Working Draft, Standard for Programming Language C++

Note: this is an early draft. It’s known to be incomplet and incorrekt, and it has lots of bad formatting.
# Contents

1 Scope 1

2 Normative references 2

3 Terms and definitions 3

4 General principles 6
   4.1 Implementation compliance 6
   4.2 Structure of this document 8
   4.3 Syntax notation 8
   4.4 Acknowledgments 8

5 Lexical conventions 9
   5.1 Separate translation 9
   5.2 Phases of translation 9
   5.3 Character sets 10
   5.4 Preprocessing tokens 11
   5.5 Alternative tokens 12
   5.6 Tokens 12
   5.7 Comments 12
   5.8 Header names 12
   5.9 Preprocessing numbers 13
   5.10 Identifiers 13
   5.11 Keywords 14
   5.12 Operators and punctuators 15
   5.13 Literals 15

6 Basics 24
   6.1 Declarations and definitions 24
   6.2 One-definition rule 26
   6.3 Scope 29
   6.4 Name lookup 34
   6.5 Program and linkage 46
   6.6 Memory and objects 48
   6.7 Types 60
   6.8 Program execution 66

7 Expressions 78
   7.1 Preamble 78
   7.2 Properties of expressions 78
   7.3 Standard conversions 81
   7.4 Usual arithmetic conversions 86
   7.5 Primary expressions 87
   7.6 Compound expressions 102
   7.7 Constant expressions 129

8 Statements 134
   8.1 Labeled statement 134
   8.2 Expression statement 135
   8.3 Compound statement or block 135
   8.4 Selection statements 135
   8.5 Iteration statements 137
   8.6 Jump statements 139
   8.7 Declaration statement 141

Index of implementation-defined behavior  1568
1 Scope

This document specifies requirements for implementations of the C++ programming language. The first such requirement is that they implement the language, so this document also defines C++. Other requirements and relaxations of the first requirement appear at various places within this document.

C++ is a general purpose programming language based on the C programming language as described in ISO/IEC 9899:2011 *Programming languages — C* (hereinafter referred to as the *C standard*). C++ provides many facilities beyond those provided by C, including additional data types, classes, templates, exceptions, namespaces, operator overloading, function name overloading, references, free store management operators, and additional library facilities.
2 Normative references

1 The following documents are referred to in the text in such a way that some or all of their content constitutes requirements of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

(1.3) — ISO/IEC 2382 (all parts), *Information technology — Vocabulary*

(1.4) — ISO 8601:2004, *Data elements and interchange formats — Information interchange — Representation of dates and times*

(1.5) — ISO/IEC 9899:2011, *Programming languages — C*

(1.6) — ISO/IEC 9945:2003, *Information Technology — Portable Operating System Interface (POSIX)*

(1.7) — ISO/IEC 10646, *Information technology — Universal Coded Character Set (UCS)*

(1.10) — ISO 80000-2:2009, *Quantities and units — Part 2: Mathematical signs and symbols to be used in the natural sciences and technology*

2 The library described in Clause 7 of ISO/IEC 9899:2011 is hereinafter called the *C standard library.*

3 The operating system interface described in ISO/IEC 9945:2003 is hereinafter called *POSIX.*

4 The ECMA standard library is a subset of the C standard library.

5 [Note: References to ISO/IEC 10646-1:1993 are used only to support deprecated features (D.13). — end note]
3 Terms and definitions [intro.defs]

1 For the purposes of this document, the terms and definitions given in ISO/IEC 2382-1:1993, the terms, definitions, and symbols given in ISO 80000-2:2009, and the following apply.

2 ISO and IEC maintain terminological databases for use in standardization at the following addresses:

— ISO Online browsing platform: available at https://www.iso.org/obp

3 15.3 defines additional terms that are used only in Clause 15 through Clause 30 and Annex D.

4 Terms that are used only in a small portion of this document are defined where they are used and italicized where they are defined.

