Introduction

This paper resolves inconsistencies allowed by C++11-17’s Clause 29 atomic specification, which allow
programs to compile under some implementations but not others. It also removes overspecification
where this is not detectable to users, and actively harmful to standard library implementations. Other
parts of Clause 29, such as kill_dependency, atomic_flag, and fences are unaffected.

Inconsistencies caused by "named base classes"

Consider the following function:

```cpp
long example(atomic<long> * a) {
    return atomic_fetch_add(a, 42);
}
```

The C++ standard is inconsistent about whether this program should compile. N4618 29.5[atomics.types.generic]/7 says:

There shall be named types corresponding to the integral specializations of atomic, as specified
in Table 138, and a named type atomic_bool corresponding to the specified atomic<bool>. Each
named type is either a typedef to the corresponding specialization or a base class of the
corresponding specialization. [...]  

And later in 29.6.3 [atomics.types.operations.arith]/2 says when describing integral nonmembers
(like atomic_fetch_add) that:

In the declarations of these functions and function template specializations, the name integral
refers to an integral type and the name atomic-integral refers to either atomic<integral> or to a
named base class for integral from Table 138 or inferred from Table 139.

This means that our example function above has 2 different answers. If an implementation does not
choose to have named base classes, then this program does not compile. The signature

```cpp
template <class T>
T atomic_fetch_add(atomic<T> * a, T x);
```

tries to deduce \( T = \text{long} \) for the parameter \( a \), and \( T = \text{int} \) for parameter \( x \), and type deduction fails.

If an implementation uses the named base class option, then the above type deduction failure still
occurs, but an additional signature is present which would be viable:

```cpp
long atomic_fetch_add(atomic_long * a, long);
```

That is, the atomic’s type "wins" and does a promotion on the second parameter from int to long.

We propose to make this program compile on all implementations, by disabling type deduction on
the second parameter of the atomic_xxx nonmember functions. We can disable type deduction by
providing `value_type` and `difference_type` typedefs in `std::atomic` (which may be useful for other uses), and changing the second parameter to use this typedef:

```cpp
template <class T>
T atomic_fetch_add(volatile atomic<T>* const, typename atomic<T>::difference_type) noexcept;
```

`atomic<T>::value_type` is always `T`, and `atomic<T>::difference_type` is the type of the second parameter for add and subtract functions; `T` for integral types and `ptrdiff_t` for pointers.

This change has a number of positive characteristics:

- The named base class and typedef based implementations of `std::atomic` become equivalent, and the C compatibility nonmember functions can be specified as "Effects: Equivalent to member function call"
- LWG 2715 is resolved, as the class definition in the synopsis now serves to indicate that list initialization is possible.
- Other kinds of operations where the user expects to convert to the atomic's type now compile. For example, the following function trips the same type deduction failure:

```cpp
void example() {
  struct X;
  atomic<X *> ptr{};
  atomic_store(&ptr, 0); // is T X * or int?
}
```

## `atomic<T *>` providing operations not available on `T *

Today, `atomic` is depicted as having a partial specialization for `T *`, and unconditionally provides operations like `++` and `--` for pointer types. However, not all pointer types themselves provide `++` and `--`. For example, that partial specialization is matched for `void *`, and for function pointer types like `int (*)(int)`, for which `++` and `--` make no semantic sense and would be ill-formed.

Because the core language doesn't say what happens with such pointers, and Clause 29 did not specify, there has been implementation divergence in this area. MSVC++ and libstdc++ implement these operations as if the `void *` or `int (*)(int)` were a `char *` (producing invalid function pointers!), and for libc++ it fails to compile.

```cpp
#include <stdio.h>
#include <atomic>

int main() {
  std::atomic<int (*)(int)> x{0};
  ++x;
  printf("%p\n", x.load());
}
```

This seems like a specification oversight and we should not be allowing such programs to compile.

### Cleaning up unobservable specification details

- The `atomic<integral>` description said that `atomic<integral>` had to be implemented as an explicit specialization, which is undetectable to users. An implementation could choose to provide the correct operations by selecting an appropriate base class.
- Fixed use of "shall" to indicate a requirement for standard libraries (rather than users).
29 Atomic operations library

29.1 General

This Clause describes components for fine-grained atomic access. This access is provided via operations on atomic objects.

The following subclauses describe atomics requirements and components for types and operations, as summarized below.

// 29.9. flag type and operations

struct atomic_flag;
bool atomic_flag_test_and_set(volatile atomic_flag*) noexcept;
bool atomic_flag_test_and_set(atomic_flag*) noexcept;
bool atomic_flag_test_and_set_explicit(volatile atomic_flag*, memory_order) noexcept;
bool atomic_flag_test_and_set_explicit(atomic_flag*, memory_order) noexcept;
void atomic_flag_clear(volatile atomic_flag*) noexcept;
namespace std {
    enum memory_order {
        memory_order_relaxed, memory_order_consume, memory_order_acquire,
        memory_order_release, memory_order_acq_rel, memory_order_seq_cst
    };
}

1 The enumeration memory_order specifies the detailed regular (non-atomic) memory synchronization order as defined in ?? and may provide for operation ordering. Its enumerated values and their meanings are as follows:

1.1 — memory_order_relaxed: no operation orders memory.
1.2 — memory_order_release, memory_order_acq_rel, and memory_order_seq_cst: a store operation performs a release operation on the affected memory location.
1.3 — memory_order_consume: a load operation performs a consume operation on the affected memory location. [Note: Prefer memory_order_acquire, which provides stronger guarantees than memory_order_consume. Implementations have found it infeasible to provide performance better than that of memory_order_acquire. Specification revisions are under consideration. — end note]
1.4 — memory_order_acquire, memory_order_acq_rel, and memory_order_seq_cst: a load operation performs an acquire operation on the affected memory location.

