A proposal to add a utility class to represent expected object (Revision 4)

Abstract

Class template \texttt{expected<T,E>} proposed here is a type that may contain a value of type \texttt{T} or a value of type \texttt{E} in its storage space. \texttt{T} represents the expected value, \texttt{E} represents the reason explaining why it doesn't contain a value of type \texttt{T}. The interface and the rational are based on \texttt{std::optional} \cite{N3793}. We can consider \texttt{expected<T,E>} as a generalization of \texttt{optional<T>}.

History

Revision 4 - Revision of \texttt{P0323R1}

The 4th revision of this proposal aligns with the late optional changes, complete the wording ensuring the never empty warranties and fixes some typos. In addition it adds more open points concerning whether \texttt{expected<T,E>} must be ordered and implicit conversions. Most of the changes come from suggestion done by Niall and from the feedback of the review of the \texttt{Boost.Outcome} library and my understanding of the use cases the \texttt{Boost.Outcome} reveal.

Next follows the main modifications:

- Added rvalue overloads for \texttt{bad_expected_access::error()} getters and remove the \texttt{constexpr}.
- Provide factories that returns \texttt{expected<const T,E>}.
- Adapt from late changes in \texttt{optional} concerning the observers.
- \texttt{get_unexpected()} returns by reference now.
- Allow construction from \texttt{expected<U,G>} when the types are convertible.
- Make \texttt{bad_expected_access} inherit from \texttt{std::exception} instead of from \texttt{std::logic_error}.
- Take in account constructor guides.

More open points:

- Consider removing \texttt{make_expected_from_call}.
- Consider adding a level on the \texttt{bad_expect_access<E>} exception hierarchy.
- Consider changing the default \texttt{Error} argument to \texttt{error_code}.
- Consider removing the comparison operators and specialize \texttt{less<>.}
- Consider \texttt{expected<T,R>}.  
- Consider a function that allows to adapt the error transported by \texttt{expected}.
- Reconsider expected with a variadic number of errors.

Revision 3 - Revision of \texttt{P0323R0} after with feedback from Oulu
The 3rd revision of this proposal fixes some typos and takes into account the feedback from Oulu meeting. Next follows the direction of the committee:

- Split the proposal on a simple `expected` class and a generic monadic interface.
- As `variant`, `expected` requires some properties in order to ensure the never-empty warranties. As the error type should be no throw movable, we are always sure to be able to ensure the never-empty warranties (Wording not yet complete).
- Removed `exception_ptr` specializations as it introduces different behavior, in particular comparisons, exception thrown, ....
- Adapted comparisons to `P0393R3` and consider `T < E` to be inline with `variant`.
- Redefined the meaning of `e = {}` as `expected<T,E>` defaults to `T()`.
- Added `const &` overloads for value getters.
- Consider to adapt the constructor and assignment from convertible to `T` and `E` to follow last changes in `std::optional` (Wording not yet complete).
- Considered making the conversion from the value type explicit and remove the mixed operations to make the interface more robust even if less friendly.
- Removed the future work section.

Revision 2 - Revision of **N4109** after discussion on the ML

- Fix default constructor to `T`. **N4109** should change the default constructor to `T`, but there were some inconsistencies.
- Complete wording comparison.
- Adapted to last version of referenced proposals.
- Moved alternative designs from open questions to an Appendix.
- Moved already answered open points to a Rationale section.
- Moved open points that can be decided later to a future directions section.
- Complete wording hash.
- Add a section for adapting to `await`.
- Add a section in future work about a possible variadic.
- Fix minor typos.

Revision 1 - Revision of **N4015** after Rapperswil feedback:

- Switch the expected class template parameter order from `expected<E,T>` to `expected<T,E>`.
- Make the unexpected value a salient attribute of the expected class concerning the relational operators.
- Removed open point about making expected and expected different classes.

Introduction

Class template `expected<T,E>` proposed here is a type that may contain a value of type `T` or a value of type `E` in its storage space. `T` represents the expected value, `E` represents the reason explaining why it doesn’t contain a value of type `T`, that is, the unexpected value. Its interface allows to query if the underlying value is either the expected value (of type `T`) or an unexpected value (of type `E`). The original idea comes from Andrei Alexandrescu C++ and Beyond 2012: Systematic Error Handling in C++ talk (Alexandrescu: Expected). The interface and the rationale are based on `std::optional` N3793. We can consider that `expected<T,E>` is a generalization of `optional<T>` providing in addition some specific functions associated to the unexpected type `E`. It requires no changes to core language, and breaks no existing code.

There is a related proposal for a class including a status and an optional value **P0262R0**, **P0157R0** describes when to use each of the different error report mechanism.

Motivation

Basically, the two main error mechanisms are exceptions and return codes. Before further explanation, we should ask what are the characteristics of a good error mechanism.

- **Error visibility**: Failure cases should appear throughout the code review. Because the debug can be painful if the errors are hidden.
- **Information on errors**: The errors should carry out as much as possible information from their origin, causes and possibly the ways to resolve it.
- **Clean code**: The treatment of errors should be in a separate layer of code and as much invisible as possible. So the code reader could notice the presence of exceptional cases without stop his reading.
- **Non-Intrusive error** The errors should not monopolize a communication channel dedicated to the normal code flow. They must be as discrete as possible. For instance, the return of a function is a channel that should not be exclusively reserved for errors.

The first and the third characteristic seem to be quite contradictory and deserve further explanation. The former points out that errors not handled should appear clearly in the code. The latter tells us that the error handling mustn’t interfere with the code reading, meaning that it clearly shows the normal execution flow. A comparison between the exception and return codes is given in the next table.
<table>
<thead>
<tr>
<th>Visibility</th>
<th>Exception</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not visible without further analysis of the code. However, if an exception is thrown, we can follow the stack trace.</td>
<td>Visible at the first sight by watching the prototype of the called function. However ignoring return error code can lead to undefined results and it can be hard to figure out the problem.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Informations</th>
<th>Return error code</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exceptions can be arbitrarily rich.</td>
<td>Historically a simple integer. Nowadays, the header provides richer error code.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Clean code</th>
<th>Non-Intrusive</th>
</tr>
</thead>
<tbody>
<tr>
<td>Provides clean code, exceptions can be completely invisible for the caller.</td>
<td>Proper communication channel. Monopolization of the return channel.</td>
</tr>
</tbody>
</table>

Expected class

We can do the same analysis for the `expected<T, E>` class and observe the advantages over the classic error reporting systems.

- **Error visibility**: It takes the best of the exception and error code. It’s visible because the return type is `expected<T, E>` and the user cannot ignore the error case if he wants to retrieve the contained value.
- **Information**: Arbitrarily rich.
- **Clean code**: The monadic interface of expected provides a framework delegating the error handling to another layer of code. Note that `expected<T, E>` can also act as a bridge between an exception-oriented code and a nothrow world.
- **Non-Intrusive**: Use the return channel without monopolizing it.

It worths mentioning the other characteristics of `expected<T, E>`:

- Associates errors with computational goals.
- Naturally allows multiple errors inflight.
- Teleportation possible.
- Across thread boundaries.
- Across no-throw subsystem boundaries.
- Across time: save now, throw later.
- Collect, group, combine errors.

Use cases

Safe division

This example shows how to define a safe divide operation checking for divide-by-zero conditions. Using exceptions, we might write something like this:

```cpp
group DivideByZero: public std::exception { ...};
double safe_divide(double i, double j)
{
    if (j==0) throw DivideByZero();
    else return i / j;
}
```

With `expected<T, E>`, we are not required to use exceptions, we can use `std::error_condition` which is easier to introspect than `std::exception_ptr` if we want to use the error. For the purpose of this example, we use the following enumeration (the boilerplate code concerning `std::error_condition` is not shown):

```cpp
enum class arithmetic_errc
{
    divide_by_zero, // 9/0 == ?
    not_integer_division // 5/2 == 2.5 (which is not an integer)
};
```

Using `expected<double, error_condition>`, the code becomes:

```cpp
expected<double, error_condition> safe_divide(double i, double j)
{
    if (j==0) return make_unexpected(arithmetic_errc::divide_by_zero); // (1)
    else return i / j; // (2)
}
```

(1) The implicit conversion from `unexpected_type<E>` to `expected<T, E>` and (2) from `T` to `expected<T, E>` prevents using too much boilerplate code. The advantages are that we have a clean way to fail without using the exception machinery, and we can give precise information about why it failed as well. The liability is that this function is going to be tedious to use. For instance, the exception-based
`function i + j/k is:

```cpp
double f1(double i, double j, double k) {
    return i + safe_divide(j, k);
}
```

but becomes using `expected<double, error_condition>:

```cpp
expected<double, error_condition> f1(double i, double j, double k) {
    auto q = safe_divide(j, k);
    if (q) return i + *q;
    else return q;
}
```

We can use `expected<T, E>` to represent different error conditions. For instance, with integer division, we might want to fail if the two numbers are not evenly divisible as well as checking for division by zero. We can overload our `safe_divide` function accordingly:

```cpp
expected<int, error_condition> safe_divide(int i, int j) {
    if (j == 0) return make_unexpected(arithmetic_errc::divide_by_zero);
    if (i % j != 0) return make_unexpected(arithmetic_errc::not_integer_division);
    else return i / j;
}
```

### Error retrieval and correction

The major advantage of `expected<T, E>` over `optional<T>` is the ability to transport an error, but we didn’t come yet to an example that retrieve the error. First of all, we should wonder what a programmer do when a function call returns an error:

1. Ignore it.
2. Delegate the responsibility of error handling to higher layer.
3. Trying to resolve the error.

Because the first behavior might lead to buggy application, we won’t consider it in a first time. The handling is dependent of the underlying error type, we consider the `exception_ptr` and the `error_condition` types.

We spoke about how to use the value contained in the `expected` but didn’t discuss yet the error usage.

A first imperative way to use our error is to simply extract it from the `expected` using the `error()` member function. The following example shows a `divide2` function that return `0` if the error is `divide_by_zero`:

```cpp
expected<int, error_condition> divide2(int i, int j) {
    auto e = safe_divide(i, j);
    if (e && e.error().value() == arithmetic_errc::divide_by_zero) {
        return 0;
    }
    return e;
}
```

### Impact on the standard

These changes are entirely based on library extensions and do not require any language features beyond what is available in C++ 17.

