Wording for fundamental bit manipulation utilities

Note: this is an early draft. It's known to be incomplete and incorrect, and it has lots of bad formatting.
1 Bit manipulation library

1.1 General

This Clause describes the contents of the header `<bit>` (1.2) that provides components that C++ programs may use to access, manipulate and process both individual bits and bit sequences.

The bit library relies on four main classes `bit_value` (1.4), `bit_reference` (1.5), `bit_pointer` (1.6) and `bit_iterator` (1.7) as well as on a helper class `binary_digits` (1.3). For generic purposes `bit_value` and `bit_reference` exhibit roughly the same interface. Most of the non-member operations on `bit_value` (1.4.9) are provided on `bit_reference` through an implicit conversion to `bit_value`.

In all the following, a `bit` refers to an object that can hold one of the two values designated as 0 and 1. As a part of the C++ memory model, `CHAR_BIT` bits are packed together in `bytes`, with `CHAR_BIT` >= 8. Bytes are themselves packed together to form `machine words`. Because the smallest addressable entity in memory are bytes in the C++ memory model, a bit object is hypothetical. The bit manipulation library provides wrapper classes to mimic the behavior of this hypothetical object.

An object of a `word` type refers to an object that provides an access to its underlying bits. An object of a `word` type shall provide the operators `>>` and `&` such that the expression `(word >> position) & static_cast<decltype(word)>(1)` is a valid expression, with `word` an object of a `word` type and `position` a value of type `size_t`.

The bit library is only compatible with word types `WordType` for which `binary_digits_v<WordType>` is defined and is not zero (1.3.3). `binary_digits_v<WordType>` corresponds to the number of individual bits within a word of type `WordType`.

The `position` of a bit within a word is the unsigned integral number `n < binary_digits_v<decltype(word)>` such that `(word >> n) & static_cast<decltype(word)>(1)` returns the `n`-th bit of the word `word`. [Note: For unsigned integral types, `(word >> n) & static_cast<decltype(word)>(1)` is equivalent to `word & (static_cast<decltype(word)>(1) << n)` for `n < binary_digits_v<decltype(word)>`. -- end note]

The least significant bit of a word, or lsb, is the bit at position 0. The most significant bit of a word, or msb, it the bit at position `binary_digits_v<WordType> - 1`.

The default direction in which bits are iterated through goes from the least significant bit to the most significant bit of each word. The next bit of the most significant bit of a word is considered to be the least significant bit of the next word. The arithmetic of bit pointers (1.6.1) and bit iterators (1.7.1) is based on this behavior.

1.2 Header `<bit>` synopsis

```cpp
namespace std {
    // 1.4, class bit_value
    class bit_value;

    // 1.5, class template bit_reference
    template <class WordType> class bit_reference;

    // 1.6, class template bit_pointer
    template <class WordType> class bit_pointer;

    // 1.7, class template bit_iterator
    template <class Iterator> class bit_iterator;
} 
```
1.4.9, bit_value operations
constexpr bit_value operator~(bit_value rhs) noexcept;
constexpr bit_value operator&(bit_value lhs, bit_value rhs) noexcept;
constexpr bit_value operator|(bit_value lhs, bit_value rhs) noexcept;
constexpr bit_value operator^(bit_value lhs, bit_value rhs) noexcept;

1.5.9, bit_reference swap
template <class T>
void swap(bit_reference<T> lhs, bit_reference<T> rhs) noexcept;
template <class T, class U>
void swap(bit_reference<T> lhs, bit_reference<U> rhs) noexcept;
template <class T>
void swap(bit_reference<T> lhs, bit_value& rhs) noexcept;
template <class U>
void swap(bit_value& lhs, bit_reference<U> rhs) noexcept;

1.6.7, bit_pointer arithmetic
template <class T>
constexpr bit_pointer<T> operator+(typename bit_pointer<T>::difference_type n,
    bit_pointer<T> x);
template <class T, class U>
constexpr common_type_t<typename bit_pointer<T>::difference_type,
    typename bit_pointer<U>::difference_type>
    operator-(bit_pointer<T> lhs, bit_pointer<U> rhs);

1.7.7, bit_iterator arithmetic
template <class T>
constexpr bit_iterator<T> operator+(typename bit_iterator<T>::difference_type n,
    const bit_iterator<T>& i);
template <class T, class U>
constexpr common_type_t<typename bit_iterator<T>::difference_type,
    typename bit_iterator<U>::difference_type>
    operator-(const bit_iterator<T>& lhs, const bit_iterator<U>& rhs);

1.4.9, bit_value comparisons
constexpr bool operator==(bit_value lhs, bit_value rhs) noexcept;
constexpr bool operator!=(bit_value lhs, bit_value rhs) noexcept;
constexpr bool operator<(bit_value lhs, bit_value rhs) noexcept;
constexpr bool operator<=(bit_value lhs, bit_value rhs) noexcept;
constexpr bool operator>(bit_value lhs, bit_value rhs) noexcept;
constexpr bool operator>=(bit_value lhs, bit_value rhs) noexcept;

1.6.7, bit_pointer comparisons
template <class T, class U>
constexpr bool operator==(bit_pointer<T> lhs, bit_pointer<U> rhs) noexcept;
template <class T, class U>
constexpr bool operator!=(bit_pointer<T> lhs, bit_pointer<U> rhs) noexcept;
template <class T, class U>
constexpr bool operator<(bit_pointer<T> lhs, bit_pointer<U> rhs) noexcept;
template <class T, class U>
constexpr bool operator<=(bit_pointer<T> lhs, bit_pointer<U> rhs) noexcept;
template <class T, class U>
constexpr bool operator>(bit_pointer<T> lhs, bit_pointer<U> rhs) noexcept;
template <class T, class U>
constexpr bool operator>=(bit_pointer<T> lhs, bit_pointer<U> rhs) noexcept;
constexpr bool operator>(bit_pointer<T> lhs, bit_pointer<U> rhs) noexcept;

template <class T, class U>
constexpr bool operator>=(bit_pointer<T> lhs, bit_pointer<U> rhs) noexcept;

// 1.7.7, bit_iterator comparisons
template <class T, class U>
constexpr bool operator==(const bit_iterator<T>& lhs, const bit_iterator<U>& rhs);
template <class T, class U>
constexpr bool operator!=(const bit_iterator<T>& lhs, const bit_iterator<U>& rhs);
template <class T, class U>
constexpr bool operator<(const bit_iterator<T>& lhs, const bit_iterator<U>& rhs);
template <class T, class U>
constexpr bool operator<=(const bit_iterator<T>& lhs, const bit_iterator<U>& rhs);

// 1.4.9, bit_value input and output
template <class charT, class traits>
basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& is, bit_value& x);

// 1.5.9, bit_reference input and output
template <class charT, class traits, class T>
basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& is, bit_reference<T>& x);

// 1.3, helper class binary_digits
template <class T> struct binary_digits;

1.3 Helper class binary_digits

1.3.1 Class binary_digits overview

template <class UIntType> struct binary_digits : integral_constant<size_t, numeric_limits<UIntType>::digits> { };  

1 Requires: UIntType shall be a (possibly cv-qualified) unsigned integer type [ Note: This excludes (possibly cv-qualified) bool. — end note ], otherwise the program is ill-formed.