[Note: Atomic operations specifying memory_order_relaxed are relaxed with respect to memory ordering. Implementations must still guarantee that any given atomic access to a particular atomic object be indivisible with respect to all other atomic accesses to that object. — end note]

2 An atomic operation $A$ that performs a release operation on an atomic object $M$ synchronizes with an atomic operation $B$ that performs an acquire operation on $M$ and takes its value from any side effect in the release sequence headed by $A$.

3 There shall be a single total order $S$ on all memory_order_seq_cst operations, consistent with the “happens before” order and modification orders for all affected locations, such that each memory_order_seq_cst operation $B$ that loads a value from an atomic object $M$ observes one of the following values:

3.1 — the result of the last modification $A$ of $M$ that precedes $B$ in $S$, if it exists, or
3.2 — if $A$ exists, the result of some modification of $M$ that is not memory_order_seq_cst and that does not happen before $A$, or
3.3 — if $A$ does not exist, the result of some modification of $M$ that is not memory_order_seq_cst.
[Note: Although it is not explicitly required that $S$ include locks, it can always be extended to an order that does include lock and unlock operations, since the ordering between those is already included in the “happens before” ordering. — end note]

4 For an atomic operation $B$ that reads the value of an atomic object $M$, if there is a memory_order_seq_cst fence $X$ sequenced before $B$, then $B$ observes either the last memory_order_seq_cst modification of $M$
preceding $X$ in the total order $S$ or a later modification of $M$ in its modification order.

5 For atomic operations $A$ and $B$ on an atomic object $M$, where $A$ modifies $M$ and $B$ takes its value, if there is a \texttt{memory\_order\_seq\_cst} fence $X$ such that $A$ is sequenced before $X$ and $B$ follows $X$ in $S$, then $B$ observes either the effects of $A$ or a later modification of $M$ in its modification order.

6 For atomic operations $A$ and $B$ on an atomic object $M$, where $A$ modifies $M$ and $B$ takes its value, if there are \texttt{memory\_order\_seq\_cst} fences $X$ and $Y$ such that $A$ is sequenced before $X$, $Y$ is sequenced before $B$, and $X$ precedes $Y$ in $S$, then $B$ observes either the effects of $A$ or a later modification of $M$ in its modification order.

7 For atomic modifications $A$ and $B$ of an atomic object $M$, $B$ occurs later than $A$ in the modification order of $M$ if:

(7.1) there is a \texttt{memory\_order\_seq\_cst} fence $X$ such that $A$ is sequenced before $X$, and $X$ precedes $B$ in $S$, or

(7.2) there is a \texttt{memory\_order\_seq\_cst} fence $Y$ such that $Y$ is sequenced before $B$, and $A$ precedes $Y$ in $S$, or

(7.3) there are \texttt{memory\_order\_seq\_cst} fences $X$ and $Y$ such that $A$ is sequenced before $X$, $Y$ is sequenced before $B$, and $X$ precedes $Y$ in $S$.

8 \textbf{[Note:} \texttt{memory\_order\_seq\_cst} ensures sequential consistency only for a program that is free of data races and uses exclusively \texttt{memory\_order\_seq\_cst} operations. Any use of weaker ordering will invalidate this guarantee unless extreme care is used. In particular, \texttt{memory\_order\_seq\_cst} fences ensure a total order only for the fences themselves. Fences cannot, in general, be used to restore sequential consistency for atomic operations with weaker ordering specifications. \textbf{— end note]}

9 Implementations should ensure that no “out-of-thin-air” values are computed that circularly depend on their own computation.

\textbf{[Note:} For example, with $x$ and $y$ initially zero,

\begin{verbatim}
// Thread 1:
r1 = y.load(memory_order_relaxed);
x.store(r1, memory_order_relaxed);
// Thread 2:
r2 = x.load(memory_order_relaxed);
y.store(r2, memory_order_relaxed);
\end{verbatim}

should not produce $r1 == r2 == 42$, since the store of 42 to $y$ is only possible if the store to $x$ stores 42, which circularly depends on the store to $y$ storing 42. Note that without this restriction, such an execution is possible. \textbf{— end note]}

10 \textbf{[Note:} The recommendation similarly disallows $r1 == r2 == 42$ in the following example, with $x$ and $y$ again initially zero:

\begin{verbatim}
// Thread 1:
r1 = x.load(memory_order_relaxed);
if (r1 == 42) y.store(42, memory_order_relaxed);
// Thread 2:
r2 = y.load(memory_order_relaxed);
if (r2 == 42) x.store(42, memory_order_relaxed);
\end{verbatim}

\textbf{— end note]}

11 Atomic read-modify-write operations shall always read the last value (in the modification order) written before the write associated with the read-modify-write operation.

12 Implementations should make atomic stores visible to atomic loads within a reasonable amount of time.

\textbf{§ 29.3}
template <class T>
T kill_dependency(T y) noexcept;

Effects: The argument does not carry a dependency to the return value (??).

