1. Introduction
This proposal introduces a ring to the standard library operating on a span, named ring_span. The ring_span offers similar facilities to std::queue with the additional feature of storing the elements in contiguous memory and being of a fixed size. It is an update to P0059R3 to reintroduce iterator semantics at the request of several from the embedded programming community. The authors seek feedback on the design of the ring before submitting wording for the standard.

2. Motivation
Queues are widely used containers for collecting data prior to processing in order of entry to the queue (first in, first out). The std::queue container adaptor acts as a wrapper to an underlying container, typically std::deque or std::list. These containers are not of a fixed size and may grow as they fill, which means that each item that is added to a std::queue may prompt an allocation, which will lead to memory fragmentation. The ring_span operates on elements in contiguous non-owned memory, so memory allocation is eliminated. The most common uses for the ring_span would be:
   ● Storing the last n events for later recovery
   ● Communicating between threads in an allocation-constrained environment
   ● Allowing idiomatic access to memory used for signal processing

All of these use cases demand a single producer and a single consumer of elements.

3. Impact on the standard
This proposal is a pure library extension. It does not require changes to any standard classes, functions or headers.
4. Design decisions

Naming
In an earlier version of this paper the name ring_buffer was proposed, but given the new implementation the proposed name is ring_span. The name ring still remains the preferred choice of the authors.

Look like std::queue
There is already an object that offers FIFO support: the std::queue container. The queue grows to accommodate new entries, allocating new memory as necessary. The ring interface can therefore be similar to that of the queue with the addition of try_push, try_emplace and try_pop functions: these must now fail if they are called when the ring is full (or empty in the case of try_pop), and should therefore signal that condition by returning a success/fail value.

push_back and pop_front
Pushing items is a simple matter of assigning to a pre-existing element. The user can decide what to do on filling up the ring: it is possible to overwrite unpopped items, which would be desirable for the use case of storing the last n events for later recovery.

Popping items is a more complicated matter than in other containers. If an item is popped from a std::queue it is destroyed and the memory is released. In the case of a ring_span however, it does not own the memory so a different strategy must be pursued. There are four things that could happen when an object is popped from a ring_span, besides the usual container housekeeping:

1. The object is destroyed via the class destructor and the memory is left in an undefined state.
2. The object is replaced with a default-constructed object.
3. The object is replaced with a copy of a user-specified object.
4. The object is not replaced at all.

This is a choice that will depend on the type being contained. For example, if the type is not default-constructible, option 2 is unavailable. If the type is not assignable, options 2 and 3 are unavailable. There is no single solution that covers all these situations, so as part of the definition of ring_span a number of pop strategy objects are defined. A strategy can be chosen at the point of declaration of an instance of a ring_span as a template parameter.

Although pop could theoretically safely be called on an empty ring with the implementation supplied below, it should yield undefined behaviour.

Iteration
Iteration has been added and withdrawn through revisions of this paper. Since the last revision the use case for digital signal processing has been introduced. In this situation, the ring is used as a delay line where you will typically need to do an inner_product over some range of values in the order it arrived. This is such a common operation that some DSPs actually have built in hardware for this exact operation. There is no reason why a standard-conforming compiler for such a processor would not implement the ring_span using
these intrinsics. This is one of the basic signal processing building blocks, so it would seem perverse to add a ring without supporting iteration and thus supporting signal processing application.

The fact that the ring_span doesn’t own its memory and that the data therefore could be changed under the nose of the iterator object does present a challenge. This is solved by stating that pushing to the ring_span will invalidate iterators, or, more particularly, invalidate the view on the span. Ring_span is a long-lived object which has non-owning reference semantics, much the same as the string_view.

5. Header <ring_span> synopsis
This section contains the header declarations. Example definitions are also provided for clarity and to aid specification of the definitions.

```cpp
namespace std::experimental {
    template <typename T> struct null_popper {
        void operator()(T&);
    };

    template <typename T> struct default_popper {
        T operator()(T& t);
    };

    template <typename T> struct copy_popper {
        copy_popper(T& t);
        T operator()(T& t);
        T copy;
    };

    template <typename T, class Popper = default_popper<T>>
    class ring_iterator;

    template<typename T, class Popper = default_popper<T>>
    class ring_span {
    public:
        using type = ring_span<T, Popper>;
        using size_type = std::size_t;
        using value_type = T;
        using pointer = T*;
        using reference = T&;
        using const_reference = const T&;
        using iterator = ring_iterator<type, false>;
        using const_iterator = ring_iterator<type, true>;
    }
```
friend class ring_iterator<type, false>;
friend class ring_iterator<type, true>;

