [first, last), using the specified allocator.
   Complexity: Linear in distance(first, last).

26.3.8.3 deque capacity

void resize(size_type sz);
   Effects: If sz < size(), erases the last size() - sz elements from the sequence. Otherwise, appends
            sz - size() default-inserted elements to the sequence.
   Requires: T shall be MoveInsertable and DefaultInsertable into *this.

void resize(size_type sz, const T& c);
   Effects: If sz < size(), erases the last size() - sz elements from the sequence. Otherwise, appends
            sz - size() copies of c to the sequence.
   Requires: T shall be CopyInsertable into *this.

void shrink_to_fit();
   Requires: T shall be MoveInsertable into *this.
   Effects: shrink_to_fit is a non-binding request to reduce memory use but does not change the
            size of the sequence. [Note: The request is non-binding to allow latitude for implementation-specific
            optimizations. —end note] If an exception is thrown other than by the move constructor of a
            non-CopyInsertable T there are no effects.
   Complexity: Linear in the size of the sequence.
   Remarks: shrink_to_fit invalidates all the references, pointers, and iterators referring to the elements
            in the sequence as well as the past-the-end iterator.

26.3.8.4 deque modifiers

iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);
template <class InputIterator>
   iterator insert(const_iterator position,
InputIterator first, InputIterator last);
iterator insert(const_iterator position, initializer_list<T>);

template <class... Args> reference emplace_front(Args&&... args);
template <class... Args> reference emplace_back(Args&&... args);
template <class... Args> iterator emplace(const_iterator position, Args&&... args);
void push_front(const T& x);
void push_front(T&& x);
void push_back(const T& x);
void push_back(T&& x);

1 Effects: An insertion in the middle of the deque invalidates all the iterators and references to elements of the deque. An insertion at either end of the deque invalidates all the iterators to the deque, but has no effect on the validity of references to elements of the deque.

2 Remarks: If an exception is thrown other than by the copy constructor, move constructor, assignment operator, or move assignment operator of T there are no effects. If an exception is thrown while inserting a single element at either end, there are no effects. Otherwise, if an exception is thrown by the move constructor of a non-CopyInsertable T, the effects are unspecified.

3 Complexity: The complexity is linear in the number of elements inserted plus the lesser of the distances to the beginning and end of the deque. Inserting a single element either at the beginning or end of a deque always takes constant time and causes a single call to a constructor of T.

iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);
void pop_front();
void pop_back();

4 Effects: An erase operation that erases the last element of a deque invalidates only the past-the-end iterator and all iterators and references to the erased elements. An erase operation that erases the first element of a deque but not the last element invalidates only iterators and references to the erased elements. An erase operation that erases neither the first element nor the last element of a deque invalidates the past-the-end iterator and all iterators and references to all the elements of the deque.
[Note: pop_front and pop_back are erase operations. — end note]

5 Complexity: The number of calls to the destructor of T is the same as the number of elements erased, but the number of calls to the assignment operator of T is no more than the lesser of the number of elements before the erased elements and the number of elements after the erased elements.

Throws: Nothing unless an exception is thrown by the copy constructor, move constructor, assignment operator, or move assignment operator of T.

26.3.8.5 deque specialized algorithms
[deque.special]

template <class T, class Allocator>
void swap(deque<T, Allocator>& x, deque<T, Allocator>& y)
    noexcept(noexcept(x.swap(y)));

1 Effects: As if by x.swap(y).

26.3.9 Class template forward_list
[forwardlist]

26.3.9.1 Class template forward_list overview
[forwardlist.overview]

A forward_list is a container that supports forward iterators and allows constant time insert and erase operations anywhere within the sequence, with storage management handled automatically. Fast random access to list elements is not supported. [Note: It is intended that forward_list have zero space or time

§ 26.3.9.1 878
overhead relative to a hand-written C-style singly linked list. Features that would conflict with that goal have been omitted. —end note]

2 A forward_list satisfies all of the requirements of a container (Table 83), except that the size() member function is not provided and operator== has linear complexity. A forward_list also satisfies all of the requirements for an allocator-aware container (Table 86). In addition, a forward_list provides the assign member functions (Table 87) and several of the optional container requirements (Table 88). Descriptions are provided here only for operations on forward_list that are not described in that table or for operations where there is additional semantic information.

3 [Note: Modifying any list requires access to the element preceding the first element of interest, but in a forward_list there is no constant-time way to access a preceding element. For this reason, ranges that are modified, such as those supplied to erase and splice, must be open at the beginning. —end note]

namespace std {
    template <class T, class Allocator = allocator<T>>
    class forward_list {
public:
        // types:
        using value_type = T;
        using allocator_type = Allocator;
        using pointer = typename allocator_traits<Allocator>::pointer;
        using const_pointer = typename allocator_traits<Allocator>::const_pointer;

  noexcept(noexcept(x.swap(y)));

4 An incomplete type T may be used when instantiating forward_list if the allocator satisfies the allocator completeness requirements (20.5.3.5.1). T shall be complete before any member of the resulting specialization of forward_list is referenced.

26.3.9.2 forward_list constructors, copy, assignment [forwardlist.cons]

explicit forward_list(const Allocator&);

Effects: Constructs an empty forward_list object using the specified allocator.

Complexity: Constant.

explicit forward_list(size_type n, const Allocator& = Allocator());

Effects: Constructs a forward_list object with n default-inserted elements using the specified allocator.

Requires: T shall be DefaultInsertable into *this.
Complexity: Linear in \( n \).

\[
\text{forward\_list}(\text{size\_type } n, \text{const } T& \text{ value, const Allocator& } = \text{Allocator}());
\]

Effects: Constructs a \texttt{forward\_list} object with \( n \) copies of \texttt{value} using the specified allocator.

Requires: \texttt{T} shall be \texttt{CopyInsertable} into \texttt{*this}.

Complexity: Linear in \( n \).

\[
\text{template <class InputIterator>}
\text{forward\_list(InputIterator first, InputIterator last, const Allocator& } = \text{Allocator}());
\]

Effects: Constructs a \texttt{forward\_list} object equal to the range \([\texttt{first}, \texttt{last})\).

Complexity: Linear in \texttt{distance(first, last)}.

\section*{26.3.9.3 \texttt{forward\_list} iterators}

\begin{itemize}
\item iterator \texttt{before\_begin()} \texttt{noexcept};
\item const_iterator \texttt{before\_begin()} \texttt{const noexcept};
\item const_iterator \texttt{cbefore\_begin()} \texttt{const noexcept};
\end{itemize}

Returns: A non-dereferenceable iterator that, when incremented, is equal to the iterator returned by \texttt{begin()}.

Effects: \texttt{cbefore\_begin()} is equivalent to \texttt{const\_cast<forward\_list const&>(*this).before\_begin()}.

Remarks: \texttt{before\_begin()} == \texttt{end()} shall equal \texttt{false}.

\section*{26.3.9.4 \texttt{forward\_list} element access}

\begin{itemize}
\item reference \texttt{front()};
\item const_reference \texttt{front()} \texttt{const};
\end{itemize}

Returns: \texttt{*begin}()

\section*{26.3.9.5 \texttt{forward\_list} modifiers}

None of the overloads of \texttt{insert\_after} shall affect the validity of iterators and references, and \texttt{erase\_after} shall invalidate only iterators and references to the erased elements. If an exception is thrown during \texttt{insert\_after} there shall be no effect. Inserting \( n \) elements into a \texttt{forward\_list} is linear in \( n \), and the number of calls to the copy or move constructor of \texttt{T} is exactly equal to \( n \). Erasing \( n \) elements from a \texttt{forward\_list} is linear in \( n \) and the number of calls to the destructor of type \texttt{T} is exactly equal to \( n \).

\[
\text{template <class... Args> reference emplace\_front(Args&&... args)};
\]

Effects: Inserts an object of type \texttt{value\_type} constructed with \texttt{value\_type(std::forward<Args>(args)...) at the beginning of the list.}

void \texttt{push\_front(const T& x)};
void \texttt{push\_front(T&& x)};

Effects: Inserts a copy of \texttt{x} at the beginning of the list.

void \texttt{pop\_front()};

Effects: As if by \texttt{erase\_after(before\_begin())}.

\begin{itemize}
\item iterator \texttt{insert\_after(const_iterator position, const T& x)};
\item iterator \texttt{insert\_after(const_iterator position, T&& x)};
\end{itemize}

Requires: \texttt{position} is \texttt{before\_begin()} or is a dereferenceable iterator in the range \([\texttt{begin()}, \texttt{end}())].
6 Effects: Inserts a copy of \( x \) after \( \text{position} \).
7 Returns: An iterator pointing to the copy of \( x \).

\[
\text{iterator insert\_after(const\_iterator \text{position}, size\_type \text{n}, const T& x);}\
\]

8 Requires: \( \text{position} \) is \( \text{before\_begin()} \) or is a dereferenceable iterator in the range \( [\text{begin()}, \text{end()}]. \)
9 Effects: Inserts \( \text{n} \) copies of \( x \) after \( \text{position} \).
10 Returns: An iterator pointing to the last inserted copy of \( x \) or \( \text{position} \) if \( \text{n} == 0 \).

\[
\text{template <class InputIterator>}
\]

11 \[
\text{iterator insert\_after(const\_iterator \text{position}, InputIterator first, InputIterator last);}\
\]

12 Requires: \( \text{position} \) is \( \text{before\_begin()} \) or is a dereferenceable iterator in the range \( [\text{begin()}, \text{end()}]. \)
13 \( \text{first} \) and \( \text{last} \) are not iterators in \(*\text{this} \).
14 Effects: Inserts copies of elements in \( [\text{first}, \text{last}) \) after \( \text{position} \).
15 Returns: An iterator pointing to the last inserted element or \( \text{position} \) if \( \text{first} == \text{last} \).

\[
\text{iterator insert\_after(const\_iterator \text{position}, initializer\_list<T> \text{il});}\
\]

16 Effects: \( \text{insert\_after(p, il.begin(), il.end())} \).
17 Returns: An iterator pointing to the last inserted element or \( \text{position} \) if \( \text{il} \) is empty.

\[
\text{template <class... Args>}
\]

18 \[
\text{iterator emplace\_after(const\_iterator \text{position}, Args&&... args);}\
\]

19 Requires: \( \text{position} \) is \( \text{before\_begin()} \) or is a dereferenceable iterator in the range \( [\text{begin()}, \text{end()}]. \)
20 Effects: Inserts an object of type \( \text{value\_type} \) constructed with \( \text{value\_type(\text{std::forward<Args>(args)...})} \) after \( \text{position} \).
21 Returns: An iterator pointing to the new object.

\[
\text{iterator erase\_after(const\_iterator \text{position});}\
\]

22 Requires: The iterator following \( \text{position} \) is dereferenceable.
23 Effects: Erases the element pointed to by the iterator following \( \text{position} \).
24 Returns: An iterator pointing to the element following the one that was erased, or \( \text{end()} \) if no such element exists.
25 Throws: Nothing.

\[
\text{iterator erase\_after(const\_iterator \text{position}, const\_iterator last);}\
\]

26 Requires: All iterators in the range \( (\text{position}, \text{last}) \) are dereferenceable.
27 Effects: Erases the elements in the range \( (\text{position}, \text{last}) \).
28 Returns: \( \text{last} \).
29 Throws: Nothing.

\[
\text{void resize(size\_type \text{sz});}\
\]

30 Effects: If \( \text{sz} < \text{distance(begin(), end())}, \) erases the last \( \text{distance(begin(), end()) - sz} \) elements from the list. Otherwise, inserts \( \text{sz - distance(begin(), end())} \) default-inserted elements at the end of the list.
31 Requires: \( T \) shall be \( \text{DefaultInsertable} \) into \(*\text{this} \).

\[
\text{void resize(size\_type \text{sz}, const value\_type& c);}\
\]
Effects: If \( sz < \text{distance}(\text{begin}(), \text{end}()) \), erases the last \( \text{distance}(\text{begin}(), \text{end}()) - sz \) elements from the list. Otherwise, inserts \( sz - \text{distance}(\text{begin}(), \text{end}()) \) copies of \( c \) at the end of the list.

Requires: \( T \) shall be CopyInsertable into \(*\text{this}.*\)

void clear() noexcept;

Effects: Erases all elements in the range \([\text{begin}(), \text{end}())\).

Remarks: Does not invalidate past-the-end iterators.

26.3.9.6 forward_list operations

void splice_after(const_iterator position, forward_list& x);
void splice_after(const_iterator position, forward_list&& x);

Requires: \( \text{position} \) is \text{before_begin()} or is a dereferenceable iterator in the range \([\text{begin}(), \text{end}())\).
get_allocator() == x.get_allocator(). &x != this.

Effects: Inserts the contents of \( x \) after \( \text{position} \), and \( x \) becomes empty. Pointers and references to the moved elements of \( x \) now refer to those same elements but as members of \(*\text{this}.*\). Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into \(*\text{this}.*\), not into \( x \).

Throws: Nothing.

Complexity: \( \Theta(\text{distance}(x.\text{begin}(), x.\text{end}())) \)

void splice_after(const_iterator position, forward_list& x, const_iterator i);
void splice_after(const_iterator position, forward_list&& x, const_iterator i);

Requires: \( \text{position} \) is \text{before_begin()} or is a dereferenceable iterator in the range \([\text{begin}(), \text{end}())\).
The iterator following \( i \) is a dereferenceable iterator in \( x \). get_allocator() == x.get_allocator().

Effects: Inserts the element following \( i \) into \(*\text{this}.*\), following \( \text{position} \), and removes it from \( x \). The result is unchanged if \( \text{position} == i \) or \( \text{position} == ++i \). Pointers and references to \( *++i \) continue to refer to the same element but as a member of \(*\text{this}.*\). Iterators to \( *++i \) continue to refer to the same element, but now behave as iterators into \(*\text{this}.*\), not into \( x \).

Throws: Nothing.

Complexity: \( \Theta(1) \)

void splice_after(const_iterator position, forward_list& x, const_iterator first, const_iterator last);
void splice_after(const_iterator position, forward_list&& x, const_iterator first, const_iterator last);

Requires: \( \text{position} \) is \text{before_begin()} or is a dereferenceable iterator in the range \([\text{begin}(), \text{end}())\). (\( \text{first} \), \( \text{last} \)) is a valid range in \( x \), and all iterators in the range \([\text{first} \), \( \text{last} \)) are dereferenceable. \( \text{position} \) is not an iterator in the range \([\text{first} \), \( \text{last} \)). get_allocator() == x.get_allocator().

Effects: Inserts elements in the range \([\text{first} \), \( \text{last} \)) after \( \text{position} \) and removes the elements from \( x \). Pointers and references to the moved elements of \( x \) now refer to those same elements but as members of \(*\text{this}.*\). Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into \(*\text{this}.*\), not into \( x \).

Complexity: \( \Theta(\text{distance}(\text{first} , \text{last})) \)

void remove(const T& value);
template <class Predicate> void remove_if(Predicate pred);
© ISO/IEC

§ 26.3.9.6

§ 26.3.9.6

Effects: Erases all the elements in the list referred by a list iterator \( i \) for which the following conditions hold: \( *i == \text{value} \) (for remove()), \( \text{pred}(*i) \) is true (for remove_if()). Invalidates only the iterators and references to the erased elements.

Throws: Nothing unless an exception is thrown by the equality comparison or the predicate.

Remarks: Stable (20.5.5.7).

Complexity: Exactly \( \text{distance(begin(), end())} \) applications of the corresponding predicate.

```cpp
void unique();

template <class BinaryPredicate> void unique(BinaryPredicate pred);
```

Effects: Erases all but the first element from every consecutive group of equal elements referred to by the iterator \( i \) in the range \([\text{first} + 1, \text{last})\) for which \( *i == *(i-1) \) (for the version with no arguments) or \( \text{pred}(*i, *(i - 1)) \) (for the version with a predicate argument) holds. Invalidates only the iterators and references to the erased elements.

Throws: Nothing unless an exception is thrown by the equality comparison or the predicate.

Complexity: If the range \([\text{first}, \text{last})\) is not empty, exactly \( \text{(last} - \text{first}) - 1 \) applications of the corresponding predicate, otherwise no applications of the predicate.

```cpp
void merge(forward_list& x);
void merge(forward_list&& x);

template <class Compare> void merge(forward_list& x, Compare comp);

template <class Compare> void merge(forward_list&& x, Compare comp);
```

Requires: \( \text{comp} \) defines a strict weak ordering (28.7), and \( *\text{this} \) and \( x \) are both sorted according to this ordering. \( \text{get_allocator()} == x.\text{get_allocator()} \).

Effects: Merges the two sorted ranges \([\text{begin()}, \text{end()}\) and \([x.\text{begin()}, x.\text{end()}\). \( x \) is empty after the merge. If an exception is thrown other than by a comparison there are no effects. Pointers and references to the moved elements of \( x \) now refer to those same elements but as members of \( *\text{this} \). Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into \( *\text{this} \), not into \( x \).

Remarks: Stable (20.5.5.7). The behavior is undefined if \( \text{get_allocator()} \neq x.\text{get_allocator()} \).

Complexity: At most \( \text{distance(begin(), end()) + distance(x.begin(), x.end())} - 1 \) comparisons.

```cpp
void sort();

template <class Compare> void sort(Compare comp);
```

Requires: \( \text{operator<} \) (for the version with no arguments) or \( \text{comp} \) (for the version with a comparison argument) defines a strict weak ordering (28.7).

Effects: Sorts the list according to the \( \text{operator<} \) or the \( \text{comp} \) function object. If an exception is thrown, the order of the elements in \( *\text{this} \) is unspecified. Does not affect the validity of iterators and references.

Remarks: Stable (20.5.5.7).

Complexity: Approximately \( N \log N \) comparisons, where \( N \) is \( \text{distance(begin(), end())} \).

```cpp
void reverse() noexcept;
```

Effects: Reverses the order of the elements in the list. Does not affect the validity of iterators and references.

Complexity: Linear time.
26.3.9.7  forward_list specialized algorithms

template <class T, class Allocator>
void swap(forward_list<T, Allocator>& x, forward_list<T, Allocator>& y)
  noexcept(noexcept(x.swap(y)));

1  Effects: As if by x.swap(y).

26.3.10  Class template list

26.3.10.1  Class template list overview

1  A list is a sequence container that supports bidirectional iterators and allows constant time insert and
erase operations anywhere within the sequence, with storage management handled automatically. Unlike
vectors (26.3.11) and deques (26.3.8), fast random access to list elements is not supported, but many
algorithms only need sequential access anyway.

2  A list satisfies all of the requirements of a container, of a reversible container (given in two tables in 26.2),
of a sequence container, including most of the optional sequence container requirements (26.2.3), and of an
allocator-aware container (Table 86). The exceptions are the operator[] and at member functions, which
are not provided. Descriptions are provided here only for operations on list that are not described in
one of these tables or for operations where there is additional semantic information.

namespace std {
  template <class T, class Allocator = allocator<T>>
  class list {
  public:
    // types:
    using value_type = T;
    using allocator_type = Allocator;
    using pointer = typename allocator_traits<Allocator>::pointer;
    using const_pointer = typename allocator_traits<Allocator>::const_pointer;
    using reference = value_type&;
    using const_reference = const value_type&;
    using size_type = implementation-defined; // see 26.2
    using difference_type = implementation-defined; // see 26.2
    using iterator = implementation-defined; // see 26.2
    using const_iterator = implementation-defined; // see 26.2
    using reverse_iterator = std::reverse_iterator<iterator>;
    using const_reverse_iterator = std::reverse_iterator<const_iterator>;

    // 26.3.10.2, construct/copy/destroy
    list() : list(Allocator()) { } 
    explicit list(const Allocator&); 
    explicit list(size_type n, const Allocator& = Allocator());
    list(size_type n, const T& value, const Allocator& = Allocator());
    template <class InputIterator>
      list(InputIterator first, InputIterator last, const Allocator& = Allocator());
    list(const list& x);
    list(list&& x);
    list(const list&, const Allocator&);
    list(list&, const Allocator&);
    list(initializer_list<T>, const Allocator& = Allocator());
    -list();
    list& operator=(const list& x);
    list& operator=(list&& x)

258) These member functions are only provided by containers whose iterators are random access iterators.
```cpp
// list

noexcept(algorithm_traits<Allocator>::is_always_equal::value);
list& operator=(initializer_list<T>);
template <class InputIterator>
void assign(InputIterator first, InputIterator last);
void assign(size_type n, const T& t);
void assign(initializer_list<T>);
allocator_type get_allocator() const noexcept;

// iterators:

template <class Compare> void merge(list& x, Compare comp);
template <class Compare> void merge(list&& x, Compare comp);

void sort();
template <class Compare> void sort(Compare comp);

void reverse() noexcept;
};

template<class InputIterator,
   class Allocator = allocator<typename iterator_traits<InputIterator>::value_type>>
   list(InputIterator, InputIterator, Allocator = Allocator())
   -> list<typename iterator_traits<InputIterator>::value_type, Allocator>;

template <class T, class Allocator>
   bool operator==(const list<T, Allocator>& x, const list<T, Allocator>& y);
template <class T, class Allocator>
   bool operator<(const list<T, Allocator>& x, const list<T, Allocator>& y);
template <class T, class Allocator>
   bool operator!=(const list<T, Allocator>& x, const list<T, Allocator>& y);
template <class T, class Allocator>
   bool operator>(const list<T, Allocator>& x, const list<T, Allocator>& y);
template <class T, class Allocator>
   bool operator<=(const list<T, Allocator>& x, const list<T, Allocator>& y);
template <class T, class Allocator>
   bool operator>=(const list<T, Allocator>& x, const list<T, Allocator>& y);

// 26.3.10.6, specialized algorithms
template <class T, class Allocator>
   void swap(list<T, Allocator>& x, list<T, Allocator>& y)
An incomplete type \( T \) may be used when instantiating `list` if the allocator satisfies the allocator completeness requirements (20.5.3.5.1). \( T \) shall be complete before any member of the resulting specialization of `list` is referenced.

### 26.3.10.2 list constructors, copy, and assignment

`explicit list(const Allocator&);`

**Effects:** Constructs an empty list, using the specified allocator.

**Complexity:** Constant.

`explicit list(size_type n, const Allocator& = Allocator());`

**Effects:** Constructs a `list` with \( n \) default-inserted elements using the specified allocator.

**Requires:** \( T \) shall be `DefaultInsertable` into `*this`.

**Complexity:** Linear in \( n \).

`list(size_type n, const T& value, const Allocator& = Allocator());`

**Effects:** Constructs a `list` with \( n \) copies of `value`, using the specified allocator.

**Requires:** \( T \) shall be `CopyInsertable` into `*this`.

**Complexity:** Linear in \( n \).

`template <class InputIterator>
list(InputIterator first, InputIterator last, const Allocator& = Allocator());`

**Effects:** Constructs a `list` equal to the range \([first, last)\).

**Complexity:** Linear in `distance(first, last)`.

### 26.3.10.3 list capacity

`void resize(size_type sz);`

**Effects:** If `size() < sz`, appends \( sz - size() \) default-inserted elements to the sequence. If \( sz \leq size() \), equivalent to:

```cpp
list<\text{T}>::iterator it = begin();
advance(it, sz);
erase(it, end());
```

**Requires:** \( T \) shall be `DefaultInsertable` into `*this`.

`void resize(size_type sz, const T& c);`

**Effects:** As if by:

```cpp
if \( sz > size() \)
    insert(end(), sz-size(), c);
else if \( sz < size() \) {
    iterator i = begin();
    advance(i, sz);
    erase(i, end());
} 
else
    ; // do nothing
```

**Requires:** \( T \) shall be `CopyInsertable` into `*this`.

§ 26.3.10.3 889
26.3.10.4  list modifiers

iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);
template <class InputIterator>
    iterator insert(const_iterator position, InputIterator first,
                    InputIterator last);
iterator insert(const_iterator position, initializer_list<T>);

template <class... Args> reference emplace_front(Args&&... args);
template <class... Args> reference emplace_back(Args&&... args);
template <class... Args> iterator emplace(const_iterator position, Args&&... args);
void push_front(const T& x);
void push_front(T&& x);
void push_back(const T& x);
void push_back(T&& x);

1  Remarks: Does not affect the validity of iterators and references. If an exception is thrown there are no
effects.
2  Complexity: Insertion of a single element into a list takes constant time and exactly one call to a
constructor of T. Insertion of multiple elements into a list is linear in the number of elements inserted,
and the number of calls to the copy constructor or move constructor of T is exactly equal to the number
of elements inserted.

iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);
void pop_front();
void pop_back();
void clear() noexcept;

3  Effects: Invalidates only the iterators and references to the erased elements.
4  Throws: Nothing.
5  Complexity: Erasing a single element is a constant time operation with a single call to the destructor
of T. Erasing a range in a list is linear time in the size of the range and the number of calls to the
destructor of type T is exactly equal to the size of the range.

26.3.10.5  list operations

Since lists allow fast insertion and erasing from the middle of a list, certain operations are provided specifically
for them. list provides three splice operations that destructively move elements from one list to another. The behavior
of splice operations is undefined if get_allocator() != x.get_allocator().

void splice(const_iterator position, list& x);
void splice(const_iterator position, list&& x);

3  Requires: &x != this.
4  Effects: Inserts the contents of x before position and x becomes empty. Pointers and references to the
moved elements of x now refer to those same elements but as members of *this. Iterators referring
to the moved elements will continue to refer to their elements, but they now behave as iterators into
*this, not into x.

259) As specified in 20.5.3.5, the requirements in this Clause apply only to lists whose allocators compare equal.
void splice(const_iterator position, list& x, const_iterator i);
void splice(const_iterator position, list&& x, const_iterator i);

Requires: i is a valid dereferenceable iterator of x.

Effects: Inserts an element pointed to by i from list x before position and removes the element from x. The result is unchanged if position == i or position == ++i. Pointers and references to *i continue to refer to this same element but as a member of *this. Iterators to *i (including i itself) continue to refer to the same element, but now behave as iterators into *this, not into x.

Throws: Nothing.

Complexity: Constant time.

void splice(const_iterator position, list& x, const_iterator first, const_iterator last);
void splice(const_iterator position, list&& x, const_iterator first, const_iterator last);

Requires: [first, last) is a valid range in x. The program has undefined behavior if position is an iterator in the range [first, last).

Effects: Inserts elements in the range [first, last) before position and removes the elements from x. Pointers and references to the moved elements of x now refer to those same elements but as members of *this. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into *this, not into x.

Throws: Nothing.

Complexity: Constant time.

void remove(const T& value);
template <class Predicate> void remove_if(Predicate pred);

Effects: Erases all the elements in the list referred by a list iterator i for which the following conditions hold: *i == value, pred(*i) != false. Invalidates only the iterators and references to the erased elements.

Throws: Nothing unless an exception is thrown by *i == value or pred(*i) != false.

Remarks: Stable (20.5.5.7).

Complexity: Exactly size() applications of the corresponding predicate.

void unique();
template <class BinaryPredicate> void unique(BinaryPredicate binary_pred);

Effects: Erases all but the first element from every consecutive group of equal elements referred to by the iterator i in the range [first + 1, last) for which *i == *(i-1) (for the version of unique with no arguments) or pred(*i, *(i - 1)) (for the version of unique with a predicate argument) holds. Invalidates only the iterators and references to the erased elements.

Throws: Nothing unless an exception is thrown by *i == *(i-1) or pred(*i, *(i - 1))

Complexity: If the range [first, last) is not empty, exactly (last - first) - 1 applications of the corresponding predicate, otherwise no applications of the predicate.

void merge(list& x);
void merge(list&& x);
template <class Compare> void merge(list& x, Compare comp);

Requires: comp shall define a strict weak ordering (28.7), and both the list and the argument list shall be sorted according to this ordering.

Effects: If (&x == this) does nothing; otherwise, merges the two sorted ranges [begin(), end()) and [x.begin(), x.end()). The result is a range in which the elements will be sorted in non-decreasing order according to the ordering defined by comp; that is, for every iterator i, in the range other than the first, the condition comp(*i, *(i - 1)) will be false. Pointers and references to the moved elements of x now refer to those same elements but as members of *this. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into *this, not into x.

Remarks: Stable (20.5.5.7). If (&x != this) the range [x.begin(), x.end()) is empty after the merge. No elements are copied by this operation. The behavior is undefined if get_allocator() != x.get_allocator().

Complexity: At most size() + x.size() - 1 applications of comp if (&x != this); otherwise, no applications of comp are performed. If an exception is thrown other than by a comparison there are no effects.

void reverse() noexcept;

Effects: Reverses the order of the elements in the list. Does not affect the validity of iterators and references.

Complexity: Linear time.

void sort();

template <class Compare> void sort(Compare comp);

Requires: operator< (for the first version) or comp (for the second version) shall define a strict weak ordering (28.7).

Effects: Sorts the list according to the operator< or a Compare function object. If an exception is thrown, the order of the elements in *this is unspecified. Does not affect the validity of iterators and references.

Remarks: Stable (20.5.5.7).

Complexity: Approximately N log N comparisons, where N == size().

26.3.10.6 list specialized algorithms [list.special]

template <class T, class Allocator>
void swap(list<T, Allocator>& x, list<T, Allocator>& y)
    noexcept(noexcept(x.swap(y)));

Effects: As if by x.swap(y).

26.3.11 Class template vector [vector]

26.3.11.1 Class template vector overview [vector.overview]

A vector is a sequence container that supports (amortized) constant time insert and erase operations at the end; insert and erase in the middle take linear time. Storage management is handled automatically, though hints can be given to improve efficiency.

A vector satisfies all of the requirements of a container and of a reversible container (given in two tables in 26.2), of a sequence container, including most of the optional sequence container requirements (26.2.3), of an allocator-aware container (Table 86), and, for an element type other than bool, of a contiguous
container (26.2.1). The exceptions are the push_front, pop_front, and emplace_front member functions, which are not provided. Descriptions are provided here only for operations on vector that are not described in one of these tables or for operations where there is additional semantic information.

namespace std {
    template <class T, class Allocator = allocator<T>>
    class vector {
    public:
        // types:
        using value_type = T;
        using allocator_type = Allocator;
        using pointer = typename allocator_traits<Allocator>::pointer;
        using const_pointer = typename allocator_traits<Allocator>::const_pointer;
        using reference = value_type&;
        using const_reference = const value_type&;
        using size_type = implementation-defined; // see 26.2
        using difference_type = implementation-defined; // see 26.2
        using iterator = implementation-defined; // see 26.2
        using const_iterator = implementation-defined; // see 26.2
        using reverse_iterator = std::reverse_iterator<iterator>;
        using const_reverse_iterator = std::reverse_iterator<const_iterator>;

        // 26.3.11.2, construct/copy/destroy
        vector() noexcept(noexcept(Allocator())) : vector(Allocator()) {} 
        explicit vector(const Allocator&) noexcept;
        explicit vector(size_type n, const Allocator& = Allocator());
        vector(size_type n, const T& value, const Allocator& = Allocator());
        template <class InputIterator>
        vector(InputIterator first, InputIterator last, const Allocator& = Allocator());
        vector(const vector& x);
        vector(vector&&) noexcept;
        vector(const vector&, const Allocator&);
        vector(vector&&, const Allocator&);
        vector(initializer_list<T>, const Allocator& = Allocator());
        ~vector();
        vector& operator=(const vector& x);
        vector& operator=(vector&& x) noexcept(allocator_traits<Allocator>::propagate_on_container_move_assignment::value ||
        allocator_traits<Allocator>::is_always_equal::value);
        vector& operator=(initializer_list<T>);
        template <class InputIterator>
        void assign(InputIterator first, InputIterator last);
    
        void assign(size_type n, const T& u);
        void assign(initializer_list<T>);
        allocator_type get_allocator() const noexcept;

        // iterators:
        iterator begin() noexcept;
        const_iterator begin() const noexcept;
        iterator end() noexcept;
        const_iterator end() const noexcept;
        reverse_iterator rbegin() noexcept;
        const_reverse_iterator rbegin() const noexcept;
        reverse_iterator rend() noexcept;
        const_reverse_iterator rend() const noexcept;
    }
const_iterator cbegin() const noexcept;
const_iterator cend() const noexcept;
const_reverse_iterator crbegin() const noexcept;
const_reverse_iterator crend() const noexcept;

// 26.3.11.3, capacity
bool empty() const noexcept;
size_type size() const noexcept;
size_type max_size() const noexcept;
size_type capacity() const noexcept;
void resize(size_type sz);
void resize(size_type sz, const T& c);
void reserve(size_type n);
void shrink_to_fit();

// element access:
reference operator[](size_type n);
const_reference operator[](size_type n) const;
const_reference at(size_type n) const;
reference at(size_type n);
reference front();
const_reference front() const;
reference back();
const_reference back() const;

// 26.3.11.4, data access
T* data() noexcept;
const T* data() const noexcept;

// 26.3.11.5, modifiers
template <class... Args> reference emplace_back(Args&&... args);
void push_back(const T& x);
void push_back(T&& x);
void pop_back();

template <class... Args> iterator emplace(const_iterator position, Args&&... args);
iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);
template <class InputIterator>
iterator insert(const_iterator position, InputIterator first, InputIterator last);
iterator insert(const_iterator position, initializer_list<T> il);
iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);
void swap(vector&)
  noexcept(algorithm_traits<Allocator>::propagate_on_container_swap::value ||
            algorithm_traits<Allocator>::is_always_equal::value);
void clear() noexcept;
};

template<class InputIterator,
  class Allocator = allocator<typename iterator_traits<InputIterator>::value_type>>
vector(InputIterator, InputIterator, Allocator = Allocator())
  -> vector<typename iterator_traits<InputIterator>::value_type, Allocator>;

§ 26.3.11
template <class T, class Allocator>
bool operator==(const vector<T, Allocator>& x, const vector<T, Allocator>& y);
template <class T, class Allocator>
bool operator<(const vector<T, Allocator>& x, const vector<T, Allocator>& y);
template <class T, class Allocator>
bool operator!=(const vector<T, Allocator>& x, const vector<T, Allocator>& y);
template <class T, class Allocator>
bool operator>(const vector<T, Allocator>& x, const vector<T, Allocator>& y);
template <class T, class Allocator>
bool operator>=(const vector<T, Allocator>& x, const vector<T, Allocator>& y);
template <class T, class Allocator>
bool operator<=(const vector<T, Allocator>& x, const vector<T, Allocator>& y);

// 26.3.11.6, specialized algorithms
template <class T, class Allocator>
void swap(vector<T, Allocator>& x, vector<T, Allocator>& y)
   noexcept(noexcept(x.swap(y)));

3 An incomplete type T may be used when instantiating vector if the allocator satisfies the allocator completeness requirements (20.5.3.1). T shall be complete before any member of the resulting specialization of vector is referenced.

26.3.11.2 vector constructors, copy, and assignment

explicit vector(const Allocator&);
   Effects: Constructs an empty vector, using the specified allocator.
   Complexity: Constant.

explicit vector(size_type n, const Allocator& = Allocator());
   Effects: Constructs a vector with n default-inserted elements using the specified allocator.
   Requires: T shall be DefaultInsertable into *this.
   Complexity: Linear in n.

vector(size_type n, const T& value,
       const Allocator& = Allocator());
   Effects: Constructs a vector with n copies of value, using the specified allocator.
   Requires: T shall be CopyInsertable into *this.
   Complexity: Linear in n.

template <class InputIterator>
vector(InputIterator first, InputIterator last,
       const Allocator& = Allocator());
   Effects: Constructs a vector equal to the range [first, last), using the specified allocator.
   Complexity: Makes only N calls to the copy constructor of T (where N is the distance between first and last) and no reallocations if iterators first and last are of forward, bidirectional, or random access categories. It makes order N calls to the copy constructor of T and order log N reallocations if they are just input iterators.

26.3.11.3 vector capacity

§ 26.3.11.3
size_type capacity() const noexcept;

Returns: The total number of elements that the vector can hold without requiring reallocation.

void reserve(size_type n);

Requires: T shall be MoveInsertable into *this.

Effects: A directive that informs a vector of a planned change in size, so that it can manage the storage allocation accordingly. After reserve(), capacity() is greater or equal to the argument of reserve if reallocation happens; and equal to the previous value of capacity() otherwise. Reallocation happens at this point if and only if the current capacity is less than the argument of reserve(). If an exception is thrown other than by the move constructor of a non-CopyInsertable type, there are no effects.

Complexity: It does not change the size of the sequence and takes at most linear time in the size of the sequence.

Throws: length_error if n > max_size().260

Remarks: Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence. No reallocation shall take place during insertions that happen after a call to reserve() until the time when an insertion would make the size of the vector greater than the value of capacity().

void shrink_to_fit();

Requires: T shall be MoveInsertable into *this.

Effects: shrink_to_fit is a non-binding request to reduce capacity() to size(). [Note: The request is non-binding to allow latitude for implementation-specific optimizations. — end note] It does not increase capacity(), but may reduce capacity() by causing reallocation. If an exception is thrown other than by the move constructor of a non-CopyInsertable T there are no effects.

Complexity: Linear in the size of the sequence.

Remarks: Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence as well as the past-the-end iterator. If no reallocation happens, they remain valid.

void swap(vector& x)
noexcept(allocator_traits<Allocator>::propagate_on_container_swap::value ||
    allocator_traits<Allocator>::is_always_equal::value);

Effects: Exchanges the contents and capacity() of *this with that of x.

Complexity: Constant time.

void resize(size_type sz);

Effects: If sz < size(), erases the last size() - sz elements from the sequence. Otherwise, appends sz - size() default-inserted elements to the sequence.

Requires: T shall be MoveInsertable and DefaultInsertable into *this.

Remarks: If an exception is thrown other than by the move constructor of a non-CopyInsertable T there are no effects.

void resize(size_type sz, const T& c);

Effects: If sz < size(), erases the last size() - sz elements from the sequence. Otherwise, appends sz - size() copies of c to the sequence.

Requires: T shall be CopyInsertable into *this.

Remarks: If an exception is thrown there are no effects.

260) reserve() uses Allocator::allocate() which may throw an appropriate exception.
26.3.11.4 vector data

T* data() noexcept;
const T* data() const noexcept;

1 Returns: A pointer such that [data(), data() + size()) is a valid range. For a non-empty vector, data() == addressof(front()).

2 Complexity: Constant time.

26.3.11.5 vector modifiers

iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);
template <class InputIterator>
iterator insert(const_iterator position, InputIterator first, InputIterator last);
iterator insert(const_iterator position, initializer_list<T>);
template <class... Args> reference emplace_back(Args&&... args);
template <class... Args> iterator emplace(const_iterator position, Args&&... args);
void push_back(const T& x);
void push_back(T&& x);

1 Remarks: Causes reallocation if the new size is greater than the old capacity. Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence. If no reallocation happens, all the iterators and references before the insertion point remain valid. If an exception is thrown other than by the copy constructor, move constructor, assignment operator, or move assignment operator of T or by any InputIterator operation there are no effects. If an exception is thrown while inserting a single element at the end and T is CopyInsertable or isnothrow_move_constructible_v<T> is true, there are no effects. Otherwise, if an exception is thrown by the move constructor of a non-CopyInsertable T, the effects are unspecified.

2 Complexity: The complexity is linear in the number of elements inserted plus the distance to the end of the vector.

iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);
void pop_back();

3 Effects: Invalidates iterators and references at or after the point of the erase.

4 Complexity: The destructor of T is called the number of times equal to the number of the elements erased, but the assignment operator of T is called the number of times equal to the number of elements in the vector after the erased elements.

5 Throws: Nothing unless an exception is thrown by the assignment operator or move assignment operator of T.

26.3.11.6 vector specialized algorithms

template <class T, class Allocator>
void swap(vector<T, Allocator>& x, vector<T, Allocator>& y)
    noexcept(noexcept(x.swap(y)));

1 Effects: As if by x.swap(y).

26.3.12 Class vector<bool>

To optimize space allocation, a specialization of vector for bool elements is provided:
namespace std {
    template <class Allocator>
    class vector<bool, Allocator> {
public:
    // types:
    using value_type = bool;
    using allocator_type = Allocator;
    using pointer = implementation-defined;
    using const_pointer = implementation-defined;
    using const_reference = bool;
    using size_type = implementation-defined; // see 26.2
    using difference_type = implementation-defined; // see 26.2
    using iterator = implementation-defined; // see 26.2
    using const_iterator = implementation-defined; // see 26.2
    using reverse_iterator = std::reverse_iterator<iterator>;
    using const_reverse_iterator = std::reverse_iterator<const_iterator>;

    // bit reference:
    class reference {
    friend class vector;
    reference() noexcept;
    public:
        -reference();
        operator bool() const noexcept;
        reference& operator=(const bool x) noexcept;
        reference& operator=(const reference& x) noexcept;
        void flip() noexcept;  // flips the bit
    };

    // construct/copy/destroy:
    vector() : vector(Allocator()) { }
    explicit vector(const Allocator&);
    explicit vector(size_type n, const Allocator& = Allocator());
    vector(size_type n, const bool& value,
            const Allocator& = Allocator());
    template <class InputIterator>
        vector(InputIterator first, InputIterator last,
                const Allocator& = Allocator());
    vector(const vector<bool, Allocator>& x);
    vector(vector<bool, Allocator>&& x);
    vector(const vector&, const Allocator&);
    vector(vector&&, const Allocator&);
    vector(initializer_list<bool>, const Allocator& = Allocator());
    ~vector();
    vector<bool, Allocator>& operator=(const vector<bool, Allocator>& x);
    vector<bool, Allocator>& operator=(vector<bool, Allocator>&& x);
    vector& operator=(initializer_list<bool>);
    template <class InputIterator>
        void assign(InputIterator first, InputIterator last);
    void assign(size_type n, const bool& t);
    void assign(initializer_list<bool>);
    allocator_type get_allocator() const noexcept;

    // iterators:
    iterator begin() const noexcept;
};
const_iterator begin() const noexcept;
iterator end() noexcept;
const_iterator end() const noexcept;
reverse_iterator rbegin() noexcept;
const_reverse_iterator rbegin() const noexcept;
reverse_iterator rend() noexcept;
const_reverse_iterator rend() const noexcept;

const_iterator cbegin() const noexcept;
const_iterator cend() const noexcept;
const_reverse_iterator crbegin() const noexcept;
const_reverse_iterator crend() const noexcept;

// capacity:
bool empty() const noexcept;
size_type size() const noexcept;
size_type max_size() const noexcept;
size_type capacity() const noexcept;
void resize(size_type sz, bool c = false);
void reserve(size_type n);
void shrink_to_fit();

// element access:
reference operator[](size_type n);
const_reference operator[](size_type n) const;
const_reference at(size_type n) const;
reference at(size_type n);
reference front();
const_reference front() const;
reference back();
const_reference back() const;

// modifiers:
template <class... Args> reference emplace_back(Args&&... args);
void push_back(const bool& x);
void pop_back();
template <class... Args> iterator emplace(const_iterator position, Args&&... args);
iterator insert(const_iterator position, const bool& x);
iterator insert(const_iterator position, size_type n, const bool& x);
template <class InputIterator>
    iterator insert(const_iterator position, InputIterator first, InputIterator last);
iterator insert(const_iterator position, initializer_list<bool> il);
iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);
void swap(vector<bool, Allocator>&);
static void swap(reference x, reference y) noexcept;
void flip() noexcept; // flips all bits
void clear() noexcept;
};

2 Unless described below, all operations have the same requirements and semantics as the primary vector template, except that operations dealing with the bool value type map to bit values in the container storage
and allocator_traits::construct (23.10.8.2) is not used to construct these values.
3 There is no requirement that the data be stored as a contiguous allocation of bool values. A space-optimized representation of bits is recommended instead.
4 reference is a class that simulates the behavior of references of a single bit in vector<bool>. The conversion function returns true when the bit is set, and false otherwise. The assignment operator sets the bit when the argument is (convertible to) true and clears it otherwise. flip reverses the state of the bit.

```cpp
void flip() noexcept;
```

Effects: Replaces each element in the container with its complement.

```cpp
static void swap(reference x, reference y) noexcept;
```

Effects: Exchanges the contents of x and y as if by:

```cpp
bool b = x;
x = y;
y = b;
```

template <class Allocator> struct hash<vector<bool, Allocator>>;

The specialization is enabled (23.14.15).

26.4 Associative containers

26.4.1 In general

1 The header <map> defines the class templates map and multimap; the header <set> defines the class templates set and multiset.

2 The following exposition-only alias templates may appear in deduction guides for associative containers:

```cpp
template<class InputIterator>
using iter_key_t = remove_const_t<typename iterator_traits<InputIterator>::value_type::first_type>; // exposition only

template<class InputIterator>
using iter_val_t = typename iterator_traits<InputIterator>::value_type::second_type; // exposition only

template<class InputIterator>
using iter_to_alloc_t = pair<add_const_t<typename iterator_traits<InputIterator>::value_type::first_type>,
   typename iterator_traits<InputIterator>::value_type::second_type>; // exposition only
```

26.4.2 Header <map> synopsis

```cpp
#include <initializer_list>
namespace std {
   // 26.4.4, class template map
   template <class Key, class T, class Compare = less<Key>,
   class Allocator = allocator<pair<const Key, T>>>
      class map;
   template <class Key, class T, class Compare, class Allocator>
      bool operator==(const map<Key, T, Compare, Allocator>& x,
         const map<Key, T, Compare, Allocator>& y);
   template <class Key, class T, class Compare, class Allocator>
      bool operator<(const map<Key, T, Compare, Allocator>& x,
         const map<Key, T, Compare, Allocator>& y);
   template <class Key, class T, class Compare, class Allocator>
      bool operator!=(const map<Key, T, Compare, Allocator>& x,
         const map<Key, T, Compare, Allocator>& y);
```
const map<Key, T, Compare, Allocator>& y);
template <class Key, class T, class Compare, class Allocator>
bool operator>=(const map<Key, T, Compare, Allocator>& x,
const map<Key, T, Compare, Allocator>& y);
template <class Key, class T, class Compare, class Allocator>
bool operator<=(const map<Key, T, Compare, Allocator>& x,
const map<Key, T, Compare, Allocator>& y);
template <class Key, class T, class Compare, class Allocator>
void swap(map<Key, T, Compare, Allocator>& x,
map<Key, T, Compare, Allocator>& y)
noexcept(noexcept(x.swap(y)));

// 26.4.5, class template multimap
template <class Key, class T, class Compare = less<Key>,
class Allocator = allocator<pair<const Key, T>>>
class multimap;
template <class Key, class T, class Compare, class Allocator>
bool operator==(const multimap<Key, T, Compare, Allocator>& x,
const multimap<Key, T, Compare, Allocator>& y);
template <class Key, class T, class Compare, class Allocator>
bool operator< (const multimap<Key, T, Compare, Allocator>& x,
const multimap<Key, T, Compare, Allocator>& y);
template <class Key, class T, class Compare, class Allocator>
bool operator!=(const multimap<Key, T, Compare, Allocator>& x,
const multimap<Key, T, Compare, Allocator>& y);
template <class Key, class T, class Compare, class Allocator>
bool operator> (const multimap<Key, T, Compare, Allocator>& x,
const multimap<Key, T, Compare, Allocator>& y);
template <class Key, class T, class Compare, class Allocator>
bool operator>=(const multimap<Key, T, Compare, Allocator>& x,
const multimap<Key, T, Compare, Allocator>& y);
template <class Key, class T, class Compare, class Allocator>
bool operator<=(const multimap<Key, T, Compare, Allocator>& x,
const multimap<Key, T, Compare, Allocator>& y);
template <class Key, class T, class Compare, class Allocator>
void swap(multimap<Key, T, Compare, Allocator>& x,
multimap<Key, T, Compare, Allocator>& y)
noexcept(noexcept(x.swap(y)));

namespace pmr {
  template <class Key, class T, class Compare = less<Key>>
  using map = std::map<Key, T, Compare,
polymorphic_allocator<pair<const Key, T>>>;

  template <class Key, class T, class Compare = less<Key>>
  using multimap = std::multimap<Key, T, Compare,
polymorphic_allocator<pair<const Key, T>>>;
}

26.4.3 Header <set> synopsis

#include <initializer_list>
namespace std {
  // 26.4.6, class template set
  template <class Key, class Compare = less<Key>,
            class Allocator = allocator<Key>>
    class set;
  template <class Key, class Compare, class Allocator>
    bool operator==(const set<Key, Compare, Allocator>& x,
                    const set<Key, Compare, Allocator>& y);

26.4.4 Class template map

26.4.4.1 Class template map overview

A map is an associative container that supports unique keys (contains at most one of each key value) and provides for fast retrieval of values of another type T based on the keys. The map class supports bidirectional iterators.

A map satisfies all of the requirements of a container, of a reversible container (26.2), of an associative container (26.2.6), and of an allocator-aware container (Table 86). A map also provides most operations described in 26.2.6 for unique keys. This means that a map supports the a_uniq operations in 26.2.6 but not the a_eq operations. For a map<Key,T> the key_type is Key and the value_type is pair<const Key, T>.

Descriptions are provided here only for operations on map that are not described in one of those tables or for operations where there is additional semantic information.

namespace std {
    template <class Key, class T, class Compare = less<Key>,
              class Allocator = allocator<pair<const Key, T>>>
    class map {

}

26.4.4.2 map constructors, copy, and assignment

explicit map(const Compare& comp, const Allocator& = Allocator());
  
    Effects: Constructs an empty map using the specified comparison object and allocator.

    Complexity: Constant.

template <class InputIterator>
map(InputIterator first, InputIterator last,
    const Compare& comp = Compare(), const Allocator& = Allocator());

    Effects: Constructs an empty map using the specified comparison object and allocator, and inserts elements from the range [first, last).

    Complexity: Linear in N if the range [first, last) is already sorted using comp and otherwise N log N, where N is last - first.

26.4.4.3 map element access

T& operator[](const key_type& x);
  
    Effects: Equivalent to: return try_emplace(x).first->second;

T& operator[](key_type&& x);

    Effects: Equivalent to: return try_emplace(move(x)).first->second;

T& at(const key_type& x);
const T& at(const key_type& x) const;

    Returns: A reference to the mapped_type corresponding to x in *this.

    Throws: An exception object of type out_of_range if no such element is present.

    Complexity: Logarithmic.

26.4.4.4 map modifiers

§ 26.4.4.4
template <class P>
type insert(P& x);

Effects: The first form is equivalent to return emplace(std::forward<P>(x)). The second form is equivalent to return emplace_hint(position, std::forward<P>(x)).

Remarks: These signatures shall not participate in overload resolution unless is_constructible_<P, P&&> is true.

template <class... Args>
pair<iterator, bool> try_emplace(const key_type& k, Args&&... args);

Requires: value_type shall be EmplaceConstructible into map from piecewise_construct, forward_as_tuple(k), forward_as_tuple(std::forward<Args>(args)...).

Effects: If the map already contains an element whose key is equivalent to k, there is no effect. Otherwise inserts an object of type value_type constructed with piecewise_construct, forward_as_tuple(k), forward_as_tuple(std::forward<Args>(args)...).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

template <class... Args>
iterator try_emplace(const key_type& k, Args&&... args);

Requires: value_type shall be EmplaceConstructible into map from piecewise_construct, forward_as_tuple(std::move(k)), forward_as_tuple(std::forward<Args>(args)...).

Effects: If the map already contains an element whose key is equivalent to k, there is no effect. Otherwise inserts an object of type value_type constructed with piecewise_construct, forward_as_tuple(std::move(k)), forward_as_tuple(std::forward<Args>(args)...).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

template <class M>
pair<iterator, bool> insert_or_assign(const key_type& k, M& obj);

Requires: is_assignable_v<mapped_type&, M&> shall be true. value_type shall be EmplaceConstructible into map from k, forward<M>(obj).

Effects: If the map already contains an element e whose key is equivalent to k, assigns std::forward<M>(obj) to e.second. Otherwise inserts an object of type value_type constructed with k, std::forward<M>(obj).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.
template <class M>
pair<iterator, bool> insert_or_assign(key_type&& k, M&& obj);
template <class M>
iterator insert_or_assign(const_iterator hint, key_type&& k, M&& obj);

Requires: is_assignable_v<mapped_type&, M&&> shall be true. value_type shall be Emplace-Constructible into map from move(k), forward<M>(obj).

Effects: If the map already contains an element e whose key is equivalent to k, assigns std::forward<M>(obj) to e.second. Otherwise inserts an object of type value_type constructed with std::move(k), std::forward<M>(obj).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

26.4.4.5  map specialized algorithms

template <class Key, class T, class Compare, class Allocator>
void swap(map<Key, T, Compare, Allocator>& x,
          map<Key, T, Compare, Allocator>& y)
noexcept(noexcept(x.swap(y)));

Effects: As if by x.swap(y).

26.4.5  Class template multimap

26.4.5.1  Class template multimap overview

A multimap is an associative container that supports equivalent keys (possibly containing multiple copies of the same key value) and provides for fast retrieval of values of another type T based on the keys. The multimap class supports bidirectional iterators.

A multimap satisfies all of the requirements of a container and of a reversible container (26.2), of an associative container (26.2.6), and of an allocator-aware container (Table 86). A multimap also provides most operations described in 26.2.6 for equal keys. This means that a multimap supports the a_eq operations in 26.2.6 but not the a_uniq operations. For a multimap<Key,T> the key_type is Key and the value_type is pair<const Key, T>. Descriptions are provided here only for operations on multimap that are not described in one of those tables or for operations where there is additional semantic information.

template <class Key, class T, class Compare, class Allocator>
bool operator<=(const multimap<Key, T, Compare, Allocator>& x, const multimap<Key, T, Compare, Allocator>& y);

template <class Key, class T, class Compare, class Allocator>
bool operator>(const multimap<Key, T, Compare, Allocator>& x, const multimap<Key, T, Compare, Allocator>& y);

template <class Key, class T, class Compare, class Allocator>
bool operator>=(const multimap<Key, T, Compare, Allocator>& x, const multimap<Key, T, Compare, Allocator>& y);
template <class Key, class T, class Compare, class Allocator>
  bool operator<=(const multimap<Key, T, Compare, Allocator>& x,
                  const multimap<Key, T, Compare, Allocator>& y);

// 26.4.5.4, specialized algorithms
template <class Key, class T, class Compare, class Allocator>
void swap(multimap<Key, T, Compare, Allocator>& x,
          multimap<Key, T, Compare, Allocator>& y)
  noexcept(noexcept(x.swap(y)));
}

26.4.5.2 multimap constructors

explicit multimap(const Compare& comp, const Allocator& = Allocator());
  Effects: Constructs an empty multimap using the specified comparison object and allocator.
  Complexity: Constant.

template <class InputIterator>
  multimap(InputIterator first, InputIterator last,
            const Compare& comp = Compare(),
            const Allocator& = Allocator());
  Effects: Constructs an empty multimap using the specified comparison object and allocator, and inserts
  elements from the range [first, last).
  Complexity: Linear in N if the range [first, last) is already sorted using comp and otherwise
  N log N, where N is last - first.

26.4.5.3 multimap modifiers

template <class P> iterator insert(P&& x);
  Effects: As if by x.swap(y).

template <class P> iterator insert(const_iterator position, P&& x);
  Effects: The first form is equivalent to
  return emplace(std::forward<P>(x)). The second form is
  equivalent to
  return emplace_hint(position, std::forward<P>(x)).
  Remarks: These signatures shall not participate in overload resolution unless
  is_constructible_v<value_type, P&&> is true.

26.4.5.4 multimap specialized algorithms

template <class Key, class T, class Compare, class Allocator>
void swap(multimap<Key, T, Compare, Allocator>& x,
          multimap<Key, T, Compare, Allocator>& y)
  noexcept(noexcept(x.swap(y)));
  Effects: As if by x.swap(y).

26.4.6 Class template set

26.4.6.1 Class template set overview

A set is an associative container that supports unique keys (contains at most one of each key value) and
provides for fast retrieval of the keys themselves. The set class supports bidirectional iterators.

A set satisfies all of the requirements of a container, of a reversible container (26.2), of an associative
container (26.2.6), and of an allocator-aware container (Table 86). A set also provides most operations
described in 26.2.6 for unique keys. This means that a set supports the a_uniq operations in 26.2.6 but
not the a_eq operations. For a set<Key> both the key_type and value_type are Key. Descriptions are
provided here only for operations on `set` that are not described in one of these tables and for operations where there is additional semantic information.

```cpp
namespace std {
  template <class Key, class Compare = less<Key>,
            class Allocator = allocator<Key>>
  class set {
    public:
      // types:
      using key_type = Key;
      using key_compare = Compare;
      using value_type = Key;
      using value_compare = Compare;
      using allocator_type = Allocator;
      using pointer = typename allocator_traits<Allocator>::pointer;
      using const_pointer = typename allocator_traits<Allocator>::const_pointer;
      using reference = value_type&;
      using const_reference = const value_type&;
      using size_type = implementation-defined; // see 26.2
      using difference_type = implementation-defined; // see 26.2
      using iterator = implementation-defined; // see 26.2
      using const_iterator = implementation-defined; // see 26.2
      using reverse_iterator = std::reverse_iterator<iterator>;
      using const_reverse_iterator = std::reverse_iterator<const_iterator>
      using node_type = unspecified;
      using insert_return_type = INSERT_RETURN_TYPE<iterator, node_type>;

      // 26.4.6.2, construct/copy/destroy
      set() : set(Compare()) {}  
      explicit set(const Compare& comp, const Allocator& = Allocator());
      template <class InputIterator>
      set(InputIterator first, InputIterator last,
          const Compare& comp = Compare(), const Allocator& = Allocator());
      set(const set& x);
      set(set&& x);
      explicit set(const Allocator&);
      set(const set&, const Allocator&);
      set(set& const Allocator&);
      set(initializer_list<value_type>, const Compare& = Compare(),
           const Allocator& = Allocator());
      template <class InputIterator>
      set(InputIterator first, InputIterator last, const Allocator& a) :
        set(first, last, Compare(), a) {}

26.4.6.2 set constructors, copy, and assignment

explicit set(const Compare& comp, const Allocator& = Allocator());

Effects: Constructs an empty set using the specified comparison objects and allocator.

Complexity: Constant.

template <class InputIterator>
set(InputIterator first, InputIterator last,
    const Compare& comp = Compare(), const Allocator& = Allocator());

Effects: Constructs an empty set using the specified comparison object and allocator, and inserts elements from the range [first, last).

Complexity: Linear in N if the range [first, last) is already sorted using comp and otherwise N log N, where N is last - first.

26.4.6.3 set specialized algorithms

template <class Key, class Compare, class Allocator>
void swap(set<Key, Compare, Allocator>& x,
    set<Key, Compare, Allocator>& y)
    noexcept(noexcept(x.swap(y)));

Effects: As if by x.swap(y).

26.4.7 Class template multiset

26.4.7.1 Class template multiset overview

A multiset is an associative container that supports equivalent keys (possibly contains multiple copies of the same key value) and provides for fast retrieval of the keys themselves. The multiset class supports bidirectional iterators.

A multiset satisfies all of the requirements of a container, of a reversible container (26.2), of an associative container (26.2.6), and of an allocator-aware container (Table 86). multiset also provides most operations described in 26.2.6 for duplicate keys. This means that a multiset supports the a_eq operations in 26.2.6 but not the a_uniq operations. For a multiset<Key> both the key_type and value_type are Key. Descriptions are provided here only for operations on multiset that are not described in one of these tables and for operations where there is additional semantic information.

26.4.7.2 multiset constructors

explicit multiset(const Compare& comp, const Allocator& = Allocator());

1 Effects: Constructs an empty multiset using the specified comparison object and allocator.

2 Complexity: Constant.

template <class InputIterator>
multiset(InputIterator first, InputIterator last,
      const Compare& comp = Compare(), const Allocator& = Allocator());

3 Effects: Constructs an empty multiset using the specified comparison object and allocator, and inserts elements from the range [first, last).

4 Complexity: Linear in N if the range [first, last) is already sorted using comp and otherwise NlogN, where N is last - first.

26.4.7.3 multiset specialized algorithms

template <class Key, class Compare, class Allocator>
void swap(multiset<Key, Compare, Allocator>& x,
      multiset<Key, Compare, Allocator>& y)
      noexcept(noexcept(x.swap(y)));

1 Effects: As if by x.swap(y).

26.5 Unordered associative containers

26.5.1 In general

1 The header <unordered_map> defines the class templates unordered_map and unordered_multimap; the header <unordered_set> defines the class templates unordered_set and unordered_multiset.

2 The exposition-only alias templates iter_key_t, iter_val_t, and iter_to_alloc_t defined in 26.4.1 may appear in deduction guides for unordered containers.

26.5.2 Header <unordered_map> synopsis

#include <unordered_map>

namespace std {

    // 26.5.4, class template unordered_map
    template <class Key,
             class T,
             class Hash = hash<Key>,
             class Eq = equal_to<Key> = equal_to<T> = equal_to<Hash>,
             class Ne = not_equal_to<Key> = not_equal_to<T> = not_equal_to<Hash>,
             class Le = less<Key> = less<T> = less<Hash>,
             class Ge = greater<Key> = greater<T> = greater<Hash>,
             class Alloc = Allocator>
```cpp
class Pred = equal_to<Key>,
class Alloc = allocator<pair<const Key, T>>>
class unordered_map;

// 26.5.5, class template unordered_multimap
template <class Key,
class T,
class Hash = hash<Key>,
class Pred = equal_to<Key>,
class Alloc = allocator<pair<const Key, T>>>
class unordered_multimap;

template <class Key, class T, class Hash, class Pred, class Alloc>

    }
}

§ 26.5.3

923
26.5.4 Class template unordered_map  

26.5.4.1 Class template unordered_map overview

1 An unordered_map is an unordered associative container that supports unique keys (an unordered_map contains at most one of each key value) and that associates values of another type mapped_type with the keys. The unordered_map class supports forward iterators.

2 An unordered_map satisfies all of the requirements of a container, of an unordered associative container, and of an allocator-aware container (Table 86). It provides the operations described in the preceding requirements table for unique keys; that is, an unordered_map supports the a_uniq operations in that table, not the a_eq operations. For an unordered_map<Key, T> the key type is Key, the mapped type is T, and the value type is pair<const Key, T>.

3 This section only describes operations on unordered_map that are not described in one of the requirement tables, or for which there is additional semantic information.

```cpp
namespace std {
    template <class Key,
             class T,
             class Hash = hash<Key>,
             class Pred = equal_to<Key>,
             class Allocator = allocator<pair<const Key, T>>>
    class unordered_map {
        public:
            // types:
            using key_type = Key;
            using mapped_type = T;
            using value_type = pair<const Key, T>;
            using hasher = Hash;
            using key_equal = Pred;
            using allocator_type = Allocator;
            using pointer = typename allocator_traits<Allocator>::pointer;
            using const_pointer = typename allocator_traits<Allocator>::const_pointer;
            using reference = value_type&;
            using const_reference = const value_type&;
            using size_type = implementation-defined; // see 26.2
            using difference_type = implementation-defined; // see 26.2
            using iterator = implementation-defined; // see 26.2
            using const_iterator = implementation-defined; // see 26.2
            using local_iterator = implementation-defined; // see 26.2
            using const_local_iterator = implementation-defined; // see 26.2
            using node_type = unspecified;
            using insert_return_type = INSERT_RETURN_TYPE<iterator, node_type>;

            // 26.5.4.2, construct/copy/destroy
            unordered_map();
            explicit unordered_map(size_type n,
                                    const hasher& hf = hasher(),
                                    const key_equal& eql = key_equal(),
                                    const allocator_type& a = allocator_type());

            template <class InputIterator>
            unordered_map(InputIterator f, InputIterator l,
                           size_type n = see below,
                           const hasher& hf = hasher(),
                           const key_equal& eql = key_equal(),
```

§ 26.5.4.1
const allocator_type& a = allocator_type();
unordered_map(const unordered_map&);
unordered_map(unordered_map&);

};

template<class InputIterator,
    class Hash = hash<iter_key_t<InputIterator>>,
    class Pred = equal_to<iter_key_t<InputIterator>>,
    class Allocator = allocator<iter_to_alloc_t<InputIterator>>>
unordered_map<InputIterator, InputIterator, typename see below::size_type = see below, 
    Hash = Hash(), Pred = Pred(), Allocator = Allocator())
    -> unordered_map<iter_key_t<InputIterator>, iter_value_t<InputIterator>, Hash, Pred, 
    Allocator>;

template<class Key, class T, class Hash = hash<Key>,
    class Pred = equal_to<Key>, class Allocator = allocator<pair<const Key, T>>>
unordered_map(initializer_list<pair<const Key, T>>, typename see below::size_type = see below, 
    Hash = Hash(), Pred = Pred(), Allocator = Allocator())
    -> unordered_map<Key, T, Hash, Pred, Allocator>;

template<class InputIterator, class Allocator>
unordered_map<InputIterator, InputIterator, typename see below::size_type, Allocator)
    -> unordered_map<iter_key_t<InputIterator>, iter_val_t<InputIterator>, 
    hash<iter_key_t<InputIterator>>, equal_to<iter_key_t<InputIterator>>, 
    Allocator>;

template<class InputIterator, class Allocator>
unordered_map<InputIterator, InputIterator, Allocator)
    -> unordered_map<iter_key_t<InputIterator>, iter_val_t<InputIterator>, 
    hash<iter_key_t<InputIterator>>, equal_to<iter_key_t<InputIterator>>>,
Allocator>;

```cpp
template<class InputIterator, class Hash, class Allocator>
unordered_map(InputIterator, InputIterator, typename see below::size_type, Hash, Allocator)
-> unordered_map<iter_key_t<InputIterator>, iter_val_t<InputIterator>, Hash,
equal_to<iter_key_t<InputIterator>>, Allocator>;
```

```cpp
template<class Key, class T, typename Allocator>
unordered_map(initializer_list<pair<const Key, T>>, typename see below::size_type,
Allocator)
-> unordered_map<Key, T, Hash, equal_to<Key>, Allocator>;
```

```cpp
template<class Key, class T, class Hash, class Allocator>
unordered_map(initializer_list<pair<const Key, T>>, typename see below::size_type, Hash,
Allocator)
-> unordered_map<Key, T, Hash, equal_to<Key>, Allocator>;
```

```cpp
template<class Key, class T, class Hash, class Pred, class Alloc>
bool operator==(const unordered_map<Key, T, Hash, Pred, Alloc>& a,
const unordered_map<Key, T, Hash, Pred, Alloc>& b);
```

```cpp
template <class Key, class T, class Hash, class Pred, class Alloc>
void swap(unordered_map<Key, T, Hash, Pred, Alloc>& x,
unordered_map<Key, T, Hash, Pred, Alloc>& y)
noexcept(noexcept(x.swap(y)));}
```

A `size_type` parameter type in an `unordered_map` deduction guide refers to the `size_type` member type of the type deduced by the deduction guide.

### 26.5.4.2 unordered_map constructors

```cpp
unordered_map() : unordered_map(size_type(see below)) { }
explicit unordered_map(size_type n,
                       const hasher& hf = hasher(),
                       const key_equal& eql = key_equal(),
                       const allocator_type& a = allocator_type());
```

1. **Effects:** Constructs an empty `unordered_map` using the specified hash function, key equality predicate, and allocator, and using at least `n` buckets. For the default constructor, the number of buckets is implementation-defined. `max_load_factor()` returns 1.0.

2. **Complexity:** Constant.
const allocator_type& a = allocator_type());
unordered_map(initializer_list<value_type> il,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());

Effects: Constructs an empty unordered_map using the specified hash function, key equality predicate, and allocator, and using at least n buckets. If n is not provided, the number of buckets is implementation-defined. Then inserts elements from the range \([f, 1)\) for the first form, or from the range \([il.begin(), il.end())\) for the second form. max_load_factor() returns 1.0.

Complexity: Average case linear, worst case quadratic.

26.5.4.3 unordered_map element access

mapped_type& operator[](const key_type& k);
Effects: Equivalent to: return try_emplace(k).first->second;

mapped_type& operator[](key_type&& k);
Effects: Equivalent to: return try_emplace(move(k)).first->second;

mapped_type& at(const key_type& k);
const mapped_type& at(const key_type& k) const;
Returns: A reference to x.second, where x is the (unique) element whose key is equivalent to k.
Throws: An exception object of type out_of_range if no such element is present.

26.5.4.4 unordered_map modifiers

template <class P>
pair<iterator, bool> insert(P&& obj);
Effects: Equivalent to: return emplace(std::forward<P>(obj));
Remarks: This signature shall not participate in overload resolution unless is_constructible_v<value_type, P&&> is true.

template <class P>
iterator insert(const_iterator hint, P&& obj);
Effects: Equivalent to: return emplace_hint(hint, std::forward<P>(obj));
Remarks: This signature shall not participate in overload resolution unless is_constructible_v<value_type, P&&> is true.

template <class... Args>
pair<iterator, bool> try_emplace(const key_type& k, Args&&... args);

template <class... Args>
iterator try_emplace(const_iterator hint, const key_type& k, Args&&... args);
Requires: value_type shall be EmplaceConstructible into unordered_map from piecewise_construct, forward_as_tuple(k), forward_as_tuple(std::forward<Args>(args)...).
Effects: If the map already contains an element whose key is equivalent to k, there is no effect. Otherwise inserts an object of type value_type constructed with piecewise_construct, forward_as_tuple(k), forward_as_tuple(std::forward<Args>(args)...).
Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

§ 26.5.4.4
Complexity: The same as emplace and emplace_hint, respectively.

```cpp
template <class... Args>
pair<iterator, bool> try_emplace(key_type&& k, Args&&... args);
template <class... Args>
iterator try_emplace(const_iterator hint, key_type&& k, Args&&... args);
```

Requires: value_type shall be EmplaceConstructible into unordered_map from piecewise_construct, forward_as_tuple(std::move(k)), forward_as_tuple(std::forward<Args>(args)...).

Effects: If the map already contains an element whose key is equivalent to k, there is no effect. Otherwise inserts an object of type value_type constructed with piecewise_construct, forward_as_tuple(std::move(k)), forward_as_tuple(std::forward<Args>(args)...).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

```cpp
template <class M>
pair<iterator, bool> insert_or_assign(const key_type& k, M&& obj);
template <class M>
iterator insert_or_assign(const_iterator hint, const key_type& k, M&& obj);
```

Requires: is_assignable_v<mapped_type&, M&&> shall be true. value_type shall be EmplaceConstructible into unordered_map from std::forward<M>(obj).

Effects: If the map already contains an element e whose key is equivalent to k, assigns std::forward<M>(obj) to e.second. Otherwise inserts an object of type value_type constructed with k, std::forward<M>(obj).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

```cpp
template <class M>
pair<iterator, bool> insert_or_assign(key_type&& k, M&& obj);
template <class M>
iterator insert_or_assign(const_iterator hint, key_type&& k, M&& obj);
```

Requires: is_assignable_v<mapped_type&, M&&> shall be true. value_type shall be EmplaceConstructible into unordered_map from std::move(k), std::forward<M>(obj).

Effects: If the map already contains an element e whose key is equivalent to k, assigns std::forward<M>(obj) to e.second. Otherwise inserts an object of type value_type constructed with std::move(k), std::forward<M>(obj).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

### 26.5.4.5 unordered_map swap

```cpp
template <class Key, class T, class Hash, class Pred, class Alloc>
void swap(unordered_map<Key, T, Hash, Pred, Alloc>& x,
           unordered_map<Key, T, Hash, Pred, Alloc>& y)
    noexcept(noexcept(x.swap(y)));
```

Effects: As if by x.swap(y).

§ 26.5.4.5
26.5.5 Class template unordered_multimap

26.5.5.1 Class template unordered_multimap overview

1 An unordered_multimap is an unordered associative container that supports equivalent keys (an instance of unordered_multimap may contain multiple copies of each key value) and that associates values of another type mapped_type with the keys. The unordered_multimap class supports forward iterators.

2 An unordered_multimap satisfies all of the requirements of a container, of an unordered associative container, and of an allocator-aware container (Table 86). It provides the operations described in the preceding requirements table for equivalent keys; that is, an unordered_multimap supports the a_eq operations in that table, not the a_uniq operations. For an unordered_multimap<Key, T> the key type is Key, the mapped type is T, and the value type is pair<const Key, T>.

3 This section only describes operations on unordered_multimap that are not described in one of the requirement tables, or for which there is additional semantic information.

```cpp
namespace std {
    template <class Key,
             class T,
             class Hash = hash<Key>,
             class Pred = equal_to<Key>,
             class Allocator = allocator<pair<const Key, T>>>
    class unordered_multimap {
    public:
        // types:
        using key_type = Key;
        using mapped_type = T;
        using value_type = pair<const Key, T>;
        using hasher = Hash;
        using key_equal = Pred;
        using allocator_type = Allocator;
        using pointer = typename allocator_traits<Allocator>::pointer;
        using const_pointer = typename allocator_traits<Allocator>::const_pointer;
        using reference = value_type&;
        using const_reference = const value_type&;
        using size_type = implementation-defined; // see 26.2
        using difference_type = implementation-defined; // see 26.2

        // 26.5.5.2, construct/copy/destroy
        unordered_multimap();
        explicit unordered_multimap(size_type n,
                                      const hasher& hf = hasher(),
                                      const key_equal& eql = key_equal(),
                                      const allocator_type& a = allocator_type());

        template <class InputIterator>
        unordered_multimap(InputIterator f, InputIterator l,
                            size_type n = see below,
                            const hasher& hf = hasher(),

template <class Key, class T, class Hash, class Pred, class Alloc>
bool operator!=(const unordered_multimap<Key, T, Hash, Pred, Alloc>& a, const unordered_multimap<Key, T, Hash, Pred, Alloc>& b);

// 26.5.5.4, swap
template <class Key, class T, class Hash, class Pred, class Alloc>
void swap(unordered_multimap<Key, T, Hash, Pred, Alloc>& x,
          unordered_multimap<Key, T, Hash, Pred, Alloc>& y)
noexcept(noexcept(x.swap(y)));

A size_type parameter type in an unordered_multimap deduction guide refers to the size_type member type of the type deduced by the deduction guide.

### 26.5.5.2 unordered_multimap constructors

**unordered_multimap()** : unordered_multimap(size_type(see below)) { }

explicit unordered_multimap(size_type n,
 const hasher& hf = hasher(),
 const key_equal& eql = key_equal(),
 const allocator_type& a = allocator_type());

**Effects:** Constructs an empty unordered_multimap using the specified hash function, key equality predicate, and allocator, and using at least n buckets. For the default constructor, the number of buckets is implementation-defined. max_load_factor() returns 1.0.

**Complexity:** Constant.

**unordered_multimap(InputIterator f, InputIterator l,**
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());

**unordered_multimap(initializer_list<value_type> il,**
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());

**Effects:** Constructs an empty unordered_multimap using the specified hash function, key equality predicate, and allocator, and using at least n buckets. If n is not provided, the number of buckets is implementation-defined. Then inserts elements from the range [f, l) for the first form, or from the range [il.begin(), il.end()) for the second form. max_load_factor() returns 1.0.

**Complexity:** Average case linear, worst case quadratic.

### 26.5.5.3 unordered_multimap modifiers

**template <class P>
iterator insert(P&& obj);**

**Effects:** Equivalent to: return emplace(std::forward<P>(obj));

**Remarks:** This signature shall not participate in overload resolution unless is_constructible_v<value_type, P&&> is true.
template <class P>
    iterator insert(const_iterator hint, P&& obj);

Effects: Equivalent to: return emplace_hint(hint, std::forward<P>(obj));

Remarks: This signature shall not participate in overload resolution unless is_constructible_v<value_type, P&&> is true.

26.5.5.4 unordered_multimap swap

```cpp
template <class Key, class T, class Hash, class Pred, class Alloc>
void swap(unordered_multimap<Key, T, Hash, Pred, Alloc>& x,
          unordered_multimap<Key, T, Hash, Pred, Alloc>& y)
    noexcept(noexcept(x.swap(y)));
```

Effects: As if by x.swap(y).

26.5.6 Class template unordered_set

26.5.6.1 Class template unordered_set overview

An unordered_set is an unordered associative container that supports unique keys (an unordered_set contains at most one of each key value) and in which the elements’ keys are the elements themselves. The unordered_set class supports forward iterators.

An unordered_set satisfies all of the requirements of a container, of an unordered associative container, and of an allocator-aware container (Table 86). It provides the operations described in the preceding requirements table for unique keys; that is, an unordered_set supports the a_uniq operations in that table, not the a_eq operations. For an unordered_set<Key> the key type and the value type are both Key. The iterator and const_iterator types are both constant iterator types. It is unspecified whether they are the same type.

This section only describes operations on unordered_set that are not described in one of the requirement tables, or for which there is additional semantic information.

```cpp
namespace std {
    template <class Key,
              class Hash = hash<Key>,
              class Pred = equal_to<Key>,
              class Allocator = allocator<Key>>
    class unordered_set {
        public:
            // types:
            using key_type = Key;
            using value_type = Key;
            using hasher = Hash;
            using key_equal = Pred;
            using allocator_type = Allocator;
            using pointer = typename allocator_traits<Allocator>::pointer;
            using const_pointer = typename allocator_traits<Allocator>::const_pointer;
            using reference = value_type&;
            using const_reference = const value_type&;
            using size_type = implementation-defined; // see 26.2
            using difference_type = implementation-defined; // see 26.2

            using iterator = implementation-defined; // see 26.2
            using const_iterator = implementation-defined; // see 26.2
            using local_iterator = implementation-defined; // see 26.2
            using const_local_iterator = implementation-defined; // see 26.2
            using node_type = unspecified;

    } // class unordered_set
}
```

template <class Key, class Hash, class Pred, class Alloc>
bool operator!=(const unordered_set<Key, Hash, Pred, Alloc>& a, const unordered_set<Key, Hash, Pred, Alloc>& b);

// 26.5.6.3, swap
template <class Key, class Hash, class Pred, class Alloc>
void swap(unordered_set<Key, Hash, Pred, Alloc>& x, unordered_set<Key, Hash, Pred, Alloc>& y)
    noexcept(noexcept(x.swap(y)));
}

4 A size_type parameter type in an unordered_set deduction guide refers to the size_type member type of the primary unordered_set template.

26.5.6.2 unordered_set constructors

unordered_set() : unordered_set(size_type(see below)) {} 
explicit unordered_set(size_type n, 
    const hasher& hf = hasher(),
    const key_equal& eql = key_equal(),
    const allocator_type& a = allocator_type());

1 Effects: Constructs an empty unordered_set using the specified hash function, key equality predicate, and allocator, and using at least n buckets. For the default constructor, the number of buckets is implementation-defined. max_load_factor() returns 1.0.

Complexity: Constant.

template <class InputIterator>
unordered_set(InputIterator f, InputIterator l, 
    size_type n = see below, 
    const hasher& hf = hasher(),
    const key_equal& eql = key_equal(),
    const allocator_type& a = allocator_type());

unordered_set(initializer_list<value_type> il, 
    size_type n = see below, 
    const hasher& hf = hasher(),
    const key_equal& eql = key_equal(),
    const allocator_type& a = allocator_type());

3 Effects: Constructs an empty unordered_set using the specified hash function, key equality predicate, and allocator, and using at least n buckets. If n is not provided, the number of buckets is implementation-defined. Then inserts elements from the range [f, l) for the first form, or from the range [il.begin(), il.end()) for the second form. max_load_factor() returns 1.0.

Complexity: Average case linear, worst case quadratic.

26.5.6.3 unordered_set swap

template <class Key, class Hash, class Pred, class Alloc>
void swap(unordered_set<Key, Hash, Pred, Alloc>& x, unordered_set<Key, Hash, Pred, Alloc>& y)
    noexcept(noexcept(x.swap(y)));

1 Effects: As if by x.swap(y).

§ 26.5.6.3
```
26.5.7 Class template unordered_multiset

26.5.7.1 Class template unordered_multiset overview

1 An unordered_multiset is an unordered associative container that supports equivalent keys (an instance of unordered_multiset may contain multiple copies of the same key value) and in which each element’s key is the element itself. The unordered_multiset class supports forward iterators.

2 An unordered_multiset satisfies all of the requirements of a container, of an unordered associative container, and of an allocator-aware container (Table 86). It provides the operations described in the preceding requirements table for equivalent keys; that is, an unordered_multiset supports the a_eq operations in that table, not the a_uniq operations. For an unordered_multiset<Key> the key type and the value type are both Key. The iterator and const_iterator types are both constant iterator types. It is unspecified whether they are the same type.

3 This section only describes operations on unordered_multiset that are not described in one of the requirement tables, or for which there is additional semantic information.

// bucket interface:
size_type bucket_count() const noexcept;
size_type max_bucket_count() const noexcept;
size_type bucket_size(size_type n) const;
size_type bucket(const key_type& k) const;
local_iterator begin(size_type n);
const_local_iterator begin(size_type n) const;
local_iterator end(size_type n);
const_local_iterator end(size_type n) const;
const_local_iterator cbegin(size_type n) const;
const_local_iterator cend(size_type n) const;

// hash policy:
float load_factor() const noexcept;
float max_load_factor() const noexcept;
void max_load_factor(float z);
void rehash(size_type n);
void reserve(size_type n);
4 A `size_type` parameter type in an `unordered_multiset` deduction guide refers to the `size_type` member type of the primary `unordered_multiset` template.
26.5.7.2 unordered_multiset constructors

```cpp
unordered_multiset() : unordered_multiset(size_type(see below)) { }
explicit unordered_multiset(size_type n,
    const hasher& hf = hasher(),
    const key_equal& eql = key_equal(),
    const allocator_type& a = allocator_type());
```

**Effects:** Constructs an empty unordered_multiset using the specified hash function, key equality predicate, and allocator, and using at least n buckets. For the default constructor, the number of buckets is implementation-defined. max_load_factor() returns 1.0.

**Complexity:** Constant.

```cpp
template <class InputIterator>
unordered_multiset(InputIterator f, InputIterator l,
    size_type n = see below,
    const hasher& hf = hasher(),
    const key_equal& eql = key_equal(),
    const allocator_type& a = allocator_type());
```

```cpp
unordered_multiset(initializer_list<value_type> il,
    size_type n = see below,
    const hasher& hf = hasher(),
    const key_equal& eql = key_equal(),
    const allocator_type& a = allocator_type());
```

**Effects:** Constructs an empty unordered_multiset using the specified hash function, key equality predicate, and allocator, and using at least n buckets. If n is not provided, the number of buckets is implementation-defined. Then inserts elements from the range [f, l) for the first form, or from the range [il.begin(), il.end()) for the second form. max_load_factor() returns 1.0.

**Complexity:** Average case linear, worst case quadratic.

26.5.7.3 unordered_multiset swap

```cpp
template <class Key, class Hash, class Pred, class Alloc>
void swap(unordered_multiset<Key, Hash, Pred, Alloc>& x,
    unordered_multiset<Key, Hash, Pred, Alloc>& y)
    noexcept(noexcept(x.swap(y)));
```

**Effects:** As if by x.swap(y).

26.6 Container adaptors

26.6.1 In general

The headers <queue> and <stack> define the container adaptors queue, priority_queue, and stack.

The container adaptors each take a Container template parameter, and each constructor takes a Container reference argument. This container is copied into the Container member of each adaptor. If the container takes an allocator, then a compatible allocator may be passed in to the adaptor’s constructor. Otherwise, normal copy or move construction is used for the container argument. The first template parameter T of the container adaptors shall denote the same type as Container::value_type.

For container adaptors, no swap function throws an exception unless that exception is thrown by the swap of the adaptor’s Container or Compare object (if any).

A deduction guide for a container adaptor shall not participate in overload resolution if any of the following are true:
(4.1) — It has an **InputIterator** template parameter and a type that does not qualify as an input iterator is deduced for that parameter.

(4.2) — It has a **Compare** template parameter and a type that qualifies as an allocator is deduced for that parameter.

(4.3) — It has a **Container** template parameter and a type that qualifies as an allocator is deduced for that parameter.

(4.4) — It has an **Allocator** template parameter and a type that does not qualify as an allocator is deduced for that parameter.

(4.5) — It has both **Container** and **Allocator** template parameters, and `uses_allocator_v<Container, Allocator>` is false.

### 26.6.2 Header `<queue>` synopsis

```cpp
#include <initializer_list>

namespace std {
    template <class T, class Container = deque<T>> class queue;
    template <class T, class Container = vector<T>, class Compare = less<typename Container::value_type>>
        class priority_queue;

    template <class T, class Container>
        bool operator==(const queue<T, Container>& x, const queue<T, Container>& y);
    template <class T, class Container>
        bool operator<(const queue<T, Container>& x, const queue<T, Container>& y);
    template <class T, class Container>
        bool operator!=(const queue<T, Container>& x, const queue<T, Container>& y);
    template <class T, class Container>
        bool operator>(const queue<T, Container>& x, const queue<T, Container>& y);
    template <class T, class Container>
        bool operator>=(const queue<T, Container>& x, const queue<T, Container>& y);
    template <class T, class Container>
        bool operator<=(const queue<T, Container>& x, const queue<T, Container>& y);

    template <class T, class Container>
        void swap(queue<T, Container>& x, queue<T, Container>& y) noexcept(noexcept(x.swap(y)));
    template <class T, class Container, class Compare>
        void swap(priority_queue<T, Container, Compare>& x, priority_queue<T, Container, Compare>& y) noexcept(noexcept(x.swap(y)));
}
```

### 26.6.3 Header `<stack>` synopsis

```cpp
#include <initializer_list>

namespace std {
    template <class T, class Container = deque<T>> class stack;

    template <class T, class Container>
        bool operator==(const stack<T, Container>& x, const stack<T, Container>& y);
    template <class T, class Container>
        bool operator<(const stack<T, Container>& x, const stack<T, Container>& y);
    template <class T, class Container>
        bool operator!=(const stack<T, Container>& x, const stack<T, Container>& y);
    template <class T, class Container>
        bool operator>(const stack<T, Container>& x, const stack<T, Container>& y);
    template <class T, class Container>
        bool operator>=(const stack<T, Container>& x, const stack<T, Container>& y);
    template <class T, class Container>
        bool operator<=(const stack<T, Container>& x, const stack<T, Container>& y);

    template <class T, class Container>
        void swap(stack<T, Container>& x, stack<T, Container>& y) noexcept(noexcept(x.swap(y)));
}
```
template <class T, class Container>
bool operator>=(const stack<T, Container>& x, const stack<T, Container>& y);

template <class T, class Container>
bool operator<=(const stack<T, Container>& x, const stack<T, Container>& y);

template <class T, class Container>
void swap(stack<T, Container>& x, stack<T, Container>& y) noexcept(noexcept(x.swap(y)));

}  

26.6.4 Class template queue

26.6.4.1 queue definition

Any sequence container supporting operations \texttt{front()}, \texttt{back()}, \texttt{push\_back()} and \texttt{pop\_front()} can be used to instantiate \texttt{queue}. In particular, \texttt{list} (26.3.10) and \texttt{deque} (26.3.8) can be used.

```cpp
namespace std {
  template <class T, class Container = deque<T>>
  class queue {
public:
    using value_type = typename Container::value_type;
    using reference = typename Container::reference;
    using const_reference = typename Container::const_reference;
    using size_type = typename Container::size_type;
    using container_type = Container;

protected:
  Container c;

public:
  explicit queue(const Container&);
  explicit queue(Container&& = Container());
  template <class Alloc> explicit queue(const Alloc&);
  template <class Alloc> queue(const Container&, const Alloc&);
  template <class Alloc> queue(Container&&, const Alloc&);
  template <class Alloc> queue(const queue&, const Alloc&);
  template <class Alloc> queue(queue&&, const Alloc&);
  bool empty() const { return c.empty(); }
  size_type size() const { return c.size(); }
  reference front() { return c.front(); }
  const_reference front() const { return c.front(); }
  reference back() { return c.back(); }
  const_reference back() const { return c.back(); }
  void push(const value_type& x) { c.push_back(x); }
  void push(value_type&& x) { c.push_back(std::move(x)); }
  template <class... Args>
  reference emplace(Args&&... args) { return c.emplace_back(std::forward<Args>(args)...); }
  void pop() { c.pop_front(); }
  void swap(queue& q) noexcept(is_nothrow_swappable_v<Container>)
  { using std::swap; swap(c, q.c); }
};
```

```cpp
template<class Container>
queue(Container) -> queue<typename Container::value_type, Container>;
```

```cpp
template<class Container, class Allocator>
queue(Container, Allocator) -> queue<typename Container::value_type, Container>;
```
template <class T, class Container>
  bool operator==(const queue<T, Container>& x, const queue<T, Container>& y);

template <class T, class Container>
  bool operator< (const queue<T, Container>& x, const queue<T, Container>& y);

template <class T, class Container>
  bool operator!=(const queue<T, Container>& x, const queue<T, Container>& y);

template <class T, class Container>
  bool operator> (const queue<T, Container>& x, const queue<T, Container>& y);

template <class T, class Container>
  bool operator>=(const queue<T, Container>& x, const queue<T, Container>& y);

template <class T, class Container>
  bool operator<=(const queue<T, Container>& x, const queue<T, Container>& y);

template <class T, class Container>
  void swap(queue<T, Container>& x, queue<T, Container>& y) noexcept(noexcept(x.swap(y)));

template <class T, class Container, class Alloc>
  struct uses_allocator<queue<T, Container>, Alloc>:
      uses_allocator<Container, Alloc>::type {}; }  

26.6.4.2 queue constructors  [queue.cons]

explicit queue(const Container& cont);
1   Effects: Initializes c with cont.

explicit queue(Container&& cont = Container());
2   Effects: Initializes c with std::move(cont).

26.6.4.3 queue constructors with allocators  [queue.cons.alloc]

1 If uses_allocator_v<container_type, Alloc> is false the constructors in this subclause shall not participate in overload resolution.

template <class Alloc> explicit queue(const Alloc& a);
2   Effects: Initializes c with a.

template <class Alloc> queue(const container_type& cont, const Alloc& a);
3   Effects: Initializes c with cont as the first argument and a as the second argument.

template <class Alloc> queue(container_type&& cont, const Alloc& a);
4   Effects: Initializes c with std::move(cont) as the first argument and a as the second argument.

template <class Alloc> queue(const queue& q, const Alloc& a);
5   Effects: Initializes c with q.c as the first argument and a as the second argument.

template <class Alloc> queue(queue&& q, const Alloc& a);
6   Effects: Initializes c with std::move(q.c) as the first argument and a as the second argument.

26.6.4.4 queue operators  [queue.ops]

template <class T, class Container>
  bool operator==(const queue<T, Container>& x, const queue<T, Container>& y);
template <class T, class Container>
bool operator!=(const queue<T, Container>& x, const queue<T, Container>& y);

Returns: x.c != y.c.

template <class T, class Container>
bool operator<(const queue<T, Container>& x, const queue<T, Container>& y);

Returns: x.c < y.c.

template <class T, class Container>
bool operator<=(const queue<T, Container>& x, const queue<T, Container>& y);

Returns: x.c <= y.c.

template <class T, class Container>
bool operator>(const queue<T, Container>& x, const queue<T, Container>& y);

Returns: x.c > y.c.

template <class T, class Container>
bool operator>=(const queue<T, Container>& x, const queue<T, Container>& y);

Returns: x.c >= y.c.

26.6.4.5 queue specialized algorithms

template <class T, class Container>
void swap(queue<T, Container>& x, queue<T, Container>& y) noexcept(noexcept(x.swap(y)));

Remarks: This function shall not participate in overload resolution unless is_swappable_v<Container> is true.

Effects: As if by x.swap(y).

26.6.5 Class template priority_queue

Any sequence container with random access iterator and supporting operations front(), push_back() and pop_back() can be used to instantiate priority_queue. In particular, vector (26.3.11) and deque (26.3.8) can be used. Instantiating priority_queue also involves supplying a function or function object for making priority comparisons; the library assumes that the function or function object defines a strict weak ordering (28.7).

namespace std {
  template <class T, class Container = vector<T>, class Compare = less<typename Container::value_type>>
  class priority_queue {
public:
    using value_type = typename Container::value_type;
    using reference = typename Container::reference;
    using const_reference = typename Container::const_reference;
    using size_type = typename Container::size_type;
    using container_type = Container;
    using value_compare = Compare;
  
protected:
    Container c;
    Compare comp;

§ 26.6.5
public:
  priority_queue(const Compare& x, const Container&);
  explicit priority_queue(const Compare& x = Compare(), Container&& = Container());
  template <class InputIterator>
  priority_queue(InputIterator first, InputIterator last,
                 const Compare& x, const Container&);
  template <class InputIterator>
  priority_queue(InputIterator first, InputIterator last,
                 const Compare& x = Compare(), Container&& = Container());
  template <class Alloc> explicit priority_queue(const Alloc&);
  template <class Alloc> priority_queue(const Compare&, const Alloc&);
  template <class Alloc> priority_queue(const Compare&, const Container&, const Alloc&);
  template <class Alloc> priority_queue(const Compare&, Container&&, const Alloc&);
  template <class Alloc> priority_queue(const priority_queue&, const Alloc&);
  template <class Alloc> priority_queue(priority_queue&&, const Alloc&);
bool   empty() const { return c.empty(); }
size_type size() const { return c.size(); }
const_reference top() const { return c.front(); }
void push(const value_type& x);
void push(value_type&& x);
template <class... Args> void emplace(Args&&... args);
void pop();
void swap(priority_queue& q) noexcept(is_nothrow_swappable_v<Container> &&
         is_nothrow_swappable_v<Compare>)
{ using std::swap; swap(c, q.c); swap(comp, q.comp); }
};

template<class Compare, class Container>
priority_queue(Compare, Container)
  -> priority_queue<typename Container::value_type, Container, Compare>;

template<class InputIterator,
         class Compare = less<typename iterator_traits<InputIterator>::value_type>,
         class Container = vector<typename iterator_traits<InputIterator>::value_type>>
priority_queue(InputIterator, InputIterator, Compare = Compare(), Container = Container())
  -> priority_queue<typename iterator_traits<InputIterator>::value_type, Container, Compare>;

template<class Compare, class Container, class Allocator>
priority_queue(Compare, Container, Allocator)
  -> priority_queue<typename Container::value_type, Container, Compare>;

// no equality is provided

template <class T, class Container, class Compare>
void swap(priority_queue<T, Container, Compare>& x,
          priority_queue<T, Container, Compare>& y) noexcept(noexcept(x.swap(y)));

template <class T, class Container, class Compare, class Alloc>
struct uses_allocator<priority_queue<T, Container, Compare>, Alloc>
  : uses_allocator<Container, Alloc>::type { };
}

26.6.5.1 priority_queue constructors

§ 26.6.5.1
priority_queue(const Compare& x, const Container& y);
explicit priority_queue(const Compare& x = Compare(), Container&& y = Container());

Requires: x shall define a strict weak ordering (28.7).
Effects: Initializes comp with x and c with y (copy constructing or move constructing as appropriate);
calls make_heap(c.begin(), c.end(), comp).

template <class InputIterator>
priority_queue(InputIterator first, InputIterator last,
const Compare& x,
const Container& y);
template <class InputIterator>
priority_queue(InputIterator first, InputIterator last,
const Compare& x = Compare(),
Container&& y = Container());

Requires: x shall define a strict weak ordering (28.7).
Effects: Initializes comp with x and c with y (copy constructing or move constructing as appropriate);
calls c.insert(c.end(), first, last); and finally calls make_heap(c.begin(), c.end(), comp).

26.6.5.2 priority_queue constructors with allocators [priqueue.cons.alloc]
If uses_allocator_v<container_type, Alloc> is false the constructors in this subclause shall not par-
ticipate in overload resolution.

template <class Alloc> explicit priority_queue(const Alloc& a);

Effects: Initializes c with a and value-initializes comp.

template <class Alloc> priority_queue(const Compare& compare, const Alloc& a);

Effects: Initializes c with a and initializes comp with compare.

template <class Alloc>
priority_queue(const Compare& compare, const Container& cont, const Alloc& a);

Effects: Initializes c with cont as the first argument and a as the second argument, and initializes comp
with compare; calls make_heap(c.begin(), c.end(), comp).

template <class Alloc>
priority_queue(const Compare& compare, Container&& cont, const Alloc& a);

Effects: Initializes c with std::move(cont) as the first argument and a as the second argument, and
initializes comp with compare; calls make_heap(c.begin(), c.end(), comp).

template <class Alloc> priority_queue(const priority_queue& q, const Alloc& a);

Effects: Initializes c with q.c as the first argument and a as the second argument, and initializes comp
with q.comp.

template <class Alloc> priority_queue(priority_queue&& q, const Alloc& a);

Effects: Initializes c with std::move(q.c) as the first argument and a as the second argument, and
initializes comp with std::move(q.comp).

26.6.5.3 priority_queue members [priqueue.members]

void push(const value_type& x);

Effects: As if by:
c.push_back(x);

§ 26.6.5.3
push_heap(c.begin(), c.end(), comp);

void push(value_type&& x);

Effects: As if by:
    c.push_back(std::move(x));
    push_heap(c.begin(), c.end(), comp);

template <class... Args> void emplace(Args&&... args)

Effects: As if by:
    c.emplace_back(std::forward<Args>(args)...);
    push_heap(c.begin(), c.end(), comp);

void pop();

Effects: As if by:
    pop_heap(c.begin(), c.end(), comp);
    c.pop_back();

26.6.5.4 priority_queue specialized algorithms

template <class T, class Container, class Compare>
void swap(priority_queue<T, Container, Compare>& x,
          priority_queue<T, Container, Compare>& y) noexcept(noexcept(x.swap(y)));

Remarks: This function shall not participate in overload resolution unless is_swappable_v<Container>
          is true and is_swappable_v<Compare> is true.

Effects: As if by x.swap(y).

26.6.6 Class template stack

Any sequence container supporting operations back(), push_back() and pop_back() can be used to instantiate stack. In particular, vector (26.3.11), list (26.3.10) and deque (26.3.8) can be used.

26.6.6.1 stack definition

namespace std {
    template <class T, class Container = deque<T>>
    class stack {
        public:
            using value_type = typename Container::value_type;
            using reference = typename Container::reference;
            using const_reference = typename Container::const_reference;
            using size_type = typename Container::size_type;
            using container_type = Container;

        protected:
            Container c;

        public:
            explicit stack(const Container&);
            explicit stack(Container&& = Container());
            template <class Alloc> explicit stack(const Alloc&);
            template <class Alloc> stack(const Container&, const Alloc&);
            template <class Alloc> stack(Container&&, const Alloc&);
            template <class Alloc> stack(const stack&, const Alloc&);
            template <class Alloc> stack(stack&&, const Alloc&);

§ 26.6.6.1 952
bool empty() const { return c.empty(); }
size_type size() const { return c.size(); }
reference top() { return c.back(); }
const_reference top() const { return c.back(); }
void push(const value_type& x) { c.push_back(x); }
void push(value_type&& x) { c.push_back(std::move(x)); }
template <class... Args>
    reference emplace(Args&&... args) { return c.emplace_back(std::forward<Args>(args)...); }
void pop() { c.pop_back(); }
void swap(stack& s) noexcept(is_nothrow_swappable_v<Container>)
    { using std::swap; swap(c, s.c); }
};
template<class Container>
    stack(Container) -> stack<typename Container::value_type, Container>;
template<class Container, class Allocator>
    stack(Container, Allocator) -> stack<typename Container::value_type, Container>;
template <class T, class Container>
    bool operator==(const stack<T, Container>& x, const stack<T, Container>& y);
template <class T, class Container>
    bool operator<( const stack<T, Container>& x, const stack<T, Container>& y);
template <class T, class Container>
    bool operator!=(const stack<T, Container>& x, const stack<T, Container>& y);
template <class T, class Container>
    bool operator>( const stack<T, Container>& x, const stack<T, Container>& y);
template <class T, class Container>
    bool operator>=(const stack<T, Container>& x, const stack<T, Container>& y);
template <class T, class Container>
    bool operator<=(const stack<T, Container>& x, const stack<T, Container>& y);
template <class T, class Container, class Alloc>
    struct uses_allocator<stack<T, Container>, Alloc> : uses_allocator<Container, Alloc>::type { };
template <class Alloc> stack(const container_type& cont, const Alloc& a);

Effects: Initializes \( c \) with \( \text{cont} \) as the first argument and \( \text{a} \) as the second argument.

template <class Alloc> stack(container_type&& cont, const Alloc& a);

Effects: Initializes \( c \) with \( \text{std::move(cont)} \) as the first argument and \( \text{a} \) as the second argument.

template <class Alloc> stack(const stack& s, const Alloc& a);

Effects: Initializes \( c \) with \( s.c \) as the first argument and \( \text{a} \) as the second argument.

template <class Alloc> stack(stack&& s, const Alloc& a);

Effects: Initializes \( c \) with \( \text{std::move(s.c)} \) as the first argument and \( \text{a} \) as the second argument.

### 26.6.6.4 stack operators

template <class T, class Container>
bool operator==(const stack<T, Container>& x, const stack<T, Container>& y);

Returns: \( x.c == y.c \).

template <class T, class Container>
bool operator!=(const stack<T, Container>& x, const stack<T, Container>& y);

Returns: \( x.c != y.c \).

template <class T, class Container>
bool operator<(const stack<T, Container>& x, const stack<T, Container>& y);

Returns: \( x.c < y.c \).

template <class T, class Container>
bool operator<=(const stack<T, Container>& x, const stack<T, Container>& y);

Returns: \( x.c \leq y.c \).

template <class T, class Container>
bool operator>(const stack<T, Container>& x, const stack<T, Container>& y);

Returns: \( x.c > y.c \).

template <class T, class Container>
bool operator>=(const stack<T, Container>& x, const stack<T, Container>& y);

Returns: \( x.c \geq y.c \).

### 26.6.6.5 stack specialized algorithms

template <class T, class Container>
void swap(stack<T, Container>& x, stack<T, Container>& y) noexcept(noexcept(x.swap(y)));

Remarks: This function shall not participate in overload resolution unless \( \text{is_swappable_v<Container>} \) is true.

Effects: As if by \( x.swap(y) \).
27 Iterators library

27.1 General

1 This Clause describes components that C++ programs may use to perform iterations over containers (Clause 26), streams (30.7), and stream buffers (30.6).

2 The following subclauses describe iterator requirements, and components for iterator primitives, predefined iterators, and stream iterators, as summarized in Table 92.

Table 92 — Iterators library summary

<table>
<thead>
<tr>
<th>Subclause</th>
<th>Header(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>27.2</td>
<td>Requirements</td>
</tr>
<tr>
<td>27.4</td>
<td>Iterator primitives  &lt;iterator&gt;</td>
</tr>
<tr>

<td>Predefined iterators</td>
</tr>
<tr>
<td>27.6</td>
<td>Stream iterators</td>
</tr>
</tbody>
</table>

27.2 Iterator requirements

27.2.1 In general

1 Iterators are a generalization of pointers that allow a C++ program to work with different data structures (containers) in a uniform manner. To be able to construct template algorithms that work correctly and efficiently on different types of data structures, the library formalizes not just the interfaces but also the semantics and complexity assumptions of iterators. An input iterator \( i \) supports the expression \( \ast i \), resulting in a value of some object type \( T \), called the value type of the iterator. An output iterator \( i \) has a non-empty set of types that are writable to the iterator; for each such type \( T \), the expression \( \ast i = o \) is valid where \( o \) is a value of type \( T \). An iterator \( i \) for which the expression \( \ast\ast i.m \) is well-defined supports the expression \( i->m \) with the same semantics as \( \ast\ast i.m \). For every iterator type \( X \) for which equality is defined, there is a corresponding signed integer type called the difference type of the iterator.

2 Since iterators are an abstraction of pointers, their semantics is a generalization of most of the semantics of pointers in C++. This ensures that every function template that takes iterators works as well with regular pointers. This International Standard defines five categories of iterators, according to the operations defined on them: input iterators, output iterators, forward iterators, bidirectional iterators and random access iterators, as shown in Table 93.

Table 93 — Relations among iterator categories

<table>
<thead>
<tr>
<th>Random Access</th>
<th>Bidirectional</th>
<th>Forward</th>
<th>Input</th>
</tr>
</thead>

3 Forward iterators satisfy all the requirements of input iterators and can be used whenever an input iterator is specified; Bidirectional iterators also satisfy all the requirements of forward iterators and can be used whenever a forward iterator is specified; Random access iterators also satisfy all the requirements of bidirectional iterators and can be used whenever a bidirectional iterator is specified.

4 Iterators that further satisfy the requirements of output iterators are called mutable iterators. Nonmutable iterators are referred to as constant iterators.
In addition to the requirements in this subclause, the nested typedef-names specified in 27.4.1 shall be provided for the iterator type. [Note: Either the iterator type must provide the typedef-names directly (in which case iterator_traits pick them up automatically), or an iterator_traits specialization must provide them. —end note]

Iterators that further satisfy the requirement that, for integral values n and dereferenceable iterator values a and (a + n), *(a + n) is equivalent to *(addressof(*a) + n), are called contiguous iterators. [Note: For example, the type “pointer to int” is a contiguous iterator, but reverse_iterator<int *> is not. For a valid iterator range [a,b) with dereferenceable a, the corresponding range denoted by pointers is [addressof(*a),addressof(*a) + (b - a)); b might not be dereferenceable. —end note]

Just as a regular pointer to an array guarantees that there is a pointer value pointing past the last element of the array, so for any iterator type there is an iterator value that points past the last element of a corresponding sequence. These values are called past-the-end values. Values of an iterator i for which the expression *i is defined are called dereferenceable. The library never assumes that past-the-end values are dereferenceable. Iterators can also have singular values that are not associated with any sequence. [Example: After the declaration of an uninitialized pointer x (as with int* x;), x must always be assumed to have a singular value of a pointer. —end example] Results of most expressions are undefined for singular values; the only exceptions are destroying an iterator that holds a singular value, the assignment of a non-singular value to an iterator that holds a singular value, and, for iterators that satisfy the DefaultConstructible requirements, using a value-initialized iterator as the source of a copy or move operation. [Note: This guarantee is not offered for default-initialization, although the distinction only matters for types with trivial default constructors such as pointers or aggregates holding pointers. —end note] In these cases the singular value is overwritten the same way as any other value. Dereferenceable values are always non-singular.

An iterator j is called reachable from an iterator i if and only if there is a finite sequence of applications of the expression ++i that makes i == j. If j is reachable from i, they refer to elements of the same sequence.

Most of the library’s algorithmic templates that operate on data structures have interfaces that use ranges. A range is a pair of iterators that designate the beginning and end of the computation. A range [i, i) is an empty range; in general, a range [i, j) refers to the elements in the data structure starting with the element pointed to by i and up to but not including the element pointed to by j. Range [i, j) is valid if and only if j is reachable from i. The result of the application of functions in the library to invalid ranges is undefined.

All the categories of iterators require only those functions that are realizable for a given category in constant time (amortized). Therefore, requirement tables for the iterators do not have a complexity column.

Destruction of an iterator may invalidate pointers and references previously obtained from that iterator.

An invalid iterator is an iterator that may be singular.\(^{261}\)

In the following sections, a and b denote values of type X or const X, difference_type and reference refer to the types iterator_traits<X>::difference_type and iterator_traits<X>::reference, respectively, n denotes a value of difference_type, u, tmp, and m denote identifiers, r denotes a value of X*, t denotes a value of type T, o denotes a value of some type that is writable to the output iterator. [Note: For an iterator type X there must be an instantiation of iterator_traits<X> (27.4.1). —end note]

### 27.2.2 Iterator

The Iterator requirements form the basis of the iterator concept taxonomy; every iterator satisfies the Iterator requirements. This set of requirements specifies operations for dereferencing and incrementing an iterator. Most algorithms will require additional operations to read (27.2.3) or write (27.2.4) values, or to provide a richer set of iterator movements (27.2.5, 27.2.6, 27.2.7).

\(^{261}\) This definition applies to pointers, since pointers are iterators. The effect of dereferencing an iterator that has been invalidated is undefined.
(2.1) — X satisfies the CopyConstructible, CopyAssignable, and Destructible requirements (20.5.3.1) and lvalues of type X are swappable (20.5.3.2), and

(2.2) — the expressions in Table 94 are valid and have the indicated semantics.

Table 94 — Iterator requirements

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note pre-/post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>*r</td>
<td>unspecified</td>
<td>Requires: r is dereferenceable.</td>
<td></td>
</tr>
<tr>
<td>++r</td>
<td>X&amp;</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

27.2.3 Input iterators

A class or pointer type X satisfies the requirements of an input iterator for the value type T if X satisfies the Iterator (27.2.2) and EqualityComparable (Table 20) requirements and the expressions in Table 95 are valid and have the indicated semantics.

In Table 95, the term the domain of == is used in the ordinary mathematical sense to denote the set of values over which == is (required to be) defined. This set can change over time. Each algorithm places additional requirements on the domain of == for the iterator values it uses. These requirements can be inferred from the uses that algorithm makes of == and !=. [Example: The call find(a, b, x) is defined only if the value of a has the property p defined as follows: b has property p and a value i has property p if (*i==x) or if (*i!=x and ++i has property p). — end example]

Table 95 — Input iterator requirements (in addition to Iterator)

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note pre-/post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>a != b</td>
<td>contextually convertible to bool</td>
<td>!(a == b)</td>
<td>Requires: (a, b) is in the domain of ==.</td>
</tr>
<tr>
<td>*a</td>
<td>reference, convertible to T</td>
<td></td>
<td>Requires: a is dereferenceable. The expression (void)*a, *a is equivalent to *a. If a == b and (a, b) is in the domain of == then *a is equivalent to *b.</td>
</tr>
<tr>
<td>a-&gt;m</td>
<td>(*a).m</td>
<td>Requires: a is dereferenceable.</td>
<td></td>
</tr>
</tbody>
</table>
Table 95 — Input iterator requirements (in addition to Iterator)  
(continued)

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note pre-/post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>++r</td>
<td>X&amp;</td>
<td></td>
<td>Requires: r is dereferenceable.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Postconditions: r is dereferenceable or r is past-the-end; any copies of the previous value of r are no longer required either to be dereferenceable or to be in the domain of ==.</td>
</tr>
<tr>
<td>(void)r++</td>
<td></td>
<td></td>
<td>equivalent to (void)++r</td>
</tr>
<tr>
<td>*r++</td>
<td>convertible to T</td>
<td>{ T tmp = *r;</td>
<td>Remarks: After this operation r is not required to be dereferenceable. Postconditions: r is incremenntable.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>++r;</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>return tmp; }</td>
<td></td>
</tr>
</tbody>
</table>

3 [Note: For input iterators, a == b does not imply ++a == ++b. (Equality does not guarantee the substitution property or referential transparency.) Algorithms on input iterators should never attempt to pass through the same iterator twice. They should be single pass algorithms. Value type T is not required to be a CopyAssignable type (Table 26). These algorithms can be used with istreams as the source of the input data through the istream_iterator class template. — end note]

27.2.4 Output iterators [output.iterators]

1 A class or pointer type X satisfies the requirements of an output iterator if X satisfies the Iterator requirements (27.2.2) and the expressions in Table 96 are valid and have the indicated semantics.

Table 96 — Output iterator requirements (in addition to Iterator)

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note pre-/post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>*r = o</td>
<td></td>
<td>result is not used</td>
<td>Remarks: After this operation r is not required to be dereferenceable. Postconditions: r is incremenntable.</td>
</tr>
<tr>
<td>++r</td>
<td>X&amp;</td>
<td></td>
<td>&amp;r == &amp;++r. Remarks: After this operation r is not required to be dereferenceable. Postconditions: r is incremenntable.</td>
</tr>
<tr>
<td>r++</td>
<td>convertible to const X&amp;</td>
<td>{ X tmp = r;</td>
<td>Remarks: After this operation r is not required to be dereferenceable. Postconditions: r is incremenntable.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>++r;</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>return tmp; }</td>
<td></td>
</tr>
</tbody>
</table>
Table 96 — Output iterator requirements (in addition to Iterator)
(continued)

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note pre-/post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>*r++ = o</td>
<td></td>
<td>result is not used</td>
<td>Remarks: After this operation r is not required to be dereferenceable. Postconditions: r is incrementable.</td>
</tr>
</tbody>
</table>

Remarks:
After this operation r is not required to be dereferenceable.
Postconditions: r is incrementable.

2 [Note: The only valid use of an operator* is on the left side of the assignment statement. Assignment through the same value of the iterator happens only once. Algorithms on output iterators should never attempt to pass through the same iterator twice. They should be single pass algorithms. Equality and inequality might not be defined. Algorithms that take output iterators can be used with ostream as the destination for placing data through the ostream_iterator class as well as with insert iterators and insert pointers. —end note]

27.2.5 Forward iterators [forward.iterators]

1 A class or pointer type X satisfies the requirements of a forward iterator if

- X satisfies the requirements of an input iterator (27.2.3),
- X satisfies the DefaultConstructible requirements (20.5.3.1),
- if X is a mutable iterator, reference is a reference to T; if X is a constant iterator, reference is a reference to const T,
- the expressions in Table 97 are valid and have the indicated semantics, and
- objects of type X offer the multi-pass guarantee, described below.

2 The domain of == for forward iterators is that of iterators over the same underlying sequence. However, value-initialized iterators may be compared and shall compare equal to other value-initialized iterators of the same type. [Note: Value-initialized iterators behave as if they refer past the end of the same empty sequence. —end note]

3 Two dereferenceable iterators a and b of type X offer the multi-pass guarantee if:

- a == b implies ++a == ++b and
- X is a pointer type or the expression (void)++X(a), *a is equivalent to the expression *a.

4 [Note: The requirement that a == b implies ++a == ++b (which is not true for input and output iterators) and the removal of the restrictions on the number of the assignments through a mutable iterator (which applies to output iterators) allows the use of multi-pass one-directional algorithms with forward iterators. —end note]

Table 97 — Forward iterator requirements (in addition to input iterator)

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note pre-/post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>r++</td>
<td>convertible to</td>
<td>{ X tmp = r; ++r; return tmp; }</td>
<td></td>
</tr>
</tbody>
</table>

§ 27.2.5
Table 97 — Forward iterator requirements (in addition to input iterator) (continued)

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note pre-/post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>*r++</td>
<td>reference</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5 If \(a\) and \(b\) are equal, then either \(a\) and \(b\) are both dereferenceable or else neither is dereferenceable.

6 If \(a\) and \(b\) are both dereferenceable, then \(a == b\) if and only if \(*a\) and \(*b\) are bound to the same object.

### 27.2.6 Bidirectional iterators

A class or pointer type \(X\) satisfies the requirements of a bidirectional iterator if, in addition to satisfying the requirements for forward iterators, the following expressions are valid as shown in Table 98.

Table 98 — Bidirectional iterator requirements (in addition to forward iterator)

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note pre-/post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>(--r)</td>
<td>(X&amp;)</td>
<td></td>
<td>Requires: there exists (s) such that (r == ++s). Postconditions: (r) is dereferenceable. (--(++r) == r). (--r == --s) implies (r == s). &amp;r == &amp;--r.</td>
</tr>
</tbody>
</table>
| \(r--\)    | convertible to \(X\&) | \(--r; \{
|            | \(X\) tmp = r;
|            | \}\)         | \(--r\); \return tmp; } |
| \(*r--\)   | reference   |                       |                                   |

[Note: Bidirectional iterators allow algorithms to move iterators backward as well as forward. — end note]

### 27.2.7 Random access iterators

A class or pointer type \(X\) satisfies the requirements of a random access iterator if, in addition to satisfying the requirements for bidirectional iterators, the following expressions are valid as shown in Table 99.

[Note: Random access iterators can be moved forward, backward, or to any position within the range of the iterator. — end note]
Table 99 — Random access iterator requirements (in addition to bidirectional iterator)

27.4 Iterator primitives

To simplify the task of defining iterators, the library provides several classes and functions:

27.4.1 Iterator traits

To implement algorithms only in terms of iterators, it is often necessary to determine the value and difference types that correspond to a particular iterator type. Accordingly, it is required that if Iterator is the type of an iterator, the types

§ 27.4.1
iterator_traits<Iterator>::difference_type
iterator_traits<Iterator>::value_type
iterator_traits<Iterator>::iterator_category

be defined as the iterator’s difference type, value type and iterator category, respectively. In addition, the
types
iterator_traits<Iterator>::reference
iterator_traits<Iterator>::pointer

shall be defined as the iterator’s reference and pointer types, that is, for an iterator object \( a \), the same type
as the type of \(*a\) and \(a->\), respectively. In the case of an output iterator, the types
iterator_traits<Iterator>::difference_type
iterator_traits<Iterator>::value_type
iterator_traits<Iterator>::reference
iterator_traits<Iterator>::pointer

may be defined as void.

2 If \( \text{Iterator} \) has valid (17.8.2) member types \( \text{difference_type} \), \( \text{value_type} \), \( \text{pointer} \), \( \text{reference} \), and \( \text{iterator_category} \), \( \text{iterator_traits<Iterator>} \) shall have the following as publicly accessible members:

```cpp
using difference_type = typename Iterator::difference_type;
using value_type = typename Iterator::value_type;
using pointer = typename Iterator::pointer;
using reference = typename Iterator::reference;
using iterator_category = typename Iterator::iterator_category;
```

Otherwise, \( \text{iterator_traits<Iterator>} \) shall have no members by any of the above names.

3 It is specialized for pointers as
```cpp
namespace std {
    template<class T> struct iterator_traits<T*> {
        using difference_type = ptrdiff_t;
        using value_type = T;
        using pointer = T*;
        using reference = T&;
        using iterator_category = random_access_iterator_tag;
    };
}
```

and for pointers to const as
```cpp
namespace std {
    template<class T> struct iterator_traits<const T*> {
        using difference_type = ptrdiff_t;
        using value_type = T;
        using pointer = const T*;
        using reference = const T&;
        using iterator_category = random_access_iterator_tag;
    };
}
```

4 [Example: To implement a generic \texttt{reverse} function, a C++ program can do the following:
```cpp
template<class BidirectionalIterator>
void reverse(BidirectionalIterator first, BidirectionalIterator last) {
    typename iterator_traits<BidirectionalIterator>::difference_type n =
    distance(first, last);
}
```
--n;
while(n > 0) {
    typename iterator_traits<BidirectionalIterator>::value_type
tmp = *first;
    *first++ = *--last;
    *last = tmp;
    n -= 2;
}
}
— end example]

27.4.2 Standard iterator tags [std.iterator.tags]

1 It is often desirable for a function template specialization to find out what is the most specific category of its iterator argument, so that the function can select the most efficient algorithm at compile time. To facilitate this, the library introduces category tag classes which are used as compile time tags for algorithm selection. They are: input_iterator_tag, output_iterator_tag, forward_iterator_tag, bidirectional_iterator_tag and random_access_iterator_tag. For every iterator of type Iterator, iterator_traits<Iterator>::iterator_category shall be defined to be the most specific category tag that describes the iterator’s behavior.

namespace std {
    struct input_iterator_tag { };
    struct output_iterator_tag { };
    struct forward_iterator_tag: public input_iterator_tag { };
    struct bidirectional_iterator_tag: public forward_iterator_tag { };
    struct random_access_iterator_tag: public bidirectional_iterator_tag { };
}

2 [Example: For a program-defined iterator BinaryTreeIterator, it could be included into the bidirectional iterator category by specializing the iterator_traits template:

    template<class T> struct iterator_traits<BinaryTreeIterator<T>> {
        using iterator_category = bidirectional_iterator_tag;
        using difference_type = ptrdiff_t;
        using value_type = T;
        using pointer = T*;
        using reference = T&;
    };

— end example]

3 [Example: If evolve() is well defined for bidirectional iterators, but can be implemented more efficiently for random access iterators, then the implementation is as follows:

    template <class BidirectionalIterator>
    inline void
evolve(BidirectionalIterator first, BidirectionalIterator last) {
        evolve(first, last,
            typename iterator_traits<BidirectionalIterator>::iterator_category());
    }

    template <class BidirectionalIterator>
    void evolve(BidirectionalIterator first, BidirectionalIterator last,
        bidirectional_iterator_tag) {
        // more generic, but less efficient algorithm
    }

§ 27.4.2 966
template <class RandomAccessIterator>
void evolve(RandomAccessIterator first, RandomAccessIterator last,
random_access_iterator_tag) {
    // more efficient, but less generic algorithm
}

— end example —

27.4.3 Iterator operations

Since only random access iterators provide + and - operators, the library provides two function templates advance and distance. These function templates use + and - for random access iterators (and are, therefore, constant time for them); for input, forward and bidirectional iterators they use ++ to provide linear time implementations.

```
template <class InputIterator, class Distance>
constexpr void advance(InputIterator& i, Distance n);
```

1 Requires: n shall be negative only for bidirectional and random access iterators.

2 Effects: Increments (or decrements for negative n) iterator reference i by n.

```
template <class InputIterator>
constexpr typename iterator_traits<InputIterator>::difference_type
distance(InputIterator first, InputIterator last);
```

4 Effects: If InputIterator meets the requirements of random access iterator, returns (last - first); otherwise, returns the number of increments needed to get from first to last.

5 Requires: If InputIterator meets the requirements of random access iterator, last shall be reachable from first or first shall be reachable from last; otherwise, last shall be reachable from first.

```
template <class InputIterator>
constexpr InputIterator next(InputIterator x,
    typename iterator_traits<InputIterator>::difference_type n = 1);
```

6 Effects: Equivalent to: advance(x, n); return x;

```
template <class BidirectionalIterator>
constexpr BidirectionalIterator prev(BidirectionalIterator x,
    typename iterator_traits<BidirectionalIterator>::difference_type n = 1);
```

7 Effects: Equivalent to: advance(x, -n); return x;

27.5 Iterator adaptors

27.5.1 Reverse iterators

Class template reverse_iterator is an iterator adaptor that iterates from the end of the sequence defined by its underlying iterator to the beginning of that sequence. The fundamental relation between a reverse iterator and its corresponding iterator i is established by the identity: &*(reverse_iterator(i)) == &*(i - 1).