Returns: y.

29.4 Lock-free property

#define ATOMIC_BOOL_LOCK_FREE unspecified
#define ATOMIC_CHAR_LOCK_FREE unspecified
#define ATOMIC_CHAR16_T_LOCK_FREE unspecified
#define ATOMIC_CHAR32_T_LOCK_FREE unspecified
#define ATOMIC_WCHAR_T_LOCK_FREE unspecified
#define ATOMIC_SHORT_LOCK_FREE unspecified
#define ATOMIC_INT_LOCK_FREE unspecified
#define ATOMIC_LONG_LOCK_FREE unspecified
#define ATOMIC_LLONG_LOCK_FREE unspecified
#define ATOMIC_POINTER_LOCK_FREE unspecified

1 The ATOMIC_..._LOCK_FREE macros indicate the lock-free property of the corresponding atomic types, with
the signed and unsigned variants grouped together. The properties also apply to the corresponding (partial)
specializations of the atomic template. A value of 0 indicates that the types are never lock-free. A value of 1
indicates that the types are sometimes lock-free. A value of 2 indicates that the types are always lock-free.

2 The function atomic_is_lock_free (29.6) indicates whether the object is lock-free. In any given program
execution, the result of the lock-free query shall be consistent for all pointers of the same type.

3 Atomic operations that are not lock-free are considered to potentially block (??).

4 [Note: Operations that are lock-free should also be address-free. That is, atomic operations on the same
memory location via two different addresses will communicate atomically. The implementation should not
depend on any per-process state. This restriction enables communication by memory that is mapped into a
process more than once and by memory that is shared between two processes. — end note]

29.5 Class template atomic

namespace std {
    template <class T> struct atomic {
        using value_type = T;

        bool compare_exchange_weak(T& t, T, memory_order, memory_order) noexcept;
        bool compare_exchange_strong(T& t, T, memory_order, memory_order) volatile noexcept;
        bool compare_exchange_strong(T& t, T, memory_order, memory_order) noexcept;
        bool compare_exchange_weak(T& t, T, memory_order = memory_order_seq_cst) volatile noexcept;
        bool compare_exchange_weak(T& t, T, memory_order = memory_order_seq_cst) noexcept;
        bool compare_exchange_strong(T& t, T, memory_order = memory_order_seq_cst) volatile noexcept;
        bool compare_exchange_strong(T& t, T, memory_order = memory_order_seq_cst) noexcept;
    }
}
There is a generic class template `atomic<T>`.

The type of the template argument for T shall be trivially copyable.

_Note: Type arguments that are not also statically initializable may be difficult to use._ — end note

The semantics of the operations on specializations of `atomic` are defined in 29.6.

Specializations and instantiations of the `atomic` template shall have a deleted copy constructor, a deleted copy assignment operator, and a `constexpr` value constructor.

_Note: The representation of an atomic specialization need not have the same size as its corresponding argument type. Specializations should have the same size whenever possible, as this reduces the effort required to port existing code._ — end note

## 29.6 Operations on atomic types

[atomics.types.operations]

[Editor’s note: Remove all of the following subsections and the heading preceding this note.]

### 29.6.1 General operations on atomic types

[atomics.types.operations.general]

The implementation shall provide the functions and function templates identified as “general operations on atomic types” in 29.2.

In the declarations of these functions and function templates, the name `atomic-type` refers to either `atomic<T>` or to a named base class for T from Table ?? or inferred from Table ??.

### 29.6.2 Templated operations on atomic types

[atomics.types.operations.templ]

The implementation shall declare but not define the function templates identified as “templated operations on atomic types” in 29.2.

### 29.6.3 Arithmetic operations on atomic types

[atomics.types.operations.arith]

The implementation shall provide the functions and function template specializations identified as “arithmetic operations on atomic types” in 29.2.

In the declarations of these functions and function template specializations, the name `integral` refers to an integral type and the name `atomic-integral` refers to either `atomic<integral>` or to a named base class for `integral` from Table ?? or inferred from Table ??.

### 29.6.4 Operations on atomic pointer types

[atomics.types.operations.pointer]

The implementation shall provide the function template specializations identified as “partial specializations for pointers” in 29.2.

### 29.6.5 Requirements for operations on atomic types

[atomics.types.operations.req]

There are only a few kinds of operations on atomic types, though there are many instances on those kinds. This section specifies each general kind. The specific instances are defined in 29.5, 29.6.1, 29.6.3, and 29.6.4.

In the following operation definitions:

(2.1) an `A` refers to one of the atomic types.
(2.2) a C refers to its corresponding non-atomic type.

(2.3) an M refers to type of the other argument for arithmetic operations. For integral atomic types, M is C. For atomic address types, M is ptrdiff_t.

(2.4) the non-member functions not ending in _explicit have the semantics of their corresponding _explicit functions with memory_order arguments of memory_order_seq_cst.