### Design rationale

The same rationale described in N3672 for `optional<T>` applies to `expected<T, E>` and `expected<T, nullopt_t>` should behave almost as `optional<T>` with some exceptions. That is, we see `expected<T, E>` as `optional<T>` for which all the values of `E` collapse into a single value `nullopt`. In the following sections we present the specificities of the rationale in N3672 applied to `expected<T, E>`.

### Conceptual model of expected

`expected<T, E>` models a discriminated union of types `T` and `unexpected_type<E>`. `expected<T, E>` is viewed as a value of type `T` or value of type `unexpected_type<E>`, allocated in the same storage, along with the way of determining which of the two it is.
The interface in this model requires operations such as comparison to `T`, comparison to `E`, assignment and creation from either. It is easy to determine what the value of the expected object is in this model: the type it stores (`T` or `E`) and either the value of `T` or the value of `E`.

Additionally, within the affordable limits, we propose the view that `expected<T, E>` extends the set of the values of `T` by the values of type `E`. This is reflected in initialization, assignment, ordering, and equality comparison with both `T` and `E`. In the case of optional<T>, `T` cannot be a `nullopt_t`. As the types `T` and `E` could be the same in `expected<T, E>`, there is need to tag the values of `E` to avoid ambiguous expressions. The `make_unexpected(E)` function is proposed for this purpose. However `T` cannot be `unexpected_type<E>` for a given `E`.

```cpp
expected<int, string> ei = 0;
expected<int, string> ej = 1;
expected<int, string> ek = make_unexpected(string());
ei = 1;
ej = make_unexpected(E());
ek = 0;
ei = make_unexpected(E());
ej = 0;
ek = 1;
```

**Initialization of `expected<T, E>`**

In cases `T` and `E` have value semantic types capable of storing `n` and `m` distinct values respectively, `expected<T, E>` can be seen as an extended `T` capable of storing `n + m` values: these `T` and `E` stores. Any valid initialization scheme must provide a way to put an expected object to any of these states. In addition, some `T`’s aren’t `CopyConstructible` and their expected variants still should be constructible with any set of arguments that work for `T`.

As in N3672, the model retained is to initialize either by providing an already constructed `T` or a tagged `E`. The default constructor required `T` to be default-constructible (as `expected<T>` should behave as `T` as much as possible).

```cpp
string s"STR";
expected<string, error_condition> es[s]; // requires Copyable<T>
expected<string, error_condition> et = s; // requires Copyable<T>
expected<string, error_condition> ev = string"STR"; // requires Movable<T>
expected<string, error_condition> ew; // expected value
expected<string, error_condition> ex[]; // expected value
expected<string, error_condition> ey {}; // expected value
expected<string, error_condition> ez = expected_string(error_condition{}); // expected value
```

In order to create an unexpected object, the special function `make_unexpected` needs to be used:

```cpp
expected<string, int> ep(make_unexpected(-1)); // unexpected value, requires Movable<E>
expected<string, int> eq = make_unexpected(-1); // unexpected value, requires Movable<E>
```

As in N3672, and in order to avoid calling move/copy constructor of `T`, we use a “tagged” placement constructor:

```cpp
expected<MoveOnly, error_condition> eg; // expected value
expected<MoveOnly, error_condition> eh[]; // expected value
expected<MoveOnly, error_condition> el[1]; // calls MoveOnly{} in place
expected<MoveOnly, error_condition> ej[1]; // calls MoveOnly("arg") in place
```

To avoid calling move/copy constructor of `E`, we use a “tagged” placement constructor:

```cpp
expected<int, string> ei(unexpected); // unexpected value, calls string{} in place
expected<int, string> ej(unexpected, "arg"); // unexpected value, calls string("arg") in place
```

An alternative name for `in_place` that is coherent with `unexpected` could be `expect`. Being compatible with `optional<T>` seems more important. So this proposal doesn’t propose such a `expect` tag.

The alternative and also comprehensive initialization approach, which is compatible with the default construction of `expected<T,E>` as `T()` , could have been a variadic perfect forwarding constructor that just forwards any set of arguments to the constructor of the contained object of type `T`.

**Never-empty guaranty**

As boost:variant<T, unexpected_type<E>> . `expected<T, E>` ensures that it is never empty. All instances `v` of type `expected<T, E>` guarantee `v` has constructed content of one of the types `T` or `E`, even if an operation on `v` has previously failed.
This implies that expected may be viewed precisely as a union of exactly its bounded types. This "never-empty" property insulates the user from the possibility of undefined expected content or an expected valueless_by_exception as std::variant, and the significant additional complexity-of-use attendant with such a possibility.

In order to ensure this property the types \( T \) and \( E \) must satisfy some requirements as described in \texttt{P0110R0}. Given the nature of the parameter \( E \), that is, to transport an error, it is expected that \( \text{is_nothrow_copy_constructible\langle E \rangle} \), \( \text{is_nothrow_move_constructible\langle E \rangle} \), \( \text{is_nothrow_copy_assignable\langle E \rangle} \) and \( \text{is_nothrow_move_assignable\langle E \rangle} \).

Note however that these constraints are applied only to the operations that need them.

If \( \text{is_nothrow_constructible\langle T, Args...\rangle} \) is false expected\(\langle T, E\rangle\)::emplace\(\langle Args...\rangle\) function is not defined. In this case, it is the responsibility of the user to create a temporary and move or copy it.

### The default constructor

Similar data structure includes \texttt{optional\langle T\rangle}, \texttt{variant\langle T1,\ldots,Tn\rangle}, and \texttt{future\langle T\rangle}. We can compare how they are default constructed.

- \texttt{std::optional\langle T\rangle} default constructs to an optional with no value.
- \texttt{std::variant\langle T1,\ldots,Tn\rangle} default constructs to \( T1 \) if default constructible or it is ill-formed
- \texttt{std::future\langle T\rangle} default constructs to an invalid future with no shared state associated, that is, no value and no exception.
- \texttt{std::optional\langle T\rangle} default constructor is equivalent to \texttt{boost\::variant\langle\text{nullopt\_t}, T\rangle}.

It raises several questions about \texttt{expected\langle T, E\rangle}:

- Should the default constructor of \( \text{expected\langle T, E\rangle} \) behave like \texttt{variant\langle T, unexpected\_type\langle E\rangle\rangle} or as \texttt{variant\langle unexpected\_type\langle E\rangle, T\rangle}?
- Should the default constructor of \texttt{expected\langle T, nullopt\_t\rangle} behave like \texttt{optional\langle T\rangle}? If yes, how should behave the default constructor of \( \text{expected\langle T, E\rangle} \)? As if initialized with \texttt{make\_unexpected\langle E()\rangle}? This would be equivalent to the initialization of \texttt{variant\langle unexpected\_type\langle E\rangle, T\rangle}.
- Should \( \text{expected\langle T, E\rangle} \) provide a default constructor at all? \texttt{N3527} presents valid arguments against this approach, e.g. \texttt{array\langle \text{expected\langle T, E\rangle} \rangle} would not be possible.

Requiring \( E \) to be default constructible seems less constraining than requiring \( T \) to be default constructible (e.g. consider the \texttt{Date} example in \texttt{N3527}). With the same semantics \( \text{expected\langle Date, E\rangle} \) would be \texttt{Regular} with a meaningful not-a-date state created by default.

The authors consider the arguments in \texttt{N3527} valid for \texttt{optional\langle T\rangle} and \texttt{expected\langle T, E\rangle}, however the committee as requested it the paper proposes that \texttt{expected\langle T, E\rangle} default constructor should behave as constructed with \texttt{T()} if \( T \) is default constructible.

### Conversion from \texttt{T}

An object of type \( T \) is implicitly convertible to an expected object of type \( \text{expected\langle T, E\rangle} \):

```
expected\langle int\rangle ei = 1; // works
```

This convenience feature is not strictly necessary because you can achieve the same effect by using tagged forwarding constructor:

```
expected\langle int\rangle ei\{in\_place, 1\};
```

If the latter appears too cumbersome, one can always use function \texttt{make\_expected} described below:

```
expected\langle int\rangle ei = make\_expected(1);
auto ej = make\_expected(1);
```

or simply using deduced template parameter for constructors

```
expected\langle int\rangle ei = expected(1);
auto ej = expected(1);
```

It has been demonstrated that this implicit conversion is dangerous \texttt{a-gotcha-with-optional}.

An alternative will be to make it explicit and add a \texttt{expected\_type\langle T\rangle} (similar to \texttt{unexpected\_type\langle E\rangle}) explicitly convertible from \texttt{T} and implicitly convertible to \texttt{expected\langle T, E\rangle}.

```
expected\langle int\rangle ei = make\_expected(1);
expected\langle int\rangle ej = make\_unexpected(ec);
```

While the authors consider that it is safer to have the explicit conversion, the implicit conversion is so friendly that we don't propose yet an explicit conversion. In addition \texttt{std::optional} has already be delivered in C++17 and it has this gotcha.
An object of type \( E \) is not convertible to an unexpected object of type \( \text{expected}<T,E> \) since \( E \) and \( T \) can be of the same type. The proposed interface uses a special tag \( \text{unexpect} \) and a special non-member \( \text{make_unexpected} \) function to indicate an unexpected state for \( \text{expected}<T,E> \). It is used for construction and assignment. This might rise a couple of objections. First, this duplication is not strictly necessary because you can achieve the same effect by using the \( \text{unexpect} \) tag forwarding constructor:

```cpp
expected<string, int> exp1 = make_unexpected(1);
expected<string, int> exp2 = {unexpect, 1};
expi = make_unexpected(1);
expi = {unexpect, 1};
```

or simply using deduced template parameter for constructors

```cpp
expected<string, int> exp1 = unexpected_type(1);
expected<string, int> exp2 = unexpected_type(1);
```

While some situations would work with the \( \{\text{unexpect, ...}\} \) syntax, using \( \text{make_unexpected} \) makes the programmer’s intention as clear and less cryptic. Compare these:

```cpp
expected<vector<int>, int> get1() {}
  return {unexpect, 1};
}
expected<vector<int>, int> get2() {
  return make_unexpected(1);
}
expected<vector<int>, int> get3() {
  return make_unexpected<int>({unexpect, 1});
}
expected<vector<int>, int> get2() {
  return unexpected_type(1);
}
```

The usage of \( \text{make_unexpected} \) is also a consequence of the adapted model for \( \text{expected} \) : a discriminated union of \( T \) and \( \text{unexpected_type}<E> \).