```
namespace std {
    template <class Iterator>
class reverse_iterator {
        public:
            using iterator_type       = Iterator;
            using iterator_category   = typename iterator_traits<Iterator>::iterator_category;
    }
}
```

§ 27.5.1.1
using value_type = typename iterator_traits<Iterator>::value_type;
using difference_type = typename iterator_traits<Iterator>::difference_type;
using pointer = typename iterator_traits<Iterator>::pointer;
using reference = typename iterator_traits<Iterator>::reference;

constexpr reverse_iterator();
constexpr explicit reverse_iterator(Iterator x);
template <class U> constexpr reverse_iterator(const reverse_iterator<U>& u);
template <class U> constexpr reverse_iterator& operator=(const reverse_iterator<U>& u);

constexpr Iterator base() const;    // explicit
constexpr reference operator*() const;
constexpr pointer operator->() const;
constexpr reverse_iterator& operator++();
constexpr reverse_iterator operator++(int);
constexpr reverse_iterator& operator--();
constexpr reverse_iterator operator--(int);
constexpr reverse_iterator operator+ (difference_type n) const;
constexpr reverse_iterator& operator+=(difference_type n);
constexpr reverse_iterator operator- (difference_type n) const;
constexpr reverse_iterator& operator-=(difference_type n);
constexpr unspecified operator[](difference_type n) const;

protected:
    Iterator current;
};

template <class Iterator1, class Iterator2>
constexpr bool operator==(const reverse_iterator<Iterator1>& x, const reverse_iterator<Iterator2>& y);
template <class Iterator1, class Iterator2>
constexpr bool operator< (const reverse_iterator<Iterator1>& x, const reverse_iterator<Iterator2>& y);
template <class Iterator1, class Iterator2>
constexpr bool operator!= (const reverse_iterator<Iterator1>& x, const reverse_iterator<Iterator2>& y);
template <class Iterator1, class Iterator2>
constexpr bool operator> (const reverse_iterator<Iterator1>& x, const reverse_iterator<Iterator2>& y);
template <class Iterator1, class Iterator2>
constexpr bool operator>= (const reverse_iterator<Iterator1>& x, const reverse_iterator<Iterator2>& y);
template <class Iterator1, class Iterator2>
constexpr bool operator<= (const reverse_iterator<Iterator1>& x, const reverse_iterator<Iterator2>& y);

§ 27.5.1.1
const reverse_iterator<Iterator2>& y) -> decltype(y.base() - x.base());

template <class Iterator>
constexpr reverse_iterator<Iterator> operator+(
    typename reverse_iterator<Iterator>::difference_type n,
    const reverse_iterator<Iterator>& x);

template <class Iterator>
constexpr reverse_iterator<Iterator> make_reverse_iterator(Iterator i);
27.5.1.3.5 operator->
constexpr pointer operator->() const;

1 Returns: &operator*().

27.5.1.3.6 operator++
constexpr reverse_iterator& operator++();

1 Effects: As if by: --current;
2 Returns: *this.

constexpr reverse_iterator operator++(int);

3 Effects: As if by:
    reverse_iterator tmp = *this;
    --current;
    return tmp;

27.5.1.3.7 operator--
constexpr reverse_iterator& operator--();

1 Effects: As if by ++current.
2 Returns: *this.

constexpr reverse_iterator operator--(int);

3 Effects: As if by:
    reverse_iterator tmp = *this;
    ++current;
    return tmp;

27.5.1.3.8 operator+
constexpr reverse_iterator operator+(difference_type n) const;

1 Returns: reverse_iterator(current-n).

27.5.1.3.9 operator++
constexpr reverse_iterator& operator+=(difference_type n);

1 Effects: As if by: current -= n;
2 Returns: *this.

27.5.1.3.10 operator-
constexpr reverse_iterator operator-(difference_type n) const;

1 Returns: reverse_iterator(current+n).

27.5.1.3.11 operator--
constexpr reverse_iterator& operator-=(difference_type n);

1 Effects: As if by: current += n;
2 Returns: *this.
27.5.1.3.12  operator[]  
constexpr unspecified operator[](difference_type n) const;

Returns: current[-n-1].

27.5.1.3.13  operator==  
template <class Iterator1, class Iterator2>
constexpr bool operator==(  
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);

Returns: x.current == y.current.

27.5.1.3.14  operator<  
template <class Iterator1, class Iterator2>
constexpr bool operator<(  
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);

Returns: x.current > y.current.

27.5.1.3.15  operator!=  
template <class Iterator1, class Iterator2>
constexpr bool operator!=(  
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);

Returns: x.current != y.current.

27.5.1.3.16  operator>  
template <class Iterator1, class Iterator2>
constexpr bool operator>(  
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);

Returns: x.current < y.current.

27.5.1.3.17  operator>=  
template <class Iterator1, class Iterator2>
constexpr bool operator>=(  
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);

Returns: x.current <= y.current.

27.5.1.3.18  operator<=  
template <class Iterator1, class Iterator2>
constexpr bool operator<=(  
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y);

Returns: x.current >= y.current.

§ 27.5.1.3.18
27.5.1.3.19 operator-  [reverse.iter.opdiff]

```cpp
template <class Iterator1, class Iterator2>
constexpr auto operator-(
    const reverse_iterator<Iterator1>& x,
    const reverse_iterator<Iterator2>& y) -> decltype(y.base() - x.base());
```

1 Returns: \( y.current - x.current \).

27.5.1.3.20 operator+  [reverse.iter.opsum]

```cpp
template <class Iterator>
constexpr reverse_iterator<Iterator> operator+(typename reverse_iterator<Iterator>::difference_type n,
    const reverse_iterator<Iterator>& x);
```

1 Returns: \( \text{reverse_iterator<Iterator> (x.current - n)} \).

27.5.1.3.21 Non-member function make_reverse_iterator()  [reverse.iter.make]

```cpp
template <class Iterator>
constexpr reverse_iterator<Iterator> make_reverse_iterator(Iterator i);
```

1 Returns: \( \text{reverse_iterator<Iterator>(i)} \).

27.5.2 Insert iterators  [insert.iterators]

1 To make it possible to deal with insertion in the same way as writing into an array, a special kind of iterator adaptors, called insert iterators, are provided in the library. With regular iterator classes,

```cpp
while (first != last) *result++ = *first++;
```

causes a range \([\text{first, last})\) to be copied into a range starting with result. The same code with result being an insert iterator will insert corresponding elements into the container. This device allows all of the copying algorithms in the library to work in the insert mode instead of the regular overwrite mode.

2 An insert iterator is constructed from a container and possibly one of its iterators pointing to where insertion takes place if it is neither at the beginning nor at the end of the container. Insert iterators satisfy the requirements of output iterators. `operator*` returns the insert iterator itself. The assignment `operator=(const T& x)` is defined on insert iterators to allow writing into them, it inserts \(x\) right before where the insert iterator is pointing. In other words, an insert iterator is like a cursor pointing into the container where the insertion takes place. `back_insert_iterator` inserts elements at the end of a container, `front_insert_iterator` inserts elements at the beginning of a container, and `insert_iterator` inserts elements where the iterator points to in a container. `back_inserter`, `front_inserter`, and `inserter` are three functions making the insert iterators out of a container.

27.5.2.1 Class template back_insert_iterator  [back.insert.iterator]

```cpp
namespace std {
    template <class Container>
    class back_insert_iterator {
        protected:
            Container* container;

        public:
            using iterator_category = output_iterator_tag;
            using value_type = void;
            using difference_type = void;
            using pointer = void;
            using reference = void;
```

§ 27.5.2.1
using container_type = Container;

explicit back_insert_iterator(Container& x);
back_insert_iterator& operator=(const typename Container::value_type& value);
back_insert_iterator& operator=(typename Container::value_type&& value);
back_insert_iterator& operator*();
back_insert_iterator& operator++();
back_insert_iterator operator++(int);
}

template <class Container>
back_insert_iterator<Container> back_inserter(Container& x);

27.5.2.2 back_insert_iterator operations

27.5.2.2.1 back_insert_iterator constructor
explicit back_insert_iterator(Container& x);

Effects: Initializes container with addressof(x).

27.5.2.2.2 back_insert_iterator::operator=
back_insert_iterator& operator=(const typename Container::value_type& value);

Effects: As if by: container->push_back(value);

Returns: *this.

back_insert_iterator& operator=(typename Container::value_type&& value);

Effects: As if by: container->push_back(std::move(value));

Returns: *this.

27.5.2.2.3 back_insert_iterator::operator*
back_insert_iterator& operator*();

Returns: *this.

27.5.2.2.4 back_insert_iterator::operator++
back_insert_iterator& operator++();
back_insert_iterator operator++(int);

Returns: *this.

27.5.2.2.5 back_inserter
template <class Container>
back_insert_iterator<Container> back_inserter(Container& x);

Returns: back_insert_iterator<Container>(x).

27.5.2.3 Class template front_insert_iterator

namespace std {
    template <class Container>
    class front_insert_iterator {
        protected:
            Container* container;

§ 27.5.2.3
public:
    using iterator_category = output_iterator_tag;
    using value_type = void;
    using difference_type = void;
    using pointer = void;
    using reference = void;
    using container_type = Container;

    explicit front_insert_iterator(Container& x);
    front_insert_iterator& operator=(const typename Container::value_type& value);
    front_insert_iterator& operator=(typename Container::value_type&& value);
    front_insert_iterator& operator*();
    front_insert_iterator& operator++();
    front_insert_iterator operator++(int);
};

template <class Container>
    front_insert_iterator<Container> front_inserter(Container& x);

27.5.2.4 front_insert_iterator operations [front.insert.iter.ops]
27.5.2.4.1 front_insert_iterator constructor [front.insert.iter.cons]
    explicit front_insert_iterator(Container& x);

1 Effects: Initializes container with addressof(x).

27.5.2.4.2 front_insert_iterator::operator= [front.insert.iter.op=]
    front_insert_iterator& operator=(const typename Container::value_type& value);

1 Effects: As if by: container->push_front(value);
2 Returns: *this.

3 front_insert_iterator& operator=(typename Container::value_type&& value);

3 Effects: As if by: container->push_front(std::move(value));
4 Returns: *this.

27.5.2.4.3 front_insert_iterator::operator* [front.insert.iter.op*]
    front_insert_iterator& operator*();

1 Returns: *this.

27.5.2.4.4 front_insert_iterator::operator++ [front.insert.iter.op++]
    front_insert_iterator& operator++();
    front_insert_iterator operator++(int);

1 Returns: *this.

27.5.2.4.5 front_inserter [front.inserter]
    template <class Container>
        front_insert_iterator<Container> front_inserter(Container& x);

1 Returns: front_insert_iterator<Container>(x).
27.5.2.5  Class template insert_iterator

namespace std {
    template <class Container>
    class insert_iterator {
    protected:
        Container* container;
        typename Container::iterator iter;
    public:
        using iterator_category = output_iterator_tag;
        using value_type = void;
        using difference_type = void;
        using pointer = void;
        using reference = void;
        using container_type = Container;

        insert_iterator(Container& x, typename Container::iterator i);
        insert_iterator& operator=(const typename Container::value_type& value);
        insert_iterator& operator=(typename Container::value_type&& value);
        insert_iterator& operator*();
        insert_iterator& operator++();
        insert_iterator& operator++(int);}
    }

    template <class Container>
    insert_iterator<Container> inserter(Container& x, typename Container::iterator i);
}

27.5.2.6  insert_iterator operations

27.5.2.6.1  insert_iterator constructor

    insert_iterator(Container& x, typename Container::iterator i);

        Effects: Initializes container with addressof(x) and iter with i.

27.5.2.6.2  insert_iterator::operator=

    insert_iterator& operator=(const typename Container::value_type& value);

        Effects: As if by:
            iter = container->insert(iter, value);
            ++iter;

        Returns: *this.

    insert_iterator& operator=(typename Container::value_type&& value);

        Effects: As if by:
            iter = container->insert(iter, std::move(value));
            ++iter;

        Returns: *this.

27.5.2.6.3  insert_iterator::operator*

    insert_iterator& operator*();

        Returns: *this.
27.5.2.6.4 insert_iterator::operator++

insert_iterator& operator++();
insert_iterator& operator++(int);

1 Returns: *this.

27.5.2.6.5 inserter

template <class Container>
insert_iterator<Container> inserter(Container& x, typename Container::iterator i);

1 Returns: insert_iterator<Container>(x, i).

27.5.3 Move iterators

Class template move_iterator is an iterator adaptor with the same behavior as the underlying iterator except that its indirection operator implicitly converts the value returned by the underlying iterator’s indirection operator to an rvalue. Some generic algorithms can be called with move iterators to replace copying with moving.

Example:

```
list<string> s;
// populate the list s
vector<string> v1(s.begin(), s.end());  // copies strings into v1
vector<string> v2(make_move_iterator(s.begin()),
                 make_move_iterator(s.end()));  // moves strings into v2
```

—end example—

27.5.3.1 Class template move_iterator

namespace std {
    template <class Iterator>
    class move_iterator {
        public:
            using iterator_type = Iterator;
            using iterator_category = typename iterator_traits<Iterator>::iterator_category;
            using value_type = typename iterator_traits<Iterator>::value_type;
            using difference_type = typename iterator_traits<Iterator>::difference_type;
            using pointer = Iterator;
            using reference = see below;

            constexpr move_iterator();
            constexpr explicit move_iterator(Iterator i);
            template <class U> constexpr move_iterator(const move_iterator<U>& u);
            template <class U> constexpr move_iterator& operator=(const move_iterator<U>& u);

            constexpr iterator_type base() const;
            constexpr reference operator*() const;
            constexpr pointer operator->() const;

            constexpr move_iterator& operator++();
            constexpr move_iterator operator++(int);
            constexpr move_iterator& operator--();
            constexpr move_iterator operator--(int);

            constexpr move_iterator operator+(difference_type n) const;
            constexpr move_iterator& operator+=(difference_type n);

    } // class move_iterator
} // namespace std

§ 27.5.3.1

976
constexpr move_iterator operator-(difference_type n) const;
constexpr move_iterator& operator-=(difference_type n);
constexpr unspecified operator[](difference_type n) const;

private:
    Iterator current;  // exposition only
};

template <class Iterator1, class Iterator2>
constexpr bool operator==(
    const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
template <class Iterator1, class Iterator2>
constexpr bool operator!=(
    const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
template <class Iterator1, class Iterator2>
constexpr bool operator<=(
    const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
template <class Iterator1, class Iterator2>
constexpr bool operator>=(
    const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
template <class Iterator1, class Iterator2>
constexpr auto operator-(
    const move_iterator<Iterator1>& x,
    const move_iterator<Iterator2>& y) -> decltype(x.base() - y.base());
template <class Iterator>
constexpr move_iterator<Iterator> operator+(
    typename move_iterator<Iterator>::difference_type n, const move_iterator<Iterator>& x);

template <class Iterator1, class Iterator2>
constexpr move_iterator<Iterator1>& operator-(
    const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

Let \( R \) denote iterator_traits<Iterator>::reference. If is_reference_v<R> is true, the template specialization move_iterator<Iterator> shall define the nested type named reference as a synonym for remove_reference_t<R>&&, otherwise as a synonym for R.

27.5.3.2 move_iterator requirements

1 The template parameter Iterator shall meet the requirements of an input iterator (27.2.3). Additionally, if any of the bidirectional or random access traversal functions are instantiated, the template parameter shall meet the requirements for a Bidirectional Iterator (27.2.6) or a Random Access Iterator (27.2.7), respectively.

27.5.3.3 move_iterator operations

27.5.3.3.1 move_iterator constructors

constexpr move_iterator();

Effects: Constructs a move_iterator, value-initializing current. Iterator operations applied to the resulting iterator have defined behavior if and only if the corresponding operations are defined on a value-initialized iterator of type Iterator.
constexpr explicit move_iterator(Iterator i);

Effects: Constructs a move_iterator, initializing current with i.

template <class U> constexpr move_iterator(const move_iterator<U>& u);

Effects: Constructs a move_iterator, initializing current with u.base().

Requires: U shall be convertible to Iterator.

27.5.3.3.2 move_iterator::operator=

template <class U> constexpr move_iterator& operator=(const move_iterator<U>& u);

Effects: Assigns u.base() to current.

Requires: U shall be convertible to Iterator.

27.5.3.3.3 move_iterator conversion

constexpr Iterator base() const;

Returns: current.

27.5.3.3.4 move_iterator::operator*

constexpr reference operator*() const;

Returns: static_cast<reference>(*current).

27.5.3.3.5 move_iterator::operator->

constexpr pointer operator->() const;

Returns: current.

27.5.3.3.6 move_iterator::operator++

constexpr move_iterator& operator++();

Effects: As if by ++current.

Returns: *this.

constexpr move_iterator operator++(int);

Effects: As if by:

move_iterator tmp = *this;
++current;
return tmp;

27.5.3.3.7 move_iterator::operator--

constexpr move_iterator& operator--();

Effects: As if by --current.

Returns: *this.

constexpr move_iterator operator--(int);

Effects: As if by:

move_iterator tmp = *this;
--current;
return tmp;
27.5.3.3.8 move_iterator::operator+
constexpr move_iterator operator+(difference_type n) const;
1 Returns: move_iterator(current + n).

27.5.3.3.9 move_iterator::operator++
constexpr move_iterator& operator+=(difference_type n);
1 Effects: As if by: current += n;
2 Returns: *this.

27.5.3.3.10 move_iterator::operator-
constexpr move_iterator operator-(difference_type n) const;
1 Returns: move_iterator(current - n).

27.5.3.3.11 move_iterator::operator--
constexpr move_iterator& operator--(difference_type n);
1 Effects: As if by: current -= n;
2 Returns: *this.

27.5.3.3.12 move_iterator::operator[]
constexpr unspecified operator[](difference_type n) const;
1 Returns: std::move(current[n]).

27.5.3.3.13 move_iterator comparisons
template <class Iterator1, class Iterator2>
constexpr bool operator==(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
1 Returns: x.base() == y.base().

template <class Iterator1, class Iterator2>
constexpr bool operator!=(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
2 Returns: !(x == y).

template <class Iterator1, class Iterator2>
constexpr bool operator<(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
3 Returns: x.base() < y.base().

template <class Iterator1, class Iterator2>
constexpr bool operator<=(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
4 Returns: !(y < x).

template <class Iterator1, class Iterator2>
constexpr bool operator>(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
5 Returns: y < x.

template <class Iterator1, class Iterator2>
constexpr bool operator>=(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);
6 Returns: !(x < y).
27.5.3.3.14 move_iterator non-member functions [move.iter.nonmember]

template <class Iterator1, class Iterator2>
constexpr auto operator-(
    const move_iterator<Iterator1>& x,
    const move_iterator<Iterator2>& y) -> decltype(x.base() - y.base());

Returns: x.base() - y.base().

template <class Iterator>
constexpr move_iterator<Iterator> operator+(
    typename move_iterator<Iterator>::difference_type n, const move_iterator<Iterator>& x);

Returns: x + n.

template <class Iterator>
constexpr move_iterator<Iterator> make_move_iterator(Iterator i);

Returns: move_iterator<Iterator>(i).

27.6 Stream iterators [stream.iterators]

To make it possible for algorithmic templates to work directly with input/output streams, appropriate iterator-like class templates are provided.

[Example:
    partial_sum(istream_iterator<double, char>(cin),
                istream_iterator<double, char>(),
                ostream_iterator<double, char>(cout, "\n"));
] reads a file containing floating-point numbers from cin, and prints the partial sums onto cout. —end example]

27.6.1 Class template istream_iterator [istream.iterator]

The class template istream_iterator is an input iterator (27.2.3) that reads (using operator>>) successive elements from the input stream for which it was constructed. After it is constructed, and every time ++ is used, the iterator reads and stores a value of T. If the iterator fails to read and store a value of T (fail() on the stream returns true), the iterator becomes equal to the end-of-stream iterator value. The constructor with no arguments istream_iterator() always constructs an end-of-stream input iterator object, which is the only legitimate iterator to be used for the end condition. The result of operator* on an end-of-stream iterator is not defined. For any other iterator value a const T& is returned. The result of operator-> on an end-of-stream iterator is not defined. For any other iterator value a const T* is returned. The behavior of a program that applies operator++() to an end-of-stream iterator is undefined. It is impossible to store things into istream iterators. The type T shall meet the DefaultConstructible, CopyConstructible, and CopyAssignable requirements.

Two end-of-stream iterators are always equal. An end-of-stream iterator is not equal to a non-end-of-stream iterator. Two non-end-of-stream iterators are equal when they are constructed from the same stream.

namespace std {
    template <class T, class charT = char, class traits = char_traits<charT>,
              class Distance = ptrdiff_t>
    class istream_iterator {
    public:
        using iterator_category = input_iterator_tag;
        using value_type = T;
        using difference_type = Distance;
        using pointer = const T*;

}
using reference = const T&;
using char_type = charT;
using traits_type = traits;
using istream_type = basic_istream<charT,traits>;

constexpr istream_iterator();
istream_iterator(istream_type& s);
istream_iterator(const istream_iterator& x) = default;
~istream_iterator() = default;

const T& operator*() const;
const T* operator->() const;
istream_iterator& operator++();
istream_iterator operator++(int);

private:
  basic_istream<charT,traits>* in_stream; // exposition only
  T value; // exposition only
};

template <class T, class charT, class traits, class Distance>
bool operator==(const istream_iterator<T,charT,traits,Distance>& x,
               const istream_iterator<T,charT,traits,Distance>& y);

template <class T, class charT, class traits, class Distance>
bool operator!=(const istream_iterator<T,charT,traits,Distance>& x,
               const istream_iterator<T,charT,traits,Distance>& y);

27.6.1.1 istream_iterator constructors and destructor [istream.iterator.cons]

constexpr istream_iterator();
1
   Effects: Constructs the end-of-stream iterator. If is_trivially_default_constructible_v<T> is
           true, then this constructor is a constexpr constructor.

   Postconditions: in_stream == 0.

istream_iterator(istream_type& s);
3
   Effects: Initializes in_stream with addressof(s). value may be initialized during construction or the
            first time it is referenced.

   Postconditions: in_stream == addressof(s).

istream_iterator(const istream_iterator& x) = default;
5
   Effects: Constructs a copy of x. If is_trivially_copy_constructible_v<T> is true, then this
            constructor is a trivial copy constructor.

   Postconditions: in_stream == x.in_stream.

~istream_iterator() = default;
7
   Effects: The iterator is destroyed. If is_trivially_destructible_v<T> is true, then this destructor
            is a trivial destructor.

27.6.1.2 istream_iterator operations [istream.iterator.ops]

const T& operator*() const;
1
   Returns: value.
const T* operator->() const;

Returns: addressof(operator*()).

istream_iterator& operator++();

Requires: in_stream != 0.

Effects: As if by: *in_stream >> value;

Returns: *this.

istream_iterator operator++(int);

Requires: in_stream != 0.

Effects: As if by:
    
    istream_iterator tmp = *this;
    *in_stream >> value;
    return (tmp);

template <class T, class charT, class traits, class Distance>
bool operator==(const istream_iterator<T,charT,traits,Distance>& x,
    const istream_iterator<T,charT,traits,Distance>& y);

Returns: x.in_stream == y.in_stream.

template <class T, class charT, class traits, class Distance>
bool operator!=(const istream_iterator<T,charT,traits,Distance>& x,
    const istream_iterator<T,charT,traits,Distance>& y);

Returns: !(x == y).

27.6.2 Class template ostream_iterator

ostream_iterator writes (using operator<<) successive elements onto the output stream from which it was constructed. If it was constructed with charT* as a constructor argument, this string, called a delimiter string, is written to the stream after every T is written. It is not possible to get a value out of the output iterator. Its only use is as an output iterator in situations like

while (first != last)
    *result++ = *first++;

ostream_iterator is defined as:

namespace std {
    template <class T, class charT = char, class traits = char_traits<charT>>
    class ostream_iterator {
    public:
        using iterator_category = output_iterator_tag;
        using value_type = void;
        using difference_type = void;
        using pointer = void;
        using reference = void;
        using char_type = charT;
        using traits_type = traits;
        using ostream_type = basic_ostream<charT,traits>;

        ostream_iterator(ostream_type& s);
        ostream_iterator(ostream_type& s, const charT* delimiter);
        ostream_iterator(const ostream_iterator& x);
        ~ostream_iterator();

    }
ostream_iterator& operator=(const T& value);

ostream_iterator& operator*();
ostream_iterator& operator++();
ostream_iterator& operator++(int);
private:
basic_ostream<charT,traits>* out_stream; // exposition only
const charT* delim; // exposition only
};

27.6.2.1 ostream_iterator constructors and destructor [ostream.iterator.cons.des]

ostream_iterator(ostream_type& s);

Effects: Initializes out_stream with addressof(s) and delim with null.

ostream_iterator(ostream_type& s, const charT* delimiter);

Effects: Initializes out_stream with addressof(s) and delim with delimiter.

ostream_iterator(const ostream_iterator& x);

Effects: Constructs a copy of x.

~ostream_iterator();

Effects: The iterator is destroyed.

27.6.2.2 ostream_iterator operations [ostream.iterator.ops]

ostream_iterator& operator=(const T& value);

Effects: As if by:
    *out_stream << value;
    if (delim != 0)
        *out_stream << delim;
    return *this;

ostream_iterator& operator*();

Returns: *this.

ostream_iterator& operator++();
ostream_iterator& operator++(int);

Returns: *this.

27.6.3 Class template istreambuf_iterator [istreambuf.iterator]

The class template istreambuf_iterator defines an input iterator (27.2.3) that reads successive characters from the streambuf for which it was constructed. operator* provides access to the current input character, if any. Each time operator++ is evaluated, the iterator advances to the next input character. If the end of stream is reached (streambuf_type::sgetc() returns traits::eof()), the iterator becomes equal to the end-of-stream iterator value. The default constructor istreambuf_iterator() and the constructor istreambuf_iterator(0) both construct an end-of-stream iterator object suitable for use as an end-of-range. All specializations of istreambuf_iterator shall have a trivial copy constructor, a constexpr default constructor, and a trivial destructor.

The result of operator*() on an end-of-stream iterator is undefined. For any other iterator value a char_type value is returned. It is impossible to assign a character via an input iterator.
namespace std {

template<class charT, class traits = char_traits<charT>>
class istreambuf_iterator {
public:
    using iterator_category = input_iterator_tag;
    using value_type = charT;
    using difference_type = typename traits::off_type;
    using pointer = unspecified;
    using reference = charT;
    using char_type = charT;
    using traits_type = traits;
    using int_type = typename traits::int_type;
    using streambuf_type = basic_streambuf<charT,traits>;
    using istream_type = basic_istream<charT,traits>;
    class proxy;
    // exposition only

consexpr istreambuf_iterator() noexcept;
    istreambuf_iterator(const istreambuf_iterator&) noexcept = default;
    ~istreambuf_iterator() = default;
    istreambuf_iterator(istream_type& s) noexcept;
    istreambuf_iterator(streambuf_type* s) noexcept;
    istreambuf_iterator(const proxy& p) noexcept;
    charT operator*() const;
    istreambuf_iterator& operator++();
    proxy operator++(int);
    bool equal(const istreambuf_iterator& b) const;
};

template <class charT, class traits>
    bool operator==(const istreambuf_iterator<charT,traits>& a,
        const istreambuf_iterator<charT,traits>& b);

template <class charT, class traits>
    bool operator!=(const istreambuf_iterator<charT,traits>& a,
        const istreambuf_iterator<charT,traits>& b);
}

27.6.3.1 Class template istreambuf_iterator::proxy

namespace std {

    template <class charT, class traits = char_traits<charT>>
    class istreambuf_iterator<charT, traits>::proxy {
        // exposition only
    charT keep_;
    basic_streambuf<charT,traits>* sbuf_;
    proxy(charT c, basic_streambuf<charT,traits>* sbuf)
    : keep_(c), sbuf_(sbuf) {} 

public:
    charT operator*() { return keep_; }
    };
}

1 Class istreambuf_iterator<charT, traits>::proxy is for exposition only. An implementation is permitted to provide equivalent functionality without providing a class with this name. Class istreambuf_iterator<charT, traits>::proxy provides a temporary placeholder as the return value of the post-
increment operator (`operator++`). It keeps the character pointed to by the previous value of the iterator for some possible future access to get the character.

### 27.6.3.2 `istreambuf_iterator` constructors

For each `istreambuf_iterator` constructor in this section, an end-of-stream iterator is constructed if and only if the exposition-only member `sbuf_` is initialized with a null pointer value.

```cpp
constexpr istreambuf_iterator() noexcept;

Effects: Initializes `sbuf_` with `nullptr`.

istreambuf_iterator(istream_type& s) noexcept;

Effects: Initializes `sbuf_` with `s.rdbuf()`.

istreambuf_iterator(streambuf_type* s) noexcept;

Effects: Initializes `sbuf_` with `s`.

istreambuf_iterator(const proxy& p) noexcept;

Effects: Initializes `sbuf_` with `p.sbuf_`.
```

### 27.6.3.3 `istreambuf_iterator` operations

```cpp
charT operator*() const

Returns: The character obtained via the `streambuf` member `sbuf_->sgetc()`.

istreambuf_iterator& operator++();

Effects: As if by `sbuf_->sbumpc()`.

Returns: `*this`.

proxy operator++(int);

Returns: `proxy(sbuf_->sbumpc(), sbuf_)`.

bool equal(const istreambuf_iterator& b) const;

Returns: `true` if and only if both iterators are at end-of-stream, or neither is at end-of-stream, regardless of what `streambuf` object they use.

```

```cpp
template <class charT, class traits>
bool operator==(const istreambuf_iterator<charT,traits>& a,
               const istreambuf_iterator<charT,traits>& b);

Returns: `a.equal(b)`.

template <class charT, class traits>
bool operator!=(const istreambuf_iterator<charT,traits>& a,
               const istreambuf_iterator<charT,traits>& b);

Returns: `!a.equal(b)`.
```

### 27.6.4 Class template `ostreambuf_iterator`

```cpp
namespace std {

    template <class charT, class traits = char_traits<charT>>
    class ostreambuf_iterator {
    public:
        using iterator_category = output_iterator_tag;
        using value_type = void;
    }

} // namespace std
```

§ 27.6.4
using difference_type = void;
using pointer = void;
using reference = void;
using char_type = charT;
using traits_type = traits;
using streambuf_type = basic_streambuf<charT,traits>;
using ostream_type = basic_ostream<charT,traits>;

ostreambuf_iterator(ostream_type& s) noexcept;
ostreambuf_iterator(streambuf_type* s) noexcept;
ostreambuf_iterator& operator=(charT c);

ostreambuf_iterator& operator*();
ostreambuf_iterator& operator++();
ostreambuf_iterator& operator++(int);
bool failed() const noexcept;

private:
    streambuf_type* sbuf_;  // exposition only
};

1. The class template `ostreambuf_iterator` writes successive characters onto the output stream from which it was constructed. It is not possible to get a character value out of the output iterator.

27.6.4.1 `ostreambuf_iterator` constructors [ostreambuf.iter.cons]

`ostreambuf_iterator(ostream_type& s) noexcept;`

1. Requires: `s.rdbuf()` shall not be a null pointer.
2. Effects: Initializes `sbuf_` with `s.rdbuf()`.

`ostreambuf_iterator(streambuf_type* s) noexcept;`

3. Requires: `s` shall not be a null pointer.
4. Effects: Initializes `sbuf_` with `s`.

27.6.4.2 `ostreambuf_iterator` operations [ostreambuf.iter.ops]

`ostreambuf_iterator& operator=(charT c);`

1. Effects: If `failed()` yields `false`, calls `sbuf_->sputc(c)`; otherwise has no effect.
2. Returns: `*this`.

`ostreambuf_iterator& operator*();`

3. Returns: `*this`.

`ostreambuf_iterator& operator++();`

4. Returns: `*this`.

`ostreambuf_iterator& operator++(int);`

5. Returns: `*this`.

`bool failed() const noexcept;`

5. Returns: `true` if in any prior use of member `operator*`, the call to `sbuf_->sputc()` returned `traits::eof()`; or `false` otherwise.

§ 27.6.4.2 986
27.7 Range access

In addition to being available via inclusion of the `<iterator>` header, the function templates in 27.7 are available when any of the following headers are included: `<array>`, `<deque>`, `<forward_list>`, `<list>`, `<map>`, `<regex>`, `<set>`, `<string>`, `<string_view>`, `<unordered_map>`, `<unordered_set>`, and `<vector>`.

template <class C> constexpr auto begin(C& c) -> decltype(c.begin());

template <class C> constexpr auto begin(const C& c) -> decltype(c.begin());

Returns: c.begin().

template <class C> constexpr auto end(C& c) -> decltype(c.end());

template <class C> constexpr auto end(const C& c) -> decltype(c.end());

Returns: c.end().

template <class T, size_t N> constexpr T* begin(T (&array)[N]) noexcept;

Returns: array.

template <class T, size_t N> constexpr T* end(T (&array)[N]) noexcept;

Returns: array + N.

template <class C> constexpr auto cbegin(const C& c) noexcept(noexcept(std::begin(c)))

Returns: std::begin(c).

template <class C> constexpr auto cend(const C& c) noexcept(noexcept(std::end(c)))

Returns: std::end(c).

template <class C> constexpr auto rbegin(C& c) -> decltype(c.rbegin());

template <class C> constexpr auto rend(C& c) -> decltype(c.rend());

Returns: c.rbegin().

Returns: c.rend().

template <class E> constexpr reverse_iterator<const E*> rbegin(initializer_list<E> il);

Returns: reverse_iterator<const E*>(il.begin()).

template <class E> constexpr reverse_iterator<const E*> rend(initializer_list<E> il);

Returns: reverse_iterator<const E*>(il.end()).

template <class C> constexpr auto crbegin(const C& c) -> decltype(std::rbegin(c));

template <class C> constexpr auto crend(const C& c) -> decltype(std::rend(c));

Returns: std::rbegin(c).

§ 27.7
Returns: std::rend(c).

27.8 Container access

In addition to being available via inclusion of the <iterator> header, the function templates in 27.8 are available when any of the following headers are included: <array>, <deque>, <forward_list>, <list>, <map>, <regex>, <set>, <string>, <unordered_map>, <unordered_set>, and <vector>.

template <class C> constexpr auto size(const C& c) -> decltype(c.size());

Returns: c.size().

template <class T, size_t N> constexpr size_t size(const T (&array)[N]) noexcept;

Returns: N.

template <class C> constexpr auto empty(const C& c) -> decltype(c.empty());

Returns: c.empty().

template <class T, size_t N> constexpr bool empty(const T (&array)[N]) noexcept;

Returns: false.

template <class E> constexpr bool empty(initializer_list<E> il) noexcept;

Returns: il.size() == 0.

template <class C> constexpr auto data(C& c) -> decltype(c.data());
template <class C> constexpr auto data(const C& c) -> decltype(c.data());

Returns: c.data().

template <class T, size_t N> constexpr T* data(T (&array)[N]) noexcept;

Returns: array.

template <class E> constexpr const E* data(initializer_list<E> il) noexcept;

Returns: il.begin().
28 Algorithms library

28.1 General

1 This Clause describes components that C++ programs may use to perform algorithmic operations on containers (Clause 26) and other sequences.

2 The following subclauses describe components for non-modifying sequence operations, modifying sequence operations, sorting and related operations, and algorithms from the ISO C library, as summarized in Table 100.

Table 100 — Algorithms library summary

28.3 Algorithms requirements

1 All of the algorithms are separated from the particular implementations of data structures and are parameterized by iterator types. Because of this, they can work with program-defined data structures, as long as these data structures have iterator types satisfying the assumptions on the algorithms.

2 For purposes of determining the existence of data races, algorithms shall not modify objects referenced through an iterator argument unless the specification requires such modification.

3 Throughout this Clause, the names of template parameters are used to express type requirements.

   (3.1) If an algorithm’s template parameter is named InputIterator, InputIterator1, or InputIterator2, the template argument shall satisfy the requirements of an input iterator (27.2.3).

   (3.2) If an algorithm’s template parameter is named OutputIterator, OutputIterator1, or OutputIterator2, the template argument shall satisfy the requirements of an output iterator (27.2.4).

   (3.3) If an algorithm’s template parameter is named ForwardIterator, ForwardIterator1, or ForwardIterator2, the template argument shall satisfy the requirements of a forward iterator (27.2.5).

   (3.4) If an algorithm’s template parameter is named BidirectionalIterator, BidirectionalIterator1, or BidirectionalIterator2, the template argument shall satisfy the requirements of a bidirectional iterator (27.2.6).

   (3.5) If an algorithm’s template parameter is named RandomAccessIterator, RandomAccessIterator1, or RandomAccessIterator2, the template argument shall satisfy the requirements of a random-access iterator (27.2.7).

4 If an algorithm’s Effects: section says that a value pointed to by any iterator passed as an argument is modified, then that algorithm has an additional type requirement: The type of that argument shall satisfy the requirements of a mutable iterator (27.2). [Note: This requirement does not affect arguments that are named OutputIterator, OutputIterator1, or OutputIterator2, because output iterators must always be mutable. —end note]

5 Both in-place and copying versions are provided for certain algorithms. When such a version is provided for algorithm it is called algorithm_copy. Algorithms that take predicates end with the suffix _if (which follows the suffix _copy).

6 The Predicate parameter is used whenever an algorithm expects a function object (23.14) that, when applied to the result of dereferencing the corresponding iterator, returns a value testable as true. In other words, if an algorithm takes Predicate pred as its argument and first as its iterator argument, it should work correctly in the construct pred(*first) contextually converted to bool (Clause 7). The function object pred shall not apply any non-constant function through the dereferenced iterator.

7 The BinaryPredicate parameter is used whenever an algorithm expects a function object that when applied to the result of dereferencing two corresponding iterators or to dereferencing an iterator and type T when T is part of the signature returns a value testable as true. In other words, if an algorithm takes BinaryPredicate binary_pred as its argument and first1 and first2 as its iterator arguments, it should work correctly in the construct binary_pred(*first1, *first2) contextually converted to bool (Clause 7). BinaryPredicate always takes the first iterator’s value_type as its first argument, that is, in those cases when T value is part of the signature, it should work correctly in the construct binary_pred(*first1, value) contextually converted to bool (Clause 7). binary_pred shall not apply any non-constant function through the dereferenced iterators.

262 The decision whether to include a copying version was usually based on complexity considerations. When the cost of doing the operation dominates the cost of copy, the copying version is not included. For example, sort_copy is not included because the cost of sorting is much more significant, and users might as well do copy followed by sort.

§ 28.3
8 [Note: Unless otherwise specified, algorithms that take function objects as arguments are permitted to copy those function objects freely. Programmers for whom object identity is important should consider using a wrapper class that points to a noncopied implementation object such as `reference_wrapper<T>` (23.14.5), or some equivalent solution. — end note]

9 When the description of an algorithm gives an expression such as `*first == value` for a condition, the expression shall evaluate to either true or false in boolean contexts.

10 In the description of the algorithms operators + and - are used for some of the iterator categories for which they do not have to be defined. In these cases the semantics of `a+n` is the same as that of

```cpp
X tmp = a;
advance(tmp, n);
return tmp;
```

and that of `b-a` is the same as of

```cpp
return distance(a, b);
```

28.4 Parallel algorithms

This section describes components that C++ programs may use to perform operations on containers and other sequences in parallel.

28.4.1 Terms and definitions

A parallel algorithm is a function template listed in this International Standard with a template parameter named `ExecutionPolicy`.

Parallel algorithms access objects indirectly accessible via their arguments by invoking the following functions:

1. All operations of the categories of the iterators that the algorithm is instantiated with.
2. Operations on those sequence elements that are required by its specification.
3. User-provided function objects to be applied during the execution of the algorithm, if required by the specification.
4. Operations on those function objects required by the specification. [Note: See 28.1. — end note]

These functions are herein called element access functions. [Example: The `sort` function may invoke the following element access functions:

1. Operations of the random-access iterator of the actual template argument (as per 27.2.7), as implied by the name of the template parameter `RandomAccessIterator`.
2. The `swap` function on the elements of the sequence (as per the preconditions specified in 28.7.1.1).
3. The user-provided `Compare` function object.

—end example]

28.4.2 Requirements on user-provided function objects

Unless otherwise specified, function objects passed into parallel algorithms as objects of type `Predicate`, `BinaryPredicate`, `Compare`, `UnaryOperation`, `BinaryOperation`, `BinaryOperation1`, `BinaryOperation2`, and the operators used by the analogous overloads to these parallel algorithms that could be formed by the invocation with the specified default predicate or operation (where applicable) shall not directly or indirectly modify objects via their arguments, nor shall they rely on the identity of the provided objects.

28.4.3 Effect of execution policies on algorithm execution

Parallel algorithms have template parameters named `ExecutionPolicy` (23.19) which describe the manner in which the execution of these algorithms may be parallelized and the manner in which they apply the element
access functions.

2 Unless otherwise stated, implementations may make arbitrary copies of elements (with type T) from sequences 
where is_trivially_copy_constructible_v<T> and is_trivially_destructible_v<T> are true. [Note: This implies that user-supplied function objects should not rely on object identity of arguments for such input sequences. Users for whom the object identity of the arguments to these function objects is important should consider using a wrapping iterator that returns a non-copied implementation object such as reference_wrapper<T> (23.14.5) or some equivalent solution. — end note]

3 The invocations of element access functions in parallel algorithms invoked with an execution policy object of 
type execution::sequenced_policy all occur in the calling thread of execution. [Note: The invocations 
are not interleaved; see 4.6. — end note]

4 The invocations of element access functions in parallel algorithms invoked with an execution policy object of 
type execution::parallel_policy are permitted to execute in either the invoking thread of execution or in 
a thread of execution implicitly created by the library to support parallel algorithm execution. If the threads 
of execution created by thread (33.3.2) provide concurrent forward progress guarantees (4.7.2), then a thread 
of execution implicitly created by the library will provide parallel forward progress guarantees; otherwise, 
the provided forward progress guarantee is implementation-defined. Any such invocations executing in 
the same thread of execution are indeterminately sequenced with respect to each other. [Note: It is the 
caller’s responsibility to ensure that the invocation does not introduce data races or deadlocks. — end note]

[Example:

```cpp
int a[] = {0,1};
std::vector<int> v;
std::for_each(std::execution::par, std::begin(a), std::end(a), [&](int i) {
    v.push_back(i*2+1); // incorrect: data race
});
```

The program above has a data race because of the unsynchronized access to the container v. — end example]

[Example:

```cpp
std::atomic<int> x{0};
int a[] = {1,2};
std::for_each(std::execution::par, std::begin(a), std::end(a), [&](int) {
    x.fetch_add(1, std::memory_order_relaxed);
    // spin wait for another iteration to change the value of x
    while (x.load(std::memory_order_relaxed) == 1) {} // incorrect: assumes execution order
});
```

The above example depends on the order of execution of the iterations, and will not terminate if both 
iterations are executed sequentially on the same thread of execution. — end example]

[Example:

```cpp
int x = 0;
std::mutex m;
int a[] = {1,2};
std::for_each(std::execution::par, std::begin(a), std::end(a), [&](int) {
    std::lock_guard<mutex> guard(m);
    ++x;
});
```

The above example synchronizes access to object x ensuring that it is incremented correctly. — end example]

5 The invocations of element access functions in parallel algorithms invoked with an execution policy of type 
execution::parallel_unsequenced_policy are permitted to execute in an unordered fashion in unspecified 
threads of execution, and unsequenced with respect to one another within each thread of execution. These 
threads of execution are either the invoking thread of execution or threads of execution implicitly created 
by the library; the latter will provide weakly parallel forward progress guarantees. [Note: This means that

§ 28.4.3
multiple function object invocations may be interleaved on a single thread of execution, which overrides the usual guarantee from 4.6 that function executions do not interleave with one another. —end note]

Since `execution::parallel_unsequenced_policy` allows the execution of element access functions to be interleaved on a single thread of execution, blocking synchronization, including the use of mutexes, risks deadlock. Thus, the synchronization with `execution::parallel_unsequenced_policy` is restricted as follows: A standard library function is `vectorization-unsafe` if it is specified to synchronize with another function invocation, or another function invocation is specified to synchronize with it, and if it is not a memory allocation or deallocation function. Vectorization-unsafe standard library functions may not be invoked by user code called from `execution::parallel_unsequenced_policy` algorithms. [Note: Implementations must ensure that internal synchronization inside standard library functions does not prevent forward progress when those functions are executed by threads of execution with weakly parallel forward progress guarantees. —end note]

Example:

```c++
int x = 0;
std::mutex m;
int a[] = {1,2};
std::for_each(std::execution::par_unseq, std::begin(a), std::end(a), [&](int) {
    std::lock_guard<mutex> guard(m); // incorrect: lock_guard constructor calls m.lock()
    ++x;
});
```

The above program may result in two consecutive calls to `m.lock()` on the same thread of execution (which may deadlock), because the applications of the function object are not guaranteed to run on different threads of execution. —end example] [Note: The semantics of the `execution::parallel_policy` or the `execution::parallel_unsequenced_policy` invocation allow the implementation to fall back to sequential execution if the system cannot parallelize an algorithm invocation due to lack of resources. —end note]

6 If an invocation of a parallel algorithm uses threads of execution implicitly created by the library, then the invoking thread of execution will either

(6.1) — temporarily block with forward progress guarantee delegation (4.7.2) on the completion of these library-managed threads of execution, or

(6.2) — eventually execute an element access function;

the thread of execution will continue to do so until the algorithm is finished. [Note: In blocking with forward progress guarantee delegation in this context, a thread of execution created by the library is considered to have finished execution as soon as it has finished the execution of the particular element access function that the invoking thread of execution logically depends on. —end note]

7 The semantics of parallel algorithms invoked with an execution policy object of implementation-defined type are implementation-defined.

28.4.4 Parallel algorithm exceptions

[algorithms.parallel.exceptions]

1 During the execution of a parallel algorithm, if temporary memory resources are required for parallelization and none are available, the algorithm throws a `bad_alloc` exception.

2 During the execution of a parallel algorithm, if the invocation of an element access function exits via an uncaught exception, the behavior is determined by the `ExecutionPolicy`.

28.4.5 ExecutionPolicy algorithm overloads

[algorithms.parallel.overloads]

1 Parallel algorithms are algorithm overloads. Each parallel algorithm overload has an additional template type parameter named `ExecutionPolicy`, which is the first template parameter. Additionally, each parallel algorithm overload has an additional function parameter of type `ExecutionPolicy&&`, which is the first function parameter. [Note: Not all algorithms have parallel algorithm overloads. —end note]
Unless otherwise specified, the semantics of `ExecutionPolicy` algorithm overloads are identical to their overloads without.

3 Unless otherwise specified, the complexity requirements of `ExecutionPolicy` algorithm overloads are relaxed from the complexity requirements of the overloads without as follows: when the guarantee says “at most expr” or “exactly expr” and does not specify the number of assignments or swaps, and expr is not already expressed with \( \Theta() \) notation, the complexity of the algorithm shall be \( \Theta(expr) \).

4 Parallel algorithms shall not participate in overload resolution unless `is_execution_policy_v<decay_t<ExecutionPolicy>>` is true.

28.5 Non-modifying sequence operations

28.5.1 All of

```cpp
template <class InputIterator, class Predicate>
bool all_of(InputIterator first, InputIterator last, Predicate pred);
```

```cpp
template <class ExecutionPolicy, class ForwardIterator, class Predicate>
bool all_of(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, Predicate pred);
```

1 Returns: true if `[first, last)` is empty or if `pred(*i)` is `true` for every iterator `i` in the range `[first, last)`, and `false` otherwise.

2 Complexity: At most `last - first` applications of the predicate.

28.5.2 Any of

```cpp
template <class InputIterator, class Predicate>
bool any_of(InputIterator first, InputIterator last, Predicate pred);
```

```cpp
template <class ExecutionPolicy, class ForwardIterator, class Predicate>
bool any_of(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, Predicate pred);
```

1 Returns: false if `[first, last)` is empty or if there is no iterator `i` in the range `[first, last)` such that `pred(*i)` is `true`, and `true` otherwise.

2 Complexity: At most `last - first` applications of the predicate.

28.5.3 None of

```cpp
template <class InputIterator, class Predicate>
bool none_of(InputIterator first, InputIterator last, Predicate pred);
```

```cpp
template <class ExecutionPolicy, class ForwardIterator, class Predicate>
bool none_of(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, Predicate pred);
```

1 Returns: true if `[first, last)` is empty or if `pred(*i)` is `false` for every iterator `i` in the range `[first, last)`, and `false` otherwise.

2 Complexity: At most `last - first` applications of the predicate.

28.5.4 For each

```cpp
template<class InputIterator, class Function>
Function for_each(InputIterator first, InputIterator last, Function f);
```

1 Requires: Function shall meet the requirements of `MoveConstructible` (Table 23). [Note: Function need not meet the requirements of `CopyConstructible` (Table 24). —end note]
Effects: Applies \( f \) to the result of dereferencing every iterator in the range \([\text{first}, \text{last})\), starting from \( \text{first} \) and proceeding to \( \text{last} - 1 \). \([\text{Note: If the type of } \text{first} \text{ satisfies the requirements of a mutable iterator, } f \text{ may apply non-constant functions through the dereferenced iterator. — end note}\)

Returns: \( f \).

Complexity: Applies \( f \) exactly \( \text{last} - \text{first} \) times.

Remarks: If \( f \) returns a result, the result is ignored.

template<class ExecutionPolicy, class ForwardIterator, class Function>
void for_each(ExecutionPolicy&& exec,
             ForwardIterator first, ForwardIterator last,
             Function f);

Requires: Function shall meet the requirements of \texttt{CopyConstructible}.

Effects: Applies \( f \) to the result of dereferencing every iterator in the range \([\text{first}, \text{last})\). \([\text{Note: If the type of } \text{first} \text{ satisfies the requirements of a mutable iterator, } f \text{ may apply non-constant functions through the dereferenced iterator. — end note}\]

Complexity: Applies \( f \) exactly \( \text{last} - \text{first} \) times.

Remarks: If \( f \) returns a result, the result is ignored. Implementations do not have the freedom granted under 28.4.3 to make arbitrary copies of elements from the input sequence.

\([\text{Note: Does not return a copy of its } \text{Function} \text{ parameter, since parallelization may not permit efficient state accumulation. — end note}\]

template<class InputIterator, class Size, class Function>
 InputIterator for_each_n(InputIterator first, Size n, Function f);

Requires: \texttt{Function} shall meet the requirements of \texttt{MoveConstructible} \([\text{Note: } \text{Function need not meet the requirements of } \texttt{CopyConstructible. — end note}\]

Requires: \( n \geq 0 \).

Effects: Applies \( f \) to the result of dereferencing every iterator in the range \([\text{first}, \text{first} + n)\) in order. \([\text{Note: If the type of } \text{first} \text{ satisfies the requirements of a mutable iterator, } f \text{ may apply non-constant functions through the dereferenced iterator. — end note}\]

Returns: \( \text{first} + n \).

Remarks: If \( f \) returns a result, the result is ignored.

template<class ExecutionPolicy, class ForwardIterator, class Size, class Function>
 ForwardIterator for_each_n(ExecutionPolicy&& exec, ForwardIterator first, Size n,
                           Function f);

Requires: Function shall meet the requirements of \texttt{CopyConstructible}.

Requires: \( n \geq 0 \).

Effects: Applies \( f \) to the result of dereferencing every iterator in the range \([\text{first}, \text{first} + n)\). \([\text{Note: If the type of } \text{first} \text{ satisfies the requirements of a mutable iterator, } f \text{ may apply non-constant functions through the dereferenced iterator. — end note}\]

Returns: \( \text{first} + n \).

Remarks: If \( f \) returns a result, the result is ignored. Implementations do not have the freedom granted under 28.4.3 to make arbitrary copies of elements from the input sequence.

28.5.5 Find

[alg.find]
template<class InputIterator, class T>
    InputIterator find(InputIterator first, InputIterator last, 
                      const T& value);

template<class ExecutionPolicy, class ForwardIterator, class T>
    ForwardIterator find(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, 
                         const T& value);

template<class InputIterator, class Predicate>
    InputIterator find_if(InputIterator first, InputIterator last, 
                           Predicate pred);

template<class ExecutionPolicy, class ForwardIterator, class Predicate>
    ForwardIterator find_if(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, 
                            Predicate pred);

template<class InputIterator, class Predicate>
    InputIterator find_if_not(InputIterator first, InputIterator last, 
                               Predicate pred);

template<class ExecutionPolicy, class ForwardIterator, class Predicate>
    ForwardIterator find_if_not(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, 
                                Predicate pred);

1 Returns: The first iterator \( i \) in the range \([first, last)\) for which the following corresponding 
            conditions hold: \(*i == value, pred(*i) != false, pred(*i) == false\). Returns last if no such 
            iterator is found.
2 Complexity: At most \( last - first \) applications of the corresponding predicate.

28.5.6 Find end [alg.find.end]

template<class ForwardIterator1, class ForwardIterator2>
    ForwardIterator1
    find_end(ForwardIterator1 first1, ForwardIterator1 last1, 
             ForwardIterator2 first2, ForwardIterator2 last2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
    ForwardIterator1
    find_end(ExecutionPolicy&& exec, 
             ForwardIterator1 first1, ForwardIterator1 last1, 
             ForwardIterator2 first2, ForwardIterator2 last2);

template<class ForwardIterator1, class ForwardIterator2, 
         class BinaryPredicate>
    ForwardIterator1
    find_end(ForwardIterator1 first1, ForwardIterator1 last1, 
             ForwardIterator2 first2, ForwardIterator2 last2, 
             BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, 
         class BinaryPredicate>
    ForwardIterator1
    find_end(ExecutionPolicy&& exec, 
             ForwardIterator1 first1, ForwardIterator1 last1, 
             ForwardIterator2 first2, ForwardIterator2 last2, 
             BinaryPredicate pred);

1 Effects: Finds a subsequence of equal values in a sequence.
2 Returns: The last iterator \( i \) in the range \([first1, last1 - (last2 - first2))\) such that for every 
           non-negative integer \( n < (last2 - first2) \), the following corresponding conditions hold: 
           \(*(i +
n) == *(first2 + n), pred(*(i + n), *(first2 + n)) != false. Returns last1 if [first2, last2) is empty or if no such iterator is found.

**Complexity:** At most (last2 - first2) * (last1 - first1 - (last2 - first2) + 1) applications of the corresponding predicate.

### 28.5.7 Find first

```cpp
template<class InputIterator, class ForwardIterator>
InputIterator find_first_of(InputIterator first1, InputIterator last1,
                           ForwardIterator first2, ForwardIterator last2);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator1 find_first_of(ExecutionPolicy&& exec,
                              ForwardIterator1 first1, ForwardIterator1 last1,
                              ForwardIterator2 first2, ForwardIterator2 last2);
```

```cpp
template<class InputIterator, class ForwardIterator,
         class BinaryPredicate>
InputIterator find_first_of(InputIterator first1, InputIterator last1,
                           ForwardIterator first2, ForwardIterator last2,
                           BinaryPredicate pred);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
         class BinaryPredicate>
ForwardIterator1 find_first_of(ExecutionPolicy&& exec,
                              ForwardIterator1 first1, ForwardIterator1 last1,
                              ForwardIterator2 first2, ForwardIterator2 last2,
                              BinaryPredicate pred);
```

**Effects:** Finds an element that matches one of a set of values.

**Returns:** The first iterator i in the range [first1, last1) such that for some iterator j in the range [first2, last2) the following conditions hold: i == j, pred(i, j) != false. Returns last1 if [first2, last2) is empty or if no such iterator is found.

**Complexity:** At most (last1-first1) * (last2-first2) applications of the corresponding predicate.

### 28.5.8 Adjacent find

```cpp
template<class ForwardIterator>
ForwardIterator adjacent_find(ForwardIterator first, ForwardIterator last);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator adjacent_find(ExecutionPolicy&& exec,
                              ForwardIterator first, ForwardIterator last);
```

```cpp
template<class ForwardIterator, class BinaryPredicate>
ForwardIterator adjacent_find(ForwardIterator first, ForwardIterator last,
                              BinaryPredicate pred);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator, class BinaryPredicate>
ForwardIterator adjacent_find(ExecutionPolicy&& exec,
                              ForwardIterator first, ForwardIterator last,
                              BinaryPredicate pred);
```

**Returns:** The first iterator i such that both i and i + 1 are in the range [first, last) for which the following corresponding conditions hold: i == *(i + 1), pred(i, *(i + 1)) != false. Returns
last if no such iterator is found.

**Complexity:** For the overloads with no `ExecutionPolicy`, exactly \(\min((i - \text{first}) + 1, (\text{last} - \text{first}) - 1)\) applications of the corresponding predicate, where \(i\) is `adjacent_find`’s return value. For the overloads with an `ExecutionPolicy`, \(\Theta(\text{last} - \text{first})\) applications of the corresponding predicate.

### 28.5.9 Count

```
template<class InputIterator, class T>
    typename iterator_traits<InputIterator>::difference_type
    count(InputIterator first, InputIterator last, const T& value);
```

```
template<class ExecutionPolicy, class ForwardIterator, class T>
    typename iterator_traits<ForwardIterator>::difference_type
    count(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, const T& value);
```

```
template<class InputIterator, class Predicate>
    typename iterator_traits<InputIterator>::difference_type
    count_if(InputIterator first, InputIterator last, Predicate pred);
```

```
template<class ExecutionPolicy, class ForwardIterator, class Predicate>
    typename iterator_traits<ForwardIterator>::difference_type
    count_if(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, Predicate pred);
```

**Effects:** Returns the number of iterators \(i\) in the range \([\text{first}, \text{last})\) for which the following corresponding conditions hold: \(*i == \text{value}, \text{pred}(*i) != \text{false}\).

**Complexity:** Exactly \(\text{last} - \text{first}\) applications of the corresponding predicate.

### 28.5.10 Mismatch

```
template<class InputIterator1, class InputIterator2>
    pair<InputIterator1, InputIterator2>
    mismatch(InputIterator1 first1, InputIterator1 last1, InputIterator2 first2);
```

```
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
    pair<ForwardIterator1, ForwardIterator2>
    mismatch(ExecutionPolicy&& exec, ForwardIterator1 first1, ForwardIterator1 last1, ForwardIterator2 first2);
```

```
template<class InputIterator1, class InputIterator2, class BinaryPredicate>
    pair<InputIterator1, InputIterator2>
    mismatch(InputIterator1 first1, InputIterator1 last1, InputIterator2 first2, BinaryPredicate pred);
```

```
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class BinaryPredicate>
    pair<ForwardIterator1, ForwardIterator2>
    mismatch(ExecutionPolicy&& exec, ForwardIterator1 first1, ForwardIterator1 last1, ForwardIterator2 first2, BinaryPredicate pred);
```

**Effects:** Returns a pair \((\text{first1}, \text{first2})\) such that \(\text{first1}\) is the iterator in \([\text{first}, \text{last})\) closest to \(\text{first2}\) that satisfies the given condition, or \(\text{last} - 1\) if no such iterator is found.

**Complexity:** \(\Theta(\text{last} - \text{first})\) applications of the corresponding predicate.
pair<ForwardIterator1, ForwardIterator2>
mismatch(ExecutionPolicy&& exec,
    ForwardIterator1 first1, ForwardIterator1 last1,
    ForwardIterator2 first2, ForwardIterator2 last2);

template<class InputIterator1, class InputIterator2,
    class BinaryPredicate>
pair<InputIterator1, InputIterator2>
mismatch(InputIterator1 first1, InputIterator1 last1,
    InputIterator2 first2, InputIterator2 last2,
    BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
    class BinaryPredicate>
pair<ForwardIterator1, ForwardIterator2>
mismatch(ExecutionPolicy&& exec,
    ForwardIterator1 first1, ForwardIterator1 last1,
    ForwardIterator2 first2, ForwardIterator2 last2,
    BinaryPredicate pred);

1 Remarks: If last2 was not given in the argument list, it denotes first2 + (last1 - first1) below.

2 Returns: A pair of iterators first1 + n and first2 + n, where n is the smallest integer such that, respectively,
   — !(*(first1 + n) == *(first2 + n)) or
   — pred(*(first1 + n), *(first2 + n)) == false,
   or min(last1 - first1, last2 - first2) if no such integer exists.

3 Complexity: At most min(last1 - first1, last2 - first2) applications of the corresponding predicate.

28.5.11 Equal [alg.equal]

template<class InputIterator1, class InputIterator2>
bool equal(InputIterator1 first1, InputIterator1 last1,
    InputIterator2 first2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
bool equal(ExecutionPolicy&& exec,
    ForwardIterator1 first1, ForwardIterator1 last1,
    ForwardIterator2 first2);

template<class InputIterator1, class InputIterator2,
    class BinaryPredicate>
bool equal(InputIterator1 first1, InputIterator1 last1,
    InputIterator2 first2, BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
    class BinaryPredicate>
bool equal(ExecutionPolicy&& exec,
    ForwardIterator1 first1, ForwardIterator1 last1,
    ForwardIterator2 first2, BinaryPredicate pred);

template<class InputIterator1, class InputIterator2>
bool equal(InputIterator1 first1, InputIterator1 last1,
    InputIterator2 first2, InputIterator2 last2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
bool equal(ExecutionPolicy&& exec,
template<class InputIterator1, class InputIterator2, 
    class BinaryPredicate>
bool equal(InputIterator1 first1, InputIterator1 last1, 
    InputIterator2 first2, InputIterator2 last2, 
    BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, 
    class BinaryPredicate>
bool equal(ExecutionPolicy&& exec, 
    ForwardIterator1 first1, ForwardIterator1 last1, 
    ForwardIterator2 first2, ForwardIterator2 last2, 
    BinaryPredicate pred);

1 Remarks: If last2 was not given in the argument list, it denotes first2 + (last1 - first1) below.

2 Returns: If last1 - first1 != last2 - first2, return false. Otherwise return true if for every 
iterator i in the range [first1, last1) the following corresponding conditions hold: *i == *(first2 + (i - first1)), pred(*i, *(first2 + (i - first1))) != false. Otherwise, returns false.

3 Complexity:
(3.1) For the overloads with no ExecutionPolicy,
(3.1.1) if InputIterator1 and InputIterator2 meet the requirements of random access iterators (27.2.7) and last1 - first1 != last2 - first2, then no applications of the corresponding predicate; otherwise,
(3.1.2) at most min(last1 - first1, last2 - first2) applications of the corresponding predicate.
(3.2) For the overloads with no ExecutionPolicy,
(3.2.1) if ForwardIterator1 and ForwardIterator2 meet the requirements of random access iterators and last1 - first1 != last2 - first2, then no applications of the corresponding predicate; otherwise,
(3.2.2) O(min(last1 - first1, last2 - first2)) applications of the corresponding predicate.

28.5.12 Is permutation

template<class ForwardIterator1, class ForwardIterator2> 
bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1, 
    ForwardIterator2 first2);

template<class ForwardIterator1, class ForwardIterator2, 
    class BinaryPredicate>
bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1, 
    ForwardIterator2 first2, BinaryPredicate pred);

template<class ForwardIterator1, class ForwardIterator2> 
bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1, 
    ForwardIterator2 first2, ForwardIterator2 last2);

template<class ForwardIterator1, class ForwardIterator2, 
    class BinaryPredicate>
bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1, 
    ForwardIterator2 first2, ForwardIterator2 last2, 
    BinaryPredicate pred);

1 Requires: ForwardIterator1 and ForwardIterator2 shall have the same value type. The comparison 
function shall be an equivalence relation.
Remarks: If last2 was not given in the argument list, it denotes first2 + (last1 - first1) below.

Returns: If last1 - first1 != last2 - first2, return false. Otherwise return true if there exists a permutation of the elements in the range [first2, first2 + (last1 - first1)), beginning with ForwardIterator2 begin, such that equal(first1, last1, begin) returns true or equal(first1, last1, begin, pred) returns true; otherwise, returns false.

Complexity: No applications of the corresponding predicate if ForwardIterator1 and ForwardIterator2 meet the requirements of random access iterators and last1 - first1 != last2 - first2. Otherwise, exactly last1 - first1 applications of the corresponding predicate if equal(first1, last1, first2, last2) would return true if pred was not given in the argument list or equal(first1, last1, first2, last2, pred) would return true if pred was given in the argument list; otherwise, at worst $O(N^2)$, where $N$ has the value last1 - first1.

28.5.13 Search [alg.search]

```
template<class ForwardIterator1, class ForwardIterator2>
ForwardIterator1
search(ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator1
search(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2);

template<class ForwardIterator1, class ForwardIterator2,
class BinaryPredicate>
ForwardIterator1
search(ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2,
BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class BinaryPredicate>
ForwardIterator1
search(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2,
BinaryPredicate pred);
```

Effects: Finds a subsequence of equal values in a sequence.

Returns: The first iterator $i$ in the range [first1, last1 - (last2 - first2)) such that for every non-negative integer $n$ less than last2 - first2 the following corresponding conditions hold: *(i + n) == *(first2 + n), pred(*(i + n), *(first2 + n)) != false. Returns first1 if [first2, last2) is empty, otherwise returns last1 if no such iterator is found.

Complexity: At most $(last1 - first1) \times (last2 - first2)$ applications of the corresponding predicate.

```
template<class ForwardIterator, class Size, class T>
ForwardIterator
search_n(ForwardIterator first, ForwardIterator last, Size count,
const T& value);

template<class ForwardIterator, class Size, class T,
class BinaryPredicate>
```
ForwardIterator
search_n(ForwardIterator first, ForwardIterator last, Size count,
const T& value, BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator, class Size, class T>
ForwardIterator
search_n(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last,
Size count, const T& value);

template<class ExecutionPolicy, class ForwardIterator, class Size, class T,
class BinaryPredicate>
ForwardIterator
search_n(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last,
Size count, const T& value,
BinaryPredicate pred);

Requires: The type Size shall be convertible to integral type (7.8, 15.3).
Effects: Finds a subsequence of equal values in a sequence.
Returns: The first iterator \(i\) in the range \([\text{first}, \text{last} - \text{count})\) such that for every non-negative integer \(n\) less than \(\text{count}\) the following corresponding conditions hold: \(\ast(i + n) == \text{value}, \text{pred}(\ast(i + n), \text{value}) != \text{false}\). Returns \(\text{last}\) if no such iterator is found.
Complexity: At most \(\text{last} - \text{first}\) applications of the corresponding predicate.

template<class ForwardIterator, class Searcher>
ForwardIterator search(ForwardIterator first, ForwardIterator last,
const Searcher& searcher);

Effects: Equivalent to: return searcher(first, last).first;
Remarks: Searcher need not meet the CopyConstructible requirements.

28.6 Mutating sequence operations

28.6.1 Copy

template<class InputIterator, class OutputIterator>
OutputIterator copy(InputIterator first, InputIterator last,
OutputIterator result);

Requires: result shall not be in the range \([\text{first}, \text{last})\).
Effects: Copies elements in the range \([\text{first}, \text{last})\) into the range \([\text{result}, \text{result} + (\text{last} - \text{first}))\) starting from \text{first} and proceeding to \text{last}. For each non-negative integer \(n < (\text{last} - \text{first})\), performs \(\ast(\text{result} + n) = \ast(\text{first} + n)\).
Returns: \text{result} + (\text{last} - \text{first}).
Complexity: Exactly last - first assignments.

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2 copy(ExecutionPolicy&& policy,
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result);

Requires: The ranges \([\text{first}, \text{last})\) and \([\text{result}, \text{result} + (\text{last} - \text{first}))\) shall not overlap.
Effects: Copies elements in the range \([\text{first}, \text{last})\) into the range \([\text{result}, \text{result} + (\text{last} - \text{first}))\). For each non-negative integer \(n < (\text{last} - \text{first})\), performs \(\ast(\text{result} + n) = \ast(\text{first} + n)\).
Returns: \( \text{result} + (\text{last} - \text{first}) \).

**Complexity:** Exactly \( \text{last} - \text{first} \) assignments.

```cpp
template<class InputIterator, class Size, class OutputIterator>
OutputIterator copy_n(InputIterator first, Size n,
                       OutputIterator result);
``` 

**Effects:** For each non-negative integer \( i < n \), performs \(*(\text{result} + i) = *(\text{first} + i)\).

Returns: \( \text{result} + n \).

**Complexity:** Exactly \( n \) assignments.

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class Size, class ForwardIterator2>
ForwardIterator2 copy_n(ExecutionPolicy&& exec,
                         ForwardIterator1 first, Size n,
                         ForwardIterator2 result);
``` 

**Requires:** The ranges \([\text{first}, \text{last})\) and \([\text{result}, \text{result} + (\text{last} - \text{first}))\) shall not overlap.

**Note:** For the overload with an `ExecutionPolicy`, there may be a performance cost if `iterator_traits<ForwardIterator1>::value_type` is not `MoveConstructible` (Table 23). — end note]

**Effects:** Copies all of the elements referred to by the iterator \( i \) in the range \([\text{first}, \text{last})\) for which \( \text{pred}(\text{*i}) \) is true.

Returns: The end of the resulting range.

**Complexity:** Exactly \( \text{last} - \text{first} \) applications of the corresponding predicate.

**Remarks:** Stable (20.5.5.7).

```cpp
template<class BidirectionalIterator1, class BidirectionalIterator2>
BidirectionalIterator2
copy_backward(BidirectionalIterator1 first,
              BidirectionalIterator1 last,
              BidirectionalIterator2 result);
``` 

**Requires:** \( \text{result} \) shall not be in the range \([\text{first}, \text{last})\).

**Effects:** Copies elements in the range \([\text{first}, \text{last})\) into the range \([\text{result} - (\text{last} - \text{first}), \text{result})\) starting from \( \text{last} - 1 \) and proceeding to \( \text{first} \). For each positive integer \( n \leq (\text{last} - \text{first}) \), performs \(*(\text{result} - n) = *(\text{last} - n)\).

Returns: \( \text{result} - (\text{last} - \text{first}) \).

**Complexity:** Exactly \( \text{last} - \text{first} \) assignments.

### 28.6.2 Move

```cpp
template<class InputIterator, class OutputIterator>
OutputIterator move(InputIterator first, InputIterator last, OutputIterator result);
```        

263) `copy_backward` should be used instead of `copy` when \( \text{last} \) is in the range \([\text{result} - (\text{last} - \text{first}), \text{result})\).
Requires: `result` shall not be in the range `[first, last)
Effects: Moves elements in the range `[first, last)` into the range `[result, result + (last - first))` starting from `first` and proceeding to `last`. For each non-negative integer `n < (last - first)`, performs `*(result + n) = std::move(* (first + n)).
Returns: `result + (last - first)`.
Complexity: Exactly last - first move assignments.

```
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2 move(ExecutionPolicy&& policy,
  ForwardIterator1 first, ForwardIterator1 last,
  ForwardIterator2 result);
```

Requires: The ranges `[first, last)` and `[result, result + (last - first))` shall not overlap.
Effects: Moves elements in the range `[first, last)` into the range `[result, result + (last - first))`. For each non-negative integer `n < (last - first)`, performs `*(result + n) = std::move(* (first + n)).
Returns: `result + (last - first)`.
Complexity: Exactly last - first assignments.

```
template<class BidirectionalIterator1, class BidirectionalIterator2>
BidirectionalIterator2 move_backward(BidirectionalIterator1 first,
  BidirectionalIterator1 last,
  BidirectionalIterator2 result);
```

Requires: `result` shall not be in the range `(first, last].
Effects: Moves elements in the range `[first, last)` into the range `[result - (last - first), result)` starting from `last - 1` and proceeding to `first`. For each positive integer `n <= (last - first)`, performs `*(result - n) = std::move(* (last - n)).
Returns: `result - (last - first)`.
Complexity: Exactly last - first assignments.

### 28.6.3 Swap

```
template<class ForwardIterator1, class ForwardIterator2>
ForwardIterator2 swap_ranges(ForwardIterator1 first1, ForwardIterator1 last1,
  ForwardIterator2 first2);
```

```
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2 swap_ranges(ExecutionPolicy&& exec,
  ForwardIterator1 first1, ForwardIterator1 last1,
  ForwardIterator2 first2);
```

Requires: The two ranges `[first1, last1)` and `[first2, first2 + (last1 - first1))` shall not overlap. `*(first1 + n)` shall be swappable with `(20.5.3.2) *(first2 + n).
Effects: For each non-negative integer `n < (last1 - first1)` performs: `swap(*(first1 + n), *(first2 + n)).
Returns: `first2 + (last1 - first1)`.

---

264) `move_backward` should be used instead of `move` when `last` is in the range `[result - (last - first), result).`
Complexity: Exactly last1 - first1 swaps.

template<class ForwardIterator1, class ForwardIterator2>
void iter_swap(ForwardIterator1 a, ForwardIterator2 b);

Requires: a and b shall be dereferenceable. *a shall be swappable with (20.5.3.2) *b.

Effects: As if by swap(*a, *b).

28.6.4 Transform

```cpp
template<class InputIterator, class OutputIterator,
    class UnaryOperation>
        OutputIterator
    transform(InputIterator first, InputIterator last,
        OutputIterator result, UnaryOperation op);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
    class UnaryOperation>
        ForwardIterator2
    transform(ExecutionPolicy& exec,
        ForwardIterator1 first, ForwardIterator1 last,
        ForwardIterator2 result, UnaryOperation op);

template<class InputIterator1, class InputIterator2,
    class OutputIterator, class BinaryOperation>
        OutputIterator
    transform(InputIterator1 first1, InputIterator1 last1,
        InputIterator2 first2, OutputIterator result,
        BinaryOperation binary_op);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
    class ForwardIterator, class BinaryOperation>
        ForwardIterator
    transform(ExecutionPolicy& exec,
        ForwardIterator1 first1, ForwardIterator1 last1,
        ForwardIterator2 first2, ForwardIterator result,
        BinaryOperation binary_op);
```

Requires: op and binary_op shall not invalidate iterators or subranges, or modify elements in the ranges

(1.1) — [first1, last1],

(1.2) — [first2, first2 + (last1 - first1)], and

(1.3) — [result, result + (last1 - first1)].

Effects: Assigns through every iterator i in the range [result, result + (last1 - first1)) a new corresponding value equal to op(*(first1 + (i - result))) or binary_op(*(first1 + (i - result))), *(first2 + (i - result))).

Returns: result + (last1 - first1).

Complexity: Exactly last1 - first1 applications of op or binary_op. This requirement also applies to the overload with an ExecutionPolicy.

Remarks: result may be equal to first in case of unary transform, or to first1 or first2 in case of binary transform.

28.6.5 Replace

[alg.replace]

The use of fully closed ranges is intentional.

§ 28.6.5
template<class ForwardIterator, class T>
void replace(ForwardIterator first, ForwardIterator last,
const T& old_value, const T& new_value);

template<class ExecutionPolicy, class ForwardIterator, class T>
void replace(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last,
const T& old_value, const T& new_value);

template<class ForwardIterator, class Predicate, class T>
void replace_if(ForwardIterator first, ForwardIterator last,
Predicate pred, const T& new_value);

template<class ExecutionPolicy, class ForwardIterator, class Predicate, class T>
void replace_if(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last,
Predicate pred, const T& new_value);

1 Requires: The expression *first = new_value shall be valid.

2 Effects: Substitutes elements referred by the iterator i in the range [first, last) with new_value, when the following corresponding conditions hold: *i == old_value, pred(*i) != false.

3 Complexity: Exactly last - first applications of the corresponding predicate.

template<class InputIterator, class OutputIterator, class T>
OutputIterator
replace_copy(InputIterator first, InputIterator last,
OutputIterator result,
const T& old_value, const T& new_value);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class T>
ForwardIterator2
replace_copy(ExecutionPolicy&& exec,
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result,
const T& old_value, const T& new_value);

4 Requires: The results of the expressions *first and new_value shall be writable (27.2.1) to the result output iterator. The ranges [first, last) and [result, result + (last - first)) shall not overlap.

5 Effects: Assigns to every iterator i in the range [result, result + (last - first)) either new_value or *(first + (i - result)) depending on whether the following corresponding conditions hold:
   *(first + (i - result)) == old_value
   pred(*(first + (i - result))) != false
Returns: \( \text{result} + (\text{last} - \text{first}) \).

Complexity: Exactly \( \text{last} - \text{first} \) applications of the corresponding predicate.

### 28.6.6 Fill

**template< class ForwardIterator, class T >**

```cpp
void fill(ForwardIterator first, ForwardIterator last, const T& value);
```

**template< class ExecutionPolicy, class ForwardIterator, class T >**

```cpp
void fill(ExecutionPolicy&& exec,
          ForwardIterator first, ForwardIterator last, const T& value);
```

**template< class OutputIterator, class Size, class T >**

```cpp
OutputIterator fill_n(OutputIterator first, Size n, const T& value);
```

**template< class ExecutionPolicy, class ForwardIterator, class Size, class T >**

```cpp
ForwardIterator fill_n(ExecutionPolicy&& exec,
                       ForwardIterator first, Size n, const T& value);
```

**Requires:** The expression \( \text{value} \) shall be writable (27.2.1) to the output iterator. The type \( \text{Size} \) shall be convertible to an integral type (7.8, 15.3).

**Effects:** The \( \text{fill} \) algorithms assign \( \text{value} \) through all the iterators in the range \([\text{first}, \text{last})\). The \( \text{fill}_n \) algorithms assign \( \text{value} \) through all the iterators in the range \([\text{first}, \text{first} + \text{n})\) if \( \text{n} \) is positive, otherwise they do nothing.

**Returns:** \( \text{fill}_n \) returns \( \text{first} + \text{n} \) for non-negative values of \( \text{n} \) and \( \text{first} \) for negative values.

**Complexity:** Exactly \( \text{last} - \text{first}, \text{n}, \) or 0 assignments, respectively.

### 28.6.7 Generate

**template< class ForwardIterator, class Generator >**

```cpp
void generate(ForwardIterator first, ForwardIterator last, Generator gen);
```

**template< class ExecutionPolicy, class ForwardIterator, class Generator >**

```cpp
void generate(ExecutionPolicy&& exec,
              ForwardIterator first, ForwardIterator last, Generator gen);
```

**template< class OutputIterator, class Size, class Generator >**

```cpp
OutputIterator generate_n(OutputIterator first, Size n, Generator gen);
```

**template< class ExecutionPolicy, class ForwardIterator, class Size, class Generator >**

```cpp
ForwardIterator generate_n(ExecutionPolicy&& exec,
                           ForwardIterator first, Size n, Generator gen);
```

**Requires:** \( \text{gen} \) takes no arguments, \( \text{Size} \) shall be convertible to an integral type (7.8, 15.3).

**Effects:** The \( \text{generate} \) algorithms invoke the function object \( \text{gen} \) and assign the return value of \( \text{gen} \) through all the iterators in the range \([\text{first}, \text{last})\). The \( \text{generate}_n \) algorithms invoke the function object \( \text{gen} \) and assign the return value of \( \text{gen} \) through all the iterators in the range \([\text{first}, \text{first} + \text{n})\) if \( \text{n} \) is positive, otherwise they do nothing.

**Returns:** \( \text{generate}_n \) returns \( \text{first} + \text{n} \) for non-negative values of \( \text{n} \) and \( \text{first} \) for negative values.

**Complexity:** Exactly \( \text{last} - \text{first}, \text{n}, \) or 0 invocations of \( \text{gen} \) and assignments, respectively.

### 28.6.8 Remove

**template< class ForwardIterator, class T >**

```cpp
ForwardIterator remove(ForwardIterator first, ForwardIterator last, T);
```
const T& value);

template<class ExecutionPolicy, class ForwardIterator, class T>
ForwardIterator remove(ExecutionPolicy&& exec,
                        ForwardIterator first, ForwardIterator last,
                        const T& value);

template<class ForwardIterator, class Predicate>
ForwardIterator remove_if(ForwardIterator first, ForwardIterator last,
                          Predicate pred);

template<class ExecutionPolicy, class ForwardIterator, class Predicate>
ForwardIterator remove_if(ExecutionPolicy&& exec,
                          ForwardIterator first, ForwardIterator last,
                          Predicate pred);

Requires: The type of *first shall satisfy the MoveAssignable requirements (Table 25).

Effects: Eliminates all the elements referred to by iterator i in the range [first, last) for which the following corresponding conditions hold: *i == value, pred(*i) != false.

Returns: The end of the resulting range.

Remarks: Stable (20.5.5.7).

Complexity: Exactly last - first applications of the corresponding predicate.

[Note: Each element in the range [ret, last), where ret is the returned value, has a valid but unspecified state, because the algorithms can eliminate elements by moving from elements that were originally in that range. —end note]

template<class InputIterator, class OutputIterator, class T>
OutputIterator
    remove_copy(InputIterator first, InputIterator last,
                OutputIterator result, const T& value);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class T>
ForwardIterator2
    remove_copy(ExecutionPolicy&& exec,
                ForwardIterator1 first, ForwardIterator1 last,
                ForwardIterator2 result, const T& value);

Requires: The ranges [first, last) and [result, result + (last - first)) shall not overlap. The expression *result = *first shall be valid. [Note: For the overloads with an ExecutionPolicy, there may be a performance cost if iterator_traits<ForwardIterator1>::value_type is not MoveConstructible (Table 23). —end note]

Effects: Copies all the elements referred to by the iterator i in the range [first, last) for which the following corresponding conditions do not hold: *i == value, pred(*i) != false.

Returns: The end of the resulting range.

Complexity: Exactly last - first applications of the corresponding predicate.
Remarks: Stable (20.5.5.7).

28.6.9 Unique

[alg.unique]

```
template<class ForwardIterator>
  ForwardIterator unique(ForwardIterator first, ForwardIterator last);
template<class ExecutionPolicy, class ForwardIterator>
  ForwardIterator unique(ExecutionPolicy&& exec, 
                          ForwardIterator first, ForwardIterator last);

template<class ForwardIterator, class BinaryPredicate>
  ForwardIterator unique(ForwardIterator first, ForwardIterator last, 
                         BinaryPredicate pred);
template<class ExecutionPolicy, class ForwardIterator, class BinaryPredicate>
  ForwardIterator unique(ExecutionPolicy&& exec, 
                         ForwardIterator first, ForwardIterator last, 
                         BinaryPredicate pred);
```

1 Requires: The comparison function shall be an equivalence relation. The type of *first shall satisfy 
the MoveAssignable requirements (Table 25).

2 Effects: For a nonempty range, eliminates all but the first element from every consecutive group 
of equivalent elements referred to by the iterator i in the range [first + 1, last) for which the 
following conditions hold: *(i - 1) == *i or pred(*(i - 1), *i) != false.

3 Returns: The end of the resulting range.

4 Complexity: For nonempty ranges, exactly (last - first) - 1 applications of the corresponding 
predicate.

```
template<class InputIterator, class OutputIterator>
  OutputIterator unique_copy(InputIterator first, InputIterator last, 
                            OutputIterator result);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
  ForwardIterator2 unique_copy(ExecutionPolicy&& exec, 
                              ForwardIterator1 first, ForwardIterator1 last, 
                              ForwardIterator2 result);

template<class InputIterator, class OutputIterator, 
          class BinaryPredicate>
  OutputIterator unique_copy(InputIterator first, InputIterator last, 
                            OutputIterator result, BinaryPredicate pred);
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, 
          class BinaryPredicate>
  ForwardIterator2 unique_copy(ExecutionPolicy&& exec, 
                              ForwardIterator1 first, ForwardIterator1 last, 
                              ForwardIterator2 result, BinaryPredicate pred);
```

5 Requires: 

(5.1) The comparison function shall be an equivalence relation.
(5.2) The ranges [first, last) and [result, result+(last-first)) shall not overlap.
(5.3) The expression *result = *first shall be valid.
For the overloads with no `ExecutionPolicy`, let \( T \) be the value type of `InputIterator`. If `InputIterator` meets the forward iterator requirements, then there are no additional requirements for \( T \). Otherwise, if `OutputIterator` meets the forward iterator requirements and its value type is the same as \( T \), then \( T \) shall be `CopyAssignable` (Table 26). Otherwise, \( T \) shall be both `CopyConstructible` (Table 24) and `CopyAssignable`. [Note: For the overloads with an `ExecutionPolicy`, there may be a performance cost if the value type of `ForwardIterator1` is not both `CopyConstructible` and `CopyAssignable`. — end note]

**Effects:**
Copies only the first element from every consecutive group of equal elements referred to by the iterator \( i \) in the range \([\text{first}, \text{last})\) for which the following corresponding conditions hold: \( *i == *(i - 1) \) or \( \text{pred}(*i, *(i - 1)) \neq \text{false} \).

**Returns:** The end of the resulting range.

**Complexity:** For nonempty ranges, exactly \( \text{last} - \text{first} - 1 \) applications of the corresponding predicate.

### 28.6.10 Reverse

```cpp
#include <algorithm>

template<class BidirectionalIterator>
void reverse(BidirectionalIterator first, BidirectionalIterator last);

template<class ExecutionPolicy, class BidirectionalIterator>
void reverse(ExecutionPolicy&& exec, BidirectionalIterator first, BidirectionalIterator last);
```

**Requires:** \( *\text{first} \) shall be swappable (20.5.3.2).

**Effects:** For each non-negative integer \( i < (\text{last} - \text{first}) / 2 \), applies `iter_swap` to all pairs of iterators \( \text{first} + i, (\text{last} - i) - 1 \).

**Requires:** `BidirectionalIterator` shall satisfy the requirements of `ValueSwappable` (20.5.3.2).

**Complexity:** Exactly \( (\text{last} - \text{first})/2 \) swaps.

```cpp
#include <algorithm>

template<class BidirectionalIterator, class OutputIterator>
OutputIterator reverse_copy(BidirectionalIterator first, BidirectionalIterator last, OutputIterator result);

template<class ExecutionPolicy, class BidirectionalIterator, class ForwardIterator>
ForwardIterator reverse_copy(ExecutionPolicy&& exec, BidirectionalIterator first, BidirectionalIterator last, ForwardIterator result);
```

**Requires:** The ranges \([\text{first}, \text{last})\) and \([\text{result}, \text{result} + (\text{last} - \text{first}))\) shall not overlap.

**Effects:** Copies the range \([\text{first}, \text{last})\) to the range \([\text{result}, \text{result} + (\text{last} - \text{first}))\) such that for every non-negative integer \( i < (\text{last} - \text{first}) \) the following assignment takes place: \( *(\text{result} + (\text{last} - \text{first}) - 1 - i) = *(\text{first} + i) \).

**Returns:** \( \text{result} + (\text{last} - \text{first}) \).

**Complexity:** Exactly \( \text{last} - \text{first} \) assignments.

### 28.6.11 Rotate

```cpp
#include <algorithm>

template<class ForwardIterator>
ForwardIterator rotate(ForwardIterator first, ForwardIterator middle, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator rotate(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator middle, ForwardIterator last);
```
rotate(ExecutionPolicy&& exec, 
    ForwardIterator first, ForwardIterator middle, ForwardIterator last);

1 Requires: [first, middle) and [middle, last) shall be valid ranges. ForwardIterator shall satisfy the requirements of ValueSwappable (20.5.3.2). The type of *first shall satisfy the requirements of MoveConstructible (Table 23) and the requirements of MoveAssignable (Table 25).

2 Effects: For each non-negative integer i < (last - first), places the element from the position first + i into position first + (i + (last - middle)) % (last - first).

3 Returns: first + (last - middle).

4 Remarks: This is a left rotate.

5 Complexity: At most last - first swaps.

template<class ForwardIterator, class OutputIterator>
OutputIterator 
rotate_copy(ForwardIterator first, ForwardIterator middle, ForwardIterator last, 
OutputIterator result);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2 
rotate_copy(ExecutionPolicy&& exec, 
    ForwardIterator1 first, ForwardIterator1 middle, ForwardIterator1 last, 
    ForwardIterator2 result);

6 Requires: The ranges [first, last) and [result, result + (last - first)) shall not overlap.

7 Effects: Copies the range [first, last) to the range [result, result + (last - first)) such that for each non-negative integer i < (last - first) the following assignment takes place: *(result + i) = *(first + (i + (middle - first)) % (last - first)).

8 Returns: result + (last - first).

9 Complexity: Exactly last - first assignments.

28.6.12 Sample

template<class PopulationIterator, class SampleIterator, 
class Distance, class UniformRandomBitGenerator>
SampleIterator sample(PopulationIterator first, PopulationIterator last, 
SampleIterator out, Distance n, 
UniformRandomBitGenerator&& g);

1 Requires:

(1.1) — PopulationIterator shall satisfy the requirements of an input iterator (27.2.3).

(1.2) — SampleIterator shall satisfy the requirements of an output iterator (27.2.4).

(1.3) — SampleIterator shall satisfy the additional requirements of a random access iterator (27.2.7) unless PopulationIterator satisfies the additional requirements of a forward iterator (27.2.5).

(1.4) — PopulationIterator's value type shall be writable (27.2.1) to out.

(1.5) — Distance shall be an integer type.

(1.6) — remove_reference_t<UniformRandomBitGenerator> shall meet the requirements of a uniform random bit generator type (29.6.1.3) whose return type is convertible to Distance.

(1.7) — out shall not be in the range [first, last).

2 Effects: Copies min(last - first, n) elements (the sample) from [first, last) (the population) to out such that each possible sample has equal probability of appearance. [Note: Algorithms that
obtain such effects include selection sampling and reservoir sampling. — end note]

Returns: The end of the resulting sample range.

Complexity: $O(last - first)$.

Remarks:

(5.1) — Stable if and only if PopulationIterator satisfies the requirements of a forward iterator.

(5.2) — To the extent that the implementation of this function makes use of random numbers, the object g shall serve as the implementation’s source of randomness.

28.6.13 Shuffle [alg.random.shuffle]

```cpp
template<class RandomAccessIterator, class UniformRandomBitGenerator>
void shuffle(RandomAccessIterator first,
             RandomAccessIterator last,
             UniformRandomBitGenerator&& g);
```

Requires: RandomAccessIterator shall satisfy the requirements of ValueSwappable (20.5.3.2). The type `remove_reference_t<UniformRandomBitGenerator>` shall meet the requirements of a uniform random bit generator (29.6.1.3) type whose return type is convertible to `iterator_traits<RandomAccessIterator>::difference_type`.

Effects: Permutes the elements in the range `[first, last)` such that each possible permutation of those elements has equal probability of appearance.

Complexity: Exactly $(last - first) - 1$ swaps.

Remarks: To the extent that the implementation of this function makes use of random numbers, the object g shall serve as the implementation’s source of randomness.

28.7 Sorting and related operations [alg.sorting]

All the operations in 28.7 have two versions: one that takes a function object of type Compare and one that uses an operator<.

Compare is a function object type (23.14). The return value of the function call operation applied to an object of type Compare, when contextually converted to bool (Clause 7), yields true if the first argument of the call is less than the second, and false otherwise. Compare comp is used throughout for algorithms assuming an ordering relation. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.

For all algorithms that take Compare, there is a version that uses operator< instead. That is, `comp(*i, *j) != false` defaults to `*i < *j != false`. For algorithms other than those described in 28.7.3, comp shall induce a strict weak ordering on the values.

The term strict refers to the requirement of an irreflexive relation (!comp(x, x) for all x), and the term weak to requirements that are not as strong as those for a total ordering, but stronger than those for a partial ordering. If we define equiv(a, b) as !comp(a, b) && !comp(b, a), then the requirements are that comp and equiv both be transitive relations:

(4.1) — comp(a, b) && comp(b, c) implies comp(a, c)

(4.2) — equiv(a, b) && equiv(b, c) implies equiv(a, c)

[Note: Under these conditions, it can be shown that

(4.3) — equiv is an equivalence relation

(4.4) — comp induces a well-defined relation on the equivalence classes determined by equiv

(4.5) — The induced relation is a strict total ordering.

§ 28.7
A sequence is sorted with respect to a comparator \texttt{comp} if for every iterator \texttt{i} pointing to the sequence and every non-negative integer \texttt{n} such that \texttt{i} + \texttt{n} is a valid iterator pointing to an element of the sequence, \texttt{comp}(*\texttt{i} + \texttt{n}, *\texttt{i}) == false.

A sequence \([\texttt{start}, \texttt{finish})\) is partitioned with respect to an expression \(\texttt{f(e)}\) if there exists an integer \texttt{n} such that for all \(0 \leq i < (\texttt{finish} - \texttt{start})\), \(\texttt{f(\texttt{start} + i)}\) is true if and only if \(i < \texttt{n}\).

In the descriptions of the functions that deal with ordering relationships we frequently use a notion of equivalence to describe concepts such as stability. The equivalence to which we refer is not necessarily an \texttt{operator==}, but an equivalence relation induced by the strict weak ordering. That is, two elements \(\texttt{a}\) and \(\texttt{b}\) are considered equivalent if and only if \(! (\texttt{a < b}) \wedge \neg (\texttt{b < a}).\)

### 28.7.1 Sorting

#### 28.7.1.1 sort

```cpp
template<class RandomAccessIterator>
void sort(RandomAccessIterator first, RandomAccessIterator last);

template<class ExecutionPolicy, class RandomAccessIterator>
void sort(ExecutionPolicy&& exec,
          RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
void sort(RandomAccessIterator first, RandomAccessIterator last,
          Compare comp);

template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
void sort(ExecutionPolicy&& exec,
          RandomAccessIterator first, RandomAccessIterator last,
          Compare comp);
```

1. **Requires:** \texttt{RandomAccessIterator} shall satisfy the requirements of \texttt{ValueSwappable} (20.5.3.2). The type of \texttt{*first} shall satisfy the requirements of \texttt{MoveConstructible} (Table 23) and of \texttt{MoveAssignable} (Table 25).

2. **Effects:** Sorts the elements in the range \([\texttt{first}, \texttt{last})\).

3. **Complexity:** \(O(N \log N)\) comparisons, where \(N = \texttt{last} - \texttt{first}\).

#### 28.7.1.2 stable_sort

```cpp
template<class RandomAccessIterator>
void stable_sort(RandomAccessIterator first, RandomAccessIterator last);

template<class ExecutionPolicy, class RandomAccessIterator>
void stable_sort(ExecutionPolicy&& exec,
                 RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
void stable_sort(RandomAccessIterator first, RandomAccessIterator last,
                 Compare comp);

template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
void stable_sort(ExecutionPolicy&& exec,
                 RandomAccessIterator first, RandomAccessIterator last,
                 Compare comp);
```

1. **Requires:** \texttt{RandomAccessIterator} shall satisfy the requirements of \texttt{ValueSwappable} (20.5.3.2). The type of \texttt{*first} shall satisfy the requirements of \texttt{MoveConstructible} (Table 23) and of \texttt{MoveAssignable} (Table 25).
Effects: Sorts the elements in the range \([\textit{first}, \textit{last})\).

Complexity: At most \(N \log^2(N)\) comparisons, where \(N = \textit{last} - \textit{first}\), but only \(N \log N\) comparisons if there is enough extra memory.

Remarks: Stable (20.5.5.7).

28.7.1.3 \texttt{partial_sort} \[\texttt{partial.sort}\]

\begin{verbatim}
template<class RandomAccessIterator>
void partial_sort(RandomAccessIterator first,
                 RandomAccessIterator middle,
                 RandomAccessIterator last);

template<class ExecutionPolicy, class RandomAccessIterator>
void partial_sort(ExecutionPolicy&& exec,
                 RandomAccessIterator first,
                 RandomAccessIterator middle,
                 RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
void partial_sort(RandomAccessIterator first,
                 RandomAccessIterator middle,
                 RandomAccessIterator last,
                 Compare comp);

template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
void partial_sort(ExecutionPolicy&& exec,
                 RandomAccessIterator first,
                 RandomAccessIterator middle,
                 RandomAccessIterator last,
                 Compare comp);
\end{verbatim}

Requires: \texttt{RandomAccessIterator} shall satisfy the requirements of \texttt{ValueSwappable} (20.5.3.2). The type of \*\textit{first} shall satisfy the requirements of \texttt{MoveConstructible} (Table 23) and of \texttt{MoveAssignable} (Table 25).

Effects: Places the first \(\textit{middle} - \textit{first}\) sorted elements from the range \([\textit{first}, \textit{last})\) into the range \([\textit{first}, \textit{middle})\). The rest of the elements in the range \([\textit{middle}, \textit{last})\) are placed in an unspecified order.

Complexity: Approximately \((\textit{last} - \textit{first}) \times \log(\textit{middle} - \textit{first})\) comparisons.

28.7.1.4 \texttt{partial_sort_copy} \[\texttt{partial.sort.copy}\]

\begin{verbatim}
template<class InputIterator, class RandomAccessIterator>
RandomAccessIterator
partial_sort_copy(InputIterator first, InputIterator last,
                 RandomAccessIterator result_first,
                 RandomAccessIterator result_last);

template<class ExecutionPolicy, class ForwardIterator, class RandomAccessIterator>
RandomAccessIterator
partial_sort_copy(ExecutionPolicy&& exec,
                 ForwardIterator first, ForwardIterator last,
                 RandomAccessIterator result_first,
                 RandomAccessIterator result_last);

template<class InputIterator, class RandomAccessIterator, class Compare>
RandomAccessIterator
\end{verbatim}

§ 28.7.1.4 1032
partial_sort_copy(InputIterator first, InputIterator last,
    RandomAccessIterator result_first,
    RandomAccessIterator result_last,
    Compare comp);

template<class ExecutionPolicy, class ForwardIterator, class RandomAccessIterator,
    class Compare>
RandomAccessIterator
partial_sort_copy(ExecutionPolicy&& exec,
    ForwardIterator first, ForwardIterator last,
    RandomAccessIterator result_first,
    RandomAccessIterator result_last,
    Compare comp);

Requires: RandomAccessIterator shall satisfy the requirements of ValueSwappable (20.5.3.2). The type of *result_first shall satisfy the requirements of MoveConstructible (Table 23) and of MoveAssignable (Table 25).

Effects: Places the first min(last - first, result_last - result_first) sorted elements into the range [result_first, result_first + min(last - first, result_last - result_first)).

Returns: The smaller of: result_last or result_first + (last - first).

Complexity: Approximately (last - first) * log(min(last - first, result_last - result_first)) comparisons.

28.7.1.5 is_sorted

template<class ForwardIterator>
bool is_sorted(ForwardIterator first, ForwardIterator last);

Returns: is_sorted_until(first, last) == last

template<class ExecutionPolicy, class ForwardIterator>
bool is_sorted(ExecutionPolicy&& exec,
    ForwardIterator first, ForwardIterator last);

Returns: is_sorted_until(std::forward<ExecutionPolicy>(exec), first, last) == last

template<class ForwardIterator, class Compare>
bool is_sorted(ForwardIterator first, ForwardIterator last,
    Compare comp);

Returns: is_sorted_until(first, last, comp) == last

template<class ExecutionPolicy, class ForwardIterator, class Compare>
bool is_sorted(ExecutionPolicy&& exec,
    ForwardIterator first, ForwardIterator last,
    Compare comp);

Returns: is_sorted_until(std::forward<ExecutionPolicy>(exec), first, last, comp) == last

template<class ForwardIterator>
ForwardIterator is_sorted_until(ForwardIterator first, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator is_sorted_until(ExecutionPolicy&& exec,
    ForwardIterator first, ForwardIterator last);

template<class ForwardIterator, class Compare>
ForwardIterator is_sorted_until(ForwardIterator first, ForwardIterator last,
template<class ExecutionPolicy, class ForwardIterator, class Compare>
ForwardIterator is_sorted_until(ExecutionPolicy&& exec,
                              ForwardIterator first, ForwardIterator last,
                              Compare comp);

Returns: If (last - first) < 2, returns last. Otherwise, returns the last iterator i in [first, last] for which the range [first, i) is sorted.

Complexity: Linear.

28.7.2 Nth element

template<class RandomAccessIterator>
void nth_element(RandomAccessIterator first, RandomAccessIterator nth,
                 RandomAccessIterator last);

template<class ExecutionPolicy, class RandomAccessIterator>
void nth_element(ExecutionPolicy&& exec,
                 RandomAccessIterator first, RandomAccessIterator nth,
                 RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
void nth_element(RandomAccessIterator first, RandomAccessIterator nth,
                 RandomAccessIterator last, Compare comp);

template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
void nth_element(ExecutionPolicy&& exec,
                 RandomAccessIterator first, RandomAccessIterator nth,
                 RandomAccessIterator last, Compare comp);

Requires: RandomAccessIterator shall satisfy the requirements of ValueSwappable (20.5.3.2). The type of *first shall satisfy the requirements of MoveConstructible (Table 23) and of MoveAssignable (Table 25).

Effects: After nth_element the element in the position pointed to by nth is the element that would be in that position if the whole range were sorted, unless nth == last. Also for every iterator i in the range [first, nth) and every iterator j in the range [nth, last) it holds that: !(j < i) or comp(*j, *i) == false.

Complexity: For the overloads with no ExecutionPolicy, linear on average. For the overloads with an ExecutionPolicy, \(O(N)\) applications of the predicate, and \(O(N \log N)\) swaps, where \(N = \text{last} - \text{first}\).

28.7.3 Binary search

All of the algorithms in this section are versions of binary search and assume that the sequence being searched is partitioned with respect to an expression formed by binding the search key to an argument of the implied or explicit comparison function. They work on non-random access iterators minimizing the number of comparisons, which will be logarithmic for all types of iterators. They are especially appropriate for random access iterators, because these algorithms do a logarithmic number of steps through the data structure. For non-random access iterators they execute a linear number of steps.

28.7.3.1 lower_bound

template<class ForwardIterator, class T>
ForwardIterator lower_bound(ForwardIterator first, ForwardIterator last,
                           const T& value);
template<class ForwardIterator, class T, class Compare>
  ForwardIterator
  lower_bound(ForwardIterator first, ForwardIterator last,
              const T& value, Compare comp);

  Requires: The elements e of [first, last) shall be partitioned with respect to the expression e < value or comp(e, value).

  Returns: The furthermost iterator i in the range [first, last] such that for every iterator j in the range [first, i) the following corresponding conditions hold: *j < value or comp(*j, value) != false.

  Complexity: At most log₂(last - first) + O(1) comparisons.

28.7.3.2 upper_bound

template<class ForwardIterator, class T>
  ForwardIterator
  upper_bound(ForwardIterator first, ForwardIterator last,
              const T& value);

template<class ForwardIterator, class T, class Compare>
  ForwardIterator
  upper_bound(ForwardIterator first, ForwardIterator last,
              const T& value, Compare comp);

  Requires: The elements e of [first, last) shall be partitioned with respect to the expression !(value < e) or !comp(value, e).

  Returns: The furthermost iterator i in the range [first, last] such that for every iterator j in the range [first, i) the following corresponding conditions hold: !(value < *j) or comp(value, *j) == false.

  Complexity: At most log₂(last - first) + O(1) comparisons.

28.7.3.3 equal_range

template<class ForwardIterator, class T>
  pair<ForwardIterator, ForwardIterator>
  equal_range(ForwardIterator first, ForwardIterator last, const T& value);

template<class ForwardIterator, class T, class Compare>
  pair<ForwardIterator, ForwardIterator>
  equal_range(ForwardIterator first, ForwardIterator last, const T& value, Compare comp);

  Requires: The elements e of [first, last) shall be partitioned with respect to the expressions e < value and !(value < e) or comp(e, value) and !comp(value, e). Also, for all elements e of [first, last), e < value shall imply !(value < e) or comp(e, value) shall imply !comp(value, e).

  Returns:
    make_pair(lower_bound(first, last, value),
              upper_bound(first, last, value))
    or
    make_pair(lower_bound(first, last, value, comp),
              upper_bound(first, last, value, comp),

  Complexity: At most log₂(last - first) + O(1) comparisons.
upper_bound(first, last, value, comp)

3

Complexity: At most \(2 \times \log_2(last - first) + \mathcal{O}(1)\) comparisons.

28.7.3.4 binary_search

[binary.search]

template<class ForwardIterator, class T>
bool binary_search(ForwardIterator first, ForwardIterator last, const T& value);

template<class ForwardIterator, class T, class Compare>
bool binary_search(ForwardIterator first, ForwardIterator last, const T& value, Compare comp);

1

Requires: The elements \(e\) of \([first, last)\) are partitioned with respect to the expressions \(e < value\) and !\((value < e)\) or \(\text{comp}(e, value)\) and \(!\text{comp}(value, e)\). Also, for all elements \(e\) of \([first, last)\), \(e < value\) implies !\((value < e)\) or \(\text{comp}(e, value)\) implies \(!\text{comp}(value, e)\).

2

Returns: true if there is an iterator \(i\) in the range \([first, last)\) that satisfies the corresponding conditions: !(\(*i < value\)) && !\((value < *i)\) or \(\text{comp}(*i, value) == false \&\& \text{comp}(value, *i) == false\).

3

Complexity: At most \(\log_2(last - first) + \mathcal{O}(1)\) comparisons.

28.7.4 Partitions

[alg.partitions]

template <class InputIterator, class Predicate>
bool is_partitioned(InputIterator first, InputIterator last, Predicate pred);

template <class ExecutionPolicy, class ForwardIterator, class Predicate>
bool is_partitioned(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, Predicate pred);

1

Requires: For the overload with no ExecutionPolicy, InputIterator’s value type shall be convertible to Predicate’s argument type. For the overload with an ExecutionPolicy, ForwardIterator’s value type shall be convertible to Predicate’s argument type.

2

Returns: true if \([first, last)\) is empty or if \([first, last)\) is partitioned by \(\text{pred}\), i.e. if all elements that satisfy \(\text{pred}\) appear before those that do not.

3

Complexity: Linear. At most \(last - first\) applications of \(\text{pred}\).

template<class ForwardIterator, class Predicate>
ForwardIterator
partition(ForwardIterator first, ForwardIterator last, Predicate pred);

template<class ExecutionPolicy, class ForwardIterator, class Predicate>
ForwardIterator
partition(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, Predicate pred);

4

Requires: ForwardIterator shall satisfy the requirements of ValueSwappable (20.5.3.2).

5

Effects: Places all the elements in the range \([first, last)\) that satisfy \(\text{pred}\) before all the elements that do not satisfy it.

6

Returns: An iterator \(i\) such that for every iterator \(j\) in the range \([first, i)\) \(\text{pred}(*j) == false\), and for every iterator \(k\) in the range \([i, last)\), \(\text{pred}(*k) == false\).

7

Complexity: Let \(N = last - first\):

— For the overload with no ExecutionPolicy, exactly \(N\) applications of the predicate. At most \(N/2\) swaps if ForwardIterator meets the BidirectionalIterator requirements and at most \(N\)
swaps otherwise.

(7.2) --- For the overload with an ExecutionPolicy, \( O(N \log N) \) swaps and \( O(N) \) applications of the predicate.

\[
\text{template}<\text{class BidirectionalIterator, class Predicate}>
\begin{align*}
\text{BidirectionalIterator} \\
\text{stable_partition(BidirectionalIterator first, BidirectionalIterator last,} \\
\text{Predicate pred);}
\end{align*}
\]

8 Requires: BidirectionalIterator shall satisfy the requirements of ValueSwappable (20.5.3.2). The type of \(*\text{first}\) shall satisfy the requirements of MoveConstructible (Table 23) and of MoveAssignable (Table 25).

9 Effects: Places all the elements in the range \([\text{first}, \text{last})\) that satisfy \text{pred} before all the elements that do not satisfy it.

10 Returns: An iterator \( i \) such that for every iterator \( j \) in the range \([\text{first}, i)\), \text{pred}(*j) != \text{false}, and for every iterator \( k \) in the range \([i, \text{last})\), \text{pred}(*k) == \text{false}. The relative order of the elements in both groups is preserved.

11 Complexity: Let \( N = \text{last} - \text{first} \):

(11.1) --- For the overload with no ExecutionPolicy, at most \( N \log N \) swaps, but only \( O(N) \) swaps if there is enough extra memory. Exactly \( N \) applications of the predicate.

(11.2) --- For the overload with an ExecutionPolicy, \( O(N \log N) \) swaps and \( O(N) \) applications of the predicate.

\[
\text{template}<\text{class InputIterator, class OutputIterator1,} \\
\text{class OutputIterator2, class Predicate}>
\begin{align*}
\text{pair<OutputIterator1, OutputIterator2>}
\end{align*}
\]

12 Requires:

(12.1) --- For the overload with no ExecutionPolicy, InputIterator's value type shall be CopyAssignable (Table 26), and shall be writable (27.2.1) to the out_true and out_false OutputIterators, and shall be convertible to Predicate's argument type.

(12.2) --- For the overload with an ExecutionPolicy, ForwardIterator's value type shall be CopyAssignable, and shall be writable to the out_true and out_false ForwardIterators, and shall be convertible to Predicate's argument type. [Note: There may be a performance cost if ForwardIterator's value type is not CopyConstructible. — end note]

(12.3) --- For both overloads, the input range shall not overlap with either of the output ranges.
13  Effects: For each iterator \( i \) in \([\text{first}, \text{last})\), copies \(*i\) to the output range beginning with \text{out\_true} if \( \text{pred}(*i) \) is true, or to the output range beginning with \text{out\_false} otherwise.

14  Returns: A pair \( p \) such that \( p.\text{first} \) is the end of the output range beginning at \text{out\_true} and \( p.\text{second} \) is the end of the output range beginning at \text{out\_false}.

15  Complexity: Exactly \( \text{last} - \text{first} \) applications of \( \text{pred} \).

16  \[
\text{template}<\text{class ForwardIterator}, \text{class Predicate}>
\text{ForwardIterator partition_point(ForwardIterator first,}
\text{ ForwardIterator last,}
\text{ Predicate pred);}\]

17  Requires: \( \text{ForwardIterator} \)’s value type shall be convertible to \( \text{Predicate} \)’s argument type. \([\text{first}, \text{last})\) shall be partitioned by \( \text{pred} \), i.e. all elements that satisfy \( \text{pred} \) shall appear before those that do not.

18  Returns: An iterator \( \text{mid} \) such that \( \text{all\_of(first, mid, pred)} \) and \( \text{none\_of(mid, last, pred)} \) are both true.

19  Complexity: \( \mathcal{O}(\log(\text{last} - \text{first})) \) applications of \( \text{pred} \).

28.7.5 Merge \[\text{alg.merge}\]

20  \[
\text{template}<\text{class InputIterator1, class InputIterator2,}
\text{ class OutputIterator}>
\text{OutputIterator merge(InputIterator1 first1, InputIterator1 last1,}
\text{ InputIterator2 first2, InputIterator2 last2,}
\text{ OutputIterator result);}\]

21  \[
\text{template}<\text{class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,}
\text{ class ForwardIterator}>
\text{ForwardIterator merge(ExecutionPolicy&& exec,}
\text{ ForwardIterator1 first1, ForwardIterator1 last1,}
\text{ ForwardIterator2 first2, ForwardIterator2 last2,}
\text{ ForwardIterator result);}\]

22  \[
\text{template}<\text{class InputIterator1, class InputIterator2,}
\text{ class OutputIterator, class Compare}>
\text{OutputIterator merge(InputIterator1 first1, InputIterator1 last1,}
\text{ InputIterator2 first2, InputIterator2 last2,}
\text{ OutputIterator result, Compare comp);}\]

23  \[
\text{template}<\text{class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,}
\text{ class Compare}>
\text{ForwardIterator merge(ExecutionPolicy&& exec,}
\text{ ForwardIterator1 first1, ForwardIterator1 last1,}
\text{ ForwardIterator2 first2, ForwardIterator2 last2,}
\text{ ForwardIterator result, Compare comp);}\]

24  Requires: The ranges \([\text{first1}, \text{last1})\) and \([\text{first2}, \text{last2})\) shall be sorted with respect to \( \text{operator}\langle \) or \( \text{comp} \). The resulting range shall not overlap with either of the original ranges.

25  Effects: Copies all the elements of the two ranges \([\text{first1}, \text{last1})\) and \([\text{first2}, \text{last2})\) into the range \([\text{result}, \text{result\_last})\), where \( \text{result\_last} \) is \( \text{result} + (\text{last1} - \text{first1}) + (\text{last2} - \text{first2}) \), such that the resulting range satisfies \( \text{is\_sorted(result, result\_last)} \) or \( \text{is\_sorted(result,} \text{result\_last)} \).
result_last, comp), respectively.

3 Returns: result + (last1 - first1) + (last2 - first2).

4 Complexity: Let \( N = (last1 - first1) + (last2 - first2) \):
   (4.1) — For the overloads with no ExecutionPolicy, at most \( N - 1 \) comparisons.
   (4.2) — For the overloads with an ExecutionPolicy, \( \mathcal{O}(N) \) comparisons.

5 Remarks: Stable (20.5.5.7).

\[
\begin{align*}
\text{template<class BidirectionalIterator>}
& \quad \text{void inplace_merge(BidirectionalIterator first,} \\
& \quad \quad \text{BidirectionalIterator middle,} \\
& \quad \quad \text{BidirectionalIterator last);} \\
\text{template<class ExecutionPolicy, class BidirectionalIterator>}
& \quad \text{void inplace_merge(ExecutionPolicy&& exec,} \\
& \quad \quad \text{BidirectionalIterator first,} \\
& \quad \quad \text{BidirectionalIterator middle,} \\
& \quad \quad \text{BidirectionalIterator last);} \\
\text{template<class BidirectionalIterator, class Compare>}
& \quad \text{void inplace_merge(BidirectionalIterator first,} \\
& \quad \quad \text{BidirectionalIterator middle,} \\
& \quad \quad \text{BidirectionalIterator last, Compare comp);} \\
\text{template<class ExecutionPolicy, class BidirectionalIterator, class Compare>}
& \quad \text{void inplace_merge(ExecutionPolicy&& exec,} \\
& \quad \quad \text{BidirectionalIterator first,} \\
& \quad \quad \text{BidirectionalIterator middle,} \\
& \quad \quad \text{BidirectionalIterator last, Compare comp);} \\
\end{align*}
\]

6 Requires: The ranges \([\text{first}, \text{middle})\) and \([\text{middle}, \text{last})\) shall be sorted with respect to \(\text{operator< or comp} \). \text{BidirectionalIterator} shall satisfy the requirements of \text{ValueSwappable} (20.5.3.2). The type of \(*\text{first}\) shall satisfy the requirements of \text{MoveConstructible} (Table 23) and of \text{MoveAssignable} (Table 25).

7 Effects: Merges two sorted consecutive ranges \([\text{first}, \text{middle})\) and \([\text{middle}, \text{last})\), putting the result of the merge into the range \([\text{first}, \text{last})\). The resulting range will be in non-decreasing order; that is, for every iterator \(i\) in \([\text{first}, \text{last})\) other than \(\text{first}\), the condition \(*i < *(i - 1)\) or, respectively, \(\text{comp(*i, *(i - 1))}\) will be false.

8 Complexity: Let \( N = \text{last} - \text{first} \):
   (8.1) — For the overloads with no ExecutionPolicy, if enough additional memory is available, exactly \( N - 1 \) comparisons.
   (8.2) — For the overloads with no ExecutionPolicy if no additional memory is available, \( \mathcal{O}(N \log N) \) comparisons.
   (8.3) — For the overloads with an ExecutionPolicy, \( \mathcal{O}(N \log N) \) comparisons.

9 Remarks: Stable (20.5.5.7).

28.7.6 Set operations on sorted structures

This section defines all the basic set operations on sorted structures. They also work with multisets (26.4.7) containing multiple copies of equivalent elements. The semantics of the set operations are generalized to multisets in a standard way by defining \text{set_union()} to contain the maximum number of occurrences of every element, \text{set_intersection()} to contain the minimum, and so on.
28.7.6.1 includes

\[\text{includes} (\text{InputIterator1} \text{~first1~, \text{InputIterator1} \text{~last1~, \text{InputIterator2} \text{~first2~, \text{InputIterator2} \text{~last2~}}})\]

\[\text{includes} (\text{ExecutionPolicy} \&\& \text{exec}, \text{ForwardIterator1} \text{~first1~, \text{ForwardIterator1} \text{~last1~, \text{ForwardIterator2} \text{~first2~, \text{ForwardIterator2} \text{~last2~}}})\]

\[\text{includes} (\text{InputIterator1} \text{~first1~, \text{InputIterator1} \text{~last1~, \text{InputIterator2} \text{~first2~, \text{InputIterator2} \text{~last2~, \text{Compare} \text{~comp~}}})\]

\[\text{includes} (\text{ExecutionPolicy} \&\& \text{exec}, \text{ForwardIterator1} \text{~first1~, \text{ForwardIterator1} \text{~last1~, \text{ForwardIterator2} \text{~first2~, \text{ForwardIterator2} \text{~last2~, \text{Compare} \text{~comp~}}})\]

1 \text{Returns: true if [first2, last2) is empty or if every element in the range [first2, last2) is contained in the range [first1, last1). Returns false otherwise.}

2 \text{Complexity: At most 2 * ((last1 - first1) + (last2 - first2)) - 1 comparisons.}

28.7.6.2 set_union

\[\text{set_union} (\text{InputIterator1} \text{~first1~, \text{InputIterator1} \text{~last1~, \text{InputIterator2} \text{~first2~, \text{InputIterator2} \text{~last2~, \text{OutputIterator} \text{~result~}}})\]

\[\text{set_union} (\text{ExecutionPolicy} \&\& \text{exec}, \text{ForwardIterator1} \text{~first1~, \text{ForwardIterator1} \text{~last1~, \text{ForwardIterator2} \text{~first2~, \text{ForwardIterator2} \text{~last2~, \text{OutputIterator} \text{~result~}}})\]

\[\text{set_union} (\text{InputIterator1} \text{~first1~, \text{InputIterator1} \text{~last1~, \text{InputIterator2} \text{~first2~, \text{InputIterator2} \text{~last2~, \text{Compare} \text{~comp~}}})\]

\[\text{set_union} (\text{ExecutionPolicy} \&\& \text{exec}, \text{ForwardIterator1} \text{~first1~, \text{ForwardIterator1} \text{~last1~, \text{ForwardIterator2} \text{~first2~, \text{ForwardIterator2} \text{~last2~, \text{Compare} \text{~comp~}}})\]

1 \text{Requires: The resulting range shall not overlap with either of the original ranges.}

2 \text{Effects: Constructs a sorted union of the elements from the two ranges; that is, the set of elements that}
are present in one or both of the ranges.

*Returns:* The end of the constructed range.

*Complexity:* At most \(2 \times ((\text{last1} - \text{first1}) + (\text{last2} - \text{first2})) - 1\) comparisons.

*Remarks:* If \([\text{first1}, \text{last1})\) contains \(m\) elements that are equivalent to each other and \([\text{first2}, \text{last2})\) contains \(n\) elements that are equivalent to them, then all \(m\) elements from the first range shall be copied to the output range, in order, and then \(\max(n - m, 0)\) elements from the second range shall be copied to the output range, in order.

### 28.7.6.3 set_intersection

```cpp
template<class InputIterator1, class InputIterator2, 
         class OutputIterator>
OutputIterator
    set_intersection(InputIterator1 first1, InputIterator1 last1, 
                    InputIterator2 first2, InputIterator2 last2, 
                    OutputIterator result);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, 
          class ForwardIterator>
ForwardIterator
    set_intersection(ExecutionPolicy&& exec, 
                    ForwardIterator1 first1, ForwardIterator1 last1, 
                    ForwardIterator2 first2, ForwardIterator2 last2, 
                    ForwardIterator result);
```

```cpp
template<class InputIterator1, class InputIterator2, 
         class OutputIterator, class Compare>
OutputIterator
    set_intersection(InputIterator1 first1, InputIterator1 last1, 
                    InputIterator2 first2, InputIterator2 last2, 
                    OutputIterator result, Compare comp);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, 
          class ForwardIterator, class Compare>
ForwardIterator
    set_intersection(ExecutionPolicy&& exec, 
                    ForwardIterator1 first1, ForwardIterator1 last1, 
                    ForwardIterator2 first2, ForwardIterator2 last2, 
                    ForwardIterator result, Compare comp);
```

*Requires:* The resulting range shall not overlap with either of the original ranges.

*Effects:* Constructs a sorted intersection of the elements from the two ranges; that is, the set of elements that are present in both of the ranges.

*Returns:* The end of the constructed range.

*Complexity:* At most \(2 \times ((\text{last1} - \text{first1}) + (\text{last2} - \text{first2})) - 1\) comparisons.

*Remarks:* If \([\text{first1}, \text{last1})\) contains \(m\) elements that are equivalent to each other and \([\text{first2}, \text{last2})\) contains \(n\) elements that are equivalent to them, the first \(\min(m, n)\) elements shall be copied from the first range to the output range, in order.

### 28.7.6.4 set_difference

```cpp
template<class InputIterator1, class InputIterator2, 
         class OutputIterator>
OutputIterator
    set_difference(InputIterator1 first1, InputIterator1 last1, 
                   InputIterator2 first2, InputIterator2 last2, 
                   OutputIterator result);
```
InputIterator2 first2, InputIterator2 last2,
OutputIterator result);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class ForwardIterator>
ForwardIterator
set_difference(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2,
ForwardIterator result);

template<class InputIterator1, class InputIterator2,
class OutputIterator, class Compare>
OutputIterator
set_difference(InputIterator1 first1, InputIterator1 last1,
InputIterator2 first2, InputIterator2 last2,
OutputIterator result, Compare comp);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class ForwardIterator, class Compare>
ForwardIterator
set_difference(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2,
ForwardIterator result, Compare comp);

Requires: The resulting range shall not overlap with either of the original ranges.

Effects: Copies the elements of the range [first1, last1) which are not present in the range
[first2, last2) to the range beginning at result. The elements in the constructed range are sorted.

Returns: The end of the constructed range.

Complexity: At most 2 * ((last1 - first1) + (last2 - first2)) - 1 comparisons.

Remarks: If [first1, last1) contains m elements that are equivalent to each other and [first2,
last2) contains n elements that are equivalent to them, the last max(m - n, 0) elements from
[first1, last1) shall be copied to the output range.

28.7.6.5 set_symmetric_difference

template<class InputIterator1, class InputIterator2,
class OutputIterator>
OutputIterator
set_symmetric_difference(InputIterator1 first1, InputIterator1 last1,
InputIterator2 first2, InputIterator2 last2,
OutputIterator result);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class ForwardIterator>
ForwardIterator
set_symmetric_difference(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2,
ForwardIterator result);

template<class InputIterator1, class InputIterator2,
class OutputIterator, class Compare>
OutputIterator
set_symmetric_difference(InputIterator1 first1, InputIterator1 last1,
InputIterator2 first2, InputIterator2 last2,
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class ForwardIterator, class Compare>
ForwardIterator
set_symmetric_difference(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2,
ForwardIterator result, Compare comp);

Requires: The resulting range shall not overlap with either of the original ranges.
Effects: Copies the elements of the range [first1, last1) that are not present in the range [first2, last2),
and the elements of the range [first2, last2) that are not present in the range [first1, last1)
to the range beginning at result. The elements in the constructed range are sorted.
Returns: The end of the constructed range.
Complexity: At most \( 2 \times ((last1 - first1) + (last2 - first2)) - 1 \) comparisons.
Remarks: If [first1, last1) contains \( m \) elements that are equivalent to each other and [first2, last2) contains \( n \) elements that are equivalent to them, then \( |m - n| \) of those elements shall be copied
to the output range: the last \( m - n \) of these elements from [first1, last1) if \( m > n \),
and the last \( n - m \) of these elements from [first2, last2) if \( m < n \).

28.7.7 Heap operations

A heap is a particular organization of elements in a range between two random access iterators \([a, b)\) such that:

(1.1) With \( N = b - a \), for all \( i, 0 < i < N \), \( \text{comp}(a[\lfloor \frac{i-1}{2} \rfloor], a[i]) \) is false.
(1.2) \(*a\) may be removed by \text{pop_heap()}\), or a new element added by \text{push_heap()}\), in \( \Theta(\log N) \) time.

These properties make heaps useful as priority queues.
make_heap() converts a range into a heap and sort_heap() turns a heap into a sorted sequence.

28.7.7.1 push_heap

template<class RandomAccessIterator>
void push_heap(RandomAccessIterator first, RandomAccessIterator last);

Requires: The range \([first, last - 1)\) shall be a valid heap. The type of *first shall satisfy the
\text{MoveConstructible} requirements (Table 23) and the \text{MoveAssignable} requirements (Table 25).
Effects: Places the value in the location last - 1 into the resulting heap [first, last).
Complexity: At most \( \log(last - first) \) comparisons.

28.7.7.2 pop_heap

template<class RandomAccessIterator>
void pop_heap(RandomAccessIterator first, RandomAccessIterator last);

Requires: The range \([first, last - 1)\) shall be a valid heap. The type of *first shall satisfy the
\text{MoveConstructible} requirements (Table 23) and the \text{MoveAssignable} requirements (Table 25).
Effects: Places the value in the location last - 1 into the resulting heap [first, last).
Complexity: At most \( \log(last - first) \) comparisons.
Requires: The range \([\textit{first}, \textit{last})\) shall be a valid non-empty heap. \texttt{RandomAccessIterator} shall satisfy the requirements of \texttt{ValueSwappable} (20.5.3.2). The type of \(*\textit{first}\) shall satisfy the requirements of \texttt{MoveConstructible} (Table 23) and of \texttt{MoveAssignable} (Table 25).

Effects: Swaps the value in the location \textit{first} with the value in the location \textit{last} - 1 and makes \([\textit{first}, \textit{last} - 1)\) into a heap.

Complexity: At most \(2 \log(\textit{last} - \textit{first})\) comparisons.

28.7.7.3 \texttt{make_heap}

\[
\text{template<class RandomAccessIterator>}
\text{\hspace{1em}}
\text{void make_heap(RandomAccessIterator first, RandomAccessIterator last);}\]

\[
\text{\hspace{1em}}
\text{template<class RandomAccessIterator, class Compare>}
\text{\hspace{1em}}
\text{void make_heap(RandomAccessIterator first, RandomAccessIterator last,}
\text{\hspace{1em}}
\text{Compare comp);}\]

Requires: The type of \(*\textit{first}\) shall satisfy the \texttt{MoveConstructible} requirements (Table 23) and the \texttt{MoveAssignable} requirements (Table 25).

Effects: Constructs a heap out of the range \([\textit{first}, \textit{last})\).

Complexity: At most \(3(\textit{last} - \textit{first})\) comparisons.

28.7.7.4 \texttt{sort_heap}

\[
\text{template<class RandomAccessIterator>}
\text{\hspace{1em}}
\text{void sort_heap(RandomAccessIterator first, RandomAccessIterator last);}\]

\[
\text{\hspace{1em}}
\text{template<class RandomAccessIterator, class Compare>}
\text{\hspace{1em}}
\text{void sort_heap(RandomAccessIterator first, RandomAccessIterator last,}
\text{\hspace{1em}}
\text{Compare comp);}\]

Requires: The range \([\textit{first}, \textit{last})\) shall be a valid heap. \texttt{RandomAccessIterator} shall satisfy the requirements of \texttt{ValueSwappable} (20.5.3.2). The type of \(*\textit{first}\) shall satisfy the requirements of \texttt{MoveConstructible} (Table 23) and of \texttt{MoveAssignable} (Table 25).

Effects: Sorts elements in the heap \([\textit{first}, \textit{last})\).

Complexity: At most \(N \log N\) comparisons, where \(N = \textit{last} - \textit{first}\).

28.7.7.5 \texttt{is_heap}

\[
\text{template<class RandomAccessIterator>}
\text{\hspace{1em}}
\text{bool is_heap(RandomAccessIterator first, RandomAccessIterator last);}\]

\[
\text{template<class ExecutionPolicy, class RandomAccessIterator>}
\text{\hspace{1em}}
\text{bool is_heap(ExecutionPolicy&\& exec,}
\text{\hspace{1em}}
\text{RandomAccessIterator first, RandomAccessIterator last);}\]

Returns: \texttt{is_heap_until(\textit{first}, \textit{last}) == \textit{last}}

\[
\text{template<class ExecutionPolicy, class RandomAccessIterator>}
\text{\hspace{1em}}
\text{bool is_heap(ExecutionPolicy&\& exec,}
\text{\hspace{1em}}
\text{RandomAccessIterator first, RandomAccessIterator last);}\]

Returns: \texttt{is_heap_until(std::forward<ExecutionPolicy>(\textit{exec}), \textit{first}, \textit{last}) == \textit{last}}

\[
\text{template<class RandomAccessIterator, class Compare>}
\text{\hspace{1em}}
\text{bool is_heap(RandomAccessIterator first, RandomAccessIterator last, Compare comp);}\]

Returns: \texttt{is_heap_until(\textit{first}, \textit{last}, \textit{comp}) == \textit{last}}

\[
\text{template<class ExecutionPolicy, class RandomAccessIterator, class Compare>}
\text{\hspace{1em}}
\text{bool is_heap(ExecutionPolicy&\& exec,}
\text{\hspace{1em}}
\text{RandomAccessIterator first, RandomAccessIterator last, Compare comp);}\]

Returns: \texttt{is_heap_until(\textit{first}, \textit{last}, \textit{comp}) == \textit{last}}
is_heap_until(RandomAccessIterator first, RandomAccessIterator last, Compare comp);

Returns:

is_heap_until(std::forward<ExecutionPolicy>(exec), first, last, comp) == last

template<class RandomAccessIterator>
RandomAccessIterator is_heap_until(RandomAccessIterator first, RandomAccessIterator last);
template<class ExecutionPolicy, class RandomAccessIterator>
RandomAccessIterator is_heap_until(ExecutionPolicy&& exec,
  RandomAccessIterator first, RandomAccessIterator last);
template<class RandomAccessIterator, class Compare>
RandomAccessIterator is_heap_until(RandomAccessIterator first, RandomAccessIterator last,
  Compare comp);
template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
RandomAccessIterator is_heap_until(ExecutionPolicy&& exec,
  RandomAccessIterator first, RandomAccessIterator last,
  Compare comp);

Returns: If (last - first) < 2, returns last. Otherwise, returns the last iterator i in [first, last] for which the range [first, i) is a heap.

Complexity: Linear.

28.7.8 Minimum and maximum [alg.min.max]

template<class T> constexpr const T& min(const T& a, const T& b);
template<class T, class Compare>
constexpr const T& min(const T& a, const T& b, Compare comp);

Requires: For the first form, type T shall be LessThanComparable (Table 21).

Returns: The smaller value.

Remarks: Returns the first argument when the arguments are equivalent.

Complexity: Exactly one comparison.

template<class T>
constexpr T min(initializer_list<T> t);
template<class T, class Compare>
constexpr T min(initializer_list<T> t, Compare comp);

Requires: T shall be CopyConstructible and t.size() > 0. For the first form, type T shall be LessThanComparable.

Returns: The smallest value in the initializer_list.

Remarks: Returns a copy of the leftmost argument when several arguments are equivalent to the smallest.

Complexity: Exactly t.size() - 1 comparisons.

template<class T> constexpr const T& max(const T& a, const T& b);
template<class T, class Compare>
constexpr const T& max(const T& a, const T& b, Compare comp);

Requires: For the first form, type T shall be LessThanComparable (Table 21).

Returns: The larger value.

Remarks: Returns the first argument when the arguments are equivalent.
Complexity: Exactly one comparison.

```cpp
template<class T>
constexpr T max(initializer_list<T> t);
```

Requires: T shall be CopyConstructible and t.size() > 0. For the first form, type T shall be LessThanComparable.

Returns: The largest value in the initializer_list.

Remarks: Returns a copy of the leftmost argument when several arguments are equivalent to the largest.

Complexity: Exactly t.size() - 1 comparisons.

```cpp
template<class T, class Compare>
constexpr T max(initializer_list<T> t, Compare comp);
```

```cpp
template<class T> constexpr pair<const T&, const T&> minmax(const T& a, const T& b);
```

Requires: For the first form, type T shall be LessThanComparable (Table 21).

Returns: pair<const T&, const T&>(b, a) if b is smaller than a, and pair<const T&, const T&>(a, b) otherwise.

Remarks: Returns pair<const T&, const T&>(a, b) when the arguments are equivalent.

Complexity: Exactly one comparison.

```cpp
template<class T> constexpr pair<T, T> minmax(initializer_list<T> t);
```

Requires: T shall be CopyConstructible and t.size() > 0. For the first form, type T shall be LessThanComparable.

Returns: pair<T, T>(x, y) where x has the smallest and y has the largest value in the initializer list.

Remarks: x is a copy of the leftmost argument when several arguments are equivalent to the smallest. y is a copy of the rightmost argument when several arguments are equivalent to the largest.

Complexity: At most (3/2) t.size() applications of the corresponding predicate.

```cpp
template<class ForwardIterator>
constexpr ForwardIterator min_element(ForwardIterator first, ForwardIterator last);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator min_element(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last);
```

```cpp
template<class ForwardIterator, class Compare>
constexpr ForwardIterator min_element(ForwardIterator first, ForwardIterator last, Compare comp);
```

Returns: The first iterator i in the range [first, last) such that for every iterator j in the range [first, last) the following corresponding conditions hold: !(j < i) or comp(*j, *i) == false. Returns last if first == last.

§ 28.7.8
template<class ForwardIterator>
    constexpr ForwardIterator max_element(ForwardIterator first, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
    ForwardIterator max_element(ExecutionPolicy& exec, 
                                ForwardIterator first, ForwardIterator last);

template<class ForwardIterator, class Compare>
    constexpr ForwardIterator max_element(ForwardIterator first, ForwardIterator last, 
                                          Compare comp);

template<class ExecutionPolicy, class ForwardIterator, class Compare>
    ForwardIterator max_element(ExecutionPolicy& exec, 
                                ForwardIterator first, ForwardIterator last, 
                                Compare comp);

Returns: The first iterator i in the range [first, last) such that for every iterator j in the range [first, last) the following corresponding conditions hold: !(i < j) or comp(*i, *j) == false. Returns last if first == last.

Complexity: Exactly max(last - first - 1, 0) applications of the corresponding comparisons.

template<class ForwardIterator>
    constexpr pair<ForwardIterator, ForwardIterator> 
    minmax_element(ForwardIterator first, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
    pair<ForwardIterator, ForwardIterator> 
    minmax_element(ExecutionPolicy& exec, 
                   ForwardIterator first, ForwardIterator last);

template<class ForwardIterator, class Compare>
    constexpr pair<ForwardIterator, ForwardIterator> 
    minmax_element(ForwardIterator first, ForwardIterator last, Compare comp);

template<class ExecutionPolicy, class ForwardIterator, class Compare>
    pair<ForwardIterator, ForwardIterator> 
    minmax_element(ExecutionPolicy& exec, 
                   ForwardIterator first, ForwardIterator last, 
                   Compare comp);

Returns: make_pair(first, first) if [first, last) is empty, otherwise make_pair(m, M), where m is the first iterator in [first, last) such that no iterator in the range refers to a smaller element, and where M is the last iterator\(^ {266} \) in [first, last) such that no iterator in the range refers to a larger element.

Complexity: At most max(\( \lceil \frac{3}{2}(N - 1) \rceil, 0 \)) applications of the corresponding predicate, where N is last - first.

28.7.9 Bounded value

\[ \text{template<class T>} \]

\[ \text{constexpr T& clamp(const T& v, const T& lo, const T& hi)}; \]

\[ \text{template<class T, class Compare>} \]

\[ \text{constexpr T& clamp(const T& v, const T& lo, const T& hi, Compare comp)}; \]

1 Requires: The value of lo shall be no greater than hi. For the first form, type T shall be LessThanComparable (Table 21).

2 Returns: lo if v is less than lo, hi if hi is less than v, otherwise v.

\(^ {266} \) This behavior intentionally differs from max_element().

§ 28.7.9 1047
[Note: If NaN is avoided, T can be a floating-point type. — end note]

Complexity: At most two comparisons.

28.7.10 Lexicographical comparison [alg.lex.comparison]

template<class InputIterator1, class InputIterator2>
bool
  lexicographical_compare(InputIterator1 first1, InputIterator1 last1,
                         InputIterator2 first2, InputIterator2 last2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
bool
  lexicographical_compare(ExecutionPolicy&& exec,
                         ForwardIterator1 first1, ForwardIterator1 last1,
                         ForwardIterator2 first2, ForwardIterator2 last2);

template<class InputIterator1, class InputIterator2, class Compare>
bool
  lexicographical_compare(InputIterator1 first1, InputIterator1 last1,
                         InputIterator2 first2, InputIterator2 last2,
                         Compare comp);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class Compare>
bool
  lexicographical_compare(ExecutionPolicy&& exec,
                         ForwardIterator1 first1, ForwardIterator1 last1,
                         ForwardIterator2 first2, ForwardIterator2 last2,
                         Compare comp);

1 Returns: true if the sequence of elements defined by the range [first1, last1) is lexicographically less than the sequence of elements defined by the range [first2, last2) and false otherwise.

2 Complexity: At most 2 min(last1 - first1, last2 - first2) applications of the corresponding comparison.

3 Remarks: If two sequences have the same number of elements and their corresponding elements (if any) are equivalent, then neither sequence is lexicographically less than the other. If one sequence is a prefix of the other, then the shorter sequence is lexicographically less than the longer sequence. Otherwise, the lexicographical comparison of the sequences yields the same result as the comparison of the first corresponding pair of elements that are not equivalent.