2 Remarks: Specialization of this helper class for a type T informs other library components that this type T corresponds to a word type whose bits can be accessed through bit_value, bit_reference, bit_pointer and bit_iterator.
1.3.2 Class binary_digits specializations

```cpp
template <> struct binary_digits<byte>
    : integral_constant<size_t, numeric_limits<unsigned char>::digits> { };
template <> struct binary_digits<const byte>
    : integral_constant<size_t, numeric_limits<const unsigned char>::digits> { };
template <> struct binary_digits<volatile byte>
    : integral_constant<size_t, numeric_limits<volatile unsigned char>::digits> { };
template <> struct binary_digits<const volatile byte>
    : integral_constant<size_t, numeric_limits<const volatile unsigned char>::digits> { };
```

The specialization of binary_digits for (possibly cv-qualified) byte makes byte a viable word type to hold bits.

1.3.3 Variable template binary_digits_v

```cpp
template <class T> constexpr binary_digits_v = binary_digits<T>::value;
```

The variable template binary_digits_v provides an access to the value member of binary_digits for convenience.

1.4 Class bit_value

1.4.1 Class bit_value overview

A bit_value emulates the behavior an independent single bit, with no arithmetic behavior apart from bitwise compound assignment (1.4.5) and bitwise operators (1.4.9). It provides the bit modifier members set, reset and flip (1.4.7). [Note: A bit_value is typically implemented as a wrapper around bool. — end note]

A bit_value is implicitly convertible from a bit_reference (1.5), typically to create temporary values from references to bits.

To prevent implicit conversions to bool and int potentially leading to misleading arithmetic behaviors, a bit_value is explicitly, and not implicitly, convertible to bool (1.4.6).

For convenience, two global bit_value objects are provided (1.4.10).

```cpp
class bit_value {
public:
    // 1.4.2, types
    using size_type = see below;

    // 1.4.3, constructors
    bit_value() noexcept = default;
    template <class T> constexpr bit_value(bit_reference<T> ref) noexcept;
    template <class WordType> explicit constexpr bit_value(WordType val) noexcept;
    template <class WordType> constexpr bit_value(WordType val, size_type pos);

    // 1.4.4, assignment
    template <class T> constexpr bit_value& operator=(bit_reference<T> ref) noexcept;
    template <class WordType> constexpr bit_value& assign(WordType val) noexcept;
    template <class WordType> constexpr bit_value& assign(WordType val, size_type pos);

    // 1.4.5, compound assignment
    constexpr bit_value& operator&=(bit_value rhs) noexcept;
    constexpr bit_value& operator|=(bit_value rhs) noexcept;
    constexpr bit_value& operator^=(bit_value rhs) noexcept;

    // 1.4.6, observers
    explicit constexpr operator bool() const noexcept;

private:
    // 1.4.7, bit modifiers
    mutable bit_value private_;
    mutable size_type pos_;
}
```
1.4.7 modifiers
constexpr bit_value& set(bool b) noexcept;
constexpr bit_value& set() noexcept;
constexpr bit_value& reset() noexcept;
constexpr bit_value& flip() noexcept;

1.4.8 swap
void swap(bit_value& rhs) noexcept;
template <class T> void swap(bit_reference<T> rhs) noexcept;
};

1.4.2 bit_value member types
using size_type = see below;

Type: An implementation-defined unsigned integer type capable of holding at least as many values as `binary_digits_v<std::uintmax_t>`. Same as `decltype(binary_digits_v<std::uintmax_t>)` (1.3.3).

1.4.3 bit_value constructors

bit_value() noexcept = default;

Effects: Constructs an uninitialized object of type bit_value.

template <class T> constexpr bit_value(bit_reference<T> ref) noexcept;

Effects: Constructs an object of type bit_value from the value of the referenced bit ref.

template <class WordType> explicit constexpr bit_value(WordType val) noexcept;

Requires: `binary_digits_v<WordType>` shall be defined and shall not be zero (1.3).

Effects: Constructs an object of type bit_value from the value of the bit in val at position 0.

[Note: Contrarily to the more generic constructor that takes an arbitrary position as an argument, this constructor is marked noexcept.—end note]

template <class WordType> constexpr bit_value(WordType val, size_type pos);

Requires: `binary_digits_v<WordType>` shall be defined and shall not be zero (1.3).

Requires: `pos < binary_digits_v<WordType>`.

Effects: Constructs an object of type bit_value from the value of the bit in val at position pos.

1.4.4 bit_value assignment

template <class T> constexpr bit_value& operator=(bit_reference<T> ref) noexcept;

Effects: Assigns the value of the referenced bit ref to *this.

Returns: *this.

template <class WordType> constexpr bit_value& assign(WordType val) noexcept;

Requires: `binary_digits_v<WordType>` shall be defined and shall not be zero (1.3).

Effects: Assigns the value of the bit in val at position 0 to *this.

Returns: *this.
template <class WordType> constexpr bit_value& assign(WordType val, size_type pos);

Requires: binary_digits_v<WordType> shall be defined and shall not be zero (1.3).
Requires: pos < binary_digits_v<WordType>.
Effects: Assigns the value of the bit in val at position pos to *this.
Returns: *this.

1.4.5 bit_value compound assignment

constexpr bit_value& operator&=(bit_value rhs) noexcept;

Effects: Clears the bit if rhs is clear.
Returns: *this.

constexpr bit_value& operator|=(bit_value rhs) noexcept;

Effects: Sets the bit if rhs is set.
Returns: *this.

constexpr bit_value& operator^=(bit_value rhs) noexcept;

Effects: Toggles the bit if rhs is set.
Returns: *this.

1.4.6 bit_value observers

explicit constexpr operator bool() const noexcept;

Returns: false if the bit is cleared, true if it is set.

1.4.7 bit_value modifiers

constexpr bit_value& set(bool b) noexcept;

Effects: Stores a new value in the bit: one if b is true, zero otherwise.
Returns: *this.

constexpr bit_value& set() noexcept;

Effects: Sets the bit to one.
Returns: *this.

constexpr bit_value& reset() noexcept;

Effects: Resets the bit to zero.
Returns: *this.

constexpr bit_value& flip() noexcept;

Effects: Toggles the bit.
Returns: *this.

1.4.8 bit_value swap

§ 1.4.8
void swap(bit_value& rhs) noexcept;

   Effects: Toggles the bit stored in *this and the bit stored in rhs if their value differ as in static_cast<bool>(*this) != static_cast<bool>(rhs).

template <class T> void swap(bit_reference<T> rhs) noexcept;

   Effects: Toggles the bit stored in *this and the bit referenced by rhs if their value differ as in static_cast<bool>(*this) != static_cast<bool>(rhs).

1.4.9 bit_value non-member operations

constexpr bit_value operator~(bit_value rhs) noexcept;

   Effects: Constructs an object x of class bit_value and initializes it with rhs.