template <class ContiguousIterator>
ring_span(ContiguousIterator begin, ContiguousIterator end,
          Popper p = Popper()) noexcept;

template <class ContiguousIterator>
ring_span(ContiguousIterator begin, ContiguousIterator end,
          ContiguousIterator first, size_type size,
          Popper p = Popper()) noexcept;

ring_span(ring_span&&) = default;
ring_span& operator=(ring_span&&) = default;

bool empty() const noexcept;
bool full() const noexcept;
size_type size() const noexcept;
size_type capacity() const noexcept;

reference front() noexcept;
const_reference front() const noexcept;
reference back() noexcept;
const_reference back() const noexcept;

iterator begin() noexcept;
const_iterator begin() const noexcept;
const_iterator cbegin() const noexcept;
iterator end() noexcept;
const_iterator end() const noexcept;
const_iterator cend() const noexcept;

template<bool b = true,
         typename = std::enable_if_t<b &&
         std::is_copy_assignable<T>::value>>
void push_back(const value_type& from_value)
         noexcept(std::is_nothrow_copy_assignable<T>::value);

template<bool b = true,
         typename = std::enable_if_t<b &&
         std::is_move_assignable<T>::value>>
void push_back(value_type&& from_value)
         noexcept(std::is_nothrow_move_assignable<T>::value);

template<class... FromType>
void emplace_back(FromType&&... from_value)
```cpp
noexcept(std::is_nothrow_constructible<T, FromType...>::value &&
         std::is_nothrow_move_assignable<T>::value);

T pop_front();

void swap(type& rhs)
    noexcept (std::is_nothrow_swappable<Popper>::value);

// Example implementation
private:
    reference at(size_type idx) noexcept;
    const_reference at(size_type idx) const noexcept;
    size_type back_idx() const noexcept;
    void increase_size() noexcept;
    T* m_data;
    size_type m_size;
    size_type m_capacity;
    size_type m_front_idx;
    Popper m_popper;
};

5.1. Function specifications: *_popper
The null_popper object does nothing to the item being popped from the ring.

```cpp
template <typename T>
void null_popper::operator()(T&) const noexcept
{};
```

The default_popper object moves the item being popped from the ring into the return value.

```cpp
template <typename T>
T default_popper::operator()(T& t) const
{
    return std::move(t);
}
```

The copy_popper object replaces the item being popped from the ring with a copy of an item of the contained type, chosen at the declaration site.

```cpp
template <typename T>
explicit copy_popper::copy_popper(T& t)
    : copy(std::move(t))
{};
```

```cpp
template <typename T>
T copy_popper::operator()(T& t) const
{
    T old = std::move(t);
}```
5.2 Function specifications: ring_span

The first constructor takes a range delimited by two contiguous iterators and an instance of a popper. After this constructor is executed, the capacity of the ring is the distance between the two iterators and the size of the ring is its capacity. A typical implementation would be:

```cpp
template<typename T, class Popper>
template<class ContiguousIterator>
ring_span<T, Popper>::ring_span(ContiguousIterator begin,
                                ContiguousIterator end, Popper p) noexcept
    : m_data(&*begin)
    , m_size(0)
    , m_capacity(end - begin)
    , m_front_idx(0)
    , m_popper(std::move(p))
{}  
```

The second constructor creates a partially full ring. It takes a range delimited by two contiguous iterators, a third iterator which points to the oldest item of the ring, a size parameter which indicates how many items are in the ring, and an instance of a popper. After this constructor is executed, the capacity of the ring is the distance between the first two iterators and the size of the ring is the size parameter. A typical implementation would be:

```cpp
template<typename T, class Popper>
template<class ContiguousIterator>
ring_span<T, Popper>::ring_span(ContiguousIterator begin,
                                ContiguousIterator end, ContiguousIterator first, size_type size, Popper p = Popper()) noexcept
    : m_data(&*begin)
    , m_size(size)
    , m_capacity(end - begin)
    , m_front_idx(first - begin)
    , m_popper(std::move(p))
{}  
```

empty(), full(), size() and capacity() behave as expected. Typical implementations would be:

```cpp
template<typename T, class Popper>
bool ring_span<T, Popper>::empty() const noexcept
{ return m_size == 0; }  
```

```cpp
template<typename T, class Popper>
bool ring_span<T, Popper>::full() const noexcept
{ return m_size == m_capacity; }  
```
ring_span<T, Popper>::size_type ring_span<T, Popper>::size() const
{
    return m_size;
}

ring_span<T, Popper>::size_type ring_span<T, Popper>::capacity() const
{
    return m_capacity;
}