[Example: The following sample implementation satisfies these requirements:

    for ( ; first1 != last1 && first2 != last2 ; ++first1, (void) ++first2) {
        if (*first1 < *first2) return true;
        if (*first2 < *first1) return false;
    }
    return first1 == last1 && first2 != last2;

— end example]

5 [Note: An empty sequence is lexicographically less than any non-empty sequence, but not less than any empty sequence. — end note]

28.7.11 Permutation generators [alg.permutation.generators]

template<class BidirectionalIterator>
bool next_permutation(BidirectionalIterator first,
                      BidirectionalIterator last);
template<class BidirectionalIterator, class Compare>
bool next_permutation(BidirectionalIterator first,
      BidirectionalIterator last, Compare comp);

1 Requires: BidirectionalIterator shall satisfy the requirements of ValueSwappable (20.5.3.2).
2 Effects: Takes a sequence defined by the range [first, last) and transforms it into the next permutation. The next permutation is found by assuming that the set of all permutations is lexicographically sorted with respect to operator< or comp.
3 Returns: true if such a permutation exists. Otherwise, it transforms the sequence into the smallest permutation, that is, the ascendingly sorted one, and returns false.
4 Complexity: At most (last - first) / 2 swaps.

template<class BidirectionalIterator, class Compare>
bool prev_permutation(BidirectionalIterator first,
      BidirectionalIterator last, Compare comp);

5 Requires: BidirectionalIterator shall satisfy the requirements of ValueSwappable (20.5.3.2).
6 Effects: Takes a sequence defined by the range [first, last) and transforms it into the previous permutation. The previous permutation is found by assuming that the set of all permutations is lexicographically sorted with respect to operator< or comp.
7 Returns: true if such a permutation exists. Otherwise, it transforms the sequence into the largest permutation, that is, the descendingly sorted one, and returns false.
8 Complexity: At most (last - first) / 2 swaps.

28.8 C library algorithms
[alg.c.library]

void* bsearch(const void* key, const void* base, size_t nmemb, size_t size,
      c-compare-pred* compar);
void* bsearch(const void* key, const void* base, size_t nmemb, size_t size,
      compare-pred* compar);
void qsort(void* base, size_t nmemb, size_t size,
      c-compare-pred* compar);
void qsort(void* base, size_t nmemb, size_t size,
      compare-pred* compar);

2 Effects: These functions have the semantics specified in the C standard library.
3 Remarks: The behavior is undefined unless the objects in the array pointed to by base are of trivial type.
4 Throws: Any exception thrown by compar() (20.5.5.12).
See also: ISO C 7.22.5.
29 Numerics library

29.1 General

1 This Clause describes components that C++ programs may use to perform seminumerical operations.
2 The following subclauses describe components for complex number types, random number generation, numeric (n-at-a-time) arrays, generalized numeric algorithms, and mathematical functions for floating-point types, as summarized in Table 101.

Table 101 — Numerics library summary

<table>

29.2 Definitions

1 Define \( \text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(\text{op}, a_1, \ldots, a_N) \) as follows:

\[
\begin{align*}
(1.1) & \quad a_1 \text{ when } N = 1, \text{ otherwise} \\
(1.2) & \quad \text{op}(\text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(\text{op}, a_1, \ldots, a_K), \\
& \quad \text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(\text{op}, a_M, \ldots, a_N)) \text{ for any } K \text{ where } 1 < K + 1 = M \leq N.
\end{align*}
\]

2 Define \( \text{GENERALIZED\_SUM}(\text{op}, a_1, \ldots, a_N) \) as \( \text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(\text{op}, b_1, \ldots, b_N) \), where \( b_1, \ldots, b_N \) may be any permutation of \( a_1, \ldots, a_N \).

29.3 Numeric type requirements

1 The \text{complex} and \text{valarray} components are parameterized by the type of information they contain and manipulate. A C++ program shall instantiate these components only with a type \( T \) that satisfies the following requirements:

\[
\begin{align*}
(1.1) & \quad T \text{ is not an abstract class (it has no pure virtual member functions);} \\
(1.2) & \quad T \text{ is not a reference type;} \\
(1.3) & \quad T \text{ is not cv-qualified;} \\
(1.4) & \quad T \text{ is a class, it has a public default constructor;} \\
(1.5) & \quad T \text{ is a class, it has a public copy constructor with the signature } T::T(const T&) \\
(1.6) & \quad T \text{ is a class, it has a public destructor;}
\end{align*}
\]

\[267\) In other words, value types. These include arithmetic types, pointers, the library class \text{complex}, and instantiations of \text{valarray} for value types.

§ 29.3
If \( T \) is a class, it has a public assignment operator whose signature is either \( T & T :: \text{operator=} (\text{const} \ T &) \) or \( T & T :: \text{operator=} (T) \).

If \( T \) is a class, its assignment operator, copy and default constructors, and destructor shall correspond to each other in the following sense:

- Initialization of raw storage using the copy constructor on the value of \( T() \), however obtained, is semantically equivalent to value-initialization of the same raw storage.
- Initialization of raw storage using the default constructor, followed by assignment, is semantically equivalent to initialization of raw storage using the copy constructor.
- Destruction of an object, followed by initialization of its raw storage using the copy constructor, is semantically equivalent to assignment to the original object.

[Note: This rule states, in part, that there shall not be any subtle differences in the semantics of initialization versus assignment. This gives an implementation considerable flexibility in how arrays are initialized.

[Example: An implementation is allowed to initialize a \text{valarray} by allocating storage using the \text{new} operator (which implies a call to the default constructor for each element) and then assigning each element its value. Or the implementation can allocate raw storage and use the copy constructor to initialize each element. — end example]

If the distinction between initialization and assignment is important for a class, or if it fails to satisfy any of the other conditions listed above, the programmer should use \text{vector} (26.3.11) instead of \text{valarray} for that class. — end note]

If \( T \) is a class, it does not overload unary \text{operator\&}.

2 If any operation on \( T \) throws an exception the effects are undefined.

3 In addition, many member and related functions of \text{valarray}<T> can be successfully instantiated and will exhibit well-defined behavior if and only if \( T \) satisfies additional requirements specified for each such member or related function.

4 [Example: It is valid to instantiate \text{valarray}<\text{complex}>, but \text{operator}() will not be successfully instantiated for \text{valarray}<\text{complex}> operands, since \text{complex} does not have any ordering operators. — end example]

29.4 The floating-point environment

29.4.1 Header <cfenv> summary

```cpp
#define FE_ALL_EXCEPT see below
#define FE_DIVBYZERO see below
#define FE_INEXACT see below
#define FE_INVALID see below
#define FE_OVERFLOW see below
#define FE_UNDERFLOW see below
#define FE_DOWNWARD see below
#define FE_TONEAREST see below
#define FE_TOWARDZERO see below
#define FE_UPWARD see below
#define FE_DFL_ENV see below
```

namespace std {

```
using fenv_t = object type;
using fexcept_t = integer type;
```

§ 29.4.1
// functions
int feclastr (int except);
int fegetexceptflag(fexcept_t* pflag, int except);
int feraiseexcept(int except);
int fetestexcept(int except);

int fegetround();
int fesetround(int mode);

int fegetenv(fenv_t* penv);
int feholdexcept(fenv_t* penv);
int fesetenv(const fenv_t* penv);
int feupdateenv(const fenv_t* penv);

1 The contents and meaning of the header `<cfenv>` are the same as the C standard library header `<fenv.h>`.
[Note: This International Standard does not require an implementation to support the FENV_ACCESS pragma; it is implementation-defined (19.6) whether the pragma is supported. As a consequence, it is implementation-defined whether these functions can be used to test floating-point status flags, set floating-point control modes, or run under non-default mode settings. If the pragma is used to enable control over the floating-point environment, this International Standard does not specify the effect on floating-point evaluation in constant expressions. —end note]

2 The floating-point environment has thread storage duration (6.7.2). The initial state for a thread’s floating-point environment is the state of the floating-point environment of the thread that constructs the corresponding thread object (33.3.2) at the time it constructed the object. [Note: That is, the child thread gets the floating-point state of the parent thread at the time of the child’s creation. —end note]

3 A separate floating-point environment shall be maintained for each thread. Each function accesses the environment corresponding to its calling thread.

See also: ISO C 7.6

29.5 Complex numbers
[complex.numbers]

1 The header `<complex>` defines a class template, and numerous functions for representing and manipulating complex numbers.

2 The effect of instantiating the template complex for any type other than float, double, or long double is unspecified. The specializations complex<float>, complex<double>, and complex<long double> are literal types (6.9).

3 If the result of a function is not mathematically defined or not in the range of representable values for its type, the behavior is undefined.

4 If z is an lvalue expression of type cv complex<T> then:

(4.1) the expression reinterpret_cast<cu T(&) [2]>(z) shall be well-formed,
(4.2) reinterpret_cast<cu T(&) [2]>(z) [0] shall designate the real part of z, and
(4.3) reinterpret_cast<cu T(&) [2]>(z) [1] shall designate the imaginary part of z.

Moreover, if a is an expression of type cv complex<T>* and the expression a[i] is well-defined for an integer expression i, then:

(4.4) reinterpret_cast<cu T*>(a) [2*i] shall designate the real part of a[i], and
(4.5) reinterpret_cast<cu T*>(a) [2*i + 1] shall designate the imaginary part of a[i].

§ 29.5
29.5.1 Header <complex> synopsis

namespace std {
    template<class T> class complex;

29.5.2 Class template complex

namespace std {
  template<class T>
  class complex {
    public:
      using value_type = T;

      constexpr complex(const T& re = T(), const T& im = T());
      constexpr complex(const complex&) = default;
      template<class X> constexpr complex(const complex<X>&);

      constexpr T real() const;

  } // class complex
}

§ 29.5.2
The class `complex` describes an object that can store the Cartesian components, `real()` and `imag()`, of a complex number.

29.5.3 complex specializations

```cpp
namespace std {
    template<> class complex<float> {
        public:
            using value_type = float;
            constexpr complex(float re = 0.0f, float im = 0.0f);
            constexpr explicit complex(const complex<double>&);
            constexpr explicit complex(const complex<long double>&);
            constexpr float real() const;
            void real(float);
            constexpr float imag() const;
            void imag(float);
            complex<float>& operator= (float);
            complex<float>& operator+=(float);
            complex<float>& operator-=(float);
            complex<float>& operator*=(float);
            complex<float>& operator/=(float);
            complex<float>& operator=(const complex<float>&);
            template<class X> complex<float>& operator= (const complex<X>&);
            template<class X> complex<float>& operator+=(const complex<X>&);
            template<class X> complex<float>& operator-=(const complex<X>&);
            template<class X> complex<float>& operator*=(const complex<X>&);
            template<class X> complex<float>& operator/=(const complex<X>&);
    };
}
```

1055
constexpr complex(const complex<float>&);
constexpr explicit complex(const complex<long double>&);

constexpr double real() const;
void real(double);
constexpr double imag() const;
void imag(double);

complex<double>& operator= (double);
complex<double>& operator+=(double);
complex<double>& operator-=(double);
complex<double>& operator*=(double);
complex<double>& operator/=(double);

complex<double>& operator=(const complex<double>&);
template<class X> complex<double>& operator= (const complex<X>&);
template<class X> complex<double>& operator+=(const complex<X>&);
template<class X> complex<double>& operator-=(const complex<X>&);
template<class X> complex<double>& operator*=(const complex<X>&);
template<class X> complex<double>& operator/=(const complex<X>&);
};

29.5.4 complex member functions

```cpp
template<class T> constexpr complex(const T& re = T(), const T& im = T());
```

1 Effects: Constructs an object of class complex.
2 Postconditions: real() == re && imag() == im.
constexpr T real() const;

Returns: The value of the real component.

void real(T val);

Effects: Assigns val to the real component.

constexpr T imag() const;

Returns: The value of the imaginary component.

void imag(T val);

Effects: Assigns val to the imaginary component.

29.5.5 complex member operators

[complex.member.ops]

complex<T>& operator+=(const T& rhs);

Effects: Adds the scalar value rhs to the real part of the complex value *this and stores the result in the real part of *this, leaving the imaginary part unchanged.

Returns: *this.

complex<T>& operator-=(const T& rhs);

Effects: Subtracts the scalar value rhs from the real part of the complex value *this and stores the result in the real part of *this, leaving the imaginary part unchanged.

Returns: *this.

complex<T>& operator*=(const T& rhs);

Effects: Multiplies the scalar value rhs by the complex value *this and stores the result in *this.

Returns: *this.

complex<T>& operator/=(const T& rhs);

Effects: Divides the scalar value rhs into the complex value *this and stores the result in *this.

Returns: *this.

template<class X> complex<T>& operator+=(const complex<X>& rhs);

Effects: Adds the complex value rhs to the complex value *this and stores the sum in *this.

Returns: *this.

template<class X> complex<T>& operator-=(const complex<X>& rhs);

Effects: Subtracts the complex value rhs from the complex value *this and stores the difference in *this.

Returns: *this.

template<class X> complex<T>& operator*=(const complex<X>& rhs);

Effects: Multiplies the complex value rhs by the complex value *this and stores the product in *this.

Returns: *this.

template<class X> complex<T>& operator/=(const complex<X>& rhs);

Effects: Divides the complex value rhs into the complex value *this and stores the quotient in *this.

Returns: *this.
29.5.6 complex non-member operations

[complex.ops]

```cpp
template<class T> complex<T> operator+(const complex<T>& lhs);

Returns: complex<T>(lhs).

Remarks: unary operator.
```

```cpp
template<class T> complex<T> operator+(const complex<T>& lhs, const complex<T>& rhs);
```

```cpp
template<class T> complex<T> operator+(const complex<T>& lhs, const T& rhs);
```

```cpp
template<class T> complex<T> operator+(const T& lhs, const complex<T>& rhs);

Returns: complex<T>(lhs) += rhs.

Remarks: unary operator.
```

```cpp
template<class T> complex<T> operator-(const complex<T>& lhs);

Returns: complex<T>(-lhs.real(),-lhs.imag()).

Remarks: unary operator.
```

```cpp
template<class T> complex<T> operator-(const complex<T>& lhs, const complex<T>& rhs);
```

```cpp
template<class T> complex<T> operator-(const complex<T>& lhs, const T& rhs);
```

```cpp
template<class T> complex<T> operator-(const T& lhs, const complex<T>& rhs);

Returns: complex<T>(lhs) -= rhs.
```

```cpp
template<class T> complex<T> operator*(const complex<T>& lhs, const complex<T>& rhs);
```

```cpp
template<class T> complex<T> operator*(const complex<T>& lhs, const T& rhs);
```

```cpp
template<class T> complex<T> operator*(const T& lhs, const complex<T>& rhs);

Returns: complex<T>(lhs) *= rhs.
```

```cpp
template<class T> complex<T> operator/(const complex<T>& lhs, const complex<T>& rhs);
```

```cpp
template<class T> complex<T> operator/(const complex<T>& lhs, const T& rhs);
```

```cpp
template<class T> complex<T> operator/(const T& lhs, const complex<T>& rhs);

Returns: complex<T>(lhs) /= rhs.
```

```cpp
template<class T> constexpr bool operator==(const complex<T>& lhs, const complex<T>& rhs);
```

```cpp
template<class T> constexpr bool operator==(const complex<T>& lhs, const T& rhs);
```

```cpp
template<class T> constexpr bool operator==(const T& lhs, const complex<T>& rhs);

Returns: lhs.real() == rhs.real() && lhs.imag() == rhs.imag().

Remarks: The imaginary part is assumed to be T(), or 0.0, for the T arguments.
```

```cpp
template<class T> constexpr bool operator!=(const complex<T>& lhs, const complex<T>& rhs);
```

```cpp
template<class T> constexpr bool operator!=(const complex<T>& lhs, const T& rhs);
```

```cpp
template<class T> constexpr bool operator!=(const T& lhs, const complex<T>& rhs);

Returns: rhs.real() != lhs.real() || rhs.imag() != lhs.imag().
```

```cpp
template<class T, class charT, class traits>
basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& is, complex<T>& x);

Requires: The input values shall be convertible to T.

Effects: Extracts a complex number x of the form: u, (u), or (u,v), where u is the real part and v is the imaginary part (30.7.4.2).

If bad input is encountered, calls is.setstate(ios_base::failbit) (which may throw ios::failure (30.5.5.4)).

Returns: is.
```
N4659

© ISO/IEC

16

Remarks: This extraction is performed as a series of simpler extractions. Therefore, the skipping of
whitespace is specified to be the same for each of the simpler extractions.
template<class T, class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& o, const complex<T>& x);

17

Effects: Inserts the complex number x onto the stream o as if it were implemented as follows:
basic_ostringstream<charT, traits> s;
s.flags(o.flags());
s.imbue(o.getloc());
s.precision(o.precision());
s << ’(’ << x.real() << "," << x.imag() << ’)’;
return o << s.str();

18

[ Note: In a locale in which comma is used as a decimal point character, the use of comma as a field
separator can be ambiguous. Inserting showpoint into the output stream forces all outputs to show an
explicit decimal point character; as a result, all inserted sequences of complex numbers can be extracted
unambiguously. — end note ]

29.5.7

complex value operations

[complex.value.ops]

template<class T> constexpr T real(const complex<T>& x);
1

Returns: x.real().
template<class T> constexpr T imag(const complex<T>& x);

2

Returns: x.imag().
template<class T> T abs(const complex<T>& x);

3

Returns: The magnitude of x.
template<class T> T arg(const complex<T>& x);

4

Returns: The phase angle of x, or atan2(imag(x), real(x)).
template<class T> T norm(const complex<T>& x);

5

Returns: The squared magnitude of x.
template<class T> complex<T> conj(const complex<T>& x);

6

Returns: The complex conjugate of x.
template<class T> complex<T> proj(const complex<T>& x);

7

Returns: The projection of x onto the Riemann sphere.

8

Remarks: Behaves the same as the C function cproj, defined in 7.3.9.4.
template<class T> complex<T> polar(const T& rho, const T& theta = 0);

9
10

Requires: rho shall be non-negative and non-NaN. theta shall be finite.
Returns: The complex value corresponding to a complex number whose magnitude is rho and whose
phase angle is theta.

29.5.8

complex transcendentals

[complex.transcendentals]

template<class T> complex<T> acos(const complex<T>& x);

§ 29.5.8

1059


Returns: The complex arc cosine of \( x \).

Remarks: Behaves the same as C function \texttt{cacos}, defined in 7.3.5.1.

\[ \text{template\langle class T\rangle complex\langle T\rangle asin(const complex\langle T\rangle& x);} \]

Returns: The complex arc sine of \( x \).

Remarks: Behaves the same as C function \texttt{casin}, defined in 7.3.5.2.

\[ \text{template\langle class T\rangle complex\langle T\rangle atan(const complex\langle T\rangle& x);} \]

Returns: The complex arc tangent of \( x \).

Remarks: Behaves the same as C function \texttt{catan}, defined in 7.3.5.3.

\[ \text{template\langle class T\rangle complex\langle T\rangle acosh(const complex\langle T\rangle& x);} \]

Returns: The complex arc hyperbolic cosine of \( x \).

Remarks: Behaves the same as C function \texttt{cacosh}, defined in 7.3.6.1.

\[ \text{template\langle class T\rangle complex\langle T\rangle asinh(const complex\langle T\rangle& x);} \]

Returns: The complex arc hyperbolic sine of \( x \).

Remarks: Behaves the same as C function \texttt{casinh}, defined in 7.3.6.2.

\[ \text{template\langle class T\rangle complex\langle T\rangle atanh(const complex\langle T\rangle& x);} \]

Returns: The complex arc hyperbolic tangent of \( x \).

Remarks: Behaves the same as C function \texttt{catanh}, defined in 7.3.6.3.

\[ \text{template\langle class T\rangle complex\langle T\rangle cos(const complex\langle T\rangle& x);} \]

Returns: The complex cosine of \( x \).

\[ \text{template\langle class T\rangle complex\langle T\rangle cosh(const complex\langle T\rangle& x);} \]

Returns: The complex hyperbolic cosine of \( x \).

\[ \text{template\langle class T\rangle complex\langle T\rangle exp(const complex\langle T\rangle& x);} \]

Returns: The complex base-\( e \) exponential of \( x \).

\[ \text{template\langle class T\rangle complex\langle T\rangle log(const complex\langle T\rangle& x);} \]

Returns: The complex natural (base-\( e \)) logarithm of \( x \). For all \( x \), \texttt{imag(log(x))} lies in the interval \([-\pi, \pi]\), and when \( x \) is a negative real number, \texttt{imag(log(x))} is \( \pi \).

Remarks: The branch cuts are along the negative real axis.

\[ \text{template\langle class T\rangle complex\langle T\rangle log10(const complex\langle T\rangle& x);} \]

Returns: The complex common (base-10) logarithm of \( x \), defined as \( \log(x) / \log(10) \).

Remarks: The branch cuts are along the negative real axis.

\[ \text{template\langle class T\rangle complex\langle T\rangle pow(const complex\langle T\rangle& x, const complex\langle T\rangle& y);} \]

\[ \text{template\langle class T\rangle complex\langle T\rangle pow(const complex\langle T\rangle& x, const T& y);} \]

\[ \text{template\langle class T\rangle complex\langle T\rangle pow(const T& x, const complex\langle T\rangle& y);} \]

Returns: The complex power of base \( x \) raised to the \( y \)th power, defined as \( \exp(y \times \log(x)) \). The value returned for \( \text{pow}(0, 0) \) is implementation-defined.

Remarks: The branch cuts are along the negative real axis.

\[ \text{§ 29.5.8} \]
template<class T> complex<T> sin(const complex<T>& x);
   // Returns: The complex sine of x.

template<class T> complex<T> sinh(const complex<T>& x);
   // Returns: The complex hyperbolic sine of x.

template<class T> complex<T> sqrt(const complex<T>& x);
   // Returns: The complex square root of x, in the range of the right half-plane. If the argument is a negative real number, the value returned lies on the positive imaginary axis.

   // Remarks: The branch cuts are along the negative real axis.

template<class T> complex<T> tan(const complex<T>& x);
   // Returns: The complex tangent of x.

template<class T> complex<T> tanh(const complex<T>& x);
   // Returns: The complex hyperbolic tangent of x.

29.5.9 Additional overloads

The following function templates shall have additional overloads:

```
struct arg {
  float x, y;
};

struct conj {
  complex T x;
};

struct proj {
  complex T x;
};

struct imag {
  float y;
};

struct real {
  float x;
};
```

The additional overloads shall be sufficient to ensure:

1. If the argument has type `long double`, then it is effectively cast to `complex<long double>`.
2. Otherwise, if the argument has type `double` or an integer type, then it is effectively cast to `complex<double>`.
3. Otherwise, if the argument has type `float`, then it is effectively cast to `complex<float>`.

Function template `pow` shall have additional overloads sufficient to ensure, for a call with at least one argument of type `complex<T>`:

1. If either argument has type `complex<long double>` or type `long double`, then both arguments are effectively cast to `complex<long double>`.
2. Otherwise, if either argument has type `complex<double>`, `double`, or an integer type, then both arguments are effectively cast to `complex<double>`.
3. Otherwise, if either argument has type `complex<float>` or `float`, then both arguments are effectively cast to `complex<float>`.

29.5.10 Suffixes for complex number literals

This section describes literal suffixes for constructing complex number literals. The suffixes `i`, `il`, and `if` create complex numbers of the types `complex<double>`, `complex<long double>`, and `complex<float>` respectively, with their imaginary part denoted by the given literal number and the real part being zero.

```
constexpr complex<long double> operator "il(long double d);
constexpr complex<long double> operator "il(unsigned long long d);
```

```
constexpr complex<double> operator "i(long double d);
constexpr complex<double> operator "i(unsigned long long d);
```
Returns: complex<double>{0.0, static_cast<double>(d)}.

constexpr complex<float> operator"if(long double d);
constexpr complex<float> operator"if(unsigned long long d);
Returns: complex<float>{0.0f, static_cast<float>(d)}.

29.6 Random number generation

This subclause defines a facility for generating (pseudo-)random numbers.

In addition to a few utilities, four categories of entities are described: uniform random bit generators, random number engines, random number engine adaptors, and random number distributions. These categorizations are applicable to types that satisfy the corresponding requirements, to objects instantiated from such types, and to templates producing such types when instantiated. [Note: These entities are specified in such a way as to permit the binding of any uniform random bit generator object \( e \) as the argument to any random number distribution object \( d \), thus producing a zero-argument function object such as given by \( \text{bind}(d,e) \). —end note]

Each of the entities specified via this subclause has an associated arithmetic type (6.9.1) identified as result_type. With \( T \) as the result_type thus associated with such an entity, that entity is characterized:

a) as boolean or equivalently as boolean-valued, if \( T \) is bool;

b) otherwise as integral or equivalently as integer-valued, if \( \text{numeric_limits}<T>::\text{is_integer} \) is true;

c) otherwise as floating or equivalently as real-valued.

If integer-valued, an entity may optionally be further characterized as signed or unsigned, according to \( \text{numeric_limits}<T>::\text{is_signed} \).

Unless otherwise specified, all descriptions of calculations in this subclause use mathematical real numbers.

Throughout this subclause, the operators \( \&\& \), \( |\| \), and \( \oplus \) denote the respective conventional bitwise operations. Further:

a) the operator \( \text{rshift} \) denotes a bitwise right shift with zero-valued bits appearing in the high bits of the result,

b) the operator \( \text{lshift}_w \) denotes a bitwise left shift with zero-valued bits appearing in the low bits of the result, and whose result is always taken modulo \( 2^w \).

29.6.1 Requirements

29.6.1.1 General requirements

Throughout this subclause 29.6, the effect of instantiating a template:

a) that has a template type parameter named Sseq is undefined unless the corresponding template argument is cv-unqualified and satisfies the requirements of seed sequence (29.6.1.2).

b) that has a template type parameter named URBG is undefined unless the corresponding template argument is cv-unqualified and satisfies the requirements of uniform random bit generator (29.6.1.3).

c) that has a template type parameter named Engine is undefined unless the corresponding template argument is cv-unqualified and satisfies the requirements of random number engine (29.6.1.4).

d) that has a template type parameter named RealType is undefined unless the corresponding template argument is cv-unqualified and is one of float, double, or long double.

e) that has a template type parameter named IntType is undefined unless the corresponding template argument is cv-unqualified and is one of short, int, long, long long, unsigned short, unsigned int, unsigned long, or unsigned long long.
f) that has a template type parameter named `UIntType` is undefined unless the corresponding template argument is cv-unqualified and is one of `unsigned short`, `unsigned int`, `unsigned long`, or `unsigned long long`.

2 Throughout this subclause 29.6, phrases of the form “x is an iterator of a specific kind” shall be interpreted as equivalent to the more formal requirement that “x is a value of a type satisfying the requirements of the specified iterator type”.

3 Throughout this subclause 29.6, any constructor that can be called with a single argument and that satisfies a requirement specified in this subclause shall be declared `explicit`.

### 29.6.1.2 Seed sequence requirements  

A seed sequence is an object that consumes a sequence of integer-valued data and produces a requested number of unsigned integer values \( i, 0 \leq i < 2^{32} \), based on the consumed data.  

*Note: Such an object provides a mechanism to avoid replication of streams of random variates. This can be useful, for example, in applications requiring large numbers of random number engines. — end note*

A class \( S \) satisfies the requirements of a seed sequence if the expressions shown in Table 102 are valid and have the indicated semantics, and if \( S \) also satisfies all other requirements of this section 29.6.1.2. In that Table and throughout this section:

| a) | \( T \) is the type named by \( S \)'s associated `result_type`; |
| b) | \( q \) is a value of \( S \) and \( r \) is a possibly const value of \( S \); |
| c) | \( \text{ib} \) and \( \text{ie} \) are input iterators with an unsigned integer `value_type` of at least 32 bits; |
| d) | \( \text{rb} \) and \( \text{re} \) are mutable random access iterators with an unsigned integer `value_type` of at least 32 bits; |
| e) | \( \text{ob} \) is an output iterator; and |
| f) | \( \text{il} \) is a value of `initializer_list<T>`.

29.6.1.3 Uniform random bit generator requirements

A uniform random bit generator \( g \) of type \( G \) is a function object returning unsigned integer values such that each value in the range of possible results has (ideally) equal probability of being returned. \[Note: The degree to which \( g \)'s results approximate the ideal is often determined statistically. — end note\]

A class \( G \) satisfies the requirements of a uniform random bit generator if the expressions shown in Table 103 are valid and have the indicated semantics, and if \( G \) also satisfies all other requirements of this section 29.6.1.3. In that Table and throughout this section:

a) \( T \) is the type named by \( G \)'s associated \texttt{result_type}, and

b) \( g \) is a value of \( G \).

Table 103 — Uniform random bit generator requirements

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Pre/post-condition</th>
<th>Complexity</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>\texttt{G::max()}</td>
<td>\texttt{T}</td>
<td>Denotes the greatest value potentially returned by \texttt{operator()}.</td>
<td>compile-time</td>
</tr>
</tbody>
</table>
The following relation shall hold: \( G::\text{min}() < G::\text{max}() \).

29.6.1.4 Random number engine requirements

A random number engine (commonly shortened to engine) \( e \) of type \( E \) is a uniform random bit generator that additionally meets the requirements (e.g., for seeding and for input/output) specified in this section.

At any given time, \( e \) has a state \( e_i \) for some integer \( i \geq 0 \). Upon construction, \( e \) has an initial state \( e_0 \). An engine’s state may be established via a constructor, a \texttt{seed} function, assignment, or a suitable \texttt{operator\textgreater\textgreater}.

E’s specification shall define:

a) the size of E’s state in multiples of the size of \texttt{result\_type}, given as an integral constant expression;
b) the transition algorithm \( TA \) by which \( e \)’s state \( e_i \) is advanced to its successor state \( e_{i+1} \); and
c) the generation algorithm \( GA \) by which an engine’s state is mapped to a value of type \texttt{result\_type}.

A class \( E \) that satisfies the requirements of a uniform random bit generator (29.6.1.3) also satisfies the requirements of a random number engine if the expressions shown in Table 104 are valid and have the indicated semantics, and if \( E \) also satisfies all other requirements of this section 29.6.1.4. In that Table and throughout this section:

a) \( T \) is the type named by \( E \)’s associated \texttt{result\_type};
b) \( e \) is a value of \( E \), \( v \) is an lvalue of \( E \), \( x \) and \( y \) are (possibly \texttt{const}) values of \( E \);
c) \( s \) is a value of \( T \);
d) \( q \) is an lvalue satisfying the requirements of a seed sequence (29.6.1.2);
e) \( z \) is a value of type \texttt{unsigned long long};
f) \( os \) is an lvalue of the type of some class template specialization \texttt{basic\_ostream<\texttt{charT}, traits>}; and
g) \( is \) is an lvalue of the type of some class template specialization \texttt{basic\_istream<\texttt{charT}, traits>};

where \texttt{charT} and \texttt{traits} are constrained according to Clause 24 and Clause 30.

Table 104 — Random number engine requirements

<table>
<thead>

<td>per Table 103</td>
</tr>
<tr>
<td>e.discard(z)</td>
<td>void</td>
<td>Advances e’s state e_i to e_i+z by any means equivalent to z consecutive calls e().</td>
<td>no worse than the complexity of z consecutive calls e()</td>
</tr>
<tr>
<td>x == y</td>
<td>bool</td>
<td>This operator is an equivalence relation. With S_x and S_y as the infinite sequences of values that would be generated by repeated future calls to x() and y(), respectively, returns true if S_x = S_y; else returns false.</td>
<td>O(size of state)</td>
</tr>
<tr>
<td>x != y</td>
<td>bool</td>
<td>!(x == y).</td>
<td>O(size of state)</td>
</tr>
<tr>
<td>os &lt;&lt; x</td>
<td>reference to the type of os</td>
<td>With os.\text{fmtflags} set to ios\text{}-base::dec</td>
<td>ios\text{}-base::left and the fill character set to the space character, writes to os the textual representation of x’s current state. In the output, adjacent numbers are separated by one or more space characters. Postconditions: The os.\text{fmtflags} and fill character are unchanged.</td>
</tr>
</tbody>
</table>

269) This operation is common in user code, and can often be implemented in an engine-specific manner so as to provide significant performance improvements over an equivalent naive loop that makes z consecutive calls e().

§ 29.6.1.4
### Expression Return type Pre/post-condition Complexity

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Pre/post-condition</th>
<th>Complexity</th>
</tr>
</thead>
<tbody>
<tr>
<td>is &gt;&gt; v</td>
<td>reference to the type of is</td>
<td>With is.fmtflags set to ios_base::dec, sets v's state as determined by reading its textual representation from is. If bad input is encountered, ensures that v's state is unchanged by the operation and calls is.setstate(ios::failbit) (which may throw ios::failure (30.5.5.4)). If a textual representation written via os &lt;&lt; x was subsequently read via is &gt;&gt; v, then x == v provided that there have been no intervening invocations of x or of v. <em>Requires: is provides a textual representation that was previously written using an output stream whose imbued locale was the same as that of is, and whose type’s template specialization arguments charT and traits were respectively the same as those of is.</em> <em>Postconditions: The is.fmtflags are unchanged.</em></td>
<td>(O(\text{size of state}))</td>
</tr>
</tbody>
</table>

5 E shall meet the requirements of CopyConstructible (Table 24) and CopyAssignable (Table 26) types. These operations shall each be of complexity no worse than \(O(\text{size of state})\).

### 29.6.1.5 Random number engine adaptor requirements

A random number engine adaptor (commonly shortened to adaptor) a of type A is a random number engine that takes values produced by some other random number engine, and applies an algorithm to those values in order to deliver a sequence of values with different randomness properties. An engine b of type B adapted in this way is termed a base engine in this context. The expression a.base() shall be valid and shall return a const reference to a’s base engine.

The requirements of a random number engine type shall be interpreted as follows with respect to a random number engine adaptor type.

\[A::A();\]

*Effects: The base engine is initialized as if by its default constructor.*

bool operator==(const A& a1, const A& a2);

*Returns: true if a1’s base engine is equal to a2’s base engine. Otherwise returns false.*

\[A::A(\text{result
type } s);\]

*Effects: The base engine is initialized with s.*
template<class Sseq> A::A(Sseq & q);

Effects: The base engine is initialized with q.

void seed();

Effects: With b as the base engine, invokes b.seed().

void seed(result_type s);

Effects: With b as the base engine, invokes b.seed(s).

template<class Sseq> void seed(Sseq & q);

Effects: With b as the base engine, invokes b.seed(q).

A shall also satisfy the following additional requirements:

a) The complexity of each function shall not exceed the complexity of the corresponding function applied to the base engine.

b) The state of A shall include the state of its base engine. The size of A’s state shall be no less than the size of the base engine.

c) Copying A’s state (e.g., during copy construction or copy assignment) shall include copying the state of the base engine of A.

d) The textual representation of A shall include the textual representation of its base engine.

29.6.1.6 Random number distribution requirements

A random number distribution (commonly shortened to distribution) d of type D is a function object returning values that are distributed according to an associated mathematical probability density function \( p(z) \) or according to an associated discrete probability function \( P(z_i) \). A distribution’s specification identifies its associated probability function \( p(z) \) or \( P(z_i) \).

An associated probability function is typically expressed using certain externally-supplied quantities known as the parameters of the distribution. Such distribution parameters are identified in this context by writing, for example, \( p(z | a, b) \) or \( P(z_i | a, b) \), to name specific parameters, or by writing, for example, \( p(z | \{p\}) \) or \( P(z_i | \{p\}) \), to denote a distribution’s parameters \( p \) taken as a whole.

A class D satisfies the requirements of a random number distribution if the expressions shown in Table 105 are valid and have the indicated semantics, and if D and its associated types also satisfy all other requirements of this section 29.6.1.6. In that Table and throughout this section,

a) \( T \) is the type named by D’s associated result_type;

b) \( P \) is the type named by D’s associated param_type;

c) d is a value of D, and x and y are (possibly const) values of D;

d) glb and lub are values of T respectively corresponding to the greatest lower bound and the least upper bound on the values potentially returned by d’s operator(), as determined by the current values of d’s parameters;

e) p is a (possibly const) value of P;

f) g, g1, and g2 are lvalues of a type satisfying the requirements of a uniform random bit generator (29.6.1.3);

g) os is an lvalue of the type of some class template specialization basic_ostream<charT, traits>; and

h) is is an lvalue of the type of some class template specialization basic_istream<charT, traits>;

where charT and traits are constrained according to Clauses 24 and 30.
Table 105 — Random number distribution requirements

<td>Return type</td>
<td>Pre/post-condition</td>
<td>Complexity</td>
</tr>
<tr>
<td>------------</td>
<td>-------------</td>
<td>--------------------</td>
<td>------------</td>
</tr>
<tr>
<td>x == y</td>
<td>bool</td>
<td>This operator is an equivalence relation. Returns true if x.param() == y.param() and S1 = S2, where S1 and S2 are the infinite sequences of values that would be generated, respectively, by repeated future calls to x(g1) and y(g2) whenever g1 == g2. Otherwise returns false.</td>
<td>constant</td>
</tr>
<tr>
<td>x != y</td>
<td>bool</td>
<td>!(x == y).</td>
<td>same as x == y.</td>
</tr>
<tr>
<td>os &lt;&lt; x</td>
<td>reference to the type of os</td>
<td>Writes to os a textual representation for the parameters and the additional internal data of x. Postconditions: The os.fmtflags and fill character are unchanged.</td>
<td></td>
</tr>
<tr>
<td>is &gt;&gt; d</td>
<td>reference to the type of is</td>
<td>Restores from is the parameters and additional internal data of the lvalue d. If bad input is encountered, ensures that d is unchanged by the operation and calls is.setstate(ios::failbit) (which may throw ios::failure (30.5.5.4)). Requires: is provides a textual representation that was previously written using an os whose imbued locale and whose type's template specialization arguments charT and traits were the same as those of is. Postconditions: The is.fmtflags are unchanged.</td>
<td></td>
</tr>
</tbody>
</table>

4 D shall satisfy the requirements of CopyConstructible (Table 24) and CopyAssignable (Table 26) types.
5 The sequence of numbers produced by repeated invocations of d(g) shall be independent of any invocation of os << d or of any const member function of D between any of the invocations d(g).
6 If a textual representation is written using os << x and that representation is restored into the same or a different object y of the same type using is >> y, repeated invocations of y(g) shall produce the same sequence of numbers as would repeated invocations of x(g).
7 It is unspecified whether D::param_type is declared as a (nested) class or via a typedef. In this subclause 29.6, declarations of D::param_type are in the form of typedefs for convenience of exposition only.
8 P shall satisfy the requirements of CopyConstructible (Table 24), CopyAssignable (Table 26), and EqualityComparable (Table 20) types.
9 For each of the constructors of D taking arguments corresponding to parameters of the distribution, P shall
have a corresponding constructor subject to the same requirements and taking arguments identical in number, type, and default values. Moreover, for each of the member functions of $D$ that return values corresponding to parameters of the distribution, $P$ shall have a corresponding member function with the identical name, type, and semantics.

10 $P$ shall have a declaration of the form

```cpp
using distribution_type = D;
```

29.6.3 Random number engine class templates [rand.eng]

1. Each type instantiated from a class template specified in this section 29.6.3 satisfies the requirements of a random number engine (29.6.1.4) type.

2. Except where specified otherwise, the complexity of each function specified in this section 29.6.3 is constant.

3. Except where specified otherwise, no function described in this section 29.6.3 throws an exception.

4. Every function described in this section 29.6.3 that has a function parameter \( q \) of type \( \text{Sseq} \) for a template type parameter named \( \text{Sseq} \) that is different from type \( \text{seed_seq} \) throws what and when the invocation of \( q \).\text{generate} throws.

5. Descriptions are provided in this section 29.6.3 only for engine operations that are not described in 29.6.1.4 or for operations where there is additional semantic information. In particular, declarations for copy constructors, for copy assignment operators, for streaming operators, and for equality and inequality operators are not shown in the synopses.

6. Each template specified in this section 29.6.3 requires one or more relationships, involving the value(s) of its non-type template parameter(s), to hold. A program instantiating any of these templates is ill-formed if any such required relationship fails to hold.

7. For every random number engine and for every random number engine adaptor \( X \) defined in this subclause (29.6.3) and in subclause 29.6.4:

(7.1) — if the constructor
template <class Sseq> explicit X(Sseq& q);

is called with a type $Sseq$ that does not qualify as a seed sequence, then this constructor shall not participate in overload resolution;

(7.2) — if the member function

    template <class Sseq> void seed(Sseq& q);

is called with a type $Sseq$ that does not qualify as a seed sequence, then this function shall not participate in overload resolution.

The extent to which an implementation determines that a type cannot be a seed sequence is unspecified, except that as a minimum a type shall not qualify as a seed sequence if it is implicitly convertible to $X::result_type$.

29.6.3.1 Class template linear_congruential_engine

A linear_congruential_engine random number engine produces unsigned integer random numbers. The state $x_i$ of a linear_congruential_engine object $x$ is of size 1 and consists of a single integer. The transition algorithm is a modular linear function of the form $TA(x_i) = (a \cdot x_i + c) \mod m$; the generation algorithm is $GA(x_i) = x_i + 1$.

```cpp
template<class UIntType, UIntType a, UIntType c, UIntType m>
class linear_congruential_engine {
public:
    // types
    using result_type = UIntType;

    // engine characteristics
    static constexpr result_type multiplier = a;
    static constexpr result_type increment = c;
    static constexpr result_type modulus = m;
    static constexpr result_type min() { return c == 0u ? 1u : 0u; }
    static constexpr result_type max() { return m - 1u; }
    static constexpr result_type default_seed = 1u;

    // constructors and seeding functions
    explicit linear_congruential_engine(result_type s = default_seed);
    template<class Sseq> explicit linear_congruential_engine(Sseq& q);
    void seed(result_type s = default_seed);
    template<class Sseq> void seed(Sseq& q);

    // generating functions
    result_type operator()();
    void discard(unsigned long long z);
};
```

2 If the template parameter $m$ is 0, the modulus $m$ used throughout this section 29.6.3.1 is numeric_limits<result_type>::max() plus 1. [Note: $m$ need not be representable as a value of type result_type. —end note]

3 If the template parameter $m$ is not 0, the following relations shall hold: $a < m$ and $c < m$.

4 The textual representation consists of the value of $x_i$.

    explicit linear_congruential_engine(result_type s = default_seed);

    Effects: Constructs a linear_congruential_engine object. If $c \mod m$ is 0 and $s \mod m$ is 0, sets the engine’s state to 1, otherwise sets the engine’s state to $s \mod m$.
template<class Sseq> explicit linear_congruential_engine(Sseq& q);

Effects: Constructs a linear_congruential_engine object. With \( k = \lceil \log_2 m \rceil \) and \( a \) an array (or equivalent) of length \( k + 3 \), invokes \( q.generate(a + 0, a + k + 3) \) and then computes
\[
S = \left( \sum_{j=0}^{k-1} a_{j+3} \cdot 2^{32j} \right) \mod m.
\]
If \( c \mod m \) is 0 and \( S \) is 0, sets the engine’s state to 1, else sets the engine’s state to \( S \).

29.6.3.2 Class template mersenne_twister_engine

A mersenne_twister_engine random number engine\(^{270}\) produces unsigned integer random numbers in the closed interval \([0, 2^w - 1]\). The state \( x_i \) of a mersenne_twister_engine object \( x \) is of size \( n \) and consists of a sequence \( X \) of \( n \) values of the type delivered by \( x \); all subscripts applied to \( X \) are to be taken modulo \( n \).

The transition algorithm employs a twisted generalized feedback shift register defined by shift values \( n \) and \( m \), a twist value \( r \), and a conditional xor-mask \( a \). To improve the uniformity of the result, the bits of the raw shift register are additionally tempered (i.e., scrambled) according to a bit-scrambling matrix defined by values \( u, d, s, b, t, c, \) and \( \ell \).

The state transition is performed as follows:

a) Concatenate the upper \( w - r \) bits of \( X_{i-n} \) with the lower \( r \) bits of \( X_{i+1-n} \) to obtain an unsigned integer value \( Y \).

b) With \( \alpha = a \cdot (Y \text{bitand} 1) \), set \( X_i \) to \( X_{i+m-n} \text{xor} (Y \text{rshift} 1) \text{xor} \alpha \).

The sequence \( X \) is initialized with the help of an initialization multiplier \( f \).

The generation algorithm determines the unsigned integer values \( z_1, z_2, z_3, z_4 \) as follows, then delivers \( z_4 \) as its result:

a) Let \( z_1 = X_i \text{xor} ((X_i \text{rshift} u) \text{bitand} d) \).

b) Let \( z_2 = z_1 \text{xor} ((z_1 \text{lshift} w) \text{bitand} b) \).

c) Let \( z_3 = z_2 \text{xor} ((z_2 \text{lshift} w) \text{bitand} c) \).

d) Let \( z_4 = z_3 \text{xor} (z_3 \text{rshift} \ell) \).

\[270\) The name of this engine refers, in part, to a property of its period: For properly-selected values of the parameters, the period is closely related to a large Mersenne prime number."
static constexpr size_t tempering_t = t;
static constexpr UIntType tempering_c = c;
static constexpr size_t tempering_l = l;
static constexpr UIntType initialization_multiplier = f;
static constexpr result_type min() { return 0; }
static constexpr result_type max() { return \(2^w - 1\); }
static constexpr result_type default_seed = 5489u;

// constructors and seeding functions
explicit mersenne_twister_engine(result_type value = default_seed);
template<class Sseq> explicit mersenne_twister_engine(Sseq& q);
void seed(result_type value = default_seed);
template<class Sseq> void seed(Sseq& q);

// generating functions
result_type operator()();
void discard(unsigned long long z);

4 The following relations shall hold: \(0 < m \), \(m \leq n \), \(2^u < w \), \(r \leq w \), \(s \leq w \), \(l \leq w \), \(w \leq \) numeric_limits<UIntType>::digits, \(a \leq (1u<<w) - 1u \), \(b \leq (1u<<w) - 1u \), \(c \leq (1u<<w) - 1u \), \(d \leq (1u<<w) - 1u \), and \(f \leq (1u<<w) - 1u \).

5 The textual representation of \(x_i\) consists of the values of \(X_{i-n}, \ldots, X_{i-1}\), in that order.

explicit mersenne_twister_engine(result_type value = default_seed);

6 Effects: Constructs a mersenne_twister_engine object. Sets \(X_{i-n}\) to \(value\) mod \(2^w\). Then, iteratively for \(i = 1-n, \ldots, -1\), sets \(X_i\) to
\[
\left[ f \cdot (X_{i-1} \text{xor} (X_{i-1} \text{rshift} (w - 2))) + i \text{ mod } n \right] \text{ mod } 2^w .
\]

7 Complexity: \(\mathcal{O}(n)\).

template<class Sseq> explicit mersenne_twister_engine(Sseq& q);

8 Effects: Constructs a mersenne_twister_engine object. With \(k = \lceil w/32 \rceil\) and \(a\) an array (or equivalent) of length \(n\cdot k\), invokes q.generate(\(a+0, a+n\cdot k\)) and then, iteratively for \(i = -n, \ldots, -1\), sets \(X_i\) to \(\left( \sum_{j=0}^{k-1} a_{k(i+n)+j} \cdot 2^{32j} \right) \text{ mod } 2^w\). Finally, if the most significant \(w - r\) bits of \(X_{-n}\) are zero, and if each of the other resulting \(X_i\) is 0, changes \(X_{-n}\) to \(2^w - 1\).

29.6.3.3 Class template subtract_with_carry_engine

A subtract_with_carry_engine random number engine produces unsigned integer random numbers.

2 The state \(x_i\) of a subtract_with_carry_engine object \(x\) is of size \(\mathcal{O}(r)\), and consists of a sequence of \(r\) integer values \(0 \leq X_i < m = 2^w\); all subscripts applied to \(X\) are to be taken modulo \(r\). The state \(x_i\) additionally consists of an integer \(c\) (known as the carry) whose value is either 0 or 1.

3 The state transition is performed as follows:
   a) Let \(Y = X_{i-s} - X_{i-r} - c\).
   b) Set \(X_i\) to \(y = Y \text{ mod } m\). Set \(c\) to 1 if \(Y < 0\), otherwise set \(c\) to 0.

   [Note: This algorithm corresponds to a modular linear function of the form \(TA(x_i) = (a \cdot x_i) \text{ mod } b\), where \(b\) is of the form \(m^r - m^s + 1\) and \(a = b - (b - 1)/m\). — end note]

4 The generation algorithm is given by \(GA(x_i) = y\), where \(y\) is the value produced as a result of advancing the engine’s state as described above.
template<class UIntType, size_t w, size_t s, size_t r>
class subtract_with_carry_engine {
public:
    // types
    using result_type = UIntType;

    // engine characteristics
    static constexpr size_t word_size = w;
    static constexpr size_t short_lag = s;
    static constexpr size_t long_lag = r;
    static constexpr result_type min() { return 0; }
    static constexpr result_type max() { return m - 1; }
    static constexpr result_type default_seed = 19780503u;

    // constructors and seeding functions
    explicit subtract_with_carry_engine(result_type value = default_seed);
    template<class Sseq> explicit subtract_with_carry_engine(Sseq& q);
    void seed(result_type value = default_seed);
    template<class Sseq> void seed(Sseq& q);

    // generating functions
    result_type operator()();
    void discard(unsigned long long z);
};

The following relations shall hold: 0u < s, s < r, 0 < w, and w <= numeric_limits<UIntType>::digits.

The textual representation consists of the values of $X_{i-r}, \ldots, X_{i-1}$, in that order, followed by $c$.

explicit subtract_with_carry_engine(result_type value = default_seed);
Effects: Constructs a subtract_with_carry_engine object. Sets the values of $X_{-r}, \ldots, X_{-1}$, in that order, as specified below. If $X_{-1}$ is then 0, sets $c$ to 1; otherwise sets $c$ to 0.
To set the values $X_k$, first construct $e$, a linear_congruential_engine object, as if by the following definition:

linear_congruential_engine<result_type,
40014u,0u,2147483563u> e(value == 0u ? default_seed : value);

Then, to set each $X_k$, obtain new values $z_0, \ldots, z_{n-1}$ from $n = \lceil w/32 \rceil$ successive invocations of $e$ taken modulo $2^{32}$. Set $X_k$ to $(\sum_{j=0}^{n-1} z_j \cdot 2^{32j}) \mod m$.
Complexity: Exactly $n \cdot r$ invocations of $e$.

template<class Sseq> explicit subtract_with_carry_engine(Sseq& q);
Effects: Constructs a subtract_with_carry_engine object. With $k = \lceil w/32 \rceil$ and $a$ an array (or equivalent) of length $r \cdot k$, invokes $q$ generate $(a + 0, a + r \cdot k)$ and then, iteratively for $i = -r, \ldots, -1$, sets $X_i$ to $(\sum_{j=0}^{k-1} a_{k(i+r)+j} \cdot 2^{32j}) \mod m$. If $X_{-1}$ is then 0, sets $c$ to 1; otherwise sets $c$ to 0.

29.6.4 Random number engine adaptor class templates
29.6.4.1 In general
1 Each type instantiated from a class template specified in this section 29.6.4 satisfies the requirements of a random number engine adaptor (29.6.1.5) type.
2 Except where specified otherwise, the complexity of each function specified in this section 29.6.4 is constant.
3 Except where specified otherwise, no function described in this section 29.6.4 throws an exception.
Every function described in this section 29.6.4 that has a function parameter \( q \) of type `Sseq&` for a template type parameter named `Sseq` that is different from type `seed_seq` throws what and when the invocation of \( q\).generate \) throws.

Descriptions are provided in this section 29.6.4 only for adaptor operations that are not described in section 29.6.1.5 or for operations where there is additional semantic information. In particular, declarations for copy constructors, for copy assignment operators, for streaming operators, and for equality and inequality operators are not shown in the synopses.

Each template specified in this section 29.6.4 requires one or more relationships, involving the value(s) of its non-type template parameter(s), to hold. A program instantiating any of these templates is ill-formed if any such required relationship fails to hold.

29.6.4.2 Class template `discard_block_engine` [rand.adapt.disc]

A `discard_block_engine` random number engine adaptor produces random numbers selected from those produced by some base engine \( e \). The state \( x_i \) of a `discard_block_engine` engine adaptor object \( x \) consists of the state \( e_i \) of its base engine \( e \) and an additional integer \( n \). The size of the state is the size of \( e \)'s state plus 1.

The transition algorithm discards all but \( r > 0 \) values from each block of \( p \geq r \) values delivered by \( e \). The state transition is performed as follows: If \( n \geq r \), advance the state of \( e \) from \( e_i \) to \( e_{i+p-r} \) and set \( n \) to 0. In any case, then increment \( n \) and advance \( e \)'s then-current state \( e_j \) to \( e_{j+1} \).

The generation algorithm yields the value returned by the last invocation of \( e() \) while advancing \( e \)'s state as described above.

```cpp
template<class Engine, size_t p, size_t r>
class discard_block_engine {
    public:
        // types
        using result_type = typename Engine::result_type;

        // engine characteristics
        static constexpr size_t block_size = p;
        static constexpr size_t used_block = r;
        static constexpr result_type min() { return Engine::min(); }
        static constexpr result_type max() { return Engine::max(); }

        // constructors and seeding functions
        discard_block_engine();
        explicit discard_block_engine(const Engine& e);
        explicit discard_block_engine(Engine&& e);
        explicit discard_block_engine(result_type s);
        template<class Sseq> explicit discard_block_engine(Sseq& q);
        void seed();
        void seed(result_type s);
        template<class Sseq> void seed(Sseq& q);

        // generating functions
        result_type operator()();
        void discard(unsigned long long z);

        // property functions
        const Engine& base() const noexcept { return e; }

    private:
}
```

§ 29.6.4.2 1078
The following relations shall hold: $0 < r$ and $r \leq p$.

In addition to its behavior pursuant to section 29.6.1.5, each constructor that is not a copy constructor sets $n$ to 0.

### 29.6.4.3 Class template `independent_bits_engine` [rand.adapt.ibits]

An `independent_bits_engine` random number engine adaptor combines random numbers that are produced by some base engine $e$, so as to produce random numbers with a specified number of bits $w$. The state $x_i$ of an `independent_bits_engine` engine adaptor object $x$ consists of the state $e_i$ of its base engine $e$; the size of the state is the size of $e$’s state.

The transition and generation algorithms are described in terms of the following integral constants:

- a) Let $R = e_{\text{max}}() - e_{\text{min}}() + 1$ and $m = \lceil \log_2 R \rceil$.
- b) With $n$ as determined below, let $w_0 = \lceil w/n \rceil$, $n_0 = n - w \mod n$, $y_0 = 2^{w_0} \lfloor R/2^{w_0} \rfloor$, and $y_1 = 2^{w_0+1} \lceil R/2^{w_0+1} \rceil$.
- c) Let $n = \lceil w/m \rceil$ if and only if the relation $R - y_0 \leq \lfloor y_0/n \rfloor$ holds as a result. Otherwise let $n = 1 + \lceil w/m \rceil$.

[Note: The relation $w = n_0 w_0 + (n - n_0)(w_0 + 1)$ always holds. —end note]

The transition algorithm is carried out by invoking $e()$ as often as needed to obtain $n_0$ values less than $y_0 + e_{\text{min}}()$ and $n - n_0$ values less than $y_1 + e_{\text{min}}()$.

The generation algorithm uses the values produced while advancing the state as described above to yield a quantity $S$ obtained as if by the following algorithm:

```cpp
S = 0;
for (k = 0; k != n_0; k += 1) {
    do u = e() - e_{\text{min}}(); while (u \geq y_0);
    S = 2^{w_0} \cdot S + u \mod 2^{w_0};
}
for (k = n_0; k != n; k += 1) {
    do u = e() - e_{\text{min}}(); while (u \geq y_1);
    S = 2^{w_0+1} \cdot S + u \mod 2^{w_0+1};
}
```

```cpp
template<class Engine, size_t w, class UIntType>
class independent_bits_engine {
    public:
        // types
        using result_type = UIntType;

        // engine characteristics
        static constexpr result_type min() { return 0; }
        static constexpr result_type max() { return 2^w - 1; }

        // constructors and seeding functions
        independent_bits_engine();
        explicit independent_bits_engine(const Engine& e);
        explicit independent_bits_engine(Engine&& e);
        explicit independent_bits_engine(result_type s);
        template<class Sseq> explicit independent_bits_engine(Sseq& q);
        void seed();
}
```
void seed(result_type s);
template<class Sseq> void seed(Sseq& q);

// generating functions
result_type operator()();
void discard(unsigned long long z);

// property functions
const Engine& base() const noexcept { return e; }

private:
    Engine e; // exposition only
};

5 The following relations shall hold: 0 < w and w <= numeric_limits<result_type>::digits.
6 The textual representation consists of the textual representation of e.

29.6.4.4 Class template shuffle_order_engine [rand.adapt.shuf]

1 A shuffle_order_engine random number engine adaptor produces the same random numbers that are
produced by some base engine e, but delivers them in a different sequence. The state \( x_i \) of a shuffle-
order_engine engine adaptor object \( x \) consists of the state \( e_i \) of its base engine \( e \), an additional value \( Y \) of
the type delivered by \( e \), and an additional sequence \( V \) of \( k \) values also of the type delivered by \( e \). The size of
the state is the size of \( e \)'s state plus \( k + 1 \).
2 The transition algorithm permutes the values produced by \( e \). The state transition is performed as follows:
   a) Calculate an integer \( j = \lfloor \frac{k(Y-e_{\text{min}})}{e_{\text{max}}-e_{\text{min}}+1} \rfloor \).
   b) Set \( Y \) to \( V_j \) and then set \( V_j \) to \( e() \).
3 The generation algorithm yields the last value of \( Y \) produced while advancing \( e \)'s state as described above.

template<class Engine, size_t k>
class shuffle_order_engine {
public:
    using result_type = typename Engine::result_type;

    // engine characteristics
    static constexpr size_t table_size = k;
    static constexpr result_type min() { return Engine::min(); }  
    static constexpr result_type max() { return Engine::max(); }  

    // constructors and seeding functions
    shuffle_order_engine();
    explicit shuffle_order_engine(const Engine& e);
    explicit shuffle_order_engine(Engine&& e);
    explicit shuffle_order_engine(result_type s);
    template<class Sseq> explicit shuffle_order_engine(Sseq& q);
    void seed();
    void seed(result_type s);
    template<class Sseq> void seed(Sseq& q);

    // generating functions
    result_type operator()();
    void discard(unsigned long long z);
// property functions
const Engine& base() const noexcept { return e; };

private:
  Engine e;       // exposition only
  result_type V[k];  // exposition only
  result_type Y;   // exposition only
};

4 The following relation shall hold: 0 < k.
5 The textual representation consists of the textual representation of e, followed by the k values of V, followed by the value of Y.
6 In addition to its behavior pursuant to section 29.6.1.5, each constructor that is not a copy constructor initializes V[0],...V[k-1] and Y, in that order, with values returned by successive invocations of e().

29.6.5 Engines and engine adaptors with predefined parameters [rand.predef]

using minstd_rand0 =
  linear_congruential_engine<uint_fast32_t, 16807, 0, 2147483647>;
1 Required behavior: The 10000th consecutive invocation of a default-constructed object of type minstd_rand0 shall produce the value 1043618065.

using minstd_rand =
  linear_congruential_engine<uint_fast32_t, 48271, 0, 2147483647>;
2 Required behavior: The 10000th consecutive invocation of a default-constructed object of type minstd_rand shall produce the value 399268537.

using mt19937 =
  mersenne_twister_engine<uint_fast32_t,
    32,624,397,31,0x9908b0df,11,0xffffffff,7,0x9d2c5680,15,0xefc60000,18,1812433253>;
3 Required behavior: The 10000th consecutive invocation of a default-constructed object of type mt19937 shall produce the value 4123659995.

using mt19937_64 =
  mersenne_twister_engine<uint_fast64_t,
    64,312,156,31,0xb5026f5aa96619e9,9,29,
    0x5555555555555555,17,
    0x71d67ffbeda60000,37,
    0xfffffffff000000000,43,
    6364136223846793005>;
4 Required behavior: The 10000th consecutive invocation of a default-constructed object of type mt19937_64 shall produce the value 9981545732273789042.

using ranlux24_base =
  subtract_with_carry_engine<uint_fast32_t, 24, 10, 24>;
5 Required behavior: The 10000th consecutive invocation of a default-constructed object of type ranlux24_base shall produce the value 7937952.

using ranlux48_base =
  subtract_with_carry_engine<uint_fast64_t, 48, 5, 12>;
6 Required behavior: The 10000th consecutive invocation of a default-constructed object of type ranlux48_base shall produce the value 61839128582725.
using ranlux24 = discard_block_engine<ranlux24_base, 223, 23>;

Required behavior: The 10000\textsuperscript{th} consecutive invocation of a default-constructed object of type \texttt{ranlux24} shall produce the value 9901578.

using ranlux48 = discard_block_engine<ranlux48_base, 389, 11>;

Required behavior: The 10000\textsuperscript{th} consecutive invocation of a default-constructed object of type \texttt{ranlux48} shall produce the value 249142670248501.

using knuth_b = shuffle_order_engine<minstd_rand0,256>;

Required behavior: The 10000\textsuperscript{th} consecutive invocation of a default-constructed object of type \texttt{knuth_b} shall produce the value 1112339016.

using default_random_engine = \textit{implementation-defined};

Remarks: The choice of engine type named by this \texttt{typedef} is implementation-defined. [\textit{Note}: The implementation may select this type on the basis of performance, size, quality, or any combination of such factors, so as to provide at least acceptable engine behavior for relatively casual, inexpert, and/or lightweight use. Because different implementations may select different underlying engine types, code that uses this \texttt{typedef} need not generate identical sequences across implementations. —end note]

\section*{29.6.6 Class random_device} \hfill [rand.device]

A \texttt{random_device} uniform random bit generator produces nondeterministic random numbers.

If implementation limitations prevent generating nondeterministic random numbers, the implementation may employ a random number engine.

class random_device {
  public:
    // types
    using result_type = unsigned int;

    // generator characteristics
    static constexpr result_type min() { return numeric_limits<result_type>::min(); }
    static constexpr result_type max() { return numeric_limits<result_type>::max(); }

    // constructors
    explicit random_device(const string& token = \textit{implementation-defined});

    // generating functions
    result_type operator()();

    // property functions
    double entropy() const noexcept;

    // no copy functions
    random_device(const random_device&) = delete;
    void operator=(const random_device&) = delete;
  
  explicit random_device(const string& token = \textit{implementation-defined});

  Effects: Constructs a \texttt{random_device} nondeterministic uniform random bit generator object. The semantics and default value of the \texttt{token} parameter are implementation-defined.\textsuperscript{271}

\textsuperscript{271) The parameter is intended to allow an implementation to differentiate between different sources of randomness.}
4. **Throws:** A value of an implementation-defined type derived from `exception` if the `random_device` could not be initialized.

   ```cpp
double entropy() const noexcept;
```

5. **Returns:** If the implementation employs a random number engine, returns 0.0. Otherwise, returns an entropy estimate\(^{272}\) for the random numbers returned by `operator()`, in the range \(\text{min}()\) to \(\log_2(\text{max}() + 1)\).

   ```cpp
result_type operator()();
```

6. **Returns:** A nondeterministic random value, uniformly distributed between \(\text{min}()\) and \(\text{max}()\), inclusive. It is implementation-defined how these values are generated.

7. **Throws:** A value of an implementation-defined type derived from `exception` if a random number could not be obtained.

### 29.6.7 Utilities

#### 29.6.7.1 Class `seed_seq`\(^{272}\)

```cpp
class seed_seq {
public:
    // types
    using result_type = uint_least32_t;

    // constructors
    seed_seq();
    template<class T>
    seed_seq(initializer_list<T> il);
    template<class InputIterator>
    seed_seq(InputIterator begin, InputIterator end);

    // generating functions
    template<class RandomAccessIterator>
    void generate(RandomAccessIterator begin, RandomAccessIterator end);

    // property functions
    size_t size() const noexcept;
    template<class OutputIterator>
    void param(OutputIterator dest) const;

    // no copy functions
    seed_seq(const seed_seq& ) = delete;
    void operator=(const seed_seq& ) = delete;

private:
    vector<result_type> v; // exposition only
};
```

1. **Effects:** Constructs a `seed_seq` object as if by default-constructing its member `v`.

2. **Throws:** Nothing.

---

\(^{272}\) If a device has \(n\) states whose respective probabilities are \(P_0, \ldots, P_{n-1}\), the device entropy \(S\) is defined as

\[
S = - \sum_{i=0}^{n-1} P_i \cdot \log P_i.
\]
seed_seq(initializer_list<T> il);

Requires: T shall be an integer type.

Effects: Same as seed_seq(il.begin(), il.end()).

template<class InputIterator>
seed_seq(InputIterator begin, InputIterator end);

Requires: InputIterator shall satisfy the requirements of an input iterator (Table 95) type. Moreover, iterator_traits<InputIterator>::value_type shall denote an integer type.

Effects: Constructs a seed_seq object by the following algorithm:

for( InputIterator s = begin; s != end; ++s)
v.push_back((*s) mod 2^32);

template<class RandomAccessIterator>
void generate(RandomAccessIterator begin, RandomAccessIterator end);

Requires: RandomAccessIterator shall meet the requirements of a mutable random access iterator (27.2.7). Moreover, iterator_traits<RandomAccessIterator>::value_type shall denote an unsigned integer type capable of accommodating 32-bit quantities.

Effects: Does nothing if begin == end. Otherwise, with s = v.size() and n = end - begin, fills the supplied range [begin, end) according to the following algorithm in which each operation is to be carried out modulo 2^32, each indexing operator applied to begin is to be taken modulo n, and T(x) is defined as x xor (x rshift 27):

a) By way of initialization, set each element of the range to the value 0xb8b8b8b8. Additionally, for use in subsequent steps, let p = (n - t)/2 and let q = p + t, where

\[ t = \begin{cases} 
  11 & (n \geq 623) \\
  7 & (n \geq 68) \\
  5 & (n \geq 39) \\
  3 & (n \geq 7) \\
  (n-1)/2 & \text{otherwise} 
\end{cases} \]

b) With m as the larger of s + 1 and n, transform the elements of the range: iteratively for \( k = 0, \ldots, m - 1 \), calculate values

\[ r_1 = 1664525 \cdot T(\text{begin}[k] \ xor \ \text{begin}[k + p] \ xor \ \text{begin}[k - 1]) \]

\[ r_2 = r_1 + \begin{cases} 
  s & k = 0 \\
  k \ mod \ n + v[k - 1] & 0 < k \leq s \\
  k \ mod \ n & s < k 
\end{cases} \]

and, in order, increment \( \text{begin}[k + p] \) by \( r_1 \), increment \( \text{begin}[k + q] \) by \( r_2 \), and set \( \text{begin}[k] \) to \( r_2 \).

c) Transform the elements of the range again, beginning where the previous step ended: iteratively for \( k = m, \ldots, m+n-1 \), calculate values

\[ r_3 = 1566083941 \cdot T(\text{begin}[k] + \text{begin}[k + p] + \text{begin}[k - 1]) \]

\[ r_4 = r_3 - (k \ mod \ n) \]

and, in order, update \( \text{begin}[k + p] \) by xoring it with \( r_3 \), update \( \text{begin}[k + q] \) by xoring it with \( r_4 \), and set \( \text{begin}[k] \) to \( r_4 \).

Throws: What and when RandomAccessIterator operations of begin and end throw.

size_t size() const noexcept;

Returns: The number of 32-bit units that would be returned by a call to param().

Complexity: Constant time.
template<class OutputIterator>
    void param(OutputIterator dest) const;

12  Requires: OutputIterator shall satisfy the requirements of an output iterator (27.2.4). Moreover, the 
      expression *dest = rt shall be valid for a value rt of type result_type.

13  Effects: Copies the sequence of prepared 32-bit units to the given destination, as if by executing the 
      following statement:

      copy(v.begin(), v.end(), dest);

14  Throws: What and when OutputIterator operations of dest throw.

29.6.7.2 Function template generate_canonical

Each function instantiated from the template described in this section 29.6.7.2 maps the result of one or 
more invocations of a supplied uniform random bit generator g to one member of the specified RealType 
such that, if the values \( g_i \) produced by g are uniformly distributed, the instantiation’s results \( t_j, 0 \leq t_j < 1 \), 
are distributed as uniformly as possible as specified below.

[Note: Obtaining a value in this way can be a useful step in the process of transforming a value generated by 
a uniform random bit generator into a value that can be delivered by a random number distribution. — end 
note]

template<class RealType, size_t bits, class URBG>
    RealType generate_canonical(URBG& g);

3  Complexity: Exactly \( k = \max(1, \lceil b/\log_2 R \rceil) \) invocations of g, where \( b^{273} \) is the lesser of numeric_-
      limits<RealType>::digits and bits, and \( R \) is the value of g.max() – g.min() + 1.

4  Effects: Invokes g() \( k \) times to obtain values \( g_0, \ldots, g_{k-1} \), respectively. Calculates a quantity

\[
S = \sum_{i=0}^{k-1} (g_i - g.min()) \cdot R^i
\]

using arithmetic of type RealType.

5  Returns: \( S/R^k \).

6  Throws: What and when g throws.

29.6.8 Random number distribution class templates

29.6.8.1 In general

Each type instantiated from a class template specified in this section 29.6.8 satisfies the requirements of a 
random number distribution (29.6.1.6) type.

2 Descriptions are provided in this section 29.6.8 only for distribution operations that are not described in 
29.6.1.6 or for operations where there is additional semantic information. In particular, declarations for 
copy constructors, for copy assignment operators, for streaming operators, and for equality and inequality 
operators are not shown in the synopses.

3 The algorithms for producing each of the specified distributions are implementation-defined.

4 The value of each probability density function \( p(z) \) and of each discrete probability function \( P(z_i) \) specified 
in this section is 0 everywhere outside its stated domain.

\(273\) b is introduced to avoid any attempt to produce more bits of randomness than can be held in RealType.
29.6.8.2 Uniform distributions

29.6.8.2.1 Class template uniform_int_distribution

A uniform_int_distribution random number distribution produces random integers \( i, a \leq i \leq b \), distributed according to the constant discrete probability function

\[
P(i \mid a, b) = \frac{1}{b - a + 1}.
\]

```cpp
template<class IntType = int>
class uniform_int_distribution {
public:
    // types
    using result_type = IntType;
    using param_type = unspecified;

    // constructors and reset functions
    explicit uniform_int_distribution(IntType a = 0, IntType b = numeric_limits<IntType>::max());
    explicit uniform_int_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

    // property functions
    result_type a() const;
    result_type b() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

2

Requires: \( a \leq b \).

Effects: Constructs a uniform_int_distribution object; \( a \) and \( b \) correspond to the respective parameters of the distribution.

result_type a() const;

Returns: The value of the \( a \) parameter with which the object was constructed.

result_type b() const;

Returns: The value of the \( b \) parameter with which the object was constructed.

29.6.8.2.2 Class template uniform_real_distribution

A uniform_real_distribution random number distribution produces random numbers \( x, a \leq x < b \), distributed according to the constant probability density function

\[
p(x \mid a, b) = \frac{1}{b - a}.
\]

[Note: This implies that \( p(x \mid a, b) \) is undefined when \( a = b \). — end note]
template<class RealType = double>
class uniform_real_distribution {

public:
    // types
    using result_type = RealType;
    using param_type = unspecified;

    // constructors and reset functions
    explicit uniform_real_distribution(RealType a = 0.0, RealType b = 1.0);
    explicit uniform_real_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

    // property functions
    result_type a() const;
    result_type b() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};

explicit uniform_real_distribution(RealType a = 0.0, RealType b = 1.0);

Requires: \( a \leq b \) and \( b - a \leq \text{numeric\_limits<RealType>::max()} \).

Effects: Constructs a uniform_real_distribution object; \( a \) and \( b \) correspond to the respective parameters of the distribution.

result_type a() const;

Returns: The value of the \( a \) parameter with which the object was constructed.

result_type b() const;

Returns: The value of the \( b \) parameter with which the object was constructed.

29.6.8.3 Bernoulli distributions

29.6.8.3.1 Class bernoulli_distribution

A bernoulli_distribution random number distribution produces bool values \( b \) distributed according to the discrete probability function

\[
P(b \mid p) = \begin{cases} 
p & \text{if } b = \text{true} \\
1 - p & \text{if } b = \text{false} 
\end{cases}
\]

class bernoulli_distribution {
public:
    // types
    using result_type = bool;
    using param_type = unspecified;

    // constructors and reset functions

§ 29.6.8.3.1
explicit bernoulli_distribution(double p = 0.5);
explicit bernoulli_distribution(const param_type& parm);
void reset();

// generating functions
template<class URBG>
result_type operator()(URBG& g);
template<class URBG>
result_type operator()(URBG& g, const param_type& parm);

// property functions
double p() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;

explicit bernoulli_distribution(double p = 0.5);

Requires: 0 ≤ p ≤ 1.
Effects: Constructs a bernoulli_distribution object; p corresponds to the parameter of the distribution.

double p() const;
Returns: The value of the p parameter with which the object was constructed.

29.6.8.3.2 Class template binomial_distribution [rand.dist.bern.bin]
A binomial_distribution random number distribution produces integer values i ≥ 0 distributed according to the discrete probability function

\[ P(i \mid t, p) = \binom{t}{i} \cdot p^i \cdot (1 - p)^{t-i} \]

template<class IntType = int>
class binomial_distribution {
public:

// types
using result_type = IntType;
using param_type = unspecified;

// constructors and reset functions
explicit binomial_distribution(IntType t = 1, double p = 0.5);
explicit binomial_distribution(const param_type& parm);
void reset();

// generating functions
template<class URBG>
result_type operator()(URBG& g);
template<class URBG>
result_type operator()(URBG& g, const param_type& parm);

// property functions
IntType t() const;
double p() const;
explicit binomial_distribution(IntType t = 1, double p = 0.5);

2

Requires: $0 \leq p \leq 1$ and $0 \leq t$.

3

Effects: Constructs a `binomial_distribution` object; $t$ and $p$ correspond to the respective parameters of the distribution.

IntType t() const;

4

Returns: The value of the $t$ parameter with which the object was constructed.

double p() const;

5

Returns: The value of the $p$ parameter with which the object was constructed.

29.6.8.3.3 Class template geometric_distribution

A `geometric_distribution` random number distribution produces integer values $i \geq 0$ distributed according to the discrete probability function

$$P(i \mid p) = p \cdot (1 - p)^i.$$

explicit geometric_distribution(double p = 0.5);

2

Requires: $0 < p < 1$.

3

Effects: Constructs a `geometric_distribution` object; $p$ corresponds to the parameter of the distribution.
double p() const;

Returns: The value of the \( p \) parameter with which the object was constructed.

29.6.8.3.4 Class template \texttt{negative\_binomial\_distribution} \[\text{rand.dist.bern.negbin}\]

A \texttt{negative\_binomial\_distribution} random number distribution produces random integers \( i \geq 0 \) distributed according to the discrete probability function

\[
P(i \mid k, p) = \binom{k + i - 1}{i} \cdot p^k \cdot (1 - p)^i.
\]

[Note: This implies that \( P(i \mid k, p) \) is undefined when \( p == 1 \). — end note]

template<class IntType = int>
class negative_binomial_distribution {
public:

// types
using result_type = IntType;
using param_type = unspecified;

// constructor and reset functions
explicit negative_binomial_distribution(IntType k = 1, double p = 0.5);
explicit negative_binomial_distribution(const param_type& parm);
void reset();

// generating functions
template<class URBG>
result_type operator()(URBG& g);
template<class URBG>
result_type operator()(URBG& g, const param_type& parm);

// property functions
IntType k() const;
double p() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;
};

explicit negative_binomial_distribution(IntType k = 1, double p = 0.5);

Requires: \( 0 < p \leq 1 \) and \( 0 < k \).

Effects: Constructs a \texttt{negative\_binomial\_distribution} object; \( k \) and \( p \) correspond to the respective parameters of the distribution.

IntType k() const;

Returns: The value of the \( k \) parameter with which the object was constructed.

double p() const;

Returns: The value of the \( p \) parameter with which the object was constructed.

§ 29.6.8.3.4
29.6.8.4 Poisson distributions

29.6.8.4.1 Class template poisson_distribution

A poisson_distribution random number distribution produces integer values \( i \geq 0 \) distributed according to the discrete probability function

\[
P(i | \mu) = \frac{e^{-\mu} \mu^i}{i!}.
\]

The distribution parameter \( \mu \) is also known as this distribution’s mean.

\[
\text{template<class IntType = int>}
\text{class poisson_distribution}
\{
\text{public:}
// types
using result_type = IntType;
using param_type = unspecified;
// constructors and reset functions
explicit poisson_distribution(double mean = 1.0);
explicit poisson_distribution(const param_type& parm);
void reset();
// generating functions
\text{template<class URBG>}
\text{result_type operator()}(URBG& g);
\text{template<class URBG>}
\text{result_type operator()}(URBG& g, const param_type& parm);
// property functions
\text{double mean() const;}
\text{param_type param() const;}
\text{void param(const param_type& parm);} 
\text{result_type min() const;}
\text{result_type max() const;}
\};
\]

\[
\text{explicit poisson_distribution(double mean = 1.0);} 
\]

2 Requires: \( 0 < \text{mean} \).

3 Effects: Constructs a poisson_distribution object; mean corresponds to the parameter of the distribution.

\[
donotag \text{double mean() const;}
\]

4 Returns: The value of the mean parameter with which the object was constructed.

29.6.8.4.2 Class template exponential_distribution

An exponential_distribution random number distribution produces random numbers \( x > 0 \) distributed according to the probability density function

\[
p(x | \lambda) = \lambda e^{-\lambda x}.
\]

\[
\text{template<class RealType = double>}
\text{class exponential_distribution}
\{
\text{public:}
// types
\}
\]
using result_type = RealType;
using param_type = unspecified;

// constructors and reset functions
explicit exponential_distribution(RealType lambda = 1.0);
explicit exponential_distribution(const param_type& parm);
void reset();

// generating functions
template<class URBG>
result_type operator()(URBG& g);
template<class URBG>
result_type operator()(URBG& g, const param_type& parm);

// property functions
RealType lambda() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;

explicit exponential_distribution(RealType lambda = 1.0);

2 Requires: 0 < lambda.
3 Effects: Constructs an exponential_distribution object; lambda corresponds to the parameter of the distribution.

RealType lambda() const;
4 Returns: The value of the lambda parameter with which the object was constructed.

29.6.8.4.3 Class template gamma_distribution [rand.dist.pois.gamma]
1 A gamma_distribution random number distribution produces random numbers x > 0 distributed according to the probability density function

\[ p(x | \alpha, \beta) = \frac{e^{-x/\beta}}{\beta^\alpha \cdot \Gamma(\alpha)} \cdot x^{\alpha-1}. \]

template<class RealType = double>
class gamma_distribution {
public:
  // types
  using result_type = RealType;
  using param_type = unspecified;

  // constructors and reset functions
  explicit gamma_distribution(RealType alpha = 1.0, RealType beta = 1.0);
  explicit gamma_distribution(const param_type& parm);
  void reset();

  // generating functions
  template<class URBG>
  result_type operator()(URBG& g);
  template<class URBG>
  result_type operator()(URBG& g, const param_type& parm);

§ 29.6.8.4.3

29.6.8.4.4 Class template weibull_distribution

A weibull_distribution random number distribution produces random numbers \( x \geq 0 \) distributed according to the probability density function

\[
p(x \mid a, b) = \frac{a}{b} \cdot \left(\frac{x}{b}\right)^{a-1} \cdot \exp\left(-\left(\frac{x}{b}\right)^a\right).
\]

```cpp
template<class RealType = double>
class weibull_distribution {
    public:
        // types
        using result_type = RealType;
        using param_type = unspecified;

        // constructor and reset functions
        explicit weibull_distribution(RealType a = 1.0, RealType b = 1.0);
        explicit weibull_distribution(const param_type& parm);
        void reset();

        // generating functions
        template<class URBG>
        result_type operator()(URBG& g);
        template<class URBG>
        result_type operator()(URBG& g, const param_type& parm);

        // property functions
        RealType a() const;
        RealType b() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;
    };
};
```
explicit weibull_distribution(RealType a = 1.0, RealType b = 1.0);

Requires: 0 < a and 0 < b.

Effects: Constructs a weibull_distribution object; a and b correspond to the respective parameters of the distribution.

RealType a() const;

Returns: The value of the a parameter with which the object was constructed.

RealType b() const;

Returns: The value of the b parameter with which the object was constructed.

29.6.8.4.5 Class template extreme_value_distribution

An extreme_value_distribution random number distribution produces random numbers x distributed according to the probability density function\(^2\):

\[
p(x \mid a, b) = \frac{1}{b} \cdot \exp \left( \frac{a - x}{b} - \exp \left( \frac{a - x}{b} \right) \right).
\]

\(^2\) The distribution corresponding to this probability density function is also known (with a possible change of variable) as the Gumbel Type I, the log-Weibull, or the Fisher-Tippett Type I distribution.
RealType a() const;

Returns: The value of the a parameter with which the object was constructed.

RealType b() const;

Returns: The value of the b parameter with which the object was constructed.

29.6.8.5 Normal distributions  
29.6.8.5.1 Class template normal_distribution

A `normal_distribution` random number distribution produces random numbers \(x\) distributed according to the probability density function

\[
p(x | \mu, \sigma) = \frac{1}{\sigma \sqrt{2\pi}} \exp\left(-\frac{(x - \mu)^2}{2\sigma^2}\right).
\]

The distribution parameters \(\mu\) and \(\sigma\) are also known as this distribution’s `mean` and `standard deviation`.

```cpp
template<class RealType = double>
class normal_distribution {
public:
    using result_type = RealType;
    using param_type = unspecified;

    explicit normal_distribution(RealType mean = 0.0, RealType stddev = 1.0);
    explicit normal_distribution(const param_type& parm);
    void reset();

    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

    RealType mean() const;
    RealType stddev() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

```
explicit normal_distribution(RealType mean = 0.0, RealType stddev = 1.0);

Requires: 0 < stddev.

Effects: Constructs a `normal_distribution` object; `mean` and `stddev` correspond to the respective parameters of the distribution.

RealType mean() const;

Returns: The value of the `mean` parameter with which the object was constructed.

RealType stddev() const;

Returns: The value of the `stddev` parameter with which the object was constructed.
```
29.6.8.5.2 Class template lognormal_distribution

A `lognormal_distribution` random number distribution produces random numbers \( x > 0 \) distributed according to the probability density function

\[
p(x | m, s) = \frac{1}{sx\sqrt{2\pi}} \cdot \exp\left(-\frac{(\ln x - m)^2}{2s^2}\right).
\]

```cpp
template<class RealType = double>
class lognormal_distribution {
public:
    // types
    using result_type = RealType;
    using param_type = unspecified;

    // constructor and reset functions
    explicit lognormal_distribution(RealType m = 0.0, RealType s = 1.0);
    explicit lognormal_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

    // property functions
    RealType m() const;
    RealType s() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

**explicit lognormal_distribution(RealType m = 0.0, RealType s = 1.0);**

2 Requires: \( 0 < s \).

3 **Effects:** Constructs a `lognormal_distribution` object; \( m \) and \( s \) correspond to the respective parameters of the distribution.

**RealType m() const;**

4 **Returns:** The value of the \( m \) parameter with which the object was constructed.

**RealType s() const;**

5 **Returns:** The value of the \( s \) parameter with which the object was constructed.

29.6.8.5.3 Class template chi_squared_distribution

A `chi_squared_distribution` random number distribution produces random numbers \( x > 0 \) distributed according to the probability density function

\[
p(x | n) = \frac{x^{(n/2)-1} \cdot e^{-x/2}}{\Gamma(n/2) \cdot 2^{n/2}}.
\]

§ 29.6.8.5.3
template<class RealType = double>
class chi_squared_distribution {
public:
  // types
  using result_type = RealType;
  using param_type = unspecified;

  // constructor and reset functions
  explicit chi_squared_distribution(RealType n = 1);
  explicit chi_squared_distribution(const param_type& parm);
  void reset();

  // generating functions
  template<class URBG>
  result_type operator()(URBG& g);
  template<class URBG>
  result_type operator()(URBG& g, const param_type& parm);

  // property functions
  RealType n() const;
  param_type param() const;
  void param(const param_type& parm);
  result_type min() const;
  result_type max() const;
};

explicit chi_squared_distribution(RealType n = 1);

Requires: 0 < n.

Effects: Constructs a chi_squared_distribution object; n corresponds to the parameter of the distribution.

RealType n() const;

Returns: The value of the n parameter with which the object was constructed.

29.6.8.5.4 Class template cauchy_distribution
[ rand.dist.norm.cauchy]

A cauchy_distribution random number distribution produces random numbers \( x \) distributed according to the probability density function

\[
p(x \mid a, b) = \frac{1}{\pi b \left( 1 + \left( \frac{x - a}{b} \right)^2 \right)}^{-1}.
\]

template<class RealType = double>
class cauchy_distribution {
public:
  // types
  using result_type = RealType;
  using param_type = unspecified;

  // constructor and reset functions
  explicit cauchy_distribution(RealType a = 0.0, RealType b = 1.0);
  explicit cauchy_distribution(const param_type& parm);
  void reset();
// generating functions
template<class URBG>
    result_type operator()(URBG& g);
template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

// property functions
RealType a() const;
RealType b() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;

explicit cauchy_distribution(RealType a = 0.0, RealType b = 1.0);

Requires: 0 < b.
Effects: Constructs a cauchy_distribution object; a and b correspond to the respective parameters of the distribution.

RealType a() const;
Returns: The value of the a parameter with which the object was constructed.

RealType b() const;
Returns: The value of the b parameter with which the object was constructed.

29.6.8.5.5 Class template fisher_f_distribution

A fisher_f_distribution random number distribution produces random numbers \( x \geq 0 \) distributed according to the probability density function

\[
p(x \mid m, n) = \frac{\Gamma((m + n)/2)}{\Gamma(m/2) \Gamma(n/2)} \cdot \left( \frac{m}{n} \right)^{m/2} \cdot x^{(m/2)-1} \cdot \left( 1 + \frac{mx}{n} \right)^{-(m+n)/2}.
\]

template<class RealType = double>
class fisher_f_distribution {
public:
    // types
    using result_type = RealType;
    using param_type = unspecified;

    // constructor and reset functions
    explicit fisher_f_distribution(RealType m = 1, RealType n = 1);
    explicit fisher_f_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
        result_type operator()(URBG& g);
    template<class URBG>
        result_type operator()(URBG& g, const param_type& parm);

    // property functions
    RealType m() const;
A `student_t_distribution` random number distribution produces random numbers \( x \) distributed according to the probability density function

\[
p(x \mid n) = \frac{1}{\sqrt{n \pi}} \frac{\Gamma((n + 1)/2)}{\Gamma(n/2)} \left( 1 + \frac{x^2}{n} \right)^{-(n+1)/2}.
\]

### 29.6.8.5.6 Class template `student_t_distribution` [rand.dist.norm.t]

```cpp
template<class RealType = double>
class student_t_distribution {
public:
  // types
  using result_type = RealType;
  using param_type = unspecified;

  // constructor and reset functions
  explicit student_t_distribution(RealType n = 1);
  explicit student_t_distribution(const param_type& parm);
  void reset();

  // generating functions
  template<class URBG>
  result_type operator()(URBG& g);
  template<class URBG>
  result_type operator()(URBG& g, const param_type& parm);

  // property functions
  RealType n() const;
  param_type param() const;
  void param(const param_type& parm);
  result_type min() const;
  result_type max() const;
};
```

### 29.6.8.5.6 Class template `student_t_distribution` [rand.dist.norm.t]

1 A `student_t_distribution` random number distribution produces random numbers \( x \) distributed according to the probability density function

\[
p(x \mid n) = \frac{1}{\sqrt{n \pi}} \frac{\Gamma((n + 1)/2)}{\Gamma(n/2)} \left( 1 + \frac{x^2}{n} \right)^{-(n+1)/2}.
\]

2 Requires: 0 < \( m \) and 0 < \( n \).

3 Effects: Constructs a `fisher_f_distribution` object; \( m \) and \( n \) correspond to the respective parameters of the distribution.

4 Returns: The value of the \( m \) parameter with which the object was constructed.

5 Returns: The value of the \( n \) parameter with which the object was constructed.
Effects: Constructs a **student_t_distribution** object; \( n \) corresponds to the parameter of the distribution.

RealType n() const;

Returns: The value of the \( n \) parameter with which the object was constructed.

### 29.6.8.6 Sampling distributions

#### 29.6.8.6.1 Class template **discrete_distribution**

A **discrete_distribution** random number distribution produces random integers \( i, 0 \leq i < n \), distributed according to the discrete probability function

\[
P(i | p_0, \ldots, p_{n-1}) = p_i.
\]

Unless specified otherwise, the distribution parameters are calculated as: \( p_k = w_k / S \) for \( k = 0, \ldots, n-1 \), in which the values \( w_k \), commonly known as the *weights*, shall be non-negative, non-NaN, and non-infinity. Moreover, the following relation shall hold: \( 0 < S = w_0 + \cdots + w_{n-1} \).

```cpp
template<class IntType = int>
class discrete_distribution {
  public:
    // types
    using result_type = IntType;
    using param_type = unspecified;

    // constructor and reset functions
    discrete_distribution();
    template<class InputIterator>
    discrete_distribution(InputIterator firstW, InputIterator lastW);
    discrete_distribution(initializer_list<double> wl);
    template<class UnaryOperation>
    discrete_distribution(size_t nw, double xmin, double xmax, UnaryOperation fw);
    explicit discrete_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

    // property functions
    vector<double> probabilities() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

Effects: Constructs a **discrete_distribution** object with \( n = 1 \) and \( p_0 = 1 \). [Note: Such an object will always deliver the value 0. —end note]
Requires: InputIterator shall satisfy the requirements of an input iterator (27.2.3). Moreover, iterator_traits<InputIterator>::value_type shall denote a type that is convertible to double. If firstW == lastW, let n = 1 and w0 = 1. Otherwise, \([\text{firstW}, \text{lastW}]\) shall form a sequence w of length \(n > 0\).

Effects: Constructs a discrete_distribution object with probabilities given by the formula above.

discrete_distribution(initializer_list<double> wl);

Effects: Same as discrete_distribution(wl.begin(), wl.end()).

template<class UnaryOperation>

discrete_distribution(size_t nw, double xmin, double xmax, UnaryOperation fw);

Requires: Each instance of type UnaryOperation shall be a function object (23.14) whose return type shall be convertible to double. Moreover, double shall be convertible to the type of UnaryOperation's sole parameter. If nw = 0, let n = 1, otherwise let n = nw. The relation \(0 < \delta = (xmax - xmin)/n\) shall hold.

Effects: Constructs a discrete_distribution object with probabilities given by the formula above, using the following values: If nw = 0, let w0 = 1. Otherwise, let \(w_k = fw(xmin + k \cdot \delta + \delta/2)\) for \(k = 0, \ldots, n-1\).

Complexity: The number of invocations of fw shall not exceed n.

vector<double> probabilities() const;

Returns: A vector<double> whose size member returns n and whose operator[] member returns \(p_k\) when invoked with argument k for \(k = 0, \ldots, n-1\).

29.6.8.6.2 Class template piecewise_constant_distribution  [rand.dist.samp.pconst]

A piecewise_constant_distribution random number distribution produces random numbers \(x, b_0 \leq x < b_n\), uniformly distributed over each subinterval \([b_i, b_{i+1})\) according to the probability density function

\[ p(x | b_0, \ldots, b_n, \rho_0, \ldots, \rho_{n-1}) = \rho_i, \quad \text{for } b_i \leq x < b_{i+1}. \]

The \(n + 1\) distribution parameters \(b_i\), also known as this distribution's interval boundaries, shall satisfy the relation \(b_i < b_{i+1}\) for \(i = 0, \ldots, n-1\). Unless specified otherwise, the remaining \(n\) distribution parameters are calculated as:

\[ \rho_k = \frac{w_k}{S \cdot (b_{k+1} - b_k)} \quad \text{for } k = 0, \ldots, n-1, \]

in which the values \(w_k\), commonly known as the weights, shall be non-negative, non-NaN, and non-infinity. Moreover, the following relation shall hold: \(0 < S = w_0 + \cdots + w_{n-1}\).

template<class RealType = double>

class piecewise_constant_distribution {
  public:
    // types
    using result_type = RealType;
    using param_type = unspecified;

    // constructor and reset functions
    piecewise_constant_distribution();

    template<class InputIteratorB, class InputIteratorW>
    piecewise_constant_distribution(InputIteratorB firstB, InputIteratorB lastB,
                                    InputIteratorW firstW);

    template<class UnaryOperation>
    piecewise_constant_distribution(initializer_list<RealType> bl, UnaryOperation fw);

}
template<class UnaryOperation>
    piecewise_constant_distribution(size_t nw, RealType xmin, RealType xmax,
        UnaryOperation fw);

explicit piecewise_constant_distribution(const param_type& parm);
void reset();

// generating functions
template<class URBG>
    result_type operator()(URBG& g);
template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

// property functions
vector<result_type> intervals() const;
vector<result_type> densities() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;
};

Effects: Constructs a piecewise_constant_distribution object with
n = 1, \rho_0 = 1, b_0 = 0, and b_1 = 1.

template<class InputIteratorB, class InputIteratorW>
    piecewise_constant_distribution(InputIteratorB firstB, InputIteratorB lastB,
        InputIteratorW firstW);

Requires: InputIteratorB and InputIteratorW shall each satisfy the requirements of an input iterator (Table 95) type. Moreover, iterator_traits<InputIteratorB>::value_type and iterator_traits<InputIteratorW>::value_type shall each denote a type that is convertible to double. If firstB == lastB or ++firstB == lastB, let n = 1, w_0 = 1, b_0 = 0, and b_1 = 1. Otherwise, (firstB, lastB) shall form a sequence b of length n + 1, the length of the sequence w starting from firstW shall be at least n, and any w_k for k \geq n shall be ignored by the distribution.

Effects: Constructs a piecewise_constant_distribution object with parameters as specified above.

template<class UnaryOperation>
    piecewise_constant_distribution(initializer_list<RealType> bl, UnaryOperation fw);

Requires: Each instance of type UnaryOperation shall be a function object (23.14) whose return type shall be convertible to double. Moreover, double shall be convertible to the type of UnaryOperation's sole parameter.

Effects: Constructs a piecewise_constant_distribution object with parameters taken or calculated from the following values: If bl.size() < 2, let n = 1, w_0 = 1, b_0 = 0, and b_1 = 1. Otherwise, (bl.begin(), bl.end()) form a sequence b_0, ..., b_n, and let w_k = fw((b_{k+1} + b_k)/2) for k = 0, ..., n−1.

Complexity: The number of invocations of fw shall not exceed n.

template<class UnaryOperation>
    piecewise_constant_distribution(size_t nw, RealType xmin, RealType xmax, UnaryOperation fw);

Requires: Each instance of type UnaryOperation shall be a function object (23.14) whose return type shall be convertible to double. Moreover, double shall be convertible to the type of UnaryOperation's sole parameter. If nw = 0, let n = 1, otherwise let n = nw. The relation 0 < \delta = (xmax − xmin)/n shall
Effects: Constructs a `piecewise_constant_distribution` object with parameters taken or calculated from the following values: Let $b_k = x_{\min} + k \cdot \delta$ for $k = 0, \ldots, n$, and $w_k = f_w(b_k + \delta/2)$ for $k = 0, \ldots, n-1$.

Complexity: The number of invocations of $f_w$ shall not exceed $n$.

```
vector<result_type> intervals() const;

Returns: A `vector<result_type>` whose `size` member returns $n + 1$ and whose `operator[]` member returns $b_k$ when invoked with argument $k$ for $k = 0, \ldots, n$.

vector<result_type> densities() const;

Returns: A `vector<result_type>` whose `size` member returns $n$ and whose `operator[]` member returns $\rho_k$ when invoked with argument $k$ for $k = 0, \ldots, n-1$.
```

29.6.8.6.3 Class template `piecewise_linear_distribution` [rand.dist.samp.plinear]

A `piecewise_linear_distribution` random number distribution produces random numbers $x$, $b_0 \leq x < b_n$, distributed over each subinterval $[b_i, b_{i+1})$ according to the probability density function

$$p(x | b_0, \ldots, b_n, \rho_0, \ldots, \rho_n) = \rho_i \cdot \frac{b_{i+1} - x}{b_{i+1} - b_i} + \rho_{i+1} \cdot \frac{x - b_i}{b_{i+1} - b_i}, \text{ for } b_i \leq x < b_{i+1}.$$  

2 The $n + 1$ distribution parameters $b_i$, also known as this distribution’s `interval boundaries`, shall satisfy the relation $b_i < b_{i+1}$ for $i = 0, \ldots, n-1$. Unless specified otherwise, the remaining $n + 1$ distribution parameters are calculated as $\rho_k = w_k / S$ for $k = 0, \ldots, n$, in which the values $w_k$, commonly known as the `weights at boundaries`, shall be non-negative, non-NaN, and non-infinity. Moreover, the following relation shall hold:

$$0 < S = \frac{1}{2} \cdot \sum_{k=0}^{n-1} (w_k + w_{k+1}) \cdot (b_{k+1} - b_k).$$

```template<class RealType = double>
class piecewise_linear_distribution {
public:
    // types
    using result_type = RealType;
    using param_type = unspecified;

    // constructor and reset functions
    piecewise_linear_distribution();
    template<class InputIteratorB, class InputIteratorW>
        piecewise_linear_distribution(InputIteratorB firstB, InputIteratorB lastB,
                                        InputIteratorW firstW);
    template<class UnaryOperation>
        piecewise_linear_distribution(initializer_list<RealType> bl, UnaryOperation fw);
    template<class UnaryOperation>
        piecewise_linear_distribution(size_t nw, RealType xmin, RealType xmax, UnaryOperation fw);
    explicit piecewise_linear_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
        result_type operator()(URBG& g);
    template<class URBG>
        result_type operator()(URBG& g, const param_type& parm);

```
// property functions
vector<result_type> intervals() const;
vector<result_type> densities() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;

piecewise_linear_distribution();

Effects: Constructs a piecewise_linear_distribution object with \( n = 1, \rho_0 = \rho_1 = 1, b_0 = 0, \) and \( b_1 = 1 \).

template<class InputIteratorB, class InputIteratorW>
piecewise_linear_distribution(InputIteratorB firstB, InputIteratorB lastB,
InputIteratorW firstW);

Requires: InputIteratorB and InputIteratorW shall each satisfy the requirements of an input iter-
ator (Table 95) type. Moreover, iterator_traits<InputIteratorB>::value_type
and iterator_traits<InputIteratorW>::value_type shall each denote a type that is convertible to double. If
firstB == lastB or ++firstB == lastB, let \( n = 1, \rho_0 = \rho_1 = 1, b_0 = 0, \) and \( b_1 = 1 \). Otherwise,
[firstB,lastB) shall form a sequence \( b \) of length \( n + 1 \), the length of the sequence \( w \) starting from
firstW shall be at least \( n + 1 \), and any \( w_k \) for \( k \geq n + 1 \) shall be ignored by the distribution.

Effects: Constructs a piecewise_linear_distribution object with parameters as specified above.

template<class UnaryOperation>
piecewise_linear_distribution(initializer_list<RealType> bl, UnaryOperation fw);

Requires: Each instance of type UnaryOperation shall be a function object (23.14) whose return type
shall be convertible to double. Moreover, double shall be convertible to the type of UnaryOperation's
sole parameter.

Effects: Constructs a piecewise_linear_distribution object with parameters taken or calculated
from the following values: If bl.size() < 2, let \( n = 1, \rho_0 = \rho_1 = 1, b_0 = 0, \) and \( b_1 = 1 \). Otherwise, let
[bl.begin(),bl.end()) form a sequence \( b_0, \ldots, b_n \), and let \( w_k = fw(b_k) \) for \( k = 0, \ldots, n \).

Complexity: The number of invocations of \( fw \) shall not exceed \( n + 1 \).

template<class UnaryOperation>
piecewise_linear_distribution(size_t nw, RealType xmin, RealType xmax, UnaryOperation fw);

Requires: Each instance of type UnaryOperation shall be a function object (23.14) whose return type
shall be convertible to double. Moreover, double shall be convertible to the type of UnaryOperation's
sole parameter. If \( nw = 0 \), let \( n = 1 \), otherwise let \( n = nw \). The relation \( 0 < \delta = (xmax - xmin)/n \) shall
hold.

Effects: Constructs a piecewise_linear_distribution object with parameters taken or calculated
from the following values: Let \( b_k = xmin + k \cdot \delta \) for \( k = 0, \ldots, n \), and \( w_k = fw(b_k) \) for \( k = 0, \ldots, n \).

Complexity: The number of invocations of \( fw \) shall not exceed \( n + 1 \).

vector<result_type> intervals() const;

Returns: A vector<result_type> whose size member returns \( n + 1 \) and whose operator[] member
returns \( b_k \) when invoked with argument \( k \) for \( k = 0, \ldots, n \).

vector<result_type> densities() const;

§ 29.6.8.6.3

1104
29.6.9 Low-quality random number generation

Returns: A vector<result_type> whose size member returns n and whose operator[] member returns \( \rho_k \) when invoked with argument \( k \) for \( k = 0, \ldots, n \).

```cpp
int rand();
void srand(unsigned int seed);
```

Effects: The `rand` and `srand` functions have the semantics specified in the C standard library.

Remarks: The implementation may specify that particular library functions may call `rand`. It is implementation-defined whether the `rand` function may introduce data races (20.5.5.9). [Note: The other random number generation facilities in this International Standard (29.6) are often preferable to `rand`, because `rand`'s underlying algorithm is unspecified. Use of `rand` therefore continues to be non-portable, with unpredictable and oft-questionable quality and performance. — end note]

template<class T> valarray<bool> operator>=(const valarray<T>&, const valarray<T>&);

template<class T> valarray<bool> operator>=(const valarray<T>&, const T&);

template<class T> valarray<bool> operator>=(const T&, const valarray<T>&);

valarray<T> abs (const valarray<T>&);

valarray<T> acos (const valarray<T>&);
The header `<valarray>` defines five class templates (`valarray`, `slice_array`, `gslice_array`, `mask_array`, and `indirect_array`), two classes (`slice` and `gslice`), and a series of related function templates for representing and manipulating arrays of values.

The `valarray` array classes are defined to be free of certain forms of aliasing, thus allowing operations on these classes to be optimized.

Any function returning a `valarray<T>` is permitted to return an object of another type, provided all the `const` member functions of `valarray<T>` are also applicable to this type. This return type shall not add more than two levels of template nesting over the most deeply nested argument type.\(^{275}\)

Implementations introducing such replacement types shall provide additional functions and operators as follows:

- for every function taking a `const valarray<T>&` other than `begin` and `end` (29.7.10), identical functions taking the replacement types shall be added;

- for every function taking two `const valarray<T>&` arguments, identical functions taking every combination of `const valarray<T>&` and replacement types shall be added.

In particular, an implementation shall allow a `valarray<T>` to be constructed from such replacement types and shall allow assignments and compound assignments of such types to `valarray<T>`, `slice_array<T>`, `gslice_array<T>`, `mask_array<T>` and `indirect_array<T>` objects.

These library functions are permitted to throw a `bad_alloc` (21.6.3.1) exception if there are not sufficient resources available to carry out the operation. Note that the exception is not mandated.

\(^{275}\) Annex B recommends a minimum number of recursively nested template instantiations. This requirement thus indirectly suggests a minimum allowable complexity for valarray expressions.
29.7.2 Class template valarray

29.7.2.1 Class template valarray overview

namespace std {
    template<class T> class valarray {
    public:
        using value_type = T;

valarray\& operator\&= (const T\&);
valarray\& operator\|= (const T\&);
valarray\& operator\<<<(const T\&);
valarray\& operator\>>=(const T\&);

// 29.7.2.8, member functions
void swap(valarray&) noexcept;

size_t size() const;

T sum() const;
T min() const;
T max() const;

valarray shift (int) const;
valarray cshift(int) const;
valarray apply(T func(T)) const;
valarray apply(T func(const T&)) const;
void resize(size_t sz, T c = T());
};

template<class T, size_t cnt> valarray(const T(&)[cnt], size_t) -> valarray<T>;

The class template \texttt{valarray} is a one-dimensional smart array, with elements numbered sequentially from zero. It is a representation of the mathematical concept of an ordered set of values. For convenience, an object of type \texttt{valarray} is referred to as an “array” throughout the remainder of 29.7. The illusion of higher dimensionality may be produced by the familiar idiom of computed indices, together with the powerful subsetting capabilities provided by the generalized subscript operators.\footnote{An implementation is permitted to qualify any of the functions declared in <\texttt{valarray}> as \texttt{inline}.}

\subsection*{29.7.2.2 \texttt{valarray} constructors [\texttt{valarray.cons}]}

\texttt{valarray();}

\textit{Effects: Constructs a \texttt{valarray} that has zero length.}\footnote{The intent is to specify an array template that has the minimum functionality necessary to address aliasing ambiguities and the proliferation of temporaries. Thus, the \texttt{valarray} template is neither a matrix class nor a field class. However, it is a very useful building block for designing such classes.}

\footnote{This default constructor is essential, since arrays of \texttt{valarray} may be useful. After initialization, the length of an empty array can be increased with the \texttt{resize} member function.}
explicit valarray(size_t n);

Effects: Constructs a valarray that has length n. Each element of the array is value-initialized (11.6).

valarray(const T& v, size_t n);

Effects: Constructs a valarray that has length n. Each element of the array is initialized with v.

valarray(const T* p, size_t n);

Requires: p points to an array (11.3.4) of at least n elements.

Effects: Constructs a valarray that has length n. The values of the elements of the array are initialized with the first n values pointed to by the first argument.\textsuperscript{278}

valarray(const valarray& v);

Effects: Constructs a valarray that has the same length as v. The elements are initialized with the values of the corresponding elements of v.\textsuperscript{279}

valarray(valarray&& v) noexcept;

Effects: Constructs a valarray that has the same length as v. The elements are initialized with the values of the corresponding elements of v.

Complexity: Constant.

valarray(initializer_list<T> il);

Effects: Equivalent to valarray(il.begin(), il.size()).

valarray(const slice_array<T>&);
valarray(const gslice_array<T>&);
valarray(const mask_array<T>&);
valarray(const indirect_array<T>&);

These conversion constructors convert one of the four reference templates to a valarray.

~valarray();

Effects: The destructor is applied to every element of *this; an implementation may return all allocated memory.

29.7.2.3 valarray assignment

[ valarray.assign ]

valarray& operator=(const valarray& v);

Effects: Each element of the *this array is assigned the value of the corresponding element of v. If the length of v is not equal to the length of *this, resizes *this to make the two arrays the same length, as if by calling resize(v.size()), before performing the assignment.

Postconditions: size() == v.size().

Returns: *this.

valarray& operator=(valarray&& v) noexcept;

Effects: *this obtains the value of v. The value of v after the assignment is not specified.

Returns: *this.

Complexity: Linear.

\textsuperscript{278} This constructor is the preferred method for converting a C array to a valarray object.

\textsuperscript{279} This copy constructor creates a distinct array rather than an alias. Implementations in which arrays share storage are permitted, but they shall implement a copy-on-reference mechanism to ensure that arrays are conceptually distinct.
valarray& operator=(initializer_list<T> il);

Effects: Equivalent to: return *this = valarray(il);

valarray& operator=(const T& v);

Effects: Assigns v to each element of *this.

Returns: *this.

valarray& operator=(const slice_array<T>&);
valarray& operator=(const gslice_array<T>&);
valarray& operator=(const mask_array<T>&);
valarray& operator=(const indirect_array<T>&);

Requires: The length of the array to which the argument refers equals size(). The value of an element in the left-hand side of a valarray assignment operator does not depend on the value of another element in that left-hand side.

These operators allow the results of a generalized subscripting operation to be assigned directly to a valarray.

29.7.2.4 valarray element access

const T& operator[](size_t n) const;
T& operator[](size_t n);

Requires: n < size().

Returns: A reference to the corresponding element of the array. [Note: The expression (a[i] = q, a[i]) == q evaluates to true for any non-constant valarray<T> a, any T q, and for any size_t i such that the value of i is less than the length of a. — end note]

Remarks: The expression &a[i+j] == &a[i] + j evaluates to true for all size_t i and size_t j such that i+j < a.size().

The expression &a[i] != &b[j] evaluates to true for any two arrays a and b and for any size_t i and size_t j such that i < a.size() and j < b.size(). [Note: This property indicates an absence of aliasing and may be used to advantage by optimizing compilers. Compilers may take advantage of inlining, constant propagation, loop fusion, tracking of pointers obtained from operator new, and other techniques to generate efficient valarrays. — end note]

The reference returned by the subscript operator for an array shall be valid until the member function resize(size_t, T) (29.7.2.8) is called for that array or until the lifetime of that array ends, whichever happens first.

29.7.2.5 valarray subset operations

The member operator[] is overloaded to provide several ways to select sequences of elements from among those controlled by *this. Each of these operations returns a subset of the array. The const-qualified versions return this subset as a new valarray object. The non-const versions return a class template object which has reference semantics to the original array, working in conjunction with various overloads of operator= and other assigning operators to allow selective replacement (slicing) of the controlled sequence. In each case the selected element(s) must exist.

valarray operator[](slice slicearr) const;

Returns: A valarray containing those elements of the controlled sequence designated by slicearr.

[Example:

    const valarray<char> v0("abcdefgijklmnop", 16);
    // v0[slice(2, 5, 3)] returns valarray<char>("cfilo", 5)
slice_array<T> operator[](slice slicearr);

3

Returns: An object that holds references to elements of the controlled sequence selected by slicearr.

[Example:
    valarray<char> v0("abcdefghijklmnop", 16);
    valarray<char> v1("ABCDE", 5);
    v0[slice(2, 5, 3)] = v1;
    // v0 == valarray<char>("abAdBghCjkDmnEp", 16);
— end example]

valarray operator[](const gslice& gslicearr) const;

4

Returns: A valarray containing those elements of the controlled sequence designated by gslicearr.

[Example:
    const valarray<char> v0("abcdefghijklmnop", 16);
    const size_t lv[] = {2, 3};
    const size_t dv[] = {7, 2};
    const valarray<size_t> len(lv, 2), str(dv, 2);
    // v0[gslice(3, len, str)] returns
    // valarray<char>("dfhkmo", 6)
— end example]

gslice_array<T> operator[](const gslice& gslicearr);

5

Returns: An object that holds references to elements of the controlled sequence selected by gslicearr.

[Example:
    valarray<char> v0("abcdefghijklmnop", 16);
    valarray<char> v1("ABCDEF", 6);
    const size_t lv[] = {2, 3};
    const size_t dv[] = {7, 2};
    const valarray<size_t> len(lv, 2), str(dv, 2);
    v0[gslice(3, len, str)] = v1;
    // v0 == valarray<char>("abcAeBgCiJdlEnFp", 16)
— end example]

valarray operator[](const valarray<bool>& boolarr) const;

6

Returns: A valarray containing those elements of the controlled sequence designated by boolarr.

[Example:
    const valarray<char> v0("abcdefghijklmnop", 16);
    const bool vb[] = {false, false, true, true, false, true};
    // v0[valarray<bool>(vb, 6)] returns
    // valarray<char>("cdf", 3)
— end example]

mask_array<T> operator[](const valarray<bool>& boolarr);

7

Returns: An object that holds references to elements of the controlled sequence selected by boolarr.

[Example:
    valarray<char> v0("abcdefghijklmnop", 16);
    valarray<char> v1("ABC", 3);
    const bool vb[] = {false, false, true, true, false, true};

§ 29.7.2.5

1112
\begin{verbatim}
valarray operator[](const valarray<size_t>& indarr) const;

Returns: A valarray containing those elements of the controlled sequence designated by indarr.
[Example:
const valarray<char> v0("abcdefghiklmnop", 16);
const size_t vi[] = { 7, 5, 2, 3, 8 };
// v0[valarray<size_t>(vi, 5)] returns
// valarray<char>("hfcdi", 5)
—end example]

indirect_array<T> operator[](const valarray<size_t>& indarr);

Returns: An object that holds references to elements of the controlled sequence selected by indarr.
[Example:
valarray<char> v0("abcdefghiklmnop", 16);
valarray<char> v1("ABCDE", 5);
const size_t vi[] = { 7, 5, 2, 3, 8 };
v0[valarray<size_t>(vi, 5)] = v1;
// v0 == valarray<char>("abCDeBgAEjklmnop", 16)
—end example]
\end{verbatim}

29.7.2.6 valarray unary operators

valarray operator+() const;
valarray operator-() const;
valarray operator~() const;
valarray<bool> operator!() const;

Requires: Each of these operators may only be instantiated for a type T to which the indicated operator can be applied and for which the indicated operator returns a value which is of type T (bool for operator!) or which may be unambiguously implicitly converted to type T (bool for operator!).

Returns: A valarray whose length is size(). Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding element of the array.

29.7.2.7 valarray compound assignment

valarray& operator*= (const valarray& v);
valarray& operator/= (const valarray& v);
valarray& operator%= (const valarray& v);
valarray& operator+= (const valarray& v);
valarray& operator-= (const valarray& v);
valarray& operator^= (const valarray& v);
valarray& operator&= (const valarray& v);
valarray& operator|= (const valarray& v);
valarray& operator<<=(const valarray& v);
valarray& operator>>=(const valarray& v);

Requires: size() == v.size(). Each of these operators may only be instantiated for a type T if the indicated operator can be applied to two operands of type T. The value of an element in the left-hand side of a valarray compound assignment operator does not depend on the value of another element in that left-hand side.
Effects: Each of these operators performs the indicated operation on each of the elements of *this and the corresponding element of v.

Returns: *this.

Remarks: The appearance of an array on the left-hand side of a compound assignment does not invalidate references or pointers.

valarray& operator*= (const T& v);
valarray& operator/= (const T& v);
valarray& operator%= (const T& v);
valarray& operator+= (const T& v);
valarray& operator-= (const T& v);
valarray& operator^= (const T& v);
valarray& operator&= (const T& v);
valarray& operator|= (const T& v);
valarray& operator<<=(const T& v);
valarray& operator>>=(const T& v);

Requires: Each of these operators may only be instantiated for a type T if the indicated operator can be applied to two operands of type T.

Effects: Each of these operators applies the indicated operation to each element of *this and v.

Returns: *this

Remarks: The appearance of an array on the left-hand side of a compound assignment does not invalidate references or pointers to the elements of the array.

29.7.2.8 valarray member functions

void swap(valarray& v) noexcept;

Effects: *this obtains the value of v. v obtains the value of *this.

Complexity: Constant.

size_t size() const;

Returns: The number of elements in the array.

Complexity: Constant time.

T sum() const;

Requires: size() > 0. This function may only be instantiated for a type T to which operator++ can be applied.

Returns: The sum of all the elements of the array. If the array has length 1, returns the value of element 0. Otherwise, the returned value is calculated by applying operator+= to a copy of an element of the array and all other elements of the array in an unspecified order.

T min() const;

Requires: size() > 0

Returns: The minimum value contained in *this. For an array of length 1, the value of element 0 is returned. For all other array lengths, the determination is made using operator<.

T max() const;

Requires: size() > 0

Returns: The maximum value contained in *this. For an array of length 1, the value of element 0 is
returned. For all other array lengths, the determination is made using \texttt{operator<}.

\texttt{valarray shift(int n) const;}

11 \textit{Returns:} A \texttt{valarray} of length \texttt{size()}, each of whose elements \texttt{I} is \((\ast\texttt{this})[\texttt{I} + \texttt{n}]\) if \(\texttt{I} + \texttt{n}\) is non-negative and less than \texttt{size()}, otherwise \texttt{T}(). \textit{[Note:} If element zero is taken as the leftmost element, a positive value of \texttt{n} shifts the elements left \texttt{n} places, with zero fill. \textit{— end note]}

12 \texttt{valarray cshift(int n) const;}

\textit{Returns:} A \texttt{valarray} of length \texttt{size()} that is a circular shift of \texttt{\ast\texttt{this}}. If element zero is taken as the leftmost element, a non-negative value of \texttt{n} shifts the elements circularly left \texttt{n} places and a negative value of \texttt{n} shifts the elements circularly right \(-\texttt{n}\) places.

\texttt{valarray apply(T func(T)) const;}
\texttt{valarray apply(T func(const T&)) const;}

14 \textit{Returns:} A \texttt{valarray} whose length is \texttt{size()}. Each element of the returned array is assigned the value returned by applying the argument function to the corresponding element of \texttt{\ast\texttt{this}}.

\texttt{void resize(size_t sz, T c = T());}

15 \textit{Effects:} Changes the length of the \texttt{\ast\texttt{this}} array to \texttt{sz} and then assigns to each element the value of the second argument. Resizing invalidates all pointers and references to elements in the array.

29.7.3 \texttt{valarray} non-member operations [valarray.nonmembers]

29.7.3.1 \texttt{valarray} binary operators [valarray.binary]

\begin{verbatim}
template<class T> \texttt{valarray<T>} \texttt{operator*}
(\texttt{const valarray<T>&}, \texttt{const valarray<T>&});
template<class T> \texttt{valarray<T>} \texttt{operator/}
(\texttt{const valarray<T>&}, \texttt{const valarray<T>&});
template<class T> \texttt{valarray<T>} \texttt{operator%}
(\texttt{const valarray<T>&}, \texttt{const valarray<T>&});
template<class T> \texttt{valarray<T>} \texttt{operator+}
(\texttt{const valarray<T>&}, \texttt{const valarray<T>&});
template<class T> \texttt{valarray<T>} \texttt{operator-}
(\texttt{const valarray<T>&}, \texttt{const valarray<T>&});
template<class T> \texttt{valarray<T>} \texttt{operator^}
(\texttt{const valarray<T>&}, \texttt{const valarray<T>&});
template<class T> \texttt{valarray<T>} \texttt{operator&}
(\texttt{const valarray<T>&}, \texttt{const valarray<T>&});
template<class T> \texttt{valarray<T>} \texttt{operator|}
(\texttt{const valarray<T>&}, \texttt{const valarray<T>&});
template<class T> \texttt{valarray<T>} \texttt{operator<<}
(\texttt{const valarray<T>&}, \texttt{const valarray<T>&});
template<class T> \texttt{valarray<T>} \texttt{operator>>}
(\texttt{const valarray<T>&}, \texttt{const valarray<T>&});
\end{verbatim}

1 \textit{Requires:} Each of these operators may only be instantiated for a type \texttt{T} to which the indicated operator can be applied and for which the indicated operator returns a value which is of type \texttt{T} or which can be unambiguously implicitly converted to type \texttt{T}. The argument arrays have the same length.

2 \textit{Returns:} A \texttt{valarray} whose length is equal to the lengths of the argument arrays. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding
elements of the argument arrays.

\[
\begin{align*}

template<class T> valarray<T> pow (const valarray<T>&, const T&);
template<class T> valarray<T> pow (const T&, const valarray<T>&);
template<class T> valarray<T> sin (const valarray<T>&);
template<class T> valarray<T> sinh (const valarray<T>&);
template<class T> valarray<T> sqrt (const valarray<T>&);
template<class T> valarray<T> tan (const valarray<T>&);
template<class T> valarray<T> tanh (const valarray<T>&);

Requires: Each of these functions may only be instantiated for a type \( T \) to which a unique function with the indicated name can be applied (unqualified). This function shall return a value which is of type \( T \) or which can be unambiguously implicitly converted to type \( T \).

29.7.3.4 valarray specialized algorithms [valarray.special]

template <class T> void swap(valarray<T>& x, valarray<T>& y) noexcept;

§ 29.7.3.4
Effects: Equivalent to `x.swap(y)`.

### 29.7.4 Class slice

#### 29.7.4.1 Class slice overview

```cpp
namespace std {
    class slice {
    public:
        slice();
        slice(size_t start, size_t length, size_t stride);
        slice(const slice&);
        size_t start() const;
        size_t size() const;
        size_t stride() const;
    }
}
```

The `slice` class represents a BLAS-like slice from an array. Such a slice is specified by a starting index, a length, and a stride.

#### 29.7.4.2 slice constructors

```cpp
slice();
slice(size_t start, size_t length, size_t stride);
slice(const slice&);
```

The default constructor is equivalent to `slice(0, 0, 0)`. A default constructor is provided only to permit the declaration of arrays of slices. The constructor with arguments for a slice takes a start, length, and stride parameter.

Example: `slice(3, 8, 2)` constructs a slice which selects elements 3, 5, 7, ... 17 from an array.

#### 29.7.4.3 slice access functions

```cpp
size_t start() const;
size_t size() const;
size_t stride() const;
```

Returns: The start, length, or stride specified by a `slice` object.

Complexity: Constant time.

### 29.7.5 Class template slice_array

#### 29.7.5.1 Class template slice_array overview

```cpp
namespace std {
    template <class T> class slice_array {
    public:
        using value_type = T;

        void operator= (const valarray<T>&) const;
        void operator*= (const valarray<T>&) const;
        void operator/= (const valarray<T>&) const;
        void operator%= (const valarray<T>&) const;
        void operator+= (const valarray<T>&) const;
    }
}
```

280) BLAS stands for *Basic Linear Algebra Subprograms*. 

C++ programs may instantiate this class. See, for example, Dongarra, Du Croz, Duff, and Hammerling: *A set of Level 3 Basic Linear Algebra Subprograms*; Technical Report MCS-P1-0888, Argonne National Laboratory (USA), Mathematics and Computer Science Division, August, 1988.
void operator-= (const valarray<T>&) const;
void operator^= (const valarray<T>&) const;
void operator&= (const valarray<T>&) const;
void operator|= (const valarray<T>&) const;
void operator<<=(const valarray<T>&) const;
void operator>>=(const valarray<T>&) const;

slice_array(const slice_array&);
-slice_array();
const slice_array& operator=(const slice_array&) const;
void operator=(const T&) const;
slice_array() = delete;    // as implied by declaring copy constructor above
};

1 The slice_array template is a helper template used by the slice subscript operator

slice_array<T> valarray<T>::operator[](slice);

It has reference semantics to a subset of an array specified by a slice object.

2 Example: The expression a[slice(1, 5, 3)] = b; has the effect of assigning the elements of b to a slice
of the elements in a. For the slice shown, the elements selected from a are 1, 4, ..., 13. — end example]

29.7.5.2 slice_array assignment

void operator=(const valarray<T>&) const;
const slice_array& operator=(const slice_array&) const;

1 These assignment operators have reference semantics, assigning the values of the argument array
elements to selected elements of the valarray<T> object to which the slice_array object refers.

29.7.5.3 slice_array compound assignment

void operator**= (const valarray<T>&) const;
void operator/= (const valarray<T>&) const;
void operator%= (const valarray<T>&) const;
void operator+= (const valarray<T>&) const;
void operator-= (const valarray<T>&) const;
void operator&= (const valarray<T>&) const;
void operator|= (const valarray<T>&) const;
void operator<<=(const valarray<T>&) const;
void operator>>=(const valarray<T>&) const;

1 These compound assignments have reference semantics, applying the indicated operation to the elements
of the argument array and selected elements of the valarray<T> object to which the slice_array object refers.

29.7.5.4 slice_array fill function

void operator=(const T&) const;

1 This function has reference semantics, assigning the value of its argument to the elements of the
valarray<T> object to which the slice_array object refers.

29.7.6 The gslice class

29.7.6.1 The gslice class overview
namespace std {
    class gslice {
    public:
        gslice();
        gslice(size_t s, const valarray<size_t>& l, const valarray<size_t>& d);
        size_t start() const;
        valarray<size_t> size() const;
        valarray<size_t> stride() const;
    }
};

1 This class represents a generalized slice out of an array. A gslice is defined by a starting offset (s), a set of lengths (l_j), and a set of strides (d_j). The number of lengths shall equal the number of strides.

2 A gslice represents a mapping from a set of indices (i_j), equal in number to the number of strides, to a single index k. It is useful for building multidimensional array classes using the valarray template, which is one-dimensional. The set of one-dimensional index values specified by a gslice are

\[ k = s + \sum_{j} i_j d_j \]

where the multidimensional indices i_j range in value from 0 to l_{ij} − 1.

3 [Example: The gslice specification]

\begin{verbatim}
start = 3
length = {2, 4, 3}
stride = {19, 4, 1}
\end{verbatim}

yields the sequence of one-dimensional indices

\[ k = 3 + (0, 1) \times 19 + (0, 1, 2, 3) \times 4 + (0, 1, 2) \times 1 \]

which are ordered as shown in the following table:

\[
\begin{align*}
(i_0, & \quad i_1, \quad i_2, \quad k) = \\
(0, & \quad 0, \quad 0, \quad 3), \\
(0, & \quad 0, \quad 1, \quad 4), \\
(0, & \quad 0, \quad 2, \quad 5), \\
(0, & \quad 1, \quad 0, \quad 7), \\
(0, & \quad 1, \quad 1, \quad 8), \\
(0, & \quad 1, \quad 2, \quad 9), \\
(0, & \quad 2, \quad 0, \quad 11), \\
(0, & \quad 2, \quad 1, \quad 12), \\
(0, & \quad 2, \quad 2, \quad 13), \\
(0, & \quad 3, \quad 0, \quad 15), \\
(0, & \quad 3, \quad 1, \quad 16), \\
(0, & \quad 3, \quad 2, \quad 17), \\
(1, & \quad 0, \quad 0, \quad 22), \\
(1, & \quad 0, \quad 1, \quad 23), \\
\ldots \\
(1, & \quad 3, \quad 2, \quad 36)
\end{align*}
\]

That is, the highest-ordered index turns fastest. — end example]

4 It is possible to have degenerate generalized slices in which an address is repeated.
Example: If the stride parameters in the previous example are changed to \(\{1, 1, 1\}\), the first few elements of the resulting sequence of indices will be:

\[
(0, 0, 0, 3),
(0, 0, 1, 4),
(0, 0, 2, 5),
(0, 1, 0, 4),
(0, 1, 1, 5),
(0, 1, 2, 6),
\ldots
\]

—end example

If a degenerate slice is used as the argument to the non-\texttt{const} version of \texttt{operator[]}(\texttt{const gslice&}), the behavior is undefined.

### 29.7.6.2 gslice constructors

\texttt{gslice()};
\texttt{gslice(size_t start, const valarray<size_t>& lengths, const valarray<size_t>& strides);}
\texttt{gslice(const gslice&);}

The default constructor is equivalent to \texttt{gslice(0, valarray<size_t>(), valarray<size_t>())}.
The constructor with arguments builds a \texttt{gslice} based on a specification of start, lengths, and strides, as explained in the previous section.

### 29.7.6.3 gslice access functions

\texttt{size_t start() const;}
\texttt{valarray<size_t> size() const;}
\texttt{valarray<size_t> stride() const;}

Returns: The representation of the start, lengths, or strides specified for the \texttt{gslice}.

Complexity: \texttt{start()} is constant time. \texttt{size()} and \texttt{stride()} are linear in the number of strides.

### 29.7.7 Class template gslice_array

#### 29.7.7.1 Class template gslice_array overview

```cpp
namespace std {
    template <class T> class gslice_array {
        public:
            using value_type = T;

            void operator= (const valarray<T>&) const;
            void operator\*= (const valarray<T>&) const;
            void operator\%= (const valarray<T>&) const;
            void operator+= (const valarray<T>&) const;
            void operator\-= (const valarray<T>&) const;
            void operator^= (const valarray<T>&) const;
            void operator&= (const valarray<T>&) const;
            void operator|= (const valarray<T>&) const;
            void operator<<=(const valarray<T>&) const;
            void operator>>=(const valarray<T>&) const;
    }
}
```
gslice_array(const gslice_array&);
-gslice_array();
const gslice_array& operator=(const gslice_array& ) const;
void operator=(const T&) const;

gslice_array() = delete; // as implied by declaring copy constructor above
};

1 This template is a helper template used by the slice subscript operator

gslice_array<T> valarray<T>::operator[](const gslice&);

2 It has reference semantics to a subset of an array specified by a gslice object.

3 Thus, the expression a[gslice(1, length, stride)] = b has the effect of assigning the elements of b to a generalized slice of the elements in a.

29.7.7.2 gslice_array assignment

void operator=(const valarray<T>&) const;
const gslice_array& operator=(const gslice_array&) const;

1 These assignment operators have reference semantics, assigning the values of the argument array elements to selected elements of the valarray<T> object to which the gslice_array refers.

29.7.7.3 gslice_array compound assignment

void operator** (const valarray<T>&) const;
void operator/= (const valarray<T>&) const;
void operator%= (const valarray<T>&) const;
void operator+= (const valarray<T>&) const;
void operator-= (const valarray<T>&) const;
void operator&= (const valarray<T>&) const;
void operator|= (const valarray<T>&) const;
void operator<<=(const valarray<T>&) const;
void operator>>=(const valarray<T>&) const;

1 These compound assignments have reference semantics, applying the indicated operation to the elements of the argument array and selected elements of the valarray<T> object to which the gslice_array object refers.