   Returns: x.flip().

constexpr bit_value operator&(bit_value lhs, bit_value rhs) noexcept;

   Returns: bit_value(lhs) &= rhs.

constexpr bit_value operator|(bit_value lhs, bit_value rhs) noexcept;

   Returns: bit_value(lhs) |= rhs.

constexpr bit_value operator^(bit_value lhs, bit_value rhs) noexcept;

   Returns: bit_value(lhs) ^= rhs.

constexpr bool operator==(bit_value lhs, bit_value rhs) noexcept;

   Returns: static_cast<bool>(lhs) == static_cast<bool>(rhs).

constexpr bool operator!=(bit_value lhs, bit_value rhs) noexcept;

   Returns: static_cast<bool>(lhs) != static_cast<bool>(rhs).

constexpr bool operator<(bit_value lhs, bit_value rhs) noexcept;

   Returns: static_cast<bool>(lhs) < static_cast<bool>(rhs).

constexpr bool operator<=(bit_value lhs, bit_value rhs) noexcept;

   Returns: static_cast<bool>(lhs) <= static_cast<bool>(rhs).

constexpr bool operator>(bit_value lhs, bit_value rhs) noexcept;

   Returns: static_cast<bool>(lhs) > static_cast<bool>(rhs).

constexpr bool operator>=(bit_value lhs, bit_value rhs) noexcept;

   Returns: static_cast<bool>(lhs) >= static_cast<bool>(rhs).

template <class charT, class traits>
basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& is, bit_value& x);

   A formatted input function.

   Effects: A sentry object is first constructed. If the sentry object returns true, one character is extracted from is. If the character is successfully extracted with no end-of-file encountered, it is compared to is.widen('0') and to is.widen('1') and a temporary bit_value is set accordingly. If the character is neither equal to is.widen('0') nor to is.widen('1'), the extracted character is put back into the sequence. If the extraction succeeds, the temporary bit_value is assigned to x, otherwise
is.setstate(ios_base::failbit) is called (which may throw ios_base::failure).

Returns: is.

template <class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, bit_value x);

A formatted output function.

Effects: Outputs the bit to the stream.

Returns: os << os.widen(x ? '1' : '0').

1.4.10 bit_value objects

inline constexpr bit_value bit0(0U);

The object bit0 represents a constant bit of value 0. [Note: This is mostly a convenience feature, for example to make the call of bit manipulation algorithms less verbose and less error-prone as in count(first_bit, last_bit, bit0) instead of count(first_bit, last_bit, bit_value(0U)). — end note]

inline constexpr bit_value bit1(1U);

The object bit1 represents a constant bit of value 1. [Note: This is mostly a convenience feature, for example to make the call of bit manipulation algorithms less verbose and less error-prone as in count(first_bit, last_bit, bit1) instead of count(first_bit, last_bit, bit_value(1U)). — end note]

1.5 Class template bit_reference

1.5.1 Class template bit_reference overview

A bit_reference emulates the behavior of a reference to a bit within an object, with no arithmetic behavior apart from bitwise compound assignment (1.5.5) and bitwise operators provided through implicit conversion to bit_value (1.4.9). Comparison operators are provided through implicit conversion to bit_value (1.4.9). As for bit_value (1.4.7), it provides the bit modifier members set, reset and flip (1.5.7). [Note: A bit_reference is typically implemented in terms of a bit position or a mask, and in terms of a pointer or a reference to the object in which the bit is referenced. — end note]

The copy assignment operator = is overloaded to assign a new value to the referenced bit without changing the underlying reference itself. Specializations of swap are provided for the same reason, typically using a temporary bit_value (1.4) to ensure that the referenced values are swapped and not the references themselves.

The address-of operator & of bit_reference (1.5.6) is overloaded to return a bit_pointer (1.6) to the referenced bit. [Note: A pointer to a bit_reference can be obtained through the addressof function of the standard library. — end note]

An access to the underlying representation of a bit_reference is provided through the function members address, position and mask (1.5.6).

To prevent implicit conversions to bool and int potentially leading to misleading arithmetic behaviors, a bit_reference is explicitly, and not implicitly, convertible to bool (1.5.6).

The template parameter type WordType shall be a type such that binary_digits_v<WordType> is defined and is not zero (1.3). A reference to a constant bit shall be obtained through bit_reference<const WordType>.

Concurrently mutating multiple bits belonging to the same underlying word through bit references may result in a data race.
template <class WordType>
class bit_reference {
public:
  // 1.5.2, types
  using word_type = WordType;
  using size_type = see below;

  // 1.5.3, constructors
  template <class T> constexpr bit_reference(const bit_reference<T>& other) noexcept;
  explicit constexpr bit_reference(word_type& ref) noexcept;
  constexpr bit_reference(word_type& ref, size_type pos);

  // 1.5.4, assignment
  constexpr bit_reference& operator=(const bit_reference& other) noexcept;
  template <class T> constexpr bit_reference& operator=(const bit_reference<T>& other) noexcept;
  constexpr bit_reference& operator=(bit_value val) noexcept;
  constexpr bit_reference& assign(word_type val) noexcept;

  // 1.5.5, compound assignment
  constexpr bit_reference& operator&=(bit_value rhs) noexcept;
  constexpr bit_reference& operator|=(bit_value rhs) noexcept;
  constexpr bit_reference& operator^=(bit_value rhs) noexcept;

  // 1.5.6, observers
  explicit constexpr operator bool() const noexcept;
  constexpr bit_pointer<WordType> operator&() const noexcept;
  constexpr word_type* address() const noexcept;
  constexpr size_type position() const noexcept;
  constexpr word_type mask() const noexcept;

  // 1.5.7, modifiers
  constexpr bit_reference& set(bool b) noexcept;
  constexpr bit_reference& set() noexcept;
  constexpr bit_reference& reset() noexcept;
  constexpr bit_reference& flip() noexcept;

  // 1.5.8, swap
  template <class T> void swap(bit_reference<T> rhs) noexcept;
  void swap(bit_value& rhs) noexcept;
};

1.5.2 bit_reference member types

using word_type = WordType;

Type: Refers to the underlying word type that is being provided as a template parameter.

using size_type = see below;

Type: An implementation-defined unsigned integer type capable of holding at least as many values as
binary_digits_v<word_type>. Same as bit_value::size_type (1.4.2).

1.5.3 bit_reference constructors

template <class T> constexpr bit_reference(const bit_reference<T>& other) noexcept;
1. Requires: \( \text{is\_convertible}\_v\langle T \&, \text{word\_type}\& \rangle == \text{true} \)

2. Effects: Constructs an object of type \text{bit\_reference} from another referenced bit \text{other}. \( \text{Note:} \) This constructor is typically used for implicit conversions of cv-qualified bit references. \text{n\textend{note}}

3. \text{explicit constexpr bit\_reference}(\text{word\_type}\& \text{ref}) noexcept;

4. Effects: Constructs a reference to the bit at position 0 of \text{ref}.

5. \[ \text{Note:} \) Contrarily to the more generic constructor that takes an arbitrary position as an argument, this constructor is marked noexcept. \text{n\textend{note}}

6. constexpr bit\_reference(\text{word\_type}\& \text{ref}, \text{size\_type} \text{pos});

7. Requires: \text{pos < binary\_digits\_v\langle word\_type\rangle}.

8. Effects: Constructs a reference to the bit at position \text{pos} of \text{ref}.

1.5.4 \text{bit\_reference assignment} \[\text{bit\_reference\_assign}\]

9. constexpr bit\_reference& operator\=(\text{const bit\_reference}& \text{other}) noexcept;

1. Effects: Copies the value of the referenced bit \text{ref} to the bit referenced by \text{*this}.

2. Returns: \text{*this}.

3. Remarks: The copy assignment operator is not implicitly generated in order to ensure that the value of the referenced bit is changed instead of the underlying reference itself.