**Should we support the \( \text{exp2} = {} \)?**

Note also that the definition of \( \text{unexpected_type} \) has an explicitly deleted default constructor. This was in order to enable the reset idiom \( \text{exp2} = {} \) which would otherwise not work due to the ambiguity when deducing the right-hand side argument.

Now that \( \text{expected}<T,E> \) defaults to \( T() \) the meaning of \( \text{exp2} = {} \) is to assign \( T() \).

**Observers**

In order to be as efficient as possible, this proposal includes observers with narrow and wide contracts. Thus, the \( \text{value}() \) function has a wide contract. If the expected object doesn’t contain a value, an exception is thrown. However, when the user knows that the expected object is valid, the use of \( \text{operator*} \) would be more appropriated.

**Explicit conversion to bool**

The rational described in \[N3672\] for \( \text{optional}<T> \) applies to \( \text{expected}<T,E> \) and so, the following example combines initialization and value-checking in a boolean context.

```cpp
if (expected<char, error_condition> ch = readNextChar()) {
  // ...
}
```

\( \text{has_value}() \) following P0032

\( \text{has_value}() \) has been added to follow [P0032R2].

**Accessing the contained value**

Even if \( \text{expected}<T,E> \) has not been used in practice for enough time as \( \text{std::optional} \) or Boost.Optional, we consider that following the same interface as \( \text{std::optional}<T> \) makes the C++ standard library more homogeneous.

The rational described in \[N3672\] for \( \text{optional}<T> \) applies to \( \text{expected}<T,E> \).

**Dereference operator**
It was chosen to use the indirection operator because, along with explicit conversion to bool, it is a very common pattern for accessing a value that might not be there:

```cpp
if (p) use("p");
```

This pattern is used for all sort of pointers (smart or raw) and `optional`; it clearly indicates the fact that the value may be missing and that we return a reference rather than a value. The indirection operator has risen some objections because it may incorrectly imply `expected` and `optional` are a (possibly smart) pointer, and thus provides shallow copy and comparison semantics. All library components so far use indirection operator to return an object that is not part of the pointer/iterator's value. In contrast, `expected` as well as `optional` indirectly to the part of its own state. We do not consider it a problem in the design; it is more like an unprecedented usage of indirection operator. We believe that the cost of potential confusion is overweighted by the benefit of an intuitive interface for accessing the contained value.

We do not think that providing an implicit conversion to `T` would be a good choice. First, it would require different way of checking for the empty state; and second, such implicit conversion is not perfect and still requires other means of accessing the contained value if we want to call a member function on it.

Using the indirection operator for an object that doesn’t contain a value is undefined behavior. This behavior offers maximum runtime performance.

### Function value

In addition to the indirection operator, we propose the member function `value` as in N3672 that returns a reference to the contained value if one exists or throw an exception otherwise.

```cpp
void interact() {
  string s;
  cout << "enter number: ";
  cin >> s;
  expected<int, error> ei = str2int(s);
  try {
    process_int(ei.value());
  } catch(bad_expected_access<error>) {
    cout << "this was not a number."
  }
}
```

The exception thrown is `bad_expected_access<E>` (derived from `std::logic_error`) which will contain the stored error.

`bad_expected_access<E>` and `bad_optional_access` could inherit both from a `bad_access` exception derived from `logic_error`, but this is not proposed yet.

### Accessing the contained error

Usually, accessing the contained error is done once we know the expected object has no value. This is why the `error()` function has a narrow contract: it works only if `! bool(*this)`.

```cpp
expected<int, errc> getIntOrZero(istream_range& r) {
  auto r = getInt(); // won't throw
  if (!r && r.error() == errc::empty_stream) {
    return 0;
  }
  return r;
}
```

This behavior could not be obtained with the `value_or()` method since we want to return 0 only if the error is equal to `empty_stream`.

We could as well provide an error access function with a wide contract. We just need to see how to name each one.

### Conversion to the unexpected value

As the `error()` function, the `get_unexpected()` works only if the expected object has no value. It is used to propagate errors. Note that the following equivalences yield:

```cpp
f.get_unexpected() == make_unexpected(f.error());
f.get_unexpected() == expected<T, E>(unexpect, f.error());
```

This member is provided for convenience, it is further demonstrated in the next example:
As optional and variant, one of the design goals of expected is that objects of type expected<T, E> should be valid elements in STL containers and usable with STL algorithms (at least if objects of type T and E are). Equality comparison is essential for expected<T, E> to model concept Regular. C++ does not have concepts yet, but being regular is still essential for the type to be effectively used with STL.

Ordering is essential if we want to store expected values in ordered associative containers. A number of ways of including the unexpected state in comparisons have been suggested. The ones proposed, follows this proposal P0939R3: unexpected values stored in expected<T, E> are simply treated as additional values that are always different from T; these values are always compared as greater than any value of T when stored in an expected object. This is because we see expected<T, E> as a specialization of variant<T, unexpected_type<E>>

But how to define the relational operators for unexpected_type<E>? We can forward the request to the respective E relational operators when E defines these operators, don't support the operators if unexpected_type<E> doesn't define operator<() operator<>()

This limitation is one of the main motivations for having a user defined type E with strict weak ordering, e.g. if the user know the exact types of the exceptions that can be thrown E1, E2, En, the error parameter could be some kind of std::variant<E1, ... En> for which a strict weak ordering can be defined. If the user would like to take care of unknown exceptions something like std::variant<std::monostate, E1, ... En> would be a quite appropriated model.
Given that \texttt{expected<T,E>} is comparable and implicitly constructible from \texttt{T}, the mixed comparisons are there already. We would have to artificially create the mixed overloads only for them to cause controlled compilation errors. A consistent approach to prohibiting mixed relational operators would be to also prohibit the conversion from \texttt{T} or to also prohibit homogenous relational operators for \texttt{expected<T,E>}. We do not want to do either, for other reasons discussed in this proposal. Also, mixed relational operations are available in \texttt{std::optional<T>}. Note however that \texttt{expected<T,nullopt_t>} and \texttt{optional<T>} behave the opposite. This is a consequence of having reverted the \texttt{T} and \texttt{E} parameters and so defaulting to \texttt{T()}. 

**Modifiers**

**Reseting the value**

Reseting the value of \texttt{expected<T,E>} is similar to \texttt{optional<T>} but instead of building a disengaged \texttt{optional<T>}, we build an erroneous \texttt{expected<T,E>}.

Hence, the semantics and rationale is the same than in \texttt{N3672}.

**Tag \texttt{in\_place}**

This proposal makes use of the "in-place" tag as defined in [C++17]. This proposal provides the same kind of "in-place" constructor that forwards (perfectly) the arguments provided to \texttt{expected}'s constructor into the constructor of \texttt{T}.

In order to trigger this constructor one has to use the tag \texttt{in\_place}. We need the extra tag to disambiguate certain situations, like calling \texttt{expected}'s default constructor and requesting \texttt{T}'s default construction:

\begin{verbatim}
expected&lt;Big, error&gt; eb&lt;in\_place, "1"&gt;; // calls Big("1") in place (no moving)
expected&lt;Big, error&gt; ec&lt;in\_place&gt;; // calls Big() in place (no moving)
expected&lt;Big, error&gt; ed(); // calls Big{} (expected state)
\end{verbatim}

**Tag \texttt{unexpect}**

This proposal provides an "unexpect" constructor that forwards (perfectly) the arguments provided to \texttt{expected}'s constructor into the constructor of \texttt{E}. In order to trigger this constructor one has to use the tag \texttt{unexpect}.

We need the extra tag to disambiguate certain situations, notably if \texttt{T} and \texttt{E} are the same type.

\begin{verbatim}
expected&lt;Big, error&gt; eb&lt;unexpect, "1"&gt;; // calls error("1") in place (no moving)
expected&lt;Big, error&gt; ec&lt;unexpect&gt;; // calls error{} in place (no moving)
\end{verbatim}

In order to make the tag uniform an additional "expect" constructor could be provided but this proposal doesn't propose it.

**Requirements on \texttt{T} and \texttt{E}**

Class template \texttt{expected} imposes little requirements on \texttt{T} and \texttt{E}: they have to be complete object type satisfying the requirements of \texttt{Destructible}. Each operations on \texttt{expected&lt;T,E&gt;} have different requirements and may be disable if \texttt{T} or \texttt{E} doesn't respect these requirements. For example, \texttt{expected&lt;T,E&gt;}'s move constructor requires that \texttt{T} and \texttt{E} are \texttt{MoveConstructible}, \texttt{expected&lt;T,E&gt;}'s copy constructor requires that \texttt{T} and \texttt{E} are \texttt{CopyConstructible}, and so on. This is because \texttt{expected&lt;T,E&gt;} is a wrapper for \texttt{T} or \texttt{E}: it should resemble \texttt{T} or \texttt{E} as much as possible. If \texttt{T} and \texttt{E} are \texttt{EqualityComparable} then (and only then) we expect \texttt{expected&lt;T,E&gt;} to be \texttt{EqualityComparable}.

However in order to ensure the never empty warranties, \texttt{expected&lt;T,E&gt;} requires \texttt{E} to be no throw move constructible. This is normal as the \texttt{E} stands for an error, and throwing while reporting an error is a very bad thing.

**Expected references**

This proposal doesn't include \texttt{expected} references as \texttt{optional [C++17]} doesn't include references neither.

We need a future proposal.

**Expected void**

While it could seem weird to instantiate \texttt{optional with void}, it has more sense for \texttt{expected} as it conveys in addition, as \texttt{future&lt;T&gt;}, an error state.

**Making expected a literal type**

In \texttt{N3672}, they propose to make \texttt{optional a literal type}, the same reasoning can be applied to expected. Under some conditions, such that \texttt{T} and \texttt{E} are trivially
destructible, and the same described for \texttt{optional}, we propose that \texttt{expected} be a literal type.

### Moved from state

We follow the approach taken in \texttt{optional N3672} Moving \texttt{expected\langle T,E\rangle} do not modify the state of the source (valued or erroneous) of \texttt{expected} and the move semantics is up to \texttt{T} or \texttt{E}.

### IO operations

For the same reasons than \texttt{optional N3672} we do not add \texttt{operator<<} and \texttt{operator>>} IO operations.