29.7.7.4 gslice_array fill function

void operator=(const T&) const;

1 This function has reference semantics, assigning the value of its argument to the elements of the valarray<T> object to which the gslice_array object refers.

29.7.8 Class template mask_array

namespace std {

    template <class T> class mask_array {
        public:
            using value_type = T;

            void operator= (const valarray<T>& ) const;
            void operator** (const valarray<T>&) const;

    };

});

§ 29.7.8.1
void operator/= (const valarray<T>&) const;
void operator%= (const valarray<T>&) const;
void operator+= (const valarray<T>&) const;
void operator-= (const valarray<T>&) const;
void operator^= (const valarray<T>&) const;
void operator&= (const valarray<T>&) const;
void operator|= (const valarray<T>&) const;
void operator<<=(const valarray<T>&) const;
void operator>>=(const valarray<T>&) const;

mask_array(const mask_array&);
~mask_array();
const mask_array& operator=(const mask_array&) const;
void operator=(const T&) const;
mask_array() = delete; // as implied by declaring copy constructor above
};

1 This template is a helper template used by the mask subscript operator:

mask_array<T> valarray<T>::operator[](const valarray<bool>&).

2 It has reference semantics to a subset of an array specified by a boolean mask. Thus, the expression
a[mask] = b; has the effect of assigning the elements of b to the masked elements in a (those for
which the corresponding element in mask is true.)

29.7.8.2 mask_array assignment

void operator=(const valarray<T>&) const;
const mask_array& operator=(const mask_array&) const;

1 These assignment operators have reference semantics, assigning the values of the argument array
elements to selected elements of the valarray<T> object to which it refers.

29.7.8.3 mask_array compound assignment

void operator== (const valarray<T>&) const;
void operator!= (const valarray<T>&) const;
void operator<= (const valarray<T>&) const;
void operator>= (const valarray<T>&) const;
void operator+= (const valarray<T>&) const;
void operator-= (const valarray<T>&) const;
void operator^= (const valarray<T>&) const;
void operator&= (const valarray<T>&) const;
void operator|= (const valarray<T>&) const;
void operator<<=(const valarray<T>&) const;
void operator>>=(const valarray<T>&) const;

1 These compound assignments have reference semantics, applying the indicated operation to the elements
of the argument array and selected elements of the valarray<T> object to which the mask object refers.

29.7.8.4 mask_array fill function

void operator=(const T&) const;

1 This function has reference semantics, assigning the value of its argument to the elements of the
valarray<T> object to which the mask_array object refers.
29.7.9 Class template indirect_array

29.7.9.1 Class template indirect_array overview

namespace std {
    template <class T> class indirect_array {
        public:
            using value_type = T;

            void operator=(const valarray<T>&) const;
            void operator+=(const valarray<T>&) const;
            void operator-=(const valarray<T>&) const;
            void operator%^= (const valarray<T>&) const;
            void operator^//= (const valarray<T>&) const;
            void operator&= (const valarray<T>&) const;
            void operator|= (const valarray<T>&) const;
            void operator<<=(const valarray<T>&) const;

            indirect_array(const indirect_array&);
            indirect_array();
            const indirect_array& operator=(const indirect_array&);
            void operator=(const T&) const;
            indirect_array() = delete; // as implied by declaring copy constructor above
    };
}

1 This template is a helper template used by the indirect subscript operator

    indirect_array<T> valarray<T>::operator[](const valarray<size_t>&).

2 It has reference semantics to a subset of an array specified by an indirect_array. Thus the expression

    a[indirect] = b;

3 has the effect of assigning the elements of b to the elements in a whose indices appear in indirect.

29.7.9.2 indirect_array assignment

void operator=(const valarray<T>&) const;
const indirect_array& operator=(const indirect_array&) const;

1 These assignment operators have reference semantics, assigning the values of the argument array

2 elements to selected elements of the valarray<T> object to which it refers.

3 If the indirect_array specifies an element in the valarray<T> object to which it refers more than once, the behavior is undefined.

[Example:

    int addr[] = {2, 3, 1, 4, 4};
    valarray<size_t> indirect(addr, 5);
    valarray<double> a(0., 10), b(1., 5);
    a[indirect] = b;

    results in undefined behavior since element 4 is specified twice in the indirection. — end example]

29.7.9.3 indirect_array compound assignment

void operator^=(const valarray<T>&) const;

§ 29.7.9.3
void operator/= (const valarray<T>&) const;
void operator%= (const valarray<T>&) const;
void operator+= (const valarray<T>&) const;
void operator-= (const valarray<T>&) const;
void operator^= (const valarray<T>&) const;
void operator&= (const valarray<T>&) const;
void operator|= (const valarray<T>&) const;
void operator<<=(const valarray<T>&) const;
void operator>>=(const valarray<T>&) const;

1 These compound assignments have reference semantics, applying the indicated operation to the elements of the argument array and selected elements of the valarray<T> object to which the indirect_array object refers.

2 If the indirect_array specifies an element in the valarray<T> object to which it refers more than once, the behavior is undefined.

29.7.9.4 indirect_array fill function

void operator=(const T&) const;

1 This function has reference semantics, assigning the value of its argument to the elements of the valarray<T> object to which the indirect_array object refers.

29.7.10 valarray range access

In the begin and end function templates that follow, unspecified1 is a type that meets the requirements of a mutable random access iterator (27.2.7) and of a contiguous iterator (27.2.1) whose value_type is the template parameter T and whose reference type is T&. unspecified2 is a type that meets the requirements of a constant random access iterator (27.2.7) and of a contiguous iterator (27.2.1) whose value_type is the template parameter T and whose reference type is const T&.

2 The iterators returned by begin and end for an array are guaranteed to be valid until the member function resize(size_t, T) (29.7.2.8) is called for that array or until the lifetime of that array ends, whichever happens first.

template <class T> unspecified1 begin(valarray<T>& v);
template <class T> unspecified1 begin(const valarray<T>& v);

3 Returns: An iterator referencing the first value in the array.

template <class T> unspecified1 end(valarray<T>& v);
template <class T> unspecified1 end(const valarray<T>& v);

4 Returns: An iterator referencing one past the last value in the array.

29.8 Generalized numeric operations

29.8.1 Header <numeric> synopsis

namespace std {
  // 29.8.2, accumulate
  template <class InputIterator, class T>

      UnaryOperation unary_op);

// 29.8.10, transform inclusive scan

template<class InputIterator, class OutputIterator,
        class BinaryOperation, class UnaryOperation>
  OutputIterator transform inclusive_scan(InputIterator first, InputIterator last,
      OutputIterator result,
      BinaryOperation binary_op,
      UnaryOperation unary_op);

template<class InputIterator, class OutputIterator,
        class BinaryOperation, class UnaryOperation, class T>
  OutputIterator transform inclusive_scan(InputIterator first, InputIterator last,
      OutputIterator result,
      BinaryOperation binary_op,
      UnaryOperation unary_op,
      T init);

template<class ExecutionPolicy,
        class ForwardIterator1, class ForwardIterator2,
class BinaryOperation, class UnaryOperation>
ForwardIterator2 transform_inclusive_scan(ExecutionPolicy&& exec, // see 28.4.5
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result,
BinaryOperation binary_op,
UnaryOperation unary_op);

template<class ExecutionPolicy,
class ForwardIterator1, class ForwardIterator2,
class BinaryOperation, class UnaryOperation, class T>
ForwardIterator2 transform_inclusive_scan(ExecutionPolicy&& exec, // see 28.4.5
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result,
BinaryOperation binary_op,
UnaryOperation unary_op,
T init);

// 29.8.11, adjacent difference
template <class InputIterator, class OutputIterator>
OutputIterator adjacent_difference(InputIterator first,
InputIterator last,
OutputIterator result);

template <class InputIterator, class OutputIterator, class BinaryOperation>
OutputIterator adjacent_difference(InputIterator first,
InputIterator last,
OutputIterator result,
BinaryOperation binary_op);

template <class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2 adjacent_difference(ExecutionPolicy&& exec, // see 28.4.5
ForwardIterator1 first,
ForwardIterator1 last,
ForwardIterator2 result);

template <class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class BinaryOperation>
ForwardIterator2 adjacent_difference(ExecutionPolicy&& exec, // see 28.4.5
ForwardIterator1 first,
ForwardIterator1 last,
ForwardIterator2 result,
BinaryOperation binary_op);

// 29.8.12, iota
template <class ForwardIterator, class T>
void iota(ForwardIterator first, ForwardIterator last, T value);

// 29.8.13, greatest common divisor
template <class M, class N>
constexpr common_type_t<M,N> gcd(M m, N n);

// 29.8.14, least common multiple
template <class M, class N>
constexpr common_type_t<M,N> lcm(M m, N n);
BinaryOperation2 are used whenever an algorithm expects a function object (23.14).

3 Note: The use of closed ranges as well as semi-open ranges to specify requirements throughout this subclause is intentional. — end note]

29.8.2 Accumulate

```cpp
template <class InputIterator, class T>
T accumulate(InputIterator first, InputIterator last, T init);
template <class InputIterator, class T, class BinaryOperation>
T accumulate(InputIterator first, InputIterator last, T init,
              BinaryOperation binary_op);
```

1 Requires: T shall meet the requirements of CopyConstructible (Table 24) and CopyAssignable (Table 26) types. In the range [first, last], binary_op shall neither modify elements nor invalidate iterators or subranges.

2 Effects: Computes its result by initializing the accumulator acc with the initial value init and then modifies it with acc = acc + *i or acc = binary_op(acc, *i) for every iterator i in the range [first, last) in order.

29.8.3 Reduce

```cpp
template<class InputIterator>
typename iterator_traits<InputIterator>::value_type
reduce(InputIterator first, InputIterator last);
```

1 Effects: Equivalent to:
```
return reduce(first, last,
              typename iterator_traits<InputIterator>::value_type{});
```

```cpp
template<class ExecutionPolicy, class ForwardIterator>
typename iterator_traits<ForwardIterator>::value_type
reduce(ExecutionPolicy&& exec,
       ForwardIterator first, ForwardIterator last);
```

2 Effects: Equivalent to:
```
return reduce(std::forward<ExecutionPolicy>(exec), first, last,
              typename iterator_traits<ForwardIterator>::value_type{});
```

```cpp
template<class InputIterator, class T>
T reduce(InputIterator first, InputIterator last, T init);
```

3 Effects: Equivalent to:
```
return reduce(first, last, init, plus<>());
```

```cpp
template<class ExecutionPolicy, class ForwardIterator, class T>
T reduce(ExecutionPolicy&& exec,
         ForwardIterator first, ForwardIterator last, T init);
```

4 Effects: Equivalent to:
```
return reduce(std::forward<ExecutionPolicy>(exec), first, last, init, plus<>());
```

```cpp
template<class InputIterator, class T, class BinaryOperation>
T reduce(InputIterator first, InputIterator last, T init,
         BinaryOperation binary_op);
```

281 The use of fully closed ranges is intentional.

282 accumulate is similar to the APL reduction operator and Common Lisp reduce function, but it avoids the difficulty of defining the result of reduction on an empty sequence by always requiring an initial value.
BinaryOperation binary_op);
template<
class ExecutionPolicy,
class ForwardIterator,
class T,
class BinaryOperation
>
T reduce(ExecutionPolicy&& exec,
    ForwardIterator first, ForwardIterator last, T init,
    BinaryOperation binary_op);

Requires:

(5.1) — T shall be MoveConstructible (Table 23).

(5.2) — All of binary_op(init, *first), binary_op(*first, init), binary_op(init, init), and
        binary_op(*first, *first) shall be convertible to T.

(5.3) — binary_op shall neither invalidate iterators or subranges, nor modify elements in the range
        [first, last].

Returns: GENERALIZED_SUM(binary_op, init, *i, ...) for every i in [first, last).

Complexity: \( O((last - first)) \) applications of binary_op.

[Note: The difference between reduce and accumulate is that reduce applies binary_op in an
unspecified order, which yields a nondeterministic result for non-associative or non-commutative
binary_op such as floating-point addition. — end note]

29.8.4 Inner product [inner.product]

template<class InputIterator1, class InputIterator2, class T>
T inner_product(InputIterator1 first1, InputIterator1 last1,
    InputIterator2 first2, T init);

template<class InputIterator1, class InputIterator2, class T,
class BinaryOperation1, class BinaryOperation2>
T inner_product(InputIterator1 first1, InputIterator1 last1,
    InputIterator2 first2, T init,
    BinaryOperation1 binary_op1,
    BinaryOperation2 binary_op2);

Requires: T shall meet the requirements of CopyConstructible (Table 24) and CopyAssignable (Ta-
ble 26) types. In the ranges [first1, last1] and [first2, first2 + (last1 - first1)] binary_-
op1 and binary_op2 shall neither modify elements nor invalidate iterators or subranges.283

Effects: Computes its result by initializing the accumulator acc with the initial value init and
then modifying it with acc = acc + (*i1) * (*i2) or acc = binary_op1(acc, binary_op2(*i1,
*i2)) for every iterator i1 in the range [first1, last1] and iterator i2 in the range [first2, first2
+ (last1 - first1)] in order.

29.8.5 Transform reduce [transform.reduce]

template<class InputIterator1, class InputIterator2, class T>
T transform_reduce(InputIterator1 first1, InputIterator1 last1,
    InputIterator2 first2, T init);

template<class ExecutionPolicy,
class ForwardIterator1, class ForwardIterator2, class T>
T transform_reduce(ExecutionPolicy&& exec,
    ForwardIterator1 first1, ForwardIterator1 last1,
    ForwardIterator2 first2,
    T init);

283) The use of fully closed ranges is intentional.
**Effects:** Equivalent to:

```cpp
return transform_reduce(first1, last1, first2, init, plus<>(), multiplies<>());
```

```cpp
template <class InputIterator1, class InputIterator2, class T,
          class BinaryOperation1, class BinaryOperation2>
T transform_reduce(InputIterator1 first1, InputIterator1 last1,
                   InputIterator2 first2,
                   T init,
                   BinaryOperation1 binary_op1,
                   BinaryOperation2 binary_op2);
```

```cpp
template <class ExecutionPolicy,
          class ForwardIterator1, class ForwardIterator2, class T,
          class BinaryOperation1, class BinaryOperation2>
T transform_reduce(ExecutionPolicy&& exec,
                   ForwardIterator1 first1, ForwardIterator1 last1,
                   ForwardIterator2 first2,
                   T init,
                   BinaryOperation1 binary_op1,
                   BinaryOperation2 binary_op2);
```

**Requires:**

(2.1) — T shall be **MoveConstructible** (Table 23).

(2.2) — All of

(2.2.1) — binary_op1(init, init),

(2.2.2) — binary_op1(init, binary_op2(*first1, *first2)),

(2.2.3) — binary_op1(binary_op2(*first1, *first2), init), and

(2.2.4) — binary_op1(binary_op2(*first1, *first2), binary_op2(*first1, *first2))

shall be convertible to T.

(2.3) — Neither binary_op1 nor binary_op2 shall invalidate subranges, or modify elements in the ranges [first1, last1] and [first2, first2 + (last1 - first1)].

**Returns:**

```cpp
GENERALIZED_SUM(binary_op1, init, binary_op2(*i, *(first2 + (i - first1))), ...)
```

for every iterator i in [first1, last1).

**Complexity:** \(\mathcal{O}(last1 - first1)\) applications each of binary_op1 and binary_op2.

```cpp
template<class InputIterator, class T,
         class BinaryOperation, class UnaryOperation>
T transform_reduce(InputIterator first, InputIterator last, T init,
                   BinaryOperation binary_op, UnaryOperation unary_op);
```

```cpp
template<class ExecutionPolicy,
          class ForwardIterator, class T,
          class BinaryOperation, class UnaryOperation>
T transform_reduce(ExecutionPolicy&& exec,
                   ForwardIterator first, ForwardIterator last,
                   T init, BinaryOperation binary_op, UnaryOperation unary_op);
```

**Requires:**

(5.1) — T shall be **MoveConstructible** (Table 23).

(5.2) — All of
(5.2.1) — binary_op(init, init),
(5.2.2) — binary_op(init, unary_op(*first)),
(5.2.3) — binary_op(unary_op(*first), init), and
(5.2.4) — binary_op(unary_op(*first), unary_op(*first))
shall be convertible to T.

 Neither unary_op nor binary_op shall invalidate subranges, or modify elements in the range [first, last].

 Returns:

  GENERALIZED_SUM(binary_op, init, unary_op(*i), ...)
for every iterator i in [first, last).

 Complexity: $O(last - first)$ applications each of unary_op and binary_op.

 [Note: transform_reduce does not apply unary_op to init. — end note]

 29.8.6 Partial sum [partial.sum]

  template <class InputIterator, class OutputIterator>
  OutputIterator partial_sum(
    InputIterator first, InputIterator last,
    OutputIterator result);

  template <class InputIterator, class OutputIterator, class BinaryOperation>
  OutputIterator partial_sum(
    InputIterator first, InputIterator last,
    OutputIterator result, BinaryOperation binary_op);

  Requires: InputIterator’s value type shall be constructible from the type of *first. The result of
  the expression acc + *i or binary_op(acc, *i) shall be implicitly convertible to InputIterator’s
  value type. acc shall be writable (27.2.1) to the result output iterator. In the ranges [first, last]
  and [result, result + (last - first)] binary_op shall neither modify elements nor invalidate
  iterators or subranges.

  Effects: For a non-empty range, the function creates an accumulator acc whose type is InputIterator’s
  value type, initializes it with *first, and assigns the result to *result. For every iterator i in [first
  + 1, last) in order, acc is then modified by acc = acc + *i or acc = binary_op(acc, *i) and
  the result is assigned to *(result + (i - first)).

  Returns: result + (last - first).

  Complexity: Exactly (last - first) - 1 applications of the binary operation.

  Remarks: result may be equal to first.

 29.8.7 Exclusive scan [exclusive.scan]

  template<class InputIterator, class OutputIterator, class T>
  OutputIterator exclusive_scan(InputIterator first, InputIterator last,
                                  OutputIterator result,
                                  T init);

  Effects: Equivalent to:

  return exclusive_scan(first, last, result, init, plus<>());

  template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class T>

  284) The use of fully closed ranges is intentional.
ForwardIterator2 exclusive_scan(ExecutionPolicy&& exec,
   ForwardIterator1 first, ForwardIterator1 last,
   ForwardIterator2 result,
   T init);

Effects: Equivalent to:

return exclusive_scan(std::forward<ExecutionPolicy>(exec),
   first, last, result, init, plus<>());

template<class InputIterator, class OutputIterator, class T, class BinaryOperation>
OutputIterator exclusive_scan(InputIterator first, InputIterator last,
   OutputIterator result,
   T init, BinaryOperation binary_op);

template<class ExecutionPolicy,
   class ForwardIterator1, class ForwardIterator2, class T, class BinaryOperation>
ForwardIterator2 exclusive_scan(ExecutionPolicy&& exec,
   ForwardIterator1 first, ForwardIterator1 last,
   ForwardIterator2 result,
   T init, BinaryOperation binary_op);

Requires:

(3.1) T shall be MoveConstructible (Table 23).
(3.2) All of binary_op(init, init), binary_op(init, *first), and binary_op(*first, *first)
   shall be convertible to T.
(3.3) binary_op shall neither invalidate iterators or subranges, nor modify elements in the ranges
   [first, last] or [result, result + (last - first)].

Effects: For each integer K in [0, last - first) assigns through result + K the value of:

\[ \text{GENERALIZED NONCOMMUTATIVE SUM} \]

   binary_op, init, *(first + 0), *(first + 1), ..., *(first + K - 1)

Returns: The end of the resulting range beginning at result.

Complexity: \( O(last - first) \) applications of binary_op.

Remarks: result may be equal to first.

[ Note: The difference between exclusive_scan and inclusive_scan is that exclusive_scan excludes
the i\text{th} input element from the i\text{th} sum. If binary_op is not mathematically associative, the behavior
of exclusive_scan may be nondeterministic. — end note ]

29.8.8 Inclusive scan [inclusive.scan]

template<class InputIterator, class OutputIterator>
OutputIterator inclusive_scan(InputIterator first, InputIterator last,
   OutputIterator result);

Effects: Equivalent to:

return inclusive_scan(first, last, result, plus<>());

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2 inclusive_scan(ExecutionPolicy&& exec,
   ForwardIterator1 first, ForwardIterator1 last,
   ForwardIterator2 result);

Effects: Equivalent to:

return inclusive_scan(std::forward<ExecutionPolicy>(exec), first, last, result, plus<>());
template<class InputIterator, class OutputIterator, class BinaryOperation>
OutputIterator inclusive_scan(InputIterator first, InputIterator last,
OutputIterator result,
BinaryOperation binary_op);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class BinaryOperation>
ForwardIterator2 inclusive_scan(ExecutionPolicy&& exec,
   ForwardIterator1 first, ForwardIterator1 last,
   ForwardIterator2 result,
   BinaryOperation binary_op);

template<class InputIterator, class OutputIterator, class BinaryOperation, class T>
OutputIterator inclusive_scan(InputIterator first, InputIterator last,
OutputIterator result,
BinaryOperation binary_op, T init);

template<class ExecutionPolicy,
class ForwardIterator1, class ForwardIterator2, class BinaryOperation, class T>
ForwardIterator2 inclusive_scan(ExecutionPolicy&& exec,
   ForwardIterator1 first, ForwardIterator1 last,
   ForwardIterator2 result,
   BinaryOperation binary_op, T init);

3  Requires:
(3.1) — If init is provided, T shall be MoveConstructible (Table 23); otherwise, ForwardIterator1’s value type shall be MoveConstructible.
(3.2) — If init is provided, all of binary_op(init, init), binary_op(init, *first), and binary_op(*first, *first) shall be convertible to T; otherwise, binary_op(*first, *first) shall be convertible to ForwardIterator1’s value type.
(3.3) — binary_op shall neither invalidate iterators or subranges, nor modify elements in the ranges [first, last] or [result, result + (last - first)].

4  Effects: For each integer K in [0, last - first) assigns through result + K the value of
(4.1) — GENERALIZED_NONCOMMUTATIVE_SUM
   binary_op, init, *(first + 0), *(first + 1), ..., *(first + K)
   if init is provided, or
(4.2) — GENERALIZED_NONCOMMUTATIVE_SUM
   binary_op, *(first + 0), *(first + 1), ..., *(first + K)
   otherwise.

5  Returns: The end of the resulting range beginning at result.

6  Complexity: $O(last - first)$ applications of binary_op.

7  Remarks: result may be equal to first.

8  [Note: The difference between exclusive_scan and inclusive_scan is that inclusive_scan includes the ith input element in the ith sum. If binary_op is not mathematically associative, the behavior of inclusive_scan may be nondeterministic. — end note]

29.8.9 Transform exclusive scan [transform.exclusive.scan]

template<class InputIterator, class OutputIterator, class T,
class BinaryOperation, class UnaryOperation>
OutputIterator transform_exclusive_scan(InputIterator first, InputIterator last,
OutputIterator result,
template<class ExecutionPolicy,
    class ForwardIterator1, class ForwardIterator2, class T,
    class BinaryOperation, class UnaryOperation>
ForwardIterator2 transform_exclusive_scan(ExecutionPolicy&& exec,
    ForwardIterator1 first, ForwardIterator1 last,
    ForwardIterator2 result,
    T init,
    BinaryOperation binary_op,
    UnaryOperation unary_op);

Requires:
(1.1) — T shall be MoveConstructible (Table 23).
(1.2) — All of
(1.2.1) — binary_op(init, init),
(1.2.2) — binary_op(init, unary_op(*first)), and
(1.2.3) — binary_op(unary_op(*first), unary_op(*first))
    shall be convertible to T.
(1.3) — Neither unary_op nor binary_op shall invalidate iterators or subranges, or modify elements in
    the ranges [first, last] or [result, result + (last - first)].

Effects: For each integer K in [0, last - first) assigns through result + K the value of:

\[ \text{GENERALIZED\_NONCOMMUTATIVE\_SUM} \]
\[ \text{binary_op, init,} \]
\[ \text{unary_op(*}(\text{first + 0}), \text{unary_op(*}(\text{first + 1}), \ldots, \text{unary_op(*}(\text{first + K - 1}))\]

Returns: The end of the resulting range beginning at result.

Complexity: \(\Theta(last - first)\) applications each of unary_op and binary_op.

Remarks: result may be equal to first.

[ Note: The difference between transform_exclusive_scan and transform_inclusive_scan is that transform_exclusive_scan excludes the \(i\)th input element from the \(i\)th sum. If binary_op is not mathematically associative, the behavior of transform_exclusive_scan may be nondeterministic. transform_exclusive_scan does not apply unary_op to init. — end note ]
UnaryOperation unary_op);

template<class InputIterator, class OutputIterator,
    class BinaryOperation, class UnaryOperation, class T>
OutputIterator transform_inclusive_scan(InputIterator first, InputIterator last,
    OutputIterator result,
    BinaryOperation binary_op,
    UnaryOperation unary_op,
    T init);

template<class ExecutionPolicy,
    class ForwardIterator1, class ForwardIterator2,
    class BinaryOperation, class UnaryOperation, class T>
ForwardIterator2 transform_inclusive_scan(ExecutionPolicy&& exec,
    ForwardIterator1 first, ForwardIterator1 last,
    ForwardIterator2 result,
    BinaryOperation binary_op,
    UnaryOperation unary_op,
    T init);

1 Requires:
(1.1) If init is provided, T shall be MoveConstructible (Table 23); otherwise, ForwardIterator1's value type shall be MoveConstructible.
(1.2) If init is provided, all of
(1.2.1) binary_op(init, init),
(1.2.2) binary_op(init, unary_op(*first)), and
(1.2.3) binary_op(unary_op(*first), unary_op(*first))
shall be convertible to T; otherwise, binary_op(unary_op(*first), unary_op(*first)) shall be convertible to ForwardIterator1's value type.
(1.3) Neither unary_op nor binary_op shall invalidate iterators or subranges, nor modify elements in the ranges [first, last] or [result, result + (last - first)].

2 Effects: For each integer K in [0, last - first) assigns through result + K the value of
(2.1) GENERALIZED_NONCOMMUTATIVE_SUM(
    binary_op, init,
    unary_op(*(first + 0)), unary_op(*(first + 1)), ..., unary_op(*(first + K))
) if init is provided, or
(2.2) GENERALIZED_NONCOMMUTATIVE_SUM(
    binary_op,
    unary_op(*(first + 0)), unary_op(*(first + 1)), ..., unary_op(*(first + K))
) otherwise.

3 Returns: The end of the resulting range beginning at result.
4 Complexity: $O(last - first)$ applications each of unary_op and binary_op.
5 Remarks: result may be equal to first.
6 [Note: The difference between transform_exclusive_scan and transform_inclusive_scan is that transform_inclusive_scan includes the $i^{th}$ input element in the $i^{th}$ sum. If binary_op is not mathematically associative, the behavior of transform_inclusive_scan may be nondeterministic. transform_inclusive_scan does not apply unary_op to init. — end note]

29.8.11 Adjacent difference [adjacent.difference]
template <class InputIterator, class OutputIterator>
OutputIterator
 adjacent_difference(InputIterator first, InputIterator last,
                     OutputIterator result);

template <class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2
 adjacent_difference(ExecutionPolicy&& exec,
                     ForwardIterator1 first, ForwardIterator1 last,
                     ForwardIterator2 result);

template <class InputIterator, class OutputIterator, class BinaryOperation>
OutputIterator
 adjacent_difference(InputIterator first, InputIterator last,
                     OutputIterator result,
                     BinaryOperation binary_op);

template <class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
          class BinaryOperation>
ForwardIterator2
 adjacent_difference(ExecutionPolicy&& exec,
                     ForwardIterator1 first, ForwardIterator1 last,
                     ForwardIterator2 result,
                     BinaryOperation binary_op);

Requires:

(1.1) — For the overloads with no ExecutionPolicy, InputIterator’s value type shall be MoveAssignable (Table 25) and shall be constructible from the type of *first. acc (defined below) shall be writable (27.2.1) to the result output iterator. The result of the expression val - acc or binary_op(val, acc) shall be writable to the result output iterator.

(1.2) — For the overloads with an ExecutionPolicy, the value type of ForwardIterator1 shall be CopyConstructible (Table 24), constructible from the expression *first - *first or binary_op(*first, *first), and assignable to the value type of ForwardIterator2.

(1.3) — For all overloads, in the ranges [first, last] and [result, result + (last - first)], binary_op shall neither modify elements nor invalidate iterators or subranges.

Effects: For the overloads with no ExecutionPolicy and a non-empty range, the function creates an accumulator acc whose type is InputIterator’s value type, initializes it with *first, and assigns the result to *result. For every iterator i in [first + 1, last) in order, creates an object val whose type is InputIterator’s value type, initializes it with *i, computes val - acc or binary_op(val, acc), assigns the result to *(result + (i - first)), and move assigns from val to acc.

For the overloads with an ExecutionPolicy and a non-empty range, first the function creates an object whose type is ForwardIterator1’s value type, initializes it with *first, and assigns the result to *result. Then for every d in [1, last - first - 1], creates an object val whose type is ForwardIterator1’s value type, initializes it with *(first + d) - *(first + d - 1) or binary_op(*(first + d), *(first + d - 1)), and assigns the result to *(result + d).

Returns: result + (last - first).

Complexity: Exactly (last - first) - 1 applications of the binary operation.

Remarks: For the overloads with no ExecutionPolicy, result may be equal to first. For the overloads with an ExecutionPolicy, the ranges [first, last) and [result, result + (last - first)] shall not overlap.

285) The use of fully closed ranges is intentional.
29.8.12 Iota

```cpp
template <class ForwardIterator, class T>
void iota(ForwardIterator first, ForwardIterator last, T value);
```

1. **Requires:** T shall be convertible to ForwardIterator’s value type. The expression ++val, where val has type T, shall be well formed.
2. **Effects:** For each element referred to by the iterator i in the range [first, last), assigns *i = value and increments value as if by ++value.
3. **Complexity:** Exactly last - first increments and assignments.

29.8.13 Greatest common divisor

```cpp
template <class M, class N>
constexpr common_type_t<M,N> gcd(M m, N n);
```

1. **Requires:** |m| and |n| shall be representable as a value of common_type_t<M, N>. [Note: These requirements ensure, for example, that gcd(m, m) = |m| is representable as a value of type M. — end note]
2. **Remarks:** If either M or N is not an integer type, or if either is cv bool, the program is ill-formed.
3. **Returns:** Zero when m and n are both zero. Otherwise, returns the greatest common divisor of |m| and |n|.
4. **Throws:** Nothing.

29.8.14 Least common multiple

```cpp
template <class M, class N>
constexpr common_type_t<M,N> lcm(M m, N n);
```

1. **Requires:** |m| and |n| shall be representable as a value of common_type_t<M, N>. The least common multiple of |m| and |n| shall be representable as a value of type common_type_t<M,N>.
2. **Remarks:** If either M or N is not an integer type, or if either is cv bool the program is ill-formed.
3. **Returns:** Zero when either m or n is zero. Otherwise, returns the least common multiple of |m| and |n|.
4. **Throws:** Nothing.

29.9 Mathematical functions for floating-point types

29.9.1 Header <cmath> synopsis

```cpp
namespace std {
    using float_t = see below;
    using double_t = see below;
}
```

#define HUGE_VAL see below

long double sph_neunnal(unsigned n, long double x);
}

1 The contents and meaning of the header `<cmath>` are the same as the C standard library header `<math.h>`, with the addition of a three-dimensional hypotenuse function (29.9.3) and the mathematical special functions described in 29.9.5. [Note: Several functions have additional overloads in this International Standard, but they have the same behavior as in the C standard library (20.2). —end note]

2 For each set of overloaded functions within `<cmath>`, with the exception of `abs`, there shall be additional overloads sufficient to ensure:

1. If any argument of arithmetic type corresponding to a `double` parameter has type `long double`, then all arguments of arithmetic type (6.9.1) corresponding to `double` parameters are effectively cast to `long double`.

2. Otherwise, if any argument of arithmetic type corresponding to a `double` parameter has type `double` or an integer type, then all arguments of arithmetic type corresponding to `double` parameters are effectively cast to `double`.

3. Otherwise, all arguments of arithmetic type corresponding to `double` parameters have type `float`.

[Note: `abs` is exempted from these rules in order to stay compatible with C. —end note]

See also: ISO C 7.12

29.9.2 Absolute values [c.math.abs]

1 [Note: The headers `<cstdlib>` (21.2.2) and `<cmath>` (29.9.1) declare the functions described in this subclause. —end note]

```c
int abs(int j);
long int abs(long int j);
long long int abs(long long int j);
float abs(float j);
```
double abs(double j);
long double abs(long double j);

Effects: The abs functions have the semantics specified in the C standard library for the functions abs, labs, llabs, fabsf, fab, and fabsl.

Remarks: If abs() is called with an argument of type X for which is_unsigned_v<X> is true and if X cannot be converted to int by integral promotion (7.6), the program is ill-formed. [Note: Arguments that can be promoted to int are permitted for compatibility with C. — end note]

See also: ISO C 7.12.7.2, 7.22.6.1

29.9.3 Three-dimensional hypotenuse

[c.math.hypot3]
float hypot(float x, float y, float z);
double hypot(double x, double y, double z);
long double hypot(long double x, long double y, long double z);

Returns: \( \sqrt{x^2 + y^2 + z^2} \).

29.9.4 Classification / comparison functions

[c.math.fpclass]
The classification / comparison functions behave the same as the C macros with the corresponding names defined in the C standard library. Each function is overloaded for the three floating-point types.

See also: ISO C 7.12.3, 7.12.4

29.9.5 Mathematical special functions

[sf.cmath]
If any argument value to any of the functions specified in this subclause is a NaN (Not a Number), the function shall return a NaN but it shall not report a domain error. Otherwise, the function shall report a domain error for just those argument values for which:

\[(1.1)\] the function description's Returns: clause explicitly specifies a domain and those argument values fall outside the specified domain, or

\[(1.2)\] the corresponding mathematical function value has a nonzero imaginary component, or

\[(1.3)\] the corresponding mathematical function is not mathematically defined.\(^{286}\)

Unless otherwise specified, each function is defined for all finite values, for negative infinity, and for positive infinity.

29.9.5.1 Associated Laguerre polynomials

[sf.cmath.assoc_laguerre]
double assoc_laguerre(unsigned n, unsigned m, double x);
float assoc_laguerref(unsigned n, unsigned m, float x);
long double assoc_laguerrel(unsigned n, unsigned m, long double x);

Effects: These functions compute the associated Laguerre polynomials of their respective arguments n, m, and x.

Returns:
\[ L^m_n(x) = (-1)^m \frac{d^m}{dx^m} L_{n+m}(x), \quad \text{for } x \geq 0 \]

where \( n \) is n, \( m \) is m, and \( x \) is x.

Remarks: The effect of calling each of these functions is implementation-defined if \( n \geq 128 \) or if \( m \geq 128 \).

\(^{286}\) A mathematical function is mathematically defined for a given set of argument values (a) if it is explicitly defined for that set of argument values, or (b) if its limiting value exists and does not depend on the direction of approach.
29.9.5.2 Associated Legendre functions

double assoc_legendre(unsigned l, unsigned m, double x);
float assoc_legendref(unsigned l, unsigned m, float x);
long double assoc_legendrel(unsigned l, unsigned m, long double x);

1 Effects: These functions compute the associated Legendre functions of their respective arguments l, m, and x.
2 Returns:

\[ P^m_\ell(x) = (1 - x^2)^{m/2} \frac{d^m}{dx^m} P_\ell(x), \text{ for } |x| \leq 1 \]

where \( l \) is \( l \), \( m \) is \( m \), and \( x \) is \( x \).
3 Remarks: The effect of calling each of these functions is implementation-defined if \( l \geq 128 \).

29.9.5.3 Beta function

double beta(double x, double y);
float betaf(float x, float y);
long double betal(long double x, long double y);

1 Effects: These functions compute the beta function of their respective arguments \( x \) and \( y \).
2 Returns:

\[ B(x,y) = \frac{\Gamma(x) \Gamma(y)}{\Gamma(x+y)} , \text{ for } x > 0, y > 0 \]

where \( x \) is \( x \) and \( y \) is \( y \).

29.9.5.4 Complete elliptic integral of the first kind

double comp_ellint_1(double k);
float comp_ellint_1f(float k);
long double comp_ellint_1l(long double k);

1 Effects: These functions compute the complete elliptic integral of the first kind of their respective arguments \( k \).
2 Returns:

\[ K(k) = F(k, \pi/2) , \text{ for } |k| \leq 1 \]

where \( k \) is \( k \).
3 See also 29.9.5.11.

29.9.5.5 Complete elliptic integral of the second kind

double comp_ellint_2(double k);
float comp_ellint_2f(float k);
long double comp_ellint_2l(long double k);

1 Effects: These functions compute the complete elliptic integral of the second kind of their respective arguments \( k \).
2 Returns:

\[ E(k) = E(k, \pi/2) , \text{ for } |k| \leq 1 \]

where \( k \) is \( k \).
3 See also 29.9.5.12.
29.9.5.6 Complete elliptic integral of the third kind

```c
double comp_ellint_3(double k, double nu);
float comp_ellint_3f(float k, float nu);
long double comp_ellint_3l(long double k, long double nu);
```

1. **Effects:** These functions compute the complete elliptic integral of the third kind of their respective arguments \( k \) and \( \nu \).
2. **Returns:**
   \[
   \Pi(\nu, k) = \Pi(\nu, k, \pi/2), \quad \text{for } |k| \leq 1
   \]
   where \( k \) is \( k \) and \( \nu \) is \( \nu \).
3. See also 29.9.5.13.

29.9.5.7 Regular modified cylindrical Bessel functions

```c
double cyl_bessel_i(double nu, double x);
float cyl_bessel_if(float nu, float x);
long double cyl_bessel_il(long double nu, long double x);
```

1. **Effects:** These functions compute the regular modified cylindrical Bessel functions of their respective arguments \( \nu \) and \( x \).
2. **Returns:**
   \[
   I_{\nu}(x) = i^{-\nu}J_{\nu}(ix) = \sum_{k=0}^{\infty} \frac{(-1)^k (x/2)^{\nu+2k}}{k! \Gamma(\nu+k+1)}, \quad \text{for } x \geq 0
   \]
   where \( \nu \) is \( \nu \) and \( x \) is \( x \).
3. **Remarks:** The effect of calling each of these functions is implementation-defined if \( \nu \geq 128 \).
4. See also 29.9.5.8.

29.9.5.8 Cylindrical Bessel functions of the first kind

```c
double cyl_bessel_j(double nu, double x);
float cyl_bessel_jf(float nu, float x);
long double cyl_bessel_jl(long double nu, long double x);
```

1. **Effects:** These functions compute the cylindrical Bessel functions of the first kind of their respective arguments \( \nu \) and \( x \).
2. **Returns:**
   \[
   J_{\nu}(x) = \sum_{k=0}^{\infty} \frac{(-1)^k (x/2)^{\nu+2k}}{k! \Gamma(\nu+k+1)}, \quad \text{for } x \geq 0
   \]
   where \( \nu \) is \( \nu \) and \( x \) is \( x \).
3. **Remarks:** The effect of calling each of these functions is implementation-defined if \( \nu \geq 128 \).

29.9.5.9 Irregular modified cylindrical Bessel functions

```c
double cyl_bessel_k(double nu, double x);
float cyl_bessel_kf(float nu, float x);
long double cyl_bessel_kl(long double nu, long double x);
```

1. **Effects:** These functions compute the irregular modified cylindrical Bessel functions of their respective arguments \( \nu \) and \( x \).
Returns:

\[ K_\nu(x) = \frac{\pi}{2} i^{\nu+1} (J_\nu(i x) + i N_\nu(i x)) = \begin{align*}
\frac{\pi}{2} \lim_{\mu \to \nu} \frac{I_{-\mu}(x) - l_{\mu}(x)}{\sin \mu \pi}, & \quad \text{for } x \geq 0 \text{ and non-integral } \nu \\
\frac{\pi}{2} \frac{I_{-\nu}(x) - l_{\nu}(x)}{\sin \nu \pi}, & \quad \text{for } x \geq 0 \text{ and integral } \nu
\end{align*} \]

where \( \nu \) is \( \text{nu} \) and \( x \) is \( x \).

Remarks: The effect of calling each of these functions is implementation-defined if \( \text{nu} \geq 128 \).

See also 29.9.5.7, 29.9.5.8, 29.9.5.10.

### 29.9.5.10 Cylindrical Neumann functions

\[ \text{cyl_neumann(double nu, double x);} \]

\[ \text{cyl_neumannf(float nu, float x);} \]

\[ \text{cyl_neumannl(long double nu, long double x);} \]

Effects: These functions compute the cylindrical Neumann functions, also known as the cylindrical Bessel functions of the second kind, of their respective arguments \( \text{nu} \) and \( x \).

Returns:

\[ N_\nu(x) = \begin{align*}
\frac{J_\nu(x) \cos \nu \pi - J_{-\nu}(x)}{\sin \nu \pi}, & \quad \text{for } x \geq 0 \text{ and non-integral } \nu \\
\lim_{\mu \to \nu} \frac{J_\mu(x) \cos \mu \pi - J_{-\mu}(x)}{\sin \mu \pi}, & \quad \text{for } x \geq 0 \text{ and integral } \nu
\end{align*} \]

where \( \nu \) is \( \text{nu} \) and \( x \) is \( x \).

Remarks: The effect of calling each of these functions is implementation-defined if \( \text{nu} \geq 128 \).

See also 29.9.5.8.

### 29.9.5.11 Incomplete elliptic integral of the first kind

\[ \text{ellint_1(double k, double phi);} \]

\[ \text{ellint_1f(float k, float phi);} \]

\[ \text{ellint_1l(long double k, long double phi);} \]

Effects: These functions compute the incomplete elliptic integral of the first kind of their respective arguments \( k \) and \( \phi \) (\( \phi \) measured in radians).

Returns:

\[ F(k, \phi) = \int_0^\phi \frac{d\theta}{\sqrt{1 - k^2 \sin^2 \theta}}, \quad \text{for } |k| \leq 1 \]

where \( k \) is \( k \) and \( \phi \) is \( \phi \).

### 29.9.5.12 Incomplete elliptic integral of the second kind

\[ \text{ellint_2(double k, double phi);} \]

\[ \text{ellint_2f(float k, float phi);} \]

\[ \text{ellint_2l(long double k, long double phi);} \]

Effects: These functions compute the incomplete elliptic integral of the second kind of their respective arguments \( k \) and \( \phi \) (\( \phi \) measured in radians).

Returns:

\[ E(k, \phi) = \int_0^\phi \sqrt{1 - k^2 \sin^2 \theta} d\theta, \quad \text{for } |k| \leq 1 \]
where \( k \) is \( k \) and \( \phi \) is \( \phi \).

### 29.9.5.13 Incomplete elliptic integral of the third kind

\[
\Pi(\nu, k, \phi) = \int_{0}^{\phi} \frac{d\theta}{(1 - \nu \sin^2 \theta)^{1/2} \sqrt{1 - k^2 \sin^2 \theta}}, \quad \text{for } |k| \leq 1
\]

where \( \nu \) is \( \nu \), \( k \) is \( k \), and \( \phi \) is \( \phi \).

**Effects:** These functions compute the incomplete elliptic integral of the third kind of their respective arguments \( k \), \( \nu \), and \( \phi \) (\( \phi \) measured in radians).

**Returns:**

\[
\Pi(\nu, k, \phi) = \int_{0}^{\phi} \frac{d\theta}{(1 - \nu \sin^2 \theta)^{1/2} \sqrt{1 - k^2 \sin^2 \theta}}, \quad \text{for } |k| \leq 1
\]

### 29.9.5.14 Exponential integral

\[
\text{Ei}(x) = -\int_{-x}^{\infty} \frac{e^{-t}}{t} \, dt
\]

where \( x \) is \( x \).

**Effects:** These functions compute the exponential integral of their respective arguments \( x \).

**Returns:**

\[
\text{Ei}(x) = -\int_{-x}^{\infty} \frac{e^{-t}}{t} \, dt
\]

### 29.9.5.15 Hermite polynomials

\[
H_n(x) = (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2}
\]

where \( n \) is \( n \) and \( x \) is \( x \).

**Effects:** These functions compute the Hermite polynomials of their respective arguments \( n \) and \( x \).

**Returns:**

\[
H_n(x) = (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2}
\]

**Remarks:** The effect of calling each of these functions is implementation-defined if \( n \geq 128 \).

### 29.9.5.16 Laguerre polynomials

\[
L_n(x) = \frac{e^x}{n!} \frac{d^n}{dx^n} (x^n e^{-x}), \quad \text{for } x \geq 0
\]

where \( n \) is \( n \) and \( x \) is \( x \).

**Effects:** These functions compute the Laguerre polynomials of their respective arguments \( n \) and \( x \).

**Returns:**

\[
L_n(x) = \frac{e^x}{n!} \frac{d^n}{dx^n} (x^n e^{-x}), \quad \text{for } x \geq 0
\]

**Remarks:** The effect of calling each of these functions is implementation-defined if \( n \geq 128 \).
29.9.5.17 Legendre polynomials

\begin{verbatim}
double legendre(unsigned l, double x);
float legendref(unsigned l, float x);
long double legendrel(unsigned l, long double x);
\end{verbatim}

1 Effects: These functions compute the Legendre polynomials of their respective arguments \( l \) and \( x \).

2 Returns:

\[ P_l(x) = \frac{1}{2^l l!} \frac{d^l}{dx^l} (x^2 - 1)^l, \quad \text{for} \ |x| \leq 1 \]

where \( l \) is 1 and \( x \) is \( x \).

3 Remarks: The effect of calling each of these functions is implementation-defined if \( l \geq 128 \).

29.9.5.18 Riemann zeta function

\begin{verbatim}
double riemann_zeta(double x);
float riemann_zetaf(float x);
long double riemann_zetal(long double x);
\end{verbatim}

1 Effects: These functions compute the Riemann zeta function of their respective arguments \( x \).

2 Returns:

\[ \zeta(x) = \begin{cases} 
\sum_{k=1}^{\infty} k^{-x}, & \text{for} \ x > 1 \\
\frac{1}{1-2^{1-x}} \sum_{k=1}^{\infty} (-1)^{k-1} k^{-x}, & \text{for} \ 0 \leq x \leq 1 \\
2^x \pi^{x-1} \sin\left(\frac{\pi x}{2}\right) \Gamma\left(1-x\right) \zeta(1-x), & \text{for} \ x < 0
\end{cases} \]

where \( x \) is \( x \).

29.9.5.19 Spherical Bessel functions of the first kind

\begin{verbatim}
double sph_bessel(unsigned n, double x);
float sph_besself(unsigned n, float x);
long double sph_bessell(unsigned n, long double x);
\end{verbatim}

1 Effects: These functions compute the spherical Bessel functions of the first kind of their respective arguments \( n \) and \( x \).

2 Returns:

\[ j_n(x) = (\pi/2x)^{1/2} J_{n+1/2}(x), \quad \text{for} \ x \geq 0 \]

where \( n \) is \( n \) and \( x \) is \( x \).

3 Remarks: The effect of calling each of these functions is implementation-defined if \( n \geq 128 \).

4 See also 29.9.5.8.

29.9.5.20 Spherical associated Legendre functions

\begin{verbatim}
double sph_legendre(unsigned l, unsigned m, double theta);
float sph_legendref(unsigned l, unsigned m, float theta);
long double sph_legendrel(unsigned l, unsigned m, long double theta);
\end{verbatim}

1 Effects: These functions compute the spherical associated Legendre functions of their respective arguments \( l, m, \) and \( \theta \) (\( \theta \) measured in radians).
Returns:
\[ \mathcal{Y}_m^m(\theta, 0) \]
where
\[ \mathcal{Y}_m^m(\theta, \phi) = (-1)^m \left[ \frac{(2\ell + 1)(\ell - m)!}{4\pi (\ell + m)!} \right]^{1/2} P^m_\ell(\cos \theta) e^{im\phi}, \quad \text{for } |m| \leq \ell \]

and \( l \) is \( l \), \( m \) is \( m \), and \( \theta \) is \( \theta \).

Remarks: The effect of calling each of these functions is implementation-defined if \( l \geq 128 \).

See also 29.9.5.2.

### 29.9.5.21 Spherical Neumann functions

```c
double sph_neumann(unsigned n, double x);
float sph_neumannf(unsigned n, float x);
long double sph_neumannl(unsigned n, long double x);
```

Effects: These functions compute the spherical Neumann functions, also known as the spherical Bessel functions of the second kind, of their respective arguments \( n \) and \( x \).

Returns:
\[ n_n(x) = (\pi/2x)^{1/2}N_{n+1/2}(x), \quad \text{for } x \geq 0 \]

where \( n \) is \( n \) and \( x \) is \( x \).

Remarks: The effect of calling each of these functions is implementation-defined if \( n \geq 128 \).

See also 29.9.5.10.
30 Input/output library

30.1 General

1 This Clause describes components that C++ programs may use to perform input/output operations.

2 The following subclauses describe requirements for stream parameters, and components for forward declarations of iostreams, predefined iostreams objects, base iostreams classes, stream buffering, stream formatting and manipulators, string streams, and file streams, as summarized in Table 106.

Table 106 — Input/output library summary

<table>
<thead>
<tr>
<th>Subclause</th>
<th>Header(s)</th>

3 Figure 7 illustrates relationships among various types described in this clause. A line from A to B indicates that A is an alias (e.g. a typedef) for B or that A is defined in terms of B.

Figure 7 — Stream position, offset, and size types [non-normative]
30.2 Iostreams requirements

30.2.1 Imbue limitations

No function described in Clause 30 except for `ios_base::imbue` and `basic_filebuf::pubimbue` causes any instance of `basic_ios::imbue` or `basic_streambuf::imbue` to be called. If any user function called from a function declared in Clause 30 or as an overriding virtual function of any class declared in Clause 30 calls `imbue`, the behavior is undefined.

30.2.2 Positioning type limitations

The classes of Clause 30 with template arguments `charT` and `traits` behave as described if `traits::pos_type` and `traits::off_type` are `streampos` and `streamoff` respectively. Except as noted explicitly below, their behavior when `traits::pos_type` and `traits::off_type` are other types is implementation-defined.

In the classes of Clause 30, a template parameter with name `charT` represents a member of the set of types containing `char`, `wchar_t`, and any other implementation-defined character types that satisfy the requirements for a character on which any of the iostream components can be instantiated.

30.2.3 Thread safety

Concurrent access to a stream object (30.8, 30.9), stream buffer object (30.6), or C Library stream (30.11) by multiple threads may result in a data race (4.7) unless otherwise specified (30.4). [Note: Data races result in undefined behavior (4.7). —end note]

If one thread makes a library call `a` that writes a value to a stream and, as a result, another thread reads this value from the stream through a library call `b` such that this does not result in a data race, then `a`’s write synchronizes with `b`’s read.

30.3 Forward declarations

30.3.1 Header `<iosfwd>` synopsis

```cpp
namespace std {
    template<class charT> class char_traits;
    template<> class char_traits<char>;
    template<> class char_traits<char16_t>;
    template<> class char_traits<char32_t>;
    template<> class char_traits<wchar_t>;
    template<class T> class allocator;
    template <class charT, class traits = char_traits<charT>>
        class basic_ios;
    template <class charT, class traits = char_traits<charT>>
        class basic_streambuf;
    template <class charT, class traits = char_traits<charT>>
        class basic_istream;
    template <class charT, class traits = char_traits<charT>>
        class basic_ostream;
    template <class charT, class traits = char_traits<charT>>
        class basic_iostream;
    template <class charT, class traits = char_traits<charT>,
        class Allocator = allocator<charT>>
        class basic_stringbuf;
    template <class charT, class traits = char_traits<charT>,
        class Allocator = allocator<charT>>
        class basic_istringstream;
```

§ 30.3.1 1158
template <class charT, class traits = char_traits<charT>,
        class Allocator = allocator<charT>>
class basic_ostringstream;
template <class charT, class traits = char_traits<charT>,
        class Allocator = allocator<charT>>
class basic_stringstream;
template <class charT, class traits = char_traits<charT>,
        class Allocator = allocator<charT>>
class basic_filebuf;
template <class charT, class traits = char_traits<charT>,
        class Allocator = allocator<charT>>
class basic_ifstream;
template <class charT, class traits = char_traits<charT>,
        class Allocator = allocator<charT>>
class basic_ofstream;
template <class charT, class traits = char_traits<charT>,
        class Allocator = allocator<charT>>
class basic_fstream;
template <class charT, class traits = char_traits<charT>,
        class Allocator = allocator<charT>>
class istreambuf_iterator;
template <class charT, class traits = char_traits<charT>,
        class Allocator = allocator<charT>>
class ostreambuf_iterator;

using ios = basic_ios<char>;
using wios = basic_ios<wchar_t>;

using streambuf = basic_streambuf<char>;
using istream = basic_istream<char>;
using ostream = basic_ostream<char>;
using iostream = basic_iostream<char>;
using stringbuf = basic_stringbuf<char>;
using istringstream = basic_istringstream<char>;
using ostringstream = basic_ostringstream<char>;
using stringstream = basic_stringstream<char>;
using filebuf = basic_filebuf<char>;
using ifstream = basic_ifstream<char>;
using ofstream = basic_ofstream<char>;
using fstream = basic_fstream<char>;

using wstreambuf = basic_streambuf<wchar_t>;
using wistream = basic_istream<wchar_t>;
using wostream = basic_ostream<wchar_t>;
using wiostream = basic_iostream<wchar_t>;
using wstringbuf = basic_stringbuf<wchar_t>;
using wistringstream = basic_istringstream<wchar_t>;
using wostringstream = basic_ostringstream<wchar_t>;
using wstringstream = basic_stringstream<wchar_t>;
using wfilebuf = basic_filebuf<wchar_t>;
using wifstream = basic_ifstream<wchar_t>;
using wofstream = basic_ofstream<wchar_t>;
using wfstream = basic_fstream<wchar_t>;

template <class state> class fpos;
using streampos = fpos<char_traits<char>::state_type>;
using wstreampos = fpos<char_traits<wchar_t>::state_type>;
}

1 Default template arguments are described as appearing both in `<iosfwd>` and in the synopsis of other headers but it is well-formed to include both `<iosfwd>` and one or more of the other headers.\textsuperscript{287}

30.3.2 Overview \textsuperscript{[iostream.forward.overview]}

The class template specialization `basic_istream<charT, traits>` serves as a virtual base class for the class templates `basic_istream`, `basic_ostream`, and class templates derived from them. `basic_istream` is a class template derived from both `basic_istream<charT, traits>` and `basic_ostream<charT, traits>`.\footnote{The implementation's responsibility to implement headers so that including `<iosfwd>` and other headers does not violate the rules about multiple occurrences of default arguments.}

The class template specialization `basic_streambuf<charT, traits>` serves as a base class for class templates `basic_stringbuf` and `basic_filebuf`.

The class template specialization `basic_istream<charT, traits>` serves as a base class for class templates `basic_istringstream` and `basic_ifstream`.

The class template specialization `basic_ostream<charT, traits>` serves as a base class for class templates `basic_ostringstream` and `basic_ofstream`.

The class template specialization `basic_iostream<charT, traits>` serves as a base class for class templates `basic_stringstream` and `basic_fstream`.

Other typedef-names define instances of class templates specialized for `char` or `wchar_t` types.

Specializations of the class template `fpos` are used for specifying file position information.

The types `streampos` and `wstreampos` are used for positioning streams specialized on `char` and `wchar_t` respectively.

\textsuperscript{Note: This synopsis suggests a circularity between `streampos` and `char_traits<char>`. An implementation can avoid this circularity by substituting equivalent types. One way to do this might be

```cpp
template<class stateT> class fpos { ... }; // depends on nothing
using _STATE = ... ; // implementation private declaration of stateT

using streampos = fpos<_STATE>;

template<> struct char_traits<char> {
    using pos_type = streampos;
}
```

—end note]
extern wistream wcin;
extern wostream wcout;
extern wostream wcerr;
extern wostream wclog;
}

30.4.2 Overview

In this Clause, the type name FILE refers to the type FILE declared in <cstdio> (30.11.1).

The header <iostream> declares objects that associate objects with the standard C streams provided for by the functions declared in <cstdio> (30.11), and includes all the headers necessary to use these objects.

The objects are constructed and the associations are established at some time prior to or during the first time an object of class ios_base::Init is constructed, and in any case before the body of main (6.6.1) begins execution. The objects are not destroyed during program execution. The results of including <iostream> in a translation unit shall be as if <iostream> defined an instance of ios_base::Init with static storage duration.

Mixing operations on corresponding wide- and narrow-character streams follows the same semantics as mixing such operations on FILEs, as specified in the C standard library.

Concurrent access to a synchronized (30.5.3.4) standard iostream object’s formatted and unformatted input (30.7.4.1) and output (30.7.5.1) functions or a standard C stream by multiple threads shall not result in a data race (4.7). [Note: Users must still synchronize concurrent use of these objects and streams by multiple threads if they wish to avoid interleaved characters. —end note]

See also: ISO C 7.21.2.

30.4.3 Narrow stream objects

istream cin;

The object cin controls input from a stream buffer associated with the object stdin, declared in <cstdio> (30.11.1).

After the object cin is initialized, cin.tie() returns &cout. Its state is otherwise the same as required for basic_ios<char>::init (30.5.5.2).

ostream cout;

The object cout controls output to a stream buffer associated with the object stdout, declared in <cstdio> (30.11.1).

ostream cerr;

The object cerr controls output to a stream buffer associated with the object stderr, declared in <cstdio> (30.11.1).

After the object cerr is initialized, cerr.flags() & unitbuf is nonzero and cerr.tie() returns &cout. Its state is otherwise the same as required for basic_ios<char>::init (30.5.5.2).

ostream clog;

The object clog controls output to a stream buffer associated with the object stderr, declared in <cstdio> (30.11.1).

---

288) If it is possible for them to do so, implementations are encouraged to initialize the objects earlier than required.
289) Constructors and destructors for static objects can access these objects to read input from stdin or write output to stdout or stderr.
30.4.4 Wide stream objects

wistream wcin;

1 The object wcin controls input from a stream buffer associated with the object stdin, declared in <cstdio> (30.11.1).

2 After the object wcin is initialized, wcin.tie() returns &wcout. Its state is otherwise the same as required for basic_ios<wchar_t>::init (30.5.5.2).

wostream wcout;

3 The object wcout controls output to a stream buffer associated with the object stdout, declared in <cstdio> (30.11.1).

wostream wcerr;

4 The object wcerr controls output to a stream buffer associated with the object stderr, declared in <cstdio> (30.11.1).

5 After the object wcerr is initialized, wcerr.flags() & unitbuf is nonzero and wcerr.tie() returns &wcout. Its state is otherwise the same as required for basic_ios<wchar_t>::init (30.5.5.2).

wostream wclog;

6 The object wclog controls output to a stream buffer associated with the object stderr, declared in <cstdio> (30.11.1).

30.5 Iostreams base classes

30.5.1 Header <ios> synopsis

#include <iosfwd> // see 30.3.1

namespace std {

using streamoff = implementation-defined;
using streamsize = implementation-defined;
template <class stateT> class fpos;

class ios_base;

template <class charT, class traits = char_traits<charT>>
class basic_ios;

// 30.5.6, manipulators
ios_base& boolalpha (ios_base& str);
ios_base& noboolalpha(ios_base& str);
ios_base& showbase (ios_base& str);
ios_base& noshowbase (ios_base& str);
ios_base& showpoint (ios_base& str);
ios_base& noshowpoint(ios_base& str);
ios_base& showpos (ios_base& str);
ios_base& noshowpos (ios_base& str);
ios_base& skipws (ios_base& str);
ios_base& noskipws (ios_base& str);
ios_base& uppercase (ios_base& str);

§ 30.5.1
ios_base& nouppercase(ios_base& str);
ios_base& unitbuf (ios_base& str);
ios_base& nounitbuf (ios_base& str);

// 30.5.6.2, adjustfield
ios_base& internal (ios_base& str);
ios_base& left (ios_base& str);
ios_base& right (ios_base& str);

// 30.5.6.3, basefield
ios_base& dec (ios_base& str);
ios_base& hex (ios_base& str);
ios_base& oct (ios_base& str);

// 30.5.6.4, floatfield
ios_base& fixed (ios_base& str);
ios_base& scientific (ios_base& str);
ios_base& hexfloat (ios_base& str);
ios_base& defaultfloat(ios_base& str);

// 30.5.6.5, error reporting
enum class io_errc {
    stream = 1
};

template <> struct is_error_code_enum<io_errc> : public true_type { };
error_code make_error_code(io_errc e) noexcept;
error_condition make_error_condition(io_errc e) noexcept;
const error_category& iostream_category() noexcept;
}

30.5.2 Types

using streamoff = implementation-defined;

1 The type streamoff is a synonym for one of the signed basic integral types of sufficient size to represent the maximum possible file size for the operating system.\(^{290}\)

using streamsize = implementation-defined;

2 The type streamsize is a synonym for one of the signed basic integral types. It is used to represent the number of characters transferred in an I/O operation, or the size of I/O buffers.\(^{291}\)

30.5.3 Class ios_base

namespace std {
    class ios_base {
    public:
        class failure; // see below

        // 30.5.3.1.2, fmtflags
        using fmtflags = T1;

290) Typically long long.
291) streamsize is used in most places where ISO C would use size_t. Most of the uses of streamsize could use size_t, except for the strstreambuf constructors, which require negative values. It should probably be the signed type corresponding to size_t (which is what Posix.2 calls ssize_t).

fmtflags setf(fmtflags fmtfl);
fmtflags setf(fmtflags fmtfl, fmtflags mask);
void unsetf(fmtflags mask);

streamsize precision() const;
streamsize precision(streamsize prec);
streamsize width() const;
streamsize width(streamsize wide);
// 30.5.3.3, locales
locale imbue(const locale& loc);
locale getloc() const;

// 30.5.3.5, storage
static int xalloc();
long& iword(int index);
void*& pword(int index);

// destructor:
virtual ~ios_base();

// 30.5.3.6, callbacks;
enum event { erase_event, imbue_event, copyfmt_event };
using event_callback = void (*)(event, ios_base&, int index);
void register_callback(event_callback fn, int index);
ios_base(const ios_base&) = delete;
ios_base& operator=(const ios_base&) = delete;
static bool sync_with_stdio(bool sync = true);

protected:
  ios_base();

private:
  static int index; // exposition only
  long* iarray;    // exposition only
  void** parray;   // exposition only
};

1 ios_base defines several member types:
   (1.1) — a type failure, defined as either a class derived from system_error or a synonym for a class derived from system_error;
   (1.2) — a class Init;
   (1.3) — three bitmask types, fmtflags, iostate, and openmode;
   (1.4) — an enumerated type, seekdir.

2 It maintains several kinds of data:
   (2.1) — state information that reflects the integrity of the stream buffer;
   (2.2) — control information that influences how to interpret (format) input sequences and how to generate (format) output sequences;
   (2.3) — additional information that is stored by the program for its private use.

3 [Note: For the sake of exposition, the maintained data is presented here as:
   (3.1) — static int index, specifies the next available unique index for the integer or pointer arrays maintained for the private use of the program, initialized to an unspecified value;
   (3.2) — long iarray, points to the first element of an arbitrary-length long array maintained for the private use of the program;
   (3.3) — void** parray, points to the first element of an arbitrary-length pointer array maintained for the]
private use of the program.

— end note]

30.5.3.1 Types

30.5.3.1.1 Class ios_base::failure

namespace std {
  class ios_base::failure : public system_error {
    public:
      explicit failure(const string& msg, const error_code& ec = io_errc::stream);
      explicit failure(const char* msg, const error_code& ec = io_errc::stream);
  };
}

1 An implementation is permitted to define ios_base::failure as a synonym for a class with equivalent functionality to class ios_base::failure shown in this subclause. [ Note: When ios_base::failure is a synonym for another type it shall provide a nested type failure, to emulate the injected class name. — end note ] The class failure defines the base class for the types of all objects thrown as exceptions, by functions in the iostreams library, to report errors detected during stream buffer operations.

2 When throwing ios_base::failure exceptions, implementations should provide values of ec that identify the specific reason for the failure. [ Note: Errors arising from the operating system would typically be reported as system_category() errors with an error value of the error number reported by the operating system. Errors arising from within the stream library would typically be reported as error_code(io_errc::stream, iostream_category()). — end note ]

  explicit failure(const string& msg, const error_code& ec = io_errc::stream);

3 Effects: Constructs an object of class failure by constructing the base class with msg and ec.

  explicit failure(const char* msg, const error_code& ec = io_errc::stream);

4 Effects: Constructs an object of class failure by constructing the base class with msg and ec.

30.5.3.1.2 Type ios_base::fmtflags

using fmtflags = T1;

1 The type fmtflags is a bitmask type (20.4.2.1.4). Setting its elements has the effects indicated in Table 107.

2 Type fmtflags also defines the constants indicated in Table 108.

30.5.3.1.3 Type ios_base::iostate

using iostate = T2;

1 The type iostate is a bitmask type (20.4.2.1.4) that contains the elements indicated in Table 109.

2 Type iostate also defines the constant:

(2.1) — goodbit, the value zero.

30.5.3.1.4 Type ios_base::openmode

using openmode = T3;

1 The type openmode is a bitmask type (20.4.2.1.4). It contains the elements indicated in Table 110.

30.5.3.1.5 Type ios_base::seekdir

using seekdir = T4;

§ 30.5.3.1.5
Table 107 — **fmtflags** effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Effect(s) if set</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolalpha</td>
<td>insert and extract bool type in alphabetic format</td>
</tr>

<tr>
<td>in</td>
<td>open for input</td>
</tr>
<tr>
<td>out</td>
<td>open for output</td>
</tr>
<tr>
<td>trunc</td>
<td>truncate an existing stream when opening</td>
</tr>
</tbody>
</table>
The type `seekdir` is an enumerated type (20.4.2.1.3) that contains the elements indicated in Table 111.

Table 111 — `seekdir` effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>beg</td>
<td>request a seek (for subsequent input or output) relative to the beginning of the stream</td>
</tr>
<tr>
<td>cur</td>
<td>request a seek relative to the current position within the sequence</td>
</tr>
<tr>
<td>end</td>
<td>request a seek relative to the current end of the sequence</td>
</tr>
</tbody>
</table>

30.5.3.1.6 Class `ios_base::Init`  

namespace std {
    class ios_base::Init {
    public:
        Init();
        ~Init();
    private:
        static int init_cnt; // exposition only
    };
}

1 The class `Init` describes an object whose construction ensures the construction of the eight objects declared in `<iostream>` (30.4) that associate file stream buffers with the standard C streams provided for by the functions declared in `<cstdio>` (30.11.1).

2 For the sake of exposition, the maintained data is presented here as:

(2.1) — static int init_cnt, counts the number of constructor and destructor calls for class `Init`, initialized to zero.

    Init();

3 Effects: Constructs an object of class `Init`. Constructs and initializes the objects `cin`, `cout`, `cerr`, `clog`, `wcin`, `wcout`, `wcerr`, and `wclog` if they have not already been constructed and initialized.

    ~Init();

4 Effects: Destroys an object of class `Init`. If there are no other instances of the class still in existence, calls `cout.flush()`, `cerr.flush()`, `clog.flush()`, `wcout.flush()`, `wcerr.flush()`, `wclog.flush()`.

30.5.3.2 `ios_base` state functions  

`fmtflags flags() const;`

1 Returns: The format control information for both input and output.

    `fmtflags flags(fmtflags fmtfl);`

2 Postconditions: `fmtfl == flags()`.

3 Returns: The previous value of `flags()`.

    `fmtflags setf(fmtflags fmtfl);`

4 Effects: Sets `fmtfl` in `flags()`.

5 Returns: The previous value of `flags()`.

    `fmtflags setf(fmtflags fmtfl, fmtflags mask);`

§ 30.5.3.2
Effects: Clears mask in flags(), sets fmtfl & mask in flags().

Returns: The previous value of flags().

void unsetf(fmtflags mask);

Effects: Clears mask in flags().

streamsize precision() const;

Returns: The precision to generate on certain output conversions.

streamsize precision(streamsize prec);

Postconditions: prec == precision().

Returns: The previous value of precision().

streamsize width() const;

Returns: The minimum field width (number of characters) to generate on certain output conversions.

streamsize width(streamsize wide);

Postconditions: wide == width().

Returns: The previous value of width().

30.5.3.3 ios_base functions

locale imbue(const locale& loc);

Effects: Calls each registered callback pair (fn, index) (30.5.3.6) as (*fn)(imbue_event, *this, index) at such a time that a call to ios_base::getloc() from within fn returns the new locale value loc.

Returns: The previous value of getloc().

Postconditions: loc == getloc().

locale getloc() const;

Returns: If no locale has been imbued, a copy of the global C++ locale, locale(), in effect at the time of construction. Otherwise, returns the imbued locale, to be used to perform locale-dependent input and output operations.

30.5.3.4 ios_base static members

bool sync_with_stdio(bool sync = true);

Returns: true if the previous state of the standard iostream objects (30.4) was synchronized and otherwise returns false. The first time it is called, the function returns true.

Effects: If any input or output operation has occurred using the standard streams prior to the call, the effect is implementation-defined. Otherwise, called with a false argument, it allows the standard streams to operate independently of the standard C streams.

When a standard iostream object str is synchronized with a standard stdio stream f, the effect of inserting a character c by

fputc(f, c);

is the same as the effect of

str.rdbuf()->sputc(c);

for any sequences of characters; the effect of extracting a character c by
c = fgetc(f);
is the same as the effect of
c = str.rdbuf()->sbumpc();
for any sequences of characters; and the effect of pushing back a character c by
ungetc(c, f);
is the same as the effect of
str.rdbuf()->sputbackc(c);
for any sequence of characters.292

30.5.3.5 ios_base storage functions

static int xalloc();
Returns: index ++.
Remarks: Concurrent access to this function by multiple threads shall not result in a data race (4.7).

long& iword(int idx);
Effects: If iarray is a null pointer, allocates an array of long of unspecified size and stores a pointer
to its first element in iarray. The function then extends the array pointed at by iarray as necessary
to include the element iarray[idx]. Each newly allocated element of the array is initialized to zero.
The reference returned is invalid after any other operations on the object.293 However, the value of the
storage referred to is retained, so that until the next call to copyfmt, calling iword with the same index
yields another reference to the same value. If the function fails294 and *this is a base class subobject of
a basic_ios<> object or subobject, the effect is equivalent to calling basic_ios<>::setstate(badbit)
on the derived object (which may throw failure).
Returns: On success iarray[idx]. On failure, a valid long& initialized to 0.

void*& pword(int idx);
Effects: If parray is a null pointer, allocates an array of pointers to void of unspecified size and stores a pointer
to its first element in parray. The function then extends the array pointed at by parray as necessary to include the element parray[idx]. Each newly allocated element of the array is initialized to a null pointer. The reference returned is invalid after any other operations on the object. However, the value of the storage referred to is retained, so that until the next call to copyfmt, calling pword with the same index yields another reference to the same value. If the function fails295 and *this is a base class subobject of a basic_ios<> object or subobject, the effect is equivalent to calling basic_ios<>::setstate(badbit) on the derived object (which may throw failure).
Returns: On success parray[idx]. On failure a valid void*& initialized to 0.
Remarks: After a subsequent call to pword(int) for the same object, the earlier return value may no
longer be valid.

30.5.3.6 ios_base callbacks

void register_callback(event_callback fn, int index);

292) This implies that operations on a standard iostream object can be mixed arbitrarily with operations on the corresponding
stdio stream. In practical terms, synchronization usually means that a standard iostream object and a standard stdio object
share a buffer.
293) An implementation is free to implement both the integer array pointed at by iarray and the pointer array pointed at by
parray as sparse data structures, possibly with a one-element cache for each.
294) for example, because it cannot allocate space.
295) for example, because it cannot allocate space.
Effects: Registers the pair \((fn, index)\) such that during calls to `imbue()` (30.5.3.3), `copyfmt()`, or `~ios_base()` (30.5.3.7), the function \(fn\) is called with argument \(index\). Functions registered are called when an event occurs, in opposite order of registration. Functions registered while a callback function is active are not called until the next event.

Requires: The function \(fn\) shall not throw exceptions.

Remarks: Identical pairs are not merged. A function registered twice will be called twice.

30.5.3.7 ios_base constructors/destructor

```c
ios_base();
```

Effects: Each `ios_base` member has an indeterminate value after construction. The object’s members shall be initialized by calling `basic_ios::init` before the object’s first use or before it is destroyed, whichever comes first; otherwise the behavior is undefined.

```c
~ios_base();
```

Effects: Destroys an object of class `ios_base`. Calls each registered callback pair \((fn, index)\) (30.5.3.6) as `(*fn)(erase_event, *this, index)` at such time that any `ios_base` member function called from within \(fn\) has well defined results.

30.5.4 Class template fpos

```c
namespace std {
  template <class stateT> class fpos {
    public:
      // 30.5.4.1, members
      stateT state() const;
      void state(stateT);
    private;
      stateT st; // exposition only
  };
}
```

30.5.4.1 fpos members

```c
void state(stateT s);
```

Effects: Assigns \(s\) to \(st\).

```c
stateT state() const;
```

Returns: Current value of \(st\).

30.5.4.2 fpos requirements

Operations specified in Table 112 are permitted. In that table,

(1.1) — \(P\) refers to an instance of `fpos`,
(1.2) — \(p\) and \(q\) refer to values of type \(P\),
(1.3) — \(O\) refers to type `streamoff`,
(1.4) — \(o\) refers to a value of type `streamoff`,
(1.5) — \(sz\) refers to a value of type `streamsize` and
(1.6) — \(i\) refers to a value of type `int`. 

§ 30.5.4.2

</tr>
<tr>
<td>0(sz)</td>
<td>streamoff</td>
<td>converts</td>
<td>streamsize(0(sz)) == sz</td>
</tr>
</tbody>
</table>

2 [Note: Every implementation is required to supply overloaded operators on fpos objects to satisfy the requirements of 30.5.4.2. It is unspecified whether these operators are members of fpos, global operators, or provided in some other way. — end note]

3 Stream operations that return a value of type traits::pos_type return P(0(-1)) as an invalid value to signal an error. If this value is used as an argument to any istream, ostream, or streambuf member that accepts a value of type traits::pos_type then the behavior of that function is undefined.

30.5.5 Class template basic_ios

30.5.5.1 Overview

namespace std {
    template <class charT, class traits = char_traits<charT>>
    class basic_ios : public ios_base {
        public:
            using char_type = charT;
            using int_type = typename traits::int_type;
            using pos_type = typename traits::pos_type;
            using off_type = typename traits::off_type;
            using traits_type = traits;

            // 30.5.5.4, flags functions
            explicit operator bool() const;
            bool operator!() const;
            iostate rdstate() const;
            void clear(iostate state = goodbit);
            void setstate(iostate state);
            bool good() const;
            bool eof() const;
            bool fail() const;
            bool bad() const;
            iostate exceptions() const;

§ 30.5.5.1
void exceptions(iostate except);

// 30.5.5.2, constructor/destructor
explicit basic_ios(basic_streambuf<charT, traits>* sb);
virtual ~basic_ios();

// 30.5.5.3, members
basic_ostream<charT, traits>* tie() const;
basic_ostream<charT, traits>* tie(basic_ostream<charT, traits>* tiestr);
basic_streambuf<charT, traits>* rdbuf() const;

void move(basic_ios&& rhs);
void swap(basic_ios& rhs) noexcept;
void set_rdbuf(basic_streambuf<charT, traits>* sb);

};

30.5.5.2 basic_ios constructors [basic.ios.cons]

explicit basic_ios(basic_streambuf<charT, traits>* sb);

1 Effects: Constructs an object of class basic_ios, assigning initial values to its member objects by calling init(sb).

basic_ios();

2 Effects: Constructs an object of basic_ios (30.5.3.7) leaving its member objects uninitialized. The object shall be initialized by calling basic_ios::init before its first use or before it is destroyed, whichever comes first; otherwise the behavior is undefined.

~basic_ios();

3 Remarks: The destructor does not destroy rdbuf().

void init(basic_streambuf<charT, traits>* sb);

4 Postconditions: The postconditions of this function are indicated in Table 113.
Table 113 — basic_ios::init() effects

30.5.5.3 Member functions

basic_ostream<charT, traits>* tie() const;

1 Returns: An output sequence that is tied to (synchronized with) the sequence controlled by the stream buffer.

basic_ostream<charT, traits>* tie(basic_ostream<charT, traits>* tiestr);

2 Requires: If tiestr is not null, tiestr must not be reachable by traversing the linked list of tied stream objects starting from tiestr->tie().

3 Postconditions: tiestr == tie().
4 Returns: The previous value of tie().

basic_streambuf<charT, traits>* rdbuf() const;

5 Returns: A pointer to the streambuf associated with the stream.

basic_streambuf<charT, traits>* rdbuf(basic_streambuf<charT, traits>* sb);

6 Postconditions: sb == rdbuf().
7 Effects: Calls clear().
8 Returns: The previous value of rdbuf().

locale imbue(const locale& loc);

9 Effects: Calls ios_base::imbue(loc) (30.5.3.3) and if rdbuf() != 0 then rdbuf()->pubimbue(loc) (30.6.3.2.1).
10 Returns: The prior value of ios_base::imbue().

char narrow(char_type c, char dfault) const;

11 Returns: use_facet<ctype<char_type>>().narrow(c, dfault)

char_type widen(char c) const;

12 Returns: use_facet<ctype<char_type>>().widen(c)

char_type fill() const;

§ 30.5.5.3
13 \textit{Returns:} The character used to pad (fill) an output conversion to the specified field width.

```cpp
char_type fill(char_type fillch);
```

\textit{Postconditions:} \texttt{traits::eq(fillch, fill())}.

15 \textit{Returns:} The previous value of \texttt{fill()}. 

```cpp
basic_ios& copyfmt(const basic_ios& rhs);
```

\textit{Effects:} If (\texttt{this == &rhs}) does nothing. Otherwise assigns to the member objects of \texttt{*this} the corresponding member objects of \texttt{rhs} as follows:

1. calls each registered callback pair (\texttt{fn, index}) as (\texttt{*fn}(\texttt{erase_event, *this, index})

2. assigns to the member objects of \texttt{*this} the corresponding member objects of \texttt{rhs}, except that

   (16.1) \texttt{rdstate()}, \texttt{rdbuf()}, and \texttt{exceptions()} are left unchanged;

   (16.2) the contents of arrays pointed at by \texttt{pword} and \texttt{iword} are copied, not the pointers themselves;

   (16.3) if any newly stored pointer values in \texttt{*this} point at objects stored outside the object \texttt{rhs} and those objects are destroyed when \texttt{rhs} is destroyed, the newly stored pointer values are altered to point at newly constructed copies of the objects;

3. calls each callback pair that was copied from \texttt{rhs} as (\texttt{*fn}(\texttt{copyfmt_event, *this, index})

4. calls \texttt{exceptions(rhs.exceptions())}.

\textit{Postconditions:} The postconditions of this function are indicated in Table 114.

Table 114 — basic_ios::copyfmt() effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>rdbuf()</td>
<td>unchanged</td>
</tr>
<tr>
<td>tie()</td>
<td>rhs.tie()</td>
</tr>
<tr>
<td>rdstate()</td>
<td>unchanged</td>
</tr>
<tr>
<td>exceptions()</td>
<td>rhs.exceptions()</td>
</tr>
<tr>
<td>flags()</td>
<td>rhs.flags()</td>
</tr>
<tr>
<td>width()</td>
<td>rhs.width()</td>
</tr>
<tr>
<td>precision()</td>
<td>rhs.precision()</td>
</tr>
<tr>

<td>rhs.fill()</td>
</tr>
<tr>
<td>getloc()</td>
<td>rhs.getloc()</td>
</tr>
</tbody>
</table>

19 \textit{Returns:} \texttt{*this}.

```cpp
void move(basic_ios& rhs);
void move(basic_ios&& rhs);
```

\textit{Postconditions:} \texttt{*this} shall have the state that \texttt{rhs} had before the function call, except that \texttt{rdbuf()} shall return 0. \texttt{rhs} shall be in a valid but unspecified state, except that \texttt{rhs.rdbuf()} shall return the same value as it returned before the function call, and \texttt{rhs.tie()} shall return 0.

```cpp
void swap(basic_ios& rhs) noexcept;
```

20

\textit{Postconditions:} \texttt{*this} shall have the state that \texttt{rhs} had before the function call, except that \texttt{rdbuf()} shall return 0. \texttt{rhs} shall be in a valid but unspecified state, except that \texttt{rhs.rdbuf()} shall return the same value as it returned before the function call, and \texttt{rhs.tie()} shall return 0.

\textit{Postconditions:} The postconditions of this function are indicated in Table 114.

Table 114 — basic_ios::copyfmt() effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>rdbuf()</td>
<td>unchanged</td>

<tr>
<td>getloc()</td>
<td>rhs.getloc()</td>
</tr>
</tbody>
</table>

296) This suggests an infinite amount of copying, but the implementation can keep track of the maximum element of the arrays that is nonzero.
Effects: The states of \*this and rhs shall be exchanged, except that rdbuf() shall return the same value as it returned before the function call, and rhs.rdbuf() shall return the same value as it returned before the function call.

```cpp
void set_rdbuf(basic_streambuf<charT, traits>* sb);
```

Requires: sb != nullptr.

Effects: Associates the basic_streambuf object pointed to by sb with this stream without calling clear().

Postconditions: rdbuf() == sb.

Throws: Nothing.

### 30.5.5.4 basic_ios flags functions

#### [iostate.flags]

- **explicit operator bool() const;**
  
  Returns: !fail().

- **bool operator!() const;**
  
  Returns: fail().

- **iostate rdstate() const;**
  
  Returns: The error state of the stream buffer.

- **void clear(iostate state = goodbit);**
  
  Postconditions: If rdbuf() != 0 then state == rdstate(); otherwise rdstate() == (state | ios_base::badbit).

  Effects: If ((state | (rdbuf() ? goodbit : badbit)) & exceptions()) == 0, returns. Otherwise, the function throws an object of class basic_ios::failure (30.5.3.1.1), constructed with implementation-defined argument values.

- **void setstate(iostate state);**
  
  Effects: Calls clear(rdstate() | state) (which may throw basic_ios::failure (30.5.3.1.1)).

- **bool good() const;**
  
  Returns: rdstate() == 0

- **bool eof() const;**
  
  Returns: true if eofbit is set in rdstate().

- **bool fail() const;**
  
  Returns: true if failbit or badbit is set in rdstate().

- **bool bad() const;**
  
  Returns: true if badbit is set in rdstate().

- **iostate exceptions() const;**
  
  Returns: A mask that determines what elements set in rdstate() cause exceptions to be thrown.

- **void exceptions(iostate except);**

---

297) Checking badbit also for fail() is historical practice.
Postconditions: except == exceptions().

Effects: Calls clear(rdstate()).

30.5.6 ios_base manipulators

30.5.6.1 fmtflags manipulators

ios_base& boolalpha(ios_base& str);

Effects: Calls str.setf(ios_base::boolalpha).
Returns: str.

ios_base& noboolalpha(ios_base& str);

Effects: Calls str.unsetf(ios_base::boolalpha).
Returns: str.

ios_base& showbase(ios_base& str);

Effects: Calls str.setf(ios_base::showbase).
Returns: str.

ios_base& noshowbase(ios_base& str);

Effects: Calls str.unsetf(ios_base::showbase).
Returns: str.

ios_base& showpoint(ios_base& str);

Effects: Calls str.setf(ios_base::showpoint).
Returns: str.

ios_base& noshowpoint(ios_base& str);

Effects: Calls str.unsetf(ios_base::showpoint).
Returns: str.

ios_base& showpos(ios_base& str);

Effects: Calls str.setf(ios_base::showpos).
Returns: str.

ios_base& noshowpos(ios_base& str);

Effects: Calls str.unsetf(ios_base::showpos).
Returns: str.

ios_base& skipws(ios_base& str);

Effects: Calls str.setf(ios_base::skipws).
Returns: str.

ios_base& noskipws(ios_base& str);

Effects: Calls str.unsetf(ios_base::skipws).
Returns: str.

ios_base& uppercase(ios_base& str);

§ 30.5.6.1

[std.ios.manip]

[fmtflags.manip]
21  Effects: Calls \texttt{str.setf(ios\_base::uppercase)}.
22  Returns: \texttt{str}.
23  \texttt{ios\_base\& nouppercase(ios\_base\& str)};
24  Effects: Calls \texttt{str.unsetf(ios\_base::uppercase)}.
25  Returns: \texttt{str}.
26  \texttt{ios\_base\& unitbuf(ios\_base\& str)};
27  Effects: Calls \texttt{str.setf(ios\_base::unitbuf)}.
28  Returns: \texttt{str}.
29  \texttt{ios\_base\& nounitbuf(ios\_base\& str)};
30  Effects: Calls \texttt{str.unsetf(ios\_base::unitbuf)}.
31  Returns: \texttt{str}.

30.5.6.2 adjustfield manipulators

32  \texttt{ios\_base\& internal(ios\_base\& str)};
33  Effects: Calls \texttt{str.setf(ios\_base::internal, ios\_base::adjustfield)}.
34  Returns: \texttt{str}.
35  \texttt{ios\_base\& left(ios\_base\& str)};
36  Effects: Calls \texttt{str.setf(ios\_base::left, ios\_base::adjustfield)}.
37  Returns: \texttt{str}.
38  \texttt{ios\_base\& right(ios\_base\& str)};
39  Effects: Calls \texttt{str.setf(ios\_base::right, ios\_base::adjustfield)}.
40  Returns: \texttt{str}.

30.5.6.3 basefield manipulators

41  \texttt{ios\_base\& dec(ios\_base\& str)};
42  Effects: Calls \texttt{str.setf(ios\_base::dec, ios\_base::basefield)}.
43  Returns: \texttt{str}.\footnote{The function signature \texttt{dec(ios\_base\&)} can be called by the function signature \texttt{basic\_ostream\& stream::operator<<(ios\_base\*\* (ios\_base\&))} to permit expressions of the form \texttt{cout \textless\textless dec} to change the format flags stored in \texttt{cout}.}
44  \texttt{ios\_base\& hex(ios\_base\& str)};
45  Effects: Calls \texttt{str.setf(ios\_base::hex, ios\_base::basefield)}.
46  Returns: \texttt{str}.
47  \texttt{ios\_base\& oct(ios\_base\& str)};
48  Effects: Calls \texttt{str.setf(ios\_base::oct, ios\_base::basefield)}.
49  Returns: \texttt{str}.

30.5.6.4 floatfield manipulators

50  \texttt{ios\_base\& fixed(ios\_base\& str)};
Effects: Calls str.setf(ios_base::fixed, ios_base::floatfield).

Returns: str.

ios_base& scientific(ios_base& str);

Effects: Calls str.setf(ios_base::scientific, ios_base::floatfield).

Returns: str.

ios_base& hexfloat(ios_base& str);

Effects: Calls str.setf(ios_base::fixed | ios_base::scientific, ios_base::floatfield).

Returns: str.

[Note: The more obvious use of ios_base::hex to specify hexadecimal floating-point format would change the meaning of existing well defined programs. C++ 2003 gives no meaning to the combination of fixed and scientific. — end note]

ios_base& defaultfloat(ios_base& str);

Effects: Calls str.unsetf(ios_base::floatfield).

Returns: str.

30.5.6.5 Error reporting

error_code make_error_code(io_errc e) noexcept;

Returns: error_code(static_cast<int>(e), iostream_category()).

error_condition make_error_condition(io_errc e) noexcept;

Returns: error_condition(static_cast<int>(e), iostream_category()).

const error_category& iostream_category() noexcept;

Returns: A reference to an object of a type derived from class error_category.

The object’s default_error_condition and equivalent virtual functions shall behave as specified for the class error_category. The object’s name virtual function shall return a pointer to the string "iostream".

30.6 Stream buffers

30.6.1 Header <streambuf> synopsis

namespace std {
    template <class charT, class traits = char_traits<charT>>
    class basic_streambuf;
    using streambuf = basic_streambuf<char>;
    using wstreambuf = basic_streambuf<wchar_t>;
}

The header <streambuf> defines types that control input from and output to character sequences.

30.6.2 Stream buffer requirements

Stream buffers can impose various constraints on the sequences they control. Some constraints are:

(1.1) — The controlled input sequence can be not readable.

(1.2) — The controlled output sequence can be not writable.

(1.3) — The controlled sequences can be associated with the contents of other representations for character sequences, such as external files.
The controlled sequences can support operations directly to or from associated sequences.

The controlled sequences can impose limitations on how the program can read characters from a sequence, write characters to a sequence, put characters back into an input sequence, or alter the stream position.

Each sequence is characterized by three pointers which, if non-null, all point into the same `charT` array object. The array object represents, at any moment, a (sub)sequence of characters from the sequence. Operations performed on a sequence alter the values stored in these pointers, perform reads and writes directly to or from associated sequences, and alter “the stream position” and conversion state as needed to maintain this subsequence relationship. The three pointers are:

1. the `beginning pointer`, or lowest element address in the array (called `xbeg` here);
2. the `next pointer`, or next element address that is a current candidate for reading or writing (called `xnext` here);
3. the `end pointer`, or first element address beyond the end of the array (called `xend` here).

The following semantic constraints shall always apply for any set of three pointers for a sequence, using the pointer names given immediately above:

1. If `xnext` is not a null pointer, then `xbeg` and `xend` shall also be non-null pointers into the same `charT` array, as described above; otherwise, `xbeg` and `xend` shall also be null.
2. If `xnext` is not a null pointer and `xnext < xend` for an output sequence, then a write position is available. In this case, `*xnext` shall be assignable as the next element to write (to put, or to store a character value, into the sequence).
3. If `xnext` is not a null pointer and `xbeg < xnext` for an input sequence, then a putback position is available. In this case, `xnext[-1]` shall have a defined value and is the next (preceding) element to store a character that is put back into the input sequence.
4. If `xnext` is not a null pointer and `xnext < xend` for an input sequence, then a read position is available. In this case, `*xnext` shall have a defined value and is the next element to read (to get, or to obtain a character value, from the sequence).

### 30.6.3 Class template basic_streambuf

```cpp
amespace std {
    template <class charT, class traits = char_traits<charT>>
    class basic_streambuf {
public:
    using char_type = charT;
    using int_type = typename traits::int_type;
    using pos_type = typename traits::pos_type;
    using off_type = typename traits::off_type;
    using traits_type = traits;

    virtual ~basic_streambuf();

    // 30.6.3.2.1, locales
    locale pubimbue(const locale& loc);
    locale getloc() const;

    // 30.6.3.2.2, buffer and positioning
    basic_streambuf* pubsetbuf(char_type* s, streamsize n);
    pos_type pubseekoff(off_type off, ios_base::seekdir way,
                        ios_base::openmode which
                        = ios_base::in | ios_base::out);

§ 30.6.3
```
pos_type pubseekpos(pos_type sp,
        ios_base::openmode which
    = ios_base::in | ios_base::out);
int pubsync();

// Get and put areas
// 30.6.3.2.3, get area
streamsize in_avail();
int_type snextc();
int_type sbumpc();
int_type sgetc();
streamsize sgetn(char_type* s, streamsize n);

// 30.6.3.2.4, putback
int_type sputbackc(char_type c);
int_type sungetc();

// 30.6.3.2.5, put area
int_type sputc(char_type c);
streamsize sputn(const char_type* s, streamsize n);

protected:
basic_streambuf();
basic_streambuf(const basic_streambuf& rhs);
basic_streambuf& operator=(const basic_streambuf& rhs);

void swap(basic_streambuf& rhs);

// 30.6.3.3.2, get area access
char_type* eback() const;
char_type* gptr() const;
char_type* egptr() const;
void gbump(int n);
void setg(char_type* gbeg, char_type* gnext, char_type* gend);

// 30.6.3.3.3, put area access
char_type* pbase() const;
char_type* pptr() const;
char_type* epptr() const;
void pbump(int n);
void setp(char_type* pbeg, char_type* pend);

// 30.6.3.4, virtual functions
// 30.6.3.4.1, locales
virtual void imbue(const locale& loc);

// 30.6.3.4.2, buffer management and positioning
virtual basic_streambuf* setbuf(char_type* s, streamsize n);
virtual pos_type seekoff(off_type off, ios_base::seekdir way,
        ios_base::openmode which
    = ios_base::in | ios_base::out);
virtual pos_type seekpos(pos_type sp,
        ios_base::openmode which
    = ios_base::in | ios_base::out);
virtual int sync();
The class template basic_streambuf serves as an abstract base class for deriving various stream buffers whose objects each control two character sequences:

1.1 a character input sequence;
1.2 a character output sequence.

30.6.3.1 basic_streambuf constructors [streambuf.cons]

basic_streambuf();

Effects: Constructs an object of class basic_streambuf<charT, traits> and initializes:

1. all its pointer member objects to null pointers,
2. the getloc() member to a copy of the global locale, locale(), at the time of construction.

Remarks: Once the getloc() member is initialized, results of calling locale member functions, and of members of facets so obtained, can safely be cached until the next time the member imbue is called.

basic_streambuf(const basic_streambuf& rhs);

Effects: Constructs a copy of rhs.

Postconditions:

4.1 eback() == rhs.eback()
4.2 gptr() == rhs.gptr()
4.3 egptr() == rhs.egptr()
4.4 pbase() == rhs.pbase()
4.5 pptr() == rhs.pptr()
4.6 epptr() == rhs.epptr()
4.7 getloc() == rhs.getloc()

~basic_streambuf();

Effects: None.

30.6.3.2 basic_streambuf public member functions [streambuf.members]

30.6.3.2.1 Locales [streambuflocales]

299) The default constructor is protected for class basic_streambuf to assure that only objects for classes derived from this class may be constructed.

§ 30.6.3.2.1
locale pubimbue(const locale& loc);

Postconditions: loc == getloc().

Effects: Calls imbue(loc).

Returns: Previous value of getloc().

locale getloc() const;

Returns: If pubimbue() has ever been called, then the last value of loc supplied, otherwise the current global locale, locale(), in effect at the time of construction. If called after pubimbue() has been called but before pubimbue has returned (i.e., from within the call of imbue()) then it returns the previous value.

30.6.3.2.2 Buffer management and positioning

basic_streambuf* pubsetbuf(char_type* s, streamsize n);

Returns: setbuf(s, n).

pos_type pubseekoff(off_type off, ios_base::seekdir way,
ios_base::openmode which
    = ios_base::in | ios_base::out);

Returns: seekoff(off, way, which).

pos_type pubseekpos(pos_type sp,
    ios_base::openmode which
    = ios_base::in | ios_base::out);

Returns: seekpos(sp, which).

int pubsync();

Returns: sync().

30.6.3.2.3 Get area

streamsize in_avail();

Returns: If a read position is available, returns egptr() - gptr(). Otherwise returns showmanyc() (30.6.3.4.3).

int_type snextc();

Effects: Calls sbumpc().

Returns: If that function returns traits::eof(), returns traits::eof(). Otherwise, returns sgetc().

int_type sbumpc();

Returns: If the input sequence read position is not available, returns uflow(). Otherwise, returns traits::to_int_type(*gptr()) and increments the next pointer for the input sequence.

int_type sgetc();

Returns: If the input sequence read position is not available, returns underflow(). Otherwise, returns traits::to_int_type(*gptr()).

streamsize sgetn(char_type* s, streamsize n);

Returns: xsgetn(s, n).

30.6.3.2.4 Putback

§ 30.6.3.2.4
int_type sputbackc(char_type c);

Returns: If the input sequence putback position is not available, or if traits::eq(c, gptr()[-1]) is false, returns pbackfail(traits::to_int_type(c)). Otherwise, decrements the next pointer for the input sequence and returns traits::to_int_type(*gptr()).

int_type sungetc();

Returns: If the input sequence putback position is not available, returns pbackfail(). Otherwise, decrements the next pointer for the input sequence and returns traits::to_int_type(*gptr()).

30.6.3.2.5 Put area

int_type sputc(char_type c);

Returns: If the output sequence write position is not available, returns overflow(traits::to_int_type(c)). Otherwise, stores c at the next pointer for the output sequence, increments the pointer, and returns traits::to_int_type(c).

streamsize sputn(const char_type* s, streamsize n);

Returns: xsputn(s, n).

30.6.3.3 basic_streambuf protected member functions

30.6.3.3.1 Assignment

basic_streambuf& operator=(const basic_streambuf& rhs);

Effects: Assigns the data members of rhs to *this.

Postconditions:

(2.1) eback() == rhs.eback()
(2.2) gptr() == rhs.gptr()
(2.3) egptr() == rhs.egptr()
(2.4) pbase() == rhs.pbase()
(2.5) pptr() == rhs.pptr()
(2.6) eptr() == rhs.eptr()
(2.7) getloc() == rhs.getloc()

Returns: *this.

void swap(basic_streambuf& rhs);

Effects: Swaps the data members of rhs and *this.

30.6.3.3.2 Get area access

char_type* eback() const;

Returns: The beginning pointer for the input sequence.

char_type* gptr() const;

Returns: The next pointer for the input sequence.

char_type* egptr() const;

Returns: The end pointer for the input sequence.
void gbump(int n);
   \textit{Effects:} Adds \( n \) to the next pointer for the input sequence.

void setg(char_type* gbeg, char_type* gnext, char_type* gend);
   \textit{Postconditions:} \( \text{gbeg} == \text{eback()} \), \( \text{gnext} == \text{gptr()} \), and \( \text{gend} == \text{egptr()} \).

30.6.3.3 \textbf{Put area access} \hfill \textit{[streambuf.put.area]}

char_type* pbase() \textbf{const};
   \textit{Returns:} The beginning pointer for the output sequence.

char_type* pptr() \textbf{const};
   \textit{Returns:} The next pointer for the output sequence.

char_type* epptr() \textbf{const};
   \textit{Returns:} The end pointer for the output sequence.

void pbump(int n);
   \textit{Effects:} Adds \( n \) to the next pointer for the output sequence.

void setp(char_type* pbeg, char_type* pend);
   \textit{Postconditions:} \( \text{pbeg} == \text{pbase()} \), \( \text{pbeg} == \text{pptr()} \), and \( \text{pend} == \text{epptr()} \).

30.6.3.4 \textbf{basic\_streambuf virtual functions} \hfill \textit{[streambuf.virt.virtuals]}

30.6.3.4.1 \textbf{Locales} \hfill \textit{[streambuf.virt.locales]}

void imbue(const locale&);
   \textit{Effects:} Change any translations based on locale.

\textit{Remarks:} Allows the derived class to be informed of changes in locale at the time they occur. Between invocations of this function a class derived from streambuf can safely cache results of calls to locale functions and to members of facets so obtained.

\textit{Default behavior:} Does nothing.

30.6.3.4.2 \textbf{Buffer management and positioning} \hfill \textit{[streambuf.virt.buffer]}

basic\_streambuf* setbuf(char_type* s, streamsize n);
   \textit{Effects:} Influences stream buffering in a way that is defined separately for each class derived from \textbf{basic\_streambuf} in this Clause (30.8.2.4, 30.9.2.4).

\textit{Default behavior:} Does nothing. Returns this.

pos_type seekoff(off_type off, ios_base::seekdir way,
                  ios_base::openmode which
               = ios_base::in | ios_base::out);
   \textit{Effects:} Alters the stream positions within one or more of the controlled sequences in a way that is defined separately for each class derived from \textbf{basic\_streambuf} in this Clause (30.8.2.4, 30.9.2.4).

\textit{Default behavior:} Returns \textit{pos\_type(off\_type(-1))}.

pos_type seekpos(pos_type sp,
                 ios_base::openmode which
               = ios_base::in | ios_base::out);
Effects: Alters the stream positions within one or more of the controlled sequences in a way that is defined separately for each class derived from `basic_streambuf` in this Clause (30.8.2, 30.9.2).

Default behavior: Returns `pos_type(off_type(-1))`.

```cpp
int sync();
```

Effects: Synchronizes the controlled sequences with the arrays. That is, if `pbase()` is non-null the characters between `pbase()` and `pptr()` are written to the controlled sequence. The pointers may then be reset as appropriate.

Returns: -1 on failure. What constitutes failure is determined by each derived class (30.9.2.4).

Default behavior: Returns zero.

### 30.6.3.4.3 Get area

```cpp
streamsize showmanyc();
```

Returns: An estimate of the number of characters available in the sequence, or -1. If it returns a positive value, then successive calls to `underflow()` will not return `traits::eof()` until at least that number of characters have been extracted from the stream. If `showmanyc()` returns -1, then calls to `underflow()` or `uflow()` will fail.

Default behavior: Returns zero.

Remarks: Uses `traits::eof()`.

```cpp
streamsize xsgetn(char_type* s, streamsize n);
```

Effects: Assigns up to `n` characters to successive elements of the array whose first element is designated by `s`. The characters assigned are read from the input sequence as if by repeated calls to `sbumpc()`. Assigning stops when either `n` characters have been assigned or a call to `sbumpc()` would return `traits::eof()`.

Returns: The number of characters assigned.

Remarks: Uses `traits::eof()`.

```cpp
int_type underflow();
```

Remarks: The public members of `basic_streambuf` call this virtual function only if `gptr()` is null or `gptr() >= egptr()`.

Returns: `traits::to_int_type(c)`, where `c` is the first character of the pending sequence, without moving the input sequence position past it. If the pending sequence is null then the function returns `traits::eof()` to indicate failure.

The pending sequence of characters is defined as the concatenation of

1. the empty sequence if `gptr()` is null, otherwise the characters in `[gptr(), egptr())`, followed by
2. some (possibly empty) sequence of characters read from the input sequence.

The result character is the first character of the pending sequence if it is non-empty, otherwise the next character that would be read from the input sequence.

The backup sequence is the empty sequence if `eback()` is null, otherwise the characters in `[eback(), gptr())`.

---

300) The morphemes of `showmanyc` are “es-how-many-see”, not “show-manic”.
301) `underflow` or `uflow` might fail by throwing an exception prematurely. The intention is not only that the calls will not return `eof()` but that they will return “immediately”.
302) Classes derived from `basic_streambuf` can provide more efficient ways to implement `xsgetn()` and `xsputn()` by overriding these definitions from the base class.
Effects: The function sets up the \texttt{gptr()} and \texttt{egptr()} such that if the pending sequence is non-empty, then \texttt{egptr()} is non-null and the characters in \texttt{[gptr(), egptr()]} are the characters in the pending sequence, otherwise either \texttt{gptr()} is null or \texttt{gptr()} \texttt{== egptr(}.

If \texttt{eback()} and \texttt{gptr()} are non-null then the function is not constrained as to their contents, but the “usual backup condition” is that either

(13.1) the backup sequence contains at least \texttt{gptr()} - \texttt{eback()} characters, in which case the characters in \texttt{[eback(), gptr()]} agree with the last \texttt{gptr()} - \texttt{eback()} characters of the backup sequence, or

(13.2) the characters in \texttt{[gptr() - n, gptr()]} agree with the backup sequence (where \texttt{n} is the length of the backup sequence).

Default behavior: Returns \texttt{traits::eof(}.

\texttt{int_type uflow();}

Requires: The constraints are the same as for \texttt{underflow(}, except that the result character shall be transferred from the pending sequence to the backup sequence, and the pending sequence shall not be empty before the transfer.

Default behavior: Calls \texttt{underflow(}. If \texttt{underflow(} returns \texttt{traits::eof(}, returns \texttt{traits::eof(}. Otherwise, returns the value of \texttt{traits::to_int_type(*gptr())} and increment the value of the next pointer for the input sequence.

Returns: \texttt{traits::eof(} to indicate failure.

30.6.3.4.4 Putback \hfill [streambuf.virt.pback]

\texttt{int_type pbackfail(int_type c = traits::eof());}

Remarks: The public functions of \texttt{basic_streambuf} call this virtual function only when \texttt{gptr()} is null, \texttt{gptr()} \texttt{== eback()}, or \texttt{traits::eq(traits::to_char_type(c), gptr()[1]} returns false. Other calls shall also satisfy that constraint.

The \textit{pending sequence} is defined as for \texttt{underflow(}, with the modifications that

(1.1) If \texttt{traits::eq_int_type(c, traits::eof(}) returns \texttt{true}, then the input sequence is backed up one character before the pending sequence is determined.

(1.2) If \texttt{traits::eq_int_type(c, traits::eof(}) returns \texttt{false}, then \texttt{c} is prepended. Whether the input sequence is backed up or modified in any other way is unspecified.

Postconditions: On return, the constraints of \texttt{gptr()}, \texttt{eback()}, and \texttt{pptr()} are the same as for \texttt{underflow(}.

Returns: \texttt{traits::eof(} to indicate failure. Failure may occur because the input sequence could not be backed up, or if for some other reason the pointers could not be set consistent with the constraints. \texttt{pbackfail()} is called only when put back has really failed.

Returns some value other than \texttt{traits::eof(} to indicate success.

Default behavior: Returns \texttt{traits::eof(}.

30.6.3.4.5 Put area \hfill [streambuf.virt.put]

\texttt{streamsize xsputn(const char_type* s, streamsize n);}
traits::eof(). It is unspecified whether the function calls overflow() when pptr() == epptr() becomes true or whether it achieves the same effects by other means.

Returns: The number of characters written.

int_type overflow(int_type c = traits::eof());

Effects: Consumes some initial subsequence of the characters of the pending sequence. The pending sequence is defined as the concatenation of

(3.1) — the empty sequence if pbase() is not null, otherwise the pptr() - pbase() characters beginning at pbase(), followed by

(3.2) — the empty sequence if traits::eq_int_type(c, traits::eof()) returns true, otherwise the sequence consisting of c.

Remarks: The member functions sputc() and sputn() call this function in case that no room can be found in the put buffer enough to accommodate the argument character sequence.

Requires: Every overriding definition of this virtual function shall obey the following constraints:

1. The effect of consuming a character on the associated output sequence is specified

2. Let r be the number of characters in the pending sequence not consumed. If r is nonzero then pbase() and pptr() shall be set so that: pptr() - pbase() == r and the r characters starting at pbase() are the associated output stream. In case r is zero (all characters of the pending sequence have been consumed) then either pbase() is set to nullptr, or pbase() and pptr() are both set to the same non-null value.

3. The function may fail if either appending some character to the associated output stream fails or if it is unable to establish pbase() and pptr() according to the above rules.

Returns: traits::eof() or throws an exception if the function fails. Otherwise, returns some value other than traits::eof() to indicate success.

Default behavior: Returns traits::eof().

30.7 Formatting and manipulators

30.7.1 Header <istream> synopsis

namespace std {
    template <class charT, class traits = char_traits<charT>>
        class basic_istream;

    using istream = basic_istream<char>;
    using wistream = basic_istream<wchar_t>;

    template <class charT, class traits = char_traits<charT>>
        class basic_iostream;

    using iostream = basic_iostream<char>;
    using wiostream = basic_iostream<wchar_t>;

    template <class charT, class traits>
        basic_istream<charT, traits>& ws(basic_istream<charT, traits>& is);

303) That is, for each class derived from an instance of basic_streambuf in this Clause (30.8.2, 30.9.2), a specification of how consuming a character effects the associated output sequence is given. There is no requirement on a program-defined class.

304) Typically, overflow returns c to indicate success, except when traits::eq_int_type(c, traits::eof()) returns true. In which case it returns traits::not_eof(c).
template <class charT, class traits, class T>
    basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>&& is, T&& x);

30.7.2 Header <ostream> synopsis

namespace std {
    template <class charT, class traits = char_traits<charT>>

    T10 put_time(const struct tm* tmb, const charT* fmt);

    template <class charT>
    T11 quoted(const charT* s, charT delim = charT('"'), charT escape = charT('\'));

    template <class charT, class traits, class Allocator>
    T12 quoted(const basic_string<charT, traits, Allocator>& s,
               charT delim = charT('"'), charT escape = charT('\'));

    template <class charT, class traits, class Allocator>
    T13 quoted(basic_string<charT, traits, Allocator>& s,
               charT delim = charT('"'), charT escape = charT('\'));

    template <class charT, class traits>
    T14 quoted(basic_string_view<charT, traits> s,
               charT delim = charT('"'), charT escape = charT('\'));
}

§ 30.7.3
30.7.4 Input streams

The header `<istream>` defines two types and a function signature that control input from a stream buffer along with a function template that extracts from stream rvalues.

30.7.4.1 Class template `basic_istream`

```cpp
namespace std {
    template <class charT, class traits = char_traits<charT>>
    class basic_istream : virtual public basic_ios<charT, traits> {
        public:
            // types (inherited from basic_ios (30.5.5)):
            using char_type = charT;
            using int_type = typename traits::int_type;
            using pos_type = typename traits::pos_type;
            using off_type = typename traits::off_type;
            using traits_type = traits;

            // 30.7.4.1.1, constructor/destructor
            explicit basic_istream(basic_streambuf<charT, traits>* sb);
            virtual ~basic_istream();

            // 30.7.4.2, formatted input
            basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& (*pf)(basic_istream<charT, traits>&));
            basic_istream<charT, traits>& operator>>(basic_ios<charT, traits>& (*pf)(basic_ios<charT, traits>&));
            basic_istream<charT, traits>& operator>>(ios_base& (*pf)(ios_base&));
            basic_istream<charT, traits>& operator>>(bool& n);
            basic_istream<charT, traits>& operator>>(short& n);
            basic_istream<charT, traits>& operator>>(unsigned short& n);
            basic_istream<charT, traits>& operator>>(int& n);
            basic_istream<charT, traits>& operator>>(unsigned int& n);
            basic_istream<charT, traits>& operator>>(long& n);
            basic_istream<charT, traits>& operator>>(unsigned long& n);
            basic_istream<charT, traits>& operator>>(long long& n);
            basic_istream<charT, traits>& operator>>(unsigned long long& n);
            basic_istream<charT, traits>& operator>>(float& f);
            basic_istream<charT, traits>& operator>>(double& f);
            basic_istream<charT, traits>& operator>>(long double& f);

            basic_istream<charT, traits>& operator>>(void*& p);
            basic_istream<charT, traits>& operator>>(basic_streambuf<char_type, traits>* sb);

            // 30.7.4.3, unformatted input
            streamsize gcount() const;
            int_type get();
            basic_istream<charT, traits>& get(char_type& c);
            basic_istream<charT, traits>& get(char_type* s, streamsize n);
            basic_istream<charT, traits>& get(char_type* s, streamsize n, char_type delim);
            basic_istream<charT, traits>& get(basic_streambuf<char_type, traits>* sb);
            basic_istream<charT, traits>& get(basic_streambuf<char_type, traits>* sb, char_type delim);
    }
}
```
The class template `basic_istream` defines a number of member function signatures that assist in reading and interpreting input from sequences controlled by a stream buffer.

Two groups of member function signatures share common properties: the *formatted input functions* (or *extractors*) and the *unformatted input functions*. Both groups of input functions are described as if they obtain (or extract) input characters by calling `rdbuf()->sbumpc()` or `rdbuf()->sgetc()`. They may use other public members of `istream`.

If `rdbuf()->sbumpc()` or `rdbuf()->sgetc()` returns `traits::eof()`, then the input function, except as explicitly noted otherwise, completes its actions and does `setstate(eofbit)`, which may throw `ios_base::failure` (30.5.5.4), before returning.
If one of these called functions throws an exception, then unless explicitly noted otherwise, the input function sets `badbit` in error state. If `badbit` is on in `exceptions()`, the input function rethrows the exception without completing its actions, otherwise it does not throw anything and proceeds as if the called function had returned a failure indication.

### 30.7.4.1.1 basic_istream constructors

```cpp
explicit basic_istream(basic_streambuf<charT, traits>* sb);
```

#### Effects:
Constructs an object of class `basic_istream`, initializing the base class subobject with `basic_ios::init(sb)` (30.5.5.2).

#### Postconditions:
`gcount() == 0`.

```cpp
basic_istream(basic_istream&& rhs);
```

#### Effects:
Move constructs from the rvalue `rhs`. This is accomplished by default constructing the base class, copying the `gcount()` from `rhs`, calling `basic_ios<charT, traits>::move(rhs)` to initialize the base class, and setting the `gcount()` for `rhs` to 0.

```cpp
virtual ~basic_istream();
```

#### Effects:
Destroys an object of class `basic_istream`.

#### Remarks:
Does not perform any operations of `rdbuf()`.

### 30.7.4.1.2 Class basic_istream assign and swap

```cpp
basic_istream& operator=(basic_istream&& rhs);
```

#### Effects:
As if by `swap(rhs)`.

#### Returns:
`*this`.

```cpp
void swap(basic_istream& rhs);
```

#### Effects:
Calls `basic_ios<charT, traits>::swap(rhs)`. Exchanges the values returned by `gcount()` and `rhs.gcount()`.

### 30.7.4.1.3 Class basic_istream::sentry

```cpp
namespace std {
    template <class charT, class traits = char_traits<charT>>
    class basic_istream<charT, traits>::sentry {
        using traits_type = traits;
        bool ok_;         // exposition only
        public:
            explicit sentry(basic_istream<charT, traits>& is, bool noskipws = false);
            ~sentry();
            explicit operator bool() const { return ok_; }
            sentry(const sentry&) = delete;
            sentry& operator=(const sentry&) = delete;
    };
}
```

The class `sentry` defines a class that is responsible for doing exception safe prefix and suffix operations.

```cpp
explicit sentry(basic_istream<charT, traits>& is, bool noskipws = false);
```

#### Effects:
If `is.good()` is `false`, calls `is.setstate(failbit)`. Otherwise, prepares for formatted or unformatted input. First, if `is.tie()` is not a null pointer, the function calls `is.tie()->flush()` to synchronize the output sequence with any associated external C stream. Except that this call
can be suppressed if the put area of `is.tie()` is empty. Further an implementation is allowed to defer the call to `flush` until a call of `is.rdbuf()->underflow()` occurs. If no such call occurs before the `sentry` object is destroyed, the call to `flush` may be eliminated entirely.\footnote{This will be possible only in functions that are part of the library. The semantics of the constructor used in user code is as specified.}

If `noskipws` is zero and `is.flags() & ios_base::skipws` is nonzero, the function extracts and discards each character as long as the next available input character `c` is a whitespace character. If `is.rdbuf()->sbumpc()` or `is.rdbuf()->sgetc()` returns `traits::eof()`, the function calls `setstate(failbit | eofbit)` (which may throw `ios_base::failure`).

**Remarks:** The constructor

```c
explicit sentry(basic_istream<charT, traits>& is, bool noskipws = false)
```
uses the currently imbued locale in `is`, to determine whether the next input character is whitespace or not.

To decide if the character `c` is a whitespace character, the constructor performs as if it executes the following code fragment:

```c
const ctype<charT>& ctype = use_facet<ctype<charT>>(is.getloc());
if (ctype.is(ctype.space, c) != 0)
  // c is a whitespace character.
```

If, after any preparation is completed, `is.good()` is `true`, `ok_` is `true` otherwise, `ok_` is `false`. During preparation, the constructor may call `setstate(failbit)` (which may throw `ios_base::failure`).\footnote{The sentry constructor and destructor can also perform additional implementation-dependent operations.}

~sentry();

**Effects:** None.

```c
explicit operator bool() const;
```
Returns `ok_`.

### 30.7.4.2 Formatted input functions

#### 30.7.4.2.1 Common requirements

Each formatted input function begins execution by constructing an object of class `sentry` with the `noskipws` (second) argument `false`. If the `sentry` object returns `true`, when converted to a value of type `bool`, the function endeavors to obtain the requested input. If an exception is thrown during input then `ios::badbit` is turned on\footnote{This is done without causing an `ios::failure` to be thrown.} in `*this`’s error state. If `(exceptions() & badbit) != 0` then the exception is rethrown. In any case, the formatted input function destroys the `sentry` object. If no exception has been thrown, it returns `*this`.

### 30.7.4.2.2 Arithmetic extractors

```c
operator>>(unsigned short& val);
operator>>(unsigned int& val);
operator>>(long& val);
operator>>(unsigned long& val);
operator>>(long long& val);
operator>>(unsigned long long& val);
operator>>(float& val);
operator>>(double& val);
operator>>(long double& val);
```
operator>>(bool& val);
operator>>(void*& val);

1 As in the case of the inserters, these extractors depend on the locale’s num_get<> (25.4.2.1) object to perform parsing the input stream data. These extractors behave as formatted input functions (as described in 30.7.4.2.1). After a sentry object is constructed, the conversion occurs as if performed by the following code fragment:

```cpp
using numget = num_get<charT, istreambuf_iterator<charT, traits>>;
iostate err = iostate::goodbit;
use_facet<numget>(loc).get(*this, 0, *this, err, val);
setstate(err);
```

In the above fragment, loc stands for the private member of the basic_ios class. [Note: The first argument provides an object of the istreambuf_iterator class which is an iterator pointed to an input stream. It bypasses istreams and uses streambufs directly. — end note] Class locale relies on this type as its interface to istream, so that it does not need to depend directly on istream.

operator>>(short& val);

2 The conversion occurs as if performed by the following code fragment (using the same notation as for the preceding code fragment):

```cpp
using numget = num_get<charT, istreambuf_iterator<charT, traits>>;
iostate err = ios_base::goodbit;
long lval;
use_facet<numget>(loc).get(*this, 0, *this, err, lval);
if (lval < numeric_limits<short>::min()) {
  err |= ios_base::failbit;
  val = numeric_limits<short>::min();
} else if (numeric_limits<short>::max() < lval) {
  err |= ios_base::failbit;
  val = numeric_limits<short>::max();
} else
  val = static_cast<short>(lval);
setstate(err);
```

operator>>(int& val);

3 The conversion occurs as if performed by the following code fragment (using the same notation as for the preceding code fragment):

```cpp
using numget = num_get<charT, istreambuf_iterator<charT, traits>>;
iostate err = ios_base::goodbit;
long lval;
use_facet<numget>(loc).get(*this, 0, *this, err, lval);
if (lval < numeric_limits<int>::min()) {
  err |= ios_base::failbit;
  val = numeric_limits<int>::min();
} else if (numeric_limits<int>::max() < lval) {
  err |= ios_base::failbit;
  val = numeric_limits<int>::max();
} else
  val = static_cast<int>(lval);
setstate(err);
```
operator>>(basic_istream<charT, traits>& (*pf)(basic_istream<charT, traits>&));

Effects: None. This extractor does not behave as a formatted input function (as described in 30.7.4.2.1).

Returns: pf(*this).\textsuperscript{308}

basic_istream<charT, traits>&
operator>>(basic_ios<charT, traits>& (*pf)(basic_ios<charT, traits>&));

Effects: Calls pf(*this). This extractor does not behave as a formatted input function (as described in 30.7.4.2.1).

Returns: *this.

basic_istream<charT, traits>& operator>>(ios_base& (*pf)(ios_base&));

Effects: Calls pf(*this). This extractor does not behave as a formatted input function (as described in 30.7.4.2.1).

Returns: *this.

\begin{verbatim}
template<class charT, class traits> basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& in, charT* s);
template<class traits> basic_istream<char, traits>& operator>>(basic_istream<char, traits>& in, unsigned char* s);
template<class traits> basic_istream<char, traits>& operator>>(basic_istream<char, traits>& in, signed char* s);
\end{verbatim}

Effects: Behaves like a formatted input member (as described in 30.7.4.2.1) of in. After a sentry object is constructed, operator>> extracts characters and stores them into successive locations of an array whose first element is designated by s. If width() is greater than zero, n is width(). Otherwise n is the number of elements of the largest array of char_type that can store a terminating charT(). n is the maximum number of characters stored.

Characters are extracted and stored until any of the following occurs:

- n-1 characters are stored;
- end of file occurs on the input sequence;
- letting ct be use_facet<ctype<charT>>(in.getloc()), ct.is(ct.space, c) is true.

operator>> then stores a null byte (charT()) in the next position, which may be the first position if no characters were extracted. operator>> then calls width(0).

If the function extracted no characters, it calls setstate(failbit), which may throw ios_base::failure (30.5.5.4).

Returns: in.

\begin{verbatim}
template<class charT, class traits> basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& in, charT& c);
template<class traits> basic_istream<char, traits>& operator>>(basic_istream<char, traits>& in, unsigned char& c);
template<class traits> basic_istream<char, traits>& operator>>(basic_istream<char, traits>& in, signed char& c);
\end{verbatim}

Effects: Behaves like a formatted input member (as described in 30.7.4.2.1) of in. After a sentry object is constructed a character is extracted from in, if one is available, and stored in c. Otherwise, the function calls in.setstate(failbit).

\textsuperscript{308} See, for example, the function signature ws(basic_istream&) (30.7.4.4).
\textsuperscript{309} See, for example, the function signature dec(ios_base&) (30.5.6.3).
Returns: \texttt{in}.

\begin{verbatim}
basic_istream<charT, traits>& operator>>(basic_streambuf<charT, traits>* sb);
\end{verbatim}

Effects: Behaves as an unformatted input function (30.7.4.3). If \texttt{sb} is null, calls \texttt{setstate(failbit)}, which may throw \texttt{ios_base::failure} (30.5.5.4). After a sentry object is constructed, extracts characters from \texttt{*this} and inserts them in the output sequence controlled by \texttt{sb}. Characters are extracted and inserted until any of the following occurs:

- end-of-file occurs on the input sequence;
- inserting in the output sequence fails (in which case the character to be inserted is not extracted);
- an exception occurs (in which case the exception is caught).

If the function inserts no characters, it calls \texttt{setstate(failbit)}, which may throw \texttt{ios_base::failure} (30.5.5.4). If it inserted no characters because it caught an exception thrown while extracting characters from \texttt{*this} and \texttt{failbit} is on in \texttt{exceptions()} (30.5.5.4), then the caught exception is rethrown.

Returns: \texttt{*this}.

### 30.7.4.3 Unformatted input functions

Each unformatted input function begins execution by constructing an object of class \texttt{sentry} with the default argument \texttt{noskipws} (second) argument \texttt{true}. If the \texttt{sentry} object returns \texttt{true}, when converted to a value of type \texttt{bool}, the function endeavors to obtain the requested input. Otherwise, if the sentry constructor exits by throwing an exception or if the sentry object returns \texttt{false}, when converted to a value of type \texttt{bool}, the function returns without attempting to obtain any input. In either case the number of extracted characters is set to 0; unformatted input functions taking a character array of nonzero size as an argument shall also store a null character (using \texttt{charT()}) in the first location of the array. If an exception is thrown during input then \texttt{ios::badbit} is turned on in \texttt{*this}'s error state. (Exceptions thrown from \texttt{basic_ios<>::clear()} are not caught or rethrown.) If \texttt{(exceptions()&badbit) \neq 0} then the exception is rethrown. It also counts the number of characters extracted. If no exception has been thrown it ends by storing the count in a member object and returning the value specified. In any event the \texttt{sentry} object is destroyed before leaving the unformatted input function.

\begin{verbatim}
streamsize gcount() const;
\end{verbatim}

Effects: None. This member function does not behave as an unformatted input function (as described above).

Returns: The number of characters extracted by the last unformatted input member function called for the object.

\begin{verbatim}
int_type get();
\end{verbatim}

Effects: Behaves as an unformatted input function (as described above). After constructing a sentry object, extracts a character \texttt{c}, if one is available. Otherwise, the function calls \texttt{setstate(failbit)}, which may throw \texttt{ios_base::failure} (30.5.5.4),

Returns: \texttt{c} if available, otherwise \texttt{traits::eof()}.

\begin{verbatim}
basic_istream<charT, traits>& get(char_type& c);
\end{verbatim}

Effects: Behaves as an unformatted input function (as described above). After constructing a sentry object, extracts a character, if one is available, and assigns it to \texttt{c}.\textsuperscript{311} Otherwise, the function calls \texttt{setstate(failbit)} (which may throw \texttt{ios_base::failure} (30.5.5.4)).

\textsuperscript{310} This is done without causing an \texttt{ios::failure} to be thrown.

\textsuperscript{311} Note that this function is not overloaded on types \texttt{signed char} and \texttt{unsigned char}.
Returns: \*this.

basic_istream<charT, traits>& get(char_type* s, streamsize n, char_type delim);

Effects: Behaves as an unformatted input function (as described above). After constructing a sentry
object, extracts characters and stores them into successive locations of an array whose first element is
designated by \(s\).\(^{312}\) Characters are extracted and stored until any of the following occurs:

\[(8.1)\] \(n\) is less than one or \(n - 1\) characters are stored;
\[(8.2)\] end-of-file occurs on the input sequence (in which case the function calls setstate(eofbit));
\[(8.3)\] traits::eq(c, delim) for the next available input character \(c\) (in which case \(c\) is not extracted).

If the function stores no characters, it calls setstate(failbit) (which may throw ios_base::
failure (30.5.5.4)). In any case, if \(n\) is greater than zero it then stores a null character into the next
successive location of the array.

Returns: \*this.

basic_istream<charT, traits>& get(char_type* s, streamsize n);

Effects: Calls get(s, n, widen(‘\n’)).

Returns: Value returned by the call.

basic_istream<charT, traits>& get(basic_streambuf<char_type, traits>& sb, char_type delim);

Effects: Behaves as an unformatted input function (as described above). After constructing a sentry
object, extracts characters and inserts them in the output sequence controlled by \(sb\). Characters are
extracted and inserted until any of the following occurs:

\[(13.1)\] end-of-file occurs on the input sequence;
\[(13.2)\] inserting in the output sequence fails (in which case the character to be inserted is not extracted);
\[(13.3)\] traits::eq(c, delim) for the next available input character \(c\) (in which case \(c\) is not extracted);
\[(13.4)\] an exception occurs (in which case, the exception is caught but not rethrown).

If the function inserts no characters, it calls setstate(failbit), which may throw ios_base::
failure (30.5.5.4).

Returns: \*this.

basic_istream<charT, traits>& get(basic_streambuf<char_type, traits>& sb);

Effects: Calls get(sb, widen(‘\n’)).

Returns: Value returned by the call.

basic_istream<charT, traits>& getline(char_type* s, streamsize n, char_type delim);

Effects: Behaves as an unformatted input function (as described above). After constructing a sentry
object, extracts characters and stores them into successive locations of an array whose first element is
designated by \(s\).\(^{313}\) Characters are extracted and stored until one of the following occurs:

1. end-of-file occurs on the input sequence (in which case the function calls setstate(eofbit));
2. traits::eq(c, delim) for the next available input character \(c\) (in which case the input character
   is extracted but not stored);\(^{314}\)
3. \(n\) is less than one or \(n - 1\) characters are stored (in which case the function calls setstate("\n", gcount()));

---

\(312\) Note that this function is not overloaded on types signed char and unsigned char.

\(313\) Note that this function is not overloaded on types signed char and unsigned char.

\(314\) Since the final input character is “extracted”, it is counted in the gcount(), even though it is not stored.
failbit)). These conditions are tested in the order shown.\footnote{315} If the function extracts no characters, it calls setstate(failbit) (which may throw ios_base::failure (30.5.5.4)).\footnote{316} In any case, if \( n \) is greater than zero, it then stores a null character (using charT()) into the next successive location of the array.

\textit{Returns:} \*this.

\[\text{Example:} \] this.

\#include <iostream>

```cpp
int main() {
    using namespace std;
    const int line_buffer_size = 100;

    char buffer[line_buffer_size];
    int line_number = 0;
    while (cin.getline(buffer, line_buffer_size, '\n') || cin.gcount()) {
        int count = cin.gcount();
        if (cin.eof())
            cout << "Partial final line"; // cin.fail() is false
        else if (cin.fail()) {
            cout << "Partial long line";
            cin.clear(cin.rdstate() & -ios_base::failbit);
        } else {
            count--;
            cout << "Line " << ++line_number;
        }
        cout << " (" << count << " chars): " << buffer << endl;
    }
    \} // end example

basic_istream<charT, traits>& getline(char_type* s, streamsize n);

\textit{Returns:} getline(s, n, widen('\n'))

basic_istream<charT, traits>& ignore(streamsize n = 1, int_type delim = traits::eof());

\textit{Effects:} Behaves as an unformatted input function (as described above). After constructing a sentry object, extracts characters and discards them. Characters are extracted until any of the following occurs:

\begin{enumerate}
\item n != numeric_limits<streamsize>::max() (21.3.4) and \( n \) characters have been extracted so far
\item end-of-file occurs on the input sequence (in which case the function calls setstate(eofbit), which may throw ios_base::failure (30.5.5.4));
\item traits::eq_int_type(traits::to_int_type(c), delim) for the next available input character c (in which case c is extracted).
\end{enumerate}

\footnote{315} This allows an input line which exactly fills the buffer, without setting failbit. This is different behavior than the historical AT&T implementation.

\footnote{316} This implies an empty input line will not cause failbit to be set.
Remarks: The last condition will never occur if `traits::eq_int_type(delim, traits::eof())`.

Returns: `*this`.

```cpp
int_type peek();
```

Effects: Behaves as an unformatted input function (as described above). After constructing a sentry object, reads but does not extract the current input character.

Returns: `traits::eof()` if `good()` is `false`. Otherwise, returns `rdbuf()->sgetc()`.