3.1 access [defns.access]
(execution-time action) read or modify the value of an object

3.2 argument [defns.argument]
(function call expression) expression in the comma-separated list bounded by the parentheses (7.6.1.2)

3.3 argument [defns.argument.macro]
(function-like macro) sequence of preprocessing tokens in the comma-separated list bounded by the parentheses (14.3)

3.4 argument [defns.argument.throw]
(throw expression) operand of throw (7.6.17)

3.5 argument [defns.argument.templ]
(template instantiation) constant-expression, type-id, or id-expression in the comma-separated list bounded by the angle brackets (12.3)

3.6 block [defns.block]
wait for some condition (other than for the implementation to execute the execution steps of the thread of execution) to be satisfied before continuing execution past the blocking operation

3.7 conditionally-supported [defns.cond.supp]
program construct that an implementation is not required to support

[Note 1 to entry: Each implementation documents all conditionally-supported constructs that it does not support. — end note]

3.8 diagnostic [defns.diagnostic]
message belonging to an implementation-defined subset of the implementation’s output messages

3.9 dynamic type [defns.dynamic.type]
(glvalue) type of the most derived object (6.6.2) to which the glvalue refers

[Example: If a pointer (9.2.3.1) p whose static type is “pointer to class B” is pointing to an object of class D, derived from B (10.6), the dynamic type of the expression *p is “D”. References (9.2.3.2) are treated similarly. — end example]
3.10 \[\text{defns.dynamic.type.prvalue}\]
\textbf{dynamic type}
\begin{itemize}
\item<prvalue> static type of the prvalue expression
\end{itemize}

3.11 \[\text{defns.ill.formed}\]
\textbf{ill-formed program}
program that is not well-formed (3.29)

3.12 \[\text{defns.impl.defined}\]
\textbf{implementation-defined behavior}
behavior, for a well-formed program construct and correct data, that depends on the implementation and that each implementation documents

3.13 \[\text{defns.impl.limits}\]
\textbf{implementation limits}
restrictions imposed upon programs by the implementation

3.14 \[\text{defns.locale.specific}\]
\textbf{locale-specific behavior}
behavior that depends on local conventions of nationality, culture, and language that each implementation documents

3.15 \[\text{defns.multibyte}\]
\textbf{multibyte character}
sequence of one or more bytes representing a member of the extended character set of either the source or the execution environment

\begin{itemize}
\item[Note 1 to entry:] The extended character set is a superset of the basic character set (5.3). — end note
\end{itemize}

3.16 \[\text{defns.parameter}\]
\textbf{parameter}
\begin{itemize}
\item<function or catch clause> object or reference declared as part of a function declaration or definition or in the catch clause of an exception handler that acquires a value on entry to the function or handler
\end{itemize}

3.17 \[\text{defns.parameter.macro}\]
\textbf{parameter}
\begin{itemize}
\item<function-like macro> identifier from the comma-separated list bounded by the parentheses immediately following the macro name
\end{itemize}

3.18 \[\text{defns.parametertempl}\]
\textbf{parameter}
\begin{itemize}
\item<template> member of a \textit{template-parameter-list}
\end{itemize}

3.19 \[\text{defns.signature}\]
\textbf{signature}
\begin{itemize}
\item<function> name, parameter type list (9.2.3.5), enclosing namespace (if any), and trailing \textit{requires-clause} (9.2) (if any)
\end{itemize}

\begin{itemize}
\item[Note 1 to entry:] Signatures are used as a basis for name mangling and linking. — end note
\end{itemize}

3.20 \[\text{defns.signaturetempl}\]
\textbf{signature}
\begin{itemize}
\item<function template> name, parameter type list (9.2.3.5), enclosing namespace (if any), return type, \textit{template-head}, and trailing \textit{requires-clause} (9.2) (if any)
\end{itemize}

3.21 \[\text{defns.signature.spec}\]
\textbf{signature}
\begin{itemize}
\item<function template specialization> signature of the template of which it is a specialization and its template arguments (whether explicitly specified or deduced)
\end{itemize}
3.22 signature
(class member function) name, parameter type list (9.2.3.5), class of which the function is a member, cv-qualifiers (if any), ref-qualifier (if any), and trailing requires-clause (9.2) (if any)