[Note: Many operations are volatile-qualified. The “volatile as device register” semantics have not changed in the standard. This qualification means that volatility is preserved when applying these operations to volatile objects. It does not mean that operations on non-volatile objects become volatile. Thus, volatile qualified operations on non-volatile objects may be merged under some conditions. — end note]

```cpp
+++ atomic() noexcept = default;
```

Effects: Leaves the atomic object in an uninitialized state. [Note: These semantics ensure compatibility with C. — end note]

```cpp
constexpr +++ atomic(CT desired) noexcept;
```

Effects: Initializes the object with the value desired. Initialization is not an atomic operation (??). [Note: It is possible to have an access to an atomic object A race with its construction, for example by communicating the address of the just-constructed object A to another thread via memory_order_relaxed operations on a suitable atomic pointer variable, and then immediately accessing A in the receiving thread. This results in undefined behavior. — end note]

```cpp
#define ATOMIC_VAR_INIT(value)
see below
```

The macro expands to a token sequence suitable for constant initialization of an atomic variable of static storage duration of a type that is initialization-compatible with value. [Note: This operation may need to initialize locks. — end note] Concurrent access to the variable being initialized, even via an atomic operation, constitutes a data race. [Example:

```cpp
atomic<int> v = ATOMIC_VAR_INIT(5);
```

— end example]

```cpp
static constexpr bool is_always_lock_free = implementation-defined;
```

The static data member is_always_lock_free is true if the atomic type’s operations are always lock-free, and false otherwise. [Note: The value of is_always_lock_free is consistent with the value of the corresponding ATOMIC_LOCK_FREE macro, if defined. — end note]

```cpp
bool atomic_is_lock_free(const volatile A* object) noexcept;
bool atomic_is_lock_free(const A* object) noexcept;
bool A::is_lock_free() const volatile noexcept;
bool A::is_lock_free() const noexcept;
```

Returns: true if the object’s operations are lock-free, false otherwise. [Note: The return value of the is_lock_free member function is consistent with the value of is_always_lock_free for the same type. — end note]

```cpp
void atomic_store(volatile A* object, C desired) noexcept;
void atomic_store(A* object, C desired) noexcept;
void atomic_store_explicit(volatile A* object, C desired, memory_order order) noexcept;
void atomic_store_explicit(A* object, C desired, memory_order order) noexcept;
void A::store(CT desired, memory_order order = memory_order_seq_cst) volatile noexcept;
void A::store(CT desired, memory_order order = memory_order_seq_cst) noexcept;
```

Requires: The order argument shall not be memory_order_consume, memory_order_acquire, nor
memory_order_acq_rel.

Effects: Atomically replaces the value pointed to by object or by this with the value of desired. Memory is affected according to the value of order.

\[ A\rightarrow \text{operator}=(A \text{ desired}) \text{ volatile noexcept}; \]
\[ A\rightarrow \text{operator}=(A \text{ desired}) \text{ noexcept}; \]

Effects: As if by \( \text{store} \text{ desired} \).

Returns: desired.

\[ A\rightarrow \text{atomic} \text{ load} \text{ (const volatile } A \text{ object)} \text{ noexcept}; \]
\[ A\rightarrow \text{atomic} \text{ load} \text{ (const } A \text{ object)} \text{ noexcept}; \]
\[ A\rightarrow \text{atomic} \text{ load} \text{ explicit} \text{ (const volatile } A \text{ object, memory_order)} \text{ noexcept}; \]
\[ A\rightarrow \text{atomic} \text{ load} \text{ explicit} \text{ (const } A \text{ object, memory_order)} \text{ noexcept}; \]
\[ A\rightarrow \text{load} \text{ (memory_order order = memory_order_seq_cst) const volatile noexcept}; \]
\[ A\rightarrow \text{load} \text{ (memory_order order = memory_order_seq_cst) const noexcept}; \]

Requires: The order argument shall not be memory_order_release nor memory_order_acq_rel.

Effects: Memory is affected according to the value of order.

Returns: Atomically returns the value pointed to by object or by this.

\[ A\rightarrow \text{operator} A\rightarrow() \text{ const volatile noexcept}; \]
\[ A\rightarrow \text{operator} A\rightarrow() \text{ const noexcept}; \]

Effects: As if by \( \text{load} \) Equivalent to: return \( \text{load} \);

Returns: The result of \( \text{load} \) .

\[ A\rightarrow \text{atomic_exchange} \text{ (volatile } A \text{ object, C } \text{ desired)} \text{ noexcept}; \]
\[ A\rightarrow \text{atomic_exchange} \text{ (A } \text{ object, C } \text{ desired)} \text{ noexcept}; \]
\[ A\rightarrow \text{atomic_exchange} \text{ explicit} \text{ (volatile } A \text{ object, C } \text{ desired, memory_order)} \text{ noexcept}; \]
\[ A\rightarrow \text{atomic_exchange} \text{ explicit} \text{ (A } \text{ object, C } \text{ desired, memory_order)} \text{ noexcept}; \]
\[ A\rightarrow \text{exchange} \text{ (A } \text{ desired, memory_order order = memory_order_seq_cst) volatile noexcept}; \]
\[ A\rightarrow \text{exchange} \text{ (A } \text{ desired, memory_order order = memory_order_seq_cst) noexcept}; \]

Effects: Atomically replaces the value pointed to by object or by this with desired. Memory is affected according to the value of order. These operations are atomic read-modify-write operations (??).