### What happens when \texttt{E} is a status?

When \texttt{E} is a status, as most of the error codes are, and has more than one value that mean success, setting an \texttt{expected\langle T,E\rangle} with a successful \texttt{e} value could be misleading if the user expect in this case to have also a \texttt{T}. In this case the user should use the proposed \texttt{status\_value\langle E,T\rangle} class. However, if there is only one value \texttt{e} that mean success, there is no such need and \texttt{expected\langle T,E\rangle} compose better with the monadic interface \texttt{P0650R0}.

### Do we need an \texttt{expected\langle T,E\rangle::error\_or} function?

It has been argued that the error should be always available and that often there is a success value associated to the error. \texttt{expected\langle T,E\rangle} would be seen more like something like \texttt{struct \{E; optional\langle T\rangle\}}.

The following code show a use case

```cpp
auto e = function();
switch (e.status())
    success: ....; break;
    too_green: ....; break;
    too_pink: ....; break;
```

With the current interface the user could be tempted to do

```cpp
auto e = function();
if (e) /*success*/ ....;
else
    switch (e.error())
        case too_green: ....; break;
        case too_pink: ....; break;
```

This could be done with the current interface as follows

```cpp
auto e = function();
switch (error\_or\langle e, success\rangle)
    success: ....; break;
    too_green: ....; break;
    too_pink: ....; break;
```

where

```cpp
template <class E, class T>
E error\_or(\texttt{expected\langle T,E\rangle} const &e, E err)
{
    if (e) return err;
    else return e.error();
}
```

Do we need such an \texttt{error\_or} function? as member?

### Do we need a \texttt{expected\langle T,E\rangle::has\_error} function?

Another use case which could look much uglier is if the user had to test for whether or not there was a specific error code.
auto e = function();
while ( e.status == timeout ) {
  sleep(delay);
  delay *= 2;
  e = function();
}

Here we have a value or a hard error. This use case would need to use something like `has_error`:

```cpp
e = function();
while ( has_error(e, timeout) )
{
  sleep(delay);
  delay *= 2;
  e = function();
}
```

where

```cpp
#include <optional>

template <class T, class E>
bool has_error(expected<T,E> const & e, E err) {
  if (e) return false;
  else return e.error() == err;
}
```

Do we want to add such a `has_error` function as member?

### Do we need a `expected<T,G>::adapt_error(function<E(G))` function?

We have the constructor `expected<T,E>(expected<T,G>)` that allows to transport EXPLICITLY the contained error as soon as it is convertible.

However sometimes we cannot change neither of the error types and we could need to do this transformation. This function help to achieve this goal. The parameter is the function doing the error transformation.

This function can be defined on top of the existing interface.

```cpp
template <class T, class E>
expected<T,G> adapt_error(expected<T,E> const & e, function<G(E)> adaptor) {
  if (e) return adaptor(e.error());
  else return expected<T,G>("e");
}
```

Do we want to add such a `adapt_error` function as member?

### Open points

The authors would like to have an answer to the following points if there is any interest at all in this proposal:

**Should `expected<T,E>` be explicitly convertible from `T` and implicitly convertible from `expected_type<T>`?**

`expected<T,E>` is implicitly convertible from `T` and `unexpected_type<E>`, where `unexpected_type<E>` is explicitly convertible from `E`. We could do the same for `T` and make it implicitly convertible for `expected_type<E>`.

While implicit conversion from `T` seems to be friendly, there are cases where this implicit conversion raise some surprises (See [a-gotcha-with-optional](https://github.com/NiallMcKeever/expected/blob/master/expected/expected.hpp#L315)).

**Should `expected<T,E>` be comparable?**

Aside this [a-gotcha-with-optional](https://github.com/NiallMcKeever/expected/blob/master/expected/expected.hpp#L315), do we really `expected` to be comparable, `T` and `E` are comparable?

**What about changing the default `Error` argument to `error_code`?**

Niall has suggested that `std::error_code` is a better default for the `expected` `Error` parameter.

**Should `expected<T,E>` throw `E` instead of `bad_expected_access<E>`?**
As any type can be thrown as an exception, should `expected<T, E>` throw `E` instead of `bad_expected_access<E>`?

Some argument that standard function should throw exceptions that inherit from `std::exception`, but here the exception throw is given by the user via the type `E`, it is not the standard library that throws explicitly an exception that don’t inherit from `std::exception`.

This could be convenient as the user will have directly the `E` exception. However it will be more difficult to identify that this was due to a bad expected access.

If yes, should `optional<T>` throw `nullopt_t` instead of `bad_optional_access` to be coherent?

We don’t propose this.

Other have suggested to throw `system_error` if `E` is `error_code`, rethrow if `E` is `exception_ptr`, `E` if it inherits from `std::exception` and `bad_expected_access<E>` otherwise.

An alternative would be to add some customization point that state which exception is thrown. See the Appendix I.

**What about having a common bad_expect_access_base?**

This has the advantage to make it easier for the user to manage with any bad access to expected when the user doesn’t care of the error.

The same argument can be seen as a bad thing. It is too easy to ignore the error.

An alternative is to inherit `bad_expect_access<E>` from `bad_expect_access<void>` and default the `E` parameter to void.

**Should get_unexpected() return by reference?**

The old implementation stored `E` instead of `unexpected_type<E>`, and so we were unable to return `get_unexpected()` by reference. As we see `expected<T, E>` as `variant<T, unexpected_type<E>>` we should provide a reference access to `unexpected_type<E>`.

In addition, if we want to see as a sum type of `T` and `unexpected_type<E>`, we would need this access.

**Do we want expected<T&, E> in a separated proposal?**

**Do we really want make_expected_from_call?**

**Do we want error_or?**

As a non-member or member function?

This function should work for all the PossiblyValued types and so could belong to a future PossiblyValued proposal.

**Do we want has_error?**

As a non-member or member function?

This function should work for all the PossiblyValued types and so could belong to a future PossiblyValued proposal.

**Do we want adapt_error?**

As a non-member or member function?

This function should work for all the PossiblyValued types and so could belong to a future PossiblyValued proposal.

**Proposed Wording**

The proposed changes are expressed as edits to N4564 the Working Draft - C++ Extensions for Library Fundamentals V2. The wording has been adapted from the section “Optional objects”.

**General utilities library**

---

X.Y Unexpected objects [[unexpected]]

X.Y.1 In general [unexpected.general]

This subclause describes class template `unexpected_type` that wraps objects intended as unexpected. This wrapped unexpected object is used to be implicitly convertible to
A program that needs the instantiation of template `unexpected_type` for a reference type or `void` is ill-formed.

**X.Y.3 Unexpected object type**

```cpp
namespace std {
  namespace experimental {
    inline namespace fundamentals_v3 {
      // X.Y.3, Unexpected object type
      template <class E>
        class unexpected_type;
      // X.Y.4, Unexpected factories
      template <class E>
        constexpr unexpected_type make_unexpected(E&& v);
      // X.Y.5, unexpected_type relational operators
    }
  }
} // std::experimental
```

**Effects:** Build an `unexpected` by copying the parameter to the internal storage `val`.

```cpp
constexpr explicit unexpected_type(const E&);
```

**Returns:** `val`.

**X.Y.4 Factories**

```cpp
template <class E>
constexpr unexpected_type decay_t<E>> make_unexpected(E&& v);
```

**Effects:** Build an `unexpected` by moving the parameter to the internal storage `val`.

```cpp
constexpr explicit unexpected_type(E &&);
```

```cpp
constexpr const E& value();
constexpr const E& value() const;
```

**Effects:** Build an `unexpected` by moving the parameter to the internal storage `val`.

```cpp
constexpr const E& value();
constexpr const E& value() const;
```

**Returns:** `val`.
Returns: unexpected_type<decay_t<E>>{v}.

X.Y.5 Unexpected Relational operators [unexpectedtype.relational]

```cpp
template <class E>
constexpr bool operator==(const unexpected_type<E>& x, const unexpected_type<E>& y);
```

Requires: E shall meet the requirements of EqualityComparable.

Returns: x.value() == y.value().

Remarks: Specializations of this function template, for which x.value() == y.value() is a core constant expression, shall be constexpr functions.

```cpp
template <class E>
constexpr bool operator!=(const unexpected_type<E>& x, const unexpected_type<E>& y);
```

Requires: E shall meet the requirements of EqualityComparable.

Returns: x.value() != y.value().

Remarks: Specializations of this function template, for which x.value() != y.value() is a core constant expression, shall be constexpr functions.

```cpp
template <class E>
constexpr bool operator<(const unexpected_type<E>& x, const unexpected_type<E>& y);
```

Requires: x.value() < y.value().

Returns: x.value() < y.value().

Remarks: Specializations of this function template, for which x.value() < y.value() is a core constant expression, shall be constexpr functions.

```cpp
template <class E>
constexpr bool operator<=(const unexpected_type<E>& x, const unexpected_type<E>& y);
```

Requires: x.value() <= y.value().

Returns: x.value() <= y.value().

Remarks: Specializations of this function template, for which x.value() <= y.value() is a core constant expression, shall be constexpr functions.

```cpp
template <class E>
constexpr bool operator>(const unexpected_type<E>& x, const unexpected_type<E>& y);
```

Requires: x.value() > y.value().

Returns: x.value() > y.value().