3.23 signature
(class member function template) name, parameter type list (9.2.3.5), class of which the function is a member, cv-qualifiers (if any), ref-qualifier (if any), return type (if any), template-head, and trailing requires-clause (9.2) (if any)

3.24 signature
(class member function template specialization) signature of the member function template of which it is a specialization and its template arguments (whether explicitly specified or deduced)

3.25 static type
type of an expression (6.7) resulting from analysis of the program without considering execution semantics

[Note 1 to entry: The static type of an expression depends only on the form of the program in which the expression appears, and does not change while the program is executing. — end note]

3.26 unblock
satisfy a condition that one or more blocked threads of execution are waiting for

3.27 undefined behavior
behavior for which this document imposes no requirements

[Note 1 to entry: Undefined behavior may be expected when this document omits any explicit definition of behavior or when a program uses an erroneous construct or erroneous data. Permissible undefined behavior ranges from ignoring the situation completely with unpredictable results, to behaving during translation or program execution in a documented manner characteristic of the environment (with or without the issuance of a diagnostic message), to terminating a translation or execution (with the issuance of a diagnostic message). Many erroneous program constructs do not engender undefined behavior; they are required to be diagnosed. Evaluation of a constant expression never exhibits behavior explicitly specified as undefined in Clause 4 through Clause 14 of this document (7.7). — end note]

3.28 unspecified behavior
behavior, for a well-formed program construct and correct data, that depends on the implementation

[Note 1 to entry: The implementation is not required to document which behavior occurs. The range of possible behaviors is usually delineated by this document. — end note]

3.29 well-formed program
C++ program constructed according to the syntax rules, diagnosable semantic rules, and the one-definition rule (6.2)
4 General principles

4.1 Implementation compliance

1 The set of diagnosable rules consists of all syntactic and semantic rules in this document except for those rules containing an explicit notation that “no diagnostic is required” or which are described as resulting in “undefined behavior”.

2 Although this document states only requirements on C++ implementations, those requirements are often easier to understand if they are phrased as requirements on programs, parts of programs, or execution of programs. Such requirements have the following meaning:

(2.1) If a program contains no violations of the rules in this document, a conforming implementation shall, within its resource limits, accept and correctly execute that program.

(2.2) If a program contains a violation of any diagnosable rule or an occurrence of a construct described in this document as “conditionally-supported” when the implementation does not support that construct, a conforming implementation shall issue at least one diagnostic message.

(2.3) If a program contains a violation of a rule for which no diagnostic is required, this document places no requirement on implementations with respect to that program.

[Note: During template argument deduction and substitution, certain constructs that in other contexts require a diagnostic are treated differently; see 12.9.2. — end note]

3 For classes and class templates, the library Clauses specify partial definitions. Private members (10.8) are not specified, but each implementation shall supply them to complete the definitions according to the description in the library Clauses.

4 For functions, function templates, objects, and values, the library Clauses specify declarations. Implementations shall supply definitions consistent with the descriptions in the library Clauses.

5 The names defined in the library have namespace scope (9.7). A C++ translation unit (5.2) obtains access to these names by including the appropriate standard library header (14.2).

6 The templates, classes, functions, and objects in the library have external linkage (6.5). The implementation provides definitions for standard library entities, as necessary, while combining translation units to form a complete C++ program (5.2).

7 Two kinds of implementations are defined: a hosted implementation and a freestanding implementation. For a hosted implementation, this document defines the set of available libraries. A freestanding implementation is one in which execution may take place without the benefit of an operating system, and has an implementation-defined set of libraries that includes certain language-support libraries (15.5.1.3).

8 A conforming implementation may have extensions (including additional library functions), provided they do not alter the behavior of any well-formed program. Implementations are required to diagnose programs that use such extensions that are ill-formed according to this document. Having done so, however, they can compile and execute such programs.

9 Each implementation shall include documentation that identifies all conditionally-supported constructs that it does not support and defines all locale-specific characteristics.3

4.1.1 Abstract machine

1 The semantic descriptions in this document define a parameterized nondeterministic abstract machine. This document places no requirement on the structure of conforming implementations. In particular, they need not copy or emulate the structure of the abstract machine. Rather, conforming implementations are required to emulate (only) the observable behavior of the abstract machine as explained below.4

---

2) “Correct execution” can include undefined behavior, depending on the data being processed; see Clause 3 and 6.8.1.