front() and back() return the oldest and newest items in the ring. Typical implementations
would be:

```
template<typename T, class Popper>
ring_span<T, Popper>::reference ring_span<T, Popper>::front() noexcept
{
    return *begin();
}

template<typename T, class Popper>
ring_span<T, Popper>::reference ring_span<T, Popper>::back() noexcept
{
    return *(--end());
}
```

begin(), cbegin(), end() and cend() return iterators to the oldest and one-past-the-newest
items. Typical implementations would be:

```
template<typename T, class Popper>
ring_span<T, Popper>::iterator ring_span<T, Popper>::begin() noexcept
{
    return iterator(m_front_idx, this);
}
```

```
template<typename T, class Popper>
ring_span<T, Popper>::const_iterator ring_span<T, Popper>::begin() const
{
    return const_iterator(m_front_idx, this);
}
```

```
template<typename T, class Popper>
ring_span<T, Popper>::iterator ring_span<T, Popper>::end() noexcept
{
    return iterator(size() + m_front_idx, this);
}
```

```
template<typename T, class Popper>
ring_span<T, Popper>::const_iterator ring_span<T, Popper>::end() const
{
    return const_iterator(size() + m_front_idx, this);
}
```
The push_back() functions add an item after the most recently added item. The
emplace_back() function creates an item after the most recently added item. If the size of
the ring equals the capacity of the ring, then the oldest item is replaced. Otherwise, the size
of the ring is increased by one. Typical implementations would be:

```cpp
template<typename T, class Popper>
void ring_span<T, Popper>::push_back(const T& value)
noexcept(std::is_nothrow_copy_assignable<T>::value)
{
    m_data[back_idx()] = value;
    increase_size();
}
```

```cpp
template<typename T, class Popper>
void ring_span<T, Popper>::push_back(T&& value)
noexcept(std::is_nothrow_move_assignable<T>::value)
{
    m_data[back_idx()] = std::move(value);
    increase_size();
}
```

```cpp
template<typename T, class Popper>
void ring_span<T, Popper>::emplace_back(FromType&&... from_value)
noexcept(std::is_nothrow_constructible<T, FromType...>::value &&
         std::is_nothrow_move_assignable<T>::value);
{
    m_data[back_idx()] = T(std::forward<FromType>(from_value)...);
    increase_size();
}
```

The pop_front() function checks the size of the ring, asserting if it is zero. If it is non-zero, it
passes a reference to the oldest item to the Popper for transformation, reduces the size and
advances the front of the ring. By returning the item from pop, we are able to contain smart
pointers. A typical implementation might be:

```cpp
template<typename T, class Popper>
auto ring_span<T, Popper>::pop_front()
{
    assert(m_size != 0);
}
The swap() function is trivial. A typical implementation might be:

```cpp
void ring_span<T, Popper>::swap(ring_span<T, Popper>& rhs) noexcept(std::is_nothrow_swappable<Popper>::value)
{
    using std::swap;
    swap(m_data, rhs.m_data);
    swap(m_size, rhs.m_size);
    swap(m_capacity, rhs.m_capacity);
    swap(m_front_idx, rhs.m_front_idx);
    swap(m_popper, rhs.m_popper);
}
```

For the sake of clarity, the private implementation used to describe these functions is as follows:

```cpp
template<typename T, class Popper>
ring_span<T, Popper>::reference ring_span<T, Popper>::at(size_type i) noexcept
{ return m_data[i % m_capacity]; }
```

```cpp
template<typename T, class Popper>
ring_span<T, Popper>::const_reference ring_span<T, Popper>::at(size_type i) const noexcept
{ return m_data[i % m_capacity]; }
```

```cpp
template<typename T, class Popper>
ring_span<T, Popper>::size_type ring_span<T, Popper>::back_idx() const noexcept
{ return (m_front_idx + m_size) % m_capacity; }
```