4. \text{template <class T> constexpr bit\_reference& operator\=(\text{const bit\_reference\langle T\rangle}& \text{other}) noexcept;}

5. Requires: \( \text{is\_convertible}\_v\langle T \&, \text{word\_type}\& \rangle == \text{true} \)

6. Effects: Assigns the value of the referenced bit \text{other} to the bit referenced by \text{*this}.

7. Returns: \text{*this}.

8. constexpr bit\_reference& operator\=(\text{bit\_value} \text{val}) noexcept;

9. Effects: Assigns the value of the bit \text{val} to the bit referenced by \text{*this}.

10. Returns: \text{*this}.

11. constexpr bit\_reference& assign(\text{word\_type} \text{val}) noexcept;

12. Effects: Assigns the value of the bit in \text{val} at position 0 to the bit referenced by \text{*this}.

13. Returns: \text{*this}.

14. \[ \text{Note:} \) Contrarily to the more generic \text{assign} member function that takes an arbitrary position as an argument, this member function is marked noexcept. \text{n\textend{note}}

15. constexpr bit\_reference& assign(\text{word\_type} \text{val}, \text{size\_type} \text{pos});

16. Requires: \text{pos < binary\_digits\_v\langle word\_type\rangle}.

17. Effects: Assigns the value of the bit in \text{val} at position \text{pos} to the bit referenced by \text{*this}.

18. Returns: \text{*this}.

1.5.5 \text{bit\_reference compound assignment} \[\text{bit\_reference\_cassign}\]

19. constexpr bit\_reference& operator\&\=(\text{bit\_value} \text{rhs}) noexcept;

20. Effects: Clears the bit referenced by \text{*this} if \text{rhs} is clear.

21. Returns: \text{*this}.

§ 1.5.5 10
constexpr bit_reference& operator|=(bit_value rhs) noexcept;

Effects: Sets the bit referenced by *this if rhs is set.
Returns: *this.

constexpr bit_reference& operator^=(bit_value rhs) noexcept;

Effects: Toggles the bit referenced by *this if rhs is set.
Returns: *this.

1.5.6 bit_reference observers [bit.reference.observers]

explicit constexpr operator bool() const noexcept;

Returns: false if the bit referenced by *this is cleared, true if it is set.

constexpr bit_pointer<WordType> operator&() const noexcept;

Returns: A bit_pointer (1.6) pointing to the bit referenced by *this.
Remarks: The actual address of a bit_reference object can be obtained through the addressof function of the standard library.

constexpr word_type* address() const noexcept;

Returns: A pointer to the word containing the bit referenced by *this.

constexpr size_type position() const noexcept;

Returns: The position of the bit referenced by *this within the word containing it.

constexpr word_type mask() const noexcept;

Returns: A mask of type word_type whose only set bit is the bit at the position of the bit referenced by *this within the word containing it as in static_cast<word_type>(1) << position().

1.5.7 bit_reference modifiers [bit.reference.modifiers]

constexpr bit_reference& set(bool b) noexcept;

Effects: Stores a new value in the bit referenced by *this: one if b is true, zero otherwise.
Returns: *this.

constexpr bit_reference& set() noexcept;

Effects: Sets the bit referenced by *this to one.
Returns: *this.

constexpr bit_reference& reset() noexcept;

Effects: Resets the bit referenced by *this to zero.
Returns: *this.

constexpr bit_reference& flip() noexcept;

Effects: Toggles the bit referenced by *this.
Returns: *this.

1.5.8 bit_reference swap [bit.reference.swap]

template <class T> void swap(bit_reference<T> rhs) noexcept;
Effects: Toggles the bit referenced by `*this` and the bit referenced by `rhs` if their value differ as in `static_cast<bool>(*this) != static_cast<bool>(rhs)`.

```cpp
void swap(bit_value& rhs) noexcept;
```

Effects: Toggles the bit referenced by `*this` and the bit stored in `rhs` if their value differ as in `static_cast<bool>(*this) != static_cast<bool>(rhs)`.

Remarks: This overload of `swap` ensures that the values of the referenced bits are swapped instead of the underlying references themselves.

```cpp
template <class T> void swap(bit_reference<T> lhs, bit_reference<T> rhs) noexcept;
Effects: Toggles the bit referenced by `lhs` and the bit referenced by `rhs` if their value differ as in `static_cast<bool>(lhs) != static_cast<bool>(rhs)`.
```

Remarks: This overload of `swap` ensures that the values of the referenced bits are swapped instead of the underlying references themselves.

```cpp
template <class T, class U> void swap(bit_reference<T> lhs, bit_reference<U> rhs) noexcept;
Effects: Toggles the bit referenced by `lhs` and the bit referenced by `rhs` if their value differ as in `static_cast<bool>(lhs) != static_cast<bool>(rhs)`.
```

```cpp
template <class T> void swap(bit_reference<T> lhs, bit_value& rhs) noexcept;
Effects: Toggles the bit referenced by `lhs` and the bit stored in `rhs` if their value differ as in `static_cast<bool>(lhs) != static_cast<bool>(rhs)`.
```

```cpp
template <class T> void swap(bit_reference<T> lhs, bit_value& rhs) noexcept;
Effects: Toggles the bit stored in `lhs` and the bit referenced by `rhs` if their value differ as in `static_cast<bool>(lhs) != static_cast<bool>(rhs)`.
```

§ 1.5.9 bit_reference non-member operations [bit.reference.nonmembers]

```cpp
template <class T> void swap(bit_reference<T> lhs, bit_reference<T> rhs) noexcept;
```

Effects: Toggles the bit referenced by `lhs` and the bit referenced by `rhs` if their value differ as in `static_cast<bool>(lhs) != static_cast<bool>(rhs)`.

```cpp
template <class T, class U> void swap(bit_reference<T> lhs, bit_reference<U> rhs) noexcept;
```

Effects: Toggles the bit referenced by `lhs` and the bit referenced by `rhs` if their value differ as in `static_cast<bool>(lhs) != static_cast<bool>(rhs)`.

```cpp
template <class charT, class traits, class T>
basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& is, bit_reference<T>& x);
```

A formatted input function.

Effects: A sentry object is first constructed. If the sentry object returns `true`, one character is extracted from `is`. If the character is successfully extracted with no end-of-file encountered, it is compared to `is.widen('0')` and to `is.widen('1')` and a temporary `bit_value` is set accordingly. If the character is neither equal to `is.widen('0')` nor to `is.widen('1')`, the extracted character is put back into the sequence. If the extraction succeeds, the temporary bit value is assigned to `x`, otherwise `is.setstate(ios_base::failbit)` is called (which may throw `ios_base::failure`).

Returns: `is`.

```cpp
template <class charT, class traits, class T>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, bit_reference<T> x);
```

A formatted output function.

Effects: Outputs the bit to the stream.

Returns: `os << os.widen(x ? '1' : '0').`
1.6 Class template bit_pointer

1.6.1 Class template bit_pointer overview

A bit_pointer emulates the behavior of a pointer to a bit within an object. [Note: A bit_pointer can be implemented in terms of a pointer to a bit_reference (1.5).—end note]

The indirection operator * of bit_pointer (1.6.5) is overloaded to return a bit_reference (1.5) to the pointed bit, while the arrow operator -> is overloaded to return a pointer to a bit_reference (1.5). Bit modifiers (1.5.7) can be accessed through this interface, as well as the underlying representation (1.5.6).

A null bit pointer can be created from a nullptr (1.6.3). Deferred a null bit pointer leads to an undefined behavior. The explicit conversion to bool (1.6.5) shall return false for a null bit pointer, and true otherwise.