3) This documentation also defines implementation-defined behavior; see 6.8.1.

4) This provision is sometimes called the “as-if” rule, because an implementation is free to disregard any requirement of this document as long as the result is as if the requirement had been obeyed, as far as can be determined from the observable behavior of the program. For instance, an actual implementation need not evaluate part of an expression if it can deduce that its value is not used and that no side effects affecting the observable behavior of the program are produced.
Certain aspects and operations of the abstract machine are described in this document as implementation-defined (for example, sizeof(int)). These constitute the parameters of the abstract machine. Each implementation shall include documentation describing its characteristics and behavior in these respects. Such documentation shall define the instance of the abstract machine that corresponds to that implementation (referred to as the “corresponding instance” below).

Certain other aspects and operations of the abstract machine are described in this document as unspecified (for example, order of evaluation of arguments in a function call (7.6.1.2)). Where possible, this document defines a set of allowable behaviors. These define the nondeterministic aspects of the abstract machine. An instance of the abstract machine can thus have more than one possible execution for a given program and a given input.

Certain other operations are described in this document as undefined (for example, the effect of attempting to modify a const object). [Note: This document imposes no requirements on the behavior of programs that contain undefined behavior. — end note]

A conforming implementation executing a well-formed program shall produce the same observable behavior as one of the possible executions of the corresponding instance of the abstract machine with the same program and the same input. However, if any such execution contains an undefined operation, this document places no requirement on the implementation executing that program with that input (not even with regard to operations preceding the first undefined operation).

The least requirements on a conforming implementation are:

1. Accesses through volatile glvalues are evaluated strictly according to the rules of the abstract machine.
2. At program termination, all data written into files shall be identical to one of the possible results that execution of the program according to the abstract semantics would have produced.
3. The input and output dynamics of interactive devices shall take place in such a fashion that prompting output is actually delivered before a program waits for input. What constitutes an interactive device is implementation-defined.

These collectively are referred to as the observable behavior of the program. [Note: More stringent correspondences between abstract and actual semantics may be defined by each implementation. — end note]

Operators can be regrouped according to the usual mathematical rules only where the operators really are associative or commutative. For example, in the following fragment

```c
int a, b;
/* ... */
a = a + 32760 + b + 5;
```

the expression statement behaves exactly the same as

```c
a = (((a + 32760) + b) + 5);
```

due to the associativity and precedence of these operators. Thus, the result of the sum (a + 32760) is next added to b, and that result is then added to 5 which results in the value assigned to a. On a machine in which overflows produce an exception and in which the range of values representable by an int is [-32768, +32767], the implementation cannot rewrite this expression as

```c
a = ((a + b) + 32765);
```

since if the values for a and b were, respectively, -32754 and -15, the sum a + b would produce an exception while the original expression would not; nor can the expression be rewritten either as

```c
a = ((a + 32765) + b);
```

or

```c
a = (a + (b + 32765));
```

since the values for a and b might have been, respectively, 4 and -8 or -17 and 12. However on a machine in which overflows do not produce an exception and in which the results of overflows are reversible, the above expression statement can be rewritten by the implementation in any of the above ways because the same result will occur. — end note]
4.2 Structure of this document

Clause 5 through Clause 14 describe the C++ programming language. That description includes detailed syntactic specifications in a form described in 4.3. For convenience, Annex A repeats all such syntactic specifications.

Clause 16 through Clause 30 and Annex D (the library clauses) describe the C++ standard library. That description includes detailed descriptions of the entities and macros that constitute the library, in a form described in Clause 15.

Annex B recommends lower bounds on the capacity of conforming implementations.

Annex C summarizes the evolution of C++ since its first published description, and explains in detail the differences between C++ and C. Certain features of C++ exist solely for compatibility purposes; Annex D describes those features.