Returns: Atomically returns the value pointed to by object or by this immediately before the effects.

\[ \text{bool atomic_compare_exchange_weak(volatile } A \text{ object, C } \text{ expected, C } \text{ desired)} \text{ noexcept}; \]
\[ \text{bool atomic_compare_exchange_weak(A } \text{ object, C } \text{ expected, C } \text{ desired)} \text{ noexcept}; \]
\[ \text{bool atomic_compare_exchange_strong(volatile } A \text{ object, C } \text{ expected, C } \text{ desired)} \text{ noexcept}; \]
\[ \text{bool atomic_compare_exchange_strong(A } \text{ object, C } \text{ expected, C } \text{ desired)} \text{ noexcept}; \]
\[ \text{bool atomic_compare_exchange_weak explicit(volatile } A \text{ object, C } \text{ expected, C } \text{ desired, memory_order success, memory_order failure)} \text{ noexcept}; \]
\[ \text{bool atomic_compare_exchange_weak explicit(A } \text{ object, C } \text{ expected, C } \text{ desired, memory_order success, memory_order failure)} \text{ noexcept}; \]
\[ \text{bool atomic_compare_exchange_strong explicit(volatile } A \text{ object, C } \text{ expected, C } \text{ desired, memory_order success, memory_order failure)} \text{ noexcept}; \]
\[ \text{bool atomic_compare_exchange_strong explicit(A } \text{ object, C } \text{ expected, C } \text{ desired, memory_order success, memory_order failure)} \text{ noexcept}; \]
\[ \text{bool } \text{compare_exchange_weak(C } T \text{ & expected, C } T \text{ desired, memory_order success, memory_order failure)} \text{ volatile noexcept}; \]
\[ \text{bool } \text{compare_exchange_weak(C } T \text{ & expected, C } T \text{ desired, memory_order success, memory_order failure)} \text{ noexcept}; \]
\[ \text{bool } \text{compare_exchange_strong(C } T \text{ & expected, C } T \text{ desired, memory_order success, memory_order failure)} \text{ noexcept}; \]
bool A::compare_exchange_strong(
    const T &expected, const T &desired,
    memory_order success, memory_order failure) volatile noexcept;
bool A::compare_exchange_weak(
    const T &expected, const T &desired,
    memory_order order = memory_order_seq_cst) volatile noexcept;

Requires: The failure argument shall not be memory_order_release nor memory_order_acq_rel.

Effects: Retrieves the value in expected. It then atomically compares the contents of the memory
pointed to by object or by this for equality with that previously retrieved from expected, and if
true, replaces the contents of the memory pointed to by object or by this with that in desired.
If and only if the comparison is true, memory is affected according to the value of success, and
if the comparison is false, memory is affected according to the value of failure. When only one
memory_order argument is supplied, the value of success is order, and the value of failure is order
except that a value of memory_order_acq_rel shall be replaced by the value memory_order_acquire
and a value of memory_order_release shall be replaced by the value memory_order_relaxed. If and
only if the comparison is false then, after the atomic operation, the contents of the memory in expected
are replaced by the value read from object or by this during the atomic comparison. If the operation
returns true, these operations are atomic read-modify-write operations (??) on the memory pointed to
by this or object. Otherwise, these operations are atomic load operations on that memory.

Returns: The result of the comparison.

[Note: For example, the effect of atomic_compare_exchange_strong is

```c
if (memcmp(object this, expected, sizeof(*object)) == 0)
    memcpy(object this, &desired, sizeof(*object));
else
    memcpy(expected, object this, sizeof(*object));
```
— end note] [Example: The expected use of the compare-and-exchange operations is as follows.
The compare-and-exchange operations will update expected when another iteration of the loop is
needed.

```c
expected = current.load();
do {
    desired = function(expected);
} while (!current.compare_exchange_weak(expected, desired));
```
— end example] [Example: Because the expected value is updated only on failure, code releasing the
memory containing the expected value on success will work. E.g. list head insertion will act atomically
and would not introduce a data race in the following code:

```c
do {
    p->next = head; // make new list node point to the current head
} while (!head.compare_exchange_weak(p->next, p)); // try to insert
```
— end example]

Implementations should ensure that weak compare-and-exchange operations do not consistently return
false unless either the atomic object has value different from expected or there are concurrent
modifications to the atomic object.

Remarks: A weak compare-and-exchange operation may fail spuriously. That is, even when the
contents of memory referred to by `expected` and `object` are equal, it may return `false` and store back to `expected` the same memory contents that were originally there. [Note: This spurious failure enables implementation of compare-and-exchange on a broader class of machines, e.g., load-locked store-conditional machines. A consequence of spurious failure is that nearly all uses of weak compare-and-exchange will be in a loop.]

When a compare-and-exchange is in a loop, the weak version will yield better performance on some platforms. When a weak compare-and-exchange would require a loop and a strong one would not, the strong one is preferable. — end note]

[Note: The `memcpy` and `memcmp` semantics of the compare-and-exchange operations may result in failed comparisons for values that compare equal with `operator==` if the underlying type has padding bits, trap bits, or alternate representations of the same value. Thus, `compare_exchange_strong` should be used with extreme care. On the other hand, `compare_exchange_weak` should converge rapidly. — end note]