The arithmetic of bit pointers (1.6.6) rely on the ordering described in 1.1: a bit pointer ptr2 is considered to be the next bit pointer of ptr1 if both of them are not null and if either of the following is true:

1. ptr2->address() - ptr1->address() == 0
2. ptr2->address() - ptr1->address() == 1
   && binary_digits_v<typename decltype(ptr1)::word_type> - ptr1->position() == 1
   && ptr2->position() == 0

Comparison operators for bit_pointer (1.6.7) rely on the same ordering, first comparing the addresses of the underlying values and then comparing bit positions in case of equality.

The template parameter type WordType shall be a type such that binary_digits_v<WordType> is defined and is not zero (1.3). A pointer to a constant bit shall be obtained through bit_pointer<const WordType>. A constant pointer to a mutable bit shall be obtained through const bit_pointer<WordType>. A constant pointer to a constant bit shall be obtained through const bit_pointer<const WordType>.

The return type of the difference between two bit pointers (1.6.2) shall be an implementation-defined signed integer type capable of holding at least as many values as ptrdiff_t.

```cpp
template <class WordType>
class bit_pointer {
public:
  // 1.6.2, types
  using word_type = WordType;
  using size_type = see below;
  using difference_type = see below;

  // 1.6.3, constructors
  bit_pointer() noexcept = default;
  template <class T> constexpr bit_pointer(const bit_pointer<T>& other) noexcept;
  constexpr bit_pointer(nullptr_t) noexcept;
  explicit constexpr bit_pointer(word_type* ptr) noexcept;
  constexpr bit_pointer(word_type* ptr, size_type pos);

  // 1.6.4, assignment
  constexpr bit_pointer& operator=(nullptr_t) noexcept;
  constexpr bit_pointer& operator=(const bit_pointer& other) noexcept;
  template <class T> constexpr bit_pointer& operator=(const bit_pointer<T>& other) noexcept;

  // 1.6.5, observers
  explicit constexpr operator bool() const noexcept;
  constexpr bit_reference<WordType> operator*() const noexcept;
  constexpr bit_reference<WordType>* operator->() const noexcept;
  constexpr bit_reference<WordType> operator[](difference_type n) const;
};
```

§ 1.6.1
// 1.6.6, arithmetic
constexpr bit_pointer& operator++();
constexpr bit_pointer& operator--();
constexpr bit_pointer operator++(int);
constexpr bit_pointer operator--(int);
constexpr bit_pointer operator+(difference_type n) const;
constexpr bit_pointer operator-(difference_type n) const;
constexpr bit_pointer& operator+=(difference_type n);
constexpr bit_pointer& operator-=(difference_type n);
};

1.6.2 bit_pointer member types

using word_type = WordType;
1
Type: Refers to the underlying word type that is being provided as a template parameter.

using size_type = see below;
2
Type: An implementation-defined unsigned integer type capable of holding at least as many values as
binary_digits_v<word_type>. Same as bit_value::size_type (1.4.2).

using difference_type = see below;
3
Type: An implementation-defined signed integer type capable of holding at least as many values as
ptrdiff_t.

1.6.3 bit_pointer constructors

bit_pointer() noexcept = default;
1
Effects: Constructs an uninitialized object of type bit_pointer.

Remarks: Observing (1.6.5) an uninitialized bit pointer, calling member arithmetic operators (1.6.6)
on uninitialized bit pointers or calling non-member arithmetic operators (1.6.7) on uninitialized bit
pointers leads to an undefined behavior.

template <class T> constexpr bit_pointer(const bit_pointer<T>& other) noexcept;
3
Requires: is_convertible_v<T*, word_type*> == true
4
Effects: Constructs an object of type bit_pointer from another bit pointer other. [Note: This
constructor is typically used for implicit conversions of cv-qualified bit pointers. — end note]

constexpr bit_pointer(nullptr_t) noexcept;
5
Effects: Constructs a null bit pointer.

explicit constexpr bit_pointer(word_type* ptr) noexcept;
6
Effects: Constructs a pointer to the bit at position 0 of the word pointed to by ptr.

[Note: Contrarily to the more generic constructor that takes an arbitrary position as an argument, this
constructor is marked noexcept. — end note]

constexpr bit_pointer(word_type* ptr, size_type pos);
8
Requires: pos < binary_digits_v<word_type>.
9
Effects: Constructs a pointer to the bit at position pos of the word pointed to by ptr.

1.6.4 bit_pointer assignment

§ 1.6.4
constexpr bit_pointer& operator=(nullptr_t) noexcept;
   Effects: Assigns a null bit pointer to *this.
   Returns: *this.

constexpr bit_pointer& operator=(const bit_pointer& other) noexcept;
   Effects: Copies the bit pointer other to *this.
   Returns: *this.
   Remarks: The copy assignment operator is not implicitly generated in order to ensure that the pointer itself is changed instead of the value of the bit pointed to by *this.

template <class T> constexpr bit_pointer& operator=(const bit_pointer<T>& other) noexcept;
   Requires: is_convertible_v<T*, word_type*> == true
   Effects: Assigns the bit pointer other to *this.
   Returns: *this.

1.6.5 bit_pointer observers

explicit constexpr operator bool() const noexcept;
   Returns: false if *this is a null bit pointer, true otherwise.

constexpr bit_reference<WordType> operator*() const noexcept;
   Requires: static_cast<bool>(*this) == true.
   Returns: A bit_reference (1.5) referencing the bit pointed to by *this.

constexpr bit_reference<WordType>* operator->() const noexcept;
   Requires: static_cast<bool>(*this) == true.
   Returns: A pointer to a bit_reference (1.5) referencing the bit pointed to by *this.

constexpr bit_reference<WordType> operator[](difference_type n) const;
   Requires: static_cast<bool>(*this) == true.
   Returns: A bit_reference (1.5) referencing the n-th bit after (or before for negative n) the bit pointed to by *this according to the arithmetic of bit pointers described in 1.6.1.

1.6.6 bit_pointer arithmetic

constexpr bit_pointer& operator++();
   Requires: static_cast<bool>(*this) == true.
   Effects: Increments *this according to the arithmetic of bit pointers described in 1.6.1.
   Returns: *this

constexpr bit_pointer& operator--();
   Requires: static_cast<bool>(*this) == true.
   Effects: Decrements *this according to the arithmetic of bit pointers described in 1.6.1.
   Returns: *this

constexpr bit_pointer operator++(int);
Requires: \texttt{static\_cast<bool>(*this) == true}.

Effects: Makes a copy of \texttt{*this}, increments \texttt{*this} according to the arithmetic of bit pointers described in 1.6.1, and returns the original copy.

Returns: A copy of \texttt{*this} made before the increment.

```cpp
constexpr bit\_pointer operator--(int);
```

Requires: \texttt{static\_cast<bool>(*this) == true}.

Effects: Makes a copy of \texttt{*this}, decrements \texttt{*this} according to the arithmetic of bit pointers described in 1.6.1, and returns the original copy.

Returns: A copy of \texttt{*this} made before the decrement.

```cpp
constexpr bit\_pointer operator+(difference\_type n) const;
```

Requires: \texttt{static\_cast<bool>(*this) == true}.

Returns: A \texttt{bit\_pointer} pointing to the \texttt{n}-th bit after (or before for negative \texttt{n}) the bit pointed to by \texttt{*this} according to the arithmetic of bit pointers described in 1.6.1.

```cpp
constexpr bit\_pointer operator-(difference\_type n) const;
```

Requires: \texttt{static\_cast<bool>(*this) == true}.