Throughout this document, each example is introduced by “[Example: ]” and terminated by “— end example]”. Each note is introduced by “[Note: ” and terminated by “— end note]”. Examples and notes may be nested.

4.3 Syntax notation

In the syntax notation used in this document, syntactic categories are indicated by italic type, and literal words and characters in constant width type. Alternatives are listed on separate lines except in a few cases where a long set of alternatives is marked by the phrase “one of”. If the text of an alternative is too long to fit on a line, the text is continued on subsequent lines indented from the first one. An optional terminal or non-terminal symbol is indicated by the subscript “opt”, so

{ expression_opt } 

indicates an optional expression enclosed in braces.

Names for syntactic categories have generally been chosen according to the following rules:

(2.1) — X-name is a use of an identifier in a context that determines its meaning (e.g., class-name, typedef-name).
(2.2) — X-id is an identifier with no context-dependent meaning (e.g., qualified-id).
(2.3) — X-seq is one or more X’s without intervening delimiters (e.g., declaration-seq is a sequence of declarations).
(2.4) — X-list is one or more X’s separated by intervening commas (e.g., identifier-list is a sequence of identifiers separated by commas).

5.1 Separate translation

The text of the program is kept in units called source files in this document. A source file together with all the headers (15.5.1.2) and source files included (14.2) via the preprocessing directive #include, less any source lines skipped by any of the conditional inclusion (14.1) preprocessing directives, is called a translation unit. [Note: A C++ program need not all be translated at the same time. —end note]

[Note: Previously translated translation units and instantiation units can be preserved individually or in libraries. The separate translation units of a program communicate (6.5) by (for example) calls to functions whose identifiers have external linkage, manipulation of objects whose identifiers have external linkage, or manipulation of data files. Translation units can be separately translated and then later linked to produce an executable program (6.5). —end note]

5.2 Phases of translation

The precedence among the syntax rules of translation is specified by the following phases.7

1. Physical source file characters are mapped, in an implementation-defined manner, to the basic source character set (introducing new-line characters for end-of-line indicators) if necessary. The set of physical source file characters accepted is implementation-defined. Any source file character not in the basic source character set (5.3) is replaced by the universal-character-name that designates that character. An implementation may use any internal encoding, so long as an actual extended character encountered in the source file, and the same extended character expressed in the source file as a universal-character-name (e.g., using the \uXXXX notation), are handled equivalently except where this replacement is reverted (5.4) in a raw string literal.

2. Each instance of a backslash character (\) immediately followed by a new-line character is deleted, splicing physical source lines to form logical source lines. Only the last backslash on any physical source line shall be eligible for being part of such a splice. Except for splices reverted in a raw string literal, if a splice results in a character sequence that matches the syntax of a universal-character-name, the behavior is undefined. A source file that is not empty and that does not end in a new-line character, or that ends in a new-line character immediately preceded by a backslash character before any such splicing takes place, shall be processed as if an additional new-line character were appended to the file.

3. The source file is decomposed into preprocessing tokens (5.4) and sequences of white-space characters (including comments). A source file shall not end in a partial preprocessing token or in a partial comment.8 Each comment is replaced by one space character. New-line characters are retained. Whether each nonempty sequence of white-space characters other than new-line is retained or replaced by one space character is unspecified. The process of dividing a source file’s characters into preprocessing tokens is context-dependent. [Example: See the handling of < within a #include preprocessing directive. —end example]

4. Preprocessing directives are executed, macro invocations are expanded, and _Pragma unary operator expressions are executed. If a character sequence that matches the syntax of a universal-character-name is produced by token concatenation (14.3.3), the behavior is undefined. A #include preprocessing directive causes the named header or source file to be processed from phase 1 through phase 4, recursively. All preprocessing directives are then deleted.

5. Each source character set member in a character literal or a string literal, as well as each escape sequence and universal-character-name in a character literal or a non-raw string literal, is converted to the corresponding member of the execution character set (5.13.3, 5.13.5); if there is no corresponding member, it is converted to an implementation-defined member other than the null (wide) character.9

7) Implementations must behave as if these separate phases occur, although in practice different phases might be folded together.