```cpp
basic_istream<charT, traits>& read(char_type* s, streamsize n);
```

Effects: Behaves as an unformatted input function (as described above). After constructing a sentry object, if `!good()` calls `setstate(failbit)` which may throw an exception, and return. Otherwise extracts characters and stores them into successive locations of an array whose first element is designated by `s`.\(^\text{317}\) Characters are extracted and stored until either of the following occurs:

\begin{itemize}
\item[(30.1)] `n` characters are stored;
\item[(30.2)] end-of-file occurs on the input sequence (in which case the function calls `setstate(failbit | eofbit)`, which may throw `ios_base::failure` (30.5.5.4)).
\end{itemize}

Returns: `*this`.

```cpp
streamsize readsome(char_type* s, streamsize n);
```

Effects: Behaves as an unformatted input function (as described above). After constructing a sentry object, if `!good()` calls `setstate(failbit)` which may throw an exception, and return. Otherwise extracts characters and stores them into successive locations of an array whose first element is designated by `s`. If `rdbuf()->in_avail() == -1`, calls `setstate(eofbit)` (which may throw `ios_base::failure` (30.5.5.4)), and extracts no characters;

\begin{itemize}
\item[(32.1)] If `rdbuf()->in_avail() == 0`, extracts no characters
\item[(32.2)] If `rdbuf()->in_avail() > 0`, extracts `\min(rdbuf()->in_avail(), n)`.
\end{itemize}

Returns: The number of characters extracted.

```cpp
basic_istream<charT, traits>& putback(char_type c);
```

Effects: Behaves as an unformatted input function (as described above), except that the function first clears `eofbit`. After constructing a sentry object, if `!good()` calls `setstate(failbit)` which may throw an exception, and return. If `rdbuf()` is not null, calls `rdbuf->sputbackc()`. If `rdbuf()` is null, or if `sputbackc()` returns `traits::eof()`, calls `setstate(badbit)` (which may throw `ios_base::failure` (30.5.5.4)). [Note: This function extracts no characters, so the value returned by the next call to `gcount()` is 0. — end note]

Returns: `*this`.

```cpp
basic_istream<charT, traits>& unget();
```

Effects: Behaves as an unformatted input function (as described above), except that the function first clears `eofbit`. After constructing a sentry object, if `!good()` calls `setstate(failbit)` which may throw an exception, and return. If `rdbuf()` is not null, calls `rdbuf()->sungetc()`. If `rdbuf()` is null, or if `sungetc()` returns `traits::eof()`, calls `setstate(badbit)` (which may throw `ios_base::failure` (30.5.5.4)). [Note: This function extracts no characters, so the value returned by the next call to `gcount()` is 0. — end note]

Returns: `*this`.

\(^{317}\) Note that this function is not overloaded on types `signed char` and `unsigned char`.
int sync();

Effects: Behaves as an unformatted input function (as described above), except that it does not count
the number of characters extracted and does not affect the value returned by subsequent calls to
gcount(). After constructing a sentry object, if rdbuf() is a null pointer, returns -1. Otherwise,
calls rdbuf()->pubsync() and, if that function returns -1 calls setstate(badbit) (which may throw
ios_base::failure (30.5.5.4), and returns -1. Otherwise, returns zero.

pos_type tellg();

Effects: Behaves as an unformatted input function (as described above), except that it does not count
the number of characters extracted and does not affect the value returned by subsequent calls to
gcount().

Returns: After constructing a sentry object, if fail() != false, returns pos_type(-1) to indicate
failure. Otherwise, returns rdbuf()->pubseekoff(0, cur, in).

basic_istream<charT, traits>& seekg(pos_type pos);

Effects: Behaves as an unformatted input function (as described above), except that the function
first clears eofbit, it does not count the number of characters extracted, and it does not affect the
value returned by subsequent calls to gcount(). After constructing a sentry object, if fail() != true,
executes rdbuf()->pubseekpos(pos, ios_base::in). In case of failure, the function calls
setstate(failbit) (which may throw ios_base::failure).

Returns: *this.

basic_istream<charT, traits>& seekg(off_type off, ios_base::seekdir dir);

Effects: Behaves as an unformatted input function (as described above), except that the function
first clears eofbit, does not count the number of characters extracted, and does not affect the value
returned by subsequent calls to gcount(). After constructing a sentry object, if fail() != true,
executes rdbuf()->pubseekoff(off, dir, ios_base::in). In case of failure, the function calls
setstate(failbit) (which may throw ios_base::failure).

Returns: *this.

30.7.4.4 Standard basic_istream manipulators [istream.manip]

template <class charT, class traits>
basic_istream<charT, traits>& ws(basic_istream<charT, traits>& is);

Effects: Behaves as an unformatted input function (30.7.4.3), except that it does not count the number
of characters extracted and does not affect the value returned by subsequent calls to is.gcount(). After
constructing a sentry object extracts characters as long as the next available character c is whitespace
or until there are no more characters in the sequence. Whitespace characters are distinguished with the
same criterion as used by sentry::sentry (30.7.4.1.3). If ws stops extracting characters because there
are no more available it sets eofbit, but not failbit.

Returns: is.

30.7.4.5 Rvalue stream extraction [istream.rvalue]

template <class charT, class traits, class T>
basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>&& is, T&& x);

Effects: Equivalent to:

is >> std::forward<T>(x);
return is;
Remarks: This function shall not participate in overload resolution unless the expression is >>
std::forward<T>(x) is well-formed.

30.7.4.6 Class template basic_iostream

namespace std {

    template <class charT, class traits = char_traits<charT>>
    class basic_iostream
    : public basic_istream<charT, traits>,
    public basic_ostream<charT, traits> {
    
    public:
        using char_type = charT;
        using int_type = typename traits::int_type;
        using pos_type = typename traits::pos_type;
        using off_type = typename traits::off_type;
        using traits_type = traits;

        // 30.7.4.6.1, constructor
        explicit basic_iostream(basic_streambuf<charT, traits>* sb);

        // 30.7.4.6.2, destructor
        virtual ~basic_iostream();

    protected:
        // 30.7.4.6.1, constructor
        basic_iostream(const basic_iostream& rhs) = delete;
        basic_iostream(basic_iostream&& rhs);

        // 30.7.4.6.3, assign and swap
        basic_iostream& operator=(const basic_iostream& rhs) = delete;
        basic_iostream& operator=(basic_iostream&& rhs);
        void swap(basic_iostream& rhs);
    };
}

1 The class template basic_iostream inherits a number of functions that allow reading input and writing
output to sequences controlled by a stream buffer.

30.7.4.6.1 basic_iostream constructors

explicit basic_iostream(basic_streambuf<charT, traits>* sb);

1 Effects: Constructs an object of class basic_iostream, initializing the base class subobjects with
basic_istream<charT, traits>(sb) (30.7.4.1) and basic_ostream<charT, traits>(sb) (30.7.5.1).

2 Postconditions: rdbuf() == sb and gcount() == 0.

basic_iostream(basic_iostream&& rhs);

1 Effects: Move constructs from the rvalue rhs by constructing the basic_istream base class with
move(rhs).

30.7.4.6.2 basic_iostream destructor

virtual ~basic_iostream();

1 Effects: Destroys an object of class basic_iostream.

2 Remarks: Does not perform any operations on rdbuf().
30.7.4.6.3 basic_iostream assign and swap

basic_iostream& operator=(basic_iostream& rhs);

Effects: As if by swap(rhs).

void swap(basic_iostream& rhs);

Effects: Calls basic_istream<charT, traits>::swap(rhs).

30.7.5 Output streams

The header <ostream> defines a type and several function signatures that control output to a stream buffer along with a function template that inserts into stream rvalues.

30.7.5.1 Class template basic_ostream

namespace std {

template <class charT, class traits = char_traits<charT>>
class basic_ostream : virtual public basic_ios<charT, traits> {

public:
  // types (inherited from basic_ios (30.5.5)):
  using char_type = charT;
  using int_type = typename traits::int_type;
  using pos_type = typename traits::pos_type;
  using off_type = typename traits::off_type;
  using traits_type = traits;

  // 30.7.5.1.1, constructor/destructor
  explicit basic_ostream(basic_streambuf<char_type, traits>* sb);
  virtual ~basic_ostream();

  // 30.7.5.1.3, prefix/suffix
  class sentry;

  // 30.7.5.2, formatted output
  basic_ostream<charT, traits>&
    operator<<(basic_ostream<charT, traits>& (*pf)(basic_ostream<charT, traits>&&));
  basic_ostream<charT, traits>&
    operator<<(basic_ios<charT, traits>& (*pf)(basic_ios<charT, traits>&&));
  basic_ostream<charT, traits>&
    operator<<(ios_base& (*pf)(ios_base&));

  basic_ostream<charT, traits>&
    operator<<(bool n);
  basic_ostream<charT, traits>&
    operator<<(short n);
  basic_ostream<charT, traits>&
    operator<<(unsigned short n);
  basic_ostream<charT, traits>&
    operator<<(int n);
  basic_ostream<charT, traits>&
    operator<<(unsigned int n);
  basic_ostream<charT, traits>&
    operator<<(long n);
  basic_ostream<charT, traits>&
    operator<<(unsigned long n);
  basic_ostream<charT, traits>&
    operator<<(long long n);
  basic_ostream<charT, traits>&
    operator<<(float f);
  basic_ostream<charT, traits>&
    operator<<(double f);
  basic_ostream<charT, traits>&
    operator<<(const void* p);
  basic_ostream<charT, traits>&
    operator<<(nullptr_t);

§ 30.7.5.1
basic_ostream<char, traits>& operator<<(basic_streambuf<char_type, traits>* sb);

// 30.7.5.3, unformatted output
basic_ostream<charT, traits>& put(char_type c);
basic_ostream<charT, traits>& write(const char_type* s, streamsize n);
basic_ostream<charT, traits>& flush();

// 30.7.5.1.4, seeks
pos_type tellp();
basic_ostream<charT, traits>& seekp(pos_type);
basic_ostream<charT, traits>& seekp(off_type, ios_base::seekdir);

protected:
    // 30.7.5.1.1, copy/move constructor
    basic_ostream(const basic_ostream& rhs) = delete;
basic_ostream(basic_ostream&& rhs);

    // 30.7.5.1.2, assign and swap
    basic_ostream& operator=(const basic_ostream& rhs) = delete;
basic_ostream& operator=(basic_ostream&& rhs);
    void swap(basic_ostream& rhs);
};

// 30.7.5.2.4, character inserters
template<class charT, class traits>
    basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>&, charT);
template<class charT, class traits>
    basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>&, char);
template<class traits>
    basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>&, char);
template<class traits>
    basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>&, signed char);
template<class traits>
    basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>&, unsigned char);
template<class charT, class traits>
    basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>&, const charT*);
template<class charT, class traits>
    basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>&, const char*);
template<class traits>
    basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>&, const char*);
template<class traits>
    basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>&, const signed char*);
template<class traits>
    basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>&, const unsigned char*);

1 The class template basic_ostream defines a number of member function signatures that assist in formatting and writing output to output sequences controlled by a stream buffer.

2 Two groups of member function signatures share common properties: the formatted output functions (or inserters) and the unformatted output functions. Both groups of output functions generate (or insert) output characters by actions equivalent to calling rdbuf() -> sputc(int_type). They may use other public members
of basic_ostream except that they shall not invoke any virtual members of rdbuf() except overflow(), xsputn(), and sync().

3 If one of these called functions throws an exception, then unless explicitly noted otherwise the output function sets badbit in error state. If badbit is on in exceptions(), the output function rethrows the exception without completing its actions, otherwise it does not throw anything and treat as an error.

30.7.5.1.1 basic_ostream constructors

[ostream.cons]

explicit basic_ostream(basic_streambuf<charT, traits>* sb);

1 Effects: Constructs an object of class basic_ostream, initializing the base class subobject with basic_ostream<charT, traits>::init(sb) (30.5.5.2).

2 Postconditions: rdbuf() == sb.

basic_ostream(basic_ostream&& rhs);

3 Effects: Move constructs from the rvalue rhs. This is accomplished by default constructing the base class and calling basic_ostream<charT, traits>::move(rhs) to initialize the base class.

virtual ~basic_ostream();

4 Effects: Destroys an object of class basic_ostream.

5 Remarks: Does not perform any operations on rdbuf().

30.7.5.1.2 Class basic_ostream assign and swap

[ostream.assign]

basic_ostream& operator=(basic_ostream&& rhs);

1 Effects: As if by swap(rhs).

2 Returns: *this.

void swap(basic_ostream& rhs);

3 Effects: Calls basic_ostream::swap(rhs).

30.7.5.1.3 Class basic_ostream::sentry

[ostream::sentry]

namespace std {

template <class charT, class traits = char_traits<charT>>
class basic_ostream<charT, traits>::sentry {

  bool ok_; // exposition only

  public:

    explicit sentry(basic_ostream<charT, traits>& os);
    ~sentry();
    explicit operator bool() const { return ok_; }

    sentry(const sentry&) = delete;
    sentry& operator=(const sentry&) = delete;

};

1 The class sentry defines a class that is responsible for doing exception safe prefix and suffix operations.

explicit sentry(basic_ostream<charT, traits>& os);

2 If os.good() is nonzero, prepares for formatted or unformatted output. If os.tie() is not a null pointer, calls os.tie()->flush().318

318) The call os.tie()->flush() does not necessarily occur if the function can determine that no synchronization is necessary.
If, after any preparation is completed, `os.good()` is true, `ok_ == true` otherwise, `ok_ == false`.

During preparation, the constructor may call `setstate(failbit)` (which may throw `ios_base::failure`)\(^*\)

```cpp
~sentry();
```

If `(os.flags() & ios_base::unitbuf) && !uncaught_exceptions() && os.good()` is true, calls `os.rdbuf()->pubsync()`. If that function returns -1, sets `badbit` in `os.rdstate()` without propagating an exception.

```cpp
explicit operator bool() const;
```

**Effects:** Returns `ok_`.

### 30.7.5.1.4 basic_ostream seek members

Each seek member function begins execution by constructing an object of class `sentry`. It returns by destroying the `sentry` object.

```cpp
pos_type tellp();
```

**Returns:** If `fail() != false`, returns `pos_type(-1)` to indicate failure. Otherwise, returns `rdbuf()->pubseekoff(0, cur, out)`.

```cpp
basic_ostream<charT, traits>& seekp(pos_type pos);
```

**Effects:** If `fail() != true`, executes `rdbuf()->pubseekpos(pos, ios_base::out)`. In case of failure, the function calls `setstate(failbit)` (which may throw `ios_base::failure`).

**Returns:** `*this`.

```cpp
basic_ostream<charT, traits>& seekp(off_type off, ios_base::seekdir dir);
```

**Effects:** If `fail() != true`, executes `rdbuf()->pubseekoff(off, dir, ios_base::out)`. In case of failure, the function calls `setstate(failbit)` (which may throw `ios_base::failure`).

**Returns:** `*this`.

### 30.7.5.2 Formatted output functions

Each formatted output function begins execution by constructing an object of class `sentry`. If this object returns `true` when converted to a value of type `bool`, the function endeavors to generate the requested output. If the generation fails, then the formatted output function does `setstate(ios_base::failbit)`, which might throw an exception. If an exception is thrown during output, then `ios::badbit` is turned on\(^*\) in `*this`’s error state. If `(exceptions()&badbit) != 0` then the exception is rethrown. Whether or not an exception is thrown, the `sentry` object is destroyed before leaving the formatted output function. If no exception is thrown, the result of the formatted output function is `*this`.

The descriptions of the individual formatted output functions describe how they perform output and do not mention the `sentry` object.

If a formatted output function of a stream `os` determines padding, it does so as follows. Given a `charT` character sequence `seq` where `charT` is the character type of the stream, if the length of `seq` is less than `os.width()`, then enough copies of `os.fill()` are added to this sequence as necessary to pad to a width of `os.width()` characters. If `(os.flags() & ios_base::adjustfield) == ios_base::left` is `true`, the fill characters are placed after the character sequence; otherwise, they are placed before the character sequence.

\(^*\) The `sentry` constructor and destructor can also perform additional implementation-dependent operations.

\(^*\) without causing an `ios::failure` to be thrown.
30.7.5.2.2 Arithmetic inserters

operator<<(bool val);
operator<<(short val);
operator<<(unsigned short val);
operator<<(int val);
operator<<(unsigned int val);
operator<<(long val);
operator<<(unsigned long val);
operator<<(long long val);
operator<<(unsigned long long val);
operator<<(float val);
operator<<(double val);
operator<<(long double val);
operator<<(const void* val);

Effects: The classes num_get<> and num_put<> handle locale-dependent numeric formatting and parsing. These inserter functions use the imbued locale value to perform numeric formatting. When val is of type bool, long, unsigned long, long long, unsigned long long, double, long double, or const void*, the formatting conversion occurs as if it performed the following code fragment:

    bool failed = use_facet<
        num_put<charT, ostreambuf_iterator<charT, traits>>
    >(getloc()).put(*this, *this, fill(), val).failed();

When val is of type short the formatting conversion occurs as if it performed the following code fragment:

    ios_base::fmtflags baseflags = ios_base::flags() & ios_base::basefield;
    bool failed = use_facet<
        num_put<charT, ostreambuf_iterator<charT, traits>>
    >(getloc()).put(*this, *this, fill(),
        baseflags == ios_base::oct || baseflags == ios_base::hex
    ? static_cast<long>(static_cast<unsigned short>(val))
    : static_cast<long>(val)).failed();

When val is of type int the formatting conversion occurs as if it performed the following code fragment:

    ios_base::fmtflags baseflags = ios_base::flags() & ios_base::basefield;
    bool failed = use_facet<
        num_put<charT, ostreambuf_iterator<charT, traits>>
    >(getloc()).put(*this, *this, fill(),
        baseflags == ios_base::oct || baseflags == ios_base::hex
    ? static_cast<long>(static_cast<unsigned int>(val))
    : static_cast<long>(val)).failed();

When val is of type unsigned short or unsigned int the formatting conversion occurs as if it performed the following code fragment:

    bool failed = use_facet<
        num_put<charT, ostreambuf_iterator<charT, traits>>
    >(getloc()).put(*this, *this, fill(),
        static_cast<unsigned long>(val)).failed();

When val is of type float the formatting conversion occurs as if it performed the following code fragment:

    bool failed = use_facet<
        num_put<charT, ostreambuf_iterator<charT, traits>>
    >
The first argument provides an object of the `ostreambuf_iterator<>` class which is an iterator for class `basic_ostream<>`. It bypasses `ostreams` and uses `streambufs` directly. Class `locale` relies on these types as its interface to `iostreams`, since for flexibility it has been abstracted away from direct dependence on `ostream`. The second parameter is a reference to the base class subobject of type `ios_base`. It provides formatting specifications such as field width, and a `locale` from which to obtain other facets. If `failed` is `true` then does `setstate(badbit)`, which may throw an exception, and returns.

Returns: `*this`.

### 30.7.5.2.3 `basic_ostream::operator<<` [ostream.inserters]

`basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& (*pf)(basic_ostream<charT, traits>&&));`

Effects: None. Does not behave as a formatted output function (as described in 30.7.5.2.1).

Returns: `pf(*this)`.

`basic_ostream<charT, traits>&
operator<<(basic_ios<charT, traits>& (*pf)(basic_ios<charT, traits>&&));`

Effects: Calls `pf(*this)`. This inserter does not behave as a formatted output function (as described in 30.7.5.2.1).

Returns: `*this`.

`basic_ostream<charT, traits>&
operator<<(ios_base& (*pf)(ios_base&));`

Effects: Calls `pf(*this)`. This inserter does not behave as a formatted output function (as described in 30.7.5.2.1).

Returns: `*this`.

`basic_ostream<charT, traits>&
operator<<(basic_streambuf<charT, traits>* sb);`

Effects: Behaves as an unformatted output function (30.7.5.3). After the sentry object is constructed, if `sb` is null calls `setstate(badbit)` (which may throw `ios_base::failure`). Gets characters from `sb` and inserts them in `*this`. Characters are read from `sb` and inserted until any of the following occurs:

(8.1) end-of-file occurs on the input sequence;
(8.2) inserting in the output sequence fails (in which case the character to be inserted is not extracted);
(8.3) an exception occurs while getting a character from `sb`.

If the function inserts no characters, it calls `setstate(failbit)` (which may throw `ios_base::failure` (30.5.5.4)). If an exception was thrown while extracting a character, the function sets `failbit` in error state, and if `failbit` is on in `exceptions()` the caught exception is rethrown.

Returns: `*this`.

`basic_ostream<charT, traits>&
operator<<(nullptr_t);`

Effects: Equivalent to:

```
return *this << s;
```

321) See, for example, the function signature `endl(basic_ostream&)` (30.7.5.4).
322) See, for example, the function signature `dec(ios_base&)` (30.5.6.3).

§ 30.7.5.2.3
where \( s \) is an implementation-defined NTCTS (20.3.16).

### 30.7.5.2.4 Character inserter function templates

[ostream.inserters.character]

```cpp
template<class charT, class traits>
    basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& out, charT c);

template<class charT, class traits>
    basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& out, char c);
```

// specialization

```cpp
template<class traits>
    basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>& out, char c);
```

<table>
<thead>
<tr>
<th>signed and unsigned</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
</tr>
</tbody>
</table>

```cpp
template<class traits>
    basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>& out, signed char c);
```

```cpp
template<class traits>
    basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>& out, unsigned char c);
```

1. **Effects:** Behaves as a formatted output function (30.7.5.2.1) of `out`. Constructs a character sequence `seq`. If `c` has type `char` and the character type of the stream is not `char`, then `seq` consists of `out.widen(c)`; otherwise `seq` consists of `c`. Determines padding for `seq` as described in 30.7.5.2.1. Inserts `seq` into `out`. Calls `os.width(0)`.

2. **Returns:** `out`.

```cpp
template<class charT, class traits>
    basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& out, const charT* s);
```

```cpp
template<class charT, class traits>
    basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& out, const char* s);
```

```cpp
template<class traits>
    basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>& out, const char* s);
```

```cpp
template<class traits>
    basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>& out, const signed char* s);
```

```cpp
template<class traits>
    basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>& out, const unsigned char* s);
```

3. **Requires:** `s` shall not be a null pointer.

4. **Effects:** Behaves like a formatted inserter (as described in 30.7.5.2.1) of `out`. Creates a character sequence `seq` of `n` characters starting at `s`, each widened using `out.widen()` (30.5.5.3), where `n` is the number that would be computed as if by:

   1. `traits::length(s)` for the overload where the first argument is of type `basic_ostream<charT, traits>&` and the second is of type `const charT*`.
   2. Also for the overload where the first argument is of type `basic_ostream<const char, traits>&` and the second is of type `const char*`.
   3. `traits::length(reinterpret_cast<const char*>(s))` for the other two overloads.

5. **Returns:** `out`.

### 30.7.5.3 Unformatted output functions

[ostream.unformatted]

1. Each unformatted output function begins execution by constructing an object of class `sentry`. If this object returns `true`, while converting to a value of type `bool`, the function endeavors to generate the requested
output. If an exception is thrown during output, then `ios::badbit` is turned on\(^{323}\) in *this’s error state. If `(exceptions() & badbit) != 0` then the exception is rethrown. In any case, the unformatted output function ends by destroying the sentry object, then, if no exception was thrown, returning the value specified for the unformatted output function.

```cpp
basic_ostream<charT, traits>& put(char_type c);
```

*Effects:* Behaves as an unformatted output function (as described above). After constructing a sentry object, inserts the character `c`, if possible.\(^{324}\) Otherwise, calls `setstate(badbit)` (which may throw `ios_base::failure` (30.5.5.4)).

*Returns:* *this.

```cpp
basic_ostream& write(const char_type* s, streamsize n);
```

*Effects:* Behaves as an unformatted output function (as described above). After constructing a sentry object, obtains characters to insert from successive locations of an array whose first element is designated by `s`.\(^{325}\) Characters are inserted until either of the following occurs:

1. `n` characters are inserted;
2. inserting in the output sequence fails (in which case the function calls `setstate(badbit)`, which may throw `ios_base::failure` (30.5.5.4)).

*Returns:* *this.

```cpp
basic_ostream& flush();
```

*Effects:* Behaves as an unformatted output function (as described above). If `rdbuf()` is not a null pointer, constructs a sentry object. If this object returns `true` when converted to a value of type `bool` the function calls `rdbuf()->pubsync()`. If that function returns `-1` calls `setstate(badbit)` (which may throw `ios_base::failure` (30.5.5.4)). Otherwise, if the sentry object returns `false`, does nothing.

*Returns:* *this.

### 30.7.5.4 Standard basic_ostream manipulators

```cpp
template <class charT, class traits>
    basic_ostream<charT, traits>& endl(basic_ostream<charT, traits>& os);
```

*Effects:* Calls `os.put(os.widen(’\n’))`, then `os.flush()`.

*Returns:* `os`.

```cpp
template <class charT, class traits>
    basic_ostream<charT, traits>& ends(basic_ostream<charT, traits>& os);
```

*Effects:* Inserts a null character into the output sequence: calls `os.put(charT())`.

*Returns:* `os`.

```cpp
template <class charT, class traits>
    basic_ostream<charT, traits>& flush(basic_ostream<charT, traits>& os);
```

*Effects:* Calls `os.flush()`.

*Returns:* `os`.

### 30.7.5.5 Rvalue stream insertion

\(^{323}\) without causing an `ios::failure` to be thrown.

\(^{324}\) Note that this function is not overloaded on types `signed char` and `unsigned char`.

\(^{325}\) Note that this function is not overloaded on types `signed char` and `unsigned char`.

§ 30.7.5.5
template <class charT, class traits, class T>
    basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>&& os, const T& x);  

1 Effects: As if by: os << x;  
2 Returns: os.  
3 Remarks: This function shall not participate in overload resolution unless the expression os << x is well-formed.

30.7.6 Standard manipulators

The header `<iomanip>` defines several functions that support extractors and inserters that alter information maintained by class `ios_base` and its derived classes.

```cpp
unspecified resetiosflags(ios_base::fmtflags mask);  

2 Returns: An object of unspecified type such that if out is an object of type `basic_ostream<charT, traits>`, then the expression out << resetiosflags(mask) behaves as if it called f(out, mask), or if in is an object of type `basic_istream<charT, traits>` then the expression in >> resetiosflags(mask) behaves as if it called f(in, mask), where the function f is defined as:

```cpp
void f(ios_base& str, ios_base::fmtflags mask) {
    // reset specified flags
    str.setf(ios_base::fmtflags(0), mask);
}
```

The expression out << resetiosflags(mask) shall have type `basic_ostream<charT, traits>&` and value out. The expression in >> resetiosflags(mask) shall have type `basic_istream<charT, traits>&` and value in.

```cpp
unspecified setiosflags(ios_base::fmtflags mask);  

3 Returns: An object of unspecified type such that if out is an object of type `basic_ostream<charT, traits>`, then the expression out << setiosflags(mask) behaves as if it called f(out, mask), or if in is an object of type `basic_istream<charT, traits>` then the expression in >> setiosflags(mask) behaves as if it called f(in, mask), where the function f is defined as:

```cpp
void f(ios_base& str, ios_base::fmtflags mask) {
    // set specified flags
    str.setf(mask);
}
```

The expression out << setiosflags(mask) shall have type `basic_ostream<charT, traits>&` and value out. The expression in >> setiosflags(mask) shall have type `basic_istream<charT, traits>&` and value in.

```cpp
unspecified setbase(int base);  

4 Returns: An object of unspecified type such that if out is an object of type `basic_ostream<charT, traits>`, then the expression out << setbase(base) behaves as if it called f(out, base), or if in is an object of type `basic_istream<charT, traits>` then the expression in >> setbase(base) behaves as if it called f(in, base), where the function f is defined as:

```cpp
void f(ios_base& str, int base) {
    // set basefield
    str.setf(base == 8 ? ios_base::oct :
```

326) The expression `cin >> resetiosflags(ios_base::skipws)` clears `ios_base::skipws` in the format flags stored in the `basic_istream<charT, traits>` object `cin` (the same as `cin >> noskipws`), and the expression `cout << resetiosflags(ios_base::showbase)` clears `ios_base::showbase` in the format flags stored in the `basic_ostream<charT, traits>` object `cout` (the same as `cout << noshowbase`).

§ 30.7.6
The expression `out << setbase(base)` shall have type `basic_ostream<charT, traits>&` and value `out`. The expression `in >> setbase(base)` shall have type `basic_istream<charT, traits>&` and value `in`.

**setfill(char_type c);**

*Returns:* An object of unspecified type such that if `out` is an object of type `basic_ostream<charT, traits>&` and `c` has type `charT` then the expression `out << setfill(c)` behaves as if it called `f(out, c)`, where the function `f` is defined as:

```cpp
template<class charT, class traits>
void f(basic_ostream<charT, traits>& str, charT c) {
    // set fill character
    str.fill(c);
}
```

The expression `out << setfill(c)` shall have type `basic_ostream<charT, traits>&` and value `out`.

**setprecision(int n);**

*Returns:* An object of unspecified type such that if `out` is an object of type `basic_ostream<charT, traits>&` then the expression `out << setprecision(n)` behaves as if it called `f(out, n)`, or if `in` is an object of type `basic_istream<charT, traits>` then the expression `in >> setprecision(n)` behaves as if it called `f(in, n)`, where the function `f` is defined as:

```cpp
void f(ios_base& str, int n) {
    // set precision
    str.precision(n);
}
```

The expression `out << setprecision(n)` shall have type `basic_ostream<charT, traits>&` and value `out`. The expression `in >> setprecision(n)` shall have type `basic_istream<charT, traits>&` and value `in`.

**setw(int n);**

*Returns:* An object of unspecified type such that if `out` is an instance of `basic_ostream<charT, traits>` then the expression `out << setw(n)` behaves as if it called `f(out, n)`, or if `in` is an object of type `basic_istream<charT, traits>` then the expression `in >> setw(n)` behaves as if it called `f(in, n)`, where the function `f` is defined as:

```cpp
void f(ios_base& str, int n) {
    // set width
    str.width(n);
}
```

The expression `out << setw(n)` shall have type `basic_ostream<charT, traits>&` and value `out`. The expression `in >> setw(n)` shall have type `basic_istream<charT, traits>&` and value `in`.

### 30.7.7 Extended manipulators

The header `<iomanip>` defines several functions that support extractors and inserters that allow for the parsing and formatting of sequences and values for money and time.

```cpp
template <class moneyT> unspecified get_money(moneyT& mon, bool intl = false);
```
2. Requires: The type `moneyT` shall be either `long double` or a specialization of the `basic_string` template (Clause 24).

3. Effects: The expression `in >> get_money(mon, intl)` described below behaves as a formatted input function (30.7.4.2.1).

4. Returns: An object of unspecified type such that if `in` is an object of type `basic_istream<charT, traits>` then the expression `in >> get_money(mon, intl)` behaves as if it called `f(in, mon, intl)`, where the function `f` is defined as:

```cpp
template <class charT, class traits, class moneyT>
void f(basic_istream<charT, traits>& str, moneyT& mon, bool intl) {
    using Iter = istreambuf_iterator<charT, traits>;
    using MoneyGet = money_get<charT, Iter>;
    ios_base::iostate err = ios_base::goodbit;
    const MoneyGet& mg = use_facet<MoneyGet>(str.getloc());
    mg.get(Iter(str.rdbuf()), Iter(), intl, str, err, mon);
    if (ios_base::goodbit != err)
        str.setstate(err);
}
```

The expression `in >> get_money(mon, intl)` shall have type `basic_istream<charT, traits>&` and value `in`.

5. Requires: The type `moneyT` shall be either `long double` or a specialization of the `basic_string` template (Clause 24).

6. Returns: An object of unspecified type such that if `out` is an object of type `basic_ostream<charT, traits>` then the expression `out << put_money(mon, intl)` behaves as a formatted output function (30.7.5.2.1) that calls `f(out, mon, intl)`, where the function `f` is defined as:

```cpp
template <class charT, class traits, class moneyT>
void f(basic_ostream<charT, traits>& str, const moneyT& mon, bool intl) {
    using Iter = ostreambuf_iterator<charT, traits>;
    using MoneyPut = money_put<charT, Iter>;
    const MoneyPut& mp = use_facet<MoneyPut>(str.getloc());
    const Iter end = mp.put(Iter(str.rdbuf()), intl, str, str.fill(), mon);
    if (end.failed())
        str.setstate(ios::badbit);
}
```

The expression `out << put_money(mon, intl)` shall have type `basic_ostream<charT, traits>&` and value `out`.

7. Requires: The argument `tmb` shall be a valid pointer to an object of type `struct tm`. The argument `fmt` shall be a valid pointer to an array of objects of type `charT` with `char_traits<charT>::length(fmt)` elements.

8. Returns: An object of unspecified type such that if `in` is an object of type `basic_istream<charT, traits>` then the expression `in >> get_time(tmb, fmt)` behaves as if it called `f(in, tmb, fmt)`, where the function `f` is defined as:

§ 30.7.7
template <class charT, class traits>
void f(basic_ios<charT, traits>& str, struct tm* tmb, const charT* fmt) {
    using Iter = istreambuf_iterator<charT, traits>;
    using TimeGet = time_get<charT, Iter>;

    ios_base::iostate err = ios_base::goodbit;
    const TimeGet& tg = use_facet<TimeGet>(str.getloc());

    tg.get(Iter(str.rdbuf()), Iter(), str, err, tmb,
    fmt, fmt + traits::length(fmt));

    if (err != ios_base::goodbit)
        str.setstate(err);
}

The expression in >> get_time(tmb, fmt) shall have type basic_istream<charT, traits>& and value in.

template <class charT> unspecified put_time(const struct tm* tmb, const charT* fmt);

Requires: The argument tmb shall be a valid pointer to an object of type struct tm, and the argument fmt shall be a valid pointer to an array of objects of type charT with char_traits<charT>::length(fmt) elements.

Returns: An object of unspecified type such that if out is an object of type basic_ostream<charT, traits> then the expression out << put_time(tmb, fmt) behaves as if it called f(out, tmb, fmt), where the function f is defined as:

    template <class charT, class traits>
    void f(basic_ios<charT, traits>& str, const struct tm* tmb, const charT* fmt) {
        using Iter = ostreambuf_iterator<charT, traits>;
        using TimePut = time_put<charT, Iter>;

        const TimePut& tp = use_facet<TimePut>(str.getloc());
        const Iter end = tp.put(Iter(str.rdbuf()), str, str.fill(), tmb,
        fmt, fmt + traits::length(fmt));

        if (end.failed())
            str.setstate(ios_base::badbit);
    }

The expression out << put_time(tmb, fmt) shall have type basic_ostream<charT, traits>& and value out.

### 30.7.8 Quoted manipulators

[quoted.manip]

[Note: Quoted manipulators provide string insertion and extraction of quoted strings (for example, XML and CSV formats). Quoted manipulators are useful in ensuring that the content of a string with embedded spaces remains unchanged if inserted and then extracted via stream I/O. — end note]

```
template <class charT>
unspecced quoted(const charT* s, charT delim = charT('"'), charT escape = charT(\"));
template <class charT, class traits, class Allocator>
unspecced quoted(const basic_string<charT, traits, Allocator>& s,
charT delim = charT('"'), charT escape = charT(\"));
template <class charT, class traits>
unspecced quoted(basic_string_view<charT, traits> s,
charT delim = charT('"'), charT escape = charT(\"));
```

§ 30.7.8
Returns: An object of unspecified type such that if out is an instance of basic_ostream with member type char_type the same as charT and with member type traits_type, which in the second and third forms is the same as traits, then the expression out << quoted(s, delim, escape) behaves as a formatted output function (30.7.5.2.1) of out. This forms a character sequence seq, initially consisting of the following elements:

(2.1) — delim.
(2.2) — Each character in s. If the character to be output is equal to escape or delim, as determined by traits_type::eq, first output escape.
(2.3) — delim.

Let x be the number of elements initially in seq. Then padding is determined for seq as described in 30.7.5.2.1, seq is inserted as if by calling out.rdbuf()->sputn(seq, n), where n is the larger of out.width() and x, and out.width(0) is called. The expression out << quoted(s, delim, escape) shall have type basic_ostream<charT, traits>& and value out.

template <class charT, class traits, class Allocator>
unspecified quoted(basic_string<charT, traits, Allocator>& s,
   charT delim = charT('"'), charT escape = charT('\\'));

Returns: An object of unspecified type such that:

(3.1) — If in is an instance of basic_istream with member types char_type and traits_type the same as charT and traits, respectively, then the expression in >> quoted(s, delim, escape) behaves as if it extracts the following characters from in using operator>>(basic_istream<charT, traits>&, charT&), which may throw ios_base::failure (30.5.3.1.1):
(3.1.1) — If the first character extracted is equal to delim, as determined by traits_type::eq, then:
(3.1.1.1) — Turn off the skipws flag.
(3.1.1.2) — s.clear();
(3.1.1.3) — Until an unescaped delim character is reached or !in, extract characters from in and append them to s, except that if an escape is reached, ignore it and append the next character to s.
(3.1.1.4) — Discard the final delim character.
(3.1.1.5) — Restore the skipws flag to its original value.
(3.1.2) — Otherwise, in >> s.
(3.2) — If out is an instance of basic_ostream with member types char_type and traits_type the same as charT and traits, respectively, then the expression out << quoted(s, delim, escape) shall have type basic_ostream<charT, traits>& overload of the quoted function.

The expression in >> quoted(s, delim, escape) shall have type basic_istream<charT, traits>& and value in. The expression out << quoted(s, delim, escape) shall have type basic_ostream<charT, traits>& and value out.

30.8 String-based streams
30.8.1 Header <sstream> synopsis
namespace std {
   template <class charT, class traits = char_traits<charT>,
       class Allocator = allocator<charT>>
   class basic_stringbuf;
}
using stringbuf = basic_stringbuf<char>;
using wstringbuf = basic_stringbuf<wchar_t>;

template <class charT, class traits = char_traits<charT>,
          class Allocator = allocator<charT>>
class basic_istringstream;
using istringstream = basic_istringstream<char>;
using wistringstream = basic_istringstream<wchar_t>;

template <class charT, class traits = char_traits<charT>,
          class Allocator = allocator<charT>>
class basic_ostringstream;
using ostringstream = basic_ostringstream<char>;
using wostringstream = basic_ostringstream<wchar_t>;

template <class charT, class traits = char_traits<charT>,
          class Allocator = allocator<charT>>
class basic_stringstream;
using stringstream = basic_stringstream<char>;
using wstringstream = basic_stringstream<wchar_t>;

}  // namespace std

1 The header `<sstream>` defines four class templates and eight types that associate stream buffers with objects of class basic_string, as described in 24.3.

### 30.8.2 Class template basic_stringbuf

```cpp
namespace std {
    template <class charT, class traits = char_traits<charT>,
              class Allocator = allocator<charT>>
class basic_stringbuf : public basic_streambuf<charT, traits> {
public:
    using char_type = charT;
    using int_type = typename traits::int_type;
    using pos_type = typename traits::pos_type;
    using off_type = typename traits::off_type;
    using traits_type = traits;
    using allocator_type = Allocator;

    // 30.8.2.1, constructors
    explicit basic_stringbuf(
        ios_base::openmode which = ios_base::in | ios_base::out);
    explicit basic_stringbuf(
        const basic_string<charT, traits, Allocator>& str,
        ios_base::openmode which = ios_base::in | ios_base::out);
    basic_stringbuf(const basic_stringbuf& rhs) = delete;
    basic_stringbuf(basic_stringbuf&& rhs);

    // 30.8.2.2, assign and swap
    basic_stringbuf& operator=(const basic_stringbuf& rhs) = delete;
    basic_stringbuf& operator=(basic_stringbuf&& rhs);
    void swap(basic_stringbuf& rhs);

    // 30.8.2.3, get and set
    basic_string<charT, traits, Allocator> str() const;
    void str(const basic_string<charT, traits, Allocator>& s);
}
```
protected:

// 30.8.2.4, overridden virtual functions
int_type underflow() override;
int_type pbackfail(int_type c = traits::eof()) override;
int_type overflow (int_type c = traits::eof()) override;
basic_streambuf<charT, traits>* setbuf(charT*, streamsize) override;

pos_type seekoff(off_type off, ios_base::seekdir way,
                  ios_base::openmode which = ios_base::in | ios_base::out) override;
pos_type seekpos(pos_type sp,
                  ios_base::openmode which = ios_base::in | ios_base::out) override;

private:

ios_base::openmode mode; // exposition only
};

protected:

// 30.8.2.4, overridden virtual functions
int_type underflow() override;
int_type pbackfail(int_type c = traits::eof()) override;
int_type overflow (int_type c = traits::eof()) override;
basic_streambuf<charT, traits>* setbuf(charT*, streamsize) override;

pos_type seekoff(off_type off, ios_base::seekdir way,
                  ios_base::openmode which = ios_base::in | ios_base::out) override;
pos_type seekpos(pos_type sp,
                  ios_base::openmode which = ios_base::in | ios_base::out) override;

private:

ios_base::openmode mode; // exposition only
};

template <class charT, class traits, class Allocator>
void swap(basic_stringbuf<charT, traits, Allocator>& x,
          basic_stringbuf<charT, traits, Allocator>& y);

1 The class basic_stringbuf is derived from basic_streambuf to associate possibly the input sequence and possibly the output sequence with a sequence of arbitrary characters. The sequence can be initialized from, or made available as, an object of class basic_string.

2 For the sake of exposition, the maintained data is presented here as:

(2.1) — ios_base::openmode mode, has in set if the input sequence can be read, and out set if the output sequence can be written.

30.8.2.1 basic_stringbuf constructors

explicit basic_stringbuf(
    ios_base::openmode which = ios_base::in | ios_base::out);

Effects: Constructs an object of class basic_stringbuf, initializing the base class with basic_streambuf() (30.6.3.1), and initializing mode with which.

Postconditions: str() == "".

explicit basic_stringbuf(
    const basic_string<charT, traits, Allocator>& s,
    ios_base::openmode which = ios_base::in | ios_base::out);

Effects: Constructs an object of class basic_stringbuf, initializing the base class with basic_streambuf() (30.6.3.1), and initializing mode with which. Then calls str(s).

basic_stringbuf(basic_stringbuf&& rhs);

Effects: Move constructs from the rvalue rhs. It is implementation-defined whether the sequence pointers in *this (eback(), gptr(), egptr(), pbase(), pptr(), epptr()) obtain the values which rhs had. Whether they do or not, *this and rhs reference separate buffers (if any at all) after the construction. The openmode, locale and any other state of rhs is also copied.

Postconditions: Let rhs_p refer to the state of rhs just prior to this construction and let rhs_a refer to the state of rhs just after this construction.
30.8.2.2 Assign and swap

basic_stringbuf& operator=(basic_stringbuf&& rhs);

Effects: After the move assignment *this has the observable state it would have had if it had been move constructed from rhs (see 30.8.2.1).

Returns: *this.

void swap(basic_stringbuf& rhs);

Effects: Exchanges the state of *this and rhs.

template <class charT, class traits, class Allocator>
void swap(basic_stringbuf<charT, traits, Allocator>& x,
          basic_stringbuf<charT, traits, Allocator>& y);

Effects: As if by x.swap(y).

30.8.2.3 Member functions

basic_string< charT, traits, Allocator> str() const;

Returns: A basic_string object whose content is equal to the basic_stringbuf underlying character sequence. If the basic_stringbuf was created only in input mode, the resultant basic_string contains the character sequence in the range [eback(), egptr()). If the basic_stringbuf was created with which & ios_base::out being nonzero then the resultant basic_string contains the character sequence in the range [pbase(), high_mark), where high_mark represents the position one past the highest initialized character in the buffer. Characters can be initialized by writing to the stream, by constructing the basic_stringbuf with a basic_string, or by calling the str(basic_string) member function. In the case of calling the str(basic_string) member function, all characters initialized prior to the call are now considered uninitialized (except for those characters re-initialized by the new basic_string). Otherwise the basic_stringbuf has been created in neither input nor output mode and a zero length basic_string is returned.

void str(const basic_string< charT, traits, Allocator>& s);

Effects: Copies the content of s into the basic_stringbuf underlying character sequence and initializes the input and output sequences according to mode.

Postconditions: If mode & ios_base::out is nonzero, pbase() points to the first underlying character and eptr() >= pbase() + s.size() holds; in addition, if mode & ios_base::ate is nonzero, pptr()
== pbase() + s.size() holds, otherwise pptr() == pbase() is true. If mode & ios_base::in is nonzero, eback() points to the first underlying character, and both gptr() == eback() and egptr() == eback() + s.size() hold.

30.8.2.4 Overridden virtual functions

int_type underflow() override;
1
   Returns: If the input sequence has a read position available, returns traits::to_int_type(*gptr()). Otherwise, returns traits::eof(). Any character in the underlying buffer which has been initialized is considered to be part of the input sequence.

int_type pbackfail(int_type c = traits::eof()) override;
2
   Effects: Puts back the character designated by c to the input sequence, if possible, in one of three ways:

   (2.1) — If traits::eq_int_type(c, traits::eof()) returns false and if the input sequence has a
         putback position available, and if traits::eq(to_char_type(c), gptr()[−1]) returns true,
         assigns gptr() − 1 to gptr.
         Returns: c.

   (2.2) — If traits::eq_int_type(c, traits::eof()) returns false and if the input sequence has a
         putback position available, and if mode & ios_base::out is nonzero, assigns c to *--gptr().
         Returns: c.

   (2.3) — If traits::eq_int_type(c, traits::eof()) returns true and if the input sequence has a
         putback position available, assigns gptr() − 1 to gptr().
         Returns: traits::not_eof(c).

   Returns: traits::eof() to indicate failure.
4
   Remarks: If the function can succeed in more than one of these ways, it is unspecified which way is
   chosen.

int_type overflow(int_type c = traits::eof()) override;
5
   Effects: Appends the character designated by c to the output sequence, if possible, in one of two ways:

   (5.1) — If traits::eq_int_type(c, traits::eof()) returns false and if either the output sequence
          has a write position available or the function makes a write position available (as described below),
          the function calls sputc(c).
          Signals success by returning c.

   (5.2) — If traits::eq_int_type(c, traits::eof()) returns true, there is no character to append.
          Signals success by returning a value other than traits::eof().

   Remarks: The function can alter the number of write positions available as a result of any call.

   Returns: traits::eof() to indicate failure.
6
   The function can make a write position available only if (mode & ios_base::out) != 0. To make a
   write position available, the function reallocates (or initially allocates) an array object with a sufficient
   number of elements to hold the current array object (if any), plus at least one additional write position.
   If (mode & ios_base::in) != 0, the function alters the read end pointer egptr() to point just past
   the new write position.

pos_type seekoff(off_type off, ios_base::seekdir way,
   ios_base::openmode which
   = ios_base::in | ios_base::out) override;

§ 30.8.2.4 1218
Effects: Alters the stream position within one of the controlled sequences, if possible, as indicated in Table 115.

Table 115 — seekoff positioning

<table>
<thead>
<tr>
<th>Conditions</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>(which &amp; ios_base::in) == ios_base::in</td>
<td>positions the input sequence</td>
</tr>
<tr>
<td>(which &amp; ios_base::out) == ios_base::out</td>
<td>positions the output sequence</td>
</tr>
<tr>
<td>(which &amp; (ios_base::in</td>
<td>ios_base::out)) == (ios_base::in</td>
</tr>
<tr>
<td>Otherwise</td>
<td>the positioning operation fails.</td>
</tr>
</tbody>
</table>

For a sequence to be positioned, if its next pointer (either gptr() or pptr()) is a null pointer and the new offset newoff is nonzero, the positioning operation fails. Otherwise, the function determines newoff as indicated in Table 116.

Table 116 — newoff values

<table>
<thead>
<tr>
<th>Condition</th>
<th>newoff Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>way == ios_base::beg</td>
<td>0</td>
</tr>
<tr>
<td>way == ios_base::cur</td>
<td>the next pointer minus the beginning pointer (xnext - xbeg).</td>
</tr>
<tr>
<td>way == ios_base::end</td>
<td>the high mark pointer minus the beginning pointer (high_mark - xbeg).</td>
</tr>
</tbody>
</table>

If (newoff + off) < 0, or if newoff + off refers to an uninitialized character (30.8.2.3), the positioning operation fails. Otherwise, the function assigns xbeg + newoff + off to the next pointer xnext.

Returns: pos_type(newoff), constructed from the resultant offset newoff (of type off_type), that stores the resultant stream position, if possible. If the positioning operation fails, or if the constructed object cannot represent the resultant stream position, the return value is pos_type(off_type(-1)).

pos_type seekpos(pos_type sp, ios_base::openmode which = ios_base::in | ios_base::out) override;

Effects: Equivalent to seekoff(off_type(sp), ios_base::beg, which).

Returns: sp to indicate success, or pos_type(off_type(-1)) to indicate failure.
30.8.3 Class template basic_istringstream

namespace std {
    template <class charT, class traits = char_traits<charT>,
              class Allocator = allocator<charT>>
    class basic_istringstream : public basic_istream<charT, traits> {
public:
    using char_type = charT;
    using int_type = typename traits::int_type;
    using pos_type = typename traits::pos_type;
    using off_type = typename traits::off_type;
    using traits_type = traits;
    using allocator_type = Allocator;

    // 30.8.3.1, constructors
    explicit basic_istringstream(ios_base::openmode which = ios_base::in);
    explicit basic_istringstream(const basic_string<charT, traits, Allocator>& str, ios_base::openmode which = ios_base::in);
    basic_istringstream(const basic_istringstream& rhs) = delete;
    basic_istringstream(basic_istringstream&& rhs);

    // 30.8.3.2, assign and swap
    basic_istringstream& operator=(const basic_istringstream& rhs) = delete;
    basic_istringstream& operator=(basic_istringstream&& rhs);
    void swap(basic_istringstream& rhs);

    // 30.8.3.3, members
    basic_stringbuf<charT, traits, Allocator>* rdbuf() const;
    basic_string<charT, traits, Allocator> str() const;
    void str(const basic_string<charT, traits, Allocator>& s);
private:
    basic_stringbuf<charT, traits, Allocator> sb; // exposition only
    }
};

template <class charT, class traits, class Allocator>
void swap(basic_istringstream<charT, traits, Allocator>& x,
          basic_istringstream<charT, traits, Allocator>& y);

1 The class basic_istringstream<charT, traits, Allocator> supports reading objects of class basic_string<charT, traits, Allocator>. It uses a basic_stringbuf<charT, traits, Allocator> object to control the associated storage. For the sake of exposition, the maintained data is presented here as:

(1.1) — sb, the stringbuf object.

30.8.3.1 basic_istringstream constructors

explicit basic_istringstream(ios_base::openmode which = ios_base::in);

1 Effects: Constructs an object of class basic_istringstream<charT, traits>, initializing the base class with basic_istream(&sb) and initializing sb with basic_stringbuf<charT, traits, Allocator>(which | ios_base::in)) (30.8.2.1).

explicit basic_istringstream(
    const basic_string<charT, traits, Allocator>& str,

§ 30.8.3.1  1220
ios_base::openmode which = ios_base::in);

**Effects:** Constructs an object of class `basic_istringstream<charT, traits>`, initializing the base class with `basic_istream(&sb)` and initializing `sb` with `basic_stringbuf<charT, traits, Allocator>(str, which | ios_base::in)` (30.8.2.1).

basic_istringstream(basic_istringstream&& rhs);

**Effects:** Move constructs from the rvalue `rhs`. This is accomplished by move constructing the base class, and the contained `basic_stringbuf`. Next `basic_istream<charT, traits>::set_rdbuf(&sb)` is called to install the contained `basic_stringbuf`.

### 30.8.3.2 Assign and swap

`basic_istringstream& operator=(basic_istringstream&& rhs);`

**Effects:** Move assigns the base and members of `*this` from the base and corresponding members of `rhs`.

`void swap(basic_istringstream& rhs);`

**Effects:** Exchanges the state of `*this` and `rhs` by calling `basic_istream<charT, traits>::swap(rhs)` and `sb.swap(rhs.sb)`.

```cpp
template <class charT, class traits, class Allocator>
void swap(basic_istringstream<charT, traits, Allocator>& x, 
          basic_istringstream<charT, traits, Allocator>& y);
```

**Effects:** As if by `x.swap(y)`.

### 30.8.3.3 Member functions

`basic_stringbuf<charT, traits, Allocator>* rdbuf() const;`

**Returns:** `const_cast<basic_stringbuf<charT, traits, Allocator>*>(&sb)`.

`basic_string<charT, traits, Allocator> str() const;`

**Returns:** `rdbuf()->str()`.

`void str(const basic_string<charT, traits, Allocator>& s);`

**Effects:** Calls `rdbuf()->str(s)`.

### 30.8.4 Class template basic_ostringstream

```cpp
namespace std {

    template <class charT, class traits = char_traits<charT>,
              class Allocator = allocator<charT>>
    class basic_ostringstream : public basic_ostream<charT, traits> {

        public:

            using char_type = charT;
            using int_type = typename traits::int_type;
            using pos_type = typename traits::pos_type;
            using off_type = typename traits::off_type;
            using traits_type = traits;
            using allocator_type = Allocator;

        // 30.8.4.1, constructors

            explicit basic_ostringstream(
```
ios_base::openmode which = ios_base::out);
explicit basic_ostringstream(
    const basic_string<charT, traits, Allocator>& str,
    ios_base::openmode which = ios_base::out);
basic_ostringstream(const basic_ostringstream& rhs) = delete;
basic_ostringstream(basic_ostringstream&& rhs);

// 30.8.4.2, assign and swap
basic_ostringstream& operator=(const basic_ostringstream& rhs) = delete;
basic_ostringstream& operator=(basic_ostringstream&& rhs);
void swap(basic_ostringstream& rhs);

// 30.8.4.3, members
basic_stringbuf<charT, traits, Allocator>* rdbuf() const;

basic_string<charT, traits, Allocator> str() const;
void str(const basic_string<charT, traits, Allocator>& s);
private:
    basic_stringbuf<charT, traits, Allocator> sb; // exposition only
};

template <class charT, class traits, class Allocator>
void swap(basic_ostringstream<charT, traits, Allocator>& x,
    basic_ostringstream<charT, traits, Allocator>& y);

The class basic_ostringstream<charT, traits, Allocator> supports writing objects of class basic_string<charT, traits, Allocator>. It uses a basic_stringbuf object to control the associated storage. For the sake of exposition, the maintained data is presented here as:

sb, the stringbuf object.

30.8.4.1 basic_ostringstream constructors

explicit basic_ostringstream(
    ios_base::openmode which = ios_base::out);

Effects: Constructs an object of class basic_ostringstream, initializing the base class with basic_ostream(&sb) and initializing sb with basic_stringbuf<charT, traits, Allocator>(which | ios_base::out)) (30.8.2.1).

explicit basic_ostringstream(
    const basic_string<charT, traits, Allocator>& str,
    ios_base::openmode which = ios_base::out);

Effects: Constructs an object of class basic_ostringstream<charT, traits>, initializing the base class with basic_ostream(&sb) and initializing sb with basic_stringbuf<charT, traits, Allocator>(str, which | ios_base::out)) (30.8.2.1).

basic_ostringstream(basic_ostringstream&& rhs);

Effects: Move constructs from the rvalue rhs. This is accomplished by move constructing the base class, and the contained basic_stringbuf. Next basic_ostream<charT, traits>::set_rdbuf(&sb) is called to install the contained basic_stringbuf.

30.8.4.2 Assign and swap

basic_ostringstream& operator=(basic_ostringstream&& rhs);

§ 30.8.4.2 1222
Effects: Move assigns the base and members of *this from the base and corresponding members of rhs.

Returns: *this.

void swap(basic_ostringstream& rhs);

Effects: Exchanges the state of *this and rhs by calling basic_ostream<charT, traits>::swap(rhs) and sb.swap(rhs.sb).

template <class charT, class traits, class Allocator>
void swap(basic_ostringstream<charT, traits, Allocator>& x, basic_ostringstream<charT, traits, Allocator>& y);

Effects: As if by x.swap(y).

30.8.4.3 Member functions

basic_stringbuf<charT, traits, Allocator>* rdbuf() const;

Returns: const_cast<basic_stringbuf<charT, traits, Allocator>*>(&sb).

basic_string<charT, traits, Allocator> str() const;

Returns: rdbuf()->str().

void str(const basic_string<charT, traits, Allocator>& s);

Effects: Calls rdbuf()->str(s).

30.8.5 Class template basic_stringstream

namespace std {
  template <class charT, class traits = char_traits<charT>,
            class Allocator = allocator<charT>>
  class basic_stringstream : public basic_iostream<charT, traits> {
    public:
      using char_type = charT;
      using int_type = typename traits::int_type;
      using pos_type = typename traits::pos_type;
      using off_type = typename traits::off_type;
      using traits_type = traits;
      using allocator_type = Allocator;

      // 30.8.5.1, constructors
      explicit basic_stringstream(
        ios_base::openmode which = ios_base::out | ios_base::in);
      explicit basic_stringstream(
        const basic_string<charT, traits, Allocator>& str,
        ios_base::openmode which = ios_base::out | ios_base::in);
      basic_stringstream(const basic_stringstream& rhs) = delete;
      basic_stringstream(basic_stringstream&& rhs);

      // 30.8.5.2, assign and swap
      basic_stringstream& operator=(const basic_stringstream& rhs) = delete;
      basic_stringstream& operator=(basic_stringstream&& rhs);
      void swap(basic_stringstream& rhs);

      // 30.8.5.3, members
      basic_stringbuf<charT, traits, Allocator>* rdbuf() const;

§ 30.8.5
The class template `basic_stringstream<charT, traits>` supports reading and writing from objects of class `basic_string<charT, traits, Allocator>`. It uses a `basic_stringbuf<charT, traits, Allocator>` object to control the associated sequence. For the sake of exposition, the maintained data is presented here as

\[ \text{sb, the stringbuf object.} \]  

### 30.8.5.1 basic_stringstream constructors

**explicit basic_stringstream(**

```c++
ios_base::openmode which = ios_base::out | ios_base::in);
```

**Effects:** Constructs an object of class `basic_stringstream<charT, traits>`, initializing the base class with `basic_iostream(&sb)` and initializing `sb` with `basic_stringbuf<charT, traits, Allocator>(which)`.

**explicit basic_stringstream(**

```c++
const basic_string<charT, traits, Allocator>& str,
ios_base::openmode which = ios_base::out | ios_base::in);
```

**Effects:** Constructs an object of class `basic_stringstream<charT, traits>`, initializing the base class with `basic_iostream(&sb)` and initializing `sb` with `basic_stringbuf<charT, traits, Allocator>(str, which)`.

**basic_stringstream(basic_stringstream&& rhs);**

**Effects:** Move constructs from the rvalue `rhs`. This is accomplished by move constructing the base class, and the contained `basic_stringbuf`. Next `basic_iostream<charT, traits>::set_rdbuf(&sb)` is called to install the contained `basic_stringbuf`.

### 30.8.5.2 Assign and swap

**basic_stringstream& operator=(basic_stringstream&& rhs);**

**Effects:** Move assigns the base and members of `*this` from the base and corresponding members of `rhs`.

**Returns:** `*this`.

**void swap(basic_stringstream& rhs);**

**Effects:** Exchanges the state of `*this` and `rhs` by calling `basic_iostream<charT, traits>::swap(rhs)` and `sb.swap(rhs.sb)`.

**template <class charT, class traits, class Allocator> void swap(basic_stringstream<charT, traits, Allocator>& x,**

```c++
        basic_stringstream<charT, traits, Allocator>& y);
```

**Effects:** As if by `x.swap(y)`.
30.8.5.3 Member functions

```cpp
basic_stringbuf<charT, traits, Allocator>* rdbuf() const;
```

1. Returns: `const_cast<basic_stringbuf<charT, traits, Allocator>>(&sb)`

```cpp
basic_string<charT, traits, Allocator> str() const;
```

2. Returns: `rdbuf()->str()`.

```cpp
void str(const basic_string<charT, traits, Allocator>& str);
```

3. Effects: Calls `rdbuf()->str(str)`.

30.9 File-based streams

30.9.1 Header `<fstream>` synopsis

```cpp
namespace std {
    template <class charT, class traits = char_traits<charT>>
    class basic_filebuf;
    using filebuf = basic_filebuf<char>;
    using wfilebuf = basic_filebuf<wchar_t>;

    template <class charT, class traits = char_traits<charT>>
    class basic_ifstream;
    using ifstream = basic_ifstream<char>;
    using wifstream = basic_ifstream<wchar_t>;

    template <class charT, class traits = char_traits<charT>>
    class basic_ofstream;
    using ofstream = basic_ofstream<char>;
    using wofstream = basic_ofstream<wchar_t>;

    template <class charT, class traits = char_traits<charT>>
    class basic_fstream;
    using fstream = basic_fstream<char>;
    using wfstream = basic_fstream<wchar_t>;
}
```

1. The header `<fstream>` defines four class templates and eight types that associate stream buffers with files and assist reading and writing files.

2. [Note: The class template `basic_filebuf` treats a file as a source or sink of bytes. In an environment that uses a large character set, the file typically holds multibyte character sequences and the `basic_filebuf` object converts those multibyte sequences into wide character sequences. —end note]

3. In this subclause, member functions taking arguments of `const filesystem::path::value_type*` are only be provided on systems where `filesystem::path::value_type` is not `char`. [Note: These functions enable class path support for systems with a wide native path character type, such as `wchar_t`. —end note]

30.9.2 Class template basic_filebuf

```cpp
namespace std {
    template <class charT, class traits = char_traits<charT>>
    class basic_filebuf : public basic_streambuf<charT, traits> {
        public:
            using char_type = charT;
            using int_type = typename traits::int_type;
            using pos_type = typename traits::pos_type;
```
using off_type = typename traits::off_type;
using traits_type = traits;

// 30.9.2.1, constructors/destructor
basic_filebuf();
basic_filebuf(const basic_filebuf& rhs) = delete;
basic_filebuf(basic_filebuf&& rhs);
virtual ~basic_filebuf();

// 30.9.2.2, assign and swap
basic_filebuf& operator=(const basic_filebuf& rhs) = delete;
basic_filebuf& operator=(basic_filebuf&& rhs);
void swap(basic_filebuf& rhs);

// 30.9.2.3, members
bool is_open() const;
basic_filebuf* open(const char* s, ios_base::openmode mode);
basic_filebuf* open(const filesystem::path::value_type* s,
    ios_base::openmode mode); // wide systems only; see 30.9.1
basic_filebuf* open(const string& s,
    ios_base::openmode mode);
basic_filebuf* open(const filesystem::path& s,
    ios_base::openmode mode);
basic_filebuf* close();

protected:
// 30.9.2.4, overridden virtual functions
streamsize showmanyc() override;
int_type underflow() override;
int_type uflow() override;
int_type pbackfail(int_type c = traits::eof()) override;
int_type overflow (int_type c = traits::eof()) override;
basic_streambuf<charT, traits>* setbuf(char_type* s,
    streamsize n) override;

pos_type seekoff(off_type off, ios_base::seekdir way,
    ios_base::openmode which = ios_base::in | ios_base::out) override;
pos_type seekpos(pos_type sp,
    ios_base::openmode which = ios_base::in | ios_base::out) override;

int sync() override;
void imbue(const locale& loc) override;
};

template <class charT, class traits>
void swap(basic_filebuf<charT, traits>& x,
    basic_filebuf<charT, traits>& y);

1 The class basic_filebuf<charT, traits> associates both the input sequence and the output sequence with a file.

2 The restrictions on reading and writing a sequence controlled by an object of class basic_filebuf<charT, traits> are the same as for reading and writing with the C standard library FILEs.
In particular:

(3.1) — If the file is not open for reading the input sequence cannot be read.

(3.2) — If the file is not open for writing the output sequence cannot be written.

(3.3) — A joint file position is maintained for both the input sequence and the output sequence.

An instance of basic_filebuf behaves as described in 30.9.2 provided traits::pos_type is fpos<traits::state_type>. Otherwise the behavior is undefined.

In order to support file I/O and multibyte/wide character conversion, conversions are performed using members of a facet, referred to as a_codecvt in following sections, obtained as if by

```
const codecvt<charT, char, typename traits::state_type>& a_codecvt =
    use_facet<codecvt<charT, char, typename traits::state_type>>(getloc());
```

### 30.9.2.1 basic_filebuf constructors

#### [filebuf.cons]

**basic_filebuf();**

*Effects:* Constructs an object of class basic_filebuf<charT, traits>, initializing the base class with basic_streambuf<charT, traits>() (30.6.3.1).

*Postconditions:* is_open() == false.

**basic_filebuf(basic_filebuf&& rhs);**

*Effects:* Move constructs from the rvalue rhs. It is implementation-defined whether the sequence pointers in *this (eback(), gptr(), egptr(), pbase(), pptr(), epptr())* obtain the values which rhs had. Whether they do or not, *this and rhs reference separate buffers (if any at all) after the construction. Additionally *this references the file which rhs did before the construction, and rhs references no file after the construction. The openmode, locale and any other state of rhs is also copied.

*Postconditions:* Let rhs_p refer to the state of rhs just prior to this construction and let rhs_a refer to the state of rhs just after this construction.

(4.1) — is_open() == rhs_p.is_open()

(4.2) — rhs_a.is_open() == false

(4.3) — gptr() - eback() == rhs_p.gptr() - rhs_p.eback()

(4.4) — egptr() - eback() == rhs_p.egptr() - rhs_p.eback()

(4.5) — pptr() - pbase() == rhs_p.pptr() - rhs_p.pbase()

(4.6) — epptr() - pbase() == rhs_p.epptr() - rhs_p.pbase()

(4.7) — if (eback()) eback() != rhs_a.eback()

(4.8) — if (gptr()) gptr() != rhs_a.gptr()

(4.9) — if (egptr()) egptr() != rhs_a.egptr()

(4.10) — if (pbase()) pbase() != rhs_a.pbase()

(4.11) — if (pptr()) pptr() != rhs_a.pptr()

(4.12) — if (epptr()) epptr() != rhs_a.epptr()

**virtual ~basic_filebuf();**

*Effects:* Destroys an object of class basic_filebuf<charT, traits>. Calls close(). If an exception occurs during the destruction of the object, including the call to close(), the exception is caught but not rethrown (see 20.5.5.12).
30.9.2.2 Assign and swap

basic_filebuf& operator=(basic_filebuf&& rhs);

1 Effects: Calls close() then move assigns from rhs. After the move assignment *this has the observable state it would have had if it had been move constructed from rhs (see 30.9.2.1).

2 Returns: *this.

void swap(basic_filebuf& rhs);

3 Effects: Exchanges the state of *this and rhs.

template <class charT, class traits>
void swap(basic_filebuf<charT, traits>& x,
        basic_filebuf<charT, traits>& y);

4 Effects: As if by x.swap(y).

30.9.2.3 Member functions

bool is_open() const;

1 Returns: true if a previous call to open succeeded (returned a non-null value) and there has been no intervening call to close.

basic_filebuf* open(const char* s, ios_base::openmode mode);

2 Effects: If is_open() != false, returns a null pointer. Otherwise, initializes the filebuf as required. It then opens a file, if possible, whose name is the NTBS s (as if by calling fopen(s, modstr)). The NTBS modstr is determined from mode & ~ios_base::ate as indicated in Table 117. If mode is not some combination of flags shown in the table then the open fails.

3 If the open operation succeeds and (mode & ios_base::ate) != 0, positions the file to the end (as if by calling fseek(file, 0, SEEK_END)).

4 If the repositioning operation fails, calls close() and returns a null pointer to indicate failure.

5 Returns: *this if successful, a null pointer otherwise.

basic_filebuf* open(const string& s, ios_base::openmode mode);

6 Returns: open(s.c_str(), mode);

basic_filebuf* close();

7 Effects: If is_open() == false, returns a null pointer. If a put area exists, calls overflow(traits::eof()) to flush characters. If the last virtual member function called on *this (between underflow, overflow, seekoff, and seekpos) was overflow then calls a_codecvt.unshift (possibly several times) to determine a termination sequence, inserts those characters and calls overflow(traits::eof()) again. Finally, regardless of whether any of the preceding calls fails or throws an exception, the function closes the file (as if by calling fclose(file)). If any of the calls made by the function, including fclose, fails, close fails by returning a null pointer. If one of these calls throws an exception, the exception is caught and rethrown after closing the file.

8 Returns: *this on success, a null pointer otherwise.

327 The macro SEEK_END is defined, and the function signatures fopen(const char*, const char*) and fseek(FILE*, long, int) are declared, in <cstdio> (30.11.1).

Postconditions: `is_open() == false`.

30.9.2.4 Overridden virtual functions

```cpp
streamsize showmanyc() override;
```

1. **Effects:** Behaves the same as `basic_streambuf<charT, traits>::showmanyc()` (30.6.3.4).

2. **Remarks:** An implementation might well provide an overriding definition for this function signature if it can determine that more characters can be read from the input sequence.

```cpp
int_type underflow() override;
```

3. **Effects:** Behaves according to the description of `basic_streambuf<charT, traits>::underflow()`, with the specialization that a sequence of characters is read from the input sequence as if by reading from the associated file into an internal buffer (`extern_buf`) and then as if by doing:

```cpp
class codecvt_base
{
public:
  codecvt_base::result operator()(
    state_type state, char buf[XSIZE],
    char* end, state_type& state)
  {
    return in(state, state, state, state, state, state, state);  // Implement
  }
}
```

This shall be done in such a way that the class can recover the position (`fpos_t`) corresponding to each character between `intern_buf` and `intern_end`. If the value of `r` indicates that `a_codecvt.in()` ran out of space in `intern_buf`, retry with a larger `intern_buf`.

```cpp
int_type uflow() override;
```

§ 30.9.2.4
Effects: Behaves according to the description of `basic_streambuf<charT, traits>::uflow()`, with the specialization that a sequence of characters is read from the input with the same method as used by `underflow`.

```cpp
int_type pbackfail(int_type c = traits::eof()) override;
```

Effects: Puts back the character designated by `c` to the input sequence, if possible, in one of three ways:

1. If `traits::eq_int_type(c, traits::eof())` returns `false` and if the function makes a putback position available and if `traits::eq(to_char_type(c), gptr()[−1])` returns `true`, decrements the next pointer for the input sequence, `gptr()`.
   
   Returns: `c`.

2. If `traits::eq_int_type(c, traits::eof())` returns `false` and if the function makes a putback position available and if the function is permitted to assign to the putback position, decrements the next pointer for the input sequence, and stores `c` there.
   
   Returns: `c`.

3. If `traits::eq_int_type(c, traits::eof())` returns `true`, and if either the input sequence has a putback position available or the function makes a putback position available, decrements the next pointer for the input sequence, `gptr()`.
   
   Returns: `traits::not_eof(c)`.

Returns: `traits::eof()` to indicate failure.

Remarks: If `is_open() == false`, the function always fails.

The function does not put back a character directly to the input sequence.

If the function can succeed in more than one of these ways, it is unspecified which way is chosen. The function can alter the number of putback positions available as a result of any call.

```cpp
int_type overflow(int_type c = traits::eof()) override;
```

Effects: Behaves according to the description of `basic_streambuf<charT, traits>::overflow(c)`, except that the behavior of “consuming characters” is performed by first converting as if by:

```cpp
charT* b = pbase();
charT* p = pptr();
charT* end;
char xbuf[XSIZE];
char* xbuf_end;
codecvt_base::result r =
    a_codecvt.out(state, b, p, end, xbuf, xbuf+XSIZE, xbuf_end);
```

and then

1. If `r` == `codecvt_base::error` then fail.
2. If `r` == `codecvt_base::noconv` then output characters from `b` up to (and not including) `p`.
3. If `r` == `codecvt_base::partial` then output to the file characters from `xbuf` up to `xbuf_end`, and repeat using characters from `end` to `p`. If output fails, fail (without repeating).
4. Otherwise output from `xbuf` to `xbuf_end`, and fail if output fails. At this point if `b != p` and `b` == `end` (`xbuf` isn’t large enough) then increase `XSIZE` and repeat from the beginning.

Returns: `traits::not_eof(c)` to indicate success, and `traits::eof()` to indicate failure. If `is_open() == false`, the function always fails.

```cpp
basic_streambuf* setbuf(char_type* s, streamsize n) override;
```
Effects: If setbuf(0, 0) is called on a stream before any I/O has occurred on that stream, the stream becomes unbuffered. Otherwise the results are implementation-defined. “Unbuffered” means that pbase() and pptr() always return null and output to the file should appear as soon as possible.

Effects: Let width denote a_codecvt.encoding(). If is_open() == false, or off != 0 && width <= 0, then the positioning operation fails. Otherwise, if way != basic_ios::cur or off != 0, and if the last operation was output, then update the output sequence and write any unshift sequence. Next, seek to the new position: if width > 0, call fseek(file, width * off, whence), otherwise call fseek(file, 0, whence).

Remarks: “The last operation was output” means either the last virtual operation was overflow or the put buffer is non-empty. “Write any unshift sequence” means, if width if less than zero then call a_codecvt.unshift(state, xbuf, xbuf+XSIZE, xbuf_end) and output the resulting unshift sequence. The function determines one of three values for the argument whence, of type int, as indicated in Table 118.

Table 118 — seekoff effects

<table>
<thead>
<tr>
<th>way Value</th>
<th>stdio Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>basic_ios::beg</td>
<td>SEEK_SET</td>
</tr>
<tr>
<td>basic_ios::cur</td>
<td>SEEK_CUR</td>
</tr>
<tr>
<td>basic_ios::end</td>
<td>SEEK_END</td>
</tr>
</tbody>
</table>

Returns: A newly constructed pos_type object that stores the resultant stream position, if possible. If the positioning operation fails, or if the object cannot represent the resultant stream position, returns pos_type(off_type(-1)).

Alters the file position, if possible, to correspond to the position stored in sp (as described below). Altering the file position performs as follows:
1. if (om & ios_base::out) != 0, then update the output sequence and write any unshift sequence;
2. set the file position to sp as if by a call to fsetpos;
3. if (om & ios_base::in) != 0, then update the input sequence;
where om is the open mode passed to the last call to open(). The operation fails if is_open() returns false.

If sp is an invalid stream position, or if the function positions neither sequence, the positioning operation fails. If sp has not been obtained by a previous successful call to one of the positioning functions (seekoff or seekpos) on the same file the effects are undefined.

Returns: sp on success. Otherwise returns pos_type(off_type(-1)).

Effects: If a put area exists, calls filebuf::overflow to write the characters to the file, then flushes the file as if by calling fflush(file). If a get area exists, the effect is implementation-defined.
void imbue(const locale& loc) override;

Requires: If the file is not positioned at its beginning and the encoding of the current locale as determined by a_codecvt.encoding() is state-dependent (25.4.1.4.2) then that facet is the same as the corresponding facet of loc.

Effects: Causes characters inserted or extracted after this call to be converted according to loc until another call of imbue.

Remarks: This may require reconversion of previously converted characters. This in turn may require the implementation to be able to reconstruct the original contents of the file.

30.9.3 Class template basic_ifstream

namespace std {
  template <class charT, class traits = char_traits<charT>>
  class basic_ifstream : public basic_istream<charT, traits> {
    public:
      using char_type = charT;
      using int_type = typename traits::int_type;
      using pos_type = typename traits::pos_type;
      using off_type = typename traits::off_type;
      using traits_type = traits;

      // 30.9.3.1, constructors
      basic_ifstream();
      explicit basic_ifstream(const char* s, ios_base::openmode mode = ios_base::in);
      explicit basic_ifstream(const filesystem::path::value_type* s, ios_base::openmode mode = ios_base::in); // wide systems only; see 30.9.1
      explicit basic_ifstream(const string& s, ios_base::openmode mode = ios_base::in);
      explicit basic_ifstream(const filesystem::path& s, ios_base::openmode mode = ios_base::in);
      basic_ifstream(const basic_ifstream& rhs) = delete;
      basic_ifstream(basic_ifstream&& rhs);

      // 30.9.3.2, assign and swap
      basic_ifstream& operator=(const basic_ifstream& rhs) = delete;
      basic_ifstream& operator=(basic_ifstream&& rhs);
      void swap(basic_ifstream& rhs);

      // 30.9.3.3, members
      basic_filebuf<charT, traits>* rdbuf() const;
      bool is_open() const;
      void open(const char* s, ios_base::openmode mode = ios_base::in);
      void open(const filesystem::path::value_type* s, ios_base::openmode mode = ios_base::in); // wide systems only; see 30.9.1
      void open(const string& s, ios_base::openmode mode = ios_base::in);
      void open(const filesystem::path& s, ios_base::openmode mode = ios_base::in);
      void close();
    private:
      basic_filebuf<charT, traits> sb; // exposition only
  };

  template <class charT, class traits>

The class `basic_ifstream<charT, traits>` supports reading from named files. It uses a `basic_filebuf<charT, traits>` object to control the associated sequence. For the sake of exposition, the maintained data is presented here as:

(1.1) — `sb`, the `filebuf` object.

### 30.9.3.1 `basic_ifstream` constructors

#### [ifstream.cons]

```cpp
basic_ifstream();
```

**Effects:** Constructs an object of class `basic_ifstream<charT, traits>`, initializing the base class with `basic_istream(&sb)` and initializing `sb` with `basic_filebuf<charT, traits>()` (30.7.4.1.1, 30.9.2.1).

```cpp
explicit basic_ifstream(const char* s,
     ios_base::openmode mode = ios_base::in);
```

**Effects:** Constructs an object of class `basic_ifstream`, initializing the base class with `basic_istream(&sb)` and initializing `sb` with `basic_filebuf<charT, traits>()` (30.7.4.1.1, 30.9.2.1), then calls `rdbuf()->open(s, mode | ios_base::in)`. If that function returns a null pointer, calls `setstate(failbit)`.

```cpp
explicit basic_ifstream(const filesystem::path::value_type* s,
     ios_base::openmode mode = ios_base::in); // wide systems only; see 30.9.1
```

**Effects:** Constructs an object of class `basic_ifstream`, initializing the base class with `basic_istream(&sb)` and initializing `sb` with `basic_filebuf<charT, traits>()` (30.7.4.1.1, 30.9.2.1), then calls `rdbuf()->open(s, mode | ios_base::in)`. If that function returns a null pointer, calls `setstate(failbit)`.

```cpp
explicit basic_ifstream(const string& s,
     ios_base::openmode mode = ios_base::in);
```

**Effects:** The same as `basic_ifstream(s.c_str(), mode)`.

```cpp
basic_ifstream(basic_ifstream&& rhs);
```

**Effects:** Move constructs from the rvalue `rhs`. This is accomplished by move constructing the base class, and the contained `basic_filebuf`. Next `basic_istream<charT, traits>::set_rdbuf(&sb)` is called to install the contained `basic_filebuf`.

### 30.9.3.2 Assign and swap

#### [ifstream.assign]

```cpp
basic_ifstream& operator=(basic_ifstream&& rhs);
```

**Effects:** Move assigns the base and members of `*this` from the base and corresponding members of `rhs`.

**Returns:** `*this`.

```cpp
void swap(basic_ifstream& rhs);
```

**Effects:** Exchanges the state of `*this` and `rhs` by calling `basic_istream<charT, traits>::swap(rhs)` and `sb.swap(rhs.sb)`.

```cpp
template <class charT, class traits>
void swap(basic_ifstream<charT, traits>& x,
     basic_ifstream<charT, traits>& y);
```

**Effects:** As if by `x.swap(y)`.
30.9.3.3 Member functions

basic_filebuf<charT, traits>* rdbuf() const;

   Returns: const_cast<basic_filebuf<charT, traits>*>(&sb).

bool is_open() const;

   Returns: rdbuf()->is_open().

void open(const char* s, ios_base::openmode mode = ios_base::in);
void open(const filesystem::path::value_type* s,
         ios_base::openmode mode = ios_base::in); // wide systems only; see 30.9.1

   Effects: Calls rdbuf()->open(s, mode | ios_base::in). If that function does not return a null
            pointer calls clear(), otherwise calls setstate(failbit) (which may throw ios_base::failure)
            (30.5.5.4).

void open(const string& s, ios_base::openmode mode = ios_base::in);
void open(const filesystem::path& s, ios_base::openmode mode = ios_base::in);

   Effects: Calls open(s.c_str(), mode).

void close();

   Effects: Calls rdbuf()->close() and, if that function returns a null pointer, calls setstate(failbit)
            (which may throw ios_base::failure) (30.5.5.4).

30.9.4 Class template basic_ofstream

namespace std {

   template <class charT, class traits = char_traits<charT>>
   class basic_ofstream : public basic_ostream<charT, traits> {

   public:
      using char_type = charT;
      using int_type = typename traits::int_type;
      using pos_type = typename traits::pos_type;
      using off_type = typename traits::off_type;
      using traits_type = traits;

   // 30.9.4.1, constructors
   basic_ofstream();
   explicit basic_ofstream(const char* s,
                           ios_base::openmode mode = ios_base::out);
   explicit basic_ofstream(const filesystem::path::value_type* s,
                           ios_base::openmode mode = ios_base::out); // wide systems only; see 30.9.1
   explicit basic_ofstream(const string& s,
                           ios_base::openmode mode = ios_base::out);
   explicit basic_ofstream(const filesystem::path& s,
                           ios_base::openmode mode = ios_base::out);
   basic_ofstream(const basic_ofstream& rhs) = delete;
   basic_ofstream(basic_ofstream&& rhs);

   // 30.9.4.2, assign and swap
   basic_ofstream& operator=(const basic_ofstream& rhs) = delete;
   basic_ofstream& operator=(basic_ofstream&& rhs);
   void swap(basic_ofstream& rhs);

   // 30.9.4.3, members

§ 30.9.4
# basic_ofstream

The class `basic_ofstream<charT, traits>` supports writing to named files. It uses a `basic_filebuf<charT, traits>` object to control the associated sequence. For the sake of exposition, the maintained data is presented here as:

(1.1) — sb, the filebuf object.

## 30.9.4.1 basic_ofstream constructors

### basic_ofstream();

**Effects:** Constructs an object of class `basic_ofstream<charT, traits>`, initializing the base class with `basic_ostream(&sb)` and initializing `sb` with `basic_filebuf<charT, traits>()` ([30.7.5.1.1, 30.9.2.1]).

### explicit basic_ofstream(const char* s, ios_base::openmode mode = ios_base::out);

### explicit basic_ofstream(const filesystem::path::value_type* s, ios_base::openmode mode = ios_base::out); // wide systems only; see 30.9.1

**Effects:** Constructs an object of class `basic_ofstream<charT, traits>`, initializing the base class with `basic_ostream(&sb)` and initializing `sb` with `basic_filebuf<charT, traits>()` ([30.7.5.1.1, 30.9.2.1]), then calls `rdbuf()->open(s, mode | ios_base::out)`. If that function returns a null pointer, calls `setstate(failbit)`.

### explicit basic_ofstream(const string& s, ios_base::openmode mode = ios_base::out);

### explicit basic_ofstream(const filesystem::path& s, ios_base::openmode mode = ios_base::out);

**Effects:** The same as `basic_ofstream(s.c_str(), mode)`.

### basic_ofstream(basic_ofstream&& rhs);

**Effects:** Move constructs from the rvalue `rhs`. This is accomplished by move constructing the base class, and the contained `basic_filebuf`. Next `basic_ostream<charT, traits>::set_rdbuf(&sb)` is called to install the contained `basic_filebuf`.

## 30.9.4.2 Assign and swap

### basic_ofstream& operator=(basic_ofstream&& rhs);

§ 30.9.4.2
Effects: Move assigns the base and members of *this from the base and corresponding members of rhs.

Returns: *this.

void swap(basic_ofstream& rhs);

Effects: Exchanges the state of *this and rhs by calling basic_ostream<charT, traits>::swap(rhs) and sb.swap(rhs.sb).

template <class charT, class traits>
void swap(basic_ofstream<charT, traits>& x, basic_ofstream<charT, traits>& y);

Effects: As if by x.swap(y).

30.9.4.3 Member functions [ofstream.members]

basic_filebuf<charT, traits>* rdbuf() const;

Returns: const_cast<basic_filebuf<charT, traits>*>(&sb).

bool is_open() const;

Returns: rdbuf() -> is_open().

void open(const char* s, ios_base::openmode mode = ios_base::out);
void open(const filesystem::path::value_type* s, ios_base::openmode mode = ios_base::out);  // wide systems only; see 30.9.1

Effects: Calls rdbuf() -> open(s, mode | ios_base::out). If that function does not return a null pointer calls clear(), otherwise calls setstate(failbit) (which may throw ios_base::failure) (30.5.5.4).

void close();

Effects: Calls rdbuf() -> close() and, if that function fails (returns a null pointer), calls setstate(failbit) (which may throw ios_base::failure) (30.5.5.4).

void open(const string& s, ios_base::openmode mode = ios_base::out);

Effects: Calls open(s.c_str(), mode).

30.9.5 Class template basic_fstream [fstream]

namespace std {

template <class charT, class traits = char_traits<charT> >
class basic_fstream : public basic_iostream<charT, traits> {
  public:
    using char_type = charT;
    using int_type = typename traits::int_type;
    using pos_type = typename traits::pos_type;
    using off_type = typename traits::off_type;
    using traits_type = traits;

    // 30.9.5.1, constructors
    basic_fstream();
    explicit basic_fstream(
      const char* s,
      ios_base::openmode mode = ios_base::in | ios_base::out);

§ 30.9.5
explicit basic_fstream(
    const std::filesystem::path::value_type* s,
    ios_base::openmode mode = ios_base::in | ios_base::out); // wide systems only; see 30.9.1
explicit basic_fstream(
    const string& s,
    ios_base::openmode mode = ios_base::in | ios_base::out);
explicit basic_fstream(
    const filesystem::path& s,
    ios_base::openmode mode = ios_base::in | ios_base::out);
basic_fstream(const basic_fstream& rhs) = delete;
basic_fstream(basic_fstream&& rhs);

// 30.9.5.2, assign and swap
basic_fstream& operator=(const basic_fstream& rhs) = delete;
basic_fstream& operator=(basic_fstream&& rhs);
void swap(basic_fstream& rhs);

// 30.9.5.3, members
basic_filebuf<charT, traits>* rdbuf() const;
bool is_open() const;
void open(
    const char* s,
    ios_base::openmode mode = ios_base::in | ios_base::out);
void open(
    const std::filesystem::path::value_type* s,
    ios_base::openmode mode = ios_base::in | ios_base::out); // wide systems only; see 30.9.1
void open(
    const string& s,
    ios_base::openmode mode = ios_base::in | ios_base::out);
void open(
    const filesystem::path& s,
    ios_base::openmode mode = ios_base::in | ios_base::out);
void close();

private:
    basic_filebuf<charT, traits> sb; // exposition only
};

template <class charT, class traits>
void swap(basic_fstream<charT, traits>& x,
          basic_fstream<charT, traits>& y);

The class template basic_fstream<charT, traits> supports reading and writing from named files. It uses a basic_filebuf<charT, traits> object to control the associated sequences. For the sake of exposition, the maintained data is presented here as:

---

1. The class template basic_fstream<charT, traits> supports reading and writing from named files. It uses a basic_filebuf<charT, traits> object to control the associated sequences. For the sake of exposition, the maintained data is presented here as:

---

1. sb, the basic_filebuf object.

30.9.5.1 basic_fstream constructors [fstream.cons]
basic_fstream();

Effects: Constructs an object of class basic_fstream<charT, traits>, initializing the base class with basic_iostream(&sb) and initializing sb with basic_filebuf<charT, traits>().

explicit basic_fstream(

§ 30.9.5.1
const char* s,
ios_base::openmode mode = ios_base::in | ios_base::out);
explicit basic_fstream(
    const filesystem::path::value_type* s,
ios_base::openmode mode = ios_base::in | ios_base::out);  // wide systems only; see 30.9.1

Effects: Constructs an object of class basic_fstream<charT, traits>, initializing the base class with basic_iostream(&sb) and initializing sb with basic_filebuf<charT, traits>(). Then calls rdbuf()->open(s, mode). If that function returns a null pointer, calls setstate(failbit).

explicit basic_fstream(
    const string& s,
ios_base::openmode mode = ios_base::in | ios_base::out);
explicit basic_fstream(
    const filesystem::path& s,
ios_base::openmode mode = ios_base::in | ios_base::out);

Effects: The same as basic_fstream(s.c_str(), mode).

basic_fstream(basic_fstream&& rhs);

Effects: Move constructs from the rvalue rhs. This is accomplished by move constructing the base class, and the contained basic_filebuf. Next basic_istream<charT, traits>::set_rdbuf(&sb) is called to install the contained basic_filebuf.

30.9.5.2 Assign and swap

basic_fstream& operator=(basic_fstream&& rhs);

Effects: Move assigns the base and members of *this from the base and corresponding members of rhs.

Returns: *this.

void swap(basic_fstream& rhs);

Effects: Exchanges the state of *this and rhs by calling basic_iostream<charT, traits>::swap(rhs) and sb.swap(rhs.sb).

template <class charT, class traits>
void swap(basic_fstream<charT, traits>& x,
          basic_fstream<charT, traits>& y);

Effects: As if by x.swap(y).

30.9.5.3 Member functions

basic_filebuf<charT, traits>* rdbuf() const;

Returns: const_cast<basic_filebuf<charT, traits>*>(&sb).

bool is_open() const;

Returns: rdbuf()->is_open().

void open(
    const char* s,
    ios_base::openmode mode = ios_base::in | ios_base::out);
void open(
    const filesystem::path::value_type* s,
    ios_base::openmode mode = ios_base::in | ios_base::out);  // wide systems only; see 30.9.1
Effects: Calls rdbuf() \(\rightarrow\) open(s, mode). If that function does not return a null pointer calls clear(), otherwise calls setstate(failbit) (which may throw ios_base::failure) (30.5.5.4).

```c
void open(
    const string& s,
    ios_base::openmode mode = ios_base::in | ios_base::out);
void open(
    const filesystem::path& s,
    ios_base::openmode mode = ios_base::in | ios_base::out);
```

Effects: Calls open(s.c_str(), mode).

```c
void close();
```

Effects: Calls rdbuf() \(\rightarrow\) close() and, if that function returns a null pointer, calls setstate(failbit) (which may throw ios_base::failure) (30.5.5.4).

### 30.10 File systems [filesystems]

#### 30.10.1 General [fs.general]

1. This subclause describes operations on file systems and their components, such as paths, regular files, and directories.

#### 30.10.2 Conformance [fs.conformance]

1. Conformance is specified in terms of behavior. Ideal behavior is not always implementable, so the conformance subclauses take that into account.

##### 30.10.2.1 POSIX conformance [fs.conform.9945]

1. Some behavior is specified by reference to POSIX (30.10.3). How such behavior is actually implemented is unspecified. [Note: This constitutes an “as if” rule allowing implementations to call native operating system or other APIs. —end note]

2. Implementations are encouraged to provide such behavior as it is defined by POSIX. Implementations shall document any behavior that differs from the behavior defined by POSIX. Implementations that do not support exact POSIX behavior are encouraged to provide behavior as close to POSIX behavior as is reasonable given the limitations of actual operating systems and file systems. If an implementation cannot provide any reasonable behavior, the implementation shall report an error as specified in 30.10.7. [Note: This allows users to rely on an exception being thrown or an error code being set when an implementation cannot provide any reasonable behavior. —end note]

3. Implementations are not required to provide behavior that is not supported by a particular file system. [Example: The FAT file system used by some memory cards, camera memory, and floppy disks does not support hard links, symlinks, and many other features of more capable file systems, so implementations are not required to support those features on the FAT file system but instead are required to report an error as described above. —end example]

##### 30.10.2.2 Operating system dependent behavior conformance [fs.conform.os]

1. Some behavior is specified as being operating system dependent (30.10.4.12). The operating system an implementation is dependent upon is implementation-defined.

2. It is permissible for an implementation to be dependent upon an operating system emulator rather than the actual underlying operating system.

##### 30.10.2.3 File system race behavior [fs.race.behavior]

1. Behavior is undefined if calls to functions provided by this subclause introduce a file system race (30.10.4.5).
2 If the possibility of a file system race would make it unreliable for a program to test for a precondition before
calling a function described herein, Requires: is not specified for the function. [Note: As a design practice,
preconditions are not specified when it is unreasonable for a program to detect them prior to calling the
function. — end note]

30.10.3 Normative references

This subclause mentions commercially available operating systems for purposes of exposition.³²⁸

30.10.4 Terms and definitions

30.10.4.1 absolute path

A path that unambiguously identifies the location of a file without reference to an additional starting location.
The elements of a path that determine if it is absolute are operating system dependent.

30.10.4.2 directory

A file within a file system that acts as a container of directory entries that contain information about other
files, possibly including other directory files.

30.10.4.3 file

An object within a file system that holds user or system data. Files can be written to, or read from, or both.
A file has certain attributes, including type. File types include regular files and directories. Other types of
files, such as symbolic links (30.10.4.19), may be supported by the implementation.

30.10.4.4 file system

A collection of files and their attributes.

30.10.4.5 file system race

The condition that occurs when multiple threads, processes, or computers interleave access and modification
of the same object within a file system.

30.10.4.6 filename

The name of a file. Filenames dot and dot-dot, consisting solely of one and two period characters respectively,
have special meaning. The following characteristics of filenames are operating system dependent:

— The permitted characters. [Example: Some operating systems prohibit the ASCII control characters
(0x00 – 0x1F) in filenames. — end example]

— The maximum permitted length.

— Filenames that are not permitted.

— Filenames that have special meaning.

— Case awareness and sensitivity during path resolution.

— Special rules that may apply to file types other than regular files, such as directories.

³²⁸ POSIX® is a registered trademark of The IEEE. Windows® is a registered trademark of Microsoft Corporation. This
information is given for the convenience of users of this document and does not constitute an endorsement by ISO or IEC of
these products.
30.10.4.7  [fs.def.hardlink]  
hard link
A link (30.10.4.8) to an existing file. Some file systems support multiple hard links to a file. If the last hard link to a file is removed, the file itself is removed. [Note: A hard link can be thought of as a shared-ownership smart pointer to a file. — end note]

30.10.4.8  [fs.def.link]  
link
An object that associates a filename with a file. Several links can associate names with the same file.

30.10.4.9  [fs.def.native.encode]  
native encoding
For narrow character strings, the operating system dependent current encoding for pathnames (30.10.4.16). For wide character strings, the implementation-defined execution wide-character set encoding (5.3).

30.10.4.10  [fs.def.native]  
native pathname format
The operating system dependent pathname format accepted by the host operating system.

30.10.4.11  [fs.def.normal.form]  
normal form
A path in normal form is said to be normalized. The process of obtaining a normalized path from a path that is not in normal form is called normalization.

Normalization of a generic format pathname means:

1. If the path is empty, stop.
2. Replace each slash character in the root-name with a preferred-separator.
3. Replace each directory-separator with a preferred-separator. [Note: The generic pathname grammar (30.10.8.1) defines directory-separator as one or more slashes and preferred-separators. — end note]
4. Remove each dot filename and any immediately following directory-separator.
5. As long as any appear, remove a non-dot-dot filename immediately followed by a directory-separator and a dot-dot filename, along with any immediately following directory-separator.
6. If there is a root-directory, remove all dot-dot filenames and any directory-separators immediately following them. [Note: These dot-dot filenames attempt to refer to nonexistent parent directories. — end note]
7. If the last filename is dot-dot, remove any trailing directory-separator.
8. If the path is empty, add a dot.

30.10.4.12  [fs.def.osdep]  
operating system dependent behavior
Behavior that is dependent upon the behavior and characteristics of an operating system. See 30.10.2.2.

30.10.4.13  [fs.def.parent]  
parent directory
(of a directory) the directory that both contains a directory entry for the given directory and is represented by the filename dot-dot in the given directory.

30.10.4.14  [fs.def.parent.other]  
parent directory
(of other types of files) a directory containing a directory entry for the file under discussion.
30.10.4.15  
**path**
A sequence of elements that identify the location of a file within a filesystem. The elements are the `root-name_opt`, `root-directory_opt`, and an optional sequence of filenames. The maximum number of elements in the sequence is operating system dependent.

30.10.4.16  
**pathname**
A character string that represents the name of a path. Pathnames are formatted according to the generic pathname format grammar (30.10.8.1) or an operating system dependent native pathname format.

30.10.4.17  
**pathname resolution**
Pathname resolution is the operating system dependent mechanism for resolving a pathname to a particular file in a file hierarchy. There may be multiple pathnames that resolve to the same file. [*Example: POSIX specifies the mechanism in section 4.11, Pathname resolution. — end example*]

30.10.4.18  
**relative path**
A path that is not absolute, and as such, only unambiguously identifies the location of a file when resolved (30.10.4.17) relative to an implied starting location. The elements of a path that determine if it is relative are operating system dependent. [*Note: Pathnames “.” and “..” are relative paths. — end note*]

30.10.4.19  
**symbolic link**
A type of file with the property that when the file is encountered during pathname resolution, a string stored by the file is used to modify the pathname resolution. [*Note: Symbolic links are often called symlinks. A symbolic link can be thought of as a raw pointer to a file. If the file pointed to does not exist, the symbolic link is said to be a “dangling” symbolic link. — end note*]

30.10.5  **Requirements**

1 Throughout this subclause, `char`, `wchar_t`, `char16_t`, and `char32_t` are collectively called *encoded character types*.

2 Functions with template parameters named `EcharT` shall not participate in overload resolution unless `EcharT` is one of the encoded character types.

3 Template parameters named `InputIterator` shall meet the input iterator requirements (27.2.3) and shall have a value type that is one of the encoded character types.

4 [*Note: Use of an encoded character type implies an associated character set and encoding. Since `signed char` and `unsigned char` have no implied character set and encoding, they are not included as permitted types. — end note*]

5 Template parameters named `Allocator` shall meet the Allocator requirements (20.5.3.5).

30.10.5.1  **Namespaces and headers**

1 Unless otherwise specified, references to entities described in this subclause are assumed to be qualified with `::std::filesystem::`.

30.10.6  **Header `<filesystem>` synopsis**

```cpp
namespace std::filesystem {
  // 30.10.8, paths
  class path;
}
```

§ 30.10.6  1242

path weakly_canonical(const path& p, error_code& ec);
```

1 **trivial-clock** is an implementation-defined type that satisfies the TrivialClock requirements (23.17.3) and that is capable of representing and measuring file time values. Implementations should ensure that the resolution and range of file_time_type reflect the operating system dependent resolution and range of file

§ 30.10.6
time values.

### 30.10.7 Error reporting

1 Filesystem library functions often provide two overloads, one that throws an exception to report file system errors, and another that sets an `error_code`. [Note: This supports two common use cases:

   (1.1) Uses where file system errors are truly exceptional and indicate a serious failure. Throwing an exception is an appropriate response.

   (1.2) Uses where file system errors are routine and do not necessarily represent failure. Returning an error code is the most appropriate response. This allows application specific error handling, including simply ignoring the error.

— end note]

2 Functions not having an argument of type `error_code&` handle errors as follows, unless otherwise specified:

   (2.1) When a call by the implementation to an operating system or other underlying API results in an error that prevents the function from meeting its specifications, an exception of type `filesystem_error` shall be thrown. For functions with a single path argument, that argument shall be passed to the `filesystem_error` constructor with a single path argument. For functions with two path arguments, the first of these arguments shall be passed to the `filesystem_error` constructor as the `path1` argument, and the second shall be passed as the `path2` argument. The `filesystem_error` constructor’s `error_code` argument is set as appropriate for the specific operating system dependent error.

   (2.2) Failure to allocate storage is reported by throwing an exception as described in 20.5.5.12.

   (2.3) Destructors throw nothing.

3 Functions having an argument of type `error_code&` handle errors as follows, unless otherwise specified:

   (3.1) If a call by the implementation to an operating system or other underlying API results in an error that prevents the function from meeting its specifications, the `error_code&` argument is set as appropriate for the specific operating system dependent error. Otherwise, `clear()` is called on the `error_code&` argument.

### 30.10.8 Class path

1 An object of class `path` represents a path (30.10.4.15) and contains a pathname (30.10.4.16). Such an object is concerned only with the lexical and syntactic aspects of a path. The path does not necessarily exist in external storage, and the pathname is not necessarily valid for the current operating system or for a particular file system.

2 [Note: Class `path` is used to support the differences between the string types used by different operating systems to represent pathnames, and to perform conversions between encodings when necessary. — end note]

```cpp
namespace std::filesystem {
    class path {
        public:
            using value_type = see below;
            using string_type = basic_string<value_type>;
            static constexpr value_type preferred_separator = see below;

            // 30.10.8.4.1, constructors and destructor
            path() noexcept;
}
```

§ 30.10 1247
path(const path& p);
path(path&& p) noexcept;
path(string_type&& source, format fmt = auto_format);
template <class Source>
    path(const Source& source, format fmt = auto_format);
template <class InputIterator>
    path(InputIterator first, InputIterator last, format fmt = auto_format);
template <class Source>
    path(const Source& source, const locale& loc, format fmt = auto_format);
template <class InputIterator>
    path(const InputIterator first, const InputIterator last, const locale& loc, format fmt = auto_format);
~path();

// 30.10.8.4.2, assignments
d path operator=(const path& p);

path lexically_proximate(const path& base) const;

// 30.10.8.5, iterators
class iterator;
using const_iterator = iterator;

iterator begin() const;
iterator end() const;
};

3 value_type is a typedef for the operating system dependent encoded character type used to represent
pathnames.

4 The value of the preferred_separator member is the operating system dependent preferred-separator
character (30.10.8.1).

5 [Example: For POSIX-based operating systems, value_type is char and preferred_separator is the slash
character (’/’). For Windows-based operating systems, value_type is wchar_t and preferred_separator
is the backslash character (L’\’). — end example]

30.10.8.1 Generic pathname format

pathname:
  root-name_opt root-directory_opt relative-path

root-name:
  operating system dependent sequences of characters
  implementation-defined sequences of characters

root-directory:
  directory-separator

relative-path:
  filename
  filename directory-separator relative-path
  an empty path

filename:
  non-empty sequence of characters other than directory-separator characters

directory-separator:
  preferred-separator directory-separator_opt
  fallback-separator directory-separator_opt

preferred-separator:
  operating system dependent directory separator character

fallback-separator:
  /, if preferred-separator is not /

1 [Note: Operating systems often place restrictions on the characters that may be used in a filename. For wide
portability, users may wish to limit filename characters to the POSIX Portable Filename Character Set:

A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
a b c d e f g h i j k l m n o p q r s t u v w x y z
0 1 2 3 4 5 6 7 8 9 . _ — — end note]
Except in a root-name, multiple successive directory-separator characters are considered to be the same as one directory-separator character.

The filename dot (30.10.4.6) is treated as a reference to the current directory. The filename dot-dot (30.10.4.6) is treated as a reference to the parent directory. What the filename dot-dot refers to relative to root-directory is implementation-defined. Specific filenames may have special meanings for a particular operating system.

A root-name identifies the starting location for pathname resolution (30.10.4.17). If there are no operating system dependent root-names, at least one implementation-defined root-name is required. [Note: Many operating systems define a name beginning with two directory-separator characters as a root-name that identifies network or other resource locations. Some operating systems define a single letter followed by a colon as a drive specifier – a root-name identifying a specific device such as a disk drive. —end note]

If a root-name is otherwise ambiguous, the possibility with the longest sequence of characters is chosen. [Note: On a POSIX-like operating system, it is impossible to have a root-name and a relative-path without an intervening root-directory element. —end note]

30.10.8.2 path conversions [fs.path.cvt]

30.10.8.2.1 path argument format conversions [fs.path.fmt.cvt]

[Note: The format conversions described in this section are not applied on POSIX-based operating systems because on these systems:

1. The generic format is acceptable as a native path.
2. There is no need to distinguish between native format and generic format in function arguments.
3. Paths for regular files and paths for directories share the same syntax.

—end note]

Several functions are defined to accept detected-format arguments, which are character sequences. A detected-format argument represents a path using either a pathname in the generic format (30.10.8.1) or a pathname in the native format (30.10.4.10). Such an argument is taken to be in the generic format if and only if it matches the generic format and is not acceptable to the operating system as a native path.

[Note: Some operating systems may have no unambiguous way to distinguish between native format and generic format arguments. This is by design as it simplifies use for operating systems that do not require disambiguation. An implementation for an operating system where disambiguation is required is permitted to distinguish between the formats. —end note]

Pathnames are converted as needed between the generic and native formats in an operating-system-dependent manner. Let $G(n)$ and $N(g)$ in a mathematical sense be the implementation’s functions that convert native-to-generic and generic-to-native formats respectively. If $g=G(n)$ for some $n$, then $G(N(g))=g$; if $n=N(g)$ for some $g$, then $N(G(n))=n$. [Note: Neither $G$ nor $N$ need be invertible. —end note]

If the native format requires paths for regular files to be formatted differently from paths for directories, the path shall be treated as a directory path if its last element is a directory-separator, otherwise it shall be treated as a path to a regular file.

[Note: A path stores a native format pathname (30.10.8.4.6) and acts as if it also stores a generic format pathname, related as given below. The implementation may generate the generic format pathname based on the native format pathname (and possibly other information) when requested. —end note]

When a path is constructed from or is assigned a single representation separate from any path, the other representation is selected by the appropriate conversion function ($G$ or $N$).

When the (new) value $p$ of one representation of a path is derived from the representation of that or another path, a value $q$ is chosen for the other representation. The value $q$ converts to $p$ (by $G$ or $N$ as appropriate) if any such value does so; $q$ is otherwise unspecified. [Note: If $q$ is the result of converting any path at all, it
is the result of converting $p$. — end note]

### 30.10.8.2.2 path type and encoding conversions

For member function arguments that take character sequences representing paths and for member functions returning strings, value type and encoding conversion is performed if the value type of the argument or return value differs from `path::value_type`. For the argument or return value, the method of conversion and the encoding to be converted to is determined by its value type:

1. **char**: The encoding is the native narrow encoding (30.10.4.9). The method of conversion, if any, is operating system dependent. [Note: For POSIX-based operating systems `path::value_type` is `char` so no conversion from `char` value type arguments or to `char` value type return values is performed. For Windows-based operating systems, the native narrow encoding is determined by calling a Windows API function. — end note] [Note: This results in behavior identical to other C and C++ standard library functions that perform file operations using narrow character strings to identify paths. Changing this behavior would be surprising and error prone. — end note]

2. **wchar_t**: The encoding is the native wide encoding (30.10.4.9). The method of conversion is unspecified. [Note: For Windows-based operating systems `path::value_type` is `wchar_t` so no conversion from `wchar_t` value type arguments or to `wchar_t` value type return values is performed. — end note]

3. **char16_t**: The encoding is UTF-16. The method of conversion is unspecified.

4. **char32_t**: The encoding is UTF-32. The method of conversion is unspecified.

If the encoding being converted to has no representation for source characters, the resulting converted characters, if any, are unspecified. Implementations should not modify member function arguments if already of type `path::value_type`.

### 30.10.8.3 path requirements

In addition to the requirements (30.10.5), function template parameters named `Source` shall be one of:

1. **basic_string<CharT, traits, Allocator>**: A function argument `const Source& source` shall have an effective range `[source.begin(), source.end())`.

2. **basic_string_view<CharT, traits>**: A function argument `const Source& source` shall have an effective range `[source.begin(), source.end())`.

3. A type meeting the input iterator requirements that iterates over a NTCTS. The value type shall be an encoded character type. A function argument `const Source& source` shall have an effective range `[source, end)` where `end` is the first iterator value with an element value equal to `iterator_traits<Source>::value_type()`.

4. A character array that after array-to-pointer decay results in a pointer to the start of a NTCTS. The value type shall be an encoded character type. A function argument `const Source& source` shall have an effective range `[source, end)` where `end` is the first iterator value with an element value equal to `iterator_traits<decay_t<Source>>::value_type()`.

2 Functions taking template parameters named `Source` shall not participate in overload resolution unless either

1. `Source` is a specialization of `basic_string` or `basic_string_view`, or

2. the qualified-id `iterator_traits<decay_t<Source>>::value_type` is valid and denotes a possibly `const` encoded character type (17.8.2).

[Note: See path conversions (30.10.8.2) for how the value types above and their encodings convert to `path::value_type` and its encoding. — end note]

Arguments of type `Source` shall not be null pointers.
30.10.8.4 path members

30.10.8.4.1 path constructors

path() noexcept;

Effects: Constructs an object of class path.

Postconditions: empty() == true.

path(const path& p);
path(path&& p) noexcept;

Effects: Constructs an object of class path having the same pathname in the native and generic formats, respectively, as the original value of p. In the second form, p is left in a valid but unspecified state.

path(string_type&& source, format fmt = auto_format);

Effects: Constructs an object of class path for which the pathname in the detected-format of source has the original value of source (30.10.8.2.1), converting format if required (30.10.8.2.1). source is left in a valid but unspecified state.

template <class Source>
path(const Source& source, format fmt = auto_format);
template <class InputIterator>
path(InputIterator first, InputIterator last, format fmt = auto_format);

Effects: Let s be the effective range of source (30.10.8.3) or the range [first, last), with the encoding converted if required (30.10.8.2). Finds the detected-format of s (30.10.8.2.1) and constructs an object of class path for which the pathname in that format is s.

template <class Source>
path(const Source& source, const locale& loc, format fmt = auto_format);
template <class InputIterator>
path(InputIterator first, InputIterator last, const locale& loc, format fmt = auto_format);

Requires: The value type of Source and InputIterator is char.

Effects: Let s be the effective range of source or the range [first, last), after converting the encoding as follows:

(7.1) — If value_type is wchar_t, converts to the native wide encoding (30.10.4.9) using the codecvt<wchar_t, char, mbstate_t> facet of loc.

(7.2) — Otherwise a conversion is performed using the codecvt<wchar_t, char, mbstate_t> facet of loc, and then a second conversion to the current narrow encoding.

Finds the detected-format of s (30.10.8.2.1) and constructs an object of class path for which the pathname in that format is s.

[Example: A string is to be read from a database that is encoded in ISO/IEC 8859-1, and used to create a directory:

```cpp
namespace fs = std::filesystem;
std::string latin1_string = read_latin1_data();
codecvt_8859_1<wchar_t> latin1_facet;
std::locale latin1_locale(std::locale(), latin1_facet);
fs::create_directory(fs::path(latin1_string, latin1_locale));
```

For POSIX-based operating systems, the path is constructed by first using latin1_facet to convert ISO/IEC 8859-1 encoded latin1_string to a wide character string in the native wide encoding (30.10.4.9). The resulting wide string is then converted to a narrow character pathname string in the current native narrow encoding. If the native wide encoding is UTF-16 or UTF-32, and the current

§ 30.10.8.4.1 1253
native narrow encoding is UTF-8, all of the characters in the ISO/IEC 8859-1 character set will be
converted to their Unicode representation, but for other native narrow encodings some characters may
have no representation.

For Windows-based operating systems, the path is constructed by using `latin1_facet` to convert
ISO/IEC 8859-1 encoded `latin1_string` to a UTF-16 encoded wide character pathname string. All of
the characters in the ISO/IEC 8859-1 character set will be converted to their Unicode representation.

--- end example

### 30.10.8.4.2 path assignments

```cpp
path& operator=(const path& p);
```

1. **Effects:** If `*this` and `p` are the same object, has no effect. Otherwise, sets both respective pathnames
   of `*this` to the respective pathnames of `p`.

2. **Returns:** `*this`.

```cpp
path& operator=(path&& p) noexcept;
```

3. **Effects:** If `*this` and `p` are the same object, has no effect. Otherwise, sets both respective pathnames
   of `*this` to the respective pathnames of `p`. `p` is left in a valid but unspecified state.  
   **Note:** A valid implementation is `swap(p)`.  
   **end note**

4. **Returns:** `*this`.

```cpp
path& operator=(string_type&& source);
push_assign(string_type&& source);
```

5. **Effects:** Sets the pathname in the detected-format of `source` to the original value of `source`. `source`
   is left in a valid but unspecified state.

6. **Returns:** `*this`.

```cpp
template <class Source>
path& operator=(const Source& source);
template <class Source>
push_assign(const Source& source);
template <class InputIterator>
path& assign(InputIterator first, InputIterator last);
```

7. **Effects:** Let `s` be the effective range of `source` (30.10.8.3) or the range `[first, last)`, with the
   encoding converted if required (30.10.8.2). Finds the detected-format of `s` (30.10.8.2.1) and sets the
   pathname in that format to `s`.

8. **Returns:** `*this`.

### 30.10.8.4.3 path appends

The append operations use `operator/=` to denote their semantic effect of appending `preferred-separator`
when needed.

```cpp
path& operator/=(const path& p);
```

1. **Effects:** If `p.is_absolute() || (p.has_root_name() && p.root_name() != root_name())`, then
   `operator=(p)`.

2. **Otherwise,** modifies `*this` as if by these steps:

   - If `p.has_root_directory()`, then removes any root directory and relative path from the generic
     format pathname. Otherwise, if `!has_root_directory() && is_absolute()` is true or if `has_
     filename()` is true, then appends `path::preferred_separator` to the generic format pathname.
Then appends the native format pathname of p, omitting any root-name from its generic format pathname, to the native format pathname.

[Example: Even if //host is interpreted as a root-name, both of the paths path("//host")/"foo" and path("//host")/"foo" equal "/host/foo".]

Expression examples:

// On POSIX,
path("foo") / "";  // yields "foo/
p/tho/"bar";  // yields "/bar"  
// On Windows, backslashes replace slashes in the above yields

// On Windows,
path("foo") / "c:/bar";  // yields "c:/bar" 
path("foo") / "c:";  // yields "c:" 
path("c:" / "";  // yields "c:" 
path("c:foo") / "bar";  // yields "c:/bar" 
path("c:foo") / "c:bar";  // yields "c:foo/bar"

—end example]

Returns: *this.

template <class Source>
path& operator/=(const Source& source);
template <class Source>
path& append(const Source& source);

Effects: Equivalent to: return operator/=(path(source));

template <class InputIterator>
path& append(InputIterator first, InputIterator last);

Effects: Equivalent to: return operator/=(path(first, last));

30.10.8.4.4  path concatenation

path& operator+=(const path& x);
path& operator+=(const string_type& x);
path& operator+=(basic_string_view<value_type> x);
path& operator+=(const value_type* x);
path& operator+=(value_type x);
template <class Source>
path& operator+=(const Source& x);
template <class EcharT>
path& operator+=(EcharT x);
template <class Source>
path& concat(const Source& x);

Effects: Appends path(x).native() to the pathname in the native format. [Note: This directly manipulates the value of native() and may not be portable between operating systems. — end note]

Returns: *this.

template <class InputIterator>
path& concat(InputIterator first, InputIterator last);

Effects: Equivalent to return *this += path(first, last).

30.10.8.4.5  path modifiers
void clear() noexcept;

Postconditions: empty() == true.

path& make_preferred();

Effects: Each directory-separator of the pathname in the generic format is converted to preferred-separator.

Returns: *this.

[Example:
  path p("foo/bar");
  std::cout << p << 'n';
  p.make_preferred();
  std::cout << p << 'n';
]

On an operating system where preferred-separator is a slash, the output is:
"foo/bar"
"foo/bar"

On an operating system where preferred-separator is a backslash, the output is:
"foo/bar"
"foo\bar"
— end example]

path& remove_filename();

Postconditions: !has_filename().

Effects: Remove the generic format pathname of filename() from the generic format pathname.

Returns: *this.

[Example:
  path("foo/bar").remove_filename(); // yields "foo/
  path("foo/").remove_filename(); // yields "foo/
  path("/foo").remove_filename(); // yields "/
  path("/").remove_filename(); // yields "/
]

— end example]

path& replace_filename(const path& replacement);

Effects: Equivalent to:

remove_filename();
operator/=(replacement);

Returns: *this.

[Example:
  path("/foo").replace_filename("bar"); // yields "/bar" on POSIX
  path("/").replace_filename("bar"); // yields "/bar" on POSIX
]

— end example]

path& replace_extension(const path& replacement = path());

Effects:

— Any existing extension() (30.10.8.4.9) is removed from the pathname in the generic format, then

§ 30.10.8.4.5
If replacement is not empty and does not begin with a dot character, a dot character is appended to the pathname in the generic format, then

```
operator+=(replacement);
```

Returns: *this.

```
void swap(path& rhs) noexcept;
```

Effects: Swaps the contents (in all formats) of the two paths.

Complexity: Constant time.

### 30.10.8.4.6 path native format observers

The string returned by all native format observers is in the native pathname format (30.10.4.10).

```
const string_type& native() const noexcept;
```

Returns: The pathname in the native format.

```
const value_type* c_str() const noexcept;
```

Returns: Equivalent to native().c_str().

```
operator string_type() const;
```

Returns: native().

[Note: Conversion to string_type is provided so that an object of class path can be given as an argument to existing standard library file stream constructors and open functions. —end note]

```
template <class EcharT, class traits = char_traits<EcharT>,
         class Allocator = allocator<EcharT>>

§ 30.10.8.4.7 1257

basic_string<EcharT, traits, Allocator>
string(const Allocator& a = Allocator()) const;
```

Returns: native().

Remarks: All memory allocation, including for the return value, shall be performed by a. Conversion, if any, is specified by 30.10.8.2.

```
std::string string() const;
std::wstring wstring() const;
std::string u8string() const;
std::u16string u16string() const;
std::u32string u32string() const;
```

Returns: pathstring.

Remarks: Conversion, if any, is performed as specified by 30.10.8.2. The encoding of the string returned by u8string() is always UTF-8.

### 30.10.8.4.7 path generic format observers

Generic format observer functions return strings formatted according to the generic pathname format (30.10.8.1). A single slash (`/`) character is used as the directory-separator.

[Example: On an operating system that uses backslash as its preferred-separator,

```
path("foo\bar").generic_string()
```

returns "foo/bar". — end example]
basic_string<EcharT, traits, Allocator>
generic_string(const Allocator& a = Allocator()) const;

Returns: The pathname in the generic format.

Remarks: All memory allocation, including for the return value, shall be performed by a. Conversion, if any, is specified by 30.10.8.2.

std::string generic_string() const;
std::wstring generic_wstring() const;
std::string generic_u8string() const;
std::u16string generic_u16string() const;
std::u32string generic_u32string() const;

Returns: The pathname in the generic format.

Remarks: Conversion, if any, is specified by 30.10.8.2. The encoding of the string returned by generic_u8string() is always UTF-8.

30.10.8.4.8 path compare [fs.path.compare]

int compare(const path& p) const noexcept;

Returns:

(1.1) A value less than 0, if native() for the elements of *this are lexicographically less than native() for the elements of p; otherwise,

(1.2) a value greater than 0, if native() for the elements of *this are lexicographically greater than native() for the elements of p; otherwise,

(1.3) 0.

Remarks: The elements are determined as if by iteration over the half-open range [begin(), end()) for *this and p.

int compare(const string_type& s) const
int compare(basic_string_view<value_type> s) const;

Returns: compare(path(s)).

int compare(const value_type* s) const

Returns: compare(path(s)).

30.10.8.4.9 path decomposition [fs.path.decompose]

path root_name() const;

Returns: root-name, if the pathname in the generic format includes root-name, otherwise path().

path root_directory() const;

Returns: root-directory, if the pathname in the generic format includes root-directory, otherwise path().

path root_path() const;

Returns: root_name() / root_directory().

path relative_path() const;

Returns: A path composed from the pathname in the generic format, if !empty(), beginning with the first filename after root-path. Otherwise, path().

path parent_path() const;
Returns: *this if !has_relative_path(), otherwise a path whose generic format pathname is the longest prefix of the generic format pathname of *this that produces one fewer element in its iteration.

path filename() const;

Returns: relative_path().empty() ? path() : *--end().

<table>
<thead>
<tr>
<th>Example:</th>
</tr>
</thead>
<tbody>
<tr>
<td>path(&quot;/foo/bar.txt&quot;).filename(); // yields &quot;bar.txt&quot;</td>
</tr>
<tr>
<td>path(&quot;/foo/bar&quot;).filename(); // yields &quot;bar&quot;</td>
</tr>
<tr>
<td>path(&quot;/foo/bar/&quot;).filename(); // yields &quot;&quot;</td>
</tr>
<tr>
<td>path(&quot;/&quot;).filename(); // yields &quot;&quot;</td>
</tr>
<tr>
<td>path(&quot;/host&quot;).filename(); // yields &quot;&quot;</td>
</tr>
<tr>
<td>path(&quot;.&quot;).filename(); // yields &quot;.&quot;</td>
</tr>
<tr>
<td>path(&quot;..&quot;).filename(); // yields &quot;.&quot;</td>
</tr>
</tbody>
</table>

— end example |

path stem() const;

Returns: Let f be the generic format pathname of filename(). Returns a path whose pathname in the generic format is

(8.1) f, if it contains no periods other than a leading period or consists solely of one or two periods;

(8.2) otherwise, the prefix of f ending before its last period.

<table>
<thead>
<tr>
<th>Example:</th>
</tr>
</thead>
<tbody>
<tr>
<td>std::cout &lt;&lt; path(&quot;/foo/bar.txt&quot;).stem(); // outputs &quot;bar&quot;</td>
</tr>
<tr>
<td>path p = &quot;foo.bar.baz.tar&quot;;</td>
</tr>
<tr>
<td>for (; !p.extension().empty(); p = p.stem())</td>
</tr>
<tr>
<td>std::cout &lt;&lt; p.extension() &lt;&lt; 'n';</td>
</tr>
<tr>
<td>// outputs: .tar</td>
</tr>
<tr>
<td>// .baz</td>
</tr>
<tr>
<td>// .bar</td>
</tr>
</tbody>
</table>

— end example |

path extension() const;

Returns: a path whose pathname in the generic format is the suffix of filename() not included in stem().

<table>
<thead>
<tr>
<th>Example:</th>
</tr>
</thead>
<tbody>
<tr>
<td>path(&quot;/foo/bar.txt&quot;).extension(); // yields &quot;.txt&quot; and stem() is &quot;bar&quot;</td>
</tr>
<tr>
<td>path(&quot;/foo/bar&quot;).extension(); // yields &quot;&quot; and stem() is &quot;bar&quot;</td>
</tr>
<tr>
<td>path(&quot;/foo/.profile&quot;).extension(); // yields &quot;&quot; and stem() is &quot;.profile&quot;</td>
</tr>
<tr>
<td>path(&quot;.bar&quot;).extension(); // yields &quot;&quot; and stem() is &quot;.bar&quot;</td>
</tr>
<tr>
<td>path(&quot;..bar&quot;).extension(); // yields &quot;.bar&quot; and stem() is &quot;.&quot;</td>
</tr>
</tbody>
</table>

— end example |

[Note: The period is included in the return value so that it is possible to distinguish between no extension and an empty extension. — end note]

[Note: On non-POSIX operating systems, for a path p, it may not be the case that p.stem() + p.extension() == p.filename(), even though the generic format pathnames are the same. — end note]
bool empty() const noexcept;

Returns: true if the pathname in the generic format is empty, else false.

bool has_root_path() const;

Returns: !root_path().empty().

bool has_root_name() const;

Returns: !root_name().empty().

bool has_root_directory() const;

Returns: !root_directory().empty().

bool has_relative_path() const;

Returns: !relative_path().empty().

bool has_parent_path() const;

Returns: !parent_path().empty().

bool has_filename() const;

Returns: !filename().empty().

bool has_stem() const;

Returns: !stem().empty().

bool has_extension() const;

Returns: !extension().empty().

bool is_absolute() const;

Returns: true if the pathname in the native format contains an absolute path (30.10.4.1), else false.

[Example: path("/").is_absolute() is true for POSIX-based operating systems, and false for Windows-based operating systems. — end example]

bool is_relative() const;

Returns: !is_absolute().

30.10.8.4.11 path generation

path lexically_normal() const;

Returns: A path whose pathname in the generic format is the normal form (30.10.4.11) of the pathname in the generic format of *this.

[Example:
assert(path("foo/./bar/..").lexically_normal() == "foo/");
assert(path("foo//bar/..").lexically_normal() == "foo/");
The above assertions will succeed. On Windows, the returned path’s directory-separator characters will be backslashes rather than slashes, but that does not affect path equality. — end example]

path lexically_relative(const path& base) const;

Returns: *this made relative to base. Does not resolve (30.10.4.17) symlinks. Does not first normalize (30.10.4.11) *this or base.
Effects: If \( \text{root\_name()} \neq \text{base.root\_name()} \) is true or \( \text{is\_absolute()} \neq \text{base.is\_absolute()} \) is true or \( \text{!has\_root\_directory()} \&\& \text{base.has\_root\_directory()} \) is true, returns \( \text{path()} \). Determines the first mismatched element of \( \text{*this} \) and \( \text{base} \) as if by:

```c++
auto [a, b] = mismatch(begin(), end(), base.begin(), base.end());
```

Then,

1. if \( a == \text{end()} \) and \( b == \text{base.end()} \), returns \( \text{path(".")} \); otherwise
2. let \( n \) be the number of \text{filename} elements in \([b, \text{base.end()}]\) that are not \text{dot} or \text{dot-dot} minus the number that are \text{dot-dot}. If \( n<0 \), returns \( \text{path()} \); otherwise
   - returns an object of class \text{path} that is default-constructed, followed by
     - application of \( \text{operator/}(\text{path("."}) n \) times, and then
     - application of \( \text{operator/} \) for each element in \([a, \text{end()}]\).

[Example:]

```c++
assert(path("/a/d").lexically_relative("/a/b/c") == "../../d");
assert(path("/a/b/c").lexically_relative("/a/d") == ".../b/c");
assert(path("a/b/c").lexically_relative("a") == "b/c");
assert(path("a/b/c").lexically_relative("a/b/c/z/y") == ".../..");
assert(path("a/b/c").lexically_relative("a/b/c") == ".c");
assert(path("a/b").lexically_relative("c/d") == ".../a/b");
```

The above assertions will succeed. On Windows, the returned path’s directory-separator characters will be backslashes rather than slashes, but that does not affect path equality. — end example]

[Note: If symlink following semantics are desired, use the operational function \text{relative()}. — end note]

[Note: If normalization (30.10.4.11) is needed to ensure consistent matching of elements, apply \text{lexically\_normal()} to \text{*this}, \text{base}, or both. — end note]

\[
\text{path lexically\_proximate(const path& base) const;}
\]

Returns: If the value of \text{lexically\_relative(base)} is not an empty path, return it. Otherwise return \text{*this}.

[Note: If symlink following semantics are desired, use the operational function \text{proximate()}. — end note]

[Note: If normalization (30.10.4.11) is needed to ensure consistent matching of elements, apply \text{lexically\_normal()} to \text{*this}, \text{base}, or both. — end note]

30.10.8.5 path iterators

Path iterators iterate over the elements of the pathname in the generic format (30.10.8.1).

A \text{path\_\_iterator} is a constant iterator satisfying all the requirements of a bidirectional iterator (27.2.6) except that, for dereferenceable iterators \( a \) and \( b \) of type \text{path\_\_iterator} with \( a == b \), there is no requirement that \( \&a \) and \( \&b \) are bound to the same object. Its \text{value\_type} is \text{path}.

Calling any non-const member function of a \text{path} object invalidates all iterators referring to elements of that object.

For the elements of the pathname in the generic format, the forward traversal order is as follows:

1. The root-name element, if present.
2. The root-directory element, if present. [Note: The generic format is required to ensure lexicographical comparison works correctly. — end note]
— Each successive `filename` element, if present.
— An empty element, if a trailing non-root `directory-separator` is present.

The backward traversal order is the reverse of forward traversal.

```cpp
iterator begin() const;

Returns: An iterator for the first present element in the traversal list above. If no elements are present, the end iterator.
```

```cpp
iterator end() const;

Returns: The end iterator.
```

### 30.10.8.6 path non-member functions

#### void swap(path& lhs, path& rhs) noexcept;

**Effects:** Equivalent to: `lhs.swap(rhs);`

```cpp
size_t hash_value (const path& p) noexcept;
```

**Returns:** A hash value for the path `p`. If for two paths, `p1 == p2` then `hash_value(p1) == hash_value(p2)`.

```cpp
bool operator< (const path& lhs, const path& rhs) noexcept;
```

**Returns:** `lhs.compare(rhs) < 0`.

```cpp
bool operator<=(const path& lhs, const path& rhs) noexcept;
```

**Returns:** `!(rhs < lhs)`.

```cpp
bool operator> (const path& lhs, const path& rhs) noexcept;
```

**Returns:** `rhs < lhs`.

```cpp
bool operator>=(const path& lhs, const path& rhs) noexcept;
```

**Returns:** `!(lhs < rhs)`.

```cpp
bool operator==(const path& lhs, const path& rhs) noexcept;
```

**Returns:** `!(lhs < rhs) && !(rhs < lhs)`.

**Note:** Path equality and path equivalence have different semantics.

— Equality is determined by the `path` non-member `operator==`, which considers the two path’s lexical representations only. *Example: `path("foo") == "bar"` is never true. — end example*]

— Equivalence is determined by the `equivalent()` non-member function, which determines if two paths resolve (30.10.4.17) to the same file system entity. *Example: `equivalent("foo", "bar")` will be `true` when both paths resolve to the same file. — end example*

Programmers wishing to determine if two paths are “the same” must decide if “the same” means “the same representation” or “resolve to the same actual file”, and choose the appropriate function accordingly. — end note]

```cpp
bool operator!=(const path& lhs, const path& rhs) noexcept;
```

**Returns:** `!(lhs == rhs)`.