### 29.6.6 Specializations for integers

There shall be explicit specializations of the `atomic` template for the integral types `char`, `signed char`, `unsigned char`, `short`, `unsigned short`, `int`, `unsigned int`, `long`, `unsigned long`, `long long`, `unsigned long long`, `char16_t`, `char32_t`, `wchar_t`, and any other types needed by the typedefs in section ?? the header `<cstdint>`. For each such integral type `integral`, the specialization `atomic<integral>` provides additional atomic operations appropriate to integral types. There shall be a specialization `atomic<bool>` which provides the general atomic operations as specified in 29.6.1.

```cpp
template <> struct atomic<integral> {  
  using value_type = integral;  
  using difference_type = value_type;  
  static constexpr bool is_always_lock_free = implementation-defined;  
  bool is_lock_free() const volatile noexcept;  
  bool is_lock_free() const noexcept;  
  void store(integral, memory_order = memory_order_seq_cst) volatile noexcept;  
  void store(integral, memory_order = memory_order_seq_cst) noexcept;  
  integral load(memory_order = memory_order_seq_cst) const volatile noexcept;  
  integral load(memory_order = memory_order_seq_cst) const noexcept;  
  operator integral() const volatile noexcept;  
  operator integral() const noexcept;  
  integral exchange(integral, memory_order = memory_order_seq_cst) volatile noexcept;  
  integral exchange(integral, memory_order = memory_order_seq_cst) noexcept;  
  bool compare_exchange_weak(integral& integral,  
                            integral,  
                            memory_order, memory_order) volatile noexcept;  
  bool compare_exchange_weak(integral& integral,  
                            integral,  
                            memory_order, memory_order) noexcept;  
  bool compare_exchange_strong(integral& integral,  
                             integral,  
                             memory_order, memory_order) noexcept;  
  bool compare_exchange_strong(integral& integral,  
                             integral,  
                             memory_order, memory_order) volatile noexcept;  
  bool compare_exchange_weak(integral& integral,  
                            integral,  
                            memory_order = memory_order_seq_cst) volatile noexcept;  
  bool compare_exchange_weak(integral& integral,  
                            integral,  
                            memory_order = memory_order_seq_cst) noexcept;  
  bool compare_exchange_strong(integral& integral,  
                             integral,  
                             memory_order = memory_order_seq_cst) volatile noexcept;  
  bool compare_exchange_strong(integral& integral,  
                             integral,  
                             memory_order = memory_order_seq_cst) noexcept;  
  integral fetch_add(integral, memory_order = memory_order_seq_cst) volatile noexcept;
```
integral fetch_add(integral, memory_order = memory_order_seq_cst) noexcept;
integral fetch_sub(integral, memory_order = memory_order_seq_cst) volatile noexcept;
integral fetch_sub(integral, memory_order = memory_order_seq_cst) noexcept;
integral fetch_and(integral, memory_order = memory_order_seq_cst) volatile noexcept;
integral fetch_and(integral, memory_order = memory_order_seq_cst) noexcept;
integral fetch_or(integral, memory_order = memory_order_seq_cst) volatile noexcept;
integral fetch_or(integral, memory_order = memory_order_seq_cst) noexcept;
integral fetch_xor(integral, memory_order = memory_order_seq_cst) volatile noexcept;
integral fetch_xor(integral, memory_order = memory_order_seq_cst) noexcept;

atomic() noexcept = default;
constexpr atomic(integral) noexcept;
atomic(const atomic&) = delete;
atomic& operator=(const atomic&) = delete;
atomic& operator=(const atomic&) volatile = delete;

integral operator=(integral) volatile noexcept;
integral operator=(integral) noexcept;
integral operator++(int) volatile noexcept;
integral operator++(int) noexcept;
integral operator--(int) volatile noexcept;
integral operator--(int) noexcept;
integral operator++() volatile noexcept;
integral operator++() noexcept;
integral operator--() volatile noexcept;
integral operator--() noexcept;

Table 2 — Atomic arithmetic computations

<table>

2 The atomic integral specializations and the specialization atomic<bool> shall be standard-layout structs. They shall each have a trivial default constructor and a trivial destructor. They shall each support aggregate initialization syntax.
3 Descriptions are provided below only for members that differ from the primary template.
4 The following operations perform arithmetic computations. The key, operator, and computation correspondence is:

atomic_fetch_key(volatile A* object, M operand) noexcept;
5 Effects: Atomically replaces the value pointed to by \texttt{object} or by \texttt{this} with the result of the computation applied to the value pointed to by \texttt{object} or by \texttt{this} and the given \texttt{operand}. Memory is affected according to the value of \texttt{order}. These operations are atomic read-modify-write operations (§29.6.1).

6 Returns: Atomically, the value pointed to by \texttt{object} or by \texttt{this} immediately before the effects.

7 Remarks: For signed integer types, arithmetic is defined to use two’s complement representation. There are no undefined results. For address types, the result may be an undefined address, but the operations otherwise have no undefined behavior.

8 Effects: As if by \texttt{atomic_fetch_key(operand)}. Equivalent to: \texttt{return atomic_fetch_key(operand) \ op \ operand;}

Returns: \texttt{atomic_fetch_key(operand) \ op \ operand}.