8) A partial preprocessing token would arise from a source file ending in the first portion of a multi-character token that requires a terminating sequence of characters, such as a header-name that is missing the closing “<” or “>”. A partial comment would arise from a source file ending with an unclosed /* comment.

9) An implementation need not convert all non-corresponding source characters to the same execution character.
6. Adjacent string literal tokens are concatenated.
7. White-space characters separating tokens are no longer significant. Each preprocessing token is converted into a token (5.6). The resulting tokens are syntactically and semantically analyzed and translated as a translation unit. [Note: The process of analyzing and translating the tokens may occasionally result in one token being replaced by a sequence of other tokens (12.2). — end note] [Note: Source files, translation units and translated translation units need not necessarily be stored as files, nor need there be any one-to-one correspondence between these entities and any external representation. The description is conceptual only, and does not specify any particular implementation. — end note]
8. Translated translation units and instantiation units are combined as follows: [Note: Some or all of these may be supplied from a library. — end note] Each translated translation unit is examined to produce a list of required instantiations. [Note: This may include instantiations which have been explicitly requested (12.8.2). — end note] The definitions of the required templates are located. It is implementation-defined whether the source of the translation units containing these definitions is required to be available. [Note: An implementation could encode sufficient information into the translated translation unit so as to ensure the source is not required here. — end note] All the required instantiations are performed to produce instantiation units. [Note: These are similar to translated translation units, but contain no references to uninstantiated templates and no template definitions. — end note] The program is ill-formed if any instantiation fails.
9. All external entity references are resolved. Library components are linked to satisfy external references to entities not defined in the current translation. All such translator output is collected into a program image which contains information needed for execution in its execution environment.

5.3 Character sets

1 The basic source character set consists of 96 characters: the space character, the control characters representing horizontal tab, vertical tab, form feed, and new-line, plus the following 91 graphical characters:

\[ a b c d e f g h i j k l m n o p q r s t u v w x y z \]
\[ A B C D E F G H I J K L M N O P Q R S T U V W X Y Z \]
\[ 0 1 2 3 4 5 6 7 8 9 \]
\[ _ { } [ ] # ( ) < > \% : ; . ? * + - / ^ & | \~ \]

2 The universal-character-name construct provides a way to name other characters.

\[ \text{hex-quad:} \]

\[ \text{universal-character-name:} \]

\[ \text{hex-quad} \]

\[ \text{universal-character-name} \]

\[ \text{hex-quad} \]

\[ \text{universal-character-name} \]

The character designated by the universal-character-name \texttt{NNNNNNNN} is that character whose character short name in ISO/IEC 10646 is \texttt{NNNNNNNN}; the character designated by the universal-character-name \texttt{UNNNNNNN} is that character whose character short name in ISO/IEC 10646 is \texttt{0000NNNN}. If the hexadecimal value for a universal-character-name corresponds to a surrogate code point (in the range 0x0D800–0xDFFF, inclusive), the program is ill-formed. Additionally, if the hexadecimal value for a universal-character-name outside the c-char-sequence, s-char-sequence, or r-char-sequence of a character or string literal corresponds to a control character (in either of the ranges 0x00–0x1F or 0x7F–0x9F, both inclusive) or to a character in the basic source character set, the program is ill-formed.\[11\]

3 The basic execution character set and the basic execution wide-character set shall each contain all the members of the basic source character set, plus control characters representing alert, backspace, and carriage return, plus a null character (respectively, null wide character), whose value is 0. For each basic execution character set, the values of the members shall be non-negative and distinct from one another. In both the source and execution basic character sets, the value of each character after 0 in the above list of decimal digits shall be one greater than the value of the previous. The execution character set and the execution wide-character set are implementation-defined superset of the basic execution character set and the basic

10) The glyphs for the members of the basic source character set are intended to identify characters from the subset of ISO/IEC 10646 which corresponds to the ASCII character set. However, because the mapping from source file characters to the source character set (described in translation phase 1) is specified as implementation-defined, an implementation is required to document how the basic source characters are represented in source files.
11) A sequence of characters resembling a universal-character-name in an r-char-sequence (5.13.5) does not form a universal-character-name.
execution wide-character set, respectively. The values of the members of the execution character sets and the sets of additional members are locale-specific.