```cpp
void ring_span<T, Popper>::increase_size() noexcept
{ if (++m_size > m_capacity) { m_size = m_capacity; } }
```

5.3 Function specifications: ring_iterator

The equality and comparison operators use the index of the iterator to compare their order in the ring. The iterators must be constructed from the same ring. They are equivalent if they point to the same item. operator< will return true if the item pointed to by the member is newer than the item pointed to by the parameter. Typical implementations might be:
template<bool C>
bool ring_iterator<Ring, is_const>::operator==(const ring_iterator<Ring, C>& rhs) const noexcept
{ return (modulo_capacity(m_idx) == rhs.modulo_capacity(m_idx)) && (m_rv == rhs.m_rv); }

template<typename Ring, bool is_const>
template<bool C>
bool ring_iterator<Ring, is_const>::operator<(const ring_iterator<Ring, C>& rhs) const noexcept
{ return (modulo_capacity(m_idx) < rhs.modulo_capacity(m_idx)) && (m_rv == rhs.m_rv); }

The dereferencing operator and the pre- and post- increment operators are trivial. Typical implementations might be:

template<typename Ring, bool is_const>
ring_iterator<Ring, is_const>::reference ring_iterator<Ring, is_const>::operator*() const noexcept
{ return m_rv->at(m_idx); }

template<typename Ring, bool is_const>
ring_iterator<Ring, is_const>& ring_iterator<Ring, is_const>::operator++() noexcept
{ ++m_idx; return *this; }

template<typename Ring, bool is_const>
ring_iterator<Ring, is_const>& ring_iterator<Ring, is_const>::operator++(int) noexcept
{ auto r(*this); ++*this; return r; }

template<typename Ring, bool is_const>
ring_iterator<Ring, is_const>& ring_iterator<Ring, is_const>::operator--() noexcept
{ ++m_idx; return *this; }

template<typename Ring, bool is_const>
ring_iterator<Ring, is_const>& ring_iterator<Ring, is_const>::operator--(int) noexcept
{ auto r(*this); ++*this; return r; }

non-member operator+= and operator-= are also trivial. Typical implementations might be:

template<typename Ring, bool is_const>
ring_iterator<Ring, is_const>& operator+=(ring_iterator<Ring, is_const>& it, int i) noexcept
{ it.m_idx += i; return it; }
template <typename Ring, bool is_const>
ring_iterator<Ring, is_const>& operator-=(ring_iterator<Ring, is_const>& it, int i) noexcept
{ it.m_idx -= i; return it; }

For the sake of clarity, a private constructor might be implemented like this:
template <typename Ring, bool is_const>
ring_iterator<Ring, is_const>::ring_iterator(size_type idx, Ring* rv) noexcept
: m_idx(idx) , m_rv(rv) {}

The modulo capacity normalises the index, as required for ordering and equality functions:
template <typename Ring, bool is_const>
ring_iterator<Ring, is_const>::size_type ring_iterator<Ring, is_const>::modulo_capacity(size_type idx)
{
  return idx % m_rv->capacity();
}

6. Sample use
#include <ring_span>
#include <cassert>
using std::experimental::ring_span;

void ring_test()
{
  std::array<int, 5> A;
  std::array<int, 5> B;

  ring_span<int> Q(std::begin(A), std::end(A));

  Q.push_back(7);
  Q.push_back(3);
  assert(Q.size() == 2);
  assert(Q.front() == 7);
  Q.pop_front();
  assert(Q.size() == 1);
  Q.push_back(18);
  auto Q3 = std::move(Q);
  assert(Q3.front() == 3);
  assert(Q3.back() == 18);
  sg14::ring_span<int> Q5(std::move(Q3));
assert(Q5.front() == 3);
assert(Q5.back() == 18);
assert(Q5.size() == 2);
Q5.pop_front();
Q5.pop_front();
assert(Q5.empty());
	sg14::ring_span<int> Q6(std::begin(B), std::end(B));
Q6.push_back(6);
Q6.push_back(7);
Q6.push_back(8);
Q6.push_back(9);
Q6.emplace_back(10);
Q6.swap(Q5);
assert(Q6.empty());
assert(Q5.size() == 5);
assert(Q5.front() == 6);
assert(Q5.back() == 10);
puts("Ring test completed.\n");
}

7. Future work

n3353 describes a proposal for a concurrent queue. The interface is quite different from ring. A concurrent ring could be adapted from the interface specified therein should n3353 be accepted into the standard. Considerable demand has been expressed for such an entity by the embedded development community, but at the presentation of revision 2 of this paper to SG1 such a feature was turned down since it overlapped with n3353. Feedback from developers in the embedded community suggests that a concurrent queue would not be used in their domain because of the contingent unpredictable memory allocation, and a fixed size container such as this would be preferable, even one with the size as a template parameter.

The popper class templates are defined at an overly broad scope, rather than in the scope of the ring_span. However, no way of doing this is immediately apparent, beyond the obvious solution of creating a ring namespace and defining the poppers and the span inside it. Since this is somewhat counterintuitive in the context of the remainder of the standard library, the authors remain open to suggestions. If the popper class templates might have use in other container spans, then they could remain in the broader scope.

Requests have been made for a mechanism of providing notification when an item has been pushed. This could be achieved by creating a pusher policy, analogous to the popper objects. If this is deemed valuable then this proposal can be modified accordingly.
8. Acknowledgements
Thanks to Jonathan Wakely for sprucing up the first draft of the ring interface.