Returns: A \texttt{bit\_pointer} pointing to the \texttt{n}-th bit before (or after for negative \texttt{n}) the bit pointed to by \texttt{*this} according to the arithmetic of bit pointers described in 1.6.1.

```cpp
constexpr bit\_pointer& operator+=(difference\_type n);
```

Requires: \texttt{static\_cast<bool>(*this) == true}.

Effects: Increments \texttt{*this} (or decrements for negative \texttt{n}) \texttt{n} times according to the arithmetic of bit pointers described in 1.6.1.

Returns: \texttt{*this}.

```cpp
constexpr bit\_pointer& operator-=(difference\_type n);
```

Requires: \texttt{static\_cast<bool>(*this) == true}.

Effects: Decrements \texttt{*this} (or increments for negative \texttt{n}) \texttt{n} times according to the arithmetic of bit pointers described in 1.6.1.

Returns: \texttt{*this}.

### 1.6.7 bit\_pointer non-member operations

```cpp
template <class T>
constexpr bit\_pointer\<T\>
    operator+(typename bit\_pointer\<T\>::difference\_type n, bit\_pointer\<T\> x);
```

Requires: \texttt{static\_cast<bool>(x) == true}.

Returns: \texttt{x + n}.

```cpp
template <class T, class U>
constexpr common\_type\_<
    typename bit\_pointer\<T\>::difference\_type,
    typename bit\_pointer\<U\>::difference\_type
> operator-(bit\_pointer\<T\> lhs, bit\_pointer\<U\> rhs);
```

Requires: \texttt{static\_cast<bool>(lhs) == static\_cast<bool>(rhs)}.
Returns: The number of bits \( n \) such that \( \text{lhs} + n == \text{rhs} \).

```cpp
template <class T, class U>
constexpr bool operator==(bit_pointer<T> lhs, bit_pointer<U> rhs) noexcept;

Returns: static_cast<bool>(lhs) == static_cast<bool>(rhs) && (!static_cast<bool>(lhs)
|| (lhs->address() == rhs->address() && lhs->position() == rhs->position())).
```

```cpp
template <class T, class U>
constexpr bool operator!=(bit_pointer<T> lhs, bit_pointer<U> rhs) noexcept;

Returns: static_cast<bool>(lhs) != static_cast<bool>(rhs) || (static_cast<bool>(lhs)
&& (lhs->address() != rhs->address() || lhs->position() != rhs->position())).
```

```cpp
template <class T, class U>
constexpr bool operator<(bit_pointer<T> lhs, bit_pointer<U> rhs) noexcept;

Requires: static_cast<bool>(lhs) == static_cast<bool>(rhs).

Returns: static_cast<bool>(lhs) && (lhs->address() < rhs->address()
|| (lhs->address() == rhs->address() && lhs->position() < rhs->position())).
```

```cpp
template <class T, class U>
constexpr bool operator<=(bit_pointer<T> lhs, bit_pointer<U> rhs) noexcept;

Requires: static_cast<bool>(lhs) == static_cast<bool>(rhs).

Returns: !static_cast<bool>(lhs) || (lhs->address() < rhs->address()
|| (lhs->address() == rhs->address() && lhs->position() <= rhs->position())).
```

```cpp
template <class T, class U>
constexpr bool operator>(bit_pointer<T> lhs, bit_pointer<U> rhs) noexcept;

Requires: static_cast<bool>(lhs) == static_cast<bool>(rhs).

Returns: static_cast<bool>(lhs) && (lhs->address() > rhs->address()
|| (lhs->address() == rhs->address() && lhs->position() > rhs->position())).
```

```cpp
template <class T, class U>
constexpr bool operator>=(bit_pointer<T> lhs, bit_pointer<U> rhs) noexcept;

Requires: static_cast<bool>(lhs) == static_cast<bool>(rhs).

Returns: !static_cast<bool>(lhs) || (lhs->address() > rhs->address()
|| (lhs->address() == rhs->address() && lhs->position() >= rhs->position())).
```

1.7 Class template bit_iterator

1.7.1 Class template bit_iterator overview

A bit_iterator is an iterator adaptor to iterate over the bits of a range of underlying words. The value-type (1.7.2) of a bit_iterator is defined as a bit_value (1.4), the reference type (1.7.2) is defined as a bit_reference (1.5) and the pointer type (1.7.2) is defined as a bit_pointer (1.6). [Note: A bit_iterator is typically implemented in terms of a bit position or a mask, and in terms of an underlying iterator. — end note]

The arithmetic of bit iterators (1.7.6) rely on the ordering described in 1.1: a bit iterator it2 is considered to be the next bit iterator of it1 if either of the following is true:

1. \( \text{it2.base()} == \text{it1.base()} \)
   \&\& \( \text{it2.position()} - \text{it1.position()} == 1 \)
2. \( \text{it2.base()} == \text{next(it1.base())} \)
Comparison operators for `bit_iterator` (1.7.7) rely on the same ordering, first comparing the underlying iterator and then comparing bit positions in case of equality.

The template parameter type `Iterator` shall be an iterator such that the following types are the same:

1. `iterator_traits<Iterator>::value_type`
2. `remove_cv_t<remove_reference_t<typename iterator_traits<Iterator>::reference>>`
3. `remove_cv_t<remove_pointer_t<typename iterator_traits<Iterator>::pointer>>`
4. `bit_reference<remove_reference_t<typename iterator_traits<Iterator>::reference>>`
5. `bit_pointer<remove_pointer_t<typename iterator_traits<Iterator>::pointer>>`

and such that:

- `forward_iterator_tag`
- `input_iterator_tag`
- `output_iterator_tag`
- `random_access_iterator_tag`
- `unique_ptr_iterator_tag`
- `shared_ptr_iterator_tag`
- `transaction_iterator_tag`
- `array_iterator_tag`

The member type `word_type` (1.7.2) keeps track of the cv-qualification of the underlying word type. [Note: For this reason, the types of `iterator_traits<Iterator>::value_type` and `bit_iterator<Iterator>::word_type` may have different cv-qualifiers. Implementations may use `remove_reference_t<typename iterator_traits<Iterator>::reference>` to propagate cv-qualifiers instead of `iterator_traits<Iterator>::value_type`. — end note]

An access to the underlying representation of a `bit_iterator` is provided through the function members `base`, `position` and `mask` (1.7.5).