Remarks: Specializations of this function template, for which x.value() > y.value() is a core constant expression, shall be constexpr functions.

```cpp
template <class E>
constexpr bool operator>=(const unexpected_type<E>& x, const unexpected_type<E>& y);
```

Returns: !(x < y).

```
X.Z Expected objects [[expected]]

X.Z.1 In general [[expected.general]]

This sub-clause describes class template expected that represents expected objects. An expected<T,E> object is an object that contains the storage for another object and manages the lifetime of this contained object T, alternatively it could contain the storage for another unexpected object E. The contained object may not be initialized after the expected object has been initialized, and may not be destroyed before the expected object has been destroyed. The initialization state of the contained object is tracked by the expected object.

X.Z.2 Header <experimental/expected> synopsis [expected.synop]

```cpp
namespace std {
namespace experimental {
inline namespace fundamentals_v3 {
```
// X.Z.4, expected for object types
template <class T, class E = error_condition>
    class expected;

// X.Z.5, Specialization for void.
template <class E>
    class expected_void = E;

// X.Z.6, unexpected tag
struct unexpected_t{
    constexpr unexpected_t() = delete;
};
constexpr unexpected_t unexpected_t = implementation defined;

// X.Z.7, class bad_expected_access
class bad_expected_access;

// X.Z.8, Expected relational operators
template <class T, class E =>
    constexpr bool operator==(const expected<T,E>&, const expected<T,E>&);
template <class T, class E =>
    constexpr bool operator!=(const expected<T,E>&, const expected<T,E>&);

// X.Z.9, Comparison with T
template <class T, class E =>
    constexpr bool operator==(const expected<T,E>&, const T&);
template <class T, class E =>
    constexpr bool operator!=(const T&, const expected<T,E>&);

// X.Z.10, Comparison with unexpected_type<E>
template <class T, class E =>
    constexpr bool operator==(const T&, const unexpected_type<E>&);
template <class T, class E =>
    constexpr bool operator!=(const T&, const unexpected_type<E>&);
A program that necessitates the instantiation of template `expected<T,E>` with `T` for a reference type or for possibly cv-qualified types `in_place_t`, `unexpect_t` or `unexpected_type<E>` is ill-formed.

X.Z.3 Definitions [expected.defs]

An instance of `expected<T,E>` is said to be valued if it contains a value of type `T`. An instance of `expected<T,E>` is said to be unexpected if it contains an object of type `E`.

X.Y.4 expected for object types [expected.object]
expected\& operator-(const expected\&);
expected\& operator-(expected\&&) noexcept(see below);

template <class U>
expected\& operator-(U\&);
expected\& operator-(const unexpected_type\&E);
expected\& operator-(unexpected_type&&E) noexcept(see below);

// X.Z.4.4, swap
void swap(expected\&) noexcept(see below);

template <class... Args>
void emplace(Args\&...);

// X.Z.4.5, observers
constexpr T expected\&;

expected\&: Initializes the contained value as if direct-non-list-initializing an object of type T with the expression T{}.

Effects: Initializes the contained value as if direct-non-list-initializing an object of type T with the expression T{}.

Postconditions: bool{*this}.

Throws: Any exception thrown by the default constructor of T.

Remarks: This constructor shall be constexpr if and only if the value-initialization of T would satisfy the requirements for a constexpr function. The expression inside noexcept is equivalent to: is_nothrow_default_constructible<T>::value. This constructor shall be defined as deleted unless is_default_constructible<T>::value.
### Effects
- If `bool(rhs)` initializes the contained value as if direct-non-list-initializing an object of type `T` with the expression `*rhs`.

- If `!bool(rhs)` initializes the contained value as if direct-non-list-initializing an object of type `expected_type<E>` with the expression `rhs.get_unexpected()`.

### Postconditions
- `bool(rhs) == bool(*this)`.

### Throws
- Any exception thrown by the selected constructor of `T` or `expected_type<E>`.

### Remarks
- The expression inside noexcept is equivalent to: `is_nothrow_copy_constructible<T>::value` and `is_nothrow_copy_constructible<E>::value`. This constructor shall not participate in overload resolution unless `is_copy_constructible<T>::value` and `is_copy_constructible<E>::value`.

```cpp
template <class U, class G>
EXPLICIT expected(excepted&& rhs) noexcept('see below');
```

### Effects
- If `bool(rhs)` initializes the contained value as if direct-non-list-initializing an object of type `T` with the expression `std::move(*rhs)`.

- If `!bool(rhs)` initializes the contained value as if direct-non-list-initializing an object of type `expected_type<E>` with the expression `std::move(rhs.get_unexpected())`.

### Postconditions
- `bool(rhs) == bool(*this)` and `bool(rhs)` is unchanged.

### Throws
- Any exception thrown by the selected constructor of `T` or `expected_type<E>`.

### Remarks
- The expression inside noexcept is equivalent to: `is_nothrow_move_constructible<T>::value` and `is_nothrow_move_constructible<E>::value`. This constructor shall not participate in overload resolution unless `is_move_constructible<T>::value` and `is_move_constructible<E>::value`.

```cpp
template <class U, class G>
EXPLICIT expected(expected&& rhs) noexcept('see below');
```

### Effects
- If `bool(rhs)` initializes the contained value as if direct-non-list-initializing an object of type `T` with the expression `std::move(*rhs)`.

- If `!bool(rhs)` initializes the contained value as if direct-non-list-initializing an object of type `expected_type<E>` with the expression `std::move(rhs.get_unexpected())`.

### Postconditions
- `bool(rhs) == bool(*this)` and `bool(rhs)` is unchanged.

### Throws
- Any exception thrown by the selected constructor of `T` or `expected_type<E>`.

### Remarks
- The expression inside noexcept is equivalent to: `is_nothrow_constructible<T, U&&>::value` and `is_nothrow_constructible<E, G&&>::value`. This constructor shall not participate in overload resolution unless `is_constructible<T, U&&>::value` and `is_constructible<E, G&&>::value`. The constructor is explicit if and only if `is_convertible<U const&, T>` is false or `is_convertible` is false.

```cpp
constexpr expected(const T& v) noexcept('see below');
```

### Effects
- Initializes the contained value as if direct-non-list-initializing an object of type `T` with the expression `v`.

### Postconditions
- `bool(*this)`.

### Throws
- Any exception thrown by the selected constructor of `T`.

### Remarks
- If `T`'s selected constructor is a constexpr constructor, this constructor shall be a constexpr constructor. The expression inside noexcept is equivalent to: `is_nothrow_constructible<T, U&&>::value`. This constructor shall not participate in overload resolution unless `is_copy_constructible<T>::value`.

```cpp
constexpr expected(T&& v) noexcept('see below');
```

### Effects
- Initializes the contained value as if direct-non-list-initializing an object of type `T` with the expression `std::move(v)`.

### Postconditions
- `bool(*this)`.

### Throws
- Any exception thrown by the selected constructor of `T`.

### Remarks
- If `T`'s selected constructor is a constexpr constructor, this constructor shall be a constexpr constructor. The expression inside noexcept is equivalent to: `is_nothrow_constructible<T, U&&>::value`. This constructor shall not participate in overload resolution unless `is_copy_constructible<T>::value`.

```cpp
constexpr expected(T v) noexcept('see below');
```
Postconditions: `bool(*this)`.

**Throws:** Any exception thrown by the selected constructor of `T`.

**Remarks:** If `T`’s selected constructor is a constexpr constructor, this constructor shall be a constexpr constructor. The expression inside noexcept is equivalent to: `is_nothrow_move_constructible<T, U&&>::value`. This constructor shall not participate in overload resolution unless `is_move_constructible<T>::value`.

```cpp
template <class... U, class... Args>
constexpr explicit expected(in_place_t, initializer_list<U> il, Args&&... args);
```

**Effects:** Initializes the contained value as if direct-non-list-initializing an object of type `T` with the arguments `il, std::forward<Args>(args)...`. 

**Postconditions:** `bool(*this)`.

**Throws:** Any exception thrown by the selected constructor of `T`.

**Remarks:** If `T`’s constructor selected for the initialization is a constexpr constructor, this constructor shall be a constexpr constructor. This constructor shall not participate in overload resolution unless `is_constructible<T, Args&&...>::value`.

```cpp
constexpr expected(Unexpected_type<E> const& e) noexcept('see below');
```

**Effects:** Initializes the unexpected value as if direct-non-list-initializing an object of type `unexpected_type<E>` with the expression `e`. 

**Postconditions:** `! bool(*this)`.

**Throws:** Any exception thrown by the selected constructor of `unexpected_type<E>`.

**Remark:** `unexpected_type<E>`’s selected constructor is a constexpr constructor, this constructor shall be a constexpr constructor. The expression inside noexcept is equivalent to: `is_nothrow_copy_constructible<expected_type>::value`. This constructor shall not participate in overload resolution unless `is_copy_constructible<expected_type>::value`.

```cpp
constexpr expected(Unexpected_type<E>&& e);
```

**Effects:** Initializes the unexpected value as if direct-non-list-initializing an object of type `unexpected_type<E>` with the expression `std::move(e)`. 

**Postconditions:** `! bool(*this)`.

**Throws:** Any exception thrown by the selected constructor of `unexpected_type<E>`.

**Remark:** If `unexpected_type<E>`’s constructor selected for the initialization is a constexpr constructor, this constructor shall be a constexpr constructor. The expression inside noexcept is equivalent to: `is_nothrow_move_constructible<expected_type>::value`. This constructor shall not participate in overload resolution unless `is_move_constructible<expected_type>::value`.

```cpp
template <class... Args>
constexpr explicit expected(unexpect_t, Args&&... args);
```

**Effects:** Initializes the unexpected value as if direct-non-list-initializing an object of type `unexpected_type<E>` with the arguments `std::forward<Args>(args)...`.

**Postconditions:** `! bool(*this)`.

**Throws:** Any exception thrown by the selected constructor of `unexpected_type<E>`.

**Remarks:** If `unexpected_type<E>`’s constructor selected for the initialization is a constexpr constructor, this constructor shall be a constexpr constructor. This constructor shall not participate in overload resolution unless `is_constructible<E, Args&&...>::value`.