### 29.6.7 Partial specialization for pointers

[atomics.types.pointer]

```cpp
template <class T> struct atomic<T*> {
    using value_type = T*;
    using difference_type = ptrdiff_t;
    static constexpr bool is_always_lock_free = implementation-defined;
    bool is_lock_free() const volatile noexcept;
    bool is_lock_free() const noexcept;
    void store(T*, memory_order = memory_order_seq_cst) volatile noexcept;
    void store(T*, memory_order = memory_order_seq_cst) noexcept;
    T* load(memory_order = memory_order_seq_cst) const volatile noexcept;
    T* load(memory_order = memory_order_seq_cst) const noexcept;
    operator T*() const volatile noexcept;
    operator T*() const noexcept;
    T* exchange(T*, memory_order = memory_order_seq_cst) volatile noexcept;
    T* exchange(T*, memory_order = memory_order_seq_cst) noexcept;
    bool compare_exchange_weak(T*& T, T*, memory_order, memory_order) volatile noexcept;
    bool compare_exchange_weak(T*& T, T*, memory_order, memory_order) noexcept;
    bool compare_exchange_strong(T*& T, T*, memory_order, memory_order) volatile noexcept;
    bool compare_exchange_strong(T*& T, T*, memory_order, memory_order) noexcept;
    bool compare_exchange_weak(T*& T, T*, memory_order = memory_order_seq_cst) volatile noexcept;
    bool compare_exchange_weak(T*& T, T*, memory_order = memory_order_seq_cst) noexcept;
    bool compare_exchange_strong(T*& T, T*, memory_order = memory_order_seq_cst) volatile noexcept;
    bool compare_exchange_strong(T*& T, T*, memory_order = memory_order_seq_cst) noexcept;
    T* fetch_add(ptrdiff_t, memory_order = memory_order_seq_cst) volatile noexcept;
    T* fetch_add(ptrdiff_t, memory_order = memory_order_seq_cst) noexcept;
    T* fetch_sub(ptrdiff_t, memory_order = memory_order_seq_cst) volatile noexcept;
    T* fetch_sub(ptrdiff_t, memory_order = memory_order_seq_cst) noexcept;
    atomic() noexcept = default;
    constexpr atomic(T*) noexcept;
    atomic(const atomic&) = delete;
    atomic& operator=(const atomic&) volatile = delete;
    T* operator=(T*) volatile noexcept;
};
```

§ 29.6.7
T* operator=(T*) noexcept;
T* operator++(int) volatile noexcept;
T* operator++(int) noexcept;
T* operator--(int) volatile noexcept;
T* operator--(int) noexcept;
T* operator++() volatile noexcept;
T* operator++() noexcept;
T* operator--() volatile noexcept;
T* operator--() noexcept;
T* operator+=(ptrdiff_t) volatile noexcept;
T* operator+=(ptrdiff_t) noexcept;
T* operator-=(ptrdiff_t) volatile noexcept;
T* operator-=(ptrdiff_t) noexcept;

1 There shall be a partial specialization of the atomic class template for pointers. These Specializations shall be of this partial specialization are standard-layout structs. They shall each have a trivial default constructor and a trivial destructor. They shall each support aggregate initialization syntax.

2 Descriptions are provided below only for members that differ from the primary template.

[Editor’s note: The following provisions are cloned from the integer arithmetic section to avoid the M placeholders.]

3 The following operations perform pointer arithmetic. The key, operator, and computation correspondence is:

<table>
<thead>
<tr>
<th>Key</th>
<th>Op</th>
<th>Computation</th>
</tr>
</thead>
<tbody>
<tr>
<td>add</td>
<td>+</td>
<td>addition</td>
</tr>
<tr>
<td>sub</td>
<td>-</td>
<td>subtraction</td>
</tr>
</tbody>
</table>

T* fetch_key(ptrdiff_t operand, memory_order order = memory_order_seq_cst) volatile noexcept;
T* fetch_key(ptrdiff_t operand, memory_order order = memory_order_seq_cst) noexcept;

4 Requires: T shall be an object type. [Note: Pointer arithmetic on void* or function pointers is ill-formed. — end note]

5 Effects: Atomically replaces the value pointed to by this with the result of the computation applied to the value pointed to by this and the given operand. Memory is affected according to the value of order. These operations are atomic read-modify-write operations (?).

6 Returns: Atomically, the value pointed to by this immediately before the effects.

T* operator op=(ptrdiff_t operand) volatile noexcept;
T* operator op=(ptrdiff_t operand) noexcept;

7 Effects: Equivalent to: return fetch_key(operand) op operand;

29.6.8 Member operators common to integers and pointers [atomics.types.memop]

§ 29.6.8
29.7 Non-member functions

A non-member function template whose name matches the pattern `atomic_f` or the pattern `atomic_f_explicit` invokes the member function `f`, with the value of the first parameter as the object expression and the values of the remaining parameters (if any) as the arguments of the member function call, in order. [Note: If no such member function exists, the program is ill-formed. — end note]

```
-template<class T>
    void atomic_init(volatile atomic<T>* object, typename atomic<T>::value_type desired) noexcept;
-template<class T>
    void atomic_init(atomic<T>* object, typename atomic<T>::value_type desired) noexcept;

Effects: Non-atomically initializes *object with value desired. This function shall only be applied to objects that have been default constructed, and then only once. [Note: These semantics ensure compatibility with C. — end note] [Note: Concurrent access from another thread, even via an atomic operation, constitutes a data race. — end note]
```