```cpp
path operator/ (const path& lhs, const path& rhs);
```

**Effects:** Equivalent to: `return path(lhs) /= rhs;`
30.10.8.6.1 path inserter and extractor
[fs.path.io]

template <class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const path& p);
1 Effects: Equivalent to: os << quoted(p.string<charT, traits>()); [Note: The quoted function is described in 30.7.8. — end note]
2 Returns: os.

template <class charT, class traits>
basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& is, path& p);
3 Effects: Equivalent to:
   basic_string<charT, traits> tmp;
   is >> quoted(tmp);
   p = tmp;
4 Returns: is.

30.10.8.6.2 path factory functions
[fs.path.factory]

template <class Source>
path u8path(const Source& source);
template <class InputIterator>
path u8path(InputIterator first, InputIterator last);
1 Requires: The source and [first, last) sequences are UTF-8 encoded. The value type of Source and InputIterator is char.
2 Returns:
(2.1) — If value_type is char and the current native narrow encoding (30.10.4.9) is UTF-8, return path(source) or path(first, last); otherwise,
(2.2) — if value_type is wchar_t and the native wide encoding is UTF-16, or if value_type is char16_t or char32_t, convert source or [first, last) to a temporary, tmp, of type string_type and return path(tmp); otherwise,
(2.3) — convert source or [first, last) to a temporary, tmp, of type u32string and return path(tmp).
3 Remarks: Argument format conversion (30.10.8.2.1) applies to the arguments for these functions. How Unicode encoding conversions are performed is unspecified.
4 [Example: A string is to be read from a database that is encoded in UTF-8, and used to create a directory using the native encoding for filenames:
   namespace fs = std::filesystem;
   std::string utf8_string = read_utf8_data();
   fs::create_directory(fs::u8path(utf8_string));]
   For POSIX-based operating systems with the native narrow encoding set to UTF-8, no encoding or type conversion occurs.
   For POSIX-based operating systems with the native narrow encoding not set to UTF-8, a conversion to UTF-32 occurs, followed by a conversion to the current native narrow encoding. Some Unicode characters may have no native character set representation.
   For Windows-based operating systems a conversion from UTF-8 to UTF-16 occurs. — end example]

30.10.9 Class filesystem_error
[fs.class.filesystem_error]

§ 30.10.9
namespace std::filesystem {
    class filesystem_error : public system_error {
        public:
            filesystem_error(const string& what_arg, error_code ec);
            filesystem_error(const string& what_arg,
                             const path& p1, error_code ec);
            filesystem_error(const string& what_arg,
                             const path& p1, const path& p2, error_code ec);

            const path& path1() const noexcept;
            const path& path2() const noexcept;
            const char* what() const noexcept override;
    };
}

1 The class filesystem_error defines the type of objects thrown as exceptions to report file system errors from functions described in this subclause.

30.10.9.1 filesystem_error members

Constructors are provided that store zero, one, or two paths associated with an error.

filesystem_error(const string& what_arg, error_code ec);

2 Postconditions: The postconditions of this function are indicated in Table 119.

Table 119 — filesystem_error(const string&, error_code) effects

<table>
<thead>
<tr>
<th>Expression</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>runtime_error::what()</td>
<td>what_arg.c_str()</td>
</tr>
<tr>
<td>code()</td>
<td>ec</td>
</tr>
<tr>
<td>path1().empty()</td>
<td>true</td>
</tr>
<tr>
<td>path2().empty()</td>
<td>true</td>
</tr>
</tbody>
</table>

filesystem_error(const string& what_arg, const path& p1, error_code ec);

3 Postconditions: The postconditions of this function are indicated in Table 120.

Table 120 — filesystem_error(const string&, const path&, error_code) effects

<table>
<thead>
<tr>
<th>Expression</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>runtime_error::what()</td>
<td>what_arg.c_str()</td>
</tr>
<tr>
<td>code()</td>
<td>ec</td>
</tr>
<tr>
<td>path1()</td>
<td>Reference to stored copy of p1</td>
</tr>
<tr>
<td>path2().empty()</td>
<td>true</td>
</tr>
</tbody>
</table>

filesystem_error(const string& what_arg, const path& p1, const path& p2, error_code ec);

4 Postconditions: The postconditions of this function are indicated in Table 121.

const path& path1() const noexcept;

5 Returns: A reference to the copy of p1 stored by the constructor, or, if none, an empty path.

const path& path2() const noexcept;

§ 30.10.9.1
Table 121 — filesystem_error(const string&, const path&, const path&, error_code) effects

<table>
<thead>
<tr>
<th>Expression</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>runtime_error::what()</td>
<td>what_arg.c_str()</td>
</tr>
<tr>
<td>code()</td>
<td>ec</td>
</tr>
<tr>
<td>path1()</td>
<td>Reference to stored copy of p1</td>
</tr>
<tr>
<td>path2()</td>
<td>Reference to stored copy of p2</td>
</tr>
</tbody>
</table>

Returns: A reference to the copy of p2 stored by the constructor, or, if none, an empty path.

const char* what() const noexcept override;

Returns: A string containing runtime_error::what(). The exact format is unspecified. Implementations are encouraged but not required to include path1.native_string() if not empty, path2.native_string() if not empty, and system_error::what() strings in the returned string.

30.10.10 Enumerations

30.10.10.1 Enum path::format

This enum specifies constants used to identify the format of the character sequence, with the meanings listed in Table 122.

Table 122 — Enum path::format

<table>
<thead>
<tr>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>native_format</td>
<td>The native pathname format.</td>
</tr>
<tr>
<td>generic_format</td>
<td>The generic pathname format.</td>
</tr>
<tr>
<td>auto_format</td>
<td>The interpretation of the format of the character sequence is implementation-defined. The implementation may inspect the content of the character sequence to determine the format. [Note: For POSIX-based systems, native and generic formats are equivalent and the character sequence should always be interpreted in the same way. —end note]</td>
</tr>
</tbody>
</table>

30.10.10.2 Enum class file_type

This enum class specifies constants used to identify file types, with the meanings listed in Table 123.

30.10.10.3 Enum class copy_options

The enum class type copy_options is a bitmask type (20.4.2.1.4) that specifies bitmask constants used to control the semantics of copy operations. The constants are specified in option groups with the meanings listed in Table 124. Constant none is shown in each option group for purposes of exposition; implementations shall provide only a single definition.

30.10.10.4 Enum class perms

The enum class type perms is a bitmask type (20.4.2.1.4) that specifies bitmask constants used to identify file permissions, with the meanings listed in Table 125.
### Table 123 — Enum class `file_type`

<table>
<thead>
<tr>
<th>Constant</th>
<th>Meaning</th>
</tr>

</table>

30.10.10.5 Enum class perm_options

The enum class type perm_options is a bitmask type (20.4.2.1.4) that specifies bitmask constants used to control the semantics of permissions operations, with the meanings listed in Table 126. The bitmask constants are bitmask elements. In Table 126 perm denotes a value of type perms passed to permissions.

Table 126 — Enum class perm_options

<table>
<thead>
<tr>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>replace</td>
<td>permissions shall replace the file’s permission bits with perm</td>
</tr>
<tr>
<td>add</td>
<td>permissions shall replace the file’s permission bits with the bitwise OR of perm and the file’s current permission bits.</td>
</tr>
<tr>
<td>remove</td>
<td>permissions shall replace the file’s permission bits with the bitwise AND of the complement of perm and the file’s current permission bits.</td>
</tr>
<tr>
<td>follow</td>
<td>permissions shall change the permissions of a symbolic link itself rather than the permissions of the file the link resolves to.</td>
</tr>
</tbody>
</table>

§ 30.10.10.5
30.10.10.6 Enum class directory_options

The `enum class directory_options` is a bitmask type (20.4.2.1.4) that specifies bitmask constants used to identify directory traversal options, with the meanings listed in Table 127.

<table>
<thead>
<tr>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>(Default) Skip directory symlinks, permission denied is an error.</td>
</tr>
<tr>
<td>follow_directory_symlink</td>
<td>Follow rather than skip directory symlinks.</td>
</tr>
<tr>
<td>skip_permission_denied</td>
<td>Skip directories that would otherwise result in permission denied.</td>
</tr>
</tbody>
</table>

30.10.11 Class file_status

An object of type `file_status` stores information about the type and permissions of a file.

30.10.11.1 file_status constructors

```cpp
explicit file_status(file_type ft, perms prms = perms::unknown) noexcept;
```

Postconditions: `type() == ft` and `permissions() == prms`.

30.10.11.2 file_status observers

```cpp
file_type type() const noexcept;
perms permissions() const noexcept;
```
Returns: The value of permissions() specified by the postconditions of the most recent call to a constructor, operator=, or permissions(perms) function.

30.10.11.3 file_status modifiers

void type(file_type ft) noexcept;

Postconditions: type() == ft.

void permissions(perms prms) noexcept;

Postconditions: permissions() == prms.

30.10.12 Class directory_entry

namespace std::filesystem {
    class directory_entry {
        public:
            // 30.10.12.1, constructors and destructor
            directory_entry() noexcept = default;
            directory_entry(const directory_entry&) = default;
            directory_entry(directory_entry&&) noexcept = default;
            explicit directory_entry(const path& p);
            directory_entry(const path& p, error_code& ec);
            ~directory_entry();

            // assignments:
            directory_entry& operator=(const directory_entry&) = default;
            directory_entry& operator=(directory_entry&&) noexcept = default;

            // 30.10.12.2, modifiers
            void assign(const path& p);
            void assign(const path& p, error_code& ec);
            void replace_filename(const path& p);
            void replace_filename(const path& p, error_code& ec);
            void refresh();
            void refresh(error_code& ec) noexcept;

            // 30.10.12.3, observers
            const path& path() const noexcept;
            operator const path&() const noexcept;
            bool exists() const;
            bool exists(error_code& ec) const noexcept;
            bool is_block_file() const;
            bool is_block_file(error_code& ec) const noexcept;
            bool is_character_file() const;
            bool is_character_file(error_code& ec) const noexcept;
            bool is_directory() const;
            bool is_directory(error_code& ec) const noexcept;
            bool is_fifo() const;
            bool is_fifo(error_code& ec) const noexcept;
            bool is_other() const;
            bool is_other(error_code& ec) const noexcept;
            bool is_regular_file() const;
            bool is_regular_file(error_code& ec) const noexcept;
            bool is_socket() const;
            bool is_socket(error_code& ec) const noexcept;
    }
}
bool is_symlink() const;
bool is_symlink(error_code& ec) const noexcept;
uintmax_t file_size() const;
uintmax_t file_size(error_code& ec) const noexcept;
uintmax_t hard_link_count() const;
uintmax_t hard_link_count(error_code& ec) const noexcept;
file_time_type last_write_time() const;
file_time_type last_write_time(error_code& ec) const noexcept;
file_status status() const;
file_status status(error_code& ec) const noexcept;
file_status symlink_status() const;
file_status symlink_status(error_code& ec) const noexcept;

bool operator< (const directory_entry& rhs) const noexcept;
bool operator==(const directory_entry& rhs) const noexcept;
bool operator!=(const directory_entry& rhs) const noexcept;
bool operator<=(const directory_entry& rhs) const noexcept;
bool operator> (const directory_entry& rhs) const noexcept;
bool operator>=(const directory_entry& rhs) const noexcept;

private:
  path pathobject; // exposition only
  friend class directory_iterator; // exposition only
};

1 A directory_entry object stores a path object and may store additional objects for file attributes such as
hard link count, status, symlink status, file size, and last write time.

2 Implementations are encouraged to store such additional file attributes during directory iteration if their
values are available and storing the values would allow the implementation to eliminate file system accesses
by directory_entry observer functions (30.10.15). Such stored file attribute values are said to be cached.

[ Note: For purposes of exposition, class directory_iterator (30.10.13) is shown above as a friend of class
directory_entry. Friendship allows the directory_iterator implementation to cache already available
attribute values directly into a directory_entry object without the cost of an unneeded call to refresh().
—end note ]

4 [ Example:

  using namespace std::filesystem;

  // use possibly cached last write time to minimize disk accesses
  for (auto& x : directory_iterator("."))
  {
    std::cout << x.path() << " " << x.last_write_time() << std::endl;
  }

  // call refresh() to refresh a stale cache
  for (auto& x : directory_iterator("."))
  {
    lengthy_function(x.path()); // cache becomes stale
    x.refresh();
    std::cout << x.path() << " " << x.last_write_time() << std::endl;
  }

On implementations that do not cache the last write time, both loops will result in a potentially expensive
call to the std::filesystem::last_write_time function. On implementations that do cache the last write
time, the first loop will use the cached value and so will not result in a potentially expensive call to the
`std::filesystem::last_write_time` function. The code is portable to any implementation, regardless of
whether or not it employs caching. — end example]

30.10.12.1 directory_entry constructors

```cpp
explicit directory_entry(const path& p);
directory_entry(const path& p, error_code& ec);
```

1 Effects: Constructs an object of type `directory_entry`, then `refresh()` or `refresh(ec)`, respectively.

2 Postconditions: `path() == p` if no error occurs, otherwise `path() == std::filesystem::path()`.

3 Throws: As specified in 30.10.7.

30.10.12.2 directory_entry modifiers

```cpp
void assign(const path& p);
void assign(const path& p, error_code& ec);
```

1 Effects: Equivalent to `pathobject = p`, then `refresh()` or `refresh(ec)`, respectively. If an error
occurs, the values of any cached attributes are unspecified.

2 Throws: As specified in 30.10.7.

```cpp
void replace_filename(const path& p);
void replace_filename(const path& p, error_code& ec);
```

3 Effects: Equivalent to `pathobject.replace_filename(p)`, then `refresh()` or `refresh(ec)`, respectively. If an error
occurs, the values of any cached attributes are unspecified.

4 Throws: As specified in 30.10.7.

```cpp
void refresh();
void refresh(error_code& ec) noexcept;
```

4 Effects: Stores the current values of any cached attributes of the file `p` resolves to. If an error occurs,
an error is reported (30.10.7) and the values of any cached attributes are unspecified.

5 Throws: As specified in 30.10.7.

6 [Note: Implementations of `directory_iterator` (30.10.13) are prohibited from directly or indirectly
calling the `refresh` function since it must access the external file system, and the objective of caching
is to avoid unnecessary file system accesses. — end note]

30.10.12.3 directory_entry observers

```cpp
const path& path() const noexcept;
operator const path&() const noexcept;
```

1 Unqualified function names in the `Returns: elements of the directory_entry observers described below refer
to members of the `std::filesystem` namespace.

2 Returns: `pathobject`.

```cpp
bool exists() const;
bool exists(error_code& ec) const noexcept;
```

3 Returns: `exists(this->status())` or `exists(this->status(), ec)`, respectively.

4 Throws: As specified in 30.10.7.

```cpp
bool is_block_file() const;
bool is_block_file(error_code& ec) const noexcept;
```
Returns: is_block_file(this->status()) or is_block_file(this->status(), ec), respectively.

Throws: As specified in 30.10.7.

bool is_character_file() const;
bool is_character_file(error_code& ec) const noexcept;

Returns: is_character_file(this->status()) or is_character_file(this->status(), ec), respectively.

Throws: As specified in 30.10.7.

bool is_directory() const;
bool is_directory(error_code& ec) const noexcept;

Returns: is_directory(this->status()) or is_directory(this->status(), ec), respectively.

Throws: As specified in 30.10.7.

bool is_fifo() const;
bool is_fifo(error_code& ec) const noexcept;

Returns: is_fifo(this->status()) or is_fifo(this->status(), ec), respectively.

Throws: As specified in 30.10.7.

bool is_other() const;
bool is_other(error_code& ec) const noexcept;

Returns: is_other(this->status()) or is_other(this->status(), ec), respectively.

Throws: As specified in 30.10.7.

bool is_regular_file() const;
bool is_regular_file(error_code& ec) const noexcept;

Returns: is_regular_file(this->status()) or is_regular_file(this->status(), ec), respectively.

Throws: As specified in 30.10.7.

bool is_socket() const;
bool is_socket(error_code& ec) const noexcept;

Returns: is_socket(this->status()) or is_socket(this->status(), ec), respectively.

Throws: As specified in 30.10.7.

bool is_symlink() const;
bool is_symlink(error_code& ec) const noexcept;

Returns: is_symlink(this->status()) or is_symlink(this->status(), ec), respectively.

Throws: As specified in 30.10.7.

uintmax_t file_size() const;
uintmax_t file_size(error_code& ec) const noexcept;

Returns: If cached, the file size attribute value. Otherwise, file_size(path()) or file_size(path(), ec), respectively.

Throws: As specified in 30.10.7.

uintmax_t hard_link_count() const;
uintmax_t hard_link_count(error_code& ec) const noexcept;

Returns: If cached, the hard link count attribute value. Otherwise, hard_link_count(path()) or hard_link_count(path(), ec), respectively.

Throws: As specified in 30.10.7.

file_time_type last_write_time() const;
file_time_type last_write_time(error_code& ec) const noexcept;

Returns: If cached, the last write time attribute value. Otherwise, last_write_time(path()) or last_write_time(path(), ec), respectively.

Throws: As specified in 30.10.7.

file_status status() const;
file_status status(error_code& ec) const noexcept;

Returns: If cached, the status attribute value. Otherwise, status(path()) or status(path(), ec), respectively.

Throws: As specified in 30.10.7.

file_status symlink_status() const;
file_status symlink_status(error_code& ec) const noexcept;

Returns: If cached, the symlink status attribute value. Otherwise, symlink_status(path()) or symlink_status(path(), ec), respectively.

Throws: As specified in 30.10.7.

bool operator==(const directory_entry& rhs) const noexcept;

Returns: pathobject == rhs.pathobject.

bool operator!=(const directory_entry& rhs) const noexcept;

Returns: pathobject != rhs.pathobject.

bool operator< (const directory_entry& rhs) const noexcept;

Returns: pathobject < rhs.pathobject.

bool operator<=(const directory_entry& rhs) const noexcept;

Returns: pathobject <= rhs.pathobject.

bool operator> (const directory_entry& rhs) const noexcept;

Returns: pathobject > rhs.pathobject.

bool operator>=(const directory_entry& rhs) const noexcept;

Returns: pathobject >= rhs.pathobject.

30.10.13 Class directory_iterator [fs.class.directory_iterator]

An object of type directory_iterator provides an iterator for a sequence of directory_entry elements representing the path and any cached attribute values (30.10.12) for each file in a directory or in an implementation-defined directory-like file type. [Note: For iteration into sub-directories, see class recursive_directory_iterator (30.10.14). — end note]
using iterator_category = input_iterator_tag;
using value_type = directory_entry;
using difference_type = ptrdiff_t;
using pointer = const directory_entry*;
using reference = const directory_entry&;

// 30.10.13.1, member functions
directory_iterator() noexcept;
explicit directory_iterator(const path& p);
directory_iterator(const path& p, directory_options options);
directory_iterator(const path& p, error_code& ec) noexcept;
directory_iterator(const directory_iterator& rhs);
directory_iterator(directory_iterator&& rhs) noexcept;
~directory_iterator();
directory_iterator& operator=(const directory_iterator& rhs);
directory_iterator& operator=(directory_iterator&& rhs) noexcept;

const directory_entry& operator*() const;
const directory_entry* operator->() const;
directory_iterator& operator++();
directory_iterator& increment(error_code& ec) noexcept;

// other members as required by 27.2.3, input iterators
};
}

2 directory_iterator satisfies the requirements of an input iterator (27.2.3).

3 If an iterator of type directory_iterator reports an error or is advanced past the last directory element, that iterator shall become equal to the end iterator value. The directory_iterator default constructor shall create an iterator equal to the end iterator value, and this shall be the only valid iterator for the end condition.

4 The end iterator is not dereferenceable.

5 Two end iterators are always equal. An end iterator shall not be equal to a non-end iterator.

6 The result of calling the path() member of the directory_entry object obtained by dereferencing a directory_iterator is a reference to a path object composed of the directory argument from which the iterator was constructed with filename of the directory entry appended as if by operator/=.

7 Directory iteration shall not yield directory entries for the current (dot) and parent (dot-dot) directories.

8 The order of directory entries obtained by dereferencing successive increments of a directory_iterator is unspecified.

9 Constructors and non-const directory_iterator member functions store the values of any cached attributes (30.10.12) in the directory_entry element returned by operator*(). directory_iterator member functions shall not directly or indirectly call any directory_entry refresh function. [Note: The exact mechanism for storing cached attribute values is not exposed to users. For exposition, class directory_iterator is shown in 30.10.12 as a friend of class directory_entry. —end note]

10 [Note: Programs performing directory iteration may wish to test if the path obtained by dereferencing a directory iterator actually exists. It could be a symbolic link to a non-existent file. Programs recursively walking directory trees for purposes of removing and renaming entries may wish to avoid following symbolic links. —end note]
[Note: If a file is removed from or added to a directory after the construction of a directory_iterator for the directory, it is unspecified whether or not subsequently incrementing the iterator will ever result in an iterator referencing the removed or added directory entry. See POSIX readdir_r. —end note]

30.10.13.1 directory_iterator members

directory_iterator() noexcept;

Effects: Constructs the end iterator.

directory_iterator(const path& p);
directory_iterator(const path& p, directory_options options);
directory_iterator(const path& p, error_code& ec) noexcept;
directory_iterator(const path& p, directory_options options, error_code& ec) noexcept;

Effects: For the directory that p resolves to, constructs an iterator for the first element in a sequence of directory_entry elements representing the files in the directory, if any; otherwise the end iterator. However, if

(options & directory_options::skip_permission_denied) != directory_options::none

and construction encounters an error indicating that permission to access p is denied, constructs the end iterator and does not report an error.

Throws: As specified in 30.10.7.

[Note: To iterate over the current directory, use directory_iterator(".") rather than directory_iterator(""). —end note]

directory_iterator(const directory_iterator& rhs);
directory_iterator(directory_iterator&& rhs) noexcept;

Effects: Constructs an object of class directory_iterator.

Postconditions: *this has the original value of rhs.

directory_iterator& operator=(const directory_iterator& rhs);
directory_iterator& operator=(directory_iterator&& rhs) noexcept;

Effects: If *this and rhs are the same object, the member has no effect.

Postconditions: *this has the original value of rhs.

Returns: *this.

directory_iterator& operator++();
directory_iterator& increment(error_code& ec) noexcept;

Effects: As specified for the prefix increment operation of Input iterators (27.2.3).

Returns: *this.

Throws: As specified in 30.10.7.

30.10.13.2 directory_iterator non-member functions

These functions enable range access for directory_iterator.

directory_iterator begin(directory_iterator iter) noexcept;

Returns: iter.

directory_iterator end(const directory_iterator&) noexcept;

Returns: directory_iterator().

§ 30.10.13.2
30.10.14 Class recursive_directory_iterator  

An object of type `recursive_directory_iterator` provides an iterator for a sequence of `directory_entry` elements representing the files in a directory or in an implementation-defined directory-like file type, and its sub-directories.

```cpp
class recursive_directory_iterator {
public:
    using iterator_category = input_iterator_tag;
    using value_type = directory_entry;
    using difference_type = ptrdiff_t;
    using pointer = const directory_entry*;
    using reference = const directory_entry&;

    // 30.10.14.1, constructors and destructor
    recursive_directory_iterator() noexcept;
    explicit recursive_directory_iterator(const path& p);
    recursive_directory_iterator(const path& p, directory_options options);
    recursive_directory_iterator(const path& p, directory_options options,
                                 error_code& ec) noexcept;
    recursive_directory_iterator(const path& p, error_code& ec) noexcept;
    recursive_directory_iterator(const recursive_directory_iterator& rhs);
    recursive_directory_iterator(recursive_directory_iterator&& rhs) noexcept;
    ~recursive_directory_iterator();

    // 30.10.14.1, observers
    directory_options options() const;
    int depth() const;
    bool recursion_pending() const;
    const directory_entry& operator*() const;
    const directory_entry* operator->() const;

    // 30.10.14.1, modifiers
    recursive_directory_iterator& operator=(const recursive_directory_iterator& rhs);
    recursive_directory_iterator& operator=(recursive_directory_iterator&& rhs) noexcept;
    recursive_directory_iterator& operator++();
    recursive_directory_iterator& increment(error_code& ec) noexcept;
    void pop();
    void pop(error_code& ec);
    void disable_recursion_pending();

    // other members as required by 27.2.3, input iterators
};
```

1 Calling `options`, `depth`, `recursion_pending`, `pop` or `disable_recursion_pending` on an iterator that is not dereferenceable results in undefined behavior.

2 The behavior of a `recursive_directory_iterator` is the same as a `directory_iterator` unless otherwise specified.
[Note: If the directory structure being iterated over contains cycles then the end iterator may be unreachable. — end note]

30.10.14.1 recursive_directory_iterator members

recursive_directory_iterator() noexcept;

Effects: Constructs the end iterator.

explicit recursive_directory_iterator(const path& p);
recursive_directory_iterator(const path& p, directory_options options);
recursive_directory_iterator(const path& p, directory_options options, error_code& ec) noexcept;
recursive_directory_iterator(const path& p, error_code& ec) noexcept;

Effects: Constructs a iterator representing the first entry in the directory p resolves to, if any; otherwise, the end iterator. However, if

(options & directory_options::skip_permission_denied) != directory_options::none

and construction encounters an error indicating that permission to access p is denied, constructs the end iterator and does not report an error.

Postconditions: options() == options for the signatures with a directory_options argument, otherwise options() == directory_options::none.

Throws: As specified in 30.10.7.

[Note: To iterate over the current directory, use recursive_directory_iterator(".") rather than recursive_directory_iterator(""). — end note]

[Note: By default, recursive_directory_iterator does not follow directory symlinks. To follow directory symlinks, specify options as directory_options::follow_directory_symlink — end note]

recursive_directory_iterator(const recursive_directory_iterator& rhs);

Effects: Constructs an object of class recursive_directory_iterator.

Postconditions:

- options() == rhs.options()
- depth() == rhs.depth()
- recursion_pending() == rhs.recursion_pending()

recursive_directory_iterator(recursive_directory_iterator& rhs) noexcept;

Effects: Constructs an object of class recursive_directory_iterator.

Postconditions: options(), depth(), and recursion_pending() have the values that rhs.options(), rhs.depth(), and rhs.recursion_pending(), respectively, had before the function call.

recursive_directory_iterator& operator=(const recursive_directory_iterator& rhs);

Effects: If *this and rhs are the same object, the member has no effect.

Postconditions:

- options() == rhs.options()
- depth() == rhs.depth()
- recursion_pending() == rhs.recursion_pending()

Returns: *this.

recursive_directory_iterator& operator=(recursive_directory_iterator&& rhs) noexcept;

§ 30.10.14.1
Effects: If *this and rhs are the same object, the member has no effect.

Postconditions: options(), depth(), and recursion_pending() have the values that rhs.options(), rhs.depth(), and rhs.recursion_pending(), respectively, had before the function call.

Returns: *this.

directory_options options() const;

Returns: The value of the argument passed to the constructor for the options parameter, if present, otherwise directory_options::none.

Throws: Nothing.

int depth() const;

Returns: The current depth of the directory tree being traversed. [Note: The initial directory is depth 0, its immediate subdirectories are depth 1, and so forth. — end note]

Throws: Nothing.

bool recursion_pending() const;

Returns: true if disable_recursion_pending() has not been called subsequent to the prior construction or increment operation, otherwise false.

Throws: Nothing.

recursive_directory_iterator& operator++();
recursive_directory_iterator& increment(error_code& ec) noexcept;

Effects: As specified for the prefix increment operation of Input iterators (27.2.3), except that:

(23.1) — If there are no more entries at the current depth, then if depth() != 0 iteration over the parent directory resumes; otherwise *this = recursive_directory_iterator().

(23.2) — Otherwise if

recursion_pending() && is_directory(*this)->status()) &&
(!is_symlink(*this)->symlink_status()) ||
(options() & directory_options::follow_directory_symlink) != directory_options::none)

then either directory (*this)->path() is recursively iterated into or, if

(options() & directory_options::skip_permission_denied) != directory_options::none

and an error occurs indicating that permission to access directory (*this)->path() is denied, then directory (*this)->path() is treated as an empty directory and no error is reported.

Returns: *this.

Throws: As specified in 30.10.7.

void pop();
void pop(error_code& ec);

Effects: If depth() == 0, set *this to recursive_directory_iterator(). Otherwise, cease iteration of the directory currently being iterated over, and continue iteration over the parent directory.

Throws: As specified in 30.10.7.

void disable_recursion_pending();

Postconditions: recursion_pending() == false.

[Note: disable_recursion_pending() is used to prevent unwanted recursion into a directory. — end note]
30.10.14.2 recursive_directory_iterator non-member functions [fs.rec.dir.itr.nonmembers]

These functions enable use of recursive_directory_iterator with range-based for statements.

recursive_directory_iterator begin(recursive_directory_iterator iter) noexcept;

Returns: iter.

recursive_directory_iterator end(const recursive_directory_iterator&) noexcept;

Returns: recursive_directory_iterator().

30.10.15 Filesystem operation functions [fs.op.funcs]

Filesystem operation functions query or modify files, including directories, in external storage.

[Note: Because hardware failures, network failures, file system races (30.10.4.5), and many other kinds of errors occur frequently in file system operations, users should be aware that any filesystem operation function, no matter how apparently innocuous, may encounter an error; see 30.10.7. — end note]

30.10.15.1 Absolute [fs.op.absolute]

path absolute(const path& p);

path absolute(const path& p, error_code& ec);

Effects: Composes an absolute path referencing the same file system location as p according to the operating system (30.10.2.2).

Returns: The composed path. The signature with argument ec returns path() if an error occurs.

[Note: For the returned path, rp, rp.is_absolute() is true unless an error occurs. — end note]

Throws: As specified in 30.10.7.

Remarks: !exists(p) an error. — end note]

[Example: For POSIX-based operating systems, absolute(p) is simply current_path()/p. For Windows-based operating systems, absolute might have the same semantics as GetFullPathNameW. — end example]

30.10.15.2 Canonical [fs.op.canonical]

path canonical(const path& p, const path& base = current_path());

path canonical(const path& p, error_code& ec);

path canonical(const path& p, const path& base, error_code& ec);

Effects: Converts p, which must exist, to an absolute path that has no symbolic link, dot, or dot-dot elements in its pathname in the generic format.

Returns: A path that refers to the same file system object as absolute(p, base). For the overload without a base argument, base is current_path(). Signatures with argument ec return path() if an error occurs.

Throws: As specified in 30.10.7.

Remarks: !exists(p) is an error.

30.10.15.3 Copy [fs.op.copy]

void copy(const path& from, const path& to);
**Effects:** Equivalent to `copy(from, to, copy_options::none).

```cpp
void copy(const path& from, const path& to, error_code& ec) noexcept;
```

**Effects:** Equivalent to `copy(from, to, copy_options::none, ec).

```cpp
void copy(const path& from, const path& to, copy_options options);
void copy(const path& from, const path& to, copy_options options,
          error_code& ec) noexcept;
```

**Requires:** At most one element from each option group (30.10.10.3) is set in `options`.

**Effects:** Before the first use of `f` and `t`:

1. **Requires:** At most one element from each option group (30.10.10.3) is set in `options`.

   **Effects:** Before the first use of `f` and `t`:

   1. If
      ```
      (options & copy_options::create_symlinks) != copy_options::none ||
      (options & copy_options::skip_symlinks) != copy_options::none
      ```
      then `auto f = symlink_status(from)` and if needed `auto t = symlink_status(to)`.

   2. Otherwise, if
      ```
      (options & copy_options::copy_symlinks) != copy_options::none
      ```
      then `auto f = symlink_status(from)` and if needed `auto t = status(to)`.

   3. Otherwise, `auto f = status(from)` and if needed `auto t = status(to)`.

   Effects are then as follows:

   4. If `f.type()` or `t.type()` is an implementation-defined file type (30.10.10.2), then the effects are implementation-defined.

   5. Otherwise, an error is reported as specified in 30.10.7 if:

      1. `!exists(f)`, or
      2. `equivalent(from, to)`, or
      3. `is_other(f) || is_other(t)`, or
      4. `is_directory(f) && is_regular_file(t)`.

   6. Otherwise, if `is_symlink(f)`, then:

      1. If `(options & copy_options::skip_symlinks) != copy_options::none` then return.

      2. Otherwise if
         ```
         !exists(t) && (options & copy_options::copy_symlinks) != copy_options::none
         ```
         then `copy_symlink(from, to)`.

   7. Otherwise report an error as specified in 30.10.7.

   8. Otherwise, if `is_regular_file(f)`, then:

      1. If `(options & copy_options::directories_only) != copy_options::none`, then return.

      2. Otherwise, if `(options & copy_options::create_symlinks) != copy_options::none`, then create a symbolic link to the source file.

      3. Otherwise, if `(options & copy_options::create_hard_links) != copy_options::none`, then create a hard link to the source file.

      4. Otherwise, if `is_directory(t)`, then `copy_file(from, to/from.filename(), options)`.

   9. Otherwise, `copy_file(from, to, options)`.

   10. Otherwise, if
is_directory(f) &&
((options & copy_options::recursive) != copy_options::none ||
options == copy_options::none)

then:

— If !exists(t), then create_directory(to, from).

— Then, iterate over the files in from, as if by

  for (const directory_entry& x : directory_iterator(from))
    copy(x.path(), to/x.path().filename(), options | copy_options::unspecified)

— Otherwise, for the signature with argument ec, ec.clear().

— Otherwise, no effects.

5 Throws: As specified in 30.10.7.
6 Remarks: For the signature with argument ec, any library functions called by the implementation shall have an error_code argument if applicable.

7 [Example: Given this directory structure:

```
/dir1
  file1
  file2
  dir2
    file3
```

Calling copy("/dir1", "/dir3") would result in:

```
/dir1
  file1
  file2
  dir2
    file3
 /dir3
  file1
  file2
```

Alternatively, calling copy("/dir1", "/dir3", copy_options::recursive) would result in:

```
/dir1
  file1
  file2
  dir2
    file3
 /dir3
  file1
  file2
  dir2
    file3
```
— end example]

30.10.15.4 Copy file

bool copy_file(const path& from, const path& to);
bool copy_file(const path& from, const path& to, error_code& ec) noexcept;

1 Returns: copy_file(from, to, copy_options::none) or
   copy_file(from, to, copy_options::none, ec), respectively.

2 Throws: As specified in 30.10.7.
bool copy_file(const path& from, const path& to, copy_options options);
bool copy_file(const path& from, const path& to, copy_options options,
               error_code& ec) noexcept;

3 Requires: At most one element from each option group (30.10.10.3) is set in options.
4 Effects: As follows:

(4.1) — Report a file already exists error as specified in 30.10.7 if:
(4.1.1) — !is_regular_file(from), or
(4.1.2) — exists(to) and !is_regular_file(to), or
(4.1.3) — exists(to) and equivalent(from, to), or
(4.1.4) — exists(to) and
          (options & (copy_options::skip_existing |
                      copy_options::overwrite_existing |
                      copy_options::update_existing)) == copy_options::none

(4.2) — Otherwise, copy the contents and attributes of the file from resolves to, to the file to resolves to, if:
(4.2.1) — !exists(to), or
(4.2.2) — (options & copy_options::overwrite_existing) != copy_options::none, or
(4.2.3) — (options & copy_options::update_existing) != copy_options::none and from is more recent than to, determined as if by use of the last_write_time function (30.10.15.25).

(4.3) — Otherwise, no effects.
5 Returns: true if the from file was copied, otherwise false. The signature with argument ec returns false if an error occurs.
6 Throws: As specified in 30.10.7.
7 Complexity: At most one direct or indirect invocation of status(to).

30.10.15.5 Copy symlink

void copy_symlink(const path& existing_symlink, const path& new_symlink);
void copy_symlink(const path& existing_symlink, const path& new_symlink,
                  error_code& ec) noexcept;

1 Effects: Equivalent to function(read_symlink(existing_symlink), new_symlink) or
function(read_symlink(existing_symlink, ec), new_symlink, ec), respectively, where in each

2 case function is create_symlink or create_directory_symlink as appropriate.

2 Throws: As specified in 30.10.7.

30.10.15.6 Create directories

bool create_directories(const path& p);
bool create_directories(const path& p, error_code& ec) noexcept;

1 Effects: Establishes the postcondition by calling create_directory() for any element of p that does

2 not exist.

2 Postconditions: is_directory(p).
3 Returns: true if a new directory was created, otherwise false. The signature with argument ec returns

false if an error occurs.
4 Throws: As specified in 30.10.7.

§ 30.10.15.6 1282
Complexity: $\mathcal{O}(n)$ where $n$ is the number of elements of $p$ that do not exist.

### 30.10.15.7 Create directory

[`fs.op.create_directory`]

```c++
bool create_directory(const path& p);
bool create_directory(const path& p, error_code& ec) noexcept;
```

**Effects:** Establishes the postcondition by attempting to create the directory $p$ resolves to, as if by POSIX `mkdir()` with a second argument of `static_cast<int>(perms::all)`. Creation failure because $p$ resolves to an existing directory shall not be treated as an error.

**Postconditions:** `is_directory(p)`.

**Returns:** `true` if a new directory was created, otherwise `false`. The signature with argument `ec` returns `false` if an error occurs.

**Throws:** As specified in 30.10.7.

```c++
bool create_directory(const path& p, const path& existing_p);
bool create_directory(const path& p, const path& existing_p, error_code& ec) noexcept;
```

**Effects:** Establishes the postcondition by attempting to create the directory $p$ resolves to, with attributes copied from directory `existing_p`. The set of attributes copied is operating system dependent. Creation failure because $p$ resolves to an existing directory shall not be treated as an error.  

[Note: For POSIX-based operating systems, the attributes are those copied by native API `stat(existing_p.c_str(), &attributes_stat)` followed by `mkdir(p.c_str(), attributes_stat.st_mode)` for Windows-based operating systems, the attributes are those copied by native API `CreateDirectoryExW(existing_p.c_str(), p.c_str(), 0)`.

**Postconditions:** `is_directory(p)`.

**Returns:** `true` if a new directory was created, otherwise `false`. The signature with argument `ec` returns `false` if an error occurs.

**Throws:** As specified in 30.10.7.

### 30.10.15.8 Create directory symlink

[`fs.op.create_dir_symlk`]

```c++
void create_directory_symlink(const path& to, const path& new_symlink);
void create_directory_symlink(const path& to, const path& new_symlink, error_code& ec) noexcept;
```

**Effects:** Establishes the postcondition, as if by POSIX `symmlink()`.

**Postconditions:** `new_symlink` resolves to a symbolic link file that contains an unspecified representation of `to`.

**Throws:** As specified in 30.10.7.

[Note: Some operating systems require symlink creation to identify that the link is to a directory. Portable code should use `create_directory_symlink()` to create directory symlinks rather than `create_symlink()` — end note]

[Note: Some operating systems do not support symbolic links at all or support them only for regular files. Some file systems (such as the FAT file system) do not support symbolic links regardless of the operating system. — end note]

### 30.10.15.9 Create hard link

[`fs.op.create_hard_lk`]

```c++
void create_hard_link(const path& to, const path& new_hard_link);
void create_hard_link(const path& to, const path& new_hard_link, error_code& ec) noexcept;
```
Effects: Establishes the postcondition, as if by POSIX link().

Postconditions:

(2.1) exists(to) && exists(new_hard_link) && equivalent(to, new_hard_link)
(2.2) The contents of the file or directory to resolves to are unchanged.

Throws: As specified in 30.10.7.

[Note: Some operating systems do not support hard links at all or support them only for regular files. Some file systems (such as the FAT file system) do not support hard links regardless of the operating system. Some file systems limit the number of links per file. — end note]

30.10.15.10 Create symlink

```cpp
void create_symlink(const path& to, const path& new_symlink);
void create_symlink(const path& to, const path& new_symlink, error_code& ec) noexcept;
```

Effects: Establishes the postcondition, as if by POSIX symlink().

Postconditions: new_symlink resolves to a symbolic link file that contains an unspecified representation of to.

Throws: As specified in 30.10.7.

[Note: Some operating systems do not support symbolic links at all or support them only for regular files. Some file systems (such as the FAT file system) do not support symbolic links regardless of the operating system. — end note]

30.10.15.11 Current path

```cpp
path current_path();
path current_path(error_code& ec);
```

Returns: The absolute path of the current working directory, whose pathname in the native format is obtained as if by POSIX getcwd(). The signature with argument ec returns path() if an error occurs.

Throws: As specified in 30.10.7.

Remarks: The current working directory is the directory, associated with the process, that is used as the starting location in pathname resolution for relative paths.

[Note: The current_path() name was chosen to emphasize that the returned value is a path, not just a single directory name. — end note]

[Note: The current path as returned by many operating systems is a dangerous global variable. It may be changed unexpectedly by a third-party or system library functions, or by another thread. — end note]

```cpp
void current_path(const path& p);
void current_path(const path& p, error_code& ec) noexcept;
```

Effects: Establishes the postcondition, as if by POSIX chdir().

Postconditions: equivalent(p, current_path()).

Throws: As specified in 30.10.7.

[Note: The current path for many operating systems is a dangerous global state. It may be changed unexpectedly by a third-party or system library functions, or by another thread. — end note]

30.10.15.12 Equivalent

```cpp
§ 30.10.15.12
```

```cpp
```
bool equivalent(const path& p1, const path& p2);
bool equivalent(const path& p1, const path& p2, error_code& ec) noexcept;

1 Let s1 and s2 be file_statuss, determined as if by status(p1) and status(p2), respectively.
2 Effects: Determines s1 and s2. If !(exists(s1) && !exists(s2)) || (is_other(s1) && is_other(s2)) an error is reported (30.10.7).
3 Returns: true, if s1 == s2 and p1 and p2 resolve to the same file system entity, else false. The signature with argument ec returns false if an error occurs.
4 Two paths are considered to resolve to the same file system entity if two candidate entities reside on the same device at the same location. This is determined as if by the values of the POSIX stat structure, obtained as if by stat() for the two paths, having equal st_dev values and equal st_ino values.
5 Throws: As specified in 30.10.7.

30.10.15.13 Exists [fs.op.exists]
bool exists(file_status s) noexcept;
bool exists(const path& p);
bool exists(const path& p, error_code& ec) noexcept;

1 Returns: status_known(s) && s.type() != file_type::not_found.
2 Let s be a file_status, determined as if by status(p) or status(p, ec), respectively.
3 Effects: The signature with argument ec calls ec.clear() if status_known(s).
4 Returns: exists(s).
5 Throws: As specified in 30.10.7.

30.10.15.14 File size [fs.op.file_size]
uintmax_t file_size(const path& p);
uintmax_t file_size(const path& p, error_code& ec) noexcept;

1 Returns:
(1.1) — If !exists(p) an error is reported (30.10.7).
(1.2) — Otherwise, if is_regular_file(p), the size in bytes of the file p resolves to, determined as if by the value of the POSIX stat structure member st_size obtained as if by POSIX stat().
(1.3) — Otherwise, the result is implementation-defined.

The signature with argument ec returns static_cast<uintmax_t>(-1) if an error occurs.
2 Throws: As specified in 30.10.7.

30.10.15.15 Hard link count [fs.op.hard_lk_ct]
uintmax_t hard_link_count(const path& p);
uintmax_t hard_link_count(const path& p, error_code& ec) noexcept;

1 Returns: The number of hard links for p. The signature with argument ec returns static_cast<uintmax_t>(-1) if an error occurs.
2 Throws: As specified in 30.10.7.

30.10.15.16 Is block file [fs.op.is_block_file]
bool is_block_file(file_status s) noexcept;

1 Returns: s.type() == file_type::block.

§ 30.10.15.16
bool is_block_file(const path& p);
bool is_block_file(const path& p, error_code& ec) noexcept;

/* Returns: is_block_file(status(p)) or is_block_file(status(p, ec)), respectively. The signature with argument ec returns false if an error occurs. */

30.10.15.17 Is character file

bool is_character_file(file_status s) noexcept;

/* Returns: s.type() == file_type::character. */

bool is_character_file(const path& p);
bool is_character_file(const path& p, error_code& ec) noexcept;

/* Returns: is_character_file(status(p)) or is_character_file(status(p, ec)), respectively. The signature with argument ec returns false if an error occurs. */

30.10.15.18 Is directory

bool is_directory(file_status s) noexcept;

/* Returns: s.type() == file_type::directory. */

bool is_directory(const path& p);
bool is_directory(const path& p, error_code& ec) noexcept;

/* Returns: is_directory(status(p)) or is_directory(status(p, ec)), respectively. The signature with argument ec returns false if an error occurs. */

30.10.15.19 Is empty

bool is_empty(const path& p);
bool is_empty(const path& p, error_code& ec) noexcept;

1 Effects:
   (1.1) Determine file_status s, as if by status(p) or status(p, ec), respectively.
   (1.2) For the signature with argument ec, return false if an error occurred.
   (1.3) Otherwise, if is_directory(s):
         (1.3.1) Create a variable itr, as if by directory_iterator itr(p) or directory_iterator itr(p, ec), respectively.
         (1.3.2) For the signature with argument ec, return false if an error occurred.
         (1.3.3) Otherwise, return itr == directory_iterator().
   (1.4) Otherwise:
         (1.4.1) Determine uintmax_t sz, as if by file_size(p) or file_size(p, ec), respectively.
         (1.4.2) For the signature with argument ec, return false if an error occurred.
         (1.4.3) Otherwise, return sz == 0.

2 Throws: As specified in 30.10.7.

30.10.15.20 Is fifo

§ 30.10.15.20
bool is_fifo(file_status s) noexcept;

Returns: s.type() == file_type::fifo.

bool is_fifo(const path& p);
bool is_fifo(const path& p, error_code& ec) noexcept;

Returns: is_fifo(status(p)) or is_fifo(status(p, ec)), respectively. The signature with argument ec returns false if an error occurs.

Throws: As specified in 30.10.7.

30.10.15.21 Is other

bool is_other(file_status s) noexcept;

Returns: exists(s) && !is_regular_file(s) && !is_directory(s) && !is_symlink(s).

bool is_other(const path& p);
bool is_other(const path& p, error_code& ec) noexcept;

Returns: is_other(status(p)) or is_other(status(p, ec)), respectively. The signature with argument ec returns false if an error occurs.

Throws: As specified in 30.10.7.

30.10.15.22 Is regular file

bool is_regular_file(file_status s) noexcept;

Returns: s.type() == file_type::regular.

bool is_regular_file(const path& p);

Returns: is_regular_file(status(p)).

Throws: filesystem_error if status(p) would throw filesystem_error.

bool is_regular_file(const path& p, error_code& ec) noexcept;

Effects: Sets ec as if by status(p, ec). [Note: file_type::none, file_type::not_found and file_type::unknown cases set ec to error values. To distinguish between cases, call the status function directly. —end note]

Returns: is_regular_file(status(p, ec)). Returns false if an error occurs.

30.10.15.23 Is socket

bool is_socket(file_status s) noexcept;

Returns: s.type() == file_type::socket.

bool is_socket(const path& p);
bool is_socket(const path& p, error_code& ec) noexcept;

Returns: is_socket(status(p)) or is_socket(status(p, ec)), respectively. The signature with argument ec returns false if an error occurs.

Throws: As specified in 30.10.7.

30.10.15.24 Is symlink

bool is_symlink(file_status s) noexcept;

Returns: s.type() == file_type::symlink.
bool is_symlink(const path& p);
bool is_symlink(const path& p, error_code& ec) noexcept;

Returns: is_symlink(symlink_status(p)) or is_symlink(symlink_status(p, ec)), respectively. The signature with argument ec returns false if an error occurs.

Throws: As specified in 30.10.7.

30.10.15.25 Last write time

file_time_type last_write_time(const path& p);
file_time_type last_write_time(const path& p, error_code& ec) noexcept;

Returns: The time of last data modification of p, determined as if by the value of the POSIX stat structure member st_mtime obtained as if by POSIX stat(). The signature with argument ec returns file_time_type::min() if an error occurs.

Throws: As specified in 30.10.7.

void last_write_time(const path& p, file_time_type new_time);
void last_write_time(const path& p, file_time_type new_time,
    error_code& ec) noexcept;

Effects: Sets the time of last data modification of the file resolved to by p to new_time, as if by POSIX futimens().

Throws: As specified in 30.10.7.

[Note: A postcondition of last_write_time(p) == new_time is not specified since it might not hold for file systems with coarse time granularity. —end note]

30.10.15.26 Permissions

void permissions(const path& p, perms prms, perm_options opts=perm_options::replace);
void permissions(const path& p, perms prms, error_code& ec) noexcept;
void permissions(const path& p, perms prms, perm_options opts, error_code& ec);

Requires: Exactly one of the perm_options constants replace, add, or remove is present in opts.

Remarks: The second signature behaves as if it had an additional parameter perm_options opts with an argument of perm_options::replace.

Effects: Applies the action specified by opts to the file p resolves to, or to file p itself if p is a symbolic link and perm_options::nofollow is set in opts. The action is applied as if by POSIX fchmodat().

[Note: Conceptually permissions are viewed as bits, but the actual implementation may use some other mechanism. —end note]

Throws: As specified in 30.10.7.

30.10.15.27 Proximate

path proximate(const path& p, error_code& ec);

Returns: proximate(p, current_path(), ec).

Throws: As specified in 30.10.7.

path proximate(const path& p, const path& base = current_path());
path proximate(const path& p, const path& base, error_code& ec);

Returns: For the first form:
    weakly_canonical(p).lexically_proximate(weakly_canonical(base));

§ 30.10.15.27 1288
For the second form:

weakly_canonical(p, ec).lexically_proximate(weakly_canonical(base, ec));

or \texttt{path()} at the first error occurrence, if any.

4 Thows: As specified in 30.10.7.

30.10.15.28 Read symlink

\texttt{path read\_symlink(const path& p);}
\texttt{path read\_symlink(const path& p, error\_code& ec);}

1 Returns: If \( p \) resolves to a symbolic link, a \texttt{path} object containing the contents of that symbolic link. The signature with argument \texttt{ec} returns \texttt{path()} if an error occurs.

2 Throws: As specified in 30.10.7. [Note: It is an error if \( p \) does not resolve to a symbolic link. —end note]

30.10.15.29 Relative

\texttt{path relative(const path& p, error\_code& ec);}

1 Returns: \( \text{relative}(p, \text{current\_path}(), \text{ec}) \).

2 Throws: As specified in 30.10.7.

\texttt{path relative(const path& p, const path& base = current\_path());}
\texttt{path relative(const path& p, const path& base, error\_code& ec);}

3 Returns: For the first form:

weakly_canonical(p).lexically_relative(weakly_canonical(base));

For the second form:

weakly_canonical(p, ec).lexically_relative(weakly_canonical(base, ec));

or \texttt{path()} at the first error occurrence, if any.

4 Throws: As specified in 30.10.7.

30.10.15.30 Remove

\texttt{bool remove(const path& p);}
\texttt{bool remove(const path& p, error\_code& ec) noexcept;}

1 Effects: If \texttt{exists(symlink\_status(p, ec))}, the file \( p \) is removed as if by POSIX \texttt{remove()}. [Note: A symbolic link is itself removed, rather than the file it resolves to. —end note]

2 Postconditions: \!\texttt{exists(symlink\_status(p))}.

3 Returns: \texttt{false} if \( p \) did not exist, otherwise \texttt{true}. The signature with argument \texttt{ec} returns \texttt{false} if an error occurs.

4 Throws: As specified in 30.10.7.

30.10.15.31 Remove all

\texttt{uintmax\_t remove\_all(const path& p);}
\texttt{uintmax\_t remove\_all(const path& p, error\_code& ec) noexcept;}

1 Effects: Recursively deletes the contents of \( p \) if it exists, then deletes file \( p \) itself, as if by POSIX \texttt{remove()}. [Note: A symbolic link is itself removed, rather than the file it resolves to. —end note]

2 Postconditions: \!\texttt{exists(symlink\_status(p))}. 

§ 30.10.15.31 1289
Returns: The number of files removed. The signature with argument ec returns \texttt{static\_cast<}
\texttt{uintmax\_t>(-1)} if an error occurs.

Throws: As specified in 30.10.7.

30.10.15.32 Rename

\begin{verbatim}
void rename(const path& old_p, const path& new_p);
void rename(const path& old_p, const path& new_p, error_code& ec) noexcept;
\end{verbatim}

Effects: Renames \texttt{old\_p} to \texttt{new\_p}, as if by POSIX rename().

\begin{itemize}
\item[(1.1)] If \texttt{old\_p} and \texttt{new\_p} resolve to the same existing file, no action is taken.
\item[(1.2)] Otherwise, the rename may include the following effects:
\end{itemize}

\begin{itemize}
\item[(1.2.1)] if \texttt{new\_p} resolves to an existing non-directory file, \texttt{new\_p} is removed; otherwise,
\item[(1.2.2)] if \texttt{new\_p} resolves to an existing directory, \texttt{new\_p} is removed if empty on POSIX compliant
operating systems but may be an error on other operating systems.
\end{itemize}

A symbolic link is itself renamed, rather than the file it resolves to. \quad end note

Throws: As specified in 30.10.7.

30.10.15.33 Resize file

\begin{verbatim}
void resize_file(const path& p, uintmax_t new_size);
void resize_file(const path& p, uintmax_t new_size, error_code& ec) noexcept;
\end{verbatim}

Postconditions: \texttt{file\_size(p) == new\_size}.

Throws: As specified in 30.10.7.

Remarks: Achieves its postconditions as if by POSIX truncate().

30.10.15.34 Space

\begin{verbatim}
space_info space(const path& p);
space_info space(const path& p, error_code& ec) noexcept;
\end{verbatim}

Returns: An object of type \texttt{space\_info}. The value of the \texttt{space\_info} object is determined as if
by using POSIX \texttt{statvfs} to obtain a POSIX \texttt{struct statvfs}, and then multiplying its \texttt{f\_blocks},
\texttt{f\_bfree}, and \texttt{f\_bavail} members by its \texttt{f\_fsrsize} member, and assigning the results to the \texttt{capacity},
\texttt{free}, and \texttt{available} members respectively. Any members for which the value cannot be determined
shall be set to \texttt{static\_cast<uintmax\_t>(-1)}. For the signature with argument \texttt{ec}, all members are
set to \texttt{static\_cast<uintmax\_t>(-1)} if an error occurs.

Throws: As specified in 30.10.7.

Remarks: The value of member \texttt{space\_info::available} is operating system dependent. \quad end note

30.10.15.35 Status

\begin{verbatim}
file_status status(const path& p);
\end{verbatim}

Effects: As if:

\begin{verbatim}
    error_code ec;
    file_status result = status(p, ec);
    if (result.type() == file_type::none)
    throw filesystem_error(implementation-supplied-message, p, ec);
\end{verbatim}
return result;

Returns: See above.

Throws: filesystem_error. [Note: result values of file_status(file_type::not_found) and file_status(file_type::unknown) are not considered failures and do not cause an exception to be thrown. —end note]

file_status status(const path& p, error_code& ec) noexcept;

Effects: If possible, determines the attributes of the file p resolves to, as if by using POSIX stat() to obtain a POSIX struct stat. If, during attribute determination, the underlying file system API reports an error, sets ec to indicate the specific error reported. Otherwise, ec.clear(). [Note: This allows users to inspect the specifics of underlying API errors even when the value returned by status() is not file_status(file_type::none). —end note]

Let prms denote the result of (m & perms::mask), where m is determined as if by converting the st_mode member of the obtained struct stat to the type perms.

Returns:

(6.1) — If ec != error_code():

(6.1.1) — If the specific error indicates that p cannot be resolved because some element of the path does not exist, returns file_status(file_type::not_found).

(6.1.2) — Otherwise, if the specific error indicates that p can be resolved but the attributes cannot be determined, returns file_status(file_type::unknown).

(6.1.3) — Otherwise, returns file_status(file_type::none).

[Note: These semantics distinguish between p being known not to exist, p existing but not being able to determine its attributes, and there being an error that prevents even knowing if p exists. These distinctions are important to some use cases. —end note]

(6.2) — Otherwise,

(6.2.1) — If the attributes indicate a regular file, as if by POSIX S_ISREG, returns file_status(file_type::regular, prms). [Note: file_type::regular implies appropriate <fstream> operations would succeed, assuming no hardware, permission, access, or file system race errors. Lack of file_type::regular does not necessarily imply <fstream> operations would fail on a directory. —end note]

(6.2.2) — Otherwise, if the attributes indicate a directory, as if by POSIX S_ISDIR, returns file_status(file_type::directory, prms). [Note: file_type::directory implies that calling directory_iterator(p) would succeed. —end note]

(6.2.3) — Otherwise, if the attributes indicate a block special file, as if by POSIX S_ISBLK, returns file_status(file_type::block, prms).

(6.2.4) — Otherwise, if the attributes indicate a character special file, as if by POSIX S_ISCHR, returns file_status(file_type::character, prms).

(6.2.5) — Otherwise, if the attributes indicate a fifo or pipe file, as if by POSIX S_ISFIFO, returns file_status(file_type::fifo, prms).

(6.2.6) — Otherwise, if the attributes indicate a socket, as if by POSIX S_ISSOCK, returns file_status(file_type::socket, prms).

(6.2.7) — Otherwise, if the attributes indicate an implementation-defined file type (30.10.10.2), returns file_status(file_type::A, prms), where A is the constant for the implementation-defined file type.
Otherwise, returns \texttt{file\_status(file\_type::unknown, prms)}.

\textbf{Remarks:} If a symbolic link is encountered during pathname resolution, pathname resolution continues using the contents of the symbolic link.

\textbf{30.10.15.36 Status known} \hspace{1cm} [fs.op.status_known]

\begin{verbatim}
bool status_known(file_status s) noexcept;
\end{verbatim}

\textbf{Returns:} \(s\text{.type()} \neq \text{file\_type::none}\).

\textbf{30.10.15.37 Symlink status} \hspace{1cm} [fs.op.symlink_status]

\begin{verbatim}
file_status symlink_status(const path& p);
file_status symlink_status(const path& p, error_code& ec) noexcept;
\end{verbatim}

\textbf{Effects:} Same as \texttt{status()}, above, except that the attributes of \(p\) are determined as if by using POSIX \texttt{lstat()} to obtain a POSIX \texttt{struct stat}.

Let \(prms\) denote the result of \((m \& \text{perms::mask})\), where \(m\) is determined as if by converting the \texttt{st\_mode} member of the obtained \texttt{struct stat} to the type \texttt{perms}.

\textbf{Returns:} Same as \texttt{status()}, above, except that if the attributes indicate a symbolic link, as if by POSIX \texttt{S\_ISLNK}, returns \texttt{file\_status(file\_type::symlink, prms)}. The signature with argument \texttt{ec} returns \texttt{file\_status(file\_type::none)} if an error occurs.

\textbf{Remarks:} Pathname resolution terminates if \(p\) names a symbolic link.

\textbf{Throws:} As specified in 30.10.7.

\textbf{30.10.15.38 Temporary directory path} \hspace{1cm} [fs.op.temp_dir_path]

\begin{verbatim}
path temp_directory_path();
path temp_directory_path(error_code& ec);
\end{verbatim}

\textbf{Returns:} An unspecified directory path suitable for temporary files. An error shall be reported if \texttt{!exists(p)} \texttt{|| !is\_directory(p)}, where \(p\) is the path to be returned. The signature with argument \texttt{ec} returns \texttt{path()} if an error occurs.

\textbf{Throws:} As specified in 30.10.7.

\textbf{[Example:} For POSIX-based operating systems, an implementation might return the path supplied by the first environment variable found in the list TMPDIR, TMP, TEMP, TEMPDIR, or if none of these are found, "/tmp".

For Windows-based operating systems, an implementation might return the path reported by the Windows \texttt{GetTempPath} API function. \textit{—end example]\)

\textbf{30.10.15.39 Weakly canonical} \hspace{1cm} [fs.op.weakly_canonical]

\begin{verbatim}
path weakly_canonical(const path& p);
path weakly_canonical(const path& p, error_code& ec);
\end{verbatim}

\textbf{Returns:} \(p\) with symlinks resolved and the result normalized (30.10.4.11).

\textbf{Effects:} Using \texttt{status(p)} or \texttt{status(p, ec)}, respectively, to determine existence, return a path composed by \texttt{operator/=} from the result of calling \texttt{canonical()} without a \texttt{base} argument and with a path argument composed of the leading elements of \(p\) that exist, if any, followed by the elements of \(p\) that do not exist, if any. For the first form, \texttt{canonical()} is called without an \texttt{error\_code} argument. For the second form, \texttt{canonical()} is called with \texttt{ec} as an \texttt{error\_code} argument, and \texttt{path()} is returned at the first error occurrence, if any.

\textbf{Postconditions:} The returned path is in normal form (30.10.4.11).
Remarks: Implementations are encouraged to avoid unnecessary normalization such as when canonical has already been called on the entirety of $p$.

Throws: As specified in 30.10.7.

    int vsnprintf(char* s, size_t n, const char* format, va_list arg);
    int vsprintf(char* s, const char* format, va_list arg);
    int vsscanf(const char* s, const char* format, va_list arg);
```
int fgetc(FILE* stream);
char* fgets(char* s, int n, FILE* stream);
int fputc(int c, FILE* stream);
int fputs(const char* s, FILE* stream);
int getchar();
int putc(int c, FILE* stream);
int putchar(int c);
int puts(const char* s);
int ungetc(int c, FILE* stream);
size_t fread(void* ptr, size_t size, size_t nmemb, FILE* stream);
size_t fwrite(const void* ptr, size_t size, size_t nmemb, FILE* stream);
int fgetpos(FILE* stream, fpos_t* pos);
int fseek(FILE* stream, long int offset, int whence);
int fsetpos(FILE* stream, const fpos_t* pos);
long int ftell(FILE* stream);
void rewind(FILE* stream);
void clearerr(FILE* stream);
int feof(FILE* stream);
int ferror(FILE* stream);
void perror(const char* s);

1 The contents and meaning of the header `<cstdio>` are the same as the C standard library header `<stdio.h>`.

2 Calls to the function `tmpnam` with an argument that is a null pointer value may introduce a data race (20.5.5.9) with other calls to `tmpnam` with an argument that is a null pointer value.

See also: ISO C 7.21.

30.11.2 Header `<cinttypes>` synopsis

```cpp
#include <cstdint>

namespace std {
    using imaxdiv_t = see below;

    intmax_t imaxabs(intmax_t j);
    imaxdiv_t imaxdiv(intmax_t numer, intmax_t denom);
    intmax_t strtoimax(const char* nptr, char** endptr, int base);
    uintmax_t strtoumax(const char* nptr, char** endptr, int base);
    intmax_t wcstoimax(const wchar_t* nptr, wchar_t** endptr, int base);
    uintmax_t wcstoumax(const wchar_t* nptr, wchar_t** endptr, int base);
    intmax_t abs(intmax_t);  // optional, see below
    imaxdiv_t div(intmax_t, intmax_t);  // optional, see below
}
```

#define PRIdN see below
#define PRIaN see below
#define PRIoN see below
#define PRIxN see below
#define PRIuN see below
#define SCNdN see below
#define SCNiN see below
#define SCNoN see below
#define SCNuN see below
The contents and meaning of the header `<cinttypes>` are the same as the C standard library header `<inttypes.h>`, with the following changes:

1. The header `<cinttypes>` includes the header `<cstdint>` instead of `<stdint.h>`, and
2. if and only if the type `intmax_t` designates an extended integer type (6.9.1), the following function signatures are added:

   ```
   intmax_t abs(intmax_t);
   imaxdiv_t div(intmax_t, intmax_t);
   ```

   which shall have the same semantics as the function signatures `intmax_t imaxabs(intmax_t)` and `intmax_t imaxdiv(intmax_t, intmax_t)`.
imaxdiv_t imaxdiv(intmax_t, intmax_t), respectively.

31  Regular expressions library  [re]

31.1 General  [re.general]

1 This Clause describes components that C++ programs may use to perform operations involving regular expression matching and searching.

2 The following subclauses describe a basic regular expression class template and its traits that can handle char-like (24.1) template arguments, two specializations of this class template that handle sequences of char and wchar_t, a class template that holds the result of a regular expression match, a series of algorithms that allow a character sequence to be operated upon by a regular expression, and two iterator types for enumerating regular expression matches, as described in Table 128.

31.2  Definitions  [re.def]

1 The following definitions shall apply to this Clause:

31.2.0.1  [defns.regex.collating.element]
collating element
a sequence of one or more characters within the current locale that collate as if they were a single character.

31.2.0.2  [defns.regex.finite.state.machine]
finite state machine
an unspecified data structure that is used to represent a regular expression, and which permits efficient matches against the regular expression to be obtained.

31.2.0.3  [defns.regex.formatspecifier]
format specifier
a sequence of one or more characters that is to be replaced with some part of a regular expression match.

31.2.0.4  [defns.regex.matched]
mached
a sequence of zero or more characters is matched by a regular expression when the characters in the sequence correspond to a sequence of characters defined by the pattern.

§ 31.2.0.4
31.2.0.5  
**[defns.regex.primary.equivalence.class]**  
**primary equivalence class**  
a set of one or more characters which share the same primary sort key: that is the sort key weighting that depends only upon character shape, and not accents, case, or locale specific tailorings.

31.2.0.6  
**[defns.regex.regular.expression]**  
**regular expression**  
a pattern that selects specific strings from a set of character strings.

31.2.0.7  
**[defns.regex.subexpression]**  
**sub-expression**  
a subset of a regular expression that has been marked by parenthesis.

31.3 **Requirements**  

1. This subclause defines requirements on classes representing regular expression traits. [Note: The class template `regex_traits`, defined in Clause 31.7, satisfies these requirements. — end note]

2. The class template `basic_regex`, defined in Clause 31.8, needs a set of related types and functions to complete the definition of its semantics. These types and functions are provided as a set of member `typedef-names` and functions in the template parameter `traits` used by the `basic_regex` class template. This subclause defines the semantics of these members.

3. To specialize class template `basic_regex` for a character container `CharT` and its related regular expression traits class `Traits`, use `basic_regex<CharT, Traits>`.

4. In Table 129 `X` denotes a traits class defining types and functions for the character container type `charT`; `u` is an object of type `X`; `v` is an object of type `const X`; `p` is a value of type `const charT*`; `I1` and `I2` are input iterators (27.2.3); `F1` and `F2` are forward iterators (27.2.5); `c` is a value of type `const charT`; `s` is an object of type `X::string_type`; `cs` is an object of type `const X::string_type`; `b` is a value of type `bool`; `I` is a value of type `int`; `cl` is an object of type `X::char_class_type`, and `loc` is an object of type `X::locale_type`.

<th>Assertion/note pre-/post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>v.translate_nocase(c)</td>
<td>X::char_type</td>
<td>For all characters C that are to be considered equivalent to c when comparisons are to be performed without regard to case, then v.translate_nocase(c) == v.translate_nocase(C).</td>
</tr>
<tr>
<td>v.transform(F1, F2)</td>
<td>X::string_type</td>
<td>Returns a sort key for the character sequence designated by the iterator range [F1, F2) such that if the character sequence [G1, G2) sorts before the character sequence [H1, H2) then v.transform(G1, G2) &lt; v.transform(H1, H2).</td>
</tr>
<tr>
<td>v.transform_primary(F1, F2)</td>
<td>X::string_type</td>
<td>Returns a sort key for the character sequence designated by the iterator range [F1, F2) such that if the character sequence [G1, G2) sorts before the character sequence [H1, H2) when character case is not considered then v.transform_primary(G1, G2) &lt; v.transform_primary(H1, H2).</td>
</tr>
<tr>
<td>v.lookup_collatename(F1, F2)</td>
<td>X::string_type</td>
<td>Returns a sequence of characters that represents the collating element consisting of the character sequence designated by the iterator range [F1, F2). Returns an empty string if the character sequence is not a valid collating element.</td>
</tr>
<tr>
<td>v.lookup_classname(F1, F2, b)</td>
<td>X::char_class_type</td>
<td>Converts the character sequence designated by the iterator range [F1, F2) into a value of a bitmask type that can subsequently be passed to isctype. Values returned from lookup_classname can be bitwise or’ed together; the resulting value represents membership in either of the corresponding character classes. If b is true, the returned bitmask is suitable for matching characters without regard to their case. Returns 0 if the character sequence is not the name of a character class recognized by X. The value returned shall be independent of the case of the characters in the sequence.</td>
</tr>
<tr>
<td>v.isctype(c, cl)</td>
<td>bool</td>
<td>Returns true if character c is a member of one of the character classes designated by cl, false otherwise.</td>
</tr>
<tr>
<td>v.value(c, I)</td>
<td>int</td>
<td>Returns the value represented by the digit c in base I if the character c is a valid digit in base I; otherwise returns -1. [Note: The value of I will only be 8, 10, or 16. — end note]</td>
</tr>
</tbody>
</table>

               const charT* fmt,
               regex_constants::match_flag_type flags = regex_constants::match_default);

§ 31.4
31.12.1, class template regex_iterator

```cpp
template <class BidirectionalIterator,
         class charT = typename iterator_traits<BidirectionalIterator>::value_type,
         class traits = regex_traits<charT>>
class regex_iterator;

using cregex_iterator = regex_iterator<const char*>;
using wcregex_iterator = regex_iterator<const wchar_t*>;
using sregex_iterator = regex_iterator<string::const_iterator>;
using wsregex_iterator = regex_iterator<wstring::const_iterator>;
```

31.12.2, class template regex_token_iterator

```cpp
template <class BidirectionalIterator,
         class charT = typename iterator_traits<BidirectionalIterator>::value_type,
         class traits = regex_traits<charT>>
class regex_token_iterator;

using cregex_token_iterator = regex_token_iterator<const char*>;
using wcregex_token_iterator = regex_token_iterator<const wchar_t*>;
using sregex_token_iterator = regex_token_iterator<string::const_iterator>;
using wsregex_token_iterator = regex_token_iterator<wstring::const_iterator>;
```

namespace pmr {
    template <class BidirectionalIterator>
    using match_results =
        std::match_results<BidirectionalIterator,
        polymorphic_allocator<sub_match<BidirectionalIterator>>>;

    using cmatch = match_results<const char*>;
    using wcmatch = match_results<const wchar_t*>;
    using smatch = match_results<string::const_iterator>;
    using wsmatch = match_results<wstring::const_iterator>;
}

31.5 Namespace std::regex_constants

```cpp```

namespace std::regex_constants {
    using syntax_option_type = T1;
    inline constexpr syntax_option_type icase = unspecified;
    inline constexpr syntax_option_type nosubs = unspecified;
    inline constexpr syntax_option_type optimize = unspecified;
    inline constexpr syntax_option_type collate = unspecified;
    inline constexpr syntax_option_type ECMAScript = unspecified;
    inline constexpr syntax_option_type basic = unspecified;
    inline constexpr syntax_option_type extended = unspecified;
    inline constexpr syntax_option_type awk = unspecified;
    inline constexpr syntax_option_type grep = unspecified;
    inline constexpr syntax_option_type egrep = unspecified;
    inline constexpr syntax_option_type multiline = unspecified;
}
```
The type `syntax_option_type` is an implementation-defined bitmask type (20.4.2.1.4). Setting its elements has the effects listed in Table 130. A valid value of type `syntax_option_type` shall have at most one of the grammar elements `ECMAScript`, `basic`, `extended`, `awk`, `grep`, `egrep`, set. If no grammar element is set, the default grammar is `ECMAScript`.

Table 130 — `syntax_option_type` effects

### 31.5.2 Bitmask type `match_flag_type`

```cpp
class std::match_flag_type {
    using match_flag_type = T2;
    inline constexpr match_flag_type match_default = {};
    inline constexpr match_flag_type match_not_bol = unspecified;
    inline constexpr match_flag_type match_not_eol = unspecified;
    inline constexpr match_flag_type match_not_bow = unspecified;
    inline constexpr match_flag_type match_not_eow = unspecified;
    inline constexpr match_flag_type match_any = unspecified;
    inline constexpr match_flag_type match_not_null = unspecified;
    inline constexpr match_flag_type match_continuous = unspecified;
    inline constexpr match_flag_type match_prev_avail = unspecified;
    inline constexpr match_flag_type format_default = {};
};
```

§ 31.5.2
inline constexpr match_flag_type format_sed = unspecified;
inline constexpr match_flag_type format_no_copy = unspecified;
inline constexpr match_flag_type format_first_only = unspecified;
}

1 The type `match_flag_type` is an implementation-defined bitmask type (20.4.2.1.4). The constants of that type, except for `match_default` and `format_default`, are bitmask elements. The `match_default` and `format_default` constants are empty bitmasks. Matching a regular expression against a sequence of characters `[first, last)` proceeds according to the rules of the grammar specified for the regular expression object, modified according to the effects listed in Table 131 for any bitmask elements set.

Table 131 — `regex_constants::match_flag_type` effects when obtaining a match against a character container sequence `[first, last)`.

<table>
<thead>
<tr>
<th>Element</th>
<th>Effect(s) if set</th>
</tr>
</thead>
<tbody>
<tr>
<td>match_not_bol</td>
<td>The first character in the sequence <code>[first, last)</code> shall be treated as though it is not at the beginning of a line, so the character <code>^</code> in the regular expression shall not match <code>[first, first)</code>.</td>
</tr>
</tbody>
</table>
| match_not_eol        | The last character in the sequence `[first, last)` shall be treated as though it is not at the end of a line, so the character `"$"` in the regular expression shall not match `[last, last)`.
| match_not_bow        | The expression `"\b"` shall not match the sub-sequence `[first, first)`.
| match_not_eow        | The expression `"\b"` shall not match the sub-sequence `[last, last)`.
| match_any            | If more than one match is possible then any match is an acceptable result.
| match_not_null       | The expression shall not match an empty sequence.
| match_continuous     | The expression shall only match a sub-sequence that begins at `first`.
| match_prev_avail     | `--first` is a valid iterator position. When this flag is set the flags `match_not_bol` and `match_not_bow` shall be ignored by the regular expression algorithms (31.11) and iterators (31.12).
| format_default       | When a regular expression match is to be replaced by a new string, the new string shall be constructed using the rules used by the ECMAScript replace function in ECMA-262, part 15.5.4.11 String.prototype.replace. In addition, during search and replace operations all non-overlapping occurrences of the regular expression shall be located and replaced, and sections of the input that did not match the expression shall be copied unchanged to the output string.
| format_sed           | When a regular expression match is to be replaced by a new string, the new string shall be constructed using the rules used by the sed utility in POSIX.
| format_no_copy       | During a search and replace operation, sections of the character container sequence being searched that do not match the regular expression shall not be copied to the output string.
| format_first_only    | When specified during a search and replace operation, only the first occurrence of the regular expression shall be replaced.

31.5.3 Implementation-defined error_type

```cpp
namespace std::regex_constants {
    using error_type = T3;
    inline constexpr error_type error_collate = unspecified;
    inline constexpr error_type error_ctype = unspecified;
    inline constexpr error_type error_escape = unspecified;
}
```
inline constexpr error_type error_backref = unspecified;
inline constexpr error_type error_brack = unspecified;
inline constexpr error_type error_paren = unspecified;
inline constexpr error_type error_brace = unspecified;
inline constexpr error_type error_badbrace = unspecified;
inline constexpr error_type error_range = unspecified;
inline constexpr error_type error_space = unspecified;
inline constexpr error_type error_badrepeat = unspecified;
inline constexpr error_type error_complexity = unspecified;
inline constexpr error_type error_stack = unspecified;
}

1 The type error_type is an implementation-defined enumerated type (20.4.2.1.3). Values of type error_type represent the error conditions described in Table 132:

<table>
<thead>
<tr>
<th>Value</th>
<th>Error condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>error_collate</td>
<td>The expression contained an invalid collating element name.</td>
</tr>
<tr>
<td>error_ctype</td>
<td>The expression contained an invalid character class name.</td>
</tr>
<tr>
<td>error_escape</td>
<td>The expression contained an invalid escaped character, or a trailing escape.</td>
</tr>
<tr>
<td>error_backref</td>
<td>The expression contained an invalid back reference.</td>
</tr>
<tr>
<td>error_brack</td>
<td>The expression contained mismatched [ and ].</td>
</tr>
<tr>
<td>error_paren</td>
<td>The expression contained mismatched ( and ).</td>
</tr>
<tr>
<td>error_brace</td>
<td>The expression contained mismatched { and }.</td>
</tr>
<tr>
<td>error_badbrace</td>
<td>The expression contained an invalid range in a {} expression.</td>
</tr>
<tr>
<td>error_range</td>
<td>The expression contained an invalid character range, such as [b-a] in most encodings.</td>
</tr>
<tr>
<td>error_space</td>
<td>There was insufficient memory to convert the expression into a finite state machine.</td>
</tr>
<tr>
<td>error_badrepeat</td>
<td>One of *?+{ was not preceded by a valid regular expression.</td>
</tr>
<tr>
<td>error_complexity</td>
<td>The complexity of an attempted match against a regular expression exceeded a pre-set level.</td>
</tr>
<tr>
<td>error_stack</td>
<td>There was insufficient memory to determine whether the regular expression could match the specified character sequence.</td>
</tr>
</tbody>
</table>

31.6 Class regex_error

class regex_error : public runtime_error {
public:
    explicit regex_error(regex_constants::error_type ecode);
    regex_constants::error_type code() const;
};

1 The class regex_error defines the type of objects thrown as exceptions to report errors from the regular expression library.

regex_error(regex_constants::error_type ecode);

2 Effects: Constructs an object of class regex_error.

3 Postconditions: ecode == code().

regex_constants::error_type code() const;

4 Returns: The error code that was passed to the constructor.
namespace std {
    template <class charT>
    struct regex_traits {
        using char_type = charT;
        using string_type = basic_string<char_type>;
        using locale_type = locale;
        using char_class_type = bitmask_type;

        regex_traits();
        static size_t length(const char_type* p);
        charT translate(charT c) const;
        charT translate_nocase(charT c) const;
        template <class ForwardIterator>
        string_type transform(ForwardIterator first, ForwardIterator last) const;
        template <class ForwardIterator>
        string_type transform_primary(ForwardIterator first, ForwardIterator last) const;
        template <class ForwardIterator>
        string_type lookup_collatename(ForwardIterator first, ForwardIterator last) const;
        template <class ForwardIterator>
        char_class_type lookup_classname(ForwardIterator first, ForwardIterator last, bool icase = false) const;
        bool isctype(charT c, char_class_type f) const;
        int value(charT ch, int radix) const;
        locale_type imbue(locale_type l);
        locale_type getloc() const;
    };
}

The specializations `regex_traits<char>` and `regex_traits<wchar_t>` shall be valid and shall satisfy the requirements for a regular expression traits class (31.3).

using char_class_type = bitmask_type;

The type `char_class_type` is used to represent a character classification and is capable of holding an implementation specific set returned by `lookup_classname`.

static size_t length(const char_type* p);

Returns: `char_traits<charT>::length(p)`.

charT translate(charT c) const;

Returns: `c`.

charT translate_nocase(charT c) const;

Returns: `use_facet<ctype<charT>>(getloc()).tolower(c)`.

template <class ForwardIterator>
string_type transform(ForwardIterator first, ForwardIterator last) const;

Effects: As if by:

string_type str(first, last);
return use_facet<collate<charT>>(
    getloc()).transform(&*str.begin(), &*str.begin() + str.length());

§ 31.7 1310
template <class ForwardIterator>
string_type transform_primary(ForwardIterator first, ForwardIterator last) const;

Effects: If

typeid(use_facet<collate<charT>>) == typeid(collate_byname<charT>)
and the form of the sort key returned by collate_byname<charT>::transform(first, last) is
known and can be converted into a primary sort key then returns that key, otherwise returns an empty
string.

template <class ForwardIterator>
string_type lookup_collatename(ForwardIterator first, ForwardIterator last) const;

Returns: a sequence of one or more characters that represents the collating element consisting of the
character sequence designated by the iterator range [first, last). Returns an empty string if the
character sequence is not a valid collating element.

template <class ForwardIterator>
char_class_type lookup_classname(
  ForwardIterator first, ForwardIterator last, bool icase = false) const;

Returns: an unspecified value that represents the character classification named by the character
sequence designated by the iterator range [first, last). If the parameter icase is true then the
returned mask identifies the character classification without regard to the case of the characters being
matched, otherwise it does honor the case of the characters being matched. The value returned shall
be independent of the case of the characters in the character sequence. If the name is not recognized
then returns char_class_type().

Remarks: For regex_traits<char>, at least the narrow character names in Table 133 shall be
recognized. For regex_traits<wchar_t>, at least the wide character names in Table 133 shall be
recognized.

bool isctype(charT c, char_class_type f) const;

Effects: Determines if the character c is a member of the character classification represented by f.

Returns: Given the following function declaration:

// for exposition only
template<class C>
  ctype_base::mask convert(typename regex_traits<C>::char_class_type f);

that returns a value in which each ctype_base::mask value corresponding to a value in f named in
Table 133 is set, then the result is determined as if by:

case_base::mask m = convert<charT>(f);
const ctype<charT>& ct = use_facet<ctype<charT>>(getloc());
if (ct.is(m, c)) {
  return true;
} else if (c == ct.widen('z')) {
  charT w[1] = { ct.widen('w') };
  char_class_type x = lookup_classname(w, w+1);
  return (f&x) == x;
} else {
  return false;
}

| Example:

329) For example, if the parameter icase is true then [:lower:] is the same as [:alpha:].

§ 31.7 1311
regex_traits<char> t;
string d("d");
string u("upper");
regex_traits<char>::char_class_type f;
f = t.lookup_classname(d.begin(), d.end());
f |= t.lookup_classname(u.begin(), u.end());
ctype_base::mask m = convert<char>(f); // m == ctype_base::digit|ctype_base::upper
— end example ]
Example:
regex_traits<char> t;
string w("w");
regex_traits<char>::char_class_type f;
f = t.lookup_classname(w.begin(), w.end());
t.isctype('A', f); // returns true
t.isctype('_', f); // returns true
t.isctype(' ', f); // returns false
— end example ]

int value(charT ch, int radix) const;

Requires: The value of radix shall be 8, 10, or 16.

Returns: the value represented by the digit ch in base radix if the character ch is a valid digit in base radix; otherwise returns -1.

locale_type imbue(locale_type loc);

Effects: Imbues this with a copy of the locale loc. [Note: Calling imbue with a different locale than the one currently in use invalidates all cached data held by *this. — end note]

Returns: if no locale has been previously imbued then a copy of the global locale in effect at the time of construction of *this, otherwise a copy of the last argument passed to imbue.

Postconditions: getloc() == loc.

locale_type getloc() const;

Returns: if no locale has been imbued then a copy of the global locale in effect at the time of construction of *this, otherwise a copy of the last argument passed to imbue.

31.8 Class template basic_regex [re.regex]

For a char-like type charT, specializations of class template basic_regex represent regular expressions constructed from character sequences of charT characters. In the rest of 31.8, charT denotes a given char-like type. Storage for a regular expression is allocated and freed as necessary by the member functions of class basic_regex.

Objects of type specialization of basic_regex are responsible for converting the sequence of charT objects to an internal representation. It is not specified what form this representation takes, nor how it is accessed by algorithms that operate on regular expressions. [Note: Implementations will typically declare some function templates as friends of basic_regex to achieve this — end note]

The functions described in this Clause report errors by throwing exceptions of type regex_error.

namespace std {
    template <class charT, class traits = regex_traits<charT> >
    class basic_regex {
    public:
        // types:
        using value_type = charT;
    }}
Table 133 — Character class names and corresponding `ctype` masks

static constexpr regex_constants::syntax_option_type egrep = regex_constants::egrep;
static constexpr regex_constants::syntax_option_type multiline = regex_constants::multiline;

The static constant members are provided as synonyms for the constants declared in namespace regex_constants.

31.8.2 basic_regex constructors

basic_regex();

Effects: Constructs an object of class basic_regex that does not match any character sequence.

explicit basic_regex(const charT* p, flag_type f = regex_constants::ECMAScript);

Requires: p shall not be a null pointer.

Throws: regex_error if p is not a valid regular expression.

Effects: Constructs an object of class basic_regex; the object’s internal finite state machine is
constructed from the regular expression contained in the array of charT of length char_traits<charT>::
length(p) whose first element is designated by p, and interpreted according to the flags f.

Postconditions: flags() returns f. mark_count() returns the number of marked sub-expressions
within the expression.

basic_regex(const charT* p, size_t len, flag_type f);

Requires: p shall not be a null pointer.

Throws: regex_error if p is not a valid regular expression.

Effects: Constructs an object of class basic_regex; the object’s internal finite state machine is
constructed from the regular expression contained in the sequence of characters [p, p+len), and
interpreted according to the flags specified in f.

Postconditions: flags() returns f. mark_count() returns the number of marked sub-expressions
within the expression.

basic_regex(const basic_regex& e);

Effects: Constructs an object of class basic_regex as a copy of the object e.

Postconditions: flags() and mark_count() return e.flags() and e.mark_count(), respectively.

basic_regex(basic_regex&& e) noexcept;

Effects: Move constructs an object of class basic_regex from e.

Postconditions: flags() and mark_count() return the values that e.flags() and e.mark_count(),
respectively, had before construction. e is in a valid state with unspecified value.

template <class ST, class SA>
explicit basic_regex(const basic_string<charT, ST, SA>& s,

flag_type f = regex_constants::ECMAScript);

Throws: regex_error if s is not a valid regular expression.

§ 31.8.2
Effects: Constructs an object of class basic_regex; the object’s internal finite state machine is constructed from the regular expression contained in the string s, and interpreted according to the flags specified in f.

Postconditions: flags() returns f. mark_count() returns the number of marked sub-expressions within the expression.

```cpp
template <class ForwardIterator>
basic_regex(ForwardIterator first, ForwardIterator last,
    flag_type f = regex_constants::ECMAScript);
```

Throws: regex_error if the sequence [first, last) is not a valid regular expression.

Effects: Constructs an object of class basic_regex; the object’s internal finite state machine is constructed from the regular expression contained in the sequence of characters [first, last), and interpreted according to the flags specified in f.

Postconditions: flags() returns f. mark_count() returns the number of marked sub-expressions within the expression.

```cpp
basic_regex(initializer_list<charT> il, flag_type f = regex_constants::ECMAScript);
```

Effects: Same as basic_regex(il.begin(), il.end(), f).

### 31.8.3 basic_regex assign

```cpp
basic_regex& operator=(const basic_regex& e);
```

Effects: Copies e into *this and returns *this.

Postconditions: flags() and mark_count() return e.flags() and e.mark_count(), respectively.

```cpp
basic_regex& operator=(basic_regex&& e) noexcept;
```

Effects: Move assigns from e into *this and returns *this.

Postconditions: flags() and mark_count() return the values that e.flags() and e.mark_count(), respectively, had before assignment. e is in a valid state with unspecified value.

```cpp
basic_regex& operator=(const charT* ptr);
```

Requires: ptr shall not be a null pointer.

Effects: Returns assign(ptr).

```cpp
basic_regex& operator=(initializer_list<charT> il);
```

Effects: Returns assign(il.begin(), il.end()).

```cpp
template <class ST, class SA>
basic_regex& operator=(const basic_string<charT, ST, SA>& p);
```

Effects: Returns assign(p).

```cpp
basic_regex& assign(const basic_regex& that);
```

Effects: Equivalent to *this = that.

Returns: *this.

```cpp
basic_regex& assign(basic_regex&& that) noexcept;
```

Effects: Equivalent to *this = std::move(that).

Returns: *this.
basic_regex& assign(const charT* ptr, flag_type f = regex_constants::ECMAScript);
  
  Returns: assign(string_type(ptr), f).

basic_regex& assign(const charT* ptr, size_t len, flag_type f = regex_constants::ECMAScript);
  
  Returns: assign(string_type(ptr, len), f).

template <class string_traits, class A>
  basic_regex& assign(const basic_string<charT, string_traits, A>& s,
                     flag_type f = regex_constants::ECMAScript);
  
  Throws: regex_error if s is not a valid regular expression.

  Returns: *this.

Effects: Assigns the regular expression contained in the string s, interpreted according the flags specified in f. If an exception is thrown, *this is unchanged.

Postconditions: If no exception is thrown, flags() returns f and mark_count() returns the number of marked sub-expressions within the expression.

template <class InputIterator>
  basic_regex& assign(InputIterator first, InputIterator last,
                      flag_type f = regex_constants::ECMAScript);
  
  Requires: The type InputIterator shall satisfy the requirements for an Input Iterator (27.2.3).

  Returns: assign(string_type(first, last), f).

basic_regex& assign(initializer_list<charT> il,
                   flag_type f = regex_constants::ECMAScript);
  
  Effects: Same as assign(il.begin(), il.end(), f).

  Returns: *this.

31.8.4 basic_regex constant operations [re.regex.operations]

unsigned mark_count() const;
  
  Effects: Returns the number of marked sub-expressions within the regular expression.

flag_type flags() const;
  
  Effects: Returns a copy of the regular expression syntax flags that were passed to the object’s constructor or to the last call to assign.

31.8.5 basic_regex locale [re.regex.locale]

locale_type imbue(locale_type loc);
  
  Effects: Returns the result of traits_inst.imbue(loc) where traits_inst is a (default-initialized) instance of the template type argument traits stored within the object. After a call to imbue the basic_regex object does not match any character sequence.

locale_type getloc() const;
  
  Effects: Returns the result of traits_inst.getloc() where traits_inst is a (default-initialized) instance of the template parameter traits stored within the object.

31.8.6 basic_regex swap [re.regex.swap]

void swap(basic_regex& e);

§ 31.8.6
Effects: Swaps the contents of the two regular expressions.

Postconditions: *this contains the regular expression that was in e, e contains the regular expression that was in *this.

Complexity: Constant time.

31.8.7 basic_regex non-member functions [re.regex.nonmemb]

31.8.7.1 basic_regex non-member swap [re.regex.nmswap]

template <class charT, class traits>
void swap(basic_regex<charT, traits>& lhs, basic_regex<charT, traits>& rhs);

Effects: Calls lhs.swap(rhs).

31.9 Class template sub_match [re.submatch]

Class template sub_match denotes the sequence of characters matched by a particular marked sub-expression.

namespace std {
    template <class BidirectionalIterator>
    class sub_match : public pair<BidirectionalIterator, BidirectionalIterator> {
        public:
            using value_type = typename iterator_traits<BidirectionalIterator>::value_type;
            using difference_type = typename iterator_traits<BidirectionalIterator>::difference_type;
            using iterator = BidirectionalIterator;
            using string_type = basic_string<value_type>;

            bool matched;

            constexpr sub_match();

            difference_type length() const;
            operator string_type() const;
            string_type str() const;

            int compare(const sub_match& s) const;
            int compare(const string_type& s) const;
            int compare(const value_type* s) const;
    }
}

31.9.1 sub_match members [re.submatch.members]

constexpr sub_match();

Effects: Value-initializes the pair base class subobject and the member matched.

difference_type length() const;

Returns: matched ? distance(first, second) : 0.

operator string_type() const;

Returns: matched ? string_type(first, second) : string_type().

string_type str() const;

Returns: matched ? string_type(first, second) : string_type().
int compare(const sub_match& s) const;
  Returns: str().compare(s.str()).

int compare(const string_type& s) const;
  Returns: str().compare(s).

int compare(const value_type* s) const;
  Returns: str().compare(s).

31.9.2 sub_match non-member operators [re.submatch.op]

template <class BiIter>
  bool operator==(const sub_match<BiIter>& lhs, const sub_match<BiIter>& rhs);
  Returns: lhs.compare(rhs) == 0.

template <class BiIter>
  bool operator!=(const sub_match<BiIter>& lhs, const sub_match<BiIter>& rhs);
  Returns: lhs.compare(rhs) != 0.

template <class BiIter>
  bool operator<(const sub_match<BiIter>& lhs, const sub_match<BiIter>& rhs);
  Returns: lhs.compare(rhs) < 0.

template <class BiIter>
  bool operator<=(const sub_match<BiIter>& lhs, const sub_match<BiIter>& rhs);
  Returns: lhs.compare(rhs) <= 0.

template <class BiIter>
  bool operator>(const sub_match<BiIter>& lhs, const sub_match<BiIter>& rhs);
  Returns: lhs.compare(rhs) > 0.

template <class BiIter, class ST, class SA>
  bool operator==(
    const basic_string<typename iterator_traits<BiIter>::value_type, ST, SA>& lhs,
    const sub_match<BiIter>& rhs);
  Returns:
    rhs.compare(typename sub_match<BiIter>::string_type(lhs.data(), lhs.size())) == 0

template <class BiIter, class ST, class SA>
  bool operator!=(
    const basic_string<typename iterator_traits<BiIter>::value_type, ST, SA>& lhs,
    const sub_match<BiIter>& rhs);
  Returns: !(lhs == rhs).
template <class BiIter, class ST, class SA>
bool operator>(
    const basic_string<typename iterator_traits<BiIter>::value_type, ST, SA>&& lhs,
    const sub_match<BiIter>&& rhs);

Returns: rhs > lhs.

template <class BiIter, class ST, class SA>
bool operator<(
    const basic_string<typename iterator_traits<BiIter>::value_type, ST, SA>&& lhs,
    const sub_match<BiIter>&& rhs);

Returns: !rhs < lhs.

template <class BiIter, class ST, class SA>
bool operator==(const sub_match<BiIter>&& lhs,
    const basic_string<typename iterator_traits<BiIter>::value_type, ST, SA>& rhs);

Returns: lhs.compare(typename sub_match<BiIter>::string_type(rhs.data(), rhs.size())) == 0

template <class BiIter, class ST, class SA>
bool operator!=(const sub_match<BiIter>&& lhs,
    const basic_string<typename iterator_traits<BiIter>::value_type, ST, SA>& rhs);

Returns: !lhs == rhs.

template <class BiIter, class ST, class SA>
bool operator<=(const sub_match<BiIter>&& lhs,
    const basic_string<typename iterator_traits<BiIter>::value_type, ST, SA>& rhs);

Returns: !lhs < rhs.

template <class BiIter, class ST, class SA>
bool operator>=(const sub_match<BiIter>&& lhs,
    const basic_string<typename iterator_traits<BiIter>::value_type, ST, SA>& rhs);

Returns: !rhs < lhs.
template <class BiIter, class ST, class SA>
bool operator<=(
        const sub_match<BiIter>& lhs,
        const basic_string<typename iterator_traits<BiIter>::value_type, ST, SA>& rhs);

   Returns: !(rhs < lhs).

template <class BiIter>
bool operator==(const basic_string<typename iterator_traits<BiIter>::value_type, ST, SA>& lhs, 
        const sub_match<BiIter>& rhs);

   Returns: ! (rhs < lhs).

template <class BiIter>
bool operator==(const typename iterator_traits<BiIter>::value_type* lhs,  
        const sub_match<BiIter>& rhs);

   Returns: rhs.compare(lhs) == 0.

template <class BiIter>
bool operator!=(const typename iterator_traits<BiIter>::value_type* lhs,  
        const sub_match<BiIter>& rhs);

   Returns: !(lhs == rhs).

template <class BiIter>
bool operator<(const typename iterator_traits<BiIter>::value_type* lhs,  
        const sub_match<BiIter>& rhs);

   Returns: rhs.compare(lhs) > 0.

template <class BiIter>
bool operator>(const typename iterator_traits<BiIter>::value_type* lhs,  
        const sub_match<BiIter>& rhs);

   Returns: rhs < lhs.

§ 31.9.2
bool operator>(const sub_match<BiIter>& lhs,  
   const typename iterator_traits<BiIter>::value_type* rhs);

   Returns: rhs < lhs.

template <class BiIter>  
bool operator>=(const sub_match<BiIter>& lhs,  
   const typename iterator_traits<BiIter>::value_type* rhs);

   Returns: !(lhs < rhs).

template <class BiIter>  
bool operator<=(const sub_match<BiIter>& lhs,  
   const typename iterator_traits<BiIter>::value_type* rhs);

   Returns: !(rhs < lhs).

template <class BiIter>  
bool operator==(const typename iterator_traits<BiIter>::value_type& lhs,  
   const sub_match<BiIter>& rhs);

   Returns: rhs.compare(typename sub_match<BiIter>::string_type(1, lhs)) == 0.

template <class BiIter>  
bool operator!=(const typename iterator_traits<BiIter>::value_type& lhs,  
   const sub_match<BiIter>& rhs);

   Returns: !(lhs == rhs).

template <class BiIter>  
bool operator<(const typename iterator_traits<BiIter>::value_type& lhs,  
   const sub_match<BiIter>& rhs);

   Returns: rhs < lhs.

template <class BiIter>  
bool operator>=(const typename iterator_traits<BiIter>::value_type& lhs,  
   const sub_match<BiIter>& rhs);

   Returns: !(lhs < rhs).

template <class BiIter>  
bool operator<=(const typename iterator_traits<BiIter>::value_type& lhs,  
   const sub_match<BiIter>& rhs);

   Returns: !(rhs < lhs).

template <class BiIter>  
bool operator==(const sub_match<BiIter>& lhs,  
   const typename iterator_traits<BiIter>::value_type& rhs);

   Returns: lhs.compare(typename sub_match<BiIter>::string_type(1, rhs)) == 0.

template <class BiIter>  
bool operator!=(const sub_match<BiIter>& lhs,  
   const typename iterator_traits<BiIter>::value_type& rhs);

§ 31.9.2 1322
template <class BiIter>
bool operator<(const sub_match<BiIter>& lhs, const typename iterator_traits<BiIter>::value_type& rhs);

Returns: 

\(lhs \text{ compare}(\text{typename sub_match<BiIter>::string_type(1, rhs)}) < 0\).

template <class BiIter>
bool operator>(const sub_match<BiIter>& lhs, const typename iterator_traits<BiIter>::value_type& rhs);

Returns: 

\(\text{rhs} < \text{lhs}\).

template <class BiIter>
bool operator>=(const sub_match<BiIter>& lhs, const typename iterator_traits<BiIter>::value_type& rhs);

Returns: 

\!(\text{lhs} < \text{rhs})\).

template <class BiIter>
bool operator<=(const sub_match<BiIter>& lhs, const typename iterator_traits<BiIter>::value_type& rhs);

Returns: 

\!(\text{rhs} < \text{lhs})\).

template <class charT, class ST, class BiIter>
basic_ostream<charT, ST>& operator<<(basic_ostream<charT, ST>& os, const sub_match<BiIter>& m);

Returns: 

\(\text{os} \ll \text{m}.\text{str}()\).

31.10 Class template match_results

Class template match_results denotes a collection of character sequences representing the result of a regular expression match. Storage for the collection is allocated and freed as necessary by the member functions of class template match_results.

The class template match_results satisfies the requirements of an allocator-aware container and of a sequence container (26.2.1, 26.2.3) except that only operations defined for const-qualified sequence containers are supported and that the semantics of comparison functions are different from those required for a container.

A default-constructed match_results object has no fully established result state. A match result is ready when, as a consequence of a completed regular expression match modifying such an object, its result state becomes fully established. The effects of calling most member functions from a match_results object that is not ready are undefined.

The sub_match object stored at index 0 represents sub-expression 0, i.e., the whole match. In this case the sub_match member matched is always true. The sub_match object stored at index n denotes what matched the marked sub-expression n within the matched expression. If the sub-expression n participated in a regular expression match then the sub_match member matched evaluates to true, and members first and second denote the range of characters [first, second) which formed that match. Otherwise matched is false, and members first and second point to the end of the sequence that was searched. [Note: The sub_match objects representing different sub-expressions that did not participate in a regular expression match need not be distinct. — end note]
public:
    using value_type = sub_match<BidirectionalIterator>;
    using const_reference = const value_type&;
    using reference = value_type&;
    using const_iterator =
        implementation-defined;
    using iterator = const_iterator;
    using difference_type =
        typename iterator_traits<BidirectionalIterator>::difference_type;
    using size_type = typename allocator_traits<Allocator>::size_type;
    using allocator_type = Allocator;
    using char_type =
        typename iterator_traits<BidirectionalIterator>::value_type;
    using string_type = basic_string<char_type>;

    // 31.10.1, construct/copy/destroy
    explicit match_results(const Allocator& a = Allocator());
    match_results(const match_results& m);
    match_results(match_results&& m) noexcept;
    match_results& operator=(const match_results& m);
    match_results& operator=(match_results&& m);
    ~match_results();

    // 31.10.2, state
    bool ready() const;

    const_iterator end() const;
    const_iterator cbegin() const;
    const_iterator cend() const;

    // 31.10.5, format
    template <class OutputIter>
    OutputIter format(OutputIter out,
                      const char_type* fmt_first, const char_type* fmt_last,
                      regex_constants::match_flag_type flags = regex_constants::format_default) const;
    template <class OutputIter, class ST, class SA>
    OutputIter format(OutputIter out,
                        const basic_string<char_type, ST, SA>& fmt,
                        regex_constants::match_flag_type flags = regex_constants::format_default) const;
    template <class ST, class SA>
31.10.1 match_results constructors

In all match_results constructors, a copy of the Allocator argument shall be used for any memory allocation performed by the constructor or member functions during the lifetime of the object.

1 match_results(const Allocator& a = Allocator());
   Effects: Constructs an object of class match_results.
   Postconditions: ready() returns false. size() returns 0.

2 match_results(const Allocator& m);
   Effects: Constructs an object of class match_results, as a copy of m.

3 match_results(match_results&& m) noexcept;
   Effects: Move constructs an object of class match_results from m satisfying the same postconditions as Table 134. Additionally, the stored Allocator value is move constructed from m.get_allocator().
   Throws: Nothing.

4 match_results& operator=(const match_results& m);
   Effects: Assigns m to *this. The postconditions of this function are indicated in Table 134.

5 match_results& operator=(match_results&& m);
   Effects: Move-assigns m to *this. The postconditions of this function are indicated in Table 134.

Table 134 — match_results assignment operator effects

31.10.2 match_results state
bool ready() const;
   Returns: true if *this has a fully established result state, otherwise false.

31.10.3 match_results size
   size_type size() const; [re.results.size]
   Returns: One plus the number of marked sub-expressions in the regular expression that was matched
   if *this represents the result of a successful match. Otherwise returns 0. [Note: The state of a
   match_results object can be modified only by passing that object to regex_match or regex_search.
   Sections 31.11.2 and 31.11.3 specify the effects of those algorithms on their match_results arguments.
   —end note]

size_type max_size() const;
   Returns: The maximum number of sub_match elements that can be stored in *this.

bool empty() const;
   Returns: size() == 0.

31.10.4 match_results element access
   difference_type length(size_type sub = 0) const; [re.results.acc]
     Requires: ready() == true.
   Returns: (*this)[sub].length().

difference_type position(size_type sub = 0) const;
     Requires: ready() == true.
   Returns: The distance from the start of the target sequence to (*this)[sub].first.

string_type str(size_type sub = 0) const;
     Requires: ready() == true.
   Returns: string_type((*this)[sub]).

const_reference operator[](size_type n) const;
     Requires: ready() == true.
   Returns: A reference to the sub_match object representing the character sequence that matched marked
   sub-expression n. If n == 0 then returns a reference to a sub_match object representing the character
   sequence that matched the whole regular expression. If n >= size() then returns a sub_match object
   representing an unmatched sub-expression.

const_reference prefix() const;
     Requires: ready() == true.
   Returns: A reference to the sub_match object representing the character sequence from the start of the
   string being matched/searched to the start of the match found.

const_reference suffix() const;
     Requires: ready() == true.
   Returns: A reference to the sub_match object representing the character sequence from the end of the
   match found to the end of the string being matched/searched.
const_iterator begin() const;
const_iterator cbegin() const;

Returns: A starting iterator that enumerates over all the sub-expressions stored in *this.

const_iterator end() const;
const_iterator cend() const;

Returns: A terminating iterator that enumerates over all the sub-expressions stored in *this.

31.10.5 match_results formatting

|template <class OutputIter> |
|OutputIter format( |
|OutputIter out, |
|const char_type* fmt_first, const char_type* fmt_last, |
|regex_constants::match_flag_type flags = regex_constants::format_default) const; |
|\textbf{Requires:} \textit{ready() == true} and \textit{OutputIter} shall satisfy the requirements for an Output Iterator (27.2.4). |
|\textbf{Effects:} Copies the character sequence \([fmt\_first, fmt\_last)\) to \textit{OutputIter out}. Replaces each format specifier or escape sequence in the copied range with either the character(s) it represents or the sequence of characters within \*this to which it refers. The bitmasks specified in \textit{flags} determine which format specifiers and escape sequences are recognized. |
|\textbf{Returns:} out. |

|template <class OutputIter, class ST, class SA> |
|OutputIter format( |
|OutputIter out, |
|const basic_string<char_type, ST, SA>& fmt, |
|regex_constants::match_flag_type flags = regex_constants::format_default) const; |
|\textbf{Effects:} Equivalent to: |
|\textbf{return format(out, fmt.data(), fmt.data() + fmt.size(), flags);} |

|template <class ST, class SA> |
|basic_string<char_type, ST, SA> format( |
|const basic_string<char_type, ST, SA>& fmt, |
|regex_constants::match_flag_type flags = regex_constants::format_default) const; |
|\textbf{Requires:} \textit{ready() == true}. |
|\textbf{Effects:} Constructs an empty string \textit{result} of type basic_string<char_type, ST, SA> and calls: |
|\textbf{format(back_inserter(result), fmt, flags);} |
|\textbf{Returns:} result. |

|string_type format( |
|const char_type* fmt, |
|regex_constants::match_flag_type flags = regex_constants::format_default) const; |
|\textbf{Requires:} \textit{ready() == true}. |
|\textbf{Effects:} Constructs an empty string \textit{result} of type string_type and calls: |
|\textbf{format(back_inserter(result), fmt, fmt + char_traits<char_type>::length(fmt), flags);} |
|\textbf{Returns:} result. |

31.10.6 match_results allocator

\[re\textunderscore results\textunderscore all\]
allocator_type get_allocator() const;

Returns: A copy of the Allocator that was passed to the object’s constructor or, if that allocator has been replaced, a copy of the most recent replacement.

31.10.7 match_results swap [re.results.swap]

void swap(match_results& that);

Effects: Swaps the contents of the two sequences.

Postconditions: *this contains the sequence of matched sub-expressions that were in that, that contains the sequence of matched sub-expressions that were in *this.

Complexity: Constant time.

template <class BidirectionalIterator, class Allocator>
void swap(match_results<BidirectionalIterator, Allocator>& m1, match_results<BidirectionalIterator, Allocator>& m2);

Effects: As if by m1.swap(m2).

31.10.8 match_results non-member functions [re.results.nonmember]

template <class BidirectionalIterator, class Allocator>
bool operator==(const match_results<BidirectionalIterator, Allocator>& m1, const match_results<BidirectionalIterator, Allocator>& m2);

Returns: true if neither match result is ready, false if one match result is ready and the other is not. If both match results are ready, returns true only if:

(1.1) — m1.empty() && m2.empty(), or
(1.2) — !m1.empty() && !m2.empty(), and the following conditions are satisfied:
(1.2.1) — m1.prefix() == m2.prefix(),
(1.2.2) — m1.size() == m2.size() && equal(m1.begin(), m1.end(), m2.begin()), and
(1.2.3) — m1.suffix() == m2.suffix().

[Note: The algorithm equal is defined in Clause 28. —end note]

template <class BidirectionalIterator, class Allocator>
bool operator!=(const match_results<BidirectionalIterator, Allocator>& m1, const match_results<BidirectionalIterator, Allocator>& m2);

Returns: !(m1 == m2).

31.11 Regular expression algorithms [re.alg]

31.11.1 Exceptions [re.except]

The algorithms described in this subclause may throw an exception of type regex_error. If such an exception e is thrown, e.code() shall return either regex_constants::error_complexity or regex_constants::error_stack.

31.11.2 regex_match [re.alg.match]

template <class BidirectionalIterator, class Allocator, class charT, class traits>
bool regex_match(BidirectionalIterator first, BidirectionalIterator last, match_results<BidirectionalIterator, Allocator>& m,
                 const basic_regex<charT, traits>& e,
                 regex_constants::match_flag_type flags = regex_constants::match_default);
Requires: The type BidirectionalIterator shall satisfy the requirements of a Bidirectional Iterator (27.2.6).

Effects: Determines whether there is a match between the regular expression e, and all of the character sequence \([first, last)\). The parameter flags is used to control how the expression is matched against the character sequence. When determining if there is a match, only potential matches that match the entire character sequence are considered. Returns `true` if such a match exists, `false` otherwise. [Example:

```cpp
std::regex re("Get|GetValue");
std::cmatch m;
regex_search("GetValue", m, re);  // returns true, and m[0] contains "Get"
regex_match ("GetValue", m, re); // returns true, and m[0] contains "Get"
regex_search("GetValues", m, re); // returns true, and m[0] contains "Get"
regex_match ("GetValues", m, re); // returns false
```
—end example]

Postconditions: \(m\.ready() == \text{true}\) in all cases. If the function returns `false`, then the effect on parameter \(m\) is unspecified except that \(m\.size()\) returns 0 and \(m\.empty()\) returns `true`. Otherwise the effects on parameter \(n\) are given in Table 135.

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>(m.size())</td>
<td>(1 + e.mark_count())</td>
</tr>
<tr>
<td>(m.empty())</td>
<td><code>false</code></td>
</tr>
<tr>
<td>(m.prefix().first)</td>
<td><code>first</code></td>
</tr>
<tr>
<td>(m.prefix().second)</td>
<td><code>first</code></td>
</tr>
<tr>
<td>(m.prefix().matched)</td>
<td><code>false</code></td>
</tr>
<tr>
<td>(m.suffix().first)</td>
<td><code>last</code></td>
</tr>
<tr>
<td>(m.suffix().second)</td>
<td><code>last</code></td>
</tr>
<tr>
<td>(m.suffix().matched)</td>
<td><code>false</code></td>
</tr>
<tr>
<td>(m[0].first)</td>
<td><code>first</code></td>
</tr>
<tr>
<td>(m[0].second)</td>
<td><code>last</code></td>
</tr>
<tr>
<td>(m[0].matched)</td>
<td><code>true</code></td>
</tr>
<tr>
<td>(m[n].first)</td>
<td>For all integers (0 &lt; n &lt; m.size()), the start of the sequence that matched sub-expression (n). Alternatively, if sub-expression (n) did not participate in the match, then <code>last</code>.</td>
</tr>
<tr>
<td>(m[n].second)</td>
<td>For all integers (0 &lt; n &lt; m.size()), the end of the sequence that matched sub-expression (n). Alternatively, if sub-expression (n) did not participate in the match, then <code>last</code>.</td>
</tr>
<tr>
<td>(m[n].matched)</td>
<td>For all integers (0 &lt; n &lt; m.size()), <code>true</code> if sub-expression (n) participated in the match, <code>false</code> otherwise.</td>
</tr>
</tbody>
</table>

```
template <class BidirectionalIterator, class charT, class traits>
bool regex_match(BidirectionalIterator first, BidirectionalIterator last,
    const basic_regex<charT, traits>& e,
    regex_constants::match_flag_type flags = regex_constants::match_default);
```

Effects: Behaves “as if” by constructing an instance of `match_results<BidirectionalIterator>`
what, and then returning the result of `regex_match(first, last, what, e, flags)`.

```cpp
template <class charT, class Allocator, class traits>
bool regex_match(const charT* str,
                 match_results<const charT*, Allocator>& m,
                 const basic_regex<charT, traits>& e,
                 regex_constants::match_flag_type flags = regex_constants::match_default);
```

**Returns:** `regex_match(str, str + char_traits<charT>::length(str), m, e, flags)`.

```cpp
template <class ST, class SA, class Allocator, class charT, class traits>
bool regex_match(const basic_string<charT, ST, SA>& s,
                 match_results<typename basic_string<charT, ST, SA>::const_iterator,
                               Allocator>& m,
                 const basic_regex<charT, traits>& e,
                 regex_constants::match_flag_type flags = regex_constants::match_default);
```

**Returns:** `regex_match(s.begin(), s.end(), m, e, flags)`.

```cpp
template <class charT, class traits>
bool regex_match(const charT* str,
                 const basic_regex<charT, traits>& e,
                 regex_constants::match_flag_type flags = regex_constants::match_default);
```

**Returns:** `regex_match(str, str + char_traits<charT>::length(str), e, flags)`.

```cpp
template <class ST, class SA, class charT, class traits>
bool regex_match(const basic_string<charT, ST, SA>& s,
                 const basic_regex<charT, traits>& e,
                 regex_constants::match_flag_type flags = regex_constants::match_default);
```

**Returns:** `regex_match(s.begin(), s.end(), e, flags)`.

### 31.11.3 `regex_search` [re.alg.search]

```cpp
template <class BidirectionalIterator, class Allocator, class charT, class traits>
bool regex_search(BidirectionalIterator first, BidirectionalIterator last,
                  match_results<BidirectionalIterator, Allocator>& m,
                  const basic_regex<charT, traits>& e,
                  regex_constants::match_flag_type flags = regex_constants::match_default);
```

**Requires:** Type `BidirectionalIterator` shall satisfy the requirements of a Bidirectional Iterator (27.2.6).

**Effects:** Determines whether there is some sub-sequence within `[first, last)` that matches the regular expression `e`. The parameter `flags` is used to control how the expression is matched against the character sequence. Returns `true` if such a sequence exists, `false` otherwise.

**Postconditions:** `m.ready() == true` in all cases. If the function returns `false`, then the effect on parameter `m` is unspecified except that `m.size()` returns 0 and `m.empty()` returns `true`. Otherwise the effects on parameter `m` are given in Table 136.

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>

<td>For all integers 0 &lt; n &lt; m.size(), true if sub-expression n participated in the match, false otherwise.</td>
</tr>
</tbody>
</table>

`:template <class charT, class Allocator, class traits>

    bool regex_search(const charT* str, match_results<const charT*, Allocator>& m, const basic_regex<charT, traits>& e, regex_constants::match_flag_type flags = regex_constants::match_default);`

4  

    Returns: regex_search(str, str + char_traits<charT>::length(str), m, e, flags).

`:template <class ST, class SA, class Allocator, class charT, class traits>

    bool regex_search(const basic_string<charT, ST, SA>& s, match_results<typename basic_string<charT, ST, SA>::const_iterator, Allocator>& m, const basic_regex<charT, traits>& e, regex_constants::match_flag_type flags = regex_constants::match_default);`

5  

    Returns: regex_search(s.begin(), s.end(), m, e, flags).

`:template <class BidirectionalIterator, class charT, class traits>

    bool regex_search(BidirectionalIterator first, BidirectionalIterator last, const basic_regex<charT, traits>& e, regex_constants::match_flag_type flags = regex_constants::match_default);`

6  

    Effects: Behaves “as if” by constructing an object what of type match_results<BidirectionalIterator> and returning regex_search(first, last, what, e, flags).

`:template <class charT, class traits>

    bool regex_search(const charT* str, const basic_regex<charT, traits>& e, regex_constants::match_flag_type flags = regex_constants::match_default);`

7  

    Returns: regex_search(str, str + char_traits<charT>::length(str), e, flags).
bool regex_search(const basic_string<charT, ST, SA>& s,
               const basic_regex<charT, traits>& e,
               regex_constants::match_flag_type flags = regex_constants::match_default);

Returns: regex_search(s.begin(), s.end(), e, flags).

31.11.4  regex_replace

[re.alg.replace]

template <class OutputIterator, class BidirectionalIterator,
            class traits, class charT, class ST, class SA>
OutputIterator
regex_replace(OutputIterator out,
             BidirectionalIterator first, BidirectionalIterator last,
             const basic_regex<charT, traits>& e,
             const basic_string<charT, ST, SA>& fmt,
             regex_constants::match_flag_type flags = regex_constants::match_default);

template <class OutputIterator, class BidirectionalIterator, class traits, class charT>
OutputIterator
regex_replace(OutputIterator out,
             BidirectionalIterator first, BidirectionalIterator last,
             const basic_regex<charT, traits>& e,
             const charT* fmt,
             regex_constants::match_flag_type flags = regex_constants::match_default);

Effects: Constructs a regex_iterator object i as if by

regex_iterator<BidirectionalIterator, charT, traits> i(first, last, e, flags)

and uses i to enumerate through all of the matches m of type match_results<BidirectionalIterator> that occur within the sequence [first, last). If no such matches are found and !(flags & regex_constants::format_no_copy), then calls

out = copy(first, last, out)

If any matches are found then, for each such match:

(1.1) — If !(flags & regex_constants::format_no_copy), calls
    out = copy(m.prefix().first, m.prefix().second, out)

(1.2) — Then calls
    out = m.format(out, fmt, flags)

for the first form of the function and

out = m.format(out, fmt, fmt + char_traits<charT>::length(fmt), flags)

for the second.

Finally, if such a match is found and !(flags & regex_constants::format_no_copy), calls

out = copy(last_m.suffix().first, last_m.suffix().second, out)

where last_m is a copy of the last match found. If flags & regex_constants::format_first_only is nonzero, then only the first match found is replaced.

Returns: out.

template <class traits, class charT, class ST, class SA, class FST, class FSA>
basic_string<charT, ST, SA>
regex_replace(const basic_string<charT, ST, SA>& s,
              const basic_regex<charT, traits>& e,
              const basic_string<charT, FST, FSA>& fmt,
              regex_constants::match_flag_type flags = regex_constants::match_default);
template <class traits, class charT, class ST, class SA>
  basic_string<charT, ST, SA>
  regex_replace(const basic_string<charT, ST, SA>& s,
  const basic_regex<charT, traits>& e,
  const charT* fmt,
  regex_constants::match_flag_type flags = regex_constants::match_default);

  Effects: Constructs an empty string result of type basic_string<charT, ST, SA> and calls:
  regex_replace(back_inserter(result), s.begin(), s.end(), e, fmt, flags);

  Returns: result.

template <class traits, class charT, class ST, class SA>
  basic_string<charT>
  regex_replace(const charT* s,
  const basic_regex<charT, traits>& e,
  const basic_string<charT, ST, SA>& fmt,
  regex_constants::match_flag_type flags = regex_constants::match_default);

  Effects: Constructs an empty string result of type basic_string<charT> and calls:
  regex_replace(back_inserter(result), s, s + char_traits<charT>::length(s), e, fmt, flags);

  Returns: result.

31.12 Regular expression iterators

31.12.1 Class template regex_iterator

The class template regex_iterator is an iterator adaptor. It represents a new view of an existing iterator sequence, by enumerating all the occurrences of a regular expression within that sequence. A regex_iterator uses regex_search to find successive regular expression matches within the sequence from which it was constructed. After the iterator is constructed, and every time operator++ is used, the iterator finds and stores a value of match_results<BidirectionalIterator>. If the end of the sequence is reached (regex_search returns false), the iterator becomes equal to the end-of-sequence iterator value. The default constructor constructs an end-of-sequence iterator object, which is the only legitimate iterator to be used for the end condition. The result of operator* on an end-of-sequence iterator is not defined. For any other iterator value a const match_results<BidirectionalIterator>& is returned. The result of operator-> on an end-of-sequence iterator is not defined. For any other iterator value a const match_results<BidirectionalIterator>* is returned. It is impossible to store things into regex_iterators. Two end-of-sequence iterators are always equal. An end-of-sequence iterator is not equal to a non-end-of-sequence iterator. Two non-end-of-sequence iterators are equal when they are constructed from the same arguments.

namespace std {
  template <class BidirectionalIterator,
           class charT = typename iterator_traits<BidirectionalIterator>::value_type,
           class traits = regex_traits<charT>>
  class regex_iterator {
    public:
      using regex_type = basic_regex<charT, traits>;
      using iterator_category = forward_iterator_tag;
      using value_type = match_results<BidirectionalIterator>;
  }

§ 31.12.1
using difference_type = ptrdiff_t;
using pointer = const value_type*;
using reference = const value_type&;

regex_iterator();
regex_iterator(BidirectionalIterator a, BidirectionalIterator b,
             const regex_type& re,
             regex_constants::match_flag_type m = regex_constants::match_default);
regex_iterator(BidirectionalIterator a, BidirectionalIterator b,
             const regex_type&&,  
             regex_constants::match_flag_type = regex_constants::match_default) = delete;
regex_iterator(const regex_iterator&);
regex_iterator& operator=(const regex_iterator&);

bool operator==(const regex_iterator&) const;
bool operator!=(const regex_iterator&) const;
const value_type& operator*() const;
const value_type* operator->() const;
regex_iterator& operator++();
regex_iterator operator++(int);

private:
    BidirectionalIterator begin;  // exposition only
    BidirectionalIterator end;    // exposition only
    const regex_type* pregex;     // exposition only
    regex_constants::match_flag_type flags; // exposition only
    match_results<BidirectionalIterator> match; // exposition only
};

2 An object of type `regex_iterator` that is not an end-of-sequence iterator holds a zero-length match if `match[0].matched == true` and `match[0].first == match[0].second`. [Note: For example, this can occur when the part of the regular expression that matched consists only of an assertion (such as ‘^’, ‘$’, \b, \B). — end note]

### 31.12.1.1 regex_iterator constructors

regex_iterator();

**Effects:** Constructs an end-of-sequence iterator.

regex_iterator(BidirectionalIterator a, BidirectionalIterator b,
               const regex_type& re,
               regex_constants::match_flag_type m = regex_constants::match_default);

**Effects:** Initializes `begin` and `end` to `a` and `b`, respectively, sets `pregex` to `re`, sets `flags` to `m`, then calls `regex_search(begin, end, match, *pregex, flags)`. If this call returns `false` the constructor sets `*this` to the end-of-sequence iterator.

### 31.12.1.2 regex_iterator comparisons

bool operator==(const regex_iterator& right) const;

**Returns:** `true` if `*this` and `right` are both end-of-sequence iterators or if the following conditions all hold:

1. `begin == right.begin`,
2. `end == right.end`.

§ 31.12.1.2
(1.3) \[ \text{pregex} == \text{right.pregex}, \]
(1.4) \[ \text{flags} == \text{right.flags}, \text{and} \]
(1.5) \[ \text{match}[0] == \text{right.match}[0]; \]
otherwise false.

bool operator!=(const regex_iterator& right) const;

Returns: !(*this == right).

31.12.1.3 regex_iterator indirection

const value_type& operator*() const;

Returns: match.

const value_type* operator->() const;

Returns: &match.

31.12.1.4 regex_iterator increment

regex_iterator& operator++();

Effects: Constructs a local variable start of type BidirectionalIterator and initializes it with the value of match[0].second.

1 If the iterator holds a zero-length match and start == end the operator sets *this to the end-of-sequence iterator and returns *this.

2 Otherwise, if the iterator holds a zero-length match, the operator calls:

\[
\text{regex_search(start, end, match, } *\text{pregex},
\text{flags | regex_constants::match_not_null | regex_constants::match_continuous})
\]

If the call returns true the operator returns *this. Otherwise the operator increments start and continues as if the most recent match was not a zero-length match.

4 If the most recent match was not a zero-length match, the operator sets flags to flags | regex_constants::match_prev_avail and calls regex_search(start, end, match, *pregex, flags). If the call returns false the iterator sets *this to the end-of-sequence iterator. The iterator then returns *this.

5 In all cases in which the call to regex_search returns true, match.prefix().first shall be equal to the previous value of match[0].second, and for each index i in the half-open range [0, match.size()) for which match[i].matched is true, match.position(i) shall return distance(begin, match[i].first).

[Note: This means that match.position(i) gives the offset from the beginning of the target sequence, which is often not the same as the offset from the sequence passed in the call to regex_search. — end note]

It is unspecified how the implementation makes these adjustments.

[Note: This means that a compiler may call an implementation-specific search function, in which case a user-defined specialization of regex_search will not be called. — end note]

regex_iterator operator++(int);

Effects: As if by:

\[
\text{regex_iterator tmp = *this;}
++(*this);
\]
The class template `regex_token_iterator` is an iterator adaptor; that is to say it represents a new view of an existing iterator sequence, by enumerating all the occurrences of a regular expression within that sequence, and presenting one or more sub-expressions for each match found. Each position enumerated by the iterator is a `sub_match` class template instance that represents what matched a particular sub-expression within the regular expression.

When class `regex_token_iterator` is used to enumerate a single sub-expression with index -1 the iterator performs field splitting; that is to say it enumerates one sub-expression for each section of the character container sequence that does not match the regular expression specified.

After it is constructed, the iterator finds and stores a value `regex_iterator<BidirectionalIterator>` position and sets the internal count `N` to zero. It also maintains a sequence `subs` which contains a list of the sub-expressions which will be enumerated. Every time `operator++` is used the count `N` is incremented; if `N` exceeds or equals `subs.size()`, then the iterator increments member `position` and sets count `N` to zero.

If the end of sequence is reached (position is equal to the end of sequence iterator), the iterator becomes equal to the end-of-sequence iterator value, unless the sub-expression being enumerated has index -1, in which case the iterator enumerates one last sub-expression that contains all the characters from the end of the last regular expression match to the end of the input sequence being enumerated, provided that this would not be an empty sub-expression.

The default constructor constructs an end-of-sequence iterator object, which is the only legitimate iterator to be used for the end condition. The result of `operator*` on an end-of-sequence iterator is not defined. For any other iterator value a `const sub_match<BidirectionalIterator>&` is returned. The result of `operator->` on an end-of-sequence iterator is not defined. For any other iterator value a `const sub_match<BidirectionalIterator>*` is returned.

It is impossible to store things into `regex_token_iterator`s. Two end-of-sequence iterators are always equal. An end-of-sequence iterator is not equal to a non-end-of-sequence iterator. Two non-end-of-sequence iterators are equal when they are constructed from the same arguments.

```cpp
namespace std {
    template <class BidirectionalIterator,
              class charT = typename iterator_traits<BidirectionalIterator>::value_type,
              class traits = regex_traits<charT>>
    class regex_token_iterator {
        public:
            using regex_type = basic_regex<charT, traits>;
            using iterator_category = forward_iterator_tag;
            using value_type = sub_match<BidirectionalIterator>;
            using difference_type = ptrdiff_t;
            using pointer = const value_type*;
            using reference = const value_type&;

            regex_token_iterator();
            regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b,
                                 const regex_type& re,
                                 int submatch = 0,
                                 regex_constants::match_flag_type m =
                                 regex_constants::match_default);
            regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b,
                                 const regex_type& re,
                                 const vector<int>& submatches,
```
A suffix iterator is a regex_token_iterator object that points to a final sequence of characters at the end
of the target sequence. In a suffix iterator the member `result` holds a pointer to the data member `suffix`, the value of the member `suffix.match` is `true`, `suffix.first` points to the beginning of the final sequence, and `suffix.second` points to the end of the final sequence.

8  [Note: For a suffix iterator, data member `suffix.first` is the same as the end of the last match found, and `suffix.second` is the same as the end of the target sequence — end note]

9  The `current match` is (*position).prefix() if subs[N] == -1, or (*position)[subs[N]] for any other value of subs[N].

31.12.2.1 `regex_token_iterator` constructors

```cpp
regex_token_iterator();
```

1  `{Effects: Constructs the end-of-sequence iterator.}`

```cpp
regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b,
                 const regex_type& re,
                 int submatch = 0,
                 regex_constants::match_flag_type m = regex_constants::match_default);
```

2  `{Requires: Each of the initialization values of submatches shall be >= -1.}`

```cpp
regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b,
                 const regex_type& re,
                 const vector<int>& submatches,
                 regex_constants::match_flag_type m = regex_constants::match_default);
```

3  `{Effects: The first constructor initializes the member subs to hold the single value submatch. The second constructor initializes the member subs to hold a copy of the argument submatches. The third and fourth constructors initialize the member subs to hold a copy of the sequence of integer values pointed to by the iterator range [submatches.begin(), submatches.end()) and [&submatches, &submatches + N), respectively.}`

4  `Each constructor then sets N to 0, and position to position_iterator(a, b, re, m). If position is not an end-of-sequence iterator the constructor sets result to the address of the current match. Otherwise if any of the values stored in subs is equal to -1 the constructor sets *this to a suffix iterator that points to the range [a, b), otherwise the constructor sets *this to an end-of-sequence iterator.}`

31.12.2.2 `regex_token_iterator` comparisons

```cpp
bool operator==(const regex_token_iterator& right) const;
```

1  `{Returns: true if *this and right are both end-of-sequence iterators, or if *this and right are both suffix iterators and suffix == right.suffix; otherwise returns false if *this or right is an end-of-sequence iterator or a suffix iterator. Otherwise returns true if position == right.position, N == right.N, and subs == right.subs. Otherwise returns false.}`
bool operator!=(const regex_token_iterator& right) const;

Returns: !(*this == right).

### 31.12.2.3 regex_token_iterator indirection  
const value_type& operator*() const;

Returns: *result.

const value_type* operator->() const;

Returns: result.

### 31.12.2.4 regex_token_iterator increment

regex_token_iterator& operator++();

Effects: Constructs a local variable prev of type position_iterator, initialized with the value of position.

If *this is a suffix iterator, sets *this to an end-of-sequence iterator.

Otherwise, if N + 1 < subs.size(), increments N and sets result to the address of the current match.

Otherwise, sets N to 0 and increments position. If position is not an end-of-sequence iterator the operator sets result to the address of the current match.

Otherwise, if any of the values stored in subs is equal to -1 and prev->suffix().length() is not 0 the operator sets *this to a suffix iterator that points to the range [prev->suffix().first, prev->suffix().second).

Otherwise, sets *this to an end-of-sequence iterator.

Returns: *this

regex_token_iterator& operator++(int);

Effects: Constructs a copy tmp of *this, then calls ++(*this).

Returns: tmp.

### 31.13 Modified ECMAScript regular expression grammar

The regular expression grammar recognized by basic_regex objects constructed with the ECMAScript flag is that specified by ECMA-262, except as specified below.