The return type of the difference between two bit iterator (1.6.2) shall be an implementation-defined signed integer type capable of holding at least as many values as `ptrdiff_t`.

```cpp
template <class Iterator>
class bit_iterator {
public:
  // 1.7.2, types
  using iterator_type = Iterator;
  using word_type = see below;
  using iterator_category = typename iterator_traits<Iterator>::iterator_category;
  using value_type = bit_value;
  using difference_type = see below;
  using pointer = bit_pointer<word_type>;
  using reference = bit_reference<word_type>;
  using size_type = see below;

  // 1.7.3, constructors
  constexpr bit_iterator();
  template <class T> constexpr bit_iterator(const bit_iterator<T>& other);
  explicit constexpr bit_iterator(iterator_type i);
  constexpr bit_iterator(iterator_type i, size_type pos);

  // 1.7.4, assignment
  template <class T> constexpr bit_iterator& operator=(const bit_iterator<T>& other);

  // 1.7.5, observers
  constexpr reference operator*() const noexcept;

  § 1.7.1
}```
constexpr pointer operator->() const noexcept;
constexpr reference operator[](difference_type n) const;
constexpr iterator_type base() const;
constexpr size_type position() const noexcept;
constexpr word_type mask() const noexcept;

// 1.7.6, arithmetic
constexpr bit_iterator& operator++();
constexpr bit_iterator& operator--();
constexpr bit_iterator operator++(int);
constexpr bit_iterator operator--(int);
constexpr bit_iterator operator+(difference_type n) const;
constexpr bit_iterator operator-(difference_type n) const;
constexpr bit_iterator& operator+=(difference_type n);
constexpr bit_iterator& operator-=(difference_type n);
};

1.7.2 bit_iterator member types

using iterator_type = Iterator;

1 Type: Refers to the Iterator template type parameter that is being adapted.

using word_type = see below;

2 Type: Refers to the cv-qualified type on which the underlying iterator is iterating, which is equivalent
to remove_reference_t<typename iterator_traits<Iterator>::reference> according to 1.7.1.

using iterator_category = typename iterator_traits<Iterator>::iterator_category;

3 Type: Refers to the same iterator category as the one of the underlying iterator.

using value_type = bit_value;

4 Type: bit_value.

using difference_type = see below;

5 Type: An implementation-defined signed integer type capable of holding at least as many values as
ptrdiff_t. Same as bit_pointer<word_type>::difference_type (1.6.2).

using pointer = bit_pointer<word_type>;

6 Type: bit_pointer<word_type>.

using reference = bit_reference<word_type>;

7 Type: bit_reference<word_type>.

using size_type = see below;

8 Type: An implementation-defined unsigned integer type capable of holding at least as many values as
binary_digits_v<word_type>. Same as bit_value::size_type (1.4.2).

1.7.3 bit_iterator constructors

constexpr bit_iterator();

1 Effects: Value-initializes the underlying word iterator and the underlying bit position. Iterator operations
applied to the resulting iterator have defined behavior if and only if the corresponding operations are
defined on a value-initialized iterator of type iterator_type.

§ 1.7.3
template <class T> constexpr bit_iterator(const bit_iterator<T>& other);

Requires: is_constructible_v<iterator_type, T> == true
Effects: Constructs an object of type bit_iterator from another bit iterator other, initializing the underlying word iterator from other.base() and initializing the underlying bit position from other.position().

explicit constexpr bit_iterator(iterator_type i);

Effects: Constructs an iterator over the bit at position 0 of the word iterated over by it.

constexpr bit_iterator(iterator_type i, size_type pos);

Requires: pos < binary_digits_v<word_type>.
Effects: Constructs an iterator over the bit at position pos of the word iterated over by it.

1.7.4 bit_iterator assignment

template <class T> constexpr bit_iterator& operator=(const bit_iterator<T>& other);

Requires: is_assignable_v<iterator_type, T> == true
Effects: Assigns the bit iterator other to *this, assigning other.base() to the underlying word iterator of *this and assigning other.position() to the underlying bit position of *this.
Returns: *this.

1.7.5 bit_iterator observers

constexpr reference operator*() const noexcept;
Returns: A bit_reference (1.5) referencing the bit iterated over by *this.

constexpr pointer operator->() const noexcept;
Returns: A bit_pointer (1.6) pointing to the bit iterated over by *this.

constexpr reference operator[](difference_type n) const;
Returns: A bit_reference (1.5) referencing the n-th bit after (or before for negative n) the bit iterated over by *this according to the arithmetic of bit iterators described in 1.7.1.

constexpr iterator_type base() const;
Returns: An iterator over the word containing the bit iterated over by *this.

constexpr size_type position() const noexcept;
Returns: The position of the bit iterated over by *this within the word containing it.

constexpr word_type mask() const noexcept;
Returns: A mask of type word_type whose only set bit is the bit at the position of the bit iterated over by *this within the word containing it as in static_cast<word_type>(1) << position().

1.7.6 bit_iterator arithmetic

constexpr bit_iterator& operator++();
Effects: Increments *this according to the arithmetic of bit iterators described in 1.7.1.
Returns: *this

constexpr bit_iterator& operator--();
Effects: Decrement \(*this\) according to the arithmetic of bit iterators described in 1.7.1.

Returns: \(*this\)

```cpp
constexpr bit_iterator operator++(int);
```

Effects: Makes a copy of \(*this\), increments \(*this\) according to the arithmetic of bit iterators described in 1.7.1, and returns the original copy.

Returns: A copy of \(*this\) made before the increment.

```cpp
constexpr bit_iterator operator--(int);
```

Effects: Makes a copy of \(*this\), decrements \(*this\) according to the arithmetic of bit iterators described in 1.7.1, and returns the original copy.

Returns: A copy of \(*this\) made before the decrement.

```cpp
constexpr bit_iterator operator+(difference_type n) const;
```

Returns: A \bit_iterator\ over the \(n\)-th bit after (or before for negative \(n\)) the bit over which \(*this\) iterates according to the arithmetic of bit iterators described in 1.7.1.

```cpp
constexpr bit_iterator operator-(difference_type n) const;
```

Returns: A \bit_iterator\ over the \(n\)-th bit before (or after for negative \(n\)) the bit over which \(*this\) iterates according to the arithmetic of bit iterators described in 1.7.1.

```cpp
constexpr bit_iterator& operator+=(difference_type n);
```

Effects: Increments \(*this\) (or decrements for negative \(n\)) \(n\) times according to the arithmetic of bit iterators described in 1.7.1.

Returns: \(*this\).

```cpp
constexpr bit_iterator& operator-=(difference_type n);
```

Effects: Decrements \(*this\) (or increments for negative \(n\)) \(n\) times according to the arithmetic of bit iterators described in 1.7.1.

Returns: \(*this\).

### 1.7.7 \bit_iterator\ non-member operations [bit.iterator.nonmembers]

```cpp
template <class T>
constexpr bit_iterator<T> operator+(typename bit_iterator<T>::difference_type n, const bit_iterator<T>& i);
```

Returns: \(i + n\).

```cpp
template <class T, class U>
constexpr common_type_t<typename bit_iterator<T>::difference_type,
                       typename bit_iterator<U>::difference_type>
  operator-(const bit_iterator<T>& lhs, const bit_iterator<U>& rhs);
```

Returns: The number of bits \(n\) such that \(lhs + n == rhs\).

```cpp
template <class T, class U>
constexpr bool operator==(const bit_iterator<T>& lhs, const bit_iterator<U>& rhs);
```

Returns: \(lhs.base() == rhs.base() \&\& lhs.position() == rhs.position()\).