```cpp
template <class U, class... Args>
constexpr explicit expected(unexpect_t, initializer_list<U> il, Args&&... args);
```

**Effects:** Initializes the unexpected value as if direct-non-list-initializing an object of type `unexpected_type<E>` with the arguments `il, std::forward<Args>(args)...`.
Postconditions: I bool(*this).

Throws: Any exception thrown by the selected constructor of \texttt{unexpected\_type<E>}.  

Remarks: If \texttt{unexpected\_type<E>}'s constructor selected for the initialization is a constexpr constructor, this constructor shall be a constexpr constructor. This constructor shall not participate in overload resolution unless \texttt{is\_constructible<E, initializer\_list<U>&, Args&&...>::value}.  

X.Z.4.2 Destructor [expected.object.dtor]

\begin{verbatim}
-expected();
\end{verbatim}

Effects: If \texttt{is\_trivially\_destructible<T>::value != true} and \texttt{bool(*this)}, calls \texttt{val->T::~T()}. If \texttt{is\_trivially\_destructible<T>::value != true} and \{ \texttt{bool(*this)}, \texttt{calls unexpect->unexpected\_type<E>::~unexpected\_type<E>()} \}, then this destructor shall be a trivial destructor.  

X.Z.4.3 Assignment [expected.object.assign]

\begin{verbatim}
expected\_T,\_E& \texttt{operator=}((const expected\_T,\_E& \texttt{rhs}) noexcept(see below));
\end{verbatim}

Effects:  

If \texttt{bool(*this) and bool(rhs)}, assigns \texttt{*rhs} to the contained value \texttt{val};  
otherwise, if \texttt{! bool(*this) and bool(rhs)}, assigns \texttt{rhs.get\_unexpected()} to the contained value \texttt{unexpect};  
otherwise, if \texttt{bool(*this) and ! bool(rhs)},  
* destroys the contained value by calling \texttt{val->T::~T()},  
* initializes the contained value as if direct\-non\-list\-initializing an object of type \texttt{unexpected\_type<E>} with \texttt{rhs.get\_unexpected()};  
otherwise \{ \texttt{bool(*this) and bool(rhs)} \},  
* if \texttt{is\_nothrow\_copy\_constructible\_T::value}  
  * destroys the contained value by calling \texttt{unexpect->unexpected\_type<E>::~unexpected\_type<E>()}  
  * initializes the contained value as if direct\-non\-list\-initializing an object of type \texttt{T} with \texttt{*rhs};  
otherwise \{ \texttt{is\_nothrow\_move\_constructible\_T::value} \},  
* constructs a new \texttt{T tmp} on the stack from \texttt{*rhs},  
* destroys the contained value by calling \texttt{expected\_type\_T::~unexpected\_type\_T()}  
* initializes the contained value as if direct\-non\-list\-initializing an object of type \texttt{T} with \texttt{tmp};  
otherwise as \texttt{is\_nothrow\_move\_constructible\_E::value}  
* move constructs a new \texttt{unexpected\_type\_E} \texttt{tmp} on the stack from \texttt{this.get\_unexpected()} (which can\’t throw as \texttt{E} is nothrow\-move\-constructible),  
* destroys the contained value by calling \texttt{expected\_type\_T::~unexpected\_type\_E()}  
* initializes the contained value as if direct\-non\-list\-initializing an object of type \texttt{T} with \texttt{*rhs}. Either,  
  * the constructor didn\’t throw, so mark the expected as holding a \texttt{T} (which can\’t throw), or  
  * the constructor did throw, so move\-construct the \texttt{unexpected\_type\_E} \texttt{tmp} back into the expected storage (which can\’t throw as \texttt{E} is nothrow\-move\-constructible), and rethrow the exception.  

Returns: \texttt{*this}.  

Postconditions: \texttt{bool(*this) and bool(rhs)} remain unchanged.

Exception Safety: If any exception is thrown, the values of \texttt{bool(*this) and bool(rhs)} remain unchanged.  

If an exception is thrown during the call to \texttt{T}'s copy constructor, no effect.  

If an exception is thrown during the call to \texttt{T}'s copy assignment, the state of its contained value is as defined by the exception safety guarantee of \texttt{T}'s copy assignment.  

Remarks: This signature shall not participate in overload resolution unless \texttt{is\_copy\_assignable\_T::value} and \texttt{is\_copy\_assignable\_E::value} and \texttt{is\_copy\_constructible\_T::value} and \texttt{is\_copy\_constructible\_E::value} and \texttt{is\_nothrow\_move\_constructible\_T::value} and \texttt{is\_nothrow\_move\_constructible\_E::value}.  

\begin{verbatim}
expected\_T,\_E& \texttt{operator=}((\texttt{expected\_T,\_E& \texttt{rhs)}) noexcept(*see below*));
\end{verbatim}

Effects:  

If \texttt{bool(*this) and bool(rhs)}, move assign \texttt{*rhs} to the contained value \texttt{val};
otherwise, if ![bool(*this) and bool(rhs)], move assign rhs.get_unexpected() to the contained value unexpect;

otherwise, if ![bool(*this) and bool(rhs)],

- destroys the contained value by calling val->T::~T();
- initializes the contained value as if direct-non-list-initializing an object of type unexpected_type<E> with move(forward<T,E>(rhs).get_unexpected());

otherwise ![bool(*this) and bool(rhs)]

if is_nothrow_move_constructible<T>::value

- destroys the contained value by calling unexpect->unexpected_type<E>::~unexpected_type<E>();
- initializes the contained value as if direct-non-list-initializing an object of type T with *move(rhs);

otherwise as is_nothrow_move_constructible<E>::value

- move constructs a new unexpected_type<E> tmp on the stack from this.get_unexpected() (which can't throw as E is nothrow-move-constructible),
- destroys the contained value by calling unexpect->unexpected_type<E>::~unexpected_type<E>();
- initializes the contained value as if direct-non-list-initializing an object of type T with *move(rhs). Either,
  - The constructor didn't throw, so mark the expected as holding a T (which can't throw), or
  - The constructor did throw, so move-construct the unexpected_type<E> from the stack tmp back into the expected storage (which can't throw as E is nothrow-move-constructible), and rethrow the exception.

Returns: *this.

Postconditions: bool(rhs) == bool(*this).

Remarks: The expression inside noexcept is equivalent to: is_nothrow_move_assignable<T>::value && is_nothrow_move_constructible<T>::value.

Exception Safety: If any exception is thrown, the values of bool(*this) and bool(rhs) remain unchanged.

If an exception is thrown during the call to T's copy constructor, no effect.

If an exception is thrown during the call to T's copy assignment, the state of its contained value is as defined by the exception safety guarantee of T's copy assignment.

If an exception is thrown during the call to E's copy assignment, the state of its contained unexpected value is as defined by the exception safety guarantee of E's copy assignment.

Remarks: This signature shall not participate in overload resolution unless is_move_constructible<T>::value and is_move_assignable<T>::value and is_nothrow_move_constructible<E>::value and is_nothrow_move_assignable<E>::value

\[
\text{template } <\text{class } U, \\
\text{expected<T,E>& operator-=(U&& v);} \\

\text{If an exception is thrown during the call to T's copy assignment, the state of its contained value is as defined by the exception safety guarantee of T's copy assignment.} \]
Remarks:

This signature shall not participate in overload resolution unless `is_same<T,U>::value` and 
`is_nothrow_move_constructible<E>::value`.

[Note: The reason to provide such generic assignment and then constraining it so that effectively 
`T == U` is to guarantee that assignment of the form `o = {}` is unambiguous. —end note]

```cpp
expected<T,E>& operator=(unexpected_type<E> const& e) noexcept("see below");
```

Effects:

If `! bool(*this)`, assigns `rhs.get_unexpected()` to the contained value `unexpect`;
otherwise,

- destroys the contained value by calling `val->T::~T()`.
- initializes the contained value as if direct-non-list-initializing an object of type `unexpected_type<E>` with forward<expected<T,E>>(rhs).get_unexpected() and set `has_val` to `false`.

Returns: `*this`.

Postconditions: `! bool(*this)`.

Exception Safety: If any exception is thrown, value of valued remains unchanged.

Remarks: This signature shall not participate in overload resolution unless `is_nothrow_copy_constructible<E>::value` and `is_assignable<E&, E>::value`.

```cpp
expected<T,E>& operator=(unexpected_type<E>&& e);
```

Effects:

If `! bool(*this)`, move assign `rhs.get_unexpected()` to the contained value `unexpect`;
otherwise,

- destroys the contained value by calling `val->T::~T()`.
- initializes the contained value as if direct-non-list-initializing an object of type `unexpected_type<E>` with 
  move(forward<expected<T,E>>(rhs).get_unexpected()) and set `has_val` to `false`.

Returns: `*this`.

Postconditions: `! bool(*this)`.

Exception Safety: If any exception is thrown, value of valued remains unchanged.

Remarks: This signature shall not participate in overload resolution unless `is_nothrow_move_constructible<E>::value` and `is_move_assignable<E&, E>::value`.

```cpp
template<class... Args>
void emplace(Args&&... args);
```

Effects:

If `bool(*this)` , assigns `forward<U>(v)` to the contained value `val` as if constructing an object of type `T` with the arguments `std::forward<Args>(args)...` otherwise, if `is_nothrow_constructible<T, Args&&...>::value`

- destroys the contained value by calling `unexpected->unexpected_type<E>::~unexpected_type<E>()`.
- initializes the contained value as if direct-non-list-initializing an object of type `T` with `std::forward<Args>(args)...` and 
  `has_value` to `true`.

otherwise as `is_nothrow_constructible<T, U&&>::value`

- move constructs a new `unexpected_type<E>` `tmp` on the stack from `this.get_unexpected()` (which can't throw as `E` is nothrow-move-constructible),
- destroys the contained value by calling `unexpected->unexpected_type<E>::~unexpected_type<E>()`.
- initializes the contained value as if direct-non-list-initializing an object of type `T` with `forward<U>(v)` . Either,
  - the constructor didn't throw, so mark the expected as holding a `T` (which can't throw), that is set `has_value` to `true`, or
  - the constructor did throw, so move-construct the `unexpected_type<E>` from the stack `tmp` back into the expected storage (which can't throw as `E` is nothrow-move-constructible), and rethrow the exception.

If `bool(*this)` , assigns the contained value `val` as if constructing an object of type `T` with the arguments `std::forward<Args>(args)...`; otherwise, destroys the 
contained value by calling `unexpected->unexpected_type<E>::~unexpected_type<E>()` and initializes the contained value as if constructing an object of type `T` with
the arguments std::forward<Args>(args)....

Postconditions: bool(*this).

Exception Safety: If an exception is thrown during the call to T’s assignment, nothing changes.

Throws: Any exception thrown by the selected assignment of T.

Remarks: This signature shall not participate in overload resolution unless is_nothrow_constructible<T, Args&&...>::value.