Objects of type specialization of basic_regex store within themselves a default-constructed instance of their traits template parameter, henceforth referred to as traits_inst. This traits_inst object is used to support localization of the regular expression; basic_regex member functions shall not call any locale dependent C or C++ API, including the formatted string input functions. Instead they shall call the appropriate traits member function to achieve the required effect.

The following productions within the ECMAScript grammar are modified as follows:

```plaintext
ClassAtom ::=
  -
  ClassAtomNoDash
  ClassAtomExClass
  ClassAtomCollatingElement
  ClassAtomEquivalence

IdentityEscape ::=
  SourceCharacter but not c
```
The following new productions are then added:

```
ClassAtomExClass ::
    [: ClassName :]
```

```
ClassAtomCollatingElement ::
    [. ClassName .]
```

```
ClassAtomEquivalence ::
    [= ClassName =]
```

```
ClassName ::
    ClassNameCharacter
    ClassNameCharacter ClassName
```

```
ClassNameCharacter ::
    SourceCharacter but not one of "." "=" ":" 
```

The productions `ClassAtomExClass`, `ClassAtomCollatingElement` and `ClassAtomEquivalence` provide functionality equivalent to that of the same features in regular expressions in POSIX.

The regular expression grammar may be modified by any `regex_constants::syntax_option_type` flags specified when constructing an object of type specialization of `basic_regex` according to the rules in Table 130.

A `ClassName` production, when used in `ClassAtomExClass`, is not valid if `traits_inst.lookup_classname` returns zero for that name. The names recognized as valid `ClassNames` are determined by the type of the traits class, but at least the following names shall be recognized: `alnum`, `alpha`, `blank`, `cntrl`, `digit`, `graph`, `lower`, `print`, `punct`, `space`, `upper`, `xdigit`, `d`, `s`, `w`. In addition the following expressions shall be equivalent:

```
\d and [:digit:]
\D and [^[[:digit:]]
\s and [:space:]
\S and [^[[:space:]]
\w and [^[[:alnum:]]
\W and [^[[:alnum:]]
```

A `ClassName` production when used in a `ClassAtomCollatingElement` production is not valid if the value returned by `traits_inst.lookup_collatename` for that name is an empty string.

The results from multiple calls to `traits_inst.lookup_classname` can be bitwise OR’ed together and subsequently passed to `traits_inst.isctype`.

A `ClassName` production when used in a `ClassAtomEquivalence` production is not valid if the value returned by `traits_inst.lookup_collatename` for that name is an empty string or if the value returned by `traits_inst.transform_primary` for the result of the call to `traits_inst.lookup_collatename` is an empty string.

When the sequence of characters being transformed to a finite state machine contains an invalid class name the translator shall throw an exception object of type `regex_error`.

If the CV of a `UnicodeEscapeSequence` is greater than the largest value that can be held in an object of type `charT` the translator shall throw an exception object of type `regex_error`. [Note: This means that values of the form "uxxxx" that do not fit in a character are invalid. — end note]
Where the regular expression grammar requires the conversion of a sequence of characters to an integral value, this is accomplished by calling `traits_inst.value`.

The behavior of the internal finite state machine representation when used to match a sequence of characters is as described in ECMA-262. The behavior is modified according to any match_flag_type flags (31.5.2) specified when using the regular expression object in one of the regular expression algorithms (31.11). The behavior is also localized by interaction with the traits class template parameter as follows:

1. During matching of a regular expression finite state machine against a sequence of characters, two characters c and d are compared using the following rules:
   - If `(flags() & regex_constants::icase)` the two characters are equal if `traits_inst.translate_nocase(c) == traits_inst.translate_nocase(d);`
   - Otherwise, if `flags() & regex_constants::collate` the two characters are equal if `traits_inst.translate(c) == traits_inst.translate(d);`
   - Otherwise, the two characters are equal if `c == d`.

2. During matching of a regular expression finite state machine against a sequence of characters, comparison of a collating element range `c1-c2` against a character `c` is conducted as follows: if `flags() & regex_constants::collate` is false then the character `c` is matched if `c1 <= c && c <= c2`, otherwise `c` is matched in accordance with the following algorithm:
   ```
   string_type str1 = string_type(1, flags() & icase ?
   traits_inst.translate_nocase(c1) : traits_inst.translate(c1);
   string_type str2 = string_type(1, flags() & icase ?
   traits_inst.translate_nocase(c2) : traits_inst.translate(c2);
   string_type str = string_type(1, flags() & icase ?
   traits_inst.translate_nocase(c) : traits_inst.translate(c);
   return traits_inst.transform(str1.begin(), str1.end())
   <= traits_inst.transform(str.begin(), str.end())
   && traits_inst.transform(str.begin(), str.end())
   <= traits_inst.transform(str2.begin(), str2.end());
   ```

3. During matching of a regular expression finite state machine against a sequence of characters, testing whether a collating element is a member of a primary equivalence class is conducted by first converting the collating element and the equivalence class to sort keys using `traits::transform_primary`, and then comparing the sort keys for equality.

4. During matching of a regular expression finite state machine against a sequence of characters, a character `c` is a member of a character class designated by an iterator range `[first, last)` if `traits_inst.istctype(c, traits_inst.lookup_classname(first, last, flags() & icase))` is true.
32 Atomic operations library

32.1 General

This Clause describes components for fine-grained atomic access. This access is provided via operations on atomic objects.

The following subclauses describe atomics requirements and components for types and operations, as summarized below.

}

32.3 Type aliases

The type aliases atomic_intN_t, atomic_uintN_t, atomic_intptr_t, and atomic_uintptr_t are defined if and only if intN_t, uintN_t, intptr_t, and uintptr_t are defined, respectively.

32.4 Order and consistency

namespace std {
enum memory_order {
    memory_order_relaxed, memory_order_consume, memory_order_acquire,
    memory_order_release, memory_order_acq_rel, memory_order_seq_cst
};
}

1 The enumeration memory_order specifies the detailed regular (non-atomic) memory synchronization order as defined in 4.7 and may provide for operation ordering. Its enumerated values and their meanings are as follows:

(1.1) — memory_order_relaxed: no operation orders memory.

(1.2) — memory_order_release, memory_order_acq_rel, and memory_order_seq_cst: a store operation performs a release operation on the affected memory location.

(1.3) — memory_order_consume: a load operation performs a consume operation on the affected memory location. [Note: Prefer memory_order_acquire, which provides stronger guarantees than memory_order_consume. Implementations have found it infeasible to provide performance better than that of memory_order_acquire. Specification revisions are under consideration. — end note]

(1.4) — memory_order_acquire, memory_order_acq_rel, and memory_order_seq_cst: a load operation performs an acquire operation on the affected memory location.

[Note: Atomic operations specifying memory_order_relaxed are relaxed with respect to memory ordering. Implementations must still guarantee that any given atomic access to a particular atomic object be indivisible with respect to all other atomic accesses to that object. — end note]
An atomic operation \( A \) that performs a release operation on an atomic object \( M \) synchronizes with an atomic operation \( B \) that performs an acquire operation on \( M \) and takes its value from any side effect in the release sequence headed by \( A \).

There shall be a single total order \( S \) on all \texttt{memory\_order\_seq\_cst} operations, consistent with the “happens before” order and modification orders for all affected locations, such that each \texttt{memory\_order\_seq\_cst} operation \( B \) that loads a value from an atomic object \( M \) observes one of the following values:

\begin{enumerate}
\item[(3.1)] the result of the last modification \( A \) of \( M \) that precedes \( B \) in \( S \), if it exists, or
\item[(3.2)] if \( A \) exists, the result of some modification of \( M \) that is not \texttt{memory\_order\_seq\_cst} and that does not happen before \( A \), or
\item[(3.3)] if \( A \) does not exist, the result of some modification of \( M \) that is not \texttt{memory\_order\_seq\_cst}.
\end{enumerate}

[Note: Although it is not explicitly required that \( S \) include locks, it can always be extended to an order that does include lock and unlock operations, since the ordering between those is already included in the “happens before” ordering. — end note]

For an atomic operation \( B \) that reads the value of an atomic object \( M \), if there is a \texttt{memory\_order\_seq\_cst} fence \( X \) sequenced before \( B \), then \( B \) observes either the last \texttt{memory\_order\_seq\_cst} modification of \( M \) preceding \( X \) in the total order \( S \) or a later modification of \( M \) in its modification order.

For atomic operations \( A \) and \( B \) on an atomic object \( M \), where \( A \) modifies \( M \) and \( B \) takes its value, if there is a \texttt{memory\_order\_seq\_cst} fence \( X \) such that \( A \) is sequenced before \( X \) and \( B \) follows \( X \) in \( S \), then \( B \) observes either the effects of \( A \) or a later modification of \( M \) in its modification order.

For atomic operations \( A \) and \( B \) on an atomic object \( M \), where \( A \) modifies \( M \) and \( B \) takes its value, if there are \texttt{memory\_order\_seq\_cst} fences \( X \) and \( Y \) such that \( A \) is sequenced before \( X \), \( Y \) is sequenced before \( B \), and \( X \) precedes \( Y \) in \( S \), then \( B \) observes either the effects of \( A \) or a later modification of \( M \) in its modification order.

For atomic modifications \( A \) and \( B \) of an atomic object \( M \), \( B \) occurs later than \( A \) in the modification order of \( M \) if:

\begin{enumerate}
\item[(7.1)] there is a \texttt{memory\_order\_seq\_cst} fence \( X \) such that \( A \) is sequenced before \( X \), and \( X \) precedes \( B \) in \( S \), or
\item[(7.2)] there is a \texttt{memory\_order\_seq\_cst} fence \( Y \) such that \( Y \) is sequenced before \( B \), and \( A \) precedes \( Y \) in \( S \), or
\item[(7.3)] there are \texttt{memory\_order\_seq\_cst} fences \( X \) and \( Y \) such that \( A \) is sequenced before \( X \), \( Y \) is sequenced before \( B \), and \( X \) precedes \( Y \) in \( S \).
\end{enumerate}

[Note: \texttt{memory\_order\_seq\_cst} ensures sequential consistency only for a program that is free of data races and uses exclusively \texttt{memory\_order\_seq\_cst} operations. Any use of weaker ordering will invalidate this guarantee unless extreme care is used. In particular, \texttt{memory\_order\_seq\_cst} fences ensure a total order only for the fences themselves. Fences cannot, in general, be used to restore sequential consistency for atomic operations with weaker ordering specifications. — end note]

Implementations should ensure that no “out-of-thin-air” values are computed that circularly depend on their own computation.

[Note: For example, with \( x \) and \( y \) initially zero,]

```c
// Thread 1:
r1 = y.load(memory_order_relaxed);
x.store(r1, memory_order_relaxed);
// Thread 2:
r2 = x.load(memory_order_relaxed);
y.store(r2, memory_order_relaxed);
```
should not produce \( r_1 == r_2 == 42 \), since the store of 42 to \( y \) is only possible if the store to \( x \) stores 42, which circularly depends on the store to \( y \) storing 42. Note that without this restriction, such an execution is possible. —end note

[Note: The recommendation similarly disallows \( r_1 == r_2 == 42 \) in the following example, with \( x \) and \( y \) again initially zero:

```c
// Thread 1:
    r1 = x.load(memory_order_relaxed);
    if (r1 == 42) y.store(42, memory_order_relaxed);

// Thread 2:
    r2 = y.load(memory_order_relaxed);
    if (r2 == 42) x.store(42, memory_order_relaxed);
—end note]

Atomic read-modify-write operations shall always read the last value (in the modification order) written before the write associated with the read-modify-write operation.

Implementations should make atomic stores visible to atomic loads within a reasonable amount of time.

```c
template <class T>
T kill_dependency(T y) noexcept;
```

Effects: The argument does not carry a dependency to the return value (4.7).

Returns: \( y \).

### 32.5 Lock-free property

```c
#define ATOMIC_BOOL_LOCK_FREE unspecified
#define ATOMIC_CHAR_LOCK_FREE unspecified
#define ATOMIC_CHAR16_T_LOCK_FREE unspecified
#define ATOMIC_CHAR32_T_LOCK_FREE unspecified
#define ATOMIC_WCHAR_T_LOCK_FREE unspecified
#define ATOMIC_SHORT_LOCK_FREE unspecified
#define ATOMIC_INT_LOCK_FREE unspecified
#define ATOMIC_LONG_LOCK_FREE unspecified
#define ATOMIC_LLONG_LOCK_FREE unspecified
#define ATOMIC_POINTER_LOCK_FREE unspecified
```

1 The ATOMIC_. .. _LOCK_FREE macros indicate the lock-free property of the corresponding atomic types, with the signed and unsigned variants grouped together. The properties also apply to the corresponding (partial) specializations of the atomic template. A value of 0 indicates that the types are never lock-free. A value of 1 indicates that the types are sometimes lock-free. A value of 2 indicates that the types are always lock-free.

2 The function `atomic_is_lock_free` (32.6.1) indicates whether the object is lock-free. In any given program execution, the result of the lock-free query shall be consistent for all pointers of the same type.

3 Atomic operations that are not lock-free are considered to potentially block (4.7.2).

[Note: Operations that are lock-free should also be address-free. That is, atomic operations on the same memory location via two different addresses will communicate atomically. The implementation should not depend on any per-process state. This restriction enables communication by memory that is mapped into a process more than once and by memory that is shared between two processes. —end note]

### 32.6 Class template atomic

```c
namespace std {
    template <class T> struct atomic {
        using value_type = T;
        static constexpr bool is_always_lock_free = implementation-defined;
    }
}
```
bool is_lock_free() const volatile noexcept;
bool is_lock_free() const noexcept;
void store(T, memory_order = memory_order_seq_cst) volatile noexcept;
void store(T, memory_order = memory_order_seq_cst) noexcept;
T load(memory_order = memory_order_seq_cst) const volatile noexcept;
T load(memory_order = memory_order_seq_cst) const noexcept;
operator T() const volatile noexcept;
operator T() const noexcept;
T exchange(T, memory_order = memory_order_seq_cst) volatile noexcept;
T exchange(T, memory_order = memory_order_seq_cst) noexcept;
bool compare_exchange_weak(T&, T, memory_order, memory_order) volatile noexcept;
bool compare_exchange_weak(T&, T, memory_order, memory_order) noexcept;
bool compare_exchange_strong(T&, T, memory_order, memory_order) volatile noexcept;
bool compare_exchange_strong(T&, T, memory_order, memory_order) noexcept;
bool compare_exchange_weak(T&, T, memory_order = memory_order_seq_cst) volatile noexcept;
bool compare_exchange_weak(T&, T, memory_order = memory_order_seq_cst) noexcept;
bool compare_exchange_strong(T&, T, memory_order = memory_order_seq_cst) volatile noexcept;
bool compare_exchange_strong(T&, T, memory_order = memory_order_seq_cst) noexcept;

atomic() noexcept = default;
constexpr atomic(T) noexcept;
atomic(const atomic&) = delete;
atomic& operator=(const atomic&) = delete;
atomic& operator=(const atomic&) volatile = delete;
T operator=(T) volatile noexcept;
T operator=(T) noexcept;

1 The template argument for T shall be trivially copyable (6.9). [Note: Type arguments that are not also statically initializable may be difficult to use. —end note]

2 The specialization atomic<bool> is a standard-layout struct.

3 [Note: The representation of an atomic specialization need not have the same size as its corresponding argument type. Specializations should have the same size whenever possible, as this reduces the effort required to port existing code. —end note]

### 32.6.1 Operations on atomic types [atomics.types.operations]

1 [Note: Many operations are volatile-qualified. The “volatile as device register” semantics have not changed in the standard. This qualification means that volatility is preserved when applying these operations to volatile objects. It does not mean that operations on non-volatile objects become volatile. —end note]

atomic() noexcept = default;

2 Effects: Leaves the atomic object in an uninitialized state. [Note: These semantics ensure compatibility with C. —end note]

constexpr atomic(T desired) noexcept;

3 Effects: Initializes the object with the value desired. Initialization is not an atomic operation (4.7). [Note: It is possible to have an access to an atomic object A race with its construction, for example by communicating the address of the just-constructed object A to another thread via memory_order_relaxed operations on a suitable atomic pointer variable, and then immediately accessing A in the receiving thread. This results in undefined behavior. —end note]

#define ATOMIC_VAR_INIT(value) see below
The macro expands to a token sequence suitable for constant initialization of an atomic variable of static storage duration of a type that is initialization-compatible with value. [Note: This operation may need to initialize locks. —end note] Concurrent access to the variable being initialized, even via an atomic operation, constitutes a data race. [Example:]

```cpp
atomic<int> v = ATOMIC_VAR_INIT(5);
```

—end example]

static constexpr bool is_always_lock_free = implementation-defined;

The static data member `is_always_lock_free` is `true` if the atomic type's operations are always lock-free, and `false` otherwise. [Note: The value of `is_always_lock_free` is consistent with the value of the corresponding ATOMIC_..._LOCK_FREE macro, if defined. —end note]

bool is_lock_free() const volatile noexcept;
bool is_lock_free() const noexcept;

Returns: true if the object’s operations are lock-free, false otherwise. [Note: The return value of the `is_lock_free` member function is consistent with the value of `is_always_lock_free` for the same type. —end note]

void store(T desired, memory_order order = memory_order_seq_cst) volatile noexcept;
void store(T desired, memory_order order = memory_order_seq_cst) noexcept;

Requires: The order argument shall not be memory_order_consume, memory_order_acquire, or memory_order_acq_rel.

Effects: Atomically replaces the value pointed to by `this` with `desired`. Memory is affected according to the value of `order`.

T operator=(T desired) volatile noexcept;
T operator=(T desired) noexcept;

Effects: Equivalent to: `store(desired)`.

T load(memory_order order = memory_order_seq_cst) const volatile noexcept;
T load(memory_order order = memory_order_seq_cst) const noexcept;

Requires: The order argument shall not be memory_order_release nor memory_order_acq_rel.

Effects: Memory is affected according to the value of `order`.

Returns: Atomically returns the value pointed to by `this`.

operator T() const volatile noexcept;
operator T() const noexcept;

Effects: Equivalent to: `return load();`

T exchange(T desired, memory_order order = memory_order_seq_cst) volatile noexcept;
T exchange(T desired, memory_order order = memory_order_seq_cst) noexcept;

Effects: Atomically replaces the value pointed to by `this` with `desired`. Memory is affected according to the value of `order`. These operations are atomic read-modify-write operations (4.7).

Returns: Atomically returns the value pointed to by `this` immediately before the effects.

bool compare_exchange_weak(T& expected, T desired,
    memory_order success, memory_order failure) volatile noexcept;
bool compare_exchange_weak(T& expected, T desired,
memory_order success, memory_order failure) noexcept;
bool compare_exchange_strong(T& expected, T desired,
    memory_order success, memory_order failure) volatile noexcept;
bool compare_exchange_strong(T& expected, T desired,
    memory_order success, memory_order failure) noexcept;
bool compare_exchange_weak(T& expected, T desired,
    memory_order order = memory_order_seq_cst) volatile noexcept;
bool compare_exchange_weak(T& expected, T desired,
    memory_order order = memory_order_seq_cst) noexcept;
bool compare_exchange_strong(T& expected, T desired,
    memory_order order = memory_order_seq_cst) volatile noexcept;
bool compare_exchange_strong(T& expected, T desired,
    memory_order order = memory_order_seq_cst) noexcept;

17 Requires: The failure argument shall not be memory_order_release nor memory_order_acq_rel.

18 Effects: Retrieves the value in expected. It then atomically compares the contents of the memory pointed to by this for equality with that previously retrieved from expected, and if true, replaces the contents of the memory pointed to by this with that in desired. If and only if the comparison is true, memory is affected according to the value of success, and if the comparison is false, memory is affected according to the value of failure. When only one memory_order argument is supplied, the value of success is order, and the value of failure is order except that a value of memory_order_acq_rel shall be replaced by the value memory_order_acquire and a value of memory_order_release shall be replaced by the value memory_order_relaxed. If and only if the comparison is false then, after the atomic operation, the contents of the memory in expected are replaced by the value read from the memory pointed to by this during the atomic comparison. If the operation returns true, these operations are atomic read-modify-write operations (4.7) on the memory pointed to by this. Otherwise, these operations are atomic load operations on that memory.

19 Returns: The result of the comparison.

[Note: For example, the effect of compare_exchange_strong is

    if (memcmp(this, &expected, sizeof(*this)) == 0)
        memcpy(this, &desired, sizeof(*this));
    else
        memcpy(expected, this, sizeof(*this));

— end note] [Example: The expected use of the compare-and-exchange operations is as follows. The compare-and-exchange operations will update expected when another iteration of the loop is needed.

    expected = current.load();
    do {
        desired = function(expected);
    } while (!current.compare_exchange_weak(expected, desired));

— end example] [Example: Because the expected value is updated only on failure, code releasing the memory containing the expected value on success will work. E.g. list head insertion will act atomically and would not introduce a data race in the following code:

    do {
        p->next = head; // make new list node point to the current head
    } while (!head.compare_exchange_weak(p->next, p)); // try to insert

— end example]

21 Implementations should ensure that weak compare-and-exchange operations do not consistently return false unless either the atomic object has value different from expected or there are concurrent
modifications to the atomic object.

Remarks: A weak compare-and-exchange operation may fail spuriously. That is, even when the contents of memory referred to by expected and this are equal, it may return false and store back to expected the same memory contents that were originally there. [Note: This spurious failure enables implementation of compare-and-exchange on a broader class of machines, e.g., load-locked store-conditional machines. A consequence of spurious failure is that nearly all uses of weak compare-and-exchange will be in a loop.

When a compare-and-exchange is in a loop, the weak version will yield better performance on some platforms. When a weak compare-and-exchange would require a loop and a strong one would not, the strong one is preferable. — end note]

[Note: The memcpy and memcmp semantics of the compare-and-exchange operations may result in failed comparisons for values that compare equal with operator== if the underlying type has padding bits, trap bits, or alternate representations of the same value. Thus, compare_exchange_strong should be used with extreme care. On the other hand, compare_exchange_weak should converge rapidly. — end note]

32.6.2 Specializations for integers

There are specializations of the atomic template for the integral types char, signed char, unsigned char, short, unsigned short, int, unsigned int, long, unsigned long, long long, char16_t, char32_t, wchar_t, and any other types needed by the typedefs in the header <cstdint>. For each such integral type integral, the specialization atomic<integral> provides additional atomic operations appropriate to integral types. [Note: For the specialization atomic<bool>, see 32.6. — end note]

namespace std {
    template <> struct atomic<integral> {
        using value_type = integral;
        using difference_type = value_type;
        static constexpr bool is_always_lock_free = implementation-defined;
        bool is_lock_free() const volatile noexcept;
        bool is_lock_free() const noexcept;
        void store(integral, memory_order = memory_order_seq_cst) volatile noexcept;
        void store(integral, memory_order = memory_order_seq_cst) noexcept;
        integral load(memory_order = memory_order_seq_cst) const volatile noexcept;
        integral load(memory_order = memory_order_seq_cst) const noexcept;
        integral exchange(integral, memory_order = memory_order_seq_cst) volatile noexcept;
        integral exchange(integral, memory_order = memory_order_seq_cst) noexcept;
        bool compare_exchange_weak(integral &, integral,
                                      memory_order, memory_order) volatile noexcept;
        bool compare_exchange_weak(integral &, integral,
                                      memory_order, memory_order) noexcept;
        bool compare_exchange_strong(integral &, integral,
                                       memory_order, memory_order) volatile noexcept;
        bool compare_exchange_strong(integral &, integral,
                                       memory_order, memory_order) noexcept;
        bool compare_exchange_weak(integral &, integral,
                                       memory_order = memory_order_seq_cst) volatile noexcept;
        bool compare_exchange_weak(integral &, integral,
                                       memory_order = memory_order_seq_cst) noexcept;
        bool compare_exchange_strong(integral &, integral,
                                       memory_order = memory_order_seq_cst) noexcept;
        bool compare_exchange_strong(integral &, integral,
                                       memory_order = memory_order_seq_cst) volatile noexcept;
        bool compare_exchange_strong(integral &, integral,
                                       memory_order = memory_order_seq_cst) noexcept;
    };
}
memory_order = memory_order_seq_cst) noexcept;
integral fetch_add(integral, memory_order = memory_order_seq_cst) volatile noexcept;
integral fetch_add(integral, memory_order = memory_order_seq_cst) noexcept;

§ 32.6.2
T fetch_key(T operand, memory_order order = memory_order_seq_cst) volatile noexcept;
T fetch_key(T operand, memory_order order = memory_order_seq_cst) noexcept;

Effects: Atomically replaces the value pointed to by this with the result of the computation applied to the value pointed to by this and the given operand. Memory is affected according to the value of order. These operations are atomic read-modify-write operations (4.7).

Returns: Atomically, the value pointed to by this immediately before the effects.

Remarks: For signed integer types, arithmetic is defined to use two’s complement representation. There are no undefined results.

T operator op=(T operand) volatile noexcept;
T operator op=(T operand) noexcept;

Effects: Equivalent to: return fetch_key(operand) op operand;

32.6.3 Partial specialization for pointers

namespace std {
  template <class T> struct atomic<T*> {
    using value_type = T*;
    using difference_type = ptrdiff_t;
    static constexpr bool is_always_lock_free = implementation-defined;
    bool is_lock_free() const volatile noexcept;
    bool is_lock_free() const noexcept;
    void store(T*, memory_order = memory_order_seq_cst) volatile noexcept;
    void store(T*, memory_order = memory_order_seq_cst) noexcept;

</tbody>
</table>

T* fetch_key(ptrdiff_t operand, memory_order order = memory_order_seq_cst) volatile noexcept;
T* fetch_key(ptrdiff_t operand, memory_order order = memory_order_seq_cst) noexcept;

Requires: T shall be an object type, otherwise the program is ill-formed. [Note: Pointer arithmetic on void* or function pointers is ill-formed. —end note]

Effects: Atomically replaces the value pointed to by this with the result of the computation applied to the value pointed to by this and the given operand. Memory is affected according to the value of order. These operations are atomic read-modify-write operations (4.7).

Returns: Atomically, the value pointed to by this immediately before the effects.

Remarks: The result may be an undefined address, but the operations otherwise have no undefined behavior.

T* operator op=(ptrdiff_t operand) volatile noexcept;
T* operator op=(ptrdiff_t operand) noexcept;

Effects: Equivalent to: return fetch_key(operand) op operand;

32.6.4 Member operators common to integers and pointers to objects [atomics.types.memop]

T operator++(int) volatile noexcept;
T operator++(int) noexcept;

Effects: Equivalent to: return fetch_add(1);

T operator--(int) volatile noexcept;
T operator--(int) noexcept;

Effects: Equivalent to: return fetch_sub(1);

T operator++() volatile noexcept;
T operator++() noexcept;

§ 32.6.4

1355
1. **Effects:** Equivalent to: `return fetch_add(1) + 1;`

   T operator--() volatile noexcept;
   T operator--() noexcept;

2. **Effects:** Equivalent to: `return fetch_sub(1) - 1;`

### 32.7 Non-member functions

A non-member function template whose name matches the pattern `atomic_f` or the pattern `atomic_f_-explicit` invokes the member function `f`, with the value of the first parameter as the object expression and the values of the remaining parameters (if any) as the arguments of the member function call, in order. An argument for a parameter of type `atomic<T>::value_type*` is dereferenced when passed to the member function call. If no such member function exists, the program is ill-formed.

```cpp
template<class T>
void atomic_init(volatile atomic<T>* object, typename atomic<T>::value_type desired) noexcept;
```

1. **Effects:** Non-atomically initializes `*object` with value `desired`. This function shall only be applied to objects that have been default constructed, and then only once. [Note: These semantics ensure compatibility with C. —end note] [Note: Concurrent access from another thread, even via an atomic operation, constitutes a data race. —end note]

3. [Note: The non-member functions enable programmers to write code that can be compiled as either C or C++, for example in a shared header file. —end note]

### 32.8 Flag type and operations

```cpp
namespace std {

struct atomic_flag {
    bool test_and_set(memory_order = memory_order_seq_cst) volatile noexcept;
    bool test_and_set(memory_order = memory_order_seq_cst) noexcept;
    void clear(memory_order = memory_order_seq_cst) volatile noexcept;
    void clear(memory_order = memory_order_seq_cst) noexcept;

    atomic_flag() noexcept = default;
    atomic_flag(const atomic_flag&) = delete;
    atomic_flag& operator=(const atomic_flag&) = delete;
    atomic_flag& operator=(const atomic_flag&) volatile = delete;
};
```

```cpp
bool atomic_flag_test_and_set(volatile atomic_flag*) noexcept;
bool atomic_flag_test_and_set(atomic_flag*) noexcept;
bool atomic_flag_test_and_set_explicit(volatile atomic_flag*, memory_order) noexcept;
bool atomic_flag_test_and_set_explicit(atomic_flag*, memory_order) noexcept;
void atomic_flag_clear(volatile atomic_flag*) noexcept;
void atomic_flag_clear(atomic_flag*) noexcept;
void atomic_flag_clear_explicit(volatile atomic_flag*, memory_order) noexcept;
void atomic_flag_clear_explicit(atomic_flag*, memory_order) noexcept;
```

1. The `atomic_flag` type provides the classic test-and-set functionality. It has two states, set and clear.

2. Operations on an object of type `atomic_flag` shall be lock-free. [Note: Hence the operations should also be address-free. —end note]

§ 32.8
The `atomic_flag` type is a standard-layout struct. It has a trivial default constructor and a trivial destructor.

The macro `ATOMIC_FLAG_INIT` shall be defined in such a way that it can be used to initialize an object of type `atomic_flag` to the clear state. The macro can be used in the form:

```c
atomic_flag guard = ATOMIC_FLAG_INIT;
```

It is unspecified whether the macro can be used in other initialization contexts. For a complete static-duration object, that initialization shall be static. Unless initialized with `ATOMIC_FLAG_INIT`, it is unspecified whether an `atomic_flag` object has an initial state of set or clear.

```c
bool atomic_flag_test_and_set(volatile atomic_flag* object) noexcept;
bool atomic_flag_test_and_set(atomic_flag* object) noexcept;
bool atomic_flag_test_and_set_explicit(volatile atomic_flag* object, memory_order order) noexcept;
bool atomic_flag_test_and_set_explicit(atomic_flag* object, memory_order order) noexcept;
bool atomic_flag::test_and_set(memory_order order = memory_order_seq_cst) volatile noexcept;
bool atomic_flag::test_and_set(memory_order order = memory_order_seq_cst) noexcept;
```

**Effects:** Atomically sets the value pointed to by `object` or by `this` to true. Memory is affected according to the value of `order`. These operations are atomic read-modify-write operations (4.7).

```c
void atomic_flag_clear(volatile atomic_flag* object) noexcept;
void atomic_flag_clear(atomic_flag* object) noexcept;
void atomic_flag_clear_explicit(volatile atomic_flag* object, memory_order order) noexcept;
void atomic_flag_clear_explicit(atomic_flag* object, memory_order order) noexcept;
void atomic_flag::clear(memory_order order = memory_order_seq_cst) volatile noexcept;
void atomic_flag::clear(memory_order order = memory_order_seq_cst) noexcept;
```

**Requires:** The `order` argument shall not be `memory_order_consume`, `memory_order_acquire`, nor `memory_order_acq_rel`.

**Effects:** Atomically sets the value pointed to by `object` or by `this` to false. Memory is affected according to the value of `order`.

### 32.9 Fences

This section introduces synchronization primitives called `fences`. Fences can have acquire semantics, release semantics, or both. A fence with acquire semantics is called an `acquire fence`. A fence with release semantics is called a `release fence`.

A release fence `A` synchronizes with an acquire fence `B` if there exist atomic operations `X` and `Y`, both operating on some atomic object `M`, such that `A` is sequenced before `X`, `X` modifies `M`, `Y` is sequenced before `B`, and `Y` reads the value written by `X` or a value written by any side effect in the hypothetical release sequence `X` would head if it were a release operation.

A release fence `A` synchronizes with an atomic operation `B` that performs an acquire operation on an atomic object `M` if there exists an atomic operation `X` such that `A` is sequenced before `X`, `X` modifies `M`, and `B` reads the value written by `X` or a value written by any side effect in the hypothetical release sequence `X` would head if it were a release operation.

An atomic operation `A` that is a release operation on an atomic object `M` synchronizes with an acquire fence `B` if there exists some atomic operation `X` on `M` such that `X` is sequenced before `B` and reads the value written by `A` or a value written by any side effect in the release sequence headed by `A`.

```c
extern "C" void atomic_thread_fence(memory_order order) noexcept;
```

**Effects:** Depending on the value of `order`, this operation:

- has no effects, if `order == memory_order_relaxed`;

---

§ 32.9
— is an acquire fence, if \texttt{order == memory\_order\_acquire || order == memory\_order\_consume};
(5.3) — is a release fence, if \texttt{order == memory\_order\_release};
(5.4) — is both an acquire fence and a release fence, if \texttt{order == memory\_order\_acq\_rel};
(5.5) — is a sequentially consistent acquire and release fence, if \texttt{order == memory\_order\_seq\_cst}.

\begin{verbatim}
extern "C" void atomic_signal_fence(memory_order order) noexcept;
\end{verbatim}

\textit{Effects:} Equivalent to \texttt{atomic\_thread\_fence(order)}, except that the resulting ordering constraints are established only between a thread and a signal handler executed in the same thread.

\[\text{Note: atomic\_signal\_fence} \text{ can be used to specify the order in which actions performed by the thread become visible to the signal handler. Compiler optimizations and reorderings of loads and stores are inhibited in the same way as with } \texttt{atomic\_thread\_fence}, \text{ but the hardware fence instructions that } \texttt{atomic\_thread\_fence} \text{ would have inserted are not emitted. \textit{— end note}}\]
33 Thread support library

33.1 General

The following subclauses describe components to create and manage threads (4.7), perform mutual exclusion, and communicate conditions and values between threads, as summarized in Table 140.

Table 140 — Thread support library summary

</tbody>
</table>

33.2 Requirements

33.2.1 Template parameter names

Throughout this Clause, the names of template parameters are used to express type requirements. If a template parameter is named `Predicate`, `operator()` applied to the template argument shall return a value that is convertible to `bool`.

33.2.2 Exceptions

Some functions described in this Clause are specified to throw exceptions of type `system_error` (22.5.7). Such exceptions shall be thrown if any of the function’s error conditions is detected or a call to an operating system or other underlying API results in an error that prevents the library function from meeting its specifications. Failure to allocate storage shall be reported as described in 20.5.5.12.

Example: Consider a function in this clause that is specified to throw exceptions of type `system_error` and specifies error conditions that include `operation_not_permitted` for a thread that does not have the privilege to perform the operation. Assume that, during the execution of this function, an `errno` of `EPERM` is reported by a POSIX API call used by the implementation. Since POSIX specifies an `errno` of `EPERM` when “the caller does not have the privilege to perform the operation”, the implementation maps `EPERM` to an `error_condition` of `operation_not_permitted` (22.5) and an exception of type `system_error` is thrown.

—end example

The `error_code` reported by such an exception’s `code()` member function shall compare equal to one of the conditions specified in the function’s error condition element.

33.2.3 Native handles

Several classes described in this Clause have members `native_handle_type` and `native_handle`. The presence of these members and their semantics is implementation-defined. [Note: These members allow implementations to provide access to implementation details. Their names are specified to facilitate portable compile-time detection. Actual use of these members is inherently non-portable. —end note]
33.2.4 Timing specifications

1 Several functions described in this Clause take an argument to specify a timeout. These timeouts are specified as either a duration or a time_point type as specified in 23.17.

2 Implementations necessarily have some delay in returning from a timeout. Any overhead in interrupt response, function return, and scheduling induces a “quality of implementation” delay, expressed as duration $D_i$. Ideally, this delay would be zero. Further, any contention for processor and memory resources induces a “quality of management” delay, expressed as duration $D_m$. The delay durations may vary from timeout to timeout, but in all cases shorter is better.

3 The member functions whose names end in _for take an argument that specifies a duration. These functions produce relative timeouts. Implementations should use a steady clock to measure time for these functions. Given a duration argument $D_t$, the real-time duration of the timeout is $D_t + D_i + D_m$.

4 The member functions whose names end in _until take an argument that specifies a time point. These functions produce absolute timeouts. Implementations should use the clock specified in the time point to measure time for these functions. Given a clock time point argument $C_t$, the clock time point of the return from timeout should be $C_t + D_i + D_m$ when the clock is not adjusted during the timeout. If the clock is adjusted to the time $C_a$ during the timeout, the behavior should be as follows:

   (4.1) if $C_a > C_t$, the waiting function should wake as soon as possible, i.e. $C_a + D_i + D_m$, since the timeout is already satisfied. [Note: This specification may result in the total duration of the wait decreasing when measured against a steady clock. — end note]  

   (4.2) if $C_a \leq C_t$, the waiting function should not time out until Clock::now() returns a time $C_a \geq C_t$, i.e. waking at $C_t + D_i + D_m$. [Note: When the clock is adjusted backwards, this specification may result in the total duration of the wait increasing when measured against a steady clock. When the clock is adjusted forwards, this specification may result in the total duration of the wait decreasing when measured against a steady clock. — end note]

An implementation shall return from such a timeout at any point from the time specified above to the time it would return from a steady-clock relative timeout on the difference between $C_t$ and the time point of the call to the _until function. [Note: Implementations should decrease the duration of the wait when the clock is adjusted forwards. — end note]

5 [Note: If the clock is not synchronized with a steady clock, e.g., a CPU time clock, these timeouts might not provide useful functionality. — end note]

6 The resolution of timing provided by an implementation depends on both operating system and hardware. The finest resolution provided by an implementation is called the native resolution.

7 Implementation-provided clocks that are used for these functions shall meet the TrivialClock requirements (23.17.3).

8 A function that takes an argument which specifies a timeout will throw if, during its execution, a clock, time point, or time duration throws an exception. Such exceptions are referred to as timeout-related exceptions. [Note: Instantiations of clock, time point and duration types supplied by the implementation as specified in 23.17.7 do not throw exceptions. — end note]

33.2.5 Requirements for Lockable types

33.2.5.1 In general

1 An execution agent is an entity such as a thread that may perform work in parallel with other execution agents. [Note: Implementations or users may introduce other kinds of agents such as processes or thread-pool

330) All implementations for which standard time units are meaningful must necessarily have a steady clock within their hardware implementation.
tasks. —end note] The calling agent is determined by context, e.g. the calling thread that contains the call, and so on.

[Note: Some lockable objects are “agent oblivious” in that they work for any execution agent model because they do not determine or store the agent’s ID (e.g., an ordinary spin lock). —end note]

The standard library templates unique_lock (33.4.4.3), shared_lock (33.4.4.4), scoped_lock (33.4.4.2), lock_guard (33.4.4.1), lock, try_lock (33.4.5), and condition_variable_any (33.5.4) all operate on user-supplied lockable objects. The BasicLockable requirements, the Lockable requirements, and the TimedLockable requirements list the requirements imposed by these library types in order to acquire or release ownership of a lock by a given execution agent. [ Note: The nature of any lock ownership and any synchronization it may entail are not part of these requirements. —end note]

33.2.5.2 BasicLockable requirements [thread.req.lockable.basic]

1 A type \(L\) meets the BasicLockable requirements if the following expressions are well-formed and have the specified semantics (\(m\) denotes a value of type \(L\)).

\[
m.lock() 
\]

Effects: Blocks until a lock can be acquired for the current execution agent. If an exception is thrown then a lock shall not have been acquired for the current execution agent.

\[
m.unlock() 
\]

Requires: The current execution agent shall hold a lock on \(m\).

Effects: Releases a lock on \(m\) held by the current execution agent.

Throws: Nothing.

33.2.5.3 Lockable requirements [thread.req.lockable.req]

1 A type \(L\) meets the Lockable requirements if it meets the BasicLockable requirements and the following expressions are well-formed and have the specified semantics (\(m\) denotes a value of type \(L\)).

\[
m.try_lock() 
\]

Effects: Attempts to acquire a lock for the current execution agent without blocking. If an exception is thrown then a lock shall not have been acquired for the current execution agent.

\[
Return type: bool. 
\]

Returns: \(true\) if the lock was acquired, \(false\) otherwise.

33.2.5.4 TimedLockable requirements [thread.req.lockable.timed]

1 A type \(L\) meets the TimedLockable requirements if it meets the Lockable requirements and the following expressions are well-formed and have the specified semantics (\(m\) denotes a value of type \(L\), \(rel\_time\) denotes a value of an instantiation of duration (23.17.5), and \(abs\_time\) denotes a value of an instantiation of time_point (23.17.6)).

\[
m.try_lock_for(rel\_time) 
\]

Effects: Attempts to acquire a lock for the current execution agent within the relative timeout (33.2.4) specified by \(rel\_time\). The function shall not return within the timeout specified by \(rel\_time\) unless it has obtained a lock on \(m\) for the current execution agent. If an exception is thrown then a lock shall not have been acquired for the current execution agent.

\[
Return type: bool. 
\]

Returns: \(true\) if the lock was acquired, \(false\) otherwise.
m.try_lock_until(abs_time)

**Effects:** Attempts to acquire a lock for the current execution agent before the absolute timeout (33.2.4) specified by `abs_time`. The function shall not return before the timeout specified by `abs_time` unless it has obtained a lock on `m` for the current execution agent. If an exception is thrown then a lock shall not have been acquired for the current execution agent.

**Return type:** `bool`.

**Returns:** `true` if the lock was acquired, `false` otherwise.

### 33.2.6 decay_copy

In several places in this Clause the operation `DECAY_COPY(x)` is used. All such uses mean call the function `decay_copy(x)` and use the result, where `decay_copy` is defined as follows:

```cpp
template <class T> decay_t<T> decay_copy(T&& v)
{
    return std::forward<T>(v);
}
```

### 33.3 Threads

33.3 describes components that can be used to create and manage threads. [Note: These threads are intended to map one-to-one with operating system threads. — end note]

#### 33.3.1 Header `<thread>` synopsis

```cpp
namespace std {
    class thread;

    void swap(thread& x, thread& y) noexcept;

    namespace this_thread {
        thread::id get_id() noexcept;
        void yield() noexcept;
        template <class Clock, class Duration>
            void sleep_until(const chrono::time_point<Clock, Duration>& abs_time);
        template <class Rep, class Period>
            void sleep_for(const chrono::duration<Rep, Period>& rel_time);
    }
}
```

#### 33.3.2 Class thread

The class `thread` provides a mechanism to create a new thread of execution, to join with a thread (i.e., wait for a thread to complete), and to perform other operations that manage and query the state of a thread. A `thread` object uniquely represents a particular thread of execution. That representation may be transferred to other `thread` objects in such a way that no two `thread` objects simultaneously represent the same thread of execution. A thread of execution is `detached` when no `thread` object represents that thread. Objects of class `thread` can be in a state that does not represent a thread of execution. [Note: A `thread` object does not represent a thread of execution after default construction, after being moved from, or after a successful call to `detach` or `join`. — end note]

```cpp
namespace std {
    class thread {
        public:
            // types:
            class id;
            using native_handle_type = implementation-defined; // See 33.2.3
```
An object of type `thread::id` provides a unique identifier for each thread of execution and a single distinct value for all `thread` objects that do not represent a thread of execution (33.3.2). Each thread of execution has an associated `thread::id` object that is not equal to the `thread::id` object of any other thread of execution and that is not equal to the `thread::id` object of any `thread` object that does not represent threads of execution.

`thread::id` shall be a trivially copyable class (Clause 12). The library may reuse the value of a `thread::id` of a terminated thread that can no longer be joined.

[Note: Relational operators allow `thread::id` objects to be used as keys in associative containers. — end note]
id() noexcept;
   // Effects: Constructs an object of type id.
   // Postconditions: The constructed object does not represent a thread of execution.

bool operator==(thread::id x, thread::id y) noexcept;
   // Returns: true only if x and y represent the same thread of execution or neither x nor y represents a thread of execution.

bool operator!=(thread::id x, thread::id y) noexcept;
   // Returns: !(x == y)

bool operator<(thread::id x, thread::id y) noexcept;
   // Returns: A value such that operator< is a total ordering as described in 28.7.

bool operator<=(thread::id x, thread::id y) noexcept;
   // Returns: !(y < x).

bool operator>(thread::id x, thread::id y) noexcept;
   // Returns: y < x.

bool operator>=(thread::id x, thread::id y) noexcept;
   // Returns: !(x < y).

template<class charT, class traits>
basic_ostream<charT, traits>&
   operator<< (basic_ostream<charT, traits>& out, thread::id id);
   // Effects: Inserts an unspecified text representation of id into out. For two objects of type thread::id x and y, if x == y the thread::id objects shall have the same text representation and if x != y the thread::id objects shall have distinct text representations.
   // Returns: out.

template <> struct hash<thread::id>;
   // The specialization is enabled (23.14.15).

33.3.2.2 thread constructors

thread() noexcept;
   // Effects: Constructs a thread object that does not represent a thread of execution.
   // Postconditions: get_id() == id().

template <class F, class... Args> explicit thread(F&& f, Args&&... args);
   // Requires: F and each Ti in Args shall satisfy the MoveConstructible requirements. INVOKE(DECAY_COPY(std::forward<F>(f)), DECAY_COPY(std::forward<Args>(args))...) (23.14.3) shall be a valid expression.
   // Remarks: This constructor shall not participate in overload resolution if decay_t<F> is the same type as std::thread.
   // Effects: Constructs an object of type thread. The new thread of execution executes INVOKE(
   // DECAY_COPY(DECAY_COPY(std::forward<F>(f)), DECAY_COPY(std::forward<Args>(args))...) with the calls to DECAY_COPY being evaluated in the constructing thread. Any return value from this invocation
is ignored. [Note: This implies that any exceptions not thrown from the invocation of the copy of \texttt{f} will be thrown in the constructing thread, not the new thread. — end note] If the invocation of \texttt{INVOLVE\textunderscore{}DECAY\_COPY\textless{}std::forward\textgreater{}<(\texttt{f}), \texttt{DECAY\_COPY\textless{}std::forward\textgreater{}<(\texttt{args})\textldots{}) terminates with an uncaught exception, \texttt{terminate} shall be called.

\textit{Synchronization}: The completion of the invocation of the constructor synchronizes with the beginning of the invocation of the copy of \texttt{f}.

\textit{Postconditions}: \texttt{get\_id()} \texttt{!= id()}. \texttt{*this} represents the newly started thread.

\textit{Throws}: \texttt{system\_error} if unable to start the new thread.

\textit{Error conditions}:

\begin{itemize}
  \item \texttt{resource\_unavailable\_try\_again} — the system lacked the necessary resources to create another thread, or the system-imposed limit on the number of threads in a process would be exceeded.
\end{itemize}

\begin{verbatim}
thread(thread&& x) noexcept;
\end{verbatim}

\textit{Effects}: Constructs an object of type \texttt{thread} from \texttt{x}, and sets \texttt{x} to a default constructed state.

\textit{Postconditions}: \texttt{x.get\_id() == id()} and \texttt{get\_id()} returns the value of \texttt{x.get\_id()} prior to the start of construction.

\subsection{thread destructor} \hfill \texttt{[thread.thread.destr]}

\begin{verbatim}
~thread();
\end{verbatim}

\begin{itemize}
  \item If \texttt{joinable()}, calls \texttt{terminate()}. Otherwise, has no effects. [Note: Either implicitly detaching or joining a \texttt{joinable()} thread in its destructor could result in difficult to debug correctness (for detach) or performance (for join) bugs encountered only when an exception is thrown. Thus the programmer must ensure that the destructor is never executed while the thread is still \texttt{joinable}. — end note]
\end{itemize}

\subsection{thread assignment} \hfill \texttt{[thread.thread.assign]}

\begin{verbatim}
thread& operator=(thread&& x) noexcept;
\end{verbatim}

\textit{Effects}: If \texttt{joinable()}, calls \texttt{terminate()}. Otherwise, assigns the state of \texttt{x} to \texttt{*this} and sets \texttt{x} to a default constructed state.

\textit{Postconditions}: \texttt{x.get\_id() == id()} and \texttt{get\_id()} returns the value of \texttt{x.get\_id()} prior to the assignment.

\textit{Returns}: \texttt{*this}.

\subsection{thread members} \hfill \texttt{[thread.thread.member]}

\begin{verbatim}
void swap(thread& x) noexcept;
\end{verbatim}

\textit{Effects}: Swaps the state of \texttt{*this} and \texttt{x}.

\begin{verbatim}
bool joinable() const noexcept;
\end{verbatim}

\textit{Returns}: \texttt{get\_id() != id()}.

\begin{verbatim}
void join();
\end{verbatim}

\textit{Effects}: Blocks until the thread represented by \texttt{*this} has completed.

\textit{Synchronization}: The completion of the thread represented by \texttt{*this} synchronizes with (4.7) the corresponding successful \texttt{join()} return. [Note: Operations on \texttt{*this} are not synchronized. — end note]

\textit{Postconditions}: The thread represented by \texttt{*this} has completed. \texttt{get\_id() == id()}. 

\section*{§ 33.3.2.5}
void detach();

Effects: The thread represented by \*this continues execution without the calling thread blocking. When detach() returns, \*this no longer represents the possibly continuing thread of execution. When the thread previously represented by \*this ends execution, the implementation shall release any owned resources.

Postconditions: get_id() == id().

Throws: system_error when an exception is required (33.2.2).

Error conditions:

(11.1) — no_such_process — if the thread is not valid.
(11.2) — invalid_argument — if the thread is not joinable.

id get_id() const noexcept;

Returns: A default constructed id object if \*this does not represent a thread, otherwise this_thread::get_id() for the thread of execution represented by \*this.

33.3.3.2.6 thread static members

unsigned hardware_concurrency() noexcept;

Returns: The number of hardware thread contexts. [Note: This value should only be considered to be a hint. — end note] If this value is not computable or well defined an implementation should return 0.

33.3.3.2.7 thread specialized algorithms

void swap(thread& x, thread& y) noexcept;

Effects: As if by x.swap(y).

33.3.3 Namespace this_thread

namespace std::this_thread {
    thread::id get_id() noexcept;

    void yield() noexcept;
    template <class Clock, class Duration>
    void sleep_until(const chrono::time_point<Clock, Duration>& abs_time);
    template <class Rep, class Period>
    void sleep_for(const chrono::duration<Rep, Period>& rel_time);
}

thread::id this_thread::get_id() noexcept;

Returns: An object of type thread::id that uniquely identifies the current thread of execution. No other thread of execution shall have this id and this thread of execution shall always have this id. The object returned shall not compare equal to a default constructed thread::id.
void this_thread::yield() noexcept;

   Effects: Offers the implementation the opportunity to reschedule.

   Synchronization: None.

template <class Clock, class Duration>
void sleep_until(const chrono::time_point<Clock, Duration>& abs_time);

   Effects: Blocks the calling thread for the absolute timeout (33.2.4) specified by abs_time.

   Synchronization: None.

   Throws: Timeout-related exceptions (33.2.4).

template <class Rep, class Period>
void sleep_for(const chrono::duration<Rep, Period>& rel_time);

   Effects: Blocks the calling thread for the relative timeout (33.2.4) specified by rel_time.

   Synchronization: None.

   Throws: Timeout-related exceptions (33.2.4).

33.4 Mutual exclusion [thread.mutex]

This section provides mechanisms for mutual exclusion: mutexes, locks, and call once. These mechanisms ease the production of race-free programs (4.7).

33.4.1 Header <mutex> synopsis [mutex.syn]

namespace std {
    class mutex;
    class recursive_mutex;
    class timed_mutex;
    class recursive_timed_mutex;

    struct defer_lock_t { explicit defer_lock_t() = default; };
    struct try_to_lock_t { explicit try_to_lock_t() = default; };
    struct adopt_lock_t { explicit adopt_lock_t() = default; };

    inline constexpr defer_lock_t defer_lock { };
    inline constexpr try_to_lock_t try_to_lock { };
    inline constexpr adopt_lock_t adopt_lock { };

    template <class Mutex> class lock_guard;
    template <class... MutexTypes> class scoped_lock;
    template <class Mutex> class unique_lock;

    template <class Mutex>
    void swap(unique_lock<Mutex>& x, unique_lock<Mutex>& y) noexcept;

    template <class L1, class L2, class... L3> int try_lock(L1&, L2&, L3&...);
    template <class L1, class L2, class... L3> void lock(L1&, L2&, L3&...);

    struct once_flag;

    template<class Callable, class... Args>
    void call_once(once_flag& flag, Callable& func, Args&... args);
}

§ 33.4.1
33.4.2 Header `<shared_mutex>` synopsis

```c++
namespace std {
    class shared_mutex;
    class shared_timed_mutex;
    template <class Mutex> class shared_lock;
    template <class Mutex>
        void swap(shared_lock<Mutex>& x, shared_lock<Mutex>& y) noexcept;
}
```

33.4.3 Mutex requirements

33.4.3.1 In general

A mutex object facilitates protection against data races and allows safe synchronization of data between execution agents (33.2.5). An execution agent owns a mutex from the time it successfully calls one of the lock functions until it calls unlock. Mutexes can be either recursive or non-recursive, and can grant simultaneous ownership to one or many execution agents. Both recursive and non-recursive mutexes are supplied.

33.4.3.2 Mutex types

1 The mutex types are the standard library types `mutex`, `recursive_mutex`, `timed_mutex`, `recursive_timed_mutex`, `shared_mutex`, and `shared_timed_mutex`. They shall meet the requirements set out in this section. In this description, `m` denotes an object of a mutex type.

2 The mutex types shall meet the Lockable requirements (33.2.5.3).

3 The mutex types shall be DefaultConstructible and Destructible. If initialization of an object of a mutex type fails, an exception of type `system_error` shall be thrown. The mutex types shall not be copyable or movable.

4 The error conditions for error codes, if any, reported by member functions of the mutex types shall be:

   - (4.1) `resource_unavailable_try_again` — if any native handle type manipulated is not available.
   - (4.2) `operation_not_permitted` — if the thread does not have the privilege to perform the operation.
   - (4.3) `invalid_argument` — if any native handle type manipulated as part of mutex construction is incorrect.

5 The implementation shall provide lock and unlock operations, as described below. For purposes of determining the existence of a data race, these behave as atomic operations (4.7). The lock and unlock operations on a single mutex shall appear to occur in a single total order. [Note: This can be viewed as the modification order (4.7) of the mutex. — end note] [Note: Construction and destruction of an object of a mutex type need not be thread-safe; other synchronization should be used to ensure that mutex objects are initialized and visible to other threads. — end note]

6 The expression `m.lock()` shall be well-formed and have the following semantics:

   Requires: If `m` is of type `mutex`, `timed_mutex`, `shared_mutex`, or `shared_timed_mutex`, the calling thread does not own the mutex.

   Effects: Blocks the calling thread until ownership of the mutex can be obtained for the calling thread.

   Postconditions: The calling thread owns the mutex.

   Return type: void.

   Synchronization: Prior `unlock()` operations on the same object shall synchronize with (4.7) this operation.

   Throws: `system_error` when an exception is required (33.2.2).

   Error conditions:

   - (13.1) `operation_not_permitted` — if the thread does not have the privilege to perform the operation.
The expression \( m \text{.try_lock()} \) shall be well-formed and have the following semantics:

**Requires:** If \( m \) is of type \( \text{mutex} \), \( \text{timed_mutex} \), \( \text{shared_mutex} \), or \( \text{shared_timed_mutex} \), the calling thread does not own the mutex.

**Effects:** Attempts to obtain ownership of the mutex for the calling thread without blocking. If ownership is not obtained, there is no effect and \( \text{try_lock()} \) immediately returns. An implementation may fail to obtain the lock even if it is not held by any other thread.  

[Note: This spurious failure is normally uncommon, but allows interesting implementations based on a simple compare and exchange (Clause 32).]  

[--- end note]  

An implementation should ensure that \( \text{try_lock()} \) does not consistently return \( \text{false} \) in the absence of contending mutex acquisitions.

**Return type:** \( \text{bool} \).

**Returns:** \( \text{true} \) if ownership of the mutex was obtained for the calling thread, otherwise \( \text{false} \).

**Synchronization:** If \( \text{try_lock()} \) returns \( \text{true} \), prior \( \text{unlock()} \) operations on the same object synchronize with (4.7) this operation.  

[Note: Since \( \text{lock()} \) does not synchronize with a failed subsequent \( \text{try_lock()} \), the visibility rules are weak enough that little would be known about the state after a failure, even in the absence of spurious failures.  

[--- end note]  

**Throws:** Nothing.

The expression \( m \text{.unlock()} \) shall be well-formed and have the following semantics:

**Requires:** The calling thread shall own the mutex.

**Effects:** Releases the calling thread’s ownership of the mutex.

**Return type:** \( \text{void} \).

**Synchronization:** This operation synchronizes with (4.7) subsequent lock operations that obtain ownership on the same object.

**Throws:** Nothing.

### 33.4.3.2.1 Class `mutex`  

```cpp
namespace std {
    class mutex {
    public:
        constexpr mutex() noexcept;
        ~mutex();
        mutex(const mutex&) = delete;
        mutex& operator=(const mutex&) = delete;
        void lock();
        bool try_lock();
        void unlock();

        using native_handle_type = implementation-defined; // See 33.2.3
        native_handle_type native_handle(); // See 33.2.3
    };
}
```

1 The class `mutex` provides a non-recursive mutex with exclusive ownership semantics. If one thread owns a mutex object, attempts by another thread to acquire ownership of that object will fail (for `try_lock()`) or block (for `lock()`) until the owning thread has released ownership with a call to `unlock()`.

2 [Note: After a thread A has called `unlock()`, releasing a mutex, it is possible for another thread B to lock...```
the same mutex, observe that it is no longer in use, unlock it, and destroy it, before thread A appears to have returned from its unlock call. Implementations are required to handle such scenarios correctly, as long as thread A doesn’t access the mutex after the unlock call returns. These cases typically occur when a reference-counted object contains a mutex that is used to protect the reference count. —end note]

3 The class mutex shall satisfy all of the mutex requirements (33.4.3). It shall be a standard-layout class (Clause 12).

4 [Note: A program may deadlock if the thread that owns a mutex object calls lock() on that object. If the implementation can detect the deadlock, a resource_deadlock_would_occur error condition may be observed. —end note]

5 The behavior of a program is undefined if it destroys a mutex object owned by any thread or a thread terminates while owning a mutex object.

33.4.3.2.2 Class recursive_mutex

namespace std {
    class recursive_mutex {
        public:
            recursive_mutex();
            ~recursive_mutex();
            recursive_mutex(const recursive_mutex&) = delete;
            recursive_mutex& operator=(const recursive_mutex&) = delete;
            void lock();
            bool try_lock() noexcept;
            void unlock();

            using native_handle_type = implementation-defined; // See 33.2.3
            native_handle_type native_handle(); // See 33.2.3
    }
};

1 The class recursive_mutex provides a recursive mutex with exclusive ownership semantics. If one thread owns a recursive_mutex object, attempts by another thread to acquire ownership of that object will fail (for try_lock()) or block (for lock()) until the first thread has completely released ownership.

2 The class recursive_mutex shall satisfy all of the mutex requirements (33.4.3). It shall be a standard-layout class (Clause 12).

3 A thread that owns a recursive_mutex object may acquire additional levels of ownership by calling lock() or try_lock() on that object. It is unspecified how many levels of ownership may be acquired by a single thread. If a thread has already acquired the maximum level of ownership for a recursive_mutex object, additional calls to try_lock() shall fail, and additional calls to lock() shall throw an exception of type system_error. A thread shall call unlock() once for each level of ownership acquired by calls to lock() and try_lock(). Only when all levels of ownership have been released may ownership be acquired by another thread.

4 The behavior of a program is undefined if:

(4.1) — it destroys a recursive_mutex object owned by any thread or

(4.2) — a thread terminates while owning a recursive_mutex object.

33.4.3.3 Timed mutex types

The timed mutex types are the standard library types timed_mutex, recursive_timed_mutex, and shared_timed_mutex. They shall meet the requirements set out below. In this description, m denotes an object of a
mutex type, \texttt{rel\_time} denotes an object of an instantiation of \texttt{duration} (23.17.5), and \texttt{abs\_time} denotes an object of an instantiation of \texttt{time\_point} (23.17.6).

2 The timed mutex types shall meet the \texttt{TimedLockable} requirements (33.2.5.4).

3 The expression \texttt{m.\_try\_lock\_for(\texttt{rel\_time})} shall be well-formed and have the following semantics:

\begin{itemize}
  \item \textbf{Requires:} If \texttt{m} is of type \texttt{timed\_mutex} or \texttt{shared\_timed\_mutex}, the calling thread does not own the mutex.
  \item \textbf{Effects:} The function attempts to obtain ownership of the mutex within the relative timeout (33.2.4) specified by \texttt{rel\_time}. If the time specified by \texttt{rel\_time} is less than or equal to \texttt{rel\_time.zero()}, the function attempts to obtain ownership without blocking (as if by calling \texttt{try\_lock()}). The function shall return within the timeout specified by \texttt{rel\_time} only if it has obtained ownership of the mutex object. [Note: As with \texttt{try\_lock()}, there is no guarantee that ownership will be obtained if the lock is available, but implementations are expected to make a strong effort to do so. — end note]
  \item \textbf{Return type:} \texttt{bool}.
  \item \textbf{Returns:} \texttt{true} if ownership was obtained, otherwise \texttt{false}.
  \item \textbf{Synchronization:} If \texttt{try\_lock\_for()} returns \texttt{true}, prior \texttt{unlock()} operations on the same object synchronize with (4.7) this operation.
  \item \textbf{Throws:} Timeout-related exceptions (33.2.4).
\end{itemize}

4 The expression \texttt{m.\_try\_lock\_until(\texttt{abs\_time})} shall be well-formed and have the following semantics:

\begin{itemize}
  \item \textbf{Requires:} If \texttt{m} is of type \texttt{timed\_mutex} or \texttt{shared\_timed\_mutex}, the calling thread does not own the mutex.
  \item \textbf{Effects:} The function attempts to obtain ownership of the mutex. If \texttt{abs\_time} has already passed, the function attempts to obtain ownership without blocking (as if by calling \texttt{try\_lock()}). The function shall return before the absolute timeout (33.2.4) specified by \texttt{abs\_time} only if it has obtained ownership of the mutex object. [Note: As with \texttt{try\_lock()}, there is no guarantee that ownership will be obtained if the lock is available, but implementations are expected to make a strong effort to do so. — end note]
  \item \textbf{Return type:} \texttt{bool}.
  \item \textbf{Returns:} \texttt{true} if ownership was obtained, otherwise \texttt{false}.
  \item \textbf{Synchronization:} If \texttt{try\_lock\_until()} returns \texttt{true}, prior \texttt{unlock()} operations on the same object synchronize with (4.7) this operation.
  \item \textbf{Throws:} Timeout-related exceptions (33.2.4).
\end{itemize}

1371

\subsection*{33.4.3.3.1 Class \texttt{timed\_mutex}}

\begin{verbatim}
namespace std {
  class timed_mutex {
    public:
      timed_mutex();
      ~timed_mutex();

      timed_mutex(const timed_mutex&) = delete;
      timed_mutex& operator=(const timed_mutex&) = delete;

      void lock(); // blocking
      bool try_lock();

      template <class Rep, class Period>
        bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);
      template <class Clock, class Duration>
        bool try_lock_until(const Clock& abs_time);

  };
}
\end{verbatim}
The class `timed_mutex` provides a non-recursive mutex with exclusive ownership semantics. If one thread owns a `timed_mutex` object, attempts by another thread to acquire ownership of that object will fail (for `try_lock()` or block (for `lock()`, `try_lock_for()`, and `try_lock_until()`) until the owning thread has released ownership with a call to `unlock()` or the call to `try_lock_for()` or `try_lock_until()` times out (having failed to obtain ownership).

The class `timed_mutex` shall satisfy all of the timed mutex requirements (33.4.3.3). It shall be a standard-layout class (Clause 12).

The behavior of a program is undefined if:

1. it destroys a `timed_mutex` object owned by any thread,
2. a thread that owns a `timed_mutex` object calls `lock()`, `try_lock()`, `try_lock_for()`, or `try_lock_until()` on that object, or
3. a thread terminates while owning a `timed_mutex` object.

The class `recursive_timed_mutex` provides a recursive mutex with exclusive ownership semantics. If one thread owns a `recursive_timed_mutex` object, attempts by another thread to acquire ownership of that object will fail (for `try_lock()` or block (for `lock()`, `try_lock_for()`, and `try_lock_until()`) until the owning thread has completely released ownership or the call to `try_lock_for()` or `try_lock_until()` times out (having failed to obtain ownership).

The class `recursive_timed_mutex` shall satisfy all of the timed mutex requirements (33.4.3.3). It shall be a standard-layout class (Clause 12).

A thread that owns a `recursive_timed_mutex` object may acquire additional levels of ownership by calling
lock(), try_lock(), try_lock_for(), or try_lock_until() on that object. It is unspecified how many levels of ownership may be acquired by a single thread. If a thread has already acquired the maximum level of ownership for a recursive_timed_mutex object, additional calls to try_lock(), try_lock_for(), or try_lock_until() shall fail, and additional calls to lock() shall throw an exception of type system_error. A thread shall call unlock() once for each level of ownership acquired by calls to lock(), try_lock(), try_lock_for(), and try_lock_until(). Only when all levels of ownership have been released may ownership of the object be acquired by another thread.

The behavior of a program is undefined if:

(4.1)  — it destroys a recursive_timed_mutex object owned by any thread, or
(4.2)  — a thread terminates while owning a recursive_timed_mutex object.

33.4.3.4  Shared mutex types

The standard library types shared_mutex and shared_timed_mutex are shared mutex types. Shared mutex types shall meet the requirements of mutex types (33.4.3.2), and additionally shall meet the requirements set out below. In this description, m denotes an object of a shared mutex type.

In addition to the exclusive lock ownership mode specified in 33.4.3.2, shared mutex types provide a shared lock ownership mode. Multiple execution agents can simultaneously hold a shared lock ownership of a shared mutex type. But no execution agent shall hold a shared lock while another execution agent holds an exclusive lock on the same shared mutex type, and vice-versa. The maximum number of execution agents which can share a shared lock on a single shared mutex type is unspecified, but shall be at least 10000. If more than the maximum number of execution agents attempt to obtain a shared lock, the excess execution agents shall block until the number of shared locks are reduced below the maximum amount by other execution agents releasing their shared lock.

The expression m.lock_shared() shall be well-formed and have the following semantics:

4  Requires: The calling thread has no ownership of the mutex.
5  Effects: Blocks the calling thread until shared ownership of the mutex can be obtained for the calling thread. If an exception is thrown then a shared lock shall not have been acquired for the current thread.
6  Postconditions: The calling thread has a shared lock on the mutex.
7  Return type: void.
8  Synchronization: Prior unlock() operations on the same object shall synchronize with (4.7) this operation.
9  Throws: system_error when an exception is required (33.2.2).
10  Error conditions:
10.1  — operation_not_permitted — if the thread does not have the privilege to perform the operation.
10.2  — resource_deadlock_would_occur — if the implementation detects that a deadlock would occur.

The expression m.unlock_shared() shall be well-formed and have the following semantics:

11  Requires: The calling thread shall hold a shared lock on the mutex.
12  Effects: Releases a shared lock on the mutex held by the calling thread.
13  Return type: void.
14  Synchronization: This operation synchronizes with (4.7) subsequent lock() operations that obtain ownership on the same object.
15  Throws: Nothing.
16

The expression m.try_lock_shared() shall be well-formed and have the following semantics:
Requires: The calling thread has no ownership of the mutex.

Effects: Attempts to obtain shared ownership of the mutex for the calling thread without blocking. If shared ownership is not obtained, there is no effect and try_lock_shared() immediately returns. An implementation may fail to obtain the lock even if it is not held by any other thread.

Return type: bool.

Returns: true if the shared ownership lock was acquired, false otherwise.

Synchronization: If try_lock_shared() returns true, prior unlock() operations on the same object synchronize with (4.7) this operation.

Throws: Nothing.

33.4.3.4.1 Class shared_mutex

namespace std {
    class shared_mutex {
        public:
            shared_mutex();
            ~shared_mutex();

            shared_mutex(const shared_mutex&) = delete;
            shared_mutex& operator=(const shared_mutex&) = delete;

            // Exclusive ownership
            void lock(); // blocking
            bool try_lock();
            void unlock();

            // Shared ownership
            void lock_shared(); // blocking
            bool try_lock_shared();
            void unlock_shared();

            using native_handle_type = implementation-defined; // See 33.2.3
            native_handle_type native_handle(); // See 33.2.3
    };
}

1 The class shared_mutex provides a non-recursive mutex with shared ownership semantics.

2 The class shared_mutex shall satisfy all of the shared mutex requirements (33.4.3.4). It shall be a standard-layout class (Clause 12).

3 The behavior of a program is undefined if:

(3.1) it destroys a shared_mutex object owned by any thread,
(3.2) a thread attempts to recursively gain any ownership of a shared_mutex, or
(3.3) a thread terminates while possessing any ownership of a shared_mutex.

4 shared_mutex may be a synonym for shared_timed_mutex.

33.4.3.5 Shared timed mutex types

The standard library type shared_timed_mutex is a shared timed mutex type. Shared timed mutex types shall meet the requirements of timed mutex types (33.4.3.3), shared mutex types (33.4.3.4), and additionally shall meet the requirements set out below. In this description, m denotes an object of a shared timed mutex type, rel_type denotes an object of an instantiation of duration (23.17.5), and abs_time denotes an object
The expression `m.try_lock_shared_for(rel_time)` shall be well-formed and have the following semantics:

- **Requires:** The calling thread has no ownership of the mutex.

- **Effects:** Attempts to obtain shared lock ownership for the calling thread within the relative timeout (33.2.4) specified by `rel_time`. If the time specified by `rel_time` is less than or equal to `rel_time.zero()`, the function attempts to obtain ownership without blocking (as if by calling `try_lock_shared()`). The function shall return within the timeout specified by `rel_time` only if it has obtained shared ownership of the mutex object. [Note: As with `try_lock()`, there is no guarantee that ownership will be obtained if the lock is available, but implementations are expected to make a strong effort to do so. — end note] If an exception is thrown then a shared lock shall not have been acquired for the current thread.

- **Return type:** `bool`.

- **Returns:** `true` if the shared lock was acquired, `false` otherwise.

- **Synchronization:** If `try_lock_shared_for()` returns `true`, prior `unlock()` operations on the same object synchronize with (4.7) this operation.

- **Throes:** Timeout-related exceptions (33.2.4).

The expression `m.try_lock_shared_until(abs_time)` shall be well-formed and have the following semantics:

- **Requires:** The calling thread has no ownership of the mutex.

- **Effects:** The function attempts to obtain shared ownership of the mutex. If `abs_time` has already passed, the function attempts to obtain shared ownership without blocking (as if by calling `try_lock_shared()`). The function shall return before the absolute timeout (33.2.4) specified by `abs_time` only if it has obtained shared ownership of the mutex object. [Note: As with `try_lock()`, there is no guarantee that ownership will be obtained if the lock is available, but implementations are expected to make a strong effort to do so. — end note] If an exception is thrown then a shared lock shall not have been acquired for the current thread.

- **Return type:** `bool`.

- **Returns:** `true` if the shared lock was acquired, `false` otherwise.

- **Synchronization:** If `try_lock_shared_until()` returns `true`, prior `unlock()` operations on the same object synchronize with (4.7) this operation.

- **Throes:** Timeout-related exceptions (33.2.4).

### 33.4.3.5.1 Class shared_timed_mutex

```cpp
namespace std {
    class shared_timed_mutex {
public:
        shared_timed_mutex();
        ~shared_timed_mutex();

        shared_timed_mutex(const shared_timed_mutex&) = delete;
        shared_timed_mutex& operator=(const shared_timed_mutex&) = delete;

        // Exclusive ownership
        void lock();    // blocking
        bool try_lock();

template <class Rep, class Period>
    bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);

template <class Clock, class Duration>
```
bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);
void unlock();

// Shared ownership
void lock_shared(); // blocking
bool try_lock_shared();
template <class Rep, class Period>
bool try_lock_shared_for(const chrono::duration<Rep, Period>& rel_time);

template <class Clock, class Duration>
bool try_lock_shared_until(const chrono::time_point<Clock, Duration>& abs_time);
void unlock_shared();
};

1 The class shared_timed_mutex provides a non-recursive mutex with shared ownership semantics.

2 The class shared_timed_mutex shall satisfy all of the shared timed mutex requirements (33.4.3.5). It shall be a standard-layout class (Clause 12).

3 The behavior of a program is undefined if:
   (3.1) — it destroys a shared_timed_mutex object owned by any thread,
   (3.2) — a thread attempts to recursively gain any ownership of a shared_timed_mutex, or
   (3.3) — a thread terminates while possessing any ownership of a shared_timed_mutex.

33.4.4 Locks [thread.lock]

A lock is an object that holds a reference to a lockable object and may unlock the lockable object during the lock’s destruction (such as when leaving block scope). An execution agent may use a lock to aid in managing ownership of a lockable object in an exception safe manner. A lock is said to own a lockable object if it is currently managing the ownership of that lockable object for an execution agent. A lock does not manage the lifetime of the lockable object it references. [Note: Locks are intended to ease the burden of unlocking the lockable object under both normal and exceptional circumstances. — end note]

Some lock constructors take tag types which describe what should be done with the lockable object during the lock’s construction.

namespace std {
    struct defer_lock_t {};
    // do not acquire ownership of the mutex
    struct try_to_lock_t {};
    // try to acquire ownership of the mutex
    // without blocking
    struct adopt_lock_t {};
    // assume the calling thread has already
    // obtained mutex ownership and manage it

    inline constexpr defer_lock_t defer_lock {};
    inline constexpr try_to_lock_t try_to_lock {};
    inline constexpr adopt_lock_t adopt_lock {};
}

33.4.4.1 Class template lock_guard [thread.lock.guard]

namespace std {
    template <class Mutex>
    class lock_guard {
        public:
            using mutex_type = Mutex;

            § 33.4.4.1 1376
explicit lock_guard(mutex_type& m);
lock_guard(mutex_type& m, adopt_lock_t);
~lock_guard();

lock_guard(const lock_guard&) = delete;
lock_guard& operator=(const lock_guard&) = delete;

private:
    mutex_type& pm; // exposition only
};

template<class Mutex> lock_guard(lock_guard<Mutex>) -> lock_guard<Mutex>;

1 An object of type lock_guard controls the ownership of a lockable object within a scope. A lock_guard object maintains ownership of a lockable object throughout the lock_guard object’s lifetime (6.8). The behavior of a program is undefined if the lockable object referenced by pm does not exist for the entire lifetime of the lock_guard object. The supplied Mutex type shall meet the BasicLockable requirements (33.2.5.2).

explicit lock_guard(mutex_type& m);

2 Requires: If mutex_type is not a recursive mutex, the calling thread does not own the mutex m.
3 Effects: As if by m.lock().
4 Postconditions: &pm == &m

lock_guard(mutex_type& m, adopt_lock_t);

5 Requires: The calling thread owns the mutex m.
6 Postconditions: &pm == &m
7 Throws: Nothing.
8 Effects: As if by pm.unlock().

33.4.4.2 Class template scoped_lock [thread.lock.scoped]

namespace std {
    template <class... MutexTypes>
    class scoped_lock {
    public:
        using mutex_type = Mutex; // If MutexTypes... consists of the single type Mutex

        explicit scoped_lock(MutexTypes&... m);
        explicit scoped_lock(MutexTypes&... m, adopt_lock_t);
        ~scoped_lock();

        scoped_lock(const scoped_lock&) = delete;
        scoped_lock& operator=(const scoped_lock&) = delete;

    private:
        tuple<MutexTypes&...> pm; // exposition only
    };

template<class... MutexTypes>
An object of type `scoped_lock` controls the ownership of lockable objects within a scope. A `scoped_lock` object maintains ownership of lockable objects throughout the `scoped_lock` object’s lifetime (6.8). The behavior of a program is undefined if the lockable objects referenced by `pm` do not exist for the entire lifetime of the `scoped_lock` object. When `sizeof...(MutexTypes)` is 1, the supplied `Mutex` type shall meet the `BasicLockable` requirements (33.2.5.2). Otherwise, each of the mutex types shall meet the `Lockable` requirements (33.2.5.3).

```cpp
explicit scoped_lock(MutexTypes&... m);
```

**Requires:** If a `MutexTypes` type is not a recursive mutex, the calling thread does not own the corresponding mutex element of `m`.

**Effects:** Initializes `pm` with `tie(m...)`. Then if `sizeof...(MutexTypes)` is 0, no effects. Otherwise if `sizeof...(MutexTypes)` is 1, then `m.lock()`. Otherwise, `lock(m...)`.

```cpp
explicit scoped_lock(MutexTypes&... m, adopt_lock_t);
```

**Requires:** The calling thread owns all the mutexes in `m`.

**Effects:** Initializes `pm` with `tie(m...)`.

**Throws:** Nothing.

```cpp
~scoped_lock();
```

**Effects:** For all `i` in `[0, sizeof...(MutexTypes))`, `get<i>(pm).unlock()`.

### 33.4.4.3 Class template `unique_lock` [thread.lock.unique]

```cpp
namespace std {
    template <class Mutex>
    class unique_lock {
        public:
            using mutex_type = Mutex;

            // 33.4.4.3.1, construct/copy/destroy
            unique_lock() noexcept;
            explicit unique_lock(mutex_type& m);
            unique_lock(mutex_type& m, defer_lock_t) noexcept;
            unique_lock(mutex_type& m, try_to_lock_t);
            unique_lock(mutex_type& m, adopt_lock_t);
            template <class Clock, class Duration>
            unique_lock(mutex_type& m, const chrono::time_point<Clock, Duration>& abs_time);
            template <class Rep, class Period>
            unique_lock(mutex_type& m, const chrono::duration<Rep, Period>& rel_time);
            ~unique_lock();

            unique_lock(const unique_lock&) = delete;
            unique_lock& operator=(const unique_lock&); = delete;

            unique_lock(unique_lock&& u) noexcept;
            unique_lock& operator=(unique_lock&& u);

            // 33.4.4.3.2, locking
            void lock();
            bool try_lock();
}
```
template <class Rep, class Period>
bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);

template <class Clock, class Duration>
bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);

void unlock();

// 33.4.4.3.3, modifiers
void swap(unique_lock&amp; u) noexcept;
mutex_type* release() noexcept;

// 33.4.4.3.4, observers
bool owns_lock() const noexcept;
explicit operator bool () const noexcept;
mutex_type* mutex() const noexcept;

private:
mutex_type* pm; // exposition only
bool owns; // exposition only
};

template<class Mutex> unique_lock(unique_lock<Mutex>) -> unique_lock<Mutex>;

template <class Mutex>
void swap(unique_lock<Mutex>& x, unique_lock<Mutex>& y) noexcept;

1 An object of type unique_lock controls the ownership of a lockable object within a scope. Ownership of
the lockable object may be acquired at construction or after construction, and may be transferred, after
acquisition, to another unique_lock object. Objects of type unique_lock are not copyable but are movable.
The behavior of a program is undefined if the contained pointer pm is not null and the lockable object pointed
to by pm does not exist for the entire remaining lifetime (6.8) of the unique_lock object. The supplied Mutex
type shall meet the BasicLockable requirements (33.2.5.2).

[Note: unique_lock<Mutex> meets the BasicLockable requirements. If Mutex meets the Lockable
requirements (33.2.5.3), unique_lock<Mutex> also meets the Lockable requirements; if Mutex meets the
TimedLockable requirements (33.2.5.4), unique_lock<Mutex> also meets the TimedLockable requirements.
—end note]

33.4.4.3.1 unique_lock constructors, destructor, and assignment  [thread.lock.unique.cons]
unique_lock() noexcept;

Effects: Constructs an object of type unique_lock.

Postconditions: pm == 0 and owns == false.

explicit unique_lock(mutex_type&amp; m);

Requires: If mutex_type is not a recursive mutex the calling thread does not own the mutex.

Effects: Constructs an object of type unique_lock and calls m.lock().

Postconditions: pm == addressof(m) and owns == true.

unique_lock(mutex_type&amp; m, defer_lock_t) noexcept;

Effects: Constructs an object of type unique_lock.

Postconditions: pm == addressof(m) and owns == false.
unique_lock(mutex_type& m, try_to_lock_t);

Requires: The supplied Mutex type shall meet the Lockable requirements (33.2.5.3). If mutex_type is not a recursive mutex the calling thread does not own the mutex.

Effects: Constructs an object of type unique_lock and calls m.try_lock().

Postconditions: pm == addressof(m) and owns == res, where res is the value returned by the call to m.try_lock().

unique_lock(mutex_type& m, adopt_lock_t);

Requires: The calling thread owns the mutex.

Effects: Constructs an object of type unique_lock.

Postconditions: pm == addressof(m) and owns == true.

Throws: Nothing.

template <class Clock, class Duration>
unique_lock(mutex_type& m, const chrono::time_point<Clock, Duration>& abs_time);

Requires: If mutex_type is not a recursive mutex the calling thread does not own the mutex. The supplied Mutex type shall meet the TimedLockable requirements (33.2.5.4).

Effects: Constructs an object of type unique_lock and calls m.try_lock_until(abs_time).

Postconditions: pm == addressof(m) and owns == res, where res is the value returned by the call to m.try_lock_until(abs_time).

template <class Rep, class Period>
unique_lock(mutex_type& m, const chrono::duration<Rep, Period>& rel_time);

Requires: If mutex_type is not a recursive mutex the calling thread does not own the mutex. The supplied Mutex type shall meet the TimedLockable requirements (33.2.5.4).

Effects: Constructs an object of type unique_lock and calls m.try_lock_for(rel_time).

Postconditions: pm == addressof(m) and owns == res, where res is the value returned by the call to m.try_lock_for(rel_time).

unique_lock(unique_lock&& u) noexcept;

Postconditions: pm == u_p.pm and owns == u_p.owns (where u_p is the state of u just prior to this construction), u.pm == 0 and u.owns == false.

unique_lock& operator=(unique_lock&& u);

Effects: If owns calls pm->unlock().

Postconditions: pm == u_p.pm and owns == u_p.owns (where u_p is the state of u just prior to this construction), u.pm == 0 and u.owns == false.

[Note: With a recursive mutex it is possible for both *this and u to own the same mutex before the assignment. In this case, *this will own the mutex after the assignment and u will not. — end note]

Throws: Nothing.

unique_lock();

Effects: If owns calls pm->unlock().

33.4.4.3.2 unique_lock locking

void lock();
Effects: As if by pm->lock().

Postconditions: owns == true.

Throws: Any exception thrown by pm->lock(). system_error when an exception is required (33.2.2).

Error conditions:

— operation_not_permitted — if pm is nullptr.
— resource_deadlock_would_occur — if on entry owns is true.

bool try_lock();

Requires: The supplied Mutex shall meet the Lockable requirements (33.2.5.3).

Effects: As if by pm->try_lock().

Returns: The value returned by the call to try_lock().

Postconditions: owns == res, where res is the value returned by the call to try_lock().

Throws: Any exception thrown by pm->try_lock(). system_error when an exception is required (33.2.2).

Error conditions:

— operation_not_permitted — if pm is nullptr.
— resource_deadlock_would_occur — if on entry owns is true.

template <class Clock, class Duration>
bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);

Requires: The supplied Mutex type shall meet the TimedLockable requirements (33.2.5.4).

Effects: As if by pm->try_lock_until(abs_time).

Returns: The value returned by the call to try_lock_until(abs_time).

Postconditions: owns == res, where res is the value returned by the call to try_lock_until(abs_time).

Throws: Any exception thrown by pm->try_lock_until(). system_error when an exception is required (33.2.2).

Error conditions:

— operation_not_permitted — if pm is nullptr.
— resource_deadlock_would_occur — if on entry owns is true.

template <class Rep, class Period>
bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);

Requires: The supplied Mutex type shall meet the TimedLockable requirements (33.2.5.4).

Effects: As if by pm->try_lock_for(rel_time).

Returns: The value returned by the call to try_lock_until(rel_time).

Postconditions: owns == res, where res is the value returned by the call to try_lock_for(rel_time).

Throws: Any exception thrown by pm->try_lock_for(). system_error when an exception is required (33.2.2).

Error conditions:

— operation_not_permitted — if pm is nullptr.
— resource_deadlock_would_occur — if on entry owns is true.

```c++
void unlock();
```

**Effects:** As if by `pm->unlock()`.

**Postconditions:** `owns == false`.

**Throws:** `system_error` when an exception is required (33.2.2).

**Error conditions:**

— operation_not_permitted — if on entry owns is false.

### 33.4.4.3.3 unique_lock modifiers

```c++
void swap(unique_lock& u) noexcept;
```

**Effects:** Swaps the data members of `*this` and `u`.

```c++
mutex_type* release() noexcept;
```

**Returns:** The previous value of `pm`.

**Postconditions:** `pm == 0` and `owns == false`.

```c++
template <class Mutex>
void swap(unique_lock<Mutex>& x, unique_lock<Mutex>& y) noexcept;
```

**Effects:** As if by `x.swap(y)`.

### 33.4.4.3.4 unique_lock observers

```c++
bool owns_lock() const noexcept;
```

**Returns:** `owns`.

```c++
explicit operator bool() const noexcept;
```

**Returns:** `owns`.

```c++
mutex_type* mutex() const noexcept;
```

**Returns:** `pm`.

### 33.4.4.4 Class template shared_lock

```c++
namespace std {
    template <class Mutex>
    class shared_lock {
        public:
            using mutex_type = Mutex;

            // 33.4.4.4.1, construct/copy/destroy
            shared_lock() noexcept;
            explicit shared_lock(mutex_type& m);    // blocking
            shared_lock(mutex_type& m, defer_lock_t) noexcept;
            shared_lock(mutex_type& m, try_to_lock_t);
            shared_lock(mutex_type& m, adopt_lock_t);
            template <class Clock, class Duration>
                shared_lock(mutex_type& m,
                                const chrono::time_point<Clock, Duration>& abs_time);
            template <class Rep, class Period>
                shared_lock(mutex_type& m,
```

§ 33.4.4.4

1382
An object of type `shared_lock` controls the shared ownership of a lockable object within a scope. Shared ownership of the lockable object may be acquired at construction or after construction, and may be transferred, after acquisition, to another `shared_lock` object. Objects of type `shared_lock` are not copyable but are movable. The behavior of a program is undefined if the contained pointer `pm` is not null and the lockable object pointed to by `pm` does not exist for the entire remaining lifetime (6.8) of the `shared_lock` object. The supplied `Mutex` type shall meet the shared mutex requirements (33.4.3.5).

[Note: `shared_lock<Mutex>` meets the TimedLockable requirements (33.2.5.4). — end note]

33.4.4.4.1  `shared_lock` constructors, destructor, and assignment  [thread.lock.shared.cons]

`shared_lock()` noexcept;

Effects: Constructs an object of type `shared_lock`.

Postconditions: `pm == nullptr` and `owns == false`.

`explicit shared_lock(mutex_type& m)`;

Requires: The calling thread does not own the mutex for any ownership mode.
Effects: Constructs an object of type `shared_lock` and calls `m.lock_shared()`.
Postconditions: `pm == addressof(m)` and `owns == true`.

`shared_lock(mutex_type& m, defer_lock_t)` noexcept;

Effects: Constructs an object of type `shared_lock`.
Postconditions: `pm == addressof(m)` and `owns == false`.

`shared_lock(mutex_type& m, try_to_lock_t);`

Requires: The calling thread does not own the mutex for any ownership mode.
Effects: Constructs an object of type `shared_lock` and calls `m.try_lock_shared()`.
Postconditions: `pm == addressof(m)` and `owns == res` where `res` is the value returned by the call to `m.try_lock_shared()`.

`shared_lock(mutex_type& m, adopt_lock_t);`

Requires: The calling thread has shared ownership of the mutex.
Effects: Constructs an object of type `shared_lock`.
Postconditions: `pm == addressof(m)` and `owns == true`.

`template <class Clock, class Duration>
shared_lock(mutex_type& m,
            const chrono::time_point<Clock, Duration>& abs_time);`

Requires: The calling thread does not own the mutex for any ownership mode.
Effects: Constructs an object of type `shared_lock` and calls `m.try_lock_shared_until(abs_time)`.
Postconditions: `pm == addressof(m)` and `owns == res` where `res` is the value returned by the call to `m.try_lock_shared_until(abs_time)`.

`template <class Rep, class Period>
shared_lock(mutex_type& m,
            const chrono::duration<Rep, Period>& rel_time);`

Requires: The calling thread does not own the mutex for any ownership mode.
Effects: Constructs an object of type `shared_lock` and calls `m.try_lock_shared_for(rel_time)`.
Postconditions: `pm == addressof(m)` and `owns == res` where `res` is the value returned by the call to `m.try_lock_shared_for(rel_time)`.

~`shared_lock();`

Effects: If `owns` calls `pm->unlock_shared()`.

`shared_lock(shared_lock&& sl) noexcept;`

Postconditions: `pm == sl_p.pm` and `owns == sl_p.owns` (where `sl_p` is the state of `sl` just prior to this construction), `sl.pm == nullptr` and `sl.owns == false`.

`shared_lock& operator=(shared_lock&& sl) noexcept;`

Effects: If `owns` calls `pm->unlock_shared()`.
Postconditions: `pm == sl_p.pm` and `owns == sl_p.owns` (where `sl_p` is the state of `sl` just prior to this assignment), `sl.pm == nullptr` and `sl.owns == false`.

33.4.4.4.2 `shared_lock locking`
void lock();

Effects: As if by pm->lock_shared().

Postconditions: owns == true.

Throws: Any exception thrown by pm->lock_shared(). system_error when an exception is required (33.2.2).

Error conditions:

§ 33.4.4.4.2

bool try_lock();

Effects: As if by pm->try_lock_shared().

Returns: The value returned by the call to pm->try_lock_shared().

Postconditions: owns == res, where res is the value returned by the call to pm->try_lock_shared().

Throws: Any exception thrown by pm->try_lock_shared(). system_error when an exception is required (33.2.2).

Error conditions:

template <class Clock, class Duration>
bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);

Effects: As if by pm->try_lock_shared_until(abs_time).

Returns: The value returned by the call to pm->try_lock_shared_until(abs_time).

Postconditions: owns == res, where res is the value returned by the call to pm->try_lock_shared_until(abs_time).

Throws: Any exception thrown by pm->try_lock_shared_until(abs_time). system_error when an exception is required (33.2.2).

Error conditions:

template <class Rep, class Period>
bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);

Effects: As if by pm->try_lock_shared_for(rel_time).

Returns: The value returned by the call to pm->try_lock_shared_for(rel_time).

Postconditions: owns == res, where res is the value returned by the call to pm->try_lock_shared_for(rel_time).

Throws: Any exception thrown by pm->try_lock_shared_for(rel_time). system_error when an exception is required (33.2.2).

Error conditions:
resource_deadlock_would_occur — if on entry owns is true.

```c
void unlock();
```

**Effects:** As if by pm->unlock_shared().

**Postconditions:** owns == false.

**Throws:** system_error when an exception is required (33.2.2).

**Error conditions:**

— operation_not_permitted — if on entry owns is false.

33.4.4.4.3 shared_lock modifiers

```c
void swap(shared_lock& sl) noexcept;
```

**Effects:** Swaps the data members of *this and sl.

```c
mutex_type* release() noexcept;
```

**Returns:** The previous value of pm.

**Postconditions:** pm == nullptr and owns == false.

```c
template <class Mutex>
    void swap(shared_lock<Mutex>& x, shared_lock<Mutex>& y) noexcept;
```

**Effects:** As if by x.swap(y).

33.4.4.4.4 shared_lock observers

```c
bool owns_lock() const noexcept;
```

**Returns:** owns.

```c
explicit operator bool() const noexcept;
```

**Returns:** owns.

```c
mutex_type* mutex() const noexcept;
```

**Returns:** pm.

33.4.5 Generic locking algorithms

```c
template <class L1, class L2, class... L3> int try_lock(L1&, L2&, L3&...);
```

**Requires:** Each template parameter type shall meet the Lockable requirements. [Note: The unique_lock class template meets these requirements when suitably instantiated. — end note]

**Effects:** Calls try_lock() for each argument in order beginning with the first until all arguments have been processed or a call to try_lock() fails, either by returning false or by throwing an exception. If a call to try_lock() fails, unlock() shall be called for all prior arguments and there shall be no further calls to try_lock().

**Returns:** -1 if all calls to try_lock() returned true, otherwise a zero-based index value that indicates the argument for which try_lock() returned false.

```c
template <class L1, class L2, class... L3> void lock(L1&, L2&, L3&...);
```

**Requires:** Each template parameter type shall meet the Lockable requirements. [Note: The unique_lock class template meets these requirements when suitably instantiated. — end note]

§ 33.4.5
Effects: All arguments are locked via a sequence of calls to lock(), try_lock(), or unlock() on each argument. The sequence of calls shall not result in deadlock, but is otherwise unspecified. [Note: A deadlock avoidance algorithm such as try-and-back-off must be used, but the specific algorithm is not specified to avoid over-constraining implementations. —end note] If a call to lock() or try_lock() throws an exception, unlock() shall be called for any argument that had been locked by a call to lock() or try_lock().

33.4.6 Call once

33.4.6.1 Struct once_flag

namespace std {
    struct once_flag {
        constexpr once_flag() noexcept;
        once_flag(const once_flag&) = delete;
        once_flag& operator=(const once_flag&) = delete;
    };
}

The class once_flag is an opaque data structure that call_once uses to initialize data without causing a data race or deadlock.

call_once

Effects: Constructs an object of type once_flag.
Synchronization: The construction of a once_flag object is not synchronized.
Postconditions: The object’s internal state is set to indicate to an invocation of call_once with the object as its initial argument that no function has been called.

33.4.6.2 Function call_once

template<class Callable, class... Args>
void call_once(once_flag& flag, Callable& func, Args&... args);

Requires:

INVOKE(std::forward<Callable>(func), std::forward<Args>(args)...) (see 23.14.3) shall be a valid expression.

Effects: An execution of call_once that does not call its func is a passive execution. An execution of call_once that calls its func is an active execution. An active execution shall call INVOKE( std::forward<Callable>(func), std::forward<Args>(args)...) If such a call to func throws an exception the execution is exceptional, otherwise it is returning. An exceptional execution shall propagate the exception to the caller of call_once. Among all executions of call_once for any given once_flag: at most one shall be a returning execution; if there is a returning execution, it shall be the last active execution; and there are passive executions only if there is a returning execution. [Note: Passive executions allow other threads to reliably observe the results produced by the earlier returning execution. —end note]

Synchronization: For any given once_flag: all active executions occur in a total order; completion of an active execution synchronizes with (4.7) the start of the next one in this total order; and the returning execution synchronizes with the return from all passive executions.

Throws: system_error when an exception is required (33.2.2), or any exception thrown by func.

Example:

// global flag, regular function

§ 33.4.6.2
void init();
std::once_flag flag;

void f() {
    std::call_once(flag, init);
}

// function static flag, function object
struct initializer {
    void operator()();
};

void g() {
    static std::once_flag flag2;
    std::call_once(flag2, initializer());
}

// object flag, member function
class information {
    std::once_flag verified;
    void verifier();
public:
    void verify() { std::call_once(verified, &information::verifier, *this); }
};

— end example

33.5 Condition variables [thread.condition]

Condition variables provide synchronization primitives used to block a thread until notified by some other
thread that some condition is met or until a system time is reached. Class \texttt{condition\_variable} provides a
condition variable that can only wait on an object of type \texttt{unique\_lock<mutex>}, allowing maximum efficiency
on some platforms. Class \texttt{condition\_variable\_any} provides a general condition variable that can wait on
objects of user-supplied lock types.

Condition variables permit concurrent invocation of the \texttt{wait, wait\_for, wait\_until, notify\_one and
notify\_all} member functions.

The execution of \texttt{notify\_one} and \texttt{notify\_all} shall be atomic. The execution of \texttt{wait, wait\_for, and
wait\_until} shall be performed in three atomic parts:
1. the release of the mutex and entry into the waiting state;
2. the unblocking of the wait; and
3. the reacquisition of the lock.

The implementation shall behave as if all executions of \texttt{notify\_one, notify\_all, and each part of the wait,
wait\_for, and wait\_until} executions are executed in a single unspecified total order consistent with the
'happens before' order.

Condition variable construction and destruction need not be synchronized.

33.5.1 Header \texttt{<condition\_variable>} synopsis [condition\_variable.syn]

namespace std {
    class condition\_variable;
    class condition\_variable\_any;

    void notify\_all\_at\_thread\_exit(condition\_variable& cond, unique\_lock<mutex> lk);

§ 33.5.1
enum class cv_status { no_timeout, timeout };

33.5.2 Non-member functions

void notify_all_at_thread_exit(condition_variable& cond, unique_lock<mutex> lk);

1 Requires: lk is locked by the calling thread and either

(1.1) — no other thread is waiting on cond, or

(1.2) — lk.mutex() returns the same value for each of the lock arguments supplied by all concurrently

waiting (via wait, wait_for, or wait_until) threads.

2 Effects: Transfers ownership of the lock associated with lk into internal storage and schedules cond to

be notified when the current thread exits, after all objects of thread storage duration associated with

the current thread have been destroyed. This notification shall be as if:

lk.unlock();
cond.notify_all();

Synchronization: The implied lk.unlock() call is sequenced after the destruction of all objects with

thread storage duration associated with the current thread.

4 [Note: The supplied lock will be held until the thread exits, and care must be taken to ensure that

does not cause deadlock due to lock ordering issues. After calling notify_all_at_thread_exit

it is recommended that the thread should be exited as soon as possible, and that no blocking or

time-consuming tasks are run on that thread. — end note]

5 [Note: It is the user’s responsibility to ensure that waiting threads do not erroneously assume that the

thread has finished if they experience spurious wakeups. This typically requires that the condition being

waited for is satisfied while holding the lock on lk, and that this lock is not released and reacquired

prior to calling notify_all_at_thread_exit. — end note]

33.5.3 Class condition_variable

namespace std {
    class condition_variable {
    public:

        condition_variable();
        ~condition_variable();

        condition_variable(const condition_variable&) = delete;
        condition_variable& operator=(const condition_variable&) = delete;

        void notify_one() noexcept;
        void notify_all() noexcept;
        void wait(unique_lock<mutex>& lock);
        template <class Predicate>
            void wait(unique_lock<mutex>& lock, Predicate pred);
        template <class Clock, class Duration>
            cv_status wait_until(unique_lock<mutex>& lock,
                const chrono::time_point<Clock, Duration>& abs_time);
        template <class Clock, class Duration, class Predicate>
            bool wait_until(unique_lock<mutex>& lock,
                const chrono::time_point<Clock, Duration>& abs_time,
                Predicate pred);
}

§ 33.5.3 1389
template <class Rep, class Period>
  cv_status wait_for(unique_lock<mutex>& lock,
                      const chrono::duration<Rep, Period>& rel_time);

template <class Rep, class Period, class Predicate>
  bool wait_for(unique_lock<mutex>& lock,
                const chrono::duration<Rep, Period>& rel_time,
                Predicate pred);

using native_handle_type = implementation-defined; // See 33.2.3
native_handle_type native_handle(); // See 33.2.3
};

The class condition_variable shall be a standard-layout class (Clause 12).

condition_variable();

Effects: Constructs an object of type condition_variable.

Throws: system_error when an exception is required (33.2.2).

Error conditions:
(4.1) resource_unavailable_try_again — if some non-memory resource limitation prevents initialization.

~condition_variable();

Requires: There shall be no thread blocked on *this. [Note: That is, all threads shall have been notified; they may subsequently block on the lock specified in the wait. This relaxes the usual rules, which would have required all wait calls to happen before destruction. Only the notification to unblock the wait must happen before destruction. The user must take care to ensure that no threads wait on *this once the destructor has been started, especially when the waiting threads are calling the wait functions in a loop or using the overloads of wait, wait_for, or wait_until that take a predicate. —end note]

Effects: Destroys the object.

void notify_one() noexcept;

Effects: If any threads are blocked waiting for *this, unblocks one of those threads.

void notify_all() noexcept;

Effects: Unblocks all threads that are blocked waiting for *this.

void wait(unique_lock<mutex>& lock);

Requires: lock.owns_lock() is true and lock.mutex() is locked by the calling thread, and either
(9.1) no other thread is waiting on this condition_variable object or
(9.2) lock.mutex() returns the same value for each of the lock arguments supplied by all concurrently waiting (via wait, wait_for, or wait_until) threads.

Effects:
(10.1) Atomically calls lock.unlock() and blocks on *this.
(10.2) When unblocked, calls lock.lock() (possibly blocking on the lock), then returns.
(10.3) The function will unblock when signaled by a call to notify_one() or a call to notify_all(), or spuriously.
Remarks: If the function fails to meet the postcondition, \texttt{terminate()} shall be called (18.5.1). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

Postconditions: \texttt{lock.owns_lock()} is true and \texttt{lock.mutex()} is locked by the calling thread.

Throws: Nothing.

template <class Predicate>
void wait(unique_lock<mutex>& lock, Predicate pred);

Requires: \texttt{lock.owns_lock()} is true and \texttt{lock.mutex()} is locked by the calling thread, and either

(14.1) no other thread is waiting on this \texttt{conditionvariable} object or
(14.2) \texttt{lock.mutex()} returns the same value for each of the \texttt{lock} arguments supplied by all concurrently waiting (via \texttt{wait}, \texttt{wait_for}, or \texttt{wait_until}) threads.

Effects: Equivalent to:
\begin{verbatim}
while (!\texttt{pred()})
  \texttt{wait(lock)};
\end{verbatim}

Remarks: If the function fails to meet the postcondition, \texttt{terminate()} shall be called (18.5.1). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

Postconditions: \texttt{lock.owns_lock()} is true and \texttt{lock.mutex()} is locked by the calling thread.

Throws: Any exception thrown by \texttt{pred}.

template <class Clock, class Duration>
cv_status wait_until(unique_lock<mutex>& lock,
  const chrono::time_point<Clock, Duration>& abs_time);

Requires: \texttt{lock.owns_lock()} is true and \texttt{lock.mutex()} is locked by the calling thread, and either

(19.1) no other thread is waiting on this \texttt{conditionvariable} object or
(19.2) \texttt{lock.mutex()} returns the same value for each of the \texttt{lock} arguments supplied by all concurrently waiting (via \texttt{wait}, \texttt{wait_for}, or \texttt{wait_until}) threads.

Effects:

(20.1) Atomically calls \texttt{lock.unlock()} and blocks on \texttt{*this}.
(20.2) When unblocked, calls \texttt{lock.lock()} (possibly blocking on the lock), then returns.
(20.3) The function will unblock when signaled by a call to \texttt{notify_one()}, a call to \texttt{notify_all()}, expiration of the absolute timeout (33.2.4) specified by \texttt{abs_time}, or spuriously.
(20.4) If the function exits via an exception, \texttt{lock.lock()} shall be called prior to exiting the function.

Remarks: If the function fails to meet the postcondition, \texttt{terminate()} shall be called (18.5.1). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

Postconditions: \texttt{lock.owns_lock()} is true and \texttt{lock.mutex()} is locked by the calling thread.

Returns: \texttt{cv_status::timeout} if the absolute timeout (33.2.4) specified by \texttt{abs_time} expired, otherwise \texttt{cv_status::no_timeout}.

Throws: Timeout-related exceptions (33.2.4).

template <class Rep, class Period>
cv_status wait_for(unique_lock<mutex>& lock,
  const chrono::duration<Rep, Period>& rel_time);

Requires: \texttt{lock.owns_lock()} is true and \texttt{lock.mutex()} is locked by the calling thread, and either

(25.1) no other thread is waiting on this \texttt{conditionvariable} object or
— lock.mutex() returns the same value for each of the lock arguments supplied by all concurrently waiting (via wait, wait_for, or wait_until) threads.

26  Effects: Equivalent to:
   
   return wait_until(lock, chrono::steady_clock::now() + rel_time);

27  Returns: cv_status::timeout if the relative timeout (33.2.4) specified by rel_time expired, otherwise cv_status::no_timeout.

28  Remarks: If the function fails to meet the postcondition, terminate() shall be called (18.5.1). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

29  Postconditions: lock.owns_lock() is true and lock.mutex() is locked by the calling thread.

30  Throws: Timeout-related exceptions (33.2.4).

31  template <class Clock, class Duration, class Predicate>
   bool wait_until(unique_lock<mutex>& lock,
                  const chrono::time_point<Clock, Duration>& abs_time,
                  Predicate pred);

32  Requires: lock.owns_lock() is true and lock.mutex() is locked by the calling thread, and either
   — no other thread is waiting on this condition_variable object or
   — lock.mutex() returns the same value for each of the lock arguments supplied by all concurrently waiting (via wait, wait_for, or wait_until) threads.

33  Effects: Equivalent to:
   
   while (!pred())
      if (wait_until(lock, abs_time) == cv_status::timeout)
         return pred();
   return true;

34  Remarks: If the function fails to meet the postcondition, terminate() shall be called (18.5.1). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

35  [Note: The returned value indicates whether the predicate evaluated to true regardless of whether the timeout was triggered. — end note]

36  Throws: Timeout-related exceptions (33.2.4) or any exception thrown by pred.

37  template <class Rep, class Period, class Predicate>
   bool wait_for(unique_lock<mutex>& lock,
                 const chrono::duration<Rep, Period>& rel_time,
                 Predicate pred);

38  Requires: lock.owns_lock() is true and lock.mutex() is locked by the calling thread, and either
   — no other thread is waiting on this condition_variable object or
   — lock.mutex() returns the same value for each of the lock arguments supplied by all concurrently waiting (via wait, wait_for, or wait_until) threads.

39  Effects: Equivalent to:
   
   return wait_until(lock, chrono::steady_clock::now() + rel_time, std::move(pred));

40  [Note: There is no blocking if pred() is initially true, even if the timeout has already expired. — end note]

41  Remarks: If the function fails to meet the postcondition, terminate() shall be called (18.5.1). [Note:
This can happen if the re-locking of the mutex throws an exception. — end note]

Postconditions: lock.owns_lock() is true and lock.mutex() is locked by the calling thread.

[Note: The returned value indicates whether the predicate evaluates to true regardless of whether the
timeout was triggered. — end note]

Throws: Timeout-related exceptions (33.2.4) or any exception thrown by pred.

33.5.4 Class condition_variable_any

A Lock type shall meet the BasicLockable requirements (33.2.5.2). [ Note: All of the standard mutex types
meet this requirement. If a Lock type other than one of the standard mutex types or a unique_lock wrapper
for a standard mutex type is used with condition_variable_any, the user must ensure that any necessary
synchronization is in place with respect to the predicate associated with the condition_variable_any
instance. — end note]

namespace std {
   class condition_variable_any {
      public:
         condition_variable_any();
         ~condition_variable_any();

         condition_variable_any(const condition_variable_any&) = delete;
         condition_variable_any& operator=(const condition_variable_any&) = delete;

         void notify_one() noexcept;
         void notify_all() noexcept;
         template <class Lock>
         void wait(Lock& lock);
         template <class Lock, class Predicate>
         void wait(Lock& lock, Predicate pred);

         template <class Lock, class Clock, class Duration>
         cv_status wait_until(Lock& lock, const chrono::time_point<Clock, Duration>& abs_time);
         template <class Lock, class Clock, class Duration, class Predicate>
         bool wait_until(Lock& lock, const chrono::time_point<Clock, Duration>& abs_time,
                         Predicate pred);
         template <class Lock, class Rep, class Period>
         cv_status wait_for(Lock& lock, const chrono::duration<Rep, Period>& rel_time);
         template <class Lock, class Rep, class Period, class Predicate>
         bool wait_for(Lock& lock, const chrono::duration<Rep, Period>& rel_time,
                       Predicate pred);
   };
}

condition_variable_any();

Effects: Constructs an object of type condition_variable_any.

Throws: bad_alloc or system_error when an exception is required (33.2.2).

Error conditions:

(4.1) — resource_unavailable_try_again — if some non-memory resource limitation prevents initial-
ization.

(4.2) — operation_not_permitted — if the thread does not have the privilege to perform the operation.

~condition_variable_any();
Requires: There shall be no thread blocked on *this.  

Note: That is, all threads shall have been notified; they may subsequently block on the lock specified in the wait. This relaxes the usual rules, which would have required all wait calls to happen before destruction. Only the notification to unblock the wait must happen before destruction. The user must take care to ensure that no threads wait on *this once the destructor has been started, especially when the waiting threads are calling the wait functions in a loop or using the overloads of wait, wait_for, or wait_until that take a predicate. 

—end note

Effects: Destroys the object.

void notify_one() noexcept;

Effects: If any threads are blocked waiting for *this, unblocks one of those threads.

void notify_all() noexcept;

Effects: Unblocks all threads that are blocked waiting for *this.

template <class Lock>
void wait(Lock& lock);

[Note: If any of the wait functions exits via an exception, it is unspecified whether the Lock is held. One can use a Lock type that allows to query that, such as the unique_lock wrapper. —end note]

Effects:

(10.1) Atomically calls lock.unlock() and blocks on *this.
(10.2) When unblocked, calls lock.lock() (possibly blocking on the lock) and returns.
(10.3) The function will unblock when signaled by a call to notify_one(), a call to notify_all(), or spuriously.

Remarks: If the function fails to meet the postcondition, terminate() shall be called (18.5.1).  

Note: This can happen if the re-locking of the mutex throws an exception.  

—end note

Postconditions: lock is locked by the calling thread.

Throws: Nothing.

template <class Lock, class Predicate>
void wait(Lock& lock, Predicate pred);

Effects: Equivalent to:

while (!pred())
    wait(lock);

template <class Lock, class Clock, class Duration>
cv_status wait_until(Lock& lock, const chrono::time_point<Clock, Duration>& abs_time);

Effects:

(15.1) Atomically calls lock.unlock() and blocks on *this.
(15.2) When unblocked, calls lock.lock() (possibly blocking on the lock) and returns.
(15.3) The function will unblock when signaled by a call to notify_one(), a call to notify_all(), expiration of the absolute timeout (33.2.4) specified by abs_time, or spuriously.
(15.4) If the function exits via an exception, lock.lock() shall be called prior to exiting the function.

Remarks: If the function fails to meet the postcondition, terminate() shall be called (18.5.1).  

Note: This can happen if the re-locking of the mutex throws an exception.  

—end note

Postconditions: lock is locked by the calling thread.
Returns: `cv_status::timeout` if the absolute timeout (33.2.4) specified by `abs_time` expired, otherwise `cv_status::no_timeout`.

Throws: Timeout-related exceptions (33.2.4).

```
template <class Lock, class Rep, class Period>
    cv_status wait_for(Lock& lock, const chrono::duration<Rep, Period>& rel_time);
Effects: Equivalent to:
    return wait_until(lock, chrono::steady_clock::now() + rel_time);
Returns: `cv_status::timeout` if the relative timeout (33.2.4) specified by `rel_time` expired, otherwise `cv_status::no_timeout`.
Remarks: If the function fails to meet the postcondition, `terminate()` shall be called (18.5.1). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]
Postconditions: `lock` is locked by the calling thread.
Throws: Timeout-related exceptions (33.2.4).
```

```
template <class Lock, class Clock, class Duration, class Predicate>
    bool wait_until(Lock& lock, const chrono::time_point<Clock, Duration>& abs_time, Predicate pred);
Effects: Equivalent to:
    while (!pred())
        if (wait_until(lock, abs_time) == cv_status::timeout)
            return pred();
    return true;
[Note: There is no blocking if `pred()` is initially `true`, or if the timeout has already expired. — end note]
[Note: The returned value indicates whether the predicate evaluates to `true` regardless of whether the timeout was triggered. — end note]
```

```
template <class Lock, class Rep, class Period, class Predicate>
    bool wait_for(Lock& lock, const chrono::duration<Rep, Period>& rel_time, Predicate pred);
Effects: Equivalent to:
    return wait_until(lock, chrono::steady_clock::now() + rel_time, std::move(pred));
```

### 33.6 Futures

#### 33.6.1 Overview

33.6 describes components that a C++ program can use to retrieve in one thread the result (value or exception) from a function that has run in the same thread or another thread. [Note: These components are not restricted to multi-threaded programs but can be useful in single-threaded programs as well. — end note]

#### 33.6.2 Header `<future>` synopsis

```
namespace std {
    enum class future_errc {
        broken_promise = implementation-defined,
        future_already_retrieved = implementation-defined,
        promise_already_satisfied = implementation-defined,
        no_state = implementation-defined
    };
    enum class launch : unspecified {
```

§ 33.6.2 1395
async = unspecified,
defered = unspecified,
implementation-defined
};

enum class future_status {
    ready,
timeout,
defered
};

template <> struct is_error_code_enum<future_errc> : public true_type { };
error_code make_error_code(future_errc e) noexcept;
error_condition make_error_condition(future_errc e) noexcept;

const error_category& future_category() noexcept;

class future_error;

template <class R> class promise;
template <class R> class promise<R&>;
template <> class promise<void>;

template <class R>
    void swap(promise<R>& x, promise<R>& y) noexcept;

template <class R, class Alloc>
    struct uses_allocator<promise<R>, Alloc>;

template <class R> class future;
template <class R> class future<R&>;
template <> class future<void>;

template <class R> class shared_future;
template <class R> class shared_future<R&>;
template <> class shared_future<void>;

template <class> class packaged_task; // not defined

template <class R, class... ArgTypes>
    class packaged_task<R(ArgTypes...)>;

template <class R, class... ArgTypes>
    void swap(packaged_task<R(ArgTypes...)>&, packaged_task<R(ArgTypes...)>&) noexcept;

template <class R, class Alloc>
    struct uses_allocator<packaged_task<R>, Alloc>;

template <class F, class... Args>
    future<invoke_result_t<decay_t<F>, decay_t<Args>...>>
    async(F&& f, Args&&... args);

template <class F, class... Args>
    future<invoke_result_t<decay_t<F>, decay_t<Args>...>>
    async(launch policy, F&& f, Args&&... args);

§ 33.6.2 1396
The enum type `launch` is a bitmask type (20.4.2.1.4) with elements `launch::async` and `launch::deferred`. [Note: Implementations can provide bitmasks to specify restrictions on task interaction by functions launched by `async()` applicable to a corresponding subset of available launch policies. Implementations can extend the behavior of the first overload of `async()` by adding their extensions to the launch policy under the “as if” rule. — end note]

The enum values of `future_errc` are distinct and not zero.

### 33.6.3 Error handling

```c++
const error_category& future_category() noexcept;
```

*Returns:* A reference to an object of a type derived from class `error_category`.

```c++
error_code make_error_code(future_errc e) noexcept;
```

*Returns:* `error_code(static_cast<int>(e), future_category())`.

### 33.6.4 Class future_error

```c++
namespace std {
    class future_error : public logic_error {
        public:
            explicit future_error(future_errc e);
            const error_code& code() const noexcept;
            const char* what() const noexcept;
        private:
            error_code ec_; // exposition only
    };
}
```

*Effects:* Constructs an object of class `future_error` and initializes `ec_` with `make_error_code(e)`.

```c++
const error_code& code() const noexcept;
```

*Returns:* `ec_`.

```c++
const char* what() const noexcept;
```

*Returns:* An NTBS incorporating `code().message()`.

### 33.6.5 Shared state

Many of the classes introduced in this subclause use some state to communicate results. This shared state consists of some state information and some (possibly not yet evaluated) result, which can be a (possibly void) value or an exception. [Note: Futures, promises, and tasks defined in this clause reference such shared state. — end note]

[Note: The result can be any kind of object including a function to compute that result, as used by `async` when policy is `launch::deferred`. — end note]
An asynchronous return object is an object that reads results from a shared state. A waiting function of an asynchronous return object is one that potentially blocks to wait for the shared state to be made ready. If a waiting function can return before the state is made ready because of a timeout (33.2.5), then it is a timed waiting function, otherwise it is a non-timed waiting function.

An asynchronous provider is an object that provides a result to a shared state. The result of a shared state is set by respective functions on the asynchronous provider. [Note: Such as promises or tasks. — end note] The means of setting the result of a shared state is specified in the description of those classes and functions that create such a state object.

When an asynchronous return object or an asynchronous provider is said to release its shared state, it means:

1. if the return object or provider holds the last reference to its shared state, the shared state is destroyed; and
2. the return object or provider gives up its reference to its shared state; and
3. these actions will not block for the shared state to become ready, except that it may block if all of the following are true: the shared state was created by a call to `std::async`, the shared state is not yet ready, and this was the last reference to the shared state.

When an asynchronous provider is said to make its shared state ready, it means:

1. first, the provider marks its shared state as ready; and
2. second, the provider unblocks any execution agents waiting for its shared state to become ready.

When an asynchronous provider is said to abandon its shared state, it means:

1. if that state is not ready, the provider
   1.1. stores an exception object of type `future_error` with an error condition of `broken.promise` within its shared state; and then
   1.2. makes its shared state ready;
2. second, the provider releases its shared state.

A shared state is ready only if it holds a value or an exception ready for retrieval. Waiting for a shared state to become ready may invoke code to compute the result on the waiting thread if so specified in the description of the class or function that creates the state object.

Calls to functions that successfully set the stored result of a shared state synchronize with (4.7) calls to functions successfully detecting the ready state resulting from that setting. The storage of the result (whether normal or exceptional) into the shared state synchronizes with (4.7) the successful return from a call to a waiting function on the shared state.

Some functions (e.g., `promise::set_value_at_thread_exit`) delay making the shared state ready until the calling thread exits. The destruction of each of that thread’s objects with thread storage duration (6.7.2) is sequenced before making that shared state ready.

Access to the result of the same shared state may conflict (4.7). [Note: This explicitly specifies that the result of the shared state is visible in the objects that reference this state in the sense of data race avoidance (20.5.5.9). For example, concurrent accesses through references returned by `shared_future::get()` (33.6.8) must either use read-only operations or provide additional synchronization. — end note]

33.6.6 Class template promise

```cpp
namespace std {
  template <class R>
  class promise {
  public:
    promise();
  }
}
```
template <class Allocator>
  promise(allocator_arg_t, const Allocator& a);
promise(promise&& rhs) noexcept;
promise(const promise& rhs) = delete;
~promise();

// assignment
promise& operator=(promise&& rhs) noexcept;
promise& operator=(const promise& rhs) = delete;
void swap(promise& other) noexcept;

// retrieving the result
future<R> get_future();

// setting the result
void set_value(see below);
void set_exception(exception_ptr p);

// setting the result with deferred notification
void set_value_at_thread_exit(see below);
void set_exception_at_thread_exit(exception_ptr p);
};

template <class R>
void swap(promise<R>& x, promise<R>& y) noexcept;
template <class R, class Alloc>
struct uses_allocator<promise<R>, Alloc> : true_type {);

1 The implementation shall provide the template promise and two specializations, promise<R&> and promise<void>. These differ only in the argument type of the member functions set_value and set_value_at_thread_exit, as set out in their descriptions, below.

2 The set_value, set_exception, set_value_at_thread_exit, and set_exception_at_thread_exit member functions behave as though they acquire a single mutex associated with the promise object while updating the promise object.

3 Requires: Alloc shall be an Allocator (20.5.3.5).

4 Effects: constructs a promise object and a shared state. The second constructor uses the allocator a to allocate memory for the shared state.

5 Effects: constructs a new promise object and transfers ownership of the shared state of rhs (if any) to the newly-constructed object.

6 Postconditions: rhs has no shared state.

7 Effects: Abandons any shared state (33.6.5).
promise& operator=(promise&& rhs) noexcept;

Effects: Abandons any shared state (33.6.5) and then as if promise(std::move(rhs)).swap(*this).
Returns: *this.

void swap(promise& other) noexcept;

Effects: Exchanges the shared state of *this and other.

Postconditions: *this has the shared state (if any) that other had prior to the call to swap. other has the shared state (if any) that *this had prior to the call to swap.

future<R> get_future();

Returns: A future<R> object with the same shared state as *this.

Throws: future_error if *this has no shared state or if get_future has already been called on a promise with the same shared state as *this.

Error conditions:
(14.1) — future_already_retrieved if get_future has already been called on a promise with the same shared state as *this.
(14.2) — no_state if *this has no shared state.

void promise::set_value(const R& r);
void promise::set_value(R&& r);
void promise<R&>::set_value(R& r);
void promise<void>::set_value();

Effects: Atomically stores the value r in the shared state and makes that state ready (33.6.5).

Throws:
(16.1) — future_error if its shared state already has a stored value or exception, or
(16.2) — for the first version, any exception thrown by the constructor selected to copy an object of R, or
(16.3) — for the second version, any exception thrown by the constructor selected to move an object of R.

Error conditions:
(17.1) — promise_already_satisfied if its shared state already has a stored value or exception.
(17.2) — no_state if *this has no shared state.

void set_exception(exception_ptr p);

Requires: p is not null.

Effects: Atomically stores the exception pointer p in the shared state and makes that state ready (33.6.5).

Throws: future_error if its shared state already has a stored value or exception.

Error conditions:
(21.1) — promise_already_satisfied if its shared state already has a stored value or exception.
(21.2) — no_state if *this has no shared state.

void promise::set_value_at_thread_exit(const R& r);
void promise::set_value_at_thread_exit(R&& r);
void promise<R&>::set_value_at_thread_exit(R& r);
void promise<void>::set_value_at_thread_exit();

Effects: Stores the value r in the shared state without making that state ready immediately. Schedules
that state to be made ready when the current thread exits, after all objects of thread storage duration
associated with the current thread have been destroyed.

### Throws:

1. `future_error` if its shared state already has a stored value or exception, or
2. for the first version, any exception thrown by the constructor selected to copy an object of `R`, or
3. for the second version, any exception thrown by the constructor selected to move an object of `R`.

### Error conditions:

1. `promise_already_satisfied` if its shared state already has a stored value or exception.
2. `no_state` if `*this` has no shared state.

```cpp
void set_exception_at_thread_exit(exception_ptr p);
```

#### Requires:

- `p` is not null.

#### Effects:

Stores the exception pointer `p` in the shared state without making that state ready immediately. Schedules that state to be made ready when the current thread exits, after all objects of thread storage duration associated with the current thread have been destroyed.

### Throws:

`future_error` if an error condition occurs.

### Error conditions:

1. `promise_already_satisfied` if its shared state already has a stored value or exception.
2. `no_state` if `*this` has no shared state.