5.4 Preprocessing tokens

preprocessing-token:
  header-name
  identifier
  pp-number
  character-literal
  user-defined-character-literal
  string-literal
  user-defined-string-literal
  preprocessing-op-or-punc
  each non-white-space character that cannot be one of the above

1 Each preprocessing token that is converted to a token (5.6) shall have the lexical form of a keyword, an identifier, a literal, an operator, or a punctuator.

2 A preprocessing token is the minimal lexical element of the language in translation phases 3 through 6. The categories of preprocessing tokens are: header names, identifiers, preprocessing numbers, character literals (including user-defined character literals), string literals (including user-defined string literals), preprocessing operators and punctuators, and single non-white-space characters that do not lexically match the other preprocessing token categories. If a ’ ’ or a ” character matches the last category, the behavior is undefined. Preprocessing tokens can be separated by white space; this consists of comments (5.7), or white-space characters (space, horizontal tab, new-line, vertical tab, and form-feed), or both. As described in Clause 14, in certain circumstances during translation phase 4, white space (or the absence thereof) serves as more than preprocessing token separation. White space can appear within a preprocessing token only as part of a header name or between the quotation characters in a character literal or string literal.

3 If the input stream has been parsed into preprocessing tokens up to a given character:

(3.1) — If the next character begins a sequence of characters that could be the prefix and initial double quote of a raw string literal, such as R", the next preprocessing token shall be a raw string literal. Between the initial and final double quote characters of the raw string, any transformations performed in phases 1 and 2 (universal-character-names and line splicing) are reverted; this reversion shall apply before any d-char, r-char, or delimiting parenthesis is identified. The raw string literal is defined as the shortest sequence of characters that matches the raw-string pattern

encoding-prefix opt R raw-string

(3.2) — Otherwise, if the next three characters are <: and the subsequent character is neither : nor >, the < is treated as a preprocessing token by itself and not as the first character of the alternative token :.

(3.3) — Otherwise, the next preprocessing token is the longest sequence of characters that could constitute a preprocessing token, even if that would cause further lexical analysis to fail, except that a header-name (5.8) is only formed within a #include directive (14.2).

[Example:

```c
#define R "x"
const char* s = R"y"; // ill-formed raw string, not "x" "y"
```

— end example]

4 [Example: The program fragment 0xe+foo is parsed as a preprocessing number token (one that is not a valid floating or integer literal token), even though a parse as three preprocessing tokens 0xe, +, and foo might produce a valid expression (for example, if foo were a macro defined as 1). Similarly, the program fragment 1E1 is parsed as a preprocessing number (one that is a valid floating literal token), whether or not E is a macro name. — end example]

5 [Example: The program fragment x++++y is parsed as x ++ ++ y, which, if x and y have integral types, violates a constraint on increment operators, even though the parse x ++ + ++ y might yield a correct expression. — end example]

§ 5.4
5.5 Alternative tokens

Alternative token representations are provided for some operators and punctuators.\(^1\)

In all respects of the language, each alternative token behaves the same, respectively, as its primary token, except for its spelling.\(^2\) The set of alternative tokens is defined in Table 1.

<table>

</tbody>
</table>

5.6 Tokens

token:
  identifier
  keyword
  literal
  operator
  punctuator

There are five kinds of tokens: identifiers, keywords, literals,\(^3\) operators, and other separators. Blanks, horizontal and vertical tabs, newlines, formfeeds, and comments (collectively, “white space”), as described below, are ignored except as they serve to separate tokens. \([\text{Note: Some white space is required to separate otherwise adjacent identifiers, keywords, numeric literals, and alternative tokens containing alphabetic characters. — end note]}\)

5.7 Comments

The characters /* start a comment, which terminates with the characters */. These comments do not nest. The characters // start a comment, which terminates immediately before the next new-line character. If there is a form-feed or a vertical-tab character in such a comment, only white-space characters shall appear between it and the new-line that terminates the comment; no diagnostic is required. \([\text{Note: The comment characters //, /*, and */ have no special meaning within a // comment and are treated just like other characters. Similarly, the comment characters // and /* have no special meaning within a /* comment. — end note]}\)