```cpp
template <class U, class... Args>
void emplace(initializer_list<U> il, Args&&... args);
```

Effects: If bool(*this), assigns the contained value val as if constructing an object of type T with the arguments il, std::forward<Args>(args)...., otherwise destroys the contained value by calling unexpected_type<E>::~unexpected_type<E>() and initializes the contained value as if constructing an object of type T with the arguments il, std::forward<Args>(args)....

Postconditions: bool(*this).

Exception Safety: If an exception is thrown during the call to T’s assignment nothing changes.

Throws: Any exception thrown by the selected assignment of T.

Remarks: The function shall not participate in overload resolution unless: is_no_throw_constructible<T, initializer_list<U>&, Args&&...>::value.

X.Z.4.4 Swap [expected.object.swap]

```cpp
void swap(expected<T,E,T,RhS>& rhs) noexcept(/*see below*/);
```

Effects: If bool(*this) and bool(rhs), calls swap(val, rhs.val), otherwise if ! bool(*this) and ! bool(rhs), calls swap(err, rhs.err), otherwise exchanges values of rhs and *this.

Exception Safety: TBC

Throws: Any exceptions that the expressions in the Effects clause throw.

Remarks: The expression inside noexcept is equivalent to:

```cpp
is_nothrow_move_constructible<T>::value and noexcept(swap(declval<T&>(), declval<T&>())) and is_nothrow_move_constructible<E>::value and noexcept(swap(declval<E&>(), declval<E&>()))
```

The function shall not participate in overload resolution unless: LValues of type T shall be Swappable and is_move_constructible<T>::value and LValues of type E shall be Swappable and is_move_constructible<T>::value.

X.2.4.5 Observers [expected.object.observe]

```cpp
constexpr const T* operator->() const;
T* operator->();
```

Requires: bool(*this).

Returns: &val.

Remarks: Unless T is a user-defined type with overloaded unary operators, the first function shall be a constexpr function.

```cpp
constexpr const T& operator*() const&;
T& operator*() &;
```

Requires: bool(*this).

Returns: val.

Remarks: The first function shall be a constexpr function.

```cpp
constexpr T&& operator*() &&;
constexpr const T&& operator*() const&&;
```

Requires: bool(*this).

Returns: move(val).

Remarks: This function shall be a constexpr function.
constexpr explicit operator bool() noexcept;

Returns: has_val.
Remarks: This function shall be a constexpr function.

constexpr const T& value() const;
constexpr T& value() &;

Returns: val, if bool(*this).
Throws:
• Otherwise bad_expected_access(err) if ! bool(*this).
Remarks: The first and third functions shall be constexpr functions.

constexpr T&& value() &&;
constexpr const T&& value() const&&;

Returns: move(val), if bool(*this).
Throws:
• Otherwise bad_expected_access(err) if ! bool(*this).
Remarks: The first and third functions shall be constexpr functions.

constexpr E& error() const&;
constexpr E& error() &;

Requires: ! bool(*this).
Returns: unexpect.value().
Remarks: The first function shall be a constexpr function.

constexpr E&& error() &&;
constexpr const E&& error() const&&;

Requires: ! bool(*this).
Returns: move(unexpect.value()).
Remarks: The first function shall be a constexpr function.

constexpr unexpected_type<E> const& get_unexpected() const&;
constexpr unexpected_type<E> & get_unexpected() &;

Requires: ! bool(*this).
Returns: unexpect.

constexpr unexpected_type<E> const&& get_unexpected() const&&;
constexpr unexpected_type<E> && get_unexpected() &&;

Requires: ! bool(*this).
Returns: move(unexpect).

template <class U>
constexpr T value_or(U&& v) const&;

Returns: bool(*this) ? **this : static_cast<T>(std::forward<U>(v)).

Exception Safety: If has_val and exception is thrown during the call to T’s constructor, the value of has_val and v remains unchanged and the state of val is determined by the exception safety guarantee of the selected constructor of T. Otherwise, when exception is thrown during the call to T’s constructor, the value of *this remains unchanged and the state of v is determined by the exception safety guarantee of the selected constructor of T.
Throws: Any exception thrown by the selected constructor of \texttt{T}.

Remarks: If both constructors of \texttt{T} which could be selected are constexpr constructors, this function shall be a constexpr function.

Remarks: The function shall not participate in overload resolution unless: \texttt{is\_copy\_constructible<T>::value} and \texttt{is\_convertible<U&&, T>::value}.

```cpp
template <class U>
T value_or(U&& v) &&;
```

Returns: \texttt{bool(*this) ? std::move(**this) : static\_cast<T>{std::forward<U>(v)}}.

Exception Safety: If \texttt{has\_val} and exception is thrown during the call to \texttt{T}'s constructor, the value of \texttt{has\_val} and \texttt{v} remains unchanged and the state of \texttt{val} is determined by the exception safety guarantee of the \texttt{T}'s constructor.

Otherwise, when exception is thrown during the call to \texttt{T}'s constructor, the value of \texttt{*this} remains unchanged and the state of \texttt{v} is determined by the exception safety guarantee of the selected constructor of \texttt{T}.

Throws: Any exception thrown by the selected constructor of \texttt{T}.

Remarks: The function shall not participate in overload resolution unless: \texttt{is\_move\_constructible<T>::value} and \texttt{is\_convertible<U&&, T>::value}.

X.Z.6 expected for \texttt{void [expected.object.void]}
template <class E>
class expected<void, E> {

TODO: Describe the functions

X.Z.7 unexpected tag [expected.unexpected]

struct unexpected_t;
constexpr unexpected_t unexpected;

X.Z.8 Template Class bad_expected_access [expected.badexpectedaccess]

template <class E>
class bad_expected_access : public exception {
public:
  explicit bad_expected_access(E);
  virtual const char* what() const noexcept override;
  const E& error() const&;
  E& error() &;
  E&& error() &&;
};

The template class bad_expected_access defines the type of objects thrown as exceptions to report the situation where an attempt is made to access the value of a
unexpected expected object.

```cpp
bad_expected_access : bad_expected_access(E e);
```

**Effects:** Constructs an object of class `bad_expected_access` storing the parameter.

```cpp
const E& error() const;
E& error() &;
E&& error() &&;
```

**Returns:** The stored error.

**Remarks:** The first function shall be a constexpr function.

```cpp
virtual const char* what() const noexcept override;
```

**Returns:** An implementation-defined NTBS.

### X.Z.8 Expected Relational operators [expected.relational_op]

#### template <class T, class E>
```cpp
constexpr bool operator<(const expected<T,E>& x, const expected<T,E>& y);
```

**Requires:** `T` and `expected_type<E>` shall meet the requirements of `EqualityComparable`.

**Returns:** If `bool(x) == bool(y)`, `true`; otherwise if `bool(x) == false`, `x.get_unexpected() == y.get_unexpected()`; otherwise `*x == *y`.

**Remarks:** Specializations of this function template, for which `*x == *y` and `x.get_unexpected() == y.get_unexpected()` are core constant expression, shall be constexpr functions.

#### template <class T, class E>
```cpp
constexpr bool operator>(const expected<T,E>& x, const expected<T,E>& y);
```

**Requires:** `T` and `expected_type<E>` shall meet the requirements of `EqualityComparable`.

**Returns:** If `bool(x) == bool(y)`, `true`; otherwise if `bool(x) == false`, `x.get_unexpected() == y.get_unexpected()`; otherwise `*x != *y`.

**Remarks:** Specializations of this function template, for which `*x != *y` and `x.get_unexpected() == y.get_unexpected()` are core constant expression, shall be constexpr functions.

#### template <class T, class E>
```cpp
constexpr bool operator<=(const expected<T,E>& x, const expected<T,E>& y);
```

**Requires:** `*x < *y` and `x.get_unexpected() <= y.get_unexpected()` shall be well-formed and its result shall be convertible to `bool`.

**Returns:** If `ix && iy`, `true`; otherwise, if `ix && iy`, `true`; otherwise, if `ix && iy`, `x.get_unexpected() <= y.get_unexpected()`; otherwise `*x < *y`.

**Remarks:** Specializations of this function template, for which `*x < *y` and `x.get_unexpected() <= y.get_unexpected()` are core constant expression, shall be constexpr functions.

#### template <class T, class E>
```cpp
constexpr bool operator>=(const expected<T,E>& x, const expected<T,E>& y);
```

**Requires:** `*x > *y` and `x.get_unexpected() >= y.get_unexpected()` shall be well-formed and its result shall be convertible to `bool`.

**Returns:** If `ix && iy`, `true`; otherwise, if `ix && iy`, `true`; otherwise, if `ix && iy`, `x.get_unexpected() > y.get_unexpected()`; otherwise `*x > *y`.

**Remarks:** Specializations of this function template, for which `*x > *y` and `x.get_unexpected() >= y.get_unexpected()` are core constant expression, shall be constexpr functions.

#### template <class T, class E>
```cpp
constexpr bool operator==(const expected<T,E>& x, const expected<T,E>& y);
```

**Requires:** `*x == *y` and `x.get_unexpected() == y.get_unexpected()` shall be well-formed and its result shall be convertible to `bool`.

**Returns:** If `ix && iy`, `true`; otherwise, if `ix && iy`, `true`; otherwise, if `ix && iy`, `x.get_unexpected() == y.get_unexpected()`; otherwise `*x == *y`.

**Remarks:** Specializations of this function template, for which `*x == *y` and `x.get_unexpected() == y.get_unexpected()` are core constant expression, shall be
constexpr functions.

```cpp
template <class T, class E>
constexpr bool operator==(const expected<T,E>& x, const expected<T,E>& y);
```

Requires: \(x \geq y\) and \(x\).get_unexpected() \(\geq y\).get_unexpected() shall be well-formed and its result shall be convertible to bool.

Returns: If \(x \&\& y\), true; otherwise, if \(!x \&\& y\), false; otherwise, if \&x \&\& \&y, \(x\).get_unexpected() \(\geq y\).get_unexpected() ; otherwise \(x \geq y\).

Remarks: Specializations of this function template, for which \(x > y\) and \(x\).get_unexpected() \(> y\).get_unexpected() are core constant expression, shall be constexpr functions.

X.Z.9 Comparison with \(x\) [expected.comparison_T]

```cpp
template <class T, class E> constexpr bool operator!=(const expected<T,E>& x, const bool v);
template <class T, class E> constexpr bool operator!=(const T& x, const expected<T,E>& y);
```

Returns: bool(x) ? *x \(!= v\) : false.

```cpp
template <class T, class E> constexpr bool operator!=(const expected<T,E>& x, const T& y);
template <class T, class E> constexpr bool operator!=(const T& x, const expected<T,E>& y);
```

Returns: bool(x) ? *x \(!= v\) : false.

```cpp
template <class T, class E> constexpr bool operator<(const expected<T,E>& x, const T& y);
```

Returns: bool(x) ? *x \(< v\) : false.