```cpp
template <class R>
void swap(promise<R>& x, promise<R>& y) noexcept;
```

#### Effects:

As if by `x.swap(y)`.

#### 33.6.7 Class template future

The class template `future` defines a type for asynchronous return objects which do not share their shared state with other asynchronous return objects. A default-constructed `future` object has no shared state. A `future` object with shared state can be created by functions on asynchronous providers (33.6.5) or by the move constructor and shares its shared state with the original asynchronous provider. The result (value or exception) of a `future` object can be set by calling a respective function on an object that shares the same shared state.

1. [Note: Member functions of `future` do not synchronize with themselves or with member functions of `shared_future`. — end note]

2. The effect of calling any member function other than the destructor, the move-assignment operator, `share`, or `valid` on a `future` object for which `valid() == false` is undefined. [Note: It is valid to move from a future object for which `valid() == false`. — end note] [Note: Implementations are encouraged to detect this case and throw an object of type `future_error` with an error condition of `future_errc::no_state`. — end note]

```cpp
namespace std {
    template <class R>
    class future {
    public:
        future() noexcept;
        future(future&&) noexcept;
        future(const future& rhs) = delete;
        ~future();
    }
}
```

§ 33.6.7
future& operator=(const future& rhs) = delete;
future& operator=(future&&) noexcept;
shared_future<R> share() noexcept;

// retrieving the value
see below get();

// functions to check state
bool valid() const noexcept;
void wait() const;

template <class Rep, class Period>
future_status wait_for(const chrono::duration<Rep, Period>& rel_time) const;

template <class Clock, class Duration>
future_status wait_until(const chrono::time_point<Clock, Duration>& abs_time) const;

The implementation shall provide the template future and two specializations, future<R&> and future<
void>. These differ only in the return type and return value of the member function get, as set out in its
description, below.

future() noexcept;

Effects: Constructs an empty future object that does not refer to a shared state.

Postconditions: valid() == false.

future(future&& rhs) noexcept;

Effects: Move constructs a future object that refers to the shared state that was originally referred to
by rhs (if any).

Postconditions:
(8.1) valid() returns the same value as rhs.valid() prior to the constructor invocation.
(8.2) rhs.valid() == false.

~future();

Effects:
(9.1) Releases any shared state (33.6.5);
(9.2) destroys *this.

future& operator=(future&& rhs) noexcept;

Effects:
(10.1) Releases any shared state (33.6.5).
(10.2) move assigns the contents of rhs to *this.

Postconditions:
(11.1) valid() returns the same value as rhs.valid() prior to the assignment.
(11.2) rhs.valid() == false.

shared_future<R> share() noexcept;

Returns: shared_future<R>(std::move(*this)).
Postconditions: valid() == false.

R future::get();
R& future<R&>::get();
void future<void>::get();

[Note: As described above, the template and its two required specializations differ only in the return type and return value of the member function get. — end note]

Effects:

(15.1) wait()s until the shared state is ready, then retrieves the value stored in the shared state;
(15.2) releases any shared state (33.6.5).

Returns:

(16.1) future::get() returns the value v stored in the object’s shared state as std::move(v).
(16.2) future<R&>::get() returns the reference stored as value in the object’s shared state.
(16.3) future<void>::get() returns nothing.

Throws: the stored exception, if an exception was stored in the shared state.

Postconditions: valid() == false.

bool valid() const noexcept;

Returns: true only if *this refers to a shared state.

void wait() const;

Effects: Blocks until the shared state is ready.

template <class Rep, class Period>
future_status wait_for(const chrono::duration<Rep, Period>& rel_time) const;

Effects: None if the shared state contains a deferred function (33.6.9), otherwise blocks until the shared state is ready or until the relative timeout (33.2.4) specified by rel_time has expired.

Returns:

(22.1) future_status::deferred if the shared state contains a deferred function.
(22.2) future_status::ready if the shared state is ready.
(22.3) future_status::timeout if the function is returning because the relative timeout (33.2.4) specified by rel_time has expired.

Throws: timeout-related exceptions (33.2.4).

template <class Clock, class Duration>
future_status wait_until(const chrono::time_point<Clock, Duration>& abs_time) const;

Effects: None if the shared state contains a deferred function (33.6.9), otherwise blocks until the shared state is ready or until the absolute timeout (33.2.4) specified by abs_time has expired.

Returns:

(25.1) future_status::deferred if the shared state contains a deferred function.
(25.2) future_status::ready if the shared state is ready.
(25.3) future_status::timeout if the function is returning because the absolute timeout (33.2.4) specified by abs_time has expired.

Throws: timeout-related exceptions (33.2.4).
The class template `shared_future` defines a type for asynchronous return objects which may share their shared state with other asynchronous return objects. A default-constructed `shared_future` object has no shared state. A `shared_future` object with shared state can be created by conversion from a `future` object and shares its shared state with the original asynchronous provider (33.6.5) of the shared state. The result (value or exception) of a `shared_future` object can be set by calling a respective function on an object that shares the same shared state.

[Note: Member functions of `shared_future` do not synchronize with themselves, but they synchronize with the shared state. —end note]

The effect of calling any member function other than the destructor, the move-assignment operator, the copy-assignment operator, or `valid()` on a `shared_future` object for which `valid() == false` is undefined. [Note: It is valid to copy or move from a `shared_future` object for which `valid()` is `false`. —end note] [Note: Implementations are encouraged to detect this case and throw an object of type `future_error` with an error condition of `future_errc::no_state`. —end note]

```
namespace std {
  template <class R>
  class shared_future {
    public:
      shared_future() noexcept;
      shared_future(const shared_future& rhs) noexcept;
      shared_future(future<R>&&) noexcept;
      shared_future(shared_future&& rhs) noexcept;
      ~shared_future();
      shared_future& operator=(const shared_future& rhs) noexcept;
      shared_future& operator=(shared_future&& rhs) noexcept;

      // retrieving the value
      see below get() const;

      // functions to check state
      bool valid() const noexcept;

      void wait() const;
      template <class Rep, class Period>
        future_status wait_for(const chrono::duration<Rep, Period>& rel_time) const;
      template <class Clock, class Duration>
        future_status wait_until(const chrono::time_point<Clock, Duration>& abs_time) const;
    }
}
```

The implementation shall provide the template `shared_future` and two specializations, `shared_future<R&>` and `shared_future<void>`. These differ only in the return type and return value of the member function `get`, as set out in its description, below.

`shared_future() noexcept;`

**Effects:** Constructs an empty `shared_future` object that does not refer to a shared state.

**Postconditions:** `valid() == false`.

`shared_future(const shared_future& rhs) noexcept;`

**Effects:** Constructs a `shared_future` object that refers to the same shared state as `rhs` (if any).

**Postconditions:** `valid()` returns the same value as `rhs.valid()`.

§ 33.6.8 1404
shared_future(future<R>&& rhs) noexcept;
shared_future(shared_future&& rhs) noexcept;

9  Effects: Move constructs a shared_future object that refers to the shared state that was originally referred to by rhs (if any).

10  Postconditions:
(10.1)  — valid() returns the same value as rhs.valid() returned prior to the constructor invocation.
(10.2)  — rhs.valid() == false.

~shared_future();

11  Effects:
(11.1)  — Releases any shared state (33.6.5);
(11.2)  — destroys *this.

shared_future& operator=(shared_future&& rhs) noexcept;

12  Effects:
(12.1)  — Releases any shared state (33.6.5);
(12.2)  — move assigns the contents of rhs to *this.

Postconditions:
(13.1)  — valid() returns the same value as rhs.valid() returned prior to the assignment.
(13.2)  — rhs.valid() == false.

shared_future& operator=(const shared_future& rhs) noexcept;

14  Effects:
(14.1)  — Releases any shared state (33.6.5);
(14.2)  — assigns the contents of rhs to *this. [Note: As a result, *this refers to the same shared state as rhs (if any). — end note]

Postconditions: valid() == rhs.valid().

const R& shared_future::get() const;
R& shared_future<R>::get() const;
void shared_future<void>::get() const;

16  [Note: As described above, the template and its two required specializations differ only in the return type and return value of the member function get. — end note]

17  [Note: Access to a value object stored in the shared state is unsynchronized, so programmers should apply only those operations on R that do not introduce a data race (4.7). — end note]

Effects: wait()s until the shared state is ready, then retrieves the value stored in the shared state.

Returns:
(19.1)  — shared_future::get() returns a const reference to the value stored in the object’s shared state. [Note: Access through that reference after the shared state has been destroyed produces undefined behavior; this can be avoided by not storing the reference in any storage with a greater lifetime than the shared_future object that returned the reference. — end note]
(19.2)  — shared_future<R>::get() returns the reference stored as value in the object’s shared state.
(19.3)  — shared_future<void>::get() returns nothing.
Throws: the stored exception, if an exception was stored in the shared state.

bool valid() const noexcept;

Returns: true only if *this refers to a shared state.

void wait() const;

Effects: Blocks until the shared state is ready.

template <class Rep, class Period>
future_status wait_for(const chrono::duration<Rep, Period>& rel_time) const;

Effects: None if the shared state contains a deferred function (33.6.9), otherwise blocks until the shared state is ready or until the relative timeout (33.2.4) specified by rel_time has expired.

Returns:
(24.1) — future_status::deferred if the shared state contains a deferred function.
(24.2) — future_status::ready if the shared state is ready.
(24.3) — future_status::timeout if the function is returning because the relative timeout (33.2.4) specified by rel_time has expired.

Throws: timeout-related exceptions (33.2.4).

template <class Clock, class Duration>
future_status wait_until(const chrono::time_point<Clock, Duration>& abs_time) const;

Effects: None if the shared state contains a deferred function (33.6.9), otherwise blocks until the shared state is ready or until the absolute timeout (33.2.4) specified by abs_time has expired.

Returns:
(27.1) — future_status::deferred if the shared state contains a deferred function.
(27.2) — future_status::ready if the shared state is ready.
(27.3) — future_status::timeout if the function is returning because the absolute timeout (33.2.4) specified by abs_time has expired.

Throws: timeout-related exceptions (33.2.4).

33.6.9 Function template async

The function template async provides a mechanism to launch a function potentially in a new thread and provides the result of the function in a future object with which it shares a shared state.

template <class F, class... Args>
future<invoke_result_t<decay_t<F>, decay_t<Args>...>> async(F&& f, Args&&... args);

template <class F, class... Args>
future<invoke_result_t<decay_t<F>, decay_t<Args>...>> async(launch policy, F&& f, Args&&... args);

Requires: F and each Ti in Args shall satisfy the MoveConstructible requirements, and

\[
\text{INVOKED}(\text{DECAY\_COPY}(\text{std::forward}\langle F\rangle(f)), \text{DECAY\_COPY}(\text{std::forward}\langle A\rangle(a)...)) \quad \text{// see 23.14.3, 33.3.2.2}
\]

shall be a valid expression.

Effects: The first function behaves the same as a call to the second function with a policy argument of launch::async | launch::deferred and the same arguments for F and Args. The second function creates a shared state that is associated with the returned future object. The further behavior of
the second function depends on the policy argument as follows (if more than one of these conditions applies, the implementation may choose any of the corresponding policies):

(3.1)  — If launch::async is set in policy, calls `INVOKE(DECYCOPY(std::forward<F>(f)), DECYCOPY(std::forward<Args>(args))...)` (23.14.3, 33.3.2.2) as if in a new thread of execution represented by a thread object with the calls to `DECYCOPY()` being evaluated in the thread that called async. Any return value is stored as the result in the shared state. Any exception propagated from the execution of `INVOKE(DECYCOPY(std::forward<F>(f)), DECYCOPY(std::forward<Args>(args))...)` is stored as the exceptional result in the shared state. The thread object is stored in the shared state and affects the behavior of any asynchronous return objects that reference that state.

(3.2)  — If launch::deferred is set in policy, stores `DECYCOPY(std::forward<F>(f))` and `DECYCOPY(std::forward<Args>(args))...` in the shared state. These copies of f and args constitute a deferred function. Invocation of the deferred function evaluates `INVOKE(std::move(g), std::move(xyz))` where g is the stored value of `DECYCOPY(std::forward<F>(f))` and xyz is the stored copy of `DECYCOPY(std::forward<Args>(args))...`. Any return value is stored as the result in the shared state. Any exception propagated from the execution of the deferred function is stored as the exceptional result in the shared state. The shared state is not made ready until the function has completed. The first call to a non-timed waiting function (33.6.5) on an asynchronous return object referring to this shared state shall invoke the deferred function in the thread that called the waiting function. Once evaluation of `INVOKE(std::move(g), std::move(xyz))` begins, the function is no longer considered deferred. [Note: If this policy is specified together with other policies, such as when using a policy value of launch::async | launch::deferred, implementations should defer invocation or the selection of the policy when no more concurrency can be effectively exploited. —end note]

(3.3)  — If no value is set in the launch policy, or a value is set that is neither specified in this International Standard nor by the implementation, the behavior is undefined.

4 Returns: An object of type `future<invoke_result_t<decay_t<F>, decay_t<Args>...>>` that refers to the shared state created by this call to async. [Note: If a future obtained from async is moved outside the local scope, other code that uses the future must be aware that the future's destructor may block for the shared state to become ready. —end note]

5 Synchronization: Regardless of the provided policy argument,

(5.1)  — the invocation of async synchronizes with (4.7) the invocation of f. [Note: This statement applies even when the corresponding future object is moved to another thread. —end note]; and

(5.2)  — the completion of the function f is sequenced before (4.7) the shared state is made ready. [Note: f might not be called at all, so its completion might never happen. —end note]

If the implementation chooses the launch::async policy,

(5.3)  — a call to a waiting function on an asynchronous return object that shares the shared state created by this async call shall block until the associated thread has completed, as if joined, or else time out (33.3.2.5);

(5.4)  — the associated thread completion synchronizes with (4.7) the return from the first function that successfully detects the ready status of the shared state or with the return from the last function that releases the shared state, whichever happens first.

6 Throws: `system_error` if policy == launch::async and the implementation is unable to start a new thread, or `std::bad_alloc` if memory for the internal data structures could not be allocated.

7 Error conditions:

(7.1)  — resource_unavailable_try_again — if policy == launch::async and the system is unable
to start a new thread.

Example:

```cpp
int work1(int value);
int work2(int value);
int work(int value) {
    auto handle = std::async([=]{ return work2(value); });
    int tmp = work1(value);
    return tmp + handle.get();  // #1
}
```

[Note: Line #1 might not result in concurrency because the async call uses the default policy, which may use launch::deferred, in which case the lambda might not be invoked until the get() call; in that case, work1 and work2 are called on the same thread and there is no concurrency. — end note] — end example]

33.6.10 Class template packaged_task

The class template `packaged_task` defines a type for wrapping a function or callable object so that the return value of the function or callable object is stored in a future when it is invoked.

When the `packaged_task` object is invoked, its stored task is invoked and the result (whether normal or exceptional) stored in the shared state. Any futures that share the shared state will then be able to access the stored result.

```cpp
namespace std {
    template<class> class packaged_task; // not defined

    template<class R, class... ArgTypes>
    class packaged_task<R(ArgTypes...)> { 
    public:
        // construction and destruction
        packaged_task() noexcept;
        template <class F>
        explicit packaged_task(F&& f);
        ~packaged_task();

        // no copy
        packaged_task(const packaged_task&) = delete;
        packaged_task& operator=(const packaged_task&) = delete;

        // move support
        packaged_task(packaged_task&& rhs) noexcept;
        packaged_task& operator=(packaged_task&& rhs) noexcept;
        void swap(packaged_task& other) noexcept;

        bool valid() const noexcept;

        // result retrieval
        future<R> get_future();

        // execution
        void operator()(ArgTypes...);
        void make_ready_at_thread_exit(ArgTypes...);

        void reset();
    }
};
```
```cpp
void swap(packaged_task<R(ArgTypes...)>& x, packaged_task<R(ArgTypes...)>& y) noexcept;

template <class R, class Alloc>
struct uses_allocator<packaged_task<R>, Alloc>;
}

33.6.10.1 packaged_task member functions

packaged_task() noexcept;

Effects: Constructs a `packaged_task` object with no shared state and no stored task.

template <class F>
packaged_task(F&& f);

Requires: `INVOKE<(R, t1, t2, ..., tN)>`, where t1, t2, ..., tN are values of the corresponding types in ArgTypes..., shall be a valid expression. Invoking a copy of f shall behave the same as invoking f.

Remarks: This constructor shall not participate in overload resolution if `decay_t<F>` is the same type as `packaged_task<R(ArgTypes...)>`.

Effects: Constructs a new `packaged_task` object with a shared state and initializes the object’s stored task with `std::forward<F>(f)`.

Throws:

(5.1) — Any exceptions thrown by the copy or move constructor of f.

(5.2) — For the first version, `bad_alloc` if memory for the internal data structures could not be allocated.

(5.3) — For the second version, any exceptions thrown by `allocator_traits<Allocator>::template rebind_traits<unspecified>::allocate`.

packaged_task(packaged_task&& rhs) noexcept;

Effects: Constructs a new `packaged_task` object and transfers ownership of rhs’s shared state to *this, leaving rhs with no shared state. Moves the stored task from rhs to *this.

Postconditions: rhs has no shared state.

packaged_task& operator=(packaged_task&& rhs) noexcept;

Effects:

(8.1) — Releases any shared state (33.6.5);

(8.2) — calls packaged_task(std::move(rhs)).swap(*this).

~packaged_task();

Effects: Abandons any shared state (33.6.5).

void swap(packaged_task& other) noexcept;

Effects: Exchanges the shared states and stored tasks of *this and other.

Postconditions: *this has the same shared state and stored task (if any) as other prior to the call to swap. other has the same shared state and stored task (if any) as *this prior to the call to swap.

bool valid() const noexcept;

Returns: true only if *this has a shared state.

future<R> get_future();

Returns: A future object that shares the same shared state as *this.
```
void operator()(ArgTypes... args);

Effects: As if by \texttt{INVOKE<R>(f, t1, t2, ..., tN)} where \( f \) is the stored task of \texttt{*this} and \( t1, t2, ..., tN \) are the values in \texttt{args}... If the task returns normally, the return value is stored as the asynchronous result in the shared state of \texttt{*this}, otherwise the exception thrown by the task is stored. The shared state of \texttt{*this} is made ready, and any threads blocked in a function waiting for the shared state of \texttt{*this} to become ready are unblocked.

Throws: a \texttt{future\_error} object if an error occurs.

Error conditions:

(15.1) \texttt{future\_already\_retrieved} if \texttt{get\_future} has already been called on a \texttt{packaged\_task} object with the same shared state as \texttt{*this}.

(15.2) \texttt{no\_state} if \texttt{*this} has no shared state.

void make_ready_at_thread_exit(ArgTypes... args);

Effects: As if by \texttt{INVOKE<R>(f, t1, t2, ..., tN)} where \( f \) is the stored task and \( t1, t2, ..., tN \) are the values in \texttt{args}... If the task returns normally, the return value is stored as the asynchronous result in the shared state of \texttt{*this}, otherwise the exception thrown by the task is stored. In either case, this shall be done without making that state ready \( (33.6.5) \) immediately. Schedules the shared state to be made ready when the current thread exits, after all objects of thread storage duration associated with the current thread have been destroyed.

Throws: a \texttt{future\_error} exception object if there is no shared state or the stored task has already been invoked.

Error conditions:

(18.1) \texttt{promise\_already\_satisfied} if the stored task has already been invoked.

(18.2) \texttt{no\_state} if \texttt{*this} has no shared state.

void reset();

Effects: As if \texttt{*this = packaged\_task(std::move(f))}, where \( f \) is the task stored in \texttt{*this}. \[ Note: This constructs a new shared state for \texttt{*this}. The old state is abandoned \( (33.6.5) \). \] —end note

Throws:

(23.1) \texttt{bad\_alloc} if memory for the new shared state could not be allocated.

(23.2) any exception thrown by the move constructor of the task stored in the shared state.

(23.3) \texttt{future\_error} with an error condition of \texttt{no\_state} if \texttt{*this} has no shared state.
: true_type { }

2 Requires: Alloc shall be an Allocator (20.5.3.5).
Annex A  (informative)
Grammar summary

1 This summary of C++ grammar is intended to be an aid to comprehension. It is not an exact statement of the language. In particular, the grammar described here accepts a superset of valid C++ constructs. Disambiguation rules (9.8, 10.1, 13.2) must be applied to distinguish expressions from declarations. Further, access control, ambiguity, and type rules must be used to weed out syntactically valid but meaningless constructs.

A.1 Keywords

New context-dependent keywords are introduced into a program by typedef (10.1.3), namespace (10.3.1), class (Clause 12), enumeration (10.2), and template (Clause 17) declarations.

typedef-name:
  identifier

namespace-name:
  identifier

namespace-alias:
  identifier

class-name:
  identifier

simple-template-id

enum-name:
  identifier

template-name:
  identifier

Note that a typedef-name naming a class is also a class-name (12.1).

A.2 Lexical conventions

hex-quad:
  hexadecimal-digit hexadecimal-digit hexadecimal-digit hexadecimal-digit

universal-character-name:
  \u hex-quad
  \U hex-quad hex-quad

preprocessing-token:
  header-name
  identifier
  pp-number
  character-literal
  user-defined-character-literal
  string-literal
  user-defined-string-literal
  preprocessing-op-or-punc
  each non-white-space character that cannot be one of the above
token:
  
  identifier
  keyword
  literal
  operator
  punctuator

header-name:
  < h-char-sequence >
  " q-char-sequence ">

h-char-sequence:
  h-char
  h-char-sequence h-char

h-char:
  any member of the source character set except new-line and >

q-char-sequence:
  q-char
  q-char-sequence q-char

q-char:
  any member of the source character set except new-line and "

pp-number:
  digit
  . digit
  pp-number digit
  pp-number identifier-nondigit
  pp-number ' digit

  __has_include ( < h-pp-tokens > )
Annex B  (informative)
Implementation quantities [implimits]

1 Because computers are finite, C++ implementations are inevitably limited in the size of the programs they can successfully process. Every implementation shall document those limitations where known. This documentation may cite fixed limits where they exist, say how to compute variable limits as a function of available resources, or say that fixed limits do not exist or are unknown.

2 The limits may constrain quantities that include those described below or others. The bracketed number following each quantity is recommended as the minimum for that quantity. However, these quantities are only guidelines and do not determine compliance.

(2.1) Nesting levels of compound statements, iteration control structures, and selection control structures [256].

(2.2) Nesting levels of conditional inclusion [256].

(2.3) Pointer, array, and function declarators (in any combination) modifying a class, arithmetic, or incomplete type in a declaration [256].

(2.4) Nesting levels of parenthesized expressions within a full-expression [256].

(2.5) Number of characters in an internal identifier or macro name [1024].

(2.6) Number of characters in an external identifier [1024].

(2.7) External identifiers in one translation unit [65536].

(2.8) Identifiers with block scope declared in one block [1024].

(2.9) Structured bindings introduced in one declaration [256].

(2.10) Macro identifiers simultaneously defined in one translation unit [65536].

(2.11) Parameters in one function definition [256].

(2.12) Arguments in one function call [256].

(2.13) Parameters in one macro definition [256].

(2.14) Arguments in one macro invocation [256].

(2.15) Characters in one logical source line [65536].

(2.16) Characters in a string literal (after concatenation) [65536].

(2.17) Size of an object [262144].

(2.18) Nesting levels for #include files [256].

(2.19) Case labels for a switch statement (excluding those for any nested switch statements) [16384].

(2.20) Data members in a single class [16384].

(2.21) Lambda-captures in one lambda-expression [256].

(2.22) Enumeration constants in a single enumeration [4096].

(2.23) Levels of nested class definitions in a single member-specification [256].

(2.24) Functions registered by atexit() [32].

(2.25) Functions registered by at_quick_exit() [32].
(2.26) — Direct and indirect base classes [16384].
(2.27) — Direct base classes for a single class [1024].
(2.28) — Members declared in a single class [4096].
(2.29) — Final overriding virtual functions in a class, accessible or not [16384].
(2.30) — Direct and indirect virtual bases of a class [1024].
(2.31) — Static members of a class [1024].
(2.32) — Friend declarations in a class [4096].
(2.33) — Access control declarations in a class [4096].
(2.34) — Member initializers in a constructor definition [6144].
(2.35) — \textit{initializer-clauses} in one \textit{braced-init-list} [16384].
(2.36) — Scope qualifications of one identifier [256].
(2.37) — Nested external specifications [1024].
(2.38) — Recursive constexpr function invocations [512].
(2.39) — Full-expressions evaluated within a core constant expression [1048576].
(2.40) — Template arguments in a template declaration [1024].
(2.41) — Recursively nested template instantiations, including substitution during template argument deduc-
tion (17.8.2) [1024].
(2.42) — Handlers per try block [256].
(2.43) — Number of placeholders (23.14.11.4) [10].

Implementation quantities 1435
Annex C  (informative)  
Compatibility  

C.1  C++ and ISO C  

This subclause lists the differences between C++ and ISO C, by the chapters of this document.

C.1.1  Clause 5: lexical conventions  

5.11  
Change: New Keywords  
New keywords are added to C++; see 5.11.
Rationale: These keywords were added in order to implement the new semantics of C++.
Effect on original feature: Change to semantics of well-defined feature. Any ISO C programs that used any of these keywords as identifiers are not valid C++ programs.
Difficulty of converting: Syntactic transformation. Converting one specific program is easy. Converting a large collection of related programs takes more work.

5.13.3  
Change: Type of character literal is changed from int to char.  
Rationale: This is needed for improved overloaded function argument type matching. For example:

```c
int function( int i );
int function( char c );

function( 'x' );
```

It is preferable that this call match the second version of function rather than the first.

Effect on original feature: Change to semantics of well-defined feature. ISO C programs which depend on `sizeof('x') == sizeof(int)` will not work the same as C++ programs.
Difficulty of converting: Simple.
How widely used: Programs which depend upon `sizeof('x')` are probably rare.

Subclause 5.13.5:
Change: String literals made const.
The type of a string literal is changed from “array of char” to “array of const char”. The type of a char16_t string literal is changed from “array of some-integer-type” to “array of const char16_t”. The type of a char32_t string literal is changed from “array of some-integer-type” to “array of const char32_t”. The type of a wide string literal is changed from “array of wchar_t” to “array of const wchar_t”.
Rationale: This avoids calling an inappropriate overloaded function, which might expect to be able to modify its argument.

Effect on original feature: Change to semantics of well-defined feature.
Difficulty of converting: Syntactic transformation. The fix is to add a cast:

```c
char* p = "abc";
void f(char*) {
    char* p = (char*)"abc";  // OK: cast added
    f(p);
    f((char*)"def");  // OK: cast added
```

§ C.1.1
How widely used: Programs that have a legitimate reason to treat string literals as pointers to potentially modifiable memory are probably rare.

C.1.2 Clause 6: basic concepts

6.1 Change: C++ does not have “tentative definitions” as in C.
E.g., at file scope,

```c
int i;
int i;
```

is valid in C, invalid in C++. This makes it impossible to define mutually referential file-local static objects, if initializers are restricted to the syntactic forms of C. For example,

```c
struct X { int i; struct X* next; };
static struct X a;
static struct X b = { 0, &a }; 
static struct X a = { 1, &b }; 
```

Rationale: This avoids having different initialization rules for fundamental types and user-defined types.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Semantic transformation. In C++, the initializer for one of a set of mutually-referential file-local static objects must invoke a function call to achieve the initialization.
How widely used: Seldom.

6.3 Change: A struct is a scope in C++, not in C.
Rationale: Class scope is crucial to C++, and a struct is a class.
Effect on original feature: Change to semantics of well-defined feature.
Difficulty of converting: Semantic transformation.
How widely used: C programs use struct extremely frequently, but the change is only noticeable when struct, enumeration, or enumerator names are referred to outside the struct. The latter is probably rare.

6.5 [also 10.1.7]

Change: A name of file scope that is explicitly declared const, and not explicitly declared extern, has internal linkage, while in C it would have external linkage.
Rationale: Because const objects may be used as values during translation in C++, this feature urges programmers to provide an explicit initializer for each const object. This feature allows the user to put const objects in source files that are included in more than one translation unit.
Effect on original feature: Change to semantics of well-defined feature.
Difficulty of converting: Semantic transformation.
How widely used: Seldom.

6.6.1 Change: The main function cannot be called recursively and cannot have its address taken.
Rationale: The main function may require special actions.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Trivial: create an intermediary function such as mymain(argc, argv).
How widely used: Seldom.

6.9 Change: C allows “compatible types” in several places, C++ does not.
For example, otherwise-identical `struct` types with different tag names are “compatible” in C but are distinctly different types in C++.

**Rationale:** Stricter type checking is essential for C++.

**Effect on original feature:** Deletion of semantically well-defined feature.

**Difficulty of converting:** Semantic transformation. The “typesafe linkage” mechanism will find many, but not all, of such problems. Those problems not found by typesafe linkage will continue to function properly, according to the “layout compatibility rules” of this International Standard.

**How widely used:** Common.

### C.1.3 Clause 7: standard conversions

#### 7.11

**Change:** Converting `void*` to a pointer-to-object type requires casting.

```c
char a[10];
void* b=a;
void foo() {
    char* c=b;
}
```

ISO C will accept this usage of pointer to void being assigned to a pointer to object type. C++ will not.

**Rationale:** C++ tries harder than C to enforce compile-time type safety.

**Effect on original feature:** Deletion of semantically well-defined feature.

**Difficulty of converting:** Could be automated. Violations will be diagnosed by the C++ translator. The fix is to add a cast. For example:

```c
char* c = (char*) b;
```

**How widely used:** This is fairly widely used but it is good programming practice to add the cast when assigning pointer-to-void to pointer-to-object. Some ISO C translators will give a warning if the cast is not used.

### C.1.4 Clause 8: expressions

#### 8.2.2

**Change:** Implicit declaration of functions is not allowed.

**Rationale:** The type-safe nature of C++.

**Effect on original feature:** Deletion of semantically well-defined feature. Note: the original feature was labeled as “obsolete” in ISO C.

**Difficulty of converting:** Syntactic transformation. Facilities for producing explicit function declarations are fairly widespread commercially.

**How widely used:** Common.

#### 8.2.6, 8.3.2

**Change:** Decrement operator is not allowed with `bool` operand.

**Rationale:** Feature with surprising semantics.

**Effect on original feature:** A valid ISO C expression utilizing the decrement operator on a `bool` lvalue (for instance, via the C typedef in `<stdbool.h>`) is ill-formed in this International Standard.

#### 8.3.3, 8.4

**Change:** Types must be defined in declarations, not in expressions.

In C, a `sizeof` expression or cast expression may define a new type. For example,

```c
p = (void*)(struct x {int i;} *)0;
```

defines a new type, struct `x`.

**Rationale:** This prohibition helps to clarify the location of definitions in the source code.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Syntactic transformation.
How widely used: Seldom.

8.16, 8.18, 8.19
Change: The result of a conditional expression, an assignment expression, or a comma expression may be an lvalue.
Rationale: C++ is an object-oriented language, placing relatively more emphasis on lvalues. For example, functions may return lvalues.
Effect on original feature: Change to semantics of well-defined feature. Some C expressions that implicitly rely on lvalue-to-rvalue conversions will yield different results. For example,

```c
char arr[100];
sizeof(0, arr)
```
yields 100 in C++ and `sizeof(char*)` in C.
Difficulty of converting: Programs must add explicit casts to the appropriate rvalue.
How widely used: Rare.

C.1.5 Clause 9: statements [diff.stat]
9.4.2, 9.6.4
Change: It is now invalid to jump past a declaration with explicit or implicit initializer (except across entire block not entered).
Rationale: Constructors used in initializers may allocate resources which need to be de-allocated upon leaving the block. Allowing jump past initializers would require complicated runtime determination of allocation. Furthermore, any use of the uninitialized object could be a disaster. With this simple compile-time rule, C++ assures that if an initialized variable is in scope, then it has assuredly been initialized.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Semantic transformation.
How widely used: Seldom.

9.6.3
Change: It is now invalid to return (explicitly or implicitly) from a function which is declared to return a value without actually returning a value.
Rationale: The caller and callee may assume fairly elaborate return-value mechanisms for the return of class objects. If some flow paths execute a return without specifying any value, the implementation must embody many more complications. Besides, promising to return a value of a given type, and then not returning such a value, has always been recognized to be a questionable practice, tolerated only because very-old C had no distinction between void functions and int functions.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Semantic transformation. Add an appropriate return value to the source code, such as zero.
How widely used: Seldom. For several years, many existing C implementations have produced warnings in this case.

C.1.6 Clause 10: declarations [diff.dcl]
10.1.1
Change: In C++, the static or extern specifiers can only be applied to names of objects or functions. Using these specifiers with type declarations is illegal in C++. In C, these specifiers are ignored when used on type declarations.
Example:

```c
static struct S {
    int i;
} // valid C, invalid in C++
```
Rationale: Storage class specifiers don’t have any meaning when associated with a type. In C++, class members can be declared with the static storage class specifier. Allowing storage class specifiers on type declarations could render the code confusing for users.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Syntactic transformation.

How widely used: Seldom.

10.1.1
Change: In C++, register is not a storage class specifier.

Rationale: The storage class specifier had no effect in C++.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Syntactic transformation.

How widely used: Common.

10.1.3
Change: A C++ typedef name must be different from any class type name declared in the same scope (except if the typedef is a synonym of the class name with the same name). In C, a typedef name and a struct tag name declared in the same scope can have the same name (because they have different name spaces).

Example:
```c
typedef struct name1 { /* ... */ } name1; // valid C and C++
struct name { /* ... */ }; // valid C, invalid C++
typedef int name; // valid C, invalid C++
```

Rationale: For ease of use, C++ doesn’t require that a type name be prefixed with the keywords class, struct or union when used in object declarations or type casts.

Example:
```c
class name { /* ... */ }; // i has type class name
name i; // i has type id
```

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Semantic transformation. One of the 2 types has to be renamed.

How widely used: Seldom.

10.1.7 [see also 6.5]
Change: const objects must be initialized in C++ but can be left uninitialized in C.

Rationale: A const object cannot be assigned to so it must be initialized to hold a useful value.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Semantic transformation.

How widely used: Seldom.

10.1.7
Change: Banning implicit int.

In C++ a decl-specifier-seq must contain a type-specifier, unless it is followed by a declarator for a constructor, a destructor, or a conversion function. In the following example, the left-hand column presents valid C; the right-hand column presents equivalent C++:

```c
void f(const parm); void f(const int parm);
const n = 3; const int n = 3;
main() int main()
    /* ... */ /* ... */
```

§ C.1.6
Rationale: In C++, implicit int creates several opportunities for ambiguity between expressions involving function-like casts and declarations. Explicit declaration is increasingly considered to be proper style. Liaison with WG14 (C) indicated support for (at least) deprecating implicit int in the next revision of C.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Syntactic transformation. Could be automated.

How widely used: Common.

10.1.7.4

Change: The keyword auto cannot be used as a storage class specifier.

```c
void f() {
    auto int x; // valid C, invalid C++
}
```

Rationale: Allowing the use of auto to deduce the type of a variable from its initializer results in undesired interpretations of auto as a storage class specifier in certain contexts.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Syntactic transformation.

How widely used: Rare.

10.2

Change: C++ objects of enumeration type can only be assigned values of the same enumeration type. In C, objects of enumeration type can be assigned values of any integral type.

Example:

```c
enum color { red, blue, green };
enum color c = 1; // valid C, invalid C++
```

Rationale: The type-safe nature of C++.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Syntactic transformation. (The type error produced by the assignment can be automatically corrected by applying an explicit cast.)

How widely used: Common.

10.2

Change: In C++, the type of an enumerator is its enumeration. In C, the type of an enumerator is int.

Example:

```c
enum e { A };
sizeof(A) == sizeof(int) // in C
sizeof(A) == sizeof(e) // in C++
/* and sizeof(int) is not necessarily equal to sizeof(e) */
```

Rationale: In C++, an enumeration is a distinct type.

Effect on original feature: Change to semantics of well-defined feature.

Difficulty of converting: Semantic transformation.

How widely used: Seldom. The only time this affects existing C code is when the size of an enumerator is taken. Taking the size of an enumerator is not a common C coding practice.

C.1.7 Clause 11: declarators

11.3.5

Change: In C++, a function declared with an empty parameter list takes no arguments. In C, an empty
parameter list means that the number and type of the function arguments are unknown.

Example:

```
int f();              // means int f(void) in C++
// int f( unknown ) in C
```

**Rationale:** This is to avoid erroneous function calls (i.e., function calls with the wrong number or type of arguments).

**Effect on original feature:** Change to semantics of well-defined feature. This feature was marked as “obsolescent” in C.

**Difficulty of converting:** Syntactic transformation. The function declarations using C incomplete declaration style must be completed to become full prototype declarations. A program may need to be updated further if different calls to the same (non-prototype) function have different numbers of arguments or if the type of corresponding arguments differed.

**How widely used:** Common.

11.3.5 [see 8.3.3]

**Change:** In C++, types may not be defined in return or parameter types. In C, these type definitions are allowed.

Example:

```
void f( struct S { int a; } arg ) {}  // valid C, invalid C++
enum E { A, B, C } f() {}          // valid C, invalid C++
```

**Rationale:** When comparing types in different translation units, C++ relies on name equivalence when C relies on structural equivalence. Regarding parameter types: since the type defined in a parameter list would be in the scope of the function, the only legal calls in C++ would be from within the function itself.

**Effect on original feature:** Deletion of semantically well-defined feature.

**Difficulty of converting:** Semantic transformation. The type definitions must be moved to file scope, or in header files.

**How widely used:** Seldom. This style of type definition is seen as poor coding style.

11.4

**Change:** In C++, the syntax for function definition excludes the “old-style” C function. In C, “old-style” syntax is allowed, but deprecated as “obsolescent”.

**Rationale:** Prototypes are essential to type safety.

**Effect on original feature:** Deletion of semantically well-defined feature.

**Difficulty of converting:** Syntactic transformation.

**How widely used:** Common in old programs, but already known to be obsolescent.

11.6.2

**Change:** In C++, when initializing an array of character with a string, the number of characters in the string (including the terminating ‘\0’) must not exceed the number of elements in the array. In C, an array can be initialized with a string even if the array is not large enough to contain the string-terminating ‘\0’.

Example:

```
char array[4] = "abcd";          // valid C, invalid C++
```

**Rationale:** When these non-terminated arrays are manipulated by standard string functions, there is potential for major catastrophe.

**Effect on original feature:** Deletion of semantically well-defined feature.

**Difficulty of converting:** Semantic transformation. The arrays must be declared one element bigger to contain the string terminating ‘\0’.
How widely used: Seldom. This style of array initialization is seen as poor coding style.

C.1.8 Clause 12: classes [diff.class]

12.1 [see also 10.1.3]

Change: In C++, a class declaration introduces the class name into the scope where it is declared and hides any object, function or other declaration of that name in an enclosing scope. In C, an inner scope declaration of a struct tag name never hides the name of an object or function in an outer scope.

Example:
```c
int x[99];
void f() {
    struct x { int a; };
    sizeof(x); /* size of the array in C */
    /* size of the struct in C++ */
}
```

Rationale: This is one of the few incompatibilities between C and C++ that can be attributed to the new C++ name space definition where a name can be declared as a type and as a non-type in a single scope causing the non-type name to hide the type name and requiring that the keywords class, struct, union or enum be used to refer to the type name. This new name space definition provides important notational conveniences to C++ programmers and helps making the use of the user-defined types as similar as possible to the use of fundamental types. The advantages of the new name space definition were judged to outweigh by far the incompatibility with C described above.

Effect on original feature: Change to semantics of well-defined feature.

Difficulty of converting: Semantic transformation. If the hidden name that needs to be accessed is at global scope, the :: C++ operator can be used. If the hidden name is at block scope, either the type or the struct tag has to be renamed.

How widely used: Seldom.

12.2.4

Change: Bit-fields of type plain int are signed.

Rationale: Leaving the choice of signedness to implementations could lead to inconsistent definitions of template specializations. For consistency, the implementation freedom was eliminated for non-dependent types, too.

Effect on original feature: The choice is implementation-defined in C, but not so in C++.

Difficulty of converting: Syntactic transformation.

How widely used: Seldom.

12.2.5

Change: In C++, the name of a nested class is local to its enclosing class. In C the name of the nested class belongs to the same scope as the name of the outermost enclosing class.

Example:
```c
struct X {
    struct Y { /* ... */ } y;
};
struct Y yy; // valid C, invalid C++
```

Rationale: C++ classes have member functions which require that classes establish scopes. The C rule would leave classes as an incomplete scope mechanism which would prevent C++ programmers from maintaining locality within a class. A coherent set of scope rules for C++ based on the C rule would be very complicated and C++ programmers would be unable to predict reliably the meanings of nontrivial examples involving
nested or local functions.

**Effect on original feature:** Change to semantics of well-defined feature.

**Difficulty of converting:** Semantic transformation. To make the struct type name visible in the scope of the enclosing struct, the struct tag could be declared in the scope of the enclosing struct, before the enclosing struct is defined. Example:

```c
struct Y;  // struct Y and struct X are at the same scope
struct X {
  struct Y { /* ... */ } y;
};
```

All the definitions of C struct types enclosed in other struct definitions and accessed outside the scope of the enclosing struct could be exported to the scope of the enclosing struct. Note: this is a consequence of the difference in scope rules, which is documented in 6.3.

**How widely used:** Seldom.

12.2.6

**Change:** In C++, a typedef name may not be redeclared in a class definition after being used in that definition.

Example:

```c
typedef int I;
struct S {
  I i;
  int I;  // valid C, invalid C++
};
```

**Rationale:** When classes become complicated, allowing such a redefinition after the type has been used can create confusion for C++ programmers as to what the meaning of I really is.

**Effect on original feature:** Deletion of semantically well-defined feature.

**Difficulty of converting:** Semantic transformation. Either the type or the struct member has to be renamed.

**How widely used:** Seldom.

C.1.9 **Clause 15: special member functions**

15.8

**Change:** Copying volatile objects.

The implicitly-declared copy constructor and implicitly-declared copy assignment operator cannot make a copy of a volatile lvalue. For example, the following is valid in ISO C:

```c
struct X { int i;  };
volatile struct X x1 = {0};
struct X x2 = x1;  // invalid C++
struct X x3;
x3 = x1;  // also invalid C++
```

**Rationale:** Several alternatives were debated at length. Changing the parameter to volatile const X& would greatly complicate the generation of efficient code for class objects. Discussion of providing two alternative signatures for these implicitly-defined operations raised unanswered concerns about creating ambiguities and complicating the rules that specify the formation of these operators according to the bases and members.

**Effect on original feature:** Deletion of semantically well-defined feature.

**Difficulty of converting:** Semantic transformation. If volatile semantics are required for the copy, a
user-declared constructor or assignment must be provided. If non-volatile semantics are required, an explicit `const_cast` can be used.

**How widely used:** Seldom.

### C.1.10 Clause 19: preprocessing directives

**Change:** Whether `__STDC__` is defined and if so, what its value is, are implementation-defined.

**Rationale:** C++ is not identical to ISO C. Mandating that `__STDC__` be defined would require that translators make an incorrect claim. Each implementation must choose the behavior that will be most useful to its marketplace.

**Effect on original feature:** Change to semantics of well-defined feature.

**Difficulty of converting:** Semantic transformation.

**How widely used:** Programs and headers that reference `__STDC__` are quite common.

### C.2 C++ and ISO C++ 2003

This subclause lists the differences between C++ and ISO C++ 2003 (ISO/IEC 14882:2003, *Programming Languages — C++*), by the chapters of this document.

#### C.2.1 Clause 5: lexical conventions

**Change:** New kinds of string literals.

**Rationale:** Required for new features.

**Effect on original feature:** Valid C++ 2003 code may fail to compile or produce different results in this International Standard. Specifically, macros named `R`, `u8`, `u8R`, `u`, `uR`, `U`, `UR`, or `LR` will not be expanded when adjacent to a string literal but will be interpreted as part of the string literal. For example,

```c
#define u8 "abc"
char* s = u8"def";  // Previously "abcdef", now "def"
```

**Change:** User-defined literal string support.

**Rationale:** Required for new features.

**Effect on original feature:** Valid C++ 2003 code may fail to compile or produce different results in this International Standard, as the following example illustrates.

```c
#define _x "there"
"hello"_x  // #1
```

Previously, #1 would have consisted of two separate preprocessing tokens and the macro `_x` would have been expanded. In this International Standard, #1 consists of a single preprocessing token, so the macro is not expanded.

**Change:** New keywords.

**Rationale:** Required for new features.

**Effect on original feature:** Added to Table 5, the following identifiers are new keywords: `alignas`, `alignof`, `char16_t`, `char32_t`, `constexpr`, `decltype`, `noexcept`, `nullptr`, `static_assert`, and `thread_local`. Valid C++ 2003 code using these identifiers is invalid in this International Standard.

**Change:** Type of integer literals.

**Rationale:** C99 compatibility.

**Effect on original feature:** Certain integer literals larger than can be represented by `long` could change from an unsigned integer type to `signed long long`.

§ C.2.1
C.2.2 Clause 7: standard conversions

7.11 Change: Only literals are integer null pointer constants.
Rationale: Removing surprising interactions with templates and constant expressions.
Effect on original feature: Valid C++ 2003 code may fail to compile or produce different results in this International Standard, as the following example illustrates:

```cpp
void f(void *);  // #1
void f(...);    // #2
template<int N> void g() {
    f(0*N);      // calls #2; used to call #1
}
```

C.2.3 Clause 8: expressions

8.6 Change: Specify rounding for results of integer / and \%
Rationale: Increase portability, C99 compatibility.
Effect on original feature: Valid C++ 2003 code that uses integer division rounds the result toward 0 or toward negative infinity, whereas this International Standard always rounds the result toward 0.

8.14 Change: \&\& is valid in a type-name.
Rationale: Required for new features.
Effect on original feature: Valid C++ 2003 code may fail to compile or produce different results in this International Standard, as the following example illustrates:

```cpp
bool b1 = new int && false;        // previously false, now ill-formed
struct S { operator int() {};};   // S::operator int
bool b2 = &S::operator int && false; // previously false, now ill-formed
```

C.2.4 Clause 10: declarations

10.1 Change: Remove auto as a storage class specifier.
Rationale: New feature.
Effect on original feature: Valid C++ 2003 code that uses the keyword auto as a storage class specifier may be invalid in this International Standard. In this International Standard, auto indicates that the type of a variable is to be deduced from its initializer expression.

C.2.5 Clause 11: declarators

11.6.4 Change: Narrowing restrictions in aggregate initializers.
Rationale: Catches bugs.
Effect on original feature: Valid C++ 2003 code may fail to compile in this International Standard. For example, the following code is valid in C++ 2003 but invalid in this International Standard because double to int is a narrowing conversion:

```cpp
int x[] = { 2.0 };  // narrowing conversion, invalid
```

C.2.6 Clause 15: special member functions

15.1, 15.4, 15.8 Change: Implicitly-declared special member functions are defined as deleted when the implicit definition would have been ill-formed.
Rationale: Improves template argument deduction failure.
**Effect on original feature:** A valid C++ 2003 program that uses one of these special member functions in a context where the definition is not required (e.g., in an expression that is not potentially evaluated) becomes ill-formed.

**15.4 (destructors)**

*Change:* User-declared destructors have an implicit exception specification.

*Rationale:* Clarification of destructor requirements.

**Effect on original feature:** Valid C++ 2003 code may execute differently in this International Standard. In particular, destructors that throw exceptions will call `std::terminate` (without calling `std::unexpected`) if their exception specification is non-throwing.

**C.2.7 Clause 17: templates**

**17.1**

*Change:* Remove `export`.

*Rationale:* No implementation consensus.

**Effect on original feature:** A valid C++ 2003 declaration containing `export` is ill-formed in this International Standard.

**17.3**

*Change:* Remove whitespace requirement for nested closing template right angle brackets.

*Rationale:* Considered a persistent but minor annoyance. Template aliases representing non-class types would exacerbate whitespace issues.

**Effect on original feature:** Change to semantics of well-defined expression. A valid C++ 2003 expression containing a right angle bracket (“>”) followed immediately by another right angle bracket may now be treated as closing two templates. For example, the following code is valid in C++ 2003 because “>>>” is a right-shift operator, but invalid in this International Standard because “>>>” closes two templates.

```cpp
template <class T> struct X { 
};
template <int N> struct Y { 
};
X< Y< 1 >>> 2 > > x;
```

**17.6.4.2**

*Change:* Allow dependent calls of functions with internal linkage.

*Rationale:* Overly constrained, simplify overload resolution rules.

**Effect on original feature:** A valid C++ 2003 program could get a different result than this International Standard.

**C.2.8 Clause 20: library introduction**

**20 ~ 33**

*Change:* New reserved identifiers.

*Rationale:* Required by new features.

**Effect on original feature:** Valid C++ 2003 code that uses any identifiers added to the C++ standard library by this International Standard may fail to compile or produce different results in this International Standard. A comprehensive list of identifiers used by the C++ standard library can be found in the Index of Library Names in this International Standard.

**20.5.1.2**

*Change:* New headers.

*Rationale:* New functionality.

**Effect on original feature:** The following C++ headers are new: `<array>`, `<atomic>`, `<chrono>`, `<codecvt>`, `<condition_variable>`, `<forward_list>`, `<future>`, `<initializer_list>`, `<mutex>`, `<random>`, `<ratio>`, `<regex>`, `<scoped_allocator>`, `<system_error>`, `<thread>`, `<tuple>`, `<typeindex>`, `<type_traits>`, `<unordered_map>`, and `<unordered_set>`. In addition the following C compatibility headers are new:
Valid C++ 2003 code that includes headers with these names may be invalid in this International Standard.

20.5.3.2
Effect on original feature: Function swap moved to a different header
Rationale: Remove dependency on <algorithm> for swap.

20.5.4.2
Change: New reserved namespace.
Rationale: New functionality.
Effect on original feature: The global namespace posix is now reserved for standardization. Valid C++ 2003 code that uses a top-level namespace posix may be invalid in this International Standard.

20.5.5.3
Change: Additional restrictions on macro names.
Rationale: Avoid hard to diagnose or non-portable constructs.
Effect on original feature: Names of attribute identifiers may not be used as macro names. Valid C++ 2003 code that defines override, final, carries_dependency, or noreturn as macros is invalid in this International Standard.

C.2.9 Clause 21: language support library

21.6.2.1
Change: Linking new and delete operators.
Rationale: The two throwing single-object signatures of operator new and operator delete are now specified to form the base functionality for the other operators. This clarifies that replacing just these two signatures changes others, even if they are not explicitly changed.
Effect on original feature: Valid C++ 2003 code that replaces global new or delete operators may execute differently in this International Standard. For example, the following program should write "custom deallocation" twice, once for the single-object delete and once for the array delete.

```cpp
#include <cstdio>
#include <cstdlib>
#include <new>

void* operator new(std::size_t size) throw(std::bad_alloc) {
    return std::malloc(size);
}

void operator delete(void* ptr) throw() {
    std::puts("custom deallocation");
    std::free(ptr);
}

int main() {
    int* i = new int;     // single-object delete
    delete i;
    int* a = new int[3];  // array delete
    delete [] a;
}
```

21.6.2.1
Change: operator new may throw exceptions other than std::bad_alloc.
Rationale: Consistent application of noexcept.
Effect on original feature: Valid C++ 2003 code that assumes that global `operator new` only throws `std::bad_alloc` may execute differently in this International Standard.

C.2.10 Clause 22: diagnostics library [diff.cpp03.diagnostics]

22.4
Change: Thread-local error numbers.
Rationale: Support for new thread facilities.
Effect on original feature: Valid but implementation-specific C++ 2003 code that relies on `errno` being the same across threads may change behavior in this International Standard.

C.2.11 Clause 23: general utilities library [diff.cpp03.utilities]

23.10.4
Change: Minimal support for garbage-collected regions.
Rationale: Required by new feature.
Effect on original feature: Valid C++ 2003 code, compiled without traceable pointer support, that interacts with newer C++ code using regions declared reachable may have different runtime behavior.

Change: Standard function object types no longer derived from `std::unary_function` or `std::binary_function`.
Rationale: Superseded by new feature; `unary_function` and `binary_function` are no longer defined.
Effect on original feature: Valid C++ 2003 code that depends on function object types being derived from `unary_function` or `binary_function` may fail to compile in this International Standard.

C.2.12 Clause 24: strings library [diff.cpp03.strings]

24.3
Change: `basic_string` requirements no longer allow reference-counted strings.
Rationale: Invalidation is subtly different with reference-counted strings. This change regularizes behavior for this International Standard.
Effect on original feature: Valid C++ 2003 code may execute differently in this International Standard.

24.3.2.1
Change: Loosen `basic_string` invalidation rules.
Rationale: Allow small-string optimization.
Effect on original feature: Valid C++ 2003 code may execute differently in this International Standard. Some `const` member functions, such as `data` and `c_str`, no longer invalidate iterators.

C.2.13 Clause 26: containers library [diff.cpp03.containers]

26.2
Change: Complexity of `size()` member functions now constant.
Rationale: Lack of specification of complexity of `size()` resulted in divergent implementations with inconsistent performance characteristics.
Effect on original feature: Some container implementations that conform to C++ 2003 may not conform to the specified `size()` requirements in this International Standard. Adjusting containers such as `std::list` to the stricter requirements may require incompatible changes.

26.2
Change: Requirements change: relaxation.
Rationale: Clarification.
Effect on original feature: Valid C++ 2003 code that attempts to meet the specified container requirements may now be over-specified. Code that attempted to be portable across containers may need to be adjusted as follows:

§ C.2.13
— not all containers provide size(); use empty() instead of size() == 0;
— not all containers are empty after construction (array);
— not all containers have constant complexity for swap() (array).

26.2
Change: Requirements change: default constructible.
Rationale: Clarification of container requirements.
Effect on original feature: Valid C++ 2003 code that attempts to explicitly instantiate a container using a user-defined type with no default constructor may fail to compile.

26.2.3, 26.2.6
Change: Signature changes: from void return types.
Rationale: Old signature threw away useful information that may be expensive to recalculate.
Effect on original feature: The following member functions have changed:
— erase(iter) for set, multiset, map, multimap
— erase(begin, end) for set, multiset, map, multimap
— insert(pos, num, val) for vector, deque, list, forward_list
— insert(pos, beg, end) for vector, deque, list, forward_list
Valid C++ 2003 code that relies on these functions returning void (e.g., code that creates a pointer to member function that points to one of these functions) will fail to compile with this International Standard.

26.2.3, 26.2.6
Change: Signature changes: from iterator to const_iterator parameters.
Rationale: Overspecification.
Effect on original feature: The signatures of the following member functions changed from taking an iterator to taking a const_iterator:
— insert(iter, val) for vector, deque, list, set, multiset, map, multimap
— insert(pos, beg, end) for vector, deque, list, forward_list
— erase(begin, end) for set, multiset, map, multimap
— all forms of list::splice
— all forms of list::merge
Valid C++ 2003 code that uses these functions may fail to compile with this International Standard.

26.2.3, 26.2.6
Change: Signature changes: resize.
Rationale: Performance, compatibility with move semantics.
Effect on original feature: For vector, deque, and list the fill value passed to resize is now passed by reference instead of by value, and an additional overload of resize has been added. Valid C++ 2003 code that uses this function may fail to compile with this International Standard.

C.2.14 Clause 28: algorithms library

28.1
Change: Result state of inputs after application of some algorithms.
Rationale: Required by new feature.
Effect on original feature: A valid C++ 2003 program may detect that an object with a valid but unspecified state has a different valid but unspecified state with this International Standard. For example, std::remove and std::remove_if may leave the tail of the input sequence with a different set of values than previously.
C.2.15 Clause 29: numerics library

29.5
Change: Specified representation of complex numbers.
Rationale: Compatibility with C99.
Effect on original feature: Valid C++ 2003 code that uses implementation-specific knowledge about the binary representation of the required template specializations of \texttt{std::complex} may not be compatible with this International Standard.

C.2.16 Clause 30: input/output library

30.5.3.1.1
Change: Change base class of \texttt{std::ios_base::failure}.
Rationale: More detailed error messages.
Effect on original feature: \texttt{std::ios_base::failure} is no longer derived directly from \texttt{std::exception}, but is now derived from \texttt{std::system_error}, which in turn is derived from \texttt{std::runtime_error}. Valid C++ 2003 code that assumes that \texttt{std::ios_base::failure} is derived directly from \texttt{std::exception} may execute differently in this International Standard.

30.5.3
Change: Flag types in \texttt{std::ios_base} are now bitmasks with values defined as constexpr static members.
Rationale: Required for new features.
Effect on original feature: Valid C++ 2003 code that relies on \texttt{std::ios_base} flag types being represented as \texttt{std::bitset} or as an integer type may fail to compile with this International Standard. For example:

```
#include <iostream>

int main() {
    int flag = std::ios_base::hex;
    std::cout.setf(flag);    // error: setf does not take argument of type int
}
```

C.3 C++ and ISO C++ 2011

This subclause lists the differences between C++ and ISO C++ 2011 (ISO/IEC 14882:2011, \textit{Programming Languages — C++}), by the chapters of this document.
Standard, but the macro invocation produces different outcomes because the single quotes delimit a character literal in C++ 2011, whereas they are digit separators in this International Standard:

```c++
#define M(x, ...) __VA_ARGS__
int x[2] = { M('1','2','3','4', 5) };
// int x[2] = { 3'4, 5 }; -- this International Standard
```

C.3.2 Clause 6: basic concepts

6.7.4.2 Change: New usual (non-placement) deallocator.
Rationale: Required for sized deallocation.
Effect on original feature: Valid C++ 2011 code could declare a global placement allocation function and deallocation function as follows:

```c++
void* operator new(std::size_t, std::size_t);
void operator delete(void*, std::size_t) noexcept;
```

In this International Standard, however, the declaration of `operator delete` might match a predefined usual (non-placement) `operator delete` (6.7.4). If so, the program is ill-formed, as it was for class member allocation functions and deallocation functions (8.3.4).

C.3.3 Clause 8: expressions

8.16 Change: A conditional expression with a throw expression as its second or third operand keeps the type and value category of the other operand.
Rationale: Formerly mandated conversions (lvalue-to-rvalue (7.1), array-to-pointer (7.2), and function-to-pointer (7.3) standard conversions), especially the creation of the temporary due to lvalue-to-rvalue conversion, were considered gratuitous and surprising.
Effect on original feature: Valid C++ 2011 code that relies on the conversions may behave differently in this International Standard:

```c++
struct S {
  int x = 1;
  void mf() { x = 2; }
};
int f(bool cond) {
  S s;
  (cond ? s : throw 0).mf();
  return s.x;
}
```

In C++ 2011, `f(true)` returns 1. In this International Standard, it returns 2.
```
sizeof(true ? "" : throw 0)
```

In C++ 2011, the expression yields `sizeof(const char*)`. In this International Standard, it yields `sizeof(const char[1])`.

C.3.4 Clause 10: declarations

10.1.5 Change: constexpr non-static member functions are not implicitly `const` member functions.
Rationale: Necessary to allow constexpr member functions to mutate the object.
Effect on original feature: Valid C++ 2011 code may fail to compile in this International Standard. For example, the following code is valid in C++ 2011 but invalid in this International Standard because it declares the same member function twice with different return types:

§ C.3.4
struct S {
    constexpr const int &f();
    int &f();
};

C.3.5 Clause 11: declarators

11.6.1
Change: Classes with default member initializers can be aggregates.
Rationale: Necessary to allow default member initializers to be used by aggregate initialization.
Effect on original feature: Valid C++ 2011 code may fail to compile or may change meaning in this International Standard.

struct S { // Aggregate in C++ 2014 onwards.
    int m = 1;
};
struct X {
    operator int();
    operator S();
};
X a{};
S b{a}; // uses copy constructor in C++ 2011,
// performs aggregate initialization in this International Standard

C.3.6 Clause 20: library introduction

20.5.1.2
Change: New header.
Rationale: New functionality.
Effect on original feature: The C++ header <shared_mutex> is new. Valid C++ 2011 code that #includes a header with that name may be invalid in this International Standard.

C.3.7 Clause 30: input/output library

30.11
Change: gets is not defined.
Rationale: Use of gets is considered dangerous.
Effect on original feature: Valid C++ 2011 code that uses the gets function may fail to compile in this International Standard.

C.4 C++ and ISO C++ 2014

1 This subclause lists the differences between C++ and ISO C++ 2014 (ISO/IEC 14882:2014, Programming Languages — C++), by the chapters of this document.

C.4.1 Clause 5: lexical conventions

5.2
Change: Removal of trigraph support as a required feature.
Rationale: Prevents accidental uses of trigraphs in non-raw string literals and comments.
Effect on original feature: Valid C++ 2014 code that uses trigraphs may not be valid or may have different semantics in this International Standard. Implementations may choose to translate trigraphs as specified in C++ 2014 if they appear outside of a raw string literal, as part of the implementation-defined mapping from physical source file characters to the basic source character set.

5.9
Change: pp-number can contain p sign and P sign.

§ C.4.1
Rationale: Necessary to enable hexadecimal floating literals.

Effect on original feature: Valid C++ 2014 code may fail to compile or produce different results in this International Standard. Specifically, character sequences like 0p+0 and 0e1_p+0 are three separate tokens each in C++ 2014, but one single token in this International Standard.

```
#define F(a) b ## a
int b0p = F(0p+0);  // ill-formed; equivalent to “int b0p = b0p + 0;” in C++ 2014
```

C.4.2 Clause 8: expressions

8.2.6, 8.3.2
Change: Remove increment operator with bool operand.
Rationale: Obsolete feature with occasionally surprising semantics.
Effect on original feature: A valid C++ 2014 expression utilizing the increment operator on a bool lvalue is ill-formed in this International Standard. Note that this might occur when the lvalue has a type given by a template parameter.

8.3.4, 8.3.5
Change: Dynamic allocation mechanism for over-aligned types.
Rationale: Simplify use of over-aligned types.
Effect on original feature: In C++ 2014 code that uses a `new-expression` to allocate an object with an over-aligned class type, where that class has no allocation functions of its own, `::operator new(std::size_t)` is used to allocate the memory. In this International Standard, `::operator new(std::size_t, std::align_val_t)` is used instead.

C.4.3 Clause 10: declarations

10.1.1
Change: Removal of `register` storage-classspecifier.
Rationale: Enable repurposing of deprecated keyword in future revisions of this International Standard.
Effect on original feature: A valid C++ 2014 declaration utilizing the `register` storage-classspecifier is ill-formed in this International Standard. The specifier can simply be removed to retain the original meaning.

10.1.7.4
Change: auto deduction from braced-init-list.
Rationale: More intuitive deduction behavior.
Effect on original feature: Valid C++ 2014 code may fail to compile or may change meaning in this International Standard. For example:

```
auto x1{1};  // was std::initializer_list<int>, now int
auto x2{1, 2};  // was std::initializer_list<int>, now ill-formed
```

C.4.4 Clause 11: declarators

11.3.5
Change: Make exception specifications be part of the type system.
Rationale: Improve type-safety.
Effect on original feature: Valid C++ 2014 code may fail to compile or change meaning in this International Standard:

```
void g1() noexcept;
void g2();
template<class T> int f(T *, T *);
int x = f(g1, g2);  // ill-formed; previously well-formed
```

11.6.1
Change: Definition of an aggregate is extended to apply to user-defined types with base classes.
Rationale: To increase convenience of aggregate initialization.
Effect on original feature: Valid C++ 2014 code may fail to compile or produce different results in this International Standard; initialization from an empty initializer list will perform aggregate initialization instead of invoking a default constructor for the affected types:

```cpp
struct derived;
struct base {
    friend struct derived;
private:
    base();
};
struct derived : base {};

derived d1{}; // Error. The code was well-formed before.
derived d2; // still OK
```

C.4.5 Clause 15: special member functions

15.6.3 Change: Inheriting a constructor no longer injects a constructor into the derived class.
Rationale: Better interaction with other language features.
Effect on original feature: Valid C++ 2014 code that uses inheriting constructors may not be valid or may have different semantics. A using-declaration that names a constructor now makes the corresponding base class constructors visible to initializations of the derived class rather than declaring additional derived class constructors.

```cpp
struct A {
    template<typename T> A(T, typename T::type = 0);
    A(int);
};
struct B : A {
    using A::A;
    B(int);
};
B b(42L); // now calls B(int), used to call B<long>(long),
    // which called A(int) due to substitution failure
    // in A<long>(long).
```

C.4.6 Clause 17: templates

17.8.2.5 Change: Allowance to deduce from the type of a non-type template argument.
Rationale: In combination with the ability to declare non-type template arguments with placeholder types, allows partial specializations to decompose from the type deduced for the non-type template argument.
Effect on original feature: Valid C++ 2014 code may fail to compile or produce different results in this International Standard:

```cpp
template <int N> struct A;
template <typename T, T N> int foo(A<N> *) = delete;
void foo(void *)
void bar(A<0> *p) {
    foo(p); // ill-formed; previously well-formed
}
```

C.4.7 Clause 18: exception handling

18.4 Change: Remove dynamic exception specifications.
Rationale: Dynamic exception specifications were a deprecated feature that was complex and brittle in use. They interacted badly with the type system, which became a more significant issue in this International Standard where (non-dynamic) exception specifications are part of the function type.

Effect on original feature: A valid C++ 2014 function declaration, member function declaration, function pointer declaration, or function reference declaration, if it has a potentially throwing dynamic exception specification, will be rejected as ill-formed in this International Standard. Violating a non-throwing dynamic exception specification will call `terminate` rather than `unexpected` and might not perform stack unwinding prior to such a call.

C.4.8 Clause 20: library introduction  [diff.cpp14.library]

20.5.4.2.3

Change: New reserved namespaces.

Rationale: Reserve namespaces for future revisions of the standard library that might otherwise be incompatible with existing programs.

Effect on original feature: The global namespaces `std` followed by an arbitrary sequence of digits is reserved for future standardization. Valid C++ 2014 code that uses such a top-level namespace, e.g., `std2`, may be invalid in this International Standard.

C.4.9 Clause 23: general utilities library  [diff.cpp14.utilities]

23.14.13

Change: Constructors taking allocators removed.

Rationale: No implementation consensus.

Effect on original feature: Valid C++ 2014 code may fail to compile or may change meaning in this International Standard. Specifically, constructing a `std::function` with an allocator is ill-formed and uses-allocator construction will not pass an allocator to `std::function` constructors in this International Standard.

23.11.2.2

Change: Different constraint on conversions from `unique_ptr`.

Rationale: Adding array support to `shared_ptr`, via the syntax `shared_ptr<T[]>` and `shared_ptr<T[N]>`. Valid C++ 2014 code may fail to compile or may change meaning in this International Standard. For example:

```cpp
#include <memory>
std::unique_ptr<int[]> arr(new int[1]);
std::shared_ptr<int> ptr(std::move(arr));  // error: int(*)[] is not compatible with int*
```

C.4.10 Clause 24: strings library  [diff.cpp14.string]

24.3.2

Change: Non-const `.data()` member added.

Rationale: The lack of a non-const `.data()` differed from the similar member of `std::vector`. This change regularizes behavior for this International Standard.

Effect on original feature: Overloaded functions which have differing code paths for `char*` and `const char*` arguments will execute differently when called with a non-const string’s `.data()` member in this International Standard.

```cpp
int f(char *) = delete;
int f(const char *);
string s;
int x = f(s.data());  // ill-formed; previously well-formed
```
C.4.11 Clause 26: containers library

26.2.6 Change: Requirements change:
Rationale: Increase portability, clarification of associative container requirements.
Effect on original feature: Valid C++ 2014 code that attempts to use associative containers having a comparison object with non-const function call operator may fail to compile in this International Standard:

```cpp
#include <set>

struct compare
{
    bool operator()(int a, int b)
    {
        return a < b;
    }
};

int main()
{
    const std::set<int, compare> s;
    s.find(0);
}
```

C.4.12 Annex D: compatibility features

Change: The class templates `auto_ptr`, `unary_function`, and `binary_function`, the function templates `random_shuffle`, and the function templates (and their return types) `ptr_fun`, `mem_fun`, `mem_fun_ref`, `bind1st`, and `bind2nd` are not defined.
Rationale: Superseded by new features.
Effect on original feature: Valid C++ 2014 code that uses these class templates and function templates may fail to compile in this International Standard.

Change: Remove old iostreams members [depr.ios.members].
Rationale: Redundant feature for compatibility with pre-standard code has served its time.
Effect on original feature: A valid C++ 2014 program using these identifiers may be ill-formed in this International Standard.

C.5 C standard library

This subclause summarizes the explicit changes in headers, definitions, declarations, or behavior between the C standard library in the C standard and the parts of the C++ standard library that were included from the C standard library.

C.5.1 Modifications to headers

1 For compatibility with the C standard library, the C++ standard library provides the C headers enumerated in D.5, but their use is deprecated in C++.
2 There are no C++ headers for the C headers `<stdatomic.h>`, `<stdnoreturn.h>`, and `<threads.h>`, nor are the C headers themselves part of C++.
3 The C++ headers `<complex>` (D.4.1) and `<ctgmath>` (D.4.4), as well as their corresponding C headers `<complex.h>` and `<tgmath.h>`, do not contain any of the content from the C standard library and instead merely include other headers from the C++ standard library.
C.5.2 Modifications to definitions

C.5.2.1 Types char16_t and char32_t

The types char16_t and char32_t are distinct types rather than typedefs to existing integral types. The tokens char16_t and char32_t are keywords in this International Standard (5.11). They do not appear as macro names defined in <uchar> (24.5.5).

C.5.2.2 Type wchar_t

The type wchar_t is a distinct type rather than a typedef to an existing integral type. The token wchar_t is a keyword in this International Standard (5.11). It does not appear as a type name defined in any of <cstddef> (21.2.1), <cstdlib> (21.2.2), or <cwchar> (24.5.4).

C.5.2.3 Header <cassert.h>

The token static_assert is a keyword in this International Standard (5.11). It does not appear as a macro name defined in <cassert> (22.3.1).

C.5.2.4 Header <iso646.h>

The tokens and, and_eq, bitand, bitor, compl, not_eq, not, or, or_eq, xor, and xor_eq are keywords in this International Standard (5.11). They do not appear as macro names defined in <iso646>.

C.5.2.5 Header <stdalign.h>

The token alignas is a keyword in this International Standard (5.11). It does not appear as a macro name defined in <stdalign> (D.4.2).

C.5.2.6 Header <stdbool.h>

The tokens bool, true, and false are keywords in this International Standard (5.11). They do not appear as macro names defined in <stdbool> (D.4.3).

C.5.2.7 Macro NULL

The macro NULL, defined in any of <locale> (25.5), <cstdlib> (21.2.1), <stdio> (30.11.1), <stdlib> (21.2.2), <cstring> (24.5.3), <ctime> (23.17.8), or <cwchar> (24.5.4), is an implementation-defined C++ null pointer constant in this International Standard (21.2).

C.5.3 Modifications to declarations

Header <cstring> (24.5.3): The following functions have different declarations:

(1.1) — strchr
(1.2) — strpbrk
(1.3) — strrrchr
(1.4) — strstr
(1.5) — memchr

Subclause 24.5.3 describes the changes.

Header <cwchar> (24.5.4): The following functions have different declarations:

(2.1) — wcschr
(2.2) — wcspbrk
(2.3) — wcsrchr
Subclause 24.5.4 describes the changes.

3 Header `<cstdlib>` (21.2.2) declares the name `nullptr_t` in addition to the names declared in `<stddef.h>` in the C standard library.

**C.5.4 Modifications to behavior** [diff.mods.to.behavior]

1 Header `<cstdlib>` (21.2.2): The following functions have different behavior:

   (1.1) — `atexit`
   (1.2) — `exit`
   (1.3) — `abort`

   Subclause 21.5 describes the changes.

2 Header `<csetjmp>` (21.10.2): The following functions have different behavior:

   (2.1) — `longjmp`

   Subclause 21.10.2 describes the changes.

**C.5.4.1 Macro `offsetof(type, member-designator)`** [diff.offsetof]

1 The macro `offsetof`, defined in `<cstdlib>` (21.2.1), accepts a restricted set of `type` arguments in this International Standard. Subclause 21.2.4 describes the change.

**C.5.4.2 Memory allocation functions** [diff.malloc]

1 The functions `aligned_alloc`, `calloc`, `malloc`, and `realloc` are restricted in this International Standard. Subclause 23.10.11 describes the changes.
Annex D  (normative)
Compatibility features  [depr]

1 This Clause describes features of the C++ Standard that are specified for compatibility with existing implementations.

2 These are deprecated features, where deprecated is defined as: Normative for the current edition of this International Standard, but having been identified as a candidate for removal from future revisions. An implementation may declare library names and entities described in this section with the deprecated attribute (10.6.4).

D.1 Redeclaration of static constexpr data members  [depr.static constexpr]

1 For compatibility with prior C++ International Standards, a constexpr static data member may be redundantly redeclared outside the class with no initializer. This usage is deprecated. [Example:

```c++
struct A {
    static constexpr int n = 5;  // definition (declaration in C++ 2014)
};

constexpr int A::n;  // redundant declaration (definition in C++ 2014)
—end example]
```

D.2 Implicit declaration of copy functions  [depr.impldec]

1 The implicit definition of a copy constructor as defaulted is deprecated if the class has a user-declared copy assignment operator or a user-declared destructor. The implicit definition of a copy assignment operator as defaulted is deprecated if the class has a user-declared copy constructor or a user-declared destructor (15.4, 15.8). In a future revision of this International Standard, these implicit definitions could become deleted (11.4).

D.3 Deprecated exception specifications  [depr.except.spec]

1 The noexcept-specifier throw() is deprecated.

D.4 C++ standard library headers  [depr.cpp.headers]

1 For compatibility with prior C++ International Standards, the C++ standard library provides headers <ccomplex> (D.4.1), <cstdalign> (D.4.2), <cstdbool> (D.4.3), and <ctgmath> (D.4.4). The use of these headers is deprecated.

D.4.1 Header <ccomplex> synopsis  [depr.ccomplex.syn]

```c
#include <complex>
```
1 The header <ccomplex> behaves as if it simply includes the header <complex> (29.5.1).

D.4.2 Header <cstdalign> synopsis  [depr.cstdalign.syn]

```c
#define __alignas_is_defined 1
```
1 The contents of the header <cstdalign> are the same as the C standard library header <stdalign.h>, with the following changes: The header <cstdalign> and the header <stdalign.h> shall not define a macro named alignas.
D.4.3 Header <stdbool.h> synopsis

```
#define __bool_true_false_are_defined 1
```

The contents of the header <stdbool.h> are the same as the C standard library header <stdbool.h>, with the following changes: The header <stdbool.h> and the header <stdbool.h> shall not define macros named bool, true, or false.

See also: ISO C 7.15.

D.4.4 Header <ctgmath> synopsis

```
#include <complex>
#include <cmath>
```

The header <ctgmath> simply includes the headers <complex> (29.5.1) and <cmath> (29.9.1).

1 The header <ctgmath> simply includes the headers <complex> (29.5.1) and <cmath> (29.9.1).

2 [Note: The overloads provided in C by type-generic macros are already provided in <complex> and <cmath> by “sufficient” additional overloads. — end note]

D.5 C standard library headers

For compatibility with the C standard library, the C++ standard library provides the C headers shown in Table 141.

| <assert.h> | <inttypes.h> | <signal.h> | <stdio.h> | <wchar.h> |
| <complex.h> | <iso646.h> | <stdalign.h> | <stdlib.h> | <wctype.h> |
| <cttype.h> | <limits.h> | <stdarg.h> | <string.h> |
| <errno.h> | <locale.h> | <stdbool.h> | <tgmath.h> |
| <fenv.h> | <math.h> | <stddef.h> | <time.h> |
| <float.h> | <setjmp.h> | <stdint.h> | <uchar.h> |

2 The header <complex.h> behaves as if it simply includes the header <ccomplex>. The header <tgmath.h> behaves as if it simply includes the header <ctgmath>.

3 Every other C header, each of which has a name of the form name.h, behaves as if each name placed in the standard library namespace by the corresponding c name header is placed within the global namespace scope, except for the functions described in 29.9.5, the declaration of std::byte (21.2.1), and the functions and function templates described in 21.2.5. It is unspecified whether these names are first declared or defined within namespace scope (6.3.6) of the namespace std and are then injected into the global namespace scope by explicit using-declarations (10.3.3).

4 [Example: The header <cstdlib> assuredly provides its declarations and definitions within the namespace std. It may also provide these names within the global namespace. The header <stdlib.h> assuredly provides the same declarations and definitions within the global namespace, much as in the C Standard. It may also provide these names within the namespace std. — end example]

D.6 char* streams

The header <strstream> defines three types that associate stream buffers with character array objects and assist reading and writing such objects.

D.6.1 Class strstreambuf

```
namespace std {
    class strstreambuf : public basic_streambuf<char> {
```
public:
    explicit strstreambuf(streamsize alsize_arg = 0);
    strstreambuf(void* (*palloc_arg)(size_t), void (*pfree_arg)(void*));
    strstreambuf(char* gnext_arg, streamsize n, char* pbeg_arg = 0);
    strstreambuf(const char* gnexarg, streamsize n);

    strstreambuf(signed char* gnexarg, streamsize n,
                 signed char* pbeg_arg = 0);
    strstreambuf(const signed char* gnexarg, streamsize n);
    strstreambuf(unsigned char* gnexarg, streamsize n,
                 unsigned char* pbeg_arg = 0);
    strstreambuf(const unsigned char* gnexarg, streamsize n);

    virtual ~strstreambuf();

    void freeze(bool freezefl = true);
    char* str();
    int pcount();

protected:
    int_type overflow (int_type c = EOF) override;
    int_type pbackfail(int_type c = EOF) override;
    int_type underflow() override;
    pos_type seekoff(off_type off, ios_base::seekdir way,
                     ios_base::openmode which = ios_base::in | ios_base::out) override;
    pos_type seekpos(pos_type sp,
                     ios_base::openmode which = ios_base::in | ios_base::out) override;
    streambuf* setbuf(char* s, streamsize n) override;

private:
    using strstate = T1;  // exposition only
    static const strstate allocated;  // exposition only
    static const strstate constant;  // exposition only
    static const strstate dynamic;  // exposition only
    static const strstate frozen;  // exposition only
    strstate strmode;  // exposition only
    streamsize alsize;  // exposition only
    void* (*palloc)(size_t);  // exposition only
    void (*pfree)(void*);  // exposition only

};

1 The class strstreambuf associates the input sequence, and possibly the output sequence, with an object of some character array type, whose elements store arbitrary values. The array object has several attributes.

2 [Note: For the sake of exposition, these are represented as elements of a bitmask type (indicated here as T1) called strstate. The elements are:

   (2.1) allocated, set when a dynamic array object has been allocated, and hence should be freed by the destructor for the strstreambuf object;

   (2.2) constant, set when the array object has const elements, so the output sequence cannot be written;

   (2.3) dynamic, set when the array object is allocated (or reallocated) as necessary to hold a character sequence that can change in length;]
(2.4) — frozen, set when the program has requested that the array object not be altered, reallocated, or freed.
— end note]

3 [ Note: For the sake of exposition, the maintained data is presented here as:

(3.1) — strstate strmode, the attributes of the array object associated with the strstreambuf object;
(3.2) — int alsize, the suggested minimum size for a dynamic array object;
(3.3) — void* (*palloc)(size_t), points to the function to call to allocate a dynamic array object;
(3.4) — void (*pfree)(void*), points to the function to call to free a dynamic array object.
— end note]

Each object of class strstreambuf has a seekable area, delimited by the pointers seeklow and seekhigh. If
gnext is a null pointer, the seekable area is undefined. Otherwise, seeklow equals gbeg and seekhigh is
either pend, if pend is not a null pointer, or gend.

D.6.1.1 strstreambuf constructors [depr.strstreambuf.cons]

explicit strstreambuf(streamsize alsize_arg = 0);

1 Effects: Constructs an object of class strstreambuf, initializing the base class with streambuf(). The
postconditions of this function are indicated in Table 142.

Table 142 — strstreambuf(streamsize) effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>strmode</td>
<td>dynamic</td>
</tr>
<tr>
<td>alsize</td>
<td>alsize_arg</td>
</tr>
<tr>
<td>palloc</td>
<td>a null pointer</td>
</tr>
<tr>
<td>pfree</td>
<td>a null pointer</td>
</tr>
</tbody>
</table>

strstreambuf(void* (*palloc_arg)(size_t), void (*pfree_arg)(void*));

2 Effects: Constructs an object of class strstreambuf, initializing the base class with streambuf(). The
postconditions of this function are indicated in Table 143.

Table 143 — strstreambuf(void* (*)(size_t), void (*)(void*)) effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>strmode</td>
<td>dynamic</td>
</tr>
<tr>
<td>alsize</td>
<td>an unspecified value</td>
</tr>
<tr>
<td>palloc</td>
<td>palloc_arg</td>
</tr>
<tr>
<td>pfree</td>
<td>pfree_arg</td>
</tr>
</tbody>
</table>

strstreambuf(char* gnext_arg, streamsize n, char* pbeg_arg = 0);
strstreambuf(signed char* gnext_arg, streamsize n,
  signed char* pbeg_arg = 0);
strstreambuf(unsigned char* gnext_arg, streamsize n,
  unsigned char* pbeg_arg = 0);

3 Effects: Constructs an object of class strstreambuf, initializing the base class with streambuf(). The
postconditions of this function are indicated in Table 144.
Table 144 — `strstreambuf(charT*, streamsize, charT*)` effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>strmode</td>
<td>0</td>
</tr>
<tr>
<td>alsize</td>
<td>an unspecified value</td>
</tr>
<tr>
<td>palloc</td>
<td>a null pointer</td>
</tr>
<tr>
<td>pfree</td>
<td>a null pointer</td>
</tr>
</tbody>
</table>

4 `gnext_arg` shall point to the first element of an array object whose number of elements `N` is determined as follows:

- If `n > 0`, `N` is `n`.
- If `n == 0`, `N` is `std::strlen(gnext_arg)`.
- If `n < 0`, `N` is INT_MAX.331

5 If `pbeg_arg` is a null pointer, the function executes:

```
setg(gnext_arg, gnext_arg, gnext_arg + N);
```

Otherwise, the function executes:

```
setg(gnext_arg, gnext_arg, pbeg_arg);
setp(pbeg_arg, pbeg_arg + N);
```

`strstreambuf(const char* gnext_arg, streamsize n);`
`strstreambuf(const signed char* gnext_arg, streamsize n);`
`strstreambuf(const unsigned char* gnext_arg, streamsize n);`

7 **Effects:** Behaves the same as `strstreambuf((char*)gnext_arg,n)`, except that the constructor also sets constant in `strmode`.

virtual ~`strstreambuf();`

8 **Effects:** Destroys an object of class `strstreambuf`. The function frees the dynamically allocated array object only if `(strmode & allocated) != 0` and `(strmode & frozen) == 0`. (D.6.1.3 describes how a dynamically allocated array object is freed.)

D.6.1.2 Member functions

**void freeze(bool freezefl = true);**

1 **Effects:** If `strmode & dynamic` is nonzero, alters the freeze status of the dynamic array object as follows:

- If `freezefl` is `true`, the function sets `frozen` in `strmode`.
- Otherwise, it clears `frozen` in `strmode`.

```
char* str();
```

2 **Effects:** Calls `freeze()`, then returns the beginning pointer for the input sequence, `gbeg`.

```
int pcount() const;
```

3 **Remarks:** The return value can be a null pointer.

331) The function signature `strlen(const char*)` is declared in `<cstring>` (24.5.3). The macro INT_MAX is defined in `<climits>` (21.3.5).

§ D.6.1.2
Effects: If the next pointer for the output sequence, pnext, is a null pointer, returns zero. Otherwise, returns the current effective length of the array object as the next pointer minus the beginning pointer for the output sequence, pnext - pbeg.

D.6.1.3 strstreambuf overridden virtual functions

int_type overflow(int_type c = EOF) override;

Effects: Appends the character designated by c to the output sequence, if possible, in one of two ways:

(1.1) If c != EOF and if either the output sequence has a write position available or the function makes a write position available (as described below), assigns c to *pnext++.

Returns (unsigned char)c.

(1.2) If c == EOF, there is no character to append.

Returns a value other than EOF.

Remarks: The function can alter the number of write positions available as a result of any call.

To make a write position available, the function reallocates (or initially allocates) an array object with a sufficient number of elements n to hold the current array object (if any), plus at least one additional write position. How many additional write positions are made available is otherwise unspecified. If palloc is not a null pointer, the function calls (*palloc)(n) to allocate the new dynamic array object. Otherwise, it evaluates the expression new charT[n]. In either case, if the allocation fails, the function returnsEOF. Otherwise, it sets allocated in strmode.

To free a previously existing dynamic array object whose first element address is p: If pfree is not a null pointer, the function calls (*pfree)(p). Otherwise, it evaluates the expression delete[]p.

If (strmode & dynamic) == 0, or if (strmode & frozen) != 0, the function cannot extend the array (realloccate it with greater length) to make a write position available.

int_type pbackfail(int_type c = EOF) override;

Puts back the character designated by c to the input sequence, if possible, in one of three ways:

(7.1) If c != EOF, if the input sequence has a putback position available, and if (char)c == gnext[-1], assigns gnext - 1 to gnext.

Returns c.

(7.2) If c != EOF, if the input sequence has a putback position available, and if strmode & constant is zero, assigns c to *--gnext.

Returns c.

(7.3) If c == EOF and if the input sequence has a putback position available, assigns gnext - 1 to gnext.

Returns a value other than EOF.

Returns EOF to indicate failure.

Remarks: If the function can succeed in more than one of these ways, it is unspecified which way is chosen. The function can alter the number of putback positions available as a result of any call.

int_type underflow() override;

§ D.6.1.3
Effects: Reads a character from the input sequence, if possible, without moving the stream position past it, as follows:

(10.1) If the input sequence has a read position available, the function signals success by returning (unsigned char)*gnext.

(10.2) Otherwise, if the current write next pointer pnext is not a null pointer and is greater than the current read end pointer gend, makes a read position available by assigning to gend a value greater than gnext and no greater than pnext.

Returns (unsigned char)*gnext.

Remarks: The function can alter the number of read positions available as a result of any call.

Returns EOF to indicate failure.

pos_type seekoff(off_type off, seekdir way, openmode which = in | out) override;

Effects: Alters the stream position within one of the controlled sequences, if possible, as indicated in Table 145.

Table 145 — seekoff positioning

<table>
<thead>
<tr>
<th>Conditions</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>(which &amp; ios::in) != 0</td>
<td>positions the input sequence</td>
</tr>
<tr>
<td>(which &amp; ios::out) != 0</td>
<td>positions the output sequence</td>
</tr>
<tr>
<td>(which &amp; (ios::in</td>
<td>ios::out)) == (ios::in</td>
</tr>
<tr>
<td>Otherwise</td>
<td>the positioning operation fails.</td>
</tr>
</tbody>
</table>

For a sequence to be positioned, if its next pointer is a null pointer, the positioning operation fails. Otherwise, the function determines newoff as indicated in Table 146.

Table 146 — newoff values

<table>
<thead>
<tr>
<th>Condition</th>
<th>newoff Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>way == ios::beg</td>
<td>0</td>
</tr>
<tr>
<td>way == ios::cur</td>
<td>the next pointer minus the beginning pointer (xnext - xbeg).</td>
</tr>
<tr>
<td>way == ios::end</td>
<td>seekhigh minus the beginning pointer (seekhigh - xbeg).</td>
</tr>
</tbody>
</table>

If (newoff + off) < (seeklow - xbeg) or (seekhigh - xbeg) < (newoff + off), the positioning operation fails. Otherwise, the function assigns xbeg + newoff + off to the next pointer xnext.

Returns: pos_type(newoff), constructed from the resultant offset newoff (of type off_type), that stores the resultant stream position, if possible. If the positioning operation fails, or if the constructed object cannot represent the resultant stream position, the return value is pos_type(off_type(-1)).

pos_type seekpos(pos_type sp, ios_base::openmode which = ios_base::in | ios_base::out) override;
Effects: Alters the stream position within one of the controlled sequences, if possible, to correspond to the stream position stored in sp (as described below).

- If (which & ios::in) != 0, positions the input sequence.
- If (which & ios::out) != 0, positions the output sequence.
- If the function positions neither sequence, the positioning operation fails.

For a sequence to be positioned, if its next pointer is a null pointer, the positioning operation fails. Otherwise, the function determines newoff from sp.offset():

- If newoff is an invalid stream position, has a negative value, or has a value greater than (seekhigh - seeklow), the positioning operation fails
- Otherwise, the function adds newoff to the beginning pointer xbeg and stores the result in the next pointer xnext.

Returns: pos_type(newoff), constructed from the resultant offset newoff (of type off_type), that stores the resultant stream position, if possible. If the positioning operation fails, or if the constructed object cannot represent the resultant stream position, the return value is pos_type(off_type(-1)).

Effects: Implementation defined, except that setbuf(0, 0) has no effect.

D.6.2 Class istrstream [depr.istrstream]

namespace std {
    class istrstream : public basic_istream<char> { public:
        explicit istrstream(const char* s);
        explicit istrstream(char* s);
        istrstream(const char* s, streamsize n);
        istrstream(char* s, streamsize n);
        virtual ~istrstream();

        strstreambuf* rdbuf() const;
        char* str();
    private:
        strstreambuf sb; // exposition only
    };
}

The class istrstream supports the reading of objects of class strstreambuf. It supplies a strstreambuf object to control the associated array object. For the sake of exposition, the maintained data is presented here as:

- sb, the strstreambuf object.

D.6.2.1 istrstream constructors [depr.istrstream.cons]

explicit istrstream(const char* s);
explicit istrstream(char* s);

Effects: Constructs an object of class istrstream, initializing the base class with istream(&sb) and initializing sb with strstreambuf(s,0). s shall designate the first element of an NTBS.

istrstream(const char* s, streamsize n);
istrstream(char* s, streamsize n);
Constructs an object of class \texttt{istrstream}, initializing the base class with \texttt{istream(&sb)} and initializing \texttt{sb} with \texttt{strstreambuf(s,n)}. \texttt{s} shall designate the first element of an array whose length is \texttt{n} elements, and \texttt{n} shall be greater than zero.

\section*{D.6.2.2 Member functions \[depr.istrstream.members\]}

\begin{verbatim}
strstreambuf* rdbuf() const;

Returns: const_cast<strstreambuf*>(&sb).
\end{verbatim}

\begin{verbatim}
char* str();

Returns: rdbuf()->str().
\end{verbatim}

\section*{D.6.3 Class \texttt{ostrstream} \[depr.ostrstream\]}

\begin{verbatim}
namespace std {
    class ostrstream : public basic_ostream<char> {
        public:
            ostrstream();
            ostrstream(char* s, int n, ios_base::openmode mode = ios_base::out);
            virtual ~ostrstream();
            strstreambuf* rdbuf() const;
            void freeze(bool freezefl = true);
            char* str();
            int pcount() const;
        private:
            strstreambuf sb; // exposition only
    };
}
\end{verbatim}

The class \texttt{ostrstream} supports the writing of objects of class \texttt{strstreambuf}. It supplies a \texttt{strstreambuf} object to control the associated array object. For the sake of exposition, the maintained data is presented here as:

\begin{enumerate}
    \item \texttt{sb}, the \texttt{strstreambuf} object.
\end{enumerate}

\section*{D.6.3.1 ostrstream constructors \[depr.ostrstream.cons\]}

\begin{verbatim}
ostrstream();
\end{verbatim}

\begin{verbatim}
ostrstream(char* s, int n, ios_base::openmode mode = ios_base::out);
\end{verbatim}

\begin{verbatim}
ostrstream(char* s, int n, ios_base::openmode mode = ios_base::out);
\end{verbatim}

\begin{enumerate}
    \item Effects: Constructs an object of class \texttt{ostrstream}, initializing the base class with \texttt{ostream(&sb)} and initializing \texttt{sb} with \texttt{strstreambuf()}. \texttt{os}
    \item Effects: Constructs an object of class \texttt{ostrstream}, initializing the base class with \texttt{ostream(&sb)}, and initializing \texttt{sb} with one of two constructors:
\end{enumerate}

\begin{enumerate}
    \item If (mode & app) == 0, then \texttt{s} shall designate the first element of an array of \texttt{n} elements. The constructor is \texttt{strstreambuf(s, n, s)}.
    \item If (mode & app) != 0, then \texttt{s} shall designate the first element of an array of \texttt{n} elements that contains an NTBS whose first element is designated by \texttt{s}. The constructor is \texttt{strstreambuf(s, n, s + std::strlen(s))}.\footnote{The function signature \texttt{strlen(const char*)} is declared in \texttt{<cstring> (24.5.3)}.}
\end{enumerate}

\section*{D.6.3.2 Member functions \[depr.ostrstream.members\]}

\section*{§ D.6.3.2 1468}
strstreambuf* rdbuf() const;

   Returns: *(strstreambuf*)&sb.

void freeze(bool freezefl = true);

   Effects: Calls rdbuf()->freeze(freezefl).

char* str();

   Returns: rdbuf()->str().

int pcount() const;

   Returns: rdbuf()->pcount().

D.6.4 Class strstream

namespace std {

class strstream
   : public basic_iostream<char> {
public:
   // Types
   using char_type = char;
   using int_type = char_traits<char>::int_type;
   using pos_type = char_traits<char>::pos_type;
   using off_type = char_traits<char>::off_type;

   // constructors/destructor
   strstream();
   strstream(char* s, int n,
      ios_base::openmode mode = ios_base::in|ios_base::out);
   virtual ~strstream();

   // Members:
   strstreambuf* rdbuf() const;
   void freeze(bool freezefl = true);
   int pcount() const;
   char* str();

private:
   strstreambuf sb; // exposition only
};
}

The class strstream supports reading and writing from objects of class strstreambuf. It supplies a strstreambuf object to control the associated array object. For the sake of exposition, the maintained data is presented here as:

— sb, the strstreambuf object.

D.6.4.1 strstream constructors

strstream();

   Effects: Constructs an object of class strstream, initializing the base class with iostream(&sb).

strstream(char* s, int n,
      ios_base::openmode mode = ios_base::in|ios_base::out);
Effects: Constructs an object of class `strstream`, initializing the base class with `iostream(&sb)` and initializing `sb` with one of the two constructors:

(2.1) If `(mode & app) == 0`, then `s` shall designate the first element of an array of `n` elements. The constructor is `strstreambuf(s,n,s)`.

(2.2) If `(mode & app) != 0`, then `s` shall designate the first element of an array of `n` elements that contains an NTBS whose first element is designated by `s`. The constructor is `strstreambuf(s,n,s + std::strlen(s))`.

D.6.4.2 `strstream` destructor

```cpp
virtual ~strstream();
```

Effects: Destroys an object of class `strstream`.

D.6.4.3 `strstream` operations

```cpp
strstreambuf* rdbuf() const;
```

Returns: `&sb`.

```cpp
void freeze(bool freezefl = true);
```

Effects: Calls `rbuf()->freeze(freezefl)`.

```cpp
char* str();
```

Returns: `rbuf()->str()`.

```cpp
int pcount() const;
```

Returns: `rbuf()->pcount()`.

D.7 `uncaught_exception`

```cpp
bool uncaught_exception() noexcept;
```

Returns: `uncaught_exceptions() > 0`.

D.8 Old adaptable function bindings

D.8.1 Weak result types

A call wrapper (23.14.2) may have a weak result type. If it does, the type of its member type `result_type` is based on the type `T` of the wrapper's target object:

(1.1) if `T` is a pointer to function type, `result_type` shall be a synonym for the return type of `T`;

(1.2) if `T` is a pointer to member function, `result_type` shall be a synonym for the return type of `T`;

(1.3) if `T` is a class type and the qualified-id `T::result_type` is valid and denotes a type (17.8.2), then `result_type` shall be a synonym for `T::result_type`;

(1.4) otherwise `result_type` shall not be defined.

D.8.2 Typedefs to support function binders

To enable old function adaptors to manipulate function objects that take one or two arguments, many of the function objects in this International Standard correspondingly provide typedef-names `argument_type` and
result_type for function objects that take one argument and first_argument_type, second_argument_type, and result_type for function objects that take two arguments.

2 The following member names are defined in addition to names specified in Clause 23.14:

```cpp
namespace std {
    template<class T> struct owner_less<shared_ptr<T>> {
        using result_type = bool;
        using first_argument_type = shared_ptr<T>;
        using second_argument_type = shared_ptr<T>;
    };

    template<class T> struct owner_less<weak_ptr<T>> {
        using result_type = bool;
        using first_argument_type = weak_ptr<T>;
        using second_argument_type = weak_ptr<T>;
    };

    template <class T> class reference_wrapper {
        public:
            using result_type = see below; // not always defined
            using argument_type = see below; // not always defined
            using first_argument_type = see below; // not always defined
            using second_argument_type = see below; // not always defined
    };

    template <class T> struct plus {
        using first_argument_type = T;
        using second_argument_type = T;
        using result_type = T;
    };

    template <class T> struct minus {
        using first_argument_type = T;
        using second_argument_type = T;
        using result_type = T;
    };

    template <class T> struct multiplies {
        using first_argument_type = T;
        using second_argument_type = T;
        using result_type = T;
    };

    template <class T> struct divides {
        using first_argument_type = T;
        using second_argument_type = T;
        using result_type = T;
    };

    template <class T> struct modulus {
        using first_argument_type = T;
        using second_argument_type = T;
        using result_type = T;
    };

    § D.8.2 1471
}
template <class T> struct negate {
    using argument_type = T;
    using result_type = T;
};

template <class T> struct equal_to {
    using first_argument_type = T;
    using second_argument_type = T;
    using result_type = bool;
};

template <class T> struct not_equal_to {
    using first_argument_type = T;
    using second_argument_type = T;
    using result_type = bool;
};

template <class T> struct greater {
    using first_argument_type = T;
    using second_argument_type = T;
    using result_type = bool;
};

template <class T> struct less {
    using first_argument_type = T;
    using second_argument_type = T;
    using result_type = bool;
};

template <class T> struct greater_equal {
    using first_argument_type = T;
    using second_argument_type = T;
    using result_type = bool;
};

template <class T> struct less_equal {
    using first_argument_type = T;
    using second_argument_type = T;
    using result_type = bool;
};

template <class T> struct logical_and {
    using first_argument_type = T;
    using second_argument_type = T;
    using result_type = bool;
};

template <class T> struct logical_or {
    using first_argument_type = T;
    using second_argument_type = T;
    using result_type = bool;
};

template <class T> struct logical_not {
    using argument_type = T;
}
using result_type = bool;
};

template <class T> struct bit_and {
    using first_argument_type = T;
    using second_argument_type = T;
    using result_type = T;
};

template <class T> struct bit_or {
    using first_argument_type = T;
    using second_argument_type = T;
    using result_type = T;
};

template <class T> struct bit_xor {
    using first_argument_type = T;
    using second_argument_type = T;
    using result_type = T;
};

template <class T> struct bit_not {
    using argument_type = T;
    using result_type = T;
};

template<class R, class T1>
class function<R(T1)> { 
    public:
        using argument_type = T1;
    }

template<class R, class T1, class T2>
class function<R(T1, T2)> { 
    public:
        using first_argument_type = T1;
        using second_argument_type = T2;
    }
}

3 reference_wrapper<T> has a weak result type (D.8.1). If T is a function type, result_type shall be a synonym for the return type of T.

4 The template specialization reference_wrapper<T> shall define a nested type named argument_type as a synonym for T1 only if the type T is any of the following:

(4.1) — a function type or a pointer to function type taking one argument of type T1
(4.2) — a pointer to member function R T0::f() cv (where cv represents the member function's cv-qualifiers); the type T1 is cv T0*
(4.3) — a class type where the qualified-id T::argument_type is valid and denotes a type (17.8.2); the type T1 is T::argument_type.

5 The template instantiation reference_wrapper<T> shall define two nested types named first_argument_type and second_argument_type as synonyms for T1 and T2, respectively, only if the type T is any of the following:

§ D.8.2
— a function type or a pointer to function type taking two arguments of types \(T1\) and \(T2\)

(5.2) — a pointer to member function \(R\ T0::f(T2)\) \(cv\) (where \(cv\) represents the member function’s \(cv\)-qualifiers);
the type \(T1\) is \(cv\ T0*\)

(5.3) — a class type where the qualified-ids \(T::first_argument_type\) and \(T::second_argument_type\) are both valid and both denote types \(17.8.2\); the type \(T1\) is \(T::first_argument_type\) and the type \(T2\) is \(T::second_argument_type\).

6 All enabled specializations \(\text{hash}<Key>\) of \(\text{hash} (23.14.15)\) provide two nested types, \(\text{result_type}\) and \(\text{argument_type}\), which shall be synonyms for \(\text{size_t}\) and \(\text{Key}\), respectively.

7 The forwarding call wrapper \(g\) returned by a call to \(\text{bind}(f, \text{bound_args}...)\) \(23.14.11.3\) shall have a weak result type \(\text{D.8.1}\).

8 The forwarding call wrapper \(g\) returned by a call to \(\text{bind}<R>(f, \text{bound_args}...)\) \(23.14.11.3\) shall have a nested type \(\text{result_type}\) defined as a synonym for \(R\).

9 The simple call wrapper returned from a call to \(\text{mem_fn}(pm)\) shall have a nested type \(\text{result_type}\) that is a synonym for the return type of \(pm\) when \(pm\) is a pointer to member function.

10 The simple call wrapper returned from a call to \(\text{mem_fn}(pm)\) shall define two nested types named \(\text{argument_type}\) and \(\text{result_type}\) as synonyms for \(cv T*\) and \(\text{Ret}\), respectively, when \(pm\) is a pointer to member function with \(cv\)-qualifier \(cv\) and taking no arguments, where \(\text{Ret}\) is \(pm\)’s return type.

11 The simple call wrapper returned from a call to \(\text{mem_fn}(pm)\) shall define three nested types named \(\text{first_argument_type}\), \(\text{second_argument_type}\), and \(\text{result_type}\) as synonyms for \(cv T*, T1,\) and \(\text{Ret}\), respectively, when \(pm\) is a pointer to member function with \(cv\)-qualifier \(cv\) and taking one argument of type \(T1\), where \(\text{Ret}\) is \(pm\)’s return type.

12 The following member names are defined in addition to names specified in Clause 26:

```cpp
namespace std {
    template <class Key, class T, class Compare, class Allocator>
    class map<Key, T, Compare, Allocator>::value_compare {
         public:
            using result_type = bool;
            using first_argument_type = value_type;
            using second_argument_type = value_type;
    };

    template <class Key, class T, class Compare, class Allocator>
    class multimap<Key, T, Compare, Allocator>::value_compare {
         public:
            using result_type = bool;
            using first_argument_type = value_type;
            using second_argument_type = value_type;
    };
}
```

D.8.3 Negators

1 The header \(<\text{functional}>\) has the following additions:

```cpp
namespace std {
    template <class Predicate> class unary_negate;
    template <class Predicate>
        constexpr unary_negate<Predicate> not1(const Predicate&);
    template <class Predicate> class binary_negate;
    template <class Predicate>
        constexpr binary_negate<Predicate> not2(const Predicate&, const Predicate&);
    template <class Predicate> class tertiary_negate;
    template <class Predicate>
        constexpr tertiary_negate<Predicate> not3(const Predicate&, const Predicate&, const Predicate&);
}
```

§ D.8.3
Negators not1 and not2 take a unary and a binary predicate, respectively, and return their logical negations (8.3.1).

```cpp
template <class Predicate>
class unary_negate {
public:
    constexpr explicit unary_negate(const Predicate& pred);
    constexpr bool operator()(const typename Predicate::argument_type& x) const;
    using argument_type = typename Predicate::argument_type;
    using result_type = bool;
};
```

Returns: \(!\text{pred}(x)\).

```cpp
template <class Predicate>
constexpr unary_negate<Predicate> not1(const Predicate& pred);
```

Returns: \(\text{unary_negate}(\text{pred})\).

```cpp
template <class Predicate>
class binary_negate {
public:
    constexpr explicit binary_negate(const Predicate& pred);
    constexpr bool operator()(const typename Predicate::first_argument_type& x,
                               const typename Predicate::second_argument_type& y) const;
    using first_argument_type = typename Predicate::first_argument_type;
    using second_argument_type = typename Predicate::second_argument_type;
    using result_type = bool;
};
```

Returns: \(!\text{pred}(x,y)\).

```cpp
template <class Predicate>
constexpr binary_negate<Predicate> not2(const Predicate& pred);
```

Returns: \(\text{binary_negate}(\text{pred})\).

D.9 The default allocator [depr.default.alloactor]

The following members and explicit class template specialization are defined in addition to those specified in 23.10.9:

```cpp
namespace std {
    // specialize for void:
    template <> class allocator<void> {
    public:
        using value_type = void;
        using pointer = void*;
        using const_pointer = const void*;
        // reference-to-void members are impossible.

        template <class U> struct rebind { using other = allocator<U>; }
    }
}

§ D.9 1475
template <class T> class allocator {
    public:
        using size_type = size_t;
        using difference_type = ptrdiff_t;
        using pointer = T*;
        using const_pointer = const T*;
        using reference = T&;
        using const_reference = const T&;
        template <class U> struct rebind { using other = allocator<U>; };
        T* address(T& x) const noexcept;
        const T* address(const T& x) const noexcept;
        T* allocate(size_t n, const void* hint);
        template<class U, class... Args>
            void construct(U* p, Args&&... args);
        template <class U>
            void destroy(U* p);
        size_t max_size() const noexcept;
    }

    address(T& x) const noexcept;
    const T* address(const T& x) const noexcept;

    Returns: addressof(x).

    T* allocate(size_t n, const void* hint);

    Returns: A pointer to the initial element of an array of storage of size n * sizeof(T), aligned
    appropriately for objects of type T. It is implementation-defined whether over-aligned types are
    supported (6.11).

    Remarks: The storage is obtained by calling ::operator new(std::size_t) (21.6.2), but it is unspec-
    ified when or how often this function is called.

    Throws: bad_alloc if the storage cannot be obtained.

    template <class U, class... Args>
        void construct(U* p, Args&&... args);

    Effects: As if by: ::new((void *)p) U(std::forward<Args>(args)...);

    template <class U>
        void destroy(U* p);

    Effects: As if by p->~U().

    size_t max_size() const noexcept;

    Returns: The largest value N for which the call allocate(N, 0) might succeed.

D.10 Raw storage iterator

The header <memory> has the following addition:

namespace std {

§ D.10
template <class OutputIterator, class T>
class raw_storage_iterator {
public:
    using iterator_category = output_iterator_tag;
    using value_type = void;
    using difference_type = void;
    using pointer = void;
    using reference = void;

    explicit raw_storage_iterator(OutputIterator x);

    raw_storage_iterator& operator*();
    raw_storage_iterator& operator=(const T& element);
    raw_storage_iterator& operator=(T&& element);
    raw_storage_iterator& operator++();
    raw_storage_iterator operator++(int);
    OutputIterator base() const;
};

raw_storage_iterator is provided to enable algorithms to store their results into uninitialized memory.
The template parameter OutputIterator is required to have its operator* return an object for which
operator& is defined and returns a pointer to T, and is also required to satisfy the requirements of an output
iterator (27.2.4).

explicit raw_storage_iterator(OutputIterator x);

Effects: Initializes the iterator to point to the same value to which x points.

raw_storage_iterator& operator*();

Returns: *this

raw_storage_iterator& operator=(const T& element);

Requires: T shall be CopyConstructible.

Effects: Constructs a value from element at the location to which the iterator points.

Returns: A reference to the iterator.

raw_storage_iterator& operator=(T&& element);

Requires: T shall be MoveConstructible.

Effects: Constructs a value from std::move(element) at the location to which the iterator points.

Returns: A reference to the iterator.

raw_storage_iterator& operator++();

Effects: Pre-increment: advances the iterator and returns a reference to the updated iterator.

raw_storage_iterator operator++(int);

Effects: Post-increment: advances the iterator and returns the old value of the iterator.

OutputIterator base() const;

Returns: An iterator of type OutputIterator that points to the same value as *this points to.
D.11 Temporary buffers  

The header `<memory>` has the following additions:

```cpp
namespace std {
    template <class T>
    pair<T*, ptrdiff_t> get_temporary_buffer(ptrdiff_t n) noexcept;
    template <class T>
    void return_temporary_buffer(T* p);
}
```

```cpp
template <class T>
pair<T*, ptrdiff_t> get_temporary_buffer(ptrdiff_t n) noexcept;
```

**Effects:** Obtains a pointer to uninitialized, contiguous storage for \( N \) adjacent objects of type \( T \), for some non-negative number \( N \). It is implementation-defined whether over-aligned types are supported (6.11).

**Remarks:** Calling `get_temporary_buffer` with a positive number \( n \) is a non-binding request to return storage for \( n \) objects of type \( T \). In this case, an implementation is permitted to return instead storage for a non-negative number \( N \) of such objects, where \( N \neq n \) (including \( N == 0 \)). [Note: The request is non-binding to allow latitude for implementation-specific optimizations of its memory management. —end note]

**Returns:** If \( n \leq 0 \) or if no storage could be obtained, returns a pair \( P \) such that \( P.first \) is a null pointer value and \( P.second == 0 \); otherwise returns a pair \( P \) such that \( P.first \) refers to the address of the uninitialized storage and \( P.second \) refers to its capacity \( N \) (in the units of `sizeof(T)`).

```cpp
template <class T> void return_temporary_buffer(T* p);
```

**Effects:** Deallocates the storage referenced by \( p \).

**Requires:** \( p \) shall be a pointer value returned by an earlier call to `get_temporary_buffer` that has not been invalidated by an intervening call to `return_temporary_buffer(T*)`.

**Throws:** Nothing.

D.12 Deprecated type traits  

The header `<type_traits>` has the following addition:

```cpp
namespace std {
    template <class T> struct is_literal_type;
    template <class T> constexpr bool is_literal_type_v = is_literal_type<T>::value;
    template <class> struct result_of; // not defined
    template <class Fn, class... ArgTypes> struct result_of<Fn(ArgTypes...)>;  
    template <class T> using result_of_t = typename result_of<T>::type;
}
```

**Requires:** For `is_literal_type`, `remove_all_extents_t<T>` shall be a complete type or `cv void`. For `result_of<Fn(ArgTypes...)`, \( Fn \) and all types in the parameter pack \( ArgTypes \) shall be complete types, `cv void`, or arrays of unknown bound.

**is_literal_type<T>** is a `UnaryTypeTrait` (23.15.1) with a base characteristic of `true_type` if \( T \) is a literal type (6.9), and `false_type` otherwise. The partial specialization `result_of<Fn(ArgTypes...)` is a `TransformationTrait` whose member typedef `type` is defined if and only if `invoke_result<Fn, ArgTypes...>::type` is defined. If `type` is defined, it names the same type as `invoke_result_t<Fn, ArgTypes...>`.

§ D.12  1478
The behavior of a program that adds specializations for `is_literal_type` or `is_literal_type_v` is undefined.

D.13 Deprecated iterator primitives

D.13.1 Basic iterator

The header `<iterator>` has the following addition:

```cpp
namespace std {
    template<class Category, class T, class Distance = ptrdiff_t,
            class Pointer = T*, class Reference = T&>
    struct iterator {
        using iterator_category = Category;
        using value_type = T;
        using difference_type = Distance;
        using pointer = Pointer;
        using reference = Reference;
    };
}
```

The `iterator` template may be used as a base class to ease the definition of required types for new iterators.

[Note: If the new iterator type is a class template, then these aliases will not be visible from within the iterator class’s template definition, but only to callers of that class. — end note]

Example: If a C++ program wants to define a bidirectional iterator for some data structure containing `double` and such that it works on a large memory model of the implementation, it can do so with:

```cpp
class MyIterator :
    public iterator<bidirectional_iterator_tag, double, long, T*, T&> {
        // code implementing ++, etc.
    };
```

D.14 Deprecated shared_ptr observers

The following member is defined in addition to those members specified in 23.11.2.2:

```cpp
namespace std {
    template<class T> class shared_ptr {
        public:
            bool unique() const noexcept;
    };
}
```

bool unique() const noexcept;

Returns: `use_count() == 1`.

D.15 Deprecated standard code conversion facets

The header `<codecvt>` provides code conversion facets for various character encodings.

D.15.1 Header `<codecvt>` synopsis

```cpp
namespace std {
    enum codecvt_mode {
        consume_header = 4,
        generate_header = 2,
        little_endian = 1
    }
}
```

D.15.2 Requirements

1 For each of the three code conversion facets `codecvt_utf8`, `codecvt_utf16`, and `codecvt_utf8_utf16`:

   (1.1)  `Elem` is the wide-character type, such as `wchar_t`, `char16_t`, or `char32_t`.

   (1.2)  `Maxcode` is the largest wide-character code that the facet will read or write without reporting a conversion error.

   (1.3)  If `(Mode & consume_header)`, the facet shall consume an initial header sequence, if present, when reading a multibyte sequence to determine the endianness of the subsequent multibyte sequence to be read.

   (1.4)  If `(Mode & generate_header)`, the facet shall generate an initial header sequence when writing a multibyte sequence to advertise the endianness of the subsequent multibyte sequence to be written.

   (1.5)  If `(Mode & little_endian)`, the facet shall generate a multibyte sequence in little-endian order, as opposed to the default big-endian order.

2 For the facet `codecvt_utf8`:

   (2.1)  The facet shall convert between UTF-8 multibyte sequences and UCS2 or UCS4 (depending on the size of `Elem`) within the program.

   (2.2)  Endianness shall not affect how multibyte sequences are read or written.

   (2.3)  The multibyte sequences may be written as either a text or a binary file.

3 For the facet `codecvt_utf16`:

   (3.1)  The facet shall convert between UTF-16 multibyte sequences and UCS2 or UCS4 (depending on the size of `Elem`) within the program.

   (3.2)  Multibyte sequences shall be read or written according to the `Mode` flag, as set out above.

   (3.3)  The multibyte sequences may be written only as a binary file. Attempting to write to a text file produces undefined behavior.

4 For the facet `codecvt_utf8_utf16`:
The facet shall convert between UTF-8 multibyte sequences and UTF-16 (one or two 16-bit codes) within the program.

Endianness shall not affect how multibyte sequences are read or written.

The multibyte sequences may be written as either a text or a binary file.

See also: ISO/IEC 10646-1:1993.

D.16 Deprecated convenience conversion interfaces

The header `<locale>` has the following additions:

```cpp
namespace std {
  template <class Codecvt, class Elem = wchar_t, class Wide_alloc = allocator<Elem>, class Byte_alloc = allocator<char>>
  class wstring_convert;

  template <class Codecvt, class Elem = wchar_t, class Tr = char_traits<Elem>>
  class wbuffer_convert;
}
```

D.16.1 Class template wstring_convert

Class template `wstring_convert` performs conversions between a wide string and a byte string. It lets you specify a code conversion facet (like class template `codecvt`) to perform the conversions, without affecting any streams or locales. [Example: If you want to use the code conversion facet `codecvt_utf8` to output to `cout` a UTF-8 multibyte sequence corresponding to a wide string, but you don’t want to alter the locale for `cout`, you can write something like:

```cpp
wstring_convert<std::codecvt_utf8<wchar_t>> myconv;
std::string mbstring = myconv.to_bytes(L"Hello\n");
std::cout << mbstring;
end example]
```

```cpp
namespace std {
  template <class Codecvt, class Elem = wchar_t, class Wide_alloc = allocator<Elem>, class Byte_alloc = allocator<char>>
  class wstring_convert {
    public:
      using byte_string = basic_string<char, char_traits<char>, Byte_alloc>;
      using wide_string = basic_string<Elem, char_traits<Elem>, Wide_alloc>;
      using state_type = typename Codecvt::state_type;
      using int_type = typename wide_string::traits_type::int_type;

      explicit wstring_convert(Codecvt* pcvt = new Codecvt);
      wstring_convert(Codecvt* pcvt, state_type state);
      explicit wstring_convert(const byte_string& byte_err, const wide_string& wide_err = wide_string());
      ~wstring_convert();

      wstring_convert(const wstring_convert& = delete;
      wstring_convert& operator=(const wstring_convert& = delete;

      wide_string from_bytes(char byte);
      wide_string from_bytes(const char* ptr);
  }
}
```
wide_string from_bytes(const byte_string& str);
wide_string from_bytes(const char* first, const char* last);

byte_string to_bytes(Elem wchar);
byte_string to_bytes(const Elem* wptr);
byte_string to_bytes(const wide_string& wstr);
byte_string to_bytes(const Elem* first, const Elem* last);

size_t converted() const noexcept;
state_type state() const;

private:
  byte_string byte_err_string; // exposition only
  wide_string wide_err_string; // exposition only
  Codecvt* cvtptr; // exposition only
  state_type cvtstate; // exposition only
  size_t cvtcount; // exposition only
};

The class template describes an object that controls conversions between wide string objects of class `basic_string<Elem, char_traits<Elem>, Wide_alloc>` and byte string objects of class `basic_string<char, char_traits<char>, Byte_alloc>`. The class template defines the types `wide_string` and `byte_string` as synonyms for these two types. Conversion between a sequence of `Elem` values (stored in a `wide_string` object) and multibyte sequences (stored in a `byte_string` object) is performed by an object of class `Codecvt`, which meets the requirements of the standard code-conversion facet `codecvt<Elem, char, mbstate_t>`. An object of this class template stores:

(3.1) — `byte_err_string` — a byte string to display on errors
(3.2) — `wide_err_string` — a wide string to display on errors
(3.3) — `cvtptr` — a pointer to the allocated conversion object (which is freed when the `wstring_convert` object is destroyed)
(3.4) — `cvtstate` — a conversion state object
(3.5) — `cvtcount` — a conversion count

using byte_string = basic_string<char, char_traits<char>, Byte_alloc>;

The type shall be a synonym for `basic_string<char, char_traits<char>, Byte_alloc>`. Size_t converted() const noexcept;

Returns: `cvtcount`.

wide_string from_bytes(char byte);
wide_string from_bytes(const char* ptr);
wide_string from_bytes(const byte_string& str);
wide_string from_bytes(const char* first, const char* last);

Effects: The first member function shall convert the single-element sequence `byte` to a wide string. The second member function shall convert the null-terminated sequence beginning at `ptr` to a wide string. The third member function shall convert the sequence stored in `str` to a wide string. The fourth member function shall convert the sequence defined by the range `[first, last)` to a wide string.

In all cases:

(7.1) — If the `cvtstate` object was not constructed with an explicit value, it shall be set to its default value

§ D.16.1 1482
the initial conversion state) before the conversion begins. Otherwise it shall be left unchanged.

(7.2) — The number of input elements successfully converted shall be stored in cvtcount.

Returns: If no conversion error occurs, the member function shall return the converted wide string. Otherwise, if the object was constructed with a wide-error string, the member function shall return the wide-error string. Otherwise, the member function throws an object of class range_error.

using int_type = typename wide_string::traits_type::int_type;

The type shall be a synonym for wide_string::traits_type::int_type.

state_type state() const;

returns cvtstate.

using state_type = typename Codecvt::state_type;

The type shall be a synonym for Codecvt::state_type.

byte_string to_bytes(Elem wchar);
byte_string to_bytes(const Elem* wptr);
byte_string to_bytes(const wide_string& wstr);
byte_string to_bytes(const Elem* first, const Elem* last);

Effects: The first member function shall convert the single-element sequence wchar to a byte string. The second member function shall convert the null-terminated sequence beginning at wptr to a byte string. The third member function shall convert the sequence stored in wstr to a byte string. The fourth member function shall convert the sequence defined by the range [first, last) to a byte string.

In all cases:

(13.1) — If the cvtstate object was not constructed with an explicit value, it shall be set to its default value (the initial conversion state) before the conversion begins. Otherwise it shall be left unchanged.

(13.2) — The number of input elements successfully converted shall be stored in cvtcount.

Returns: If no conversion error occurs, the member function shall return the converted byte string. Otherwise, if the object was constructed with a byte-error string, the member function shall return the byte-error string. Otherwise, the member function shall throw an object of class range_error.

using wide_string = basic_string<Elem, char_traits<Elem>, Wide_alloc>;

The type shall be a synonym for basic_string<Elem, char_traits<Elem>, Wide_alloc>.

explicit wstring_convert(Codecvt* pcvt = new Codecvt);
wstring_convert(Codecvt* pcvt, state_type state);
exterior wstring_convert(const byte_string& byte_err,
const wide_string& wide_err = wide_string());

Requires: For the first and second constructors, pcvt != nullptr.

Effects: The first constructor shall store pcvt in cvtptr and default values in cvtstate, byte_err_string, and wide_err_string. The second constructor shall store pcvt in cvtptr, state in cvtstate, and default values in byte_err_string and wide_err_string; moreover the stored state shall be retained between calls to from_bytes and to_bytes. The third constructor shall store new Codecvt in cvtptr, state_type() in cvtstate, byte_err in byte_err_string, and wide_err in wide_err_string.

~wstring_convert();

Effects: The destructor shall delete cvtptr.

§ D.16.1

1483
D.16.2  Class template wbuffer_convert  

Class template \texttt{wbuffer\_convert} looks like a wide stream buffer, but performs all its I/O through an underlying byte stream buffer that you specify when you construct it. Like class template \texttt{wstring\_convert}, it lets you specify a code conversion facet to perform the conversions, without affecting any streams or locales.

namespace std {
    template <class Codecvt, class Elem = wchar_t, class Tr = char_traits<Elem>>
    class wbuffer_convert : public basic_streambuf<Elem, Tr> {
        public:
            using state_type = typename Codecvt::state_type;

            explicit wbuffer_convert(streambuf* bytebuf = 0,
                Codecvt* pcvt = new Codecvt,
                state_type state = state_type());

            ~wbuffer_convert();

            wbuffer_convert(const wbuffer_convert&) = delete;
            wbuffer_convert& operator=(const wbuffer_convert&) = delete;

            streambuf* rdbuf() const;
            streambuf* rdbuf(streambuf* bytebuf);

            state_type state() const;
    }
}

The class template describes a stream buffer that controls the transmission of elements of type \texttt{Elem}, whose character traits are described by the class \texttt{Tr}, to and from a byte stream buffer of type \texttt{streambuf}. Conversion between a sequence of \texttt{Elem} values and multibyte sequences is performed by an object of class \texttt{Codecvt}, which shall meet the requirements of the standard code-conversion facet \texttt{codecvt<Elem, char, mbstate_t>}.

An object of this class template stores:

- \texttt{bufptr} — a pointer to its underlying byte stream buffer
- \texttt{cvtptr} — a pointer to the allocated conversion object (which is freed when the \texttt{wbuffer\_convert} object is destroyed)
- \texttt{cvtstate} — a conversion state object

state_type state() const;

Returns: cvtstate.

streambuf* rdbuf() const;

Returns: bufptr.

streambuf* rdbuf(streambuf* bytebuf);

Effects: Stores bytebuf in bufptr.

Returns: The previous value of bufptr.
using state_type = typename Codecvt::state_type;

The type shall be a synonym for Codecvt::state_type.

explicit wbuffer_convert(
    streambuf* bytebuf = 0,
    Codecvt* pcvt = new Codecvt,
    state_type state = state_type());

Requires: pcvt != nullptr.

Effects: The constructor constructs a stream buffer object, initializes bufptr to bytebuf, initializes cvtptr to pcvt, and initializes cvtstate to state.

~wbuffer_convert();

Effects: The destructor shall delete cvtptr.

functions with predefined parameters

- `default_random_engine`, 1082
- `knuth_b`, 1082
- `minstd_rand`, 1081
- `minstd_rand0`, 1081
- `mt19937`, 1081
- `mt19937_64`, 1081
- `ranlux24`, 1081
- `ranlux24_base`, 1081
- `ranlux48`, 1082
- `ranlux48_base`, 1081

**entity**, 39
- templated, 345

**enum**, 81
- overloading and, 312
- type of, 174, 176
- underlying type, see type, underlying

**enum name**
- `typedef`, 161
- `enum-base`, 175, 1425
- `enum-head`, 174, 1424
- `enum-head-name`, 174, 1424
- `enum-key`, 175, 1424
- `enum-name`, 174, 1424
- `enum-specifier`, 174, 1424

**enumeration**, 174, 175
- linkage of, 64
- scoped, 175
- unscoped, 175
- **enumeration scope**, 49
- **enumeration type**
  - conversion to, 116
  - `static_cast`
    - conversion to, 116

**enumerator**
- definition, 41
- value of, 175
- `enumerator`, 175, 1425
- `enumerator-definition`, 175, 1425
- `enumerator-list`, 175, 1425

**environment**
- program, 66

**epoch**, 708

**equal_range**
- unordered associative containers, 866
- `equality-expression`, 133, 1420

**equivalence**
- template type, 356
- type, 160, 239

**equivalent**
- expression, see expression, equivalent

**function template**, see template, function, equivalent
- functionally
  - expression, see expression, functionally equivalent
  - function template, see template, function, functionally equivalent

**equivalent parameter declarations**, 312
- overloading and, 312
- equivalent-key group, 856
- equivalently-valued, 468

**Erasable from X**, 835

**erase**
- unordered associative containers, 865

`<errno.h>`, 517
- escape character, see backslash character
- escape sequence
  - undefined, 32

**escape-sequence**, 31, 1415
- Eulerian integral of the first kind, see beta
- evaluation, 14
  - order of argument, 110
  - signal-safe, 511
  - unspecified order of, 14, 68
  - unspecified order of argument, 110
  - unspecified order of function call, 110

**example**
- array, 209
- class definition, 243
- `const`, 205
- constant pointer, 205
- constructor, 282
- constructor and initialization, 293
- declaration, 40, 212
- declarator, 203
- definition, 40
- `delete`, 292
- derived class, 256
- destructor and `delete`, 292
- ellipsis, 210
- enumeration, 176
- explicit destructor call, 290
- explicit qualification, 260
- friend, 240
- friend function, 274
- function declaration, 211
- function definition, 216
- linkage consistency, 158
- local class, 254
- member function, 246, 274
- nested class, 250

## Index of grammar productions

The first page number for each entry is the page in the general text where the grammar production is defined. The second page number is the corresponding page in the Grammar summary (Annex A).

Index of implementation-defined behavior

The entries in this section are rough descriptions; exact specifications are at the indicated page in the general text.

`#pragma`, 444

additional execution policies supported by parallel algorithms, 724, 1011
additional `file_type` enumerators for file systems supporting additional types of file, 1266
additional formats for `time_get::do_get_date`, 816
additional supported forms of preprocessing directive, 435
algorithms for producing the standard random number distributions, 1085
alignment, 84
alignment additional values, 85
alignment of bit-fields within a class object, 249
allocation of bit-fields within a class object, 249
any use of an invalid pointer other than to perform indirection or deallocate, 70
argument values to construct `basic_ios::failure`, 1176
assignability of placeholder objects, 668

behavior of iostream classes when `traits::pos_type` is not `streampos` or when `traits::off_type` is not `streamoff`, 1158
behavior of non-standard attributes, 195
bits in a byte, 8

choice of larger or smaller value of floating literal, 34
concatenation of some types of string literals, 36
conversions between pointers and integers, 118
converting characters from source character set to execution character set, 23
converting function pointer to object pointer and vice versa, 118

default configuration of a pool, 644
default `next_buffer_size` for a `monotonic_buffer_resource`, 646
default number of buckets in `unordered_map`, 928, 929
default number of buckets in `unordered_multimap`, 935
default number of buckets in `unordered_multiset`, 945
default number of buckets in `unordered_set`, 940
defining `main` in freestanding environment, 66
definition and meaning of `__STDC__`, 445, 1445
definition and meaning of `__STDC_VERSION__`, 445
definition of `NULL`, 481, 1458
derived type for `typeid`, 114
diagnostic message, 3
dynamic initialization of static inline variables before `main`, 69
dynamic initialization of static variables before `main`, 68
dynamic initialization of thread-local variables before entry, 69
effect of calling associated Laguerre polynomials with `n >= 128` or `m >= 128`, 1150
effect of calling associated Legendre polynomials with `l >= 128`, 1151
effect of calling `basic_filebuf::setbuf` with nonzero arguments, 1231
effect of calling `basic_filebuf::sync` when a get area exists, 1231
effect of calling `basic_streambuf::setbuf` with nonzero arguments, 1219
effect of calling cylindrical Bessel functions of the first kind with `nu >= 128`, 1152
effect of calling cylindrical Neumann functions with `nu >= 128`, 1153
effect of calling Hermite polynomials with `n >= 128`, 1154
effect of calling `ios_base::sync_with_stdio` after any input or output operation on standard streams, 1169
effect of calling irregular modified cylindrical Bessel functions with `nu >= 128`, 1152
effect of calling Laguerre polynomials with `n >= 128`, 1154
effect of calling Legendre polynomials with \( l \geq 128, 1155 \)
effect of calling regular modified cylindrical Bessel functions with \( \nu \geq 128, 1152 \)
effect of calling spherical associated Legendre functions with \( l \geq 128, 1156 \)
effect of calling spherical Bessel functions with \( n \geq 128, 1155 \)
effect of calling spherical Neumann functions with \( n \geq 128, 1156 \)
effect of \texttt{filesystem::copy}, 1280

effect on \texttt{C} locale of calling \texttt{locale::global}, 790

encoding of universal character name not in execution character set, 32

\texttt{error\_category} for errors originating outside the operating system, 476

exception type when \texttt{random\_device} constructor fails, 1083

exception type when \texttt{random\_device::operator()} fails, 1083

exception type when \texttt{shared\_ptr} constructor fails, 623, 624

exceptions thrown by standard library functions that have a potentially-throwing exception specification, 476

execution character set and execution wide-character set, 24

exit status, 494

extended signed integer types, 79

file type of the file argument of \texttt{filesystem::status}, 1291

formatted character sequence generated by \texttt{time\_put::do\_put} in \texttt{C} locale, 818

forward progress guarantees for implicit threads of parallel algorithms (if not defined for \texttt{thread}), 1010

growth factor for \texttt{monotonic\_buffer\_resource}, 646

headers for freestanding implementation, 458

how \texttt{random\_device::operator()} generates values, 1083

interactive device, 12

interpretation of the path character sequence with format \texttt{path::auto\_format}, 1265

largest supported value to configure the largest allocation satisfied directly by a pool, 643

largest supported value to configure the maximum number of blocks to replenish a pool, 643

linkage of \texttt{main}, 66

linkage of names from \texttt{C} standard library, 459

linkage of objects between \texttt{C++} and other languages, 194

locale names, 788

value-to-rvalue conversion of an invalid pointer value, 87

manner of search for included source file, 438

mapping from name to catalog when calling \texttt{messages::do\_open}, 825

mapping from physical source file characters to basic source character set, 23, 1453

mapping header name to header or external source file, 26

mapping of pointer to integer, 117

mapping physical source file characters to basic source character set, 22

mapping to message when calling \texttt{messages::do\_get}, 825

maximum depth of recursive template instantiations, 394

maximum size of an allocated object, 123, 501

meaning of ‘’, \texttt{\}, \texttt{/}, \texttt{*}, or \texttt{\//} in a \texttt{q-char-sequence} or an \texttt{h-char-sequence}, 26

meaning of \texttt{asm} declaration, 191

meaning of attribute declaration, 156

meaning of \texttt{dot-dot} in \texttt{root-directory}, 1251

negative value of character literal in preprocessor, 437

nesting limit for \#include directives, 438

\texttt{NTCTS} in \texttt{basic\_ostream<charT, traits>&\_operator<<nullptr\_t}}, 1208

number of placeholders for bind expressions, 654, 668

number of threads in a program under a freestanding implementation, 15

numeric values of character literals in \#if directives, 437

operating system on which implementation depends, 1239

parameters to \texttt{main}, 66

passing argument of class type through ellipsis, 111

physical source file characters, 22

presence and meaning of \texttt{native\_handle\_type} and \texttt{native\_handle}, 1359

Index of implementation-defined behavior 1605
range defined for character literals, 32
rank of extended signed integer type, 92
representation of char, 79
required libraries for freestanding implementation, 7
resource limits on a message catalog, 826
result of filesystem::file_size, 1285
result of inexact floating-point conversion, 90
result of right shift of negative value, 133
return value of bad_alloc::what, 500
return value of bad_any_access::what, 583
return value of bad_array_new_length::what, 501
return value of bad_cast::what, 504

return value of exception::what, 506
return value of type_info::name(), 503
search locations for "" header, 438
search locations for <> header, 437
semantics and default value of token parameter to random_device constructor, 1082
semantics of an access through a volatile glvalue, 167
semantics of linkage specification on templates, 345
semantics of linkage specifiers, 192
semantics of non-standard escape sequences, 32
semantics of parallel algorithms invoked with implementation-defined execution policies, 1011
sequence of places searched for a header, 437
set of character types that iostreams templates can be instantiated for, 786, 1158
signedness of char, 79, 167
sizeof applied to fundamental types other than char, signed char, and unsigned char, 121
stack unwinding before call to std::terminate(), 429, 432
start-up and termination in freestanding environment, 66
string resulting from __func__, 217
support for extended alignment, 700
support for extended alignments, 85
support for over-aligned types, 1476, 1478
supported multibyte character encoding rules, 729, 731
supported root-names in addition to any operating system dependent root-names, 1250, 1251
text of __DATE__ when date of translation is not available, 444
text of __TIME__ when time of translation is not available, 445
threads and program points at which deferred dynamic initialization is performed, 68, 69
type of a directory-like file, 1273, 1276
type of array::const_iterator, 872
type of array::iterator, 872
type of basic_string::const_iterator, 736
type of basic_string::iterator, 736
type of basic_string_view::const_iterator, 768, 770
type of default_random_engine, 1082
type of deque::const_iterator, 874
type of deque::iterator, 874
type of filesystem trivial clock, 1246
type of forward_list::const_iterator, 879
type of forward_list::iterator, 879
type of list::const_iterator, 886
type of list::iterator, 886
type of map::const_iterator, 903
type of map::iterator, 903
type of multimap::const_iterator, 909
type of multimap::iterator, 909
type of multiset::const_iterator, 918
type of multiset::iterator, 918
type of ptrdiff_t, 132, 481
type of regex_constants::error_type, 1309
type of regex_constants::match_flag_type, 1308
type of set::const_iterator, 914
type of set::iterator, 914
type of size_t, 481
type of streamoff, 729
type of streampos, 729
type of syntax_option_type, 1307
type of utf8streampos, 730

Index of implementation-defined behavior 1606
type of u32streampos, 731
value of wide-character literal with single c-char that is not in execution wide-character set, 32
value of wide-character literal containing multiple characters, 32
value of character literal outside range of corresponding type, 32
value of ctype<char>::table_size, 796
value of multicharacter literal, 32
value of pow(0,0), 1060
value of result of inexact integer to floating-point conversion, 90
value of result of unsigned to signed conversion, 90
underlying type for enumeration, 176
value of bit-field that cannot represent assigned value, 138
incremented value, 113
initializer, 224
whether <cfenv> functions can be used to manage floating-point status, 1052
whether a given atomic type’s operations are always lock free, 1348, 1350, 1352, 1354
whether an implementation has relaxed or strict pointer safety, 74
whether functions from Annex K of the C standard library are declared when C++ headers are included, 458
whether get_pointer_safety returns pointer_safety::relaxed or pointer_safety::preferred if the implementation has relaxed pointer safety, 601
whether locale object is global or per-thread, 785
whether pragma FENV_ACCESS is supported, 1052
whether rand may introduce a data race, 1105
whether sequence pointers are copied by basic_filebuf move constructor, 1227
whether sequence pointers are copied by basic_stringbuf move constructor, 1216
whether source of translation units must be available to locate template definitions, 23
whether stack is unwound before calling std::terminate() when a noexcept specification is violated, 432
whether the lifetime of a parameter ends when the callee returns or at the end of the enclosing full-expression, 110
whether the thread that executes main and the threads created by std::thread provide concurrent forward progress guarantees, 20
whether time_get::do_get_year accepts two-digit year numbers, 816
whether values are rounded or truncated to the required precision when converting between time_t values and time_point objects, 721
whether variant supports over-aligned types, 572
Index of implementation-defined behavior 1607
which functions in the C++ standard library may be recursively reentered, 475
which scalar types have unique object representations, 693