```cpp
template <class T, class U>
```

§ 1.7.7 21
constexpr bool operator!=(const bit_iterator<T>& lhs, const bit_iterator<U>& rhs);

    Returns: lhs.base() != rhs.base() || lhs.position() != rhs.position().

template <class T, class U>
constexpr bool operator<(const bit_iterator<T>& lhs, const bit_iterator<U>& rhs);

    Returns: lhs.base() < rhs.base() || (lhs.base() == rhs.base() && lhs.position() < rhs.position()).

template <class T, class U>
constexpr bool operator<=(const bit_iterator<T>& lhs, const bit_iterator<U>& rhs);

    Returns: lhs.base() < rhs.base() || (lhs.base() == rhs.base() && lhs.position() <= rhs.position()).

template <class T, class U>
constexpr bool operator>(const bit_iterator<T>& lhs, const bit_iterator<U>& rhs);

    Returns: lhs.base() > rhs.base() || (lhs.base() == rhs.base() && lhs.position() > rhs.position()).

template <class T, class U>
constexpr bool operator>=(const bit_iterator<T>& lhs, const bit_iterator<U>& rhs);

    Returns: lhs.base() > rhs.base() || (lhs.base() == rhs.base() && lhs.position() >= rhs.position()).
Annex A Comments & remarks [bit.annex]

1 This annex is not a part of the wording, but comments and remarks on P0237R8.

2 This document corresponds to the version of the proposal that has been presented to LEWG during the Toronto meeting. LEWG decided to forward the proposal to LWG. The paper will be updated accordingly for the next meeting.

3 History of the proposal includes the original motivating and design review paper P0237R0 (pre-Jacksonville), the wording explorations P0237R1 (pre-Oulu), P0237R2 (post-Oulu), P0237R3 (pre-Issaquah), P0237R4 (post-Issaquah), P0237R5 (pre-Kona), P0237R6 (post-Kona), and the formal wording P0237R7 (pre-Toronto). The proposal has also been presented at CppCon2016. The Bit Library provides a working implementation [Note: The implementation at a given time $t$ may differ from the proposal by few minor details. —end note] that has been in use at the University of Illinois at Urbana-Champaign since late 2015 with applications in high performance tree data structures, arbitrary precision arithmetic, machine learning and bioinformatics.

4 Throughout the history of the proposal, most design questions have been debated and answered through discussions and polls as reported in the first part of P0237R6. The paper has been presented to LEWG since its first version. The early design has been reviewed by SG14. The paper has been approved by SG6 in Kona.

5 The feedback from users of The Bit Library the University of Illinois at Urbana-Champaign since late 2015 has been very positive, especially regarding to design and performances. The authors have had no problem teaching the library to students, some of whom have contributed to the implementation of bit manipulation algorithms.

6 Long term plans for the standard library based on the bit utilities described in this proposal include high performance overloads of the standard algorithms for bit iterators and a bit container adapter to replace vector<bool> and bitset. Future arbitrary precision numeric types may also benefit from bit utilities to provide an interface to access the underlying representation.

7 The motivations behind bit_value against bool are explained in great depth in P0237R0. Discussions during the Jacksonville meeting favored bit_value against bool. The authors of the paper strongly support the introduction of bit_value in order to avoid some of the misleading behavior users have experienced during the last decades with vector<bool>. Some of the advantages of bit_value over bool can be summarized as follow:

(7.1) A bit refers to memory while a bool refers to boolean logic, true, false and conditions, in the same way a byte differs from unsigned char even though both of them have 256 possible values. If a bit and a bool were the same, one could wonder why vector<bool> has been considered to be such a problem. A bit is to a bool what byte is to an unsigned char.

(7.2) Using bool instead of bit_value would allow all the implicit conversions of bool, enabling unintuitive behaviors. bit_value provides additional type safety.

(7.3) LEWG has given guidance in Oulu to favor the use of member functions for set, reset and flip. The design presented in this proposal allows bit_value and bit_reference to provide a similar interface. bit_value also provides a 2-argument constructor taking a word and a position as arguments, contrarily to bool. Removing bit_value and replacing it by bool would make the writing generic code more difficult.

The name bit_value has been chosen instead of bit to follow the same convention as in bit_reference, bit_pointer and bit_iterator. It also highlights the fact that the class is a wrapper with sizeof(bit_value) >= 1 as any other object in the C++ memory model, the size being expressed as a number of bytes.
Feedback from users of The Bit Library regarding `bit_value` has been very positive. As an additional remark, high-level code often does not use `bit_value` directly since manipulating bit sequences is achieved through `bit_iterator`, `bit_value` only serving as a helper class for `bit_iterator::value_type`. Since this proposal is targeting a Technical Specification, the Technical Specification could gather more feedback on the use of `bit_value` instead of `bool`.

The following points needed to be discussed in LEWG:

8.1 Should the default constructor of `bit_value` initialize it to zero? Should the default constructor of `bit_pointer` initialize it to a null bit pointer?

8.2 Should the wording specify `sizeof(bit_value) == 1`?

8.3 Should mutating functions of the bit library be marked `constexpr`? What about `swap` overloads and input/output operators (1.2)?

8.4 Is `size_type` (1.4.2, 1.5.2, 1.6.2, 1.7.2) the right member type name to specify the position of a bit within a word? If not, how should this type relate to `decltype(binary_digits_v<WordType>)` (1.3)? Alternatives suggested in small group discussions in Kona include `position_type`.

8.5 How should the `bit_value` objects (1.4.10) be named? Contradictory guidance has been given on this topic over the last meetings. The main options include `zero_bit/one_bit`, `bit_zero/bit_one`, `false_bit/true_bit`, `bit_false/bit_true`, `bit_0/bit_1` and `bit0/bit1`. Typical uses include bit manipulation algorithms:

```cpp
// Example of a call to std::count on bit sequences
std::count(first_bit, last_bit, std::bit_value(0u)); // default version
std::count(first_bit, last_bit, std::bit_value(1u)); // default version
std::count(first_bit, last_bit, std::zero_bit); // zero_bit/one_bit version
std::count(first_bit, last_bit, std::one_bit); // zero_bit/one_bit version
std::count(first_bit, last_bit, std::bit_zero); // bit_zero/bit_one version
std::count(first_bit, last_bit, std::bit_one); // bit_zero/bit_one version
std::count(first_bit, last_bit, std::false_bit); // false_bit/true_bit version
std::count(first_bit, last_bit, std::true_bit); // false_bit/true_bit version
std::count(first_bit, last_bit, std::bit_false); // false_bit/true_bit version
std::count(first_bit, last_bit, std::bit_true); // false_bit/true_bit version
std::count(first_bit, last_bit, std::bit_0); // bit_0/bit_1 version
std::count(first_bit, last_bit, std::bit_1); // bit_0/bit_1 version
std::count(first_bit, last_bit, std::bit0); // bit0/bit1 version
std::count(first_bit, last_bit, std::bit1); // bit0/bit1 version
```

In Kona, SG6 favored the `bit_zero/bit_one` option, while discussions in small groups in LEWG led to no conclusion apart the conclusion that the issue should be solved by a full LEWG poll. The authors of the proposal would discourage the use of `false_bit/true_bit` and `bit_false/bit_true` to avoid the confusion between `bit_value` and `bool`, as well as the `zero_bit/one_bit` option since it breaks the uniform naming convention of the library and since `one_bit` can lead to ambiguity between a bit count of 1 and a bit value of 1. Over the remaining options, the authors would slightly favor `bit0/bit1` for code brevity, code alignment (which is not provided by the `bit_zero/bit_one` option), similarity with math functions such as `log2`, `log10`, `log1p`, and existing naming practices for bit manipulation functions such as the ones suggested in N3864. Regardless of the result, consistency with P0553R1 would be a plus.

The following answers have been provided at the Toronto meeting:

9.1 The default constructor of `bit_value` should initialize to zero.

9.2 The default constructor of `bit_pointer` should initialize it to a null bit pointer.

9.3 The wording does not need to specify `sizeof(bit_value) == 1`.

9.4 Mutating functions of the bit library should be marked `constexpr`, except `swap` overloads and in-
put/output operators (1.2).

(9.5) — The name size_type (1.4.2, 1.5.2, 1.6.2, 1.7.2) is fine.

(9.6) — The names of bit constants were bikeshedded and bit_on/bit_off was suggested.