```cpp
template <class T, class E> constexpr bool operator<(const T& x, const expected<T,E>& y);
```

Returns: bool(x) ? v \(< *x\) : true.

```cpp
template <class T, class E> constexpr bool operator<(const expected<T,E>& x, const T& y);
```

Returns: bool(x) ? *x \(< v\) : false.

```cpp
template <class T, class E> constexpr bool operator<=(const expected<T,E>& x, const T& y);
```

Returns: bool(x) ? v \(< *x\) : true.

```cpp
template <class T, class E> constexpr bool operator<=(const T& x, const expected<T,E>& y);
```

Returns: bool(x) ? v \(< *x\) : false.

```cpp
template <class T, class E> constexpr bool operator<=(const expected<T,E>& x, const T& y);
```

Returns: bool(x) ? *x \(\geq v\) : true.

```cpp
template <class T, class E> constexpr bool operator<=(const T& x, const expected<T,E>& y);
```

Returns: bool(x) ? v \(\geq *x\) : false.

```cpp
template <class T, class E> constexpr bool operator<=(const expected<T,E>& x, const T& y);
```

Returns: bool(x) ? v \(\geq *x\) : false.

X.Z.10 Comparison with unexpected_type\(<E>\) [expected.comparisonunexpectedE]

```cpp
template <class T, class E> constexpr bool operator==(const expected<T,E>& x, const unexpected_type<E>& e);
template <class T, class E> constexpr bool operator==(const unexpected_type<E>& e, const expected<T,E>& x);
```

Returns: bool(x) ? true ? x.get_unexpected() \(== e\) :

X.Z.13 Hash support [expected.hash]

requires: The template specializations \(\text{hash<T>}\) and \(\text{hash<E>}\) shall meet the requirements of class template \(\text{hash}(Z.X.Y)\). The template specialization
\(\text{hash<expected<T,E}>}\) shall meet the requirements of class template \(\text{hash}(Z.X.Y)\). For an object \(e\) of type expected<T,E>, \(\text{if bool}(e), \text{hash<expected<T,E>>}()\{e\}\) shall evaluate to a combination of the hashing true and \(\text{hash<T>}()\{*e\}\); otherwise a combination of hashing false and \(\text{hash<E>}()\{e.error()\}\).

requires: The template specialization \(\text{hash<E>}\) shall meet the requirements of class template \(\text{hash}(Z.X.Y)\). The template specialization \(\text{hash<expected<void,E>>}\) shall meet the requirements of class template \(\text{hash}(Z.X.Y)\). For an object \(e\) of type expected<void,E>, \(\text{if bool}(e), \text{hash<expected<void,E>>}()\{e\}\) shall evaluate to the hashing true; otherwise it evaluates to a combination of hashing false and \(\text{hash<E>}()\{e.error()\}\).

X.Z.14 expected as a meta-fuction [expected.object.meta]

template <class E>
class expected_<T, E> { public:
  template <class T>
  using apply = expected<T,E>;
};

Implementability

This proposal can be implemented as pure library extension, without any compiler magic support, in C++14.

An almost full reference implementation of this proposal can be found at ExpectedImpl. However this implementation requires that both \(T\) and \(E\) don’t throw while constructing and assigning.

Future Work

Allocator support

As optional<T>, expected<T,E> does not allocate memory. So it can do without allocators. However it can be useful in compound types like:

typedef vector<expected< vector<int>, MyAlloc>, error>, MyAlloc> MyVec;
MyVec v{ v2, MyAlloc{} };

One could expect that the allocator argument is forwarded in this constructor call to the nested vectors that use the same allocator. Allocator support would enable this.

std::tuple and std::variant offers this functionality.

Variadic expected
A typical case could combine expected and variant : \texttt{expected<T,variant<E_1, ..., E_n>>}. We could extend \texttt{expected} to take a variadic number of errors \texttt{expected<T, E_1, ..., E_n>}, in order to provide an more user friendly interface.

Some possible advantages with \texttt{expected<T, E_2>}:  
- \texttt{expected<T>} would be valid and could be convertible to any \texttt{expected<T, E_2>}.

Some possible disadvantages with \texttt{expected<T, E_2>}:  
- no possible default \texttt{E} to \texttt{error_code}.
- \texttt{get_unexpected} cannot return by reference without additional cost elsewhere (size).

\textbf{expected}

Function that return by reference couldn't use expected to transport the error. This means that we could start seen functions that return \texttt{variant<T&, E>} instead.

\section*{Acknowledgements}

We are very grateful to Andrei Alexandrescu for his talk, which was the origin of this work. We thanks also to every one that has contributed to the Haskell either monad, as either's interface was a source of inspiration.

Thanks to Fernando Cacciola, Andrzej Krzemieński and every one that has contributed to the wording and the rationale of \texttt{N3793}.

Thanks to David Sankel, Mark Calabrese, Axel Naumann and those that participated in the Oulu's review for insisting in the extraction of the monadic interface.

Thanks to Niall Douglas for reporting some possible issues in this proposal and for raising alternative design approaches after implementing expected in its Boost Outcome library.

Thank to Andrzej Krzemieński and Peter Dimov for all its pertinent exchanges during this review.

Special thanks and recognition goes to Technical Center of Nokia - Lannion for supporting in part the production of this proposal.

Appendix I: Alternative designs

A Configurable Expected

Expected might be configurable through a trait `expected_traits`. The first variation point is the behavior of `value()` when `expected<T,E>` contains an error. The current strategy throw a `bad_expected_access` exception but it might not be satisfactory for every error type. For example, some might want to encapsulate an `error_code` into a `system_error`. Or in debug mode, they might want to use an `assert` call.

We could as well make the exception thrown depend on the Error overloading a `rethrow_on_unexpected`.

Which exception throw when the user try to get the expected value but there is none?

It has been suggested to let the user decide the exception that would be throw when the user try to get the expected value but there is none, as third parameter.

While there is no major complexity doing it, as it just needs a third parameter that could default to the appropriated class,

```cpp
template <class T, class Error, class Exception = bad_expected_access>
struct expected;
```

The authors consider that this is not really needed and that this parameter should not really be part of the type.

The user could use `value_or_throw()`.
expected<int, std::error_code> f();
expected<int, std::error_code> e = f();
auto i = value_or_throw std::system_error(e);

where

```
template <class Exception, class T, class E>
constexpr const T& value_or_throw(expected<T, E> const& e)
{
    if (!e.has_value())
        throw Exception(e.error());
    return *e;
}
```

A function like this one could be added to the standard, but this proposal doesn't request it.

An alternative is to overload the `value` function with the exception to throw.

```
template <class Exception, class T, class E>
constexpr value_type const& value() const
```

About `expected<T, ErrorCode, Exception>`

It has been suggested also to extend the design into something that contains

- a `T`, or
- an `ErrorCode`, or
- an `exception_ptr`

This is the case of [Outcome] library.

Again there is no major difficulty to implement it, but instead of having one variation point we have two, that is, is there a value, and if not, if is there an `exception_ptr`.

Better to have a variadic `expected<T, E...>`

**Appendix II: Related types**

**Variant**

`expected<T, E>` can be seen as a specialization of `boost::variant<unexpected_type<E>, T>` which gives a specific intent to its first parameter, that is, it represents the type of the expected contained value. This specificity allows to provide a pointer like interface, as it is the case for `std::optional<T>`.

Even if the standard included a class `variant<T, E>` , the interface provided by `expected<T, E>` is more specific and closer to what the user could expect as the result type of a function. In addition, `expected<T, E>` doesn't intend to be used to define recursive data as `boost::variant<>` does.

The following table presents a brief comparison between `boost::variant<unexpected_type<E>, T>` and `expected<T, E>`.

<table>
<thead>
<tr>
<th>std:variant&lt;T, unexpected_type&lt;E&gt;&gt;</th>
<th>expected&lt;T, E&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>never-empty warranty</td>
<td>no</td>
</tr>
<tr>
<td>accepts is_same&lt;T, E&gt;</td>
<td>yes</td>
</tr>
<tr>
<td>swap</td>
<td>yes</td>
</tr>
<tr>
<td>factories</td>
<td>no</td>
</tr>
<tr>
<td>hash</td>
<td>yes</td>
</tr>
<tr>
<td>value_type</td>
<td>no</td>
</tr>
<tr>
<td>default constructor</td>
<td>yes (if T is default constructible)</td>
</tr>
<tr>
<td>observers</td>
<td>boost::get&lt;T&gt; and boost::get&lt;E&gt;</td>
</tr>
<tr>
<td>visitation</td>
<td>visit</td>
</tr>
</tbody>
</table>

**Optional**

We can see `expected<T, E>` as an `std::optional<T>` that collapse all the values of `E` to `nullopt`.
We can convert an `expected<T,E>` to an `optional<T>` with the possible loss of information.

```cpp
template <class T, class E>
optional<T> make_optional(expected<T,E> v) {
    if (v) return make_optional(*v);
    else nullopt;
}
```

We can convert an `optional<T>` to an `expected<T,E>` without knowledge of the root cause. We consider that `E()` is equal to `nullopt` since it shouldn't bring more informations (however it depends on the underlying error — we considered `exception_ptr` and `error_condition`).

```cpp
template <class T, class E>
expected<T,E> make_expected(optional<T> v) {
    if (v) return make_expected(*v);
    else make_unexpected(E());
}
```

The problem is if `E` is a status and `E()` denotes a success value.

**Promise and Future**

We see `expected<T>` as an always ready `future<T>`. While `promise<> / future<>` focuses on inter-thread asynchronous communication, `excepted<T, E>` focus on eager and synchronous computations. We can move a ready `future<T>` to an `expected<T>` with no loss of information.

```cpp
template <class T, class E>
expected<T, exception_ptr> make_expected(future<T>&& f) {
    assert(f.ready() && "future not ready");
    try {
        return f.get();
    } catch (...) {
        return unexpected_type<exception_ptr>{current_exception()};
    }
}
```

We could also create a `future<T>` from an `expected<T>`

```cpp
template <class T>
future<T> make_future(expected<T> e) {
    if (e)
        return make_ready_future(*e);
    else
        return make_exceptional_future<T>{e.error()};
}
```

**Comparison between optional, expected and future**

The following table presents a brief comparison between `optional<T>`, `expected<T, E>` and `promise<T> / future<T>`.