[Note: The non-member functions enable programmers to write code that can be compiled as either C or C++, for example in a shared header file. [Example:

```
atomic_int use_count;
void init() {
    atomic_init(&use_count, 0);
}
void add_use() {
    atomic_fetch_add(&use_count, 1);
}
bool remove_use {
    // returns true if last use was removed
    return atomic_fetch_sub(&use_count, 1) == 1;
}
— end example] — end note]

29.8 Type aliases

[atomics.alias]

There shall be named types corresponding to the integral specializations of `atomic`, as specified in Table 29, and a named type `atomic_bool` corresponding to the specified `atomic<bool>`. Each named type is either a typedef to the corresponding specialization or a base class of the corresponding specialization. If it is a base class, it shall support the same member functions as the corresponding specialization.

There shall be atomic typedefs corresponding to non-atomic typedefs as specified in Table 29. The type

§ 29.8
The `atomic_flag` type provides the classic test-and-set functionality. It has two states, set and clear.

Operations on an object of type `atomic_flag` shall be lock-free. [Note: Hence the operations should also be address-free. No other type requires lock-free operations, so the `atomic_flag` type is the minimum hardware-implemented type needed to conform to this International Standard. The remaining types can be emulated with `atomic_flag`, though with less than ideal properties. — end note]

The `atomic_flag` type shall be a standard-layout struct. It shall have a trivial default constructor, a deleted copy constructor, a deleted copy assignment operator, and a trivial destructor.

The macro `ATOMIC_FLAG_INIT` shall be defined in such a way that it can be used to initialize an object of type `atomic_flag` to the clear state. The macro can be used in the form:

```cpp
atomic_flag guard = ATOMIC_FLAG_INIT;
```

It is unspecified whether the macro can be used in other initialization contexts. For a complete static-duration object, that initialization shall be static. Unless initialized with `ATOMIC_FLAG_INIT`, it is unspecified whether an `atomic_flag` object has an initial state of set or clear.

```cpp
bool atomic_flag_test_and_set(volatile atomic_flag* object) noexcept;
bool atomic_flag_test_and_set(atomic_flag* object) noexcept;
bool atomic_flag_test_and_set_explicit(volatile atomic_flag* object, memory_order order) noexcept;
bool atomic_flag_test_and_set_explicit(atomic_flag* object, memory_order order) noexcept;
void atomic_flag_clear(volatile atomic_flag* object) noexcept;
void atomic_flag_clear(atomic_flag* object) noexcept;
void atomic_flag_clear_explicit(volatile atomic_flag* object, memory_order order) noexcept;
void atomic_flag_clear_explicit(atomic_flag* object, memory_order order) noexcept;
```

**Effects:** Atomically sets the value pointed to by `object` or by `this` to `true`. Memory is affected according to the value of `order`. These operations are atomic read-modify-write operations (??).
Returns: Atomically, the value of the object immediately before the effects.

```c
void atomic_flag_clear(volatile atomic_flag* object) noexcept;
void atomic_flag_clear(atomic_flag* object) noexcept;
void atomic_flag_clear_explicit(volatile atomic_flag* object, memory_order order) noexcept;
void atomic_flag_clear_explicit(atomic_flag* object, memory_order order) noexcept;
void atomic_flag::clear(memory_order order = memory_order_seq_cst) volatile noexcept;
void atomic_flag::clear(memory_order order = memory_order_seq_cst) noexcept;
```

Requires: The `order` argument shall not be `memory_order_consume`, `memory_order_acquire`, nor `memory_order_acq_rel`.

Effects: Atomically sets the value pointed to by `object` or by `this` to `false`. Memory is affected according to the value of `order`.

29.10 Fences

This section introduces synchronization primitives called **fences**. Fences can have acquire semantics, release semantics, or both. A fence with acquire semantics is called an **acquire fence**. A fence with release semantics is called a **release fence**.

A release fence `A` synchronizes with an acquire fence `B` if there exist atomic operations `X` and `Y`, both operating on some atomic object `M`, such that `A` is sequenced before `X`, `X` modifies `M`, `Y` is sequenced before `B`, and `Y` reads the value written by `X` or a value written by any side effect in the hypothetical release sequence `X` would head if it were a release operation.

A release fence `A` synchronizes with an atomic operation `B` that performs an acquire operation on an atomic object `M` if there exists an atomic operation `X` on `M` such that `A` is sequenced before `X`, `X` modifies `M`, and `B` reads the value written by `X` or a value written by any side effect in the hypothetical release sequence `X` would head if it were a release operation.

An atomic operation `A` that is a release operation on an atomic object `M` synchronizes with an acquire fence `B` if there exists some atomic operation `X` on `M` such that `X` is sequenced before `B` and reads the value written by `A` or a value written by any side effect in the release sequence headed by `A`.

```c
extern "C" void atomic_thread_fence(memory_order order) noexcept;
```

Effects: Depending on the value of `order`, this operation:

(5.1) has no effects, if `order == memory_order_relaxed`;
(5.2) is an acquire fence, if `order == memory_order_acquire || order == memory_order_consume`;
(5.3) is a release fence, if `order == memory_order_release`;
(5.4) is both an acquire fence and a release fence, if `order == memory_order_acq_rel`;
(5.5) is a sequentially consistent acquire and release fence, if `order == memory_order_seq_cst`.

```c
extern "C" void atomic_signal_fence(memory_order order) noexcept;
```

Effects: Equivalent to `atomic_thread_fence(order)`, except that the resulting ordering constraints are established only between a thread and a signal handler executed in the same thread.

Note: `atomic_signal_fence` can be used to specify the order in which actions performed by the thread become visible to the signal handler.

Note: compiler optimizations and reorderings of loads and stores are inhibited in the same way as with `atomic_thread_fence`, but the hardware fence instructions that `atomic_thread_fence` would have inserted are not emitted.