5.8 Header names

header-name:
  < h-char-sequence >
  " q-char-sequence "
h-char-sequence:
  h-char
  h-char-sequence h-char
h-char:
  any member of the source character set except new-line and >
q-char-sequence:
  q-char
  q-char-sequence q-char
q-char:
  any member of the source character set except new-line and "

\(^1\) These include “digraphs” and additional reserved words. The term “digraph” (token consisting of two characters) is not perfectly descriptive, since one of the alternative preprocessing-tokens is %:%: and of course several primary tokens contain two characters. Nonetheless, those alternative tokens that aren’t lexical keywords are colloquially known as “digraphs”.

\(^2\) Thus the “stringized” values (14.3.2) of [ and \(<\) will be different, maintaining the source spelling, but the tokens can otherwise be freely interchanged.

\(^3\) Literals include strings and character and numeric literals.

\(\S\) 5.8
1 [Note: Header name preprocessing tokens only appear within a `#include` preprocessing directive (see 5.4). — end note] The sequences in both forms of `header-names` are mapped in an implementation-defined manner to headers or to external source file names as specified in 14.2.

2 The appearance of either of the characters `*` or `\` or of either of the character sequences `/\` or `//` in a `q-char-sequence` or an `h-char-sequence` is conditionally-supported with implementation-defined semantics, as is the appearance of the character `*` in an `h-char-sequence`.

5.9 Preprocessing numbers

`pp-number`:

```
  digit
  . digit
  `pp-number` digit
  `pp-number` identifier-nondigit
  `pp-number` * digit
  `pp-number` e sign
  `pp-number` E sign
  `pp-number` p sign
  `pp-number` P sign
  `pp-number` .
```

1 Preprocessing number tokens lexically include all integer literal tokens (5.13.2) and all floating literal tokens (5.13.4).

2 A preprocessing number does not have a type or a value; it acquires both after a successful conversion to an integer literal token or a floating literal token.

5.10 Identifiers

`identifier`:

```
  identifier-nondigit
  identifier identifier-nondigit
  identifier digit
```

`identifier-nondigit`:

```
  nondigit
  universal-character-name
```

`nondigit`: one of

```
  a b c d e f g h i j k l m
  n o p q r s t u v w x y z
  A B C D E F G H I J K L M
  N O P Q R S T U V W X Y Z
```

`digit`: one of

```
  0 1 2 3 4 5 6 7 8 9
```

1 An identifier is an arbitrarily long sequence of letters and digits. Each `universal-character-name` in an identifier shall designate a character whose encoding in ISO/IEC 10646 falls into one of the ranges specified in Table 2. The initial element shall not be a `universal-character-name` designating a character whose encoding falls into one of the ranges specified in Table 3. Upper- and lower-case letters are different. All characters are significant.

2 The identifiers in Table 4 have a special meaning when appearing in a certain context. When referred to in the grammar, these identifiers are used explicitly rather than using the `identifier` grammar production. Unless otherwise specified, any ambiguity as to whether a given `identifier` has a special meaning is resolved to interpret the token as a regular `identifier`.

3 In addition, some identifiers are reserved for use by C++ implementations and shall not be used otherwise; no diagnostic is required.

15) Thus, a sequence of characters that resembles an escape sequence might result in an error, be interpreted as the character corresponding to the escape sequence, or have a completely different meaning, depending on the implementation.

16) On systems in which linkers cannot accept extended characters, an encoding of the `universal-character-name` may be used in forming valid external identifiers. For example, some otherwise unused character or sequence of characters may be used to encode the `\u` in a `universal-character-name`. Extended characters may produce a long external identifier, but C++ does not place a translation limit on significant characters for external identifiers. In C++, upper- and lower-case letters are considered different for all identifiers, including external identifiers.

5.12 Operators and punctuators

The lexical representation of C++ programs includes a number of preprocessing tokens which are used in the syntax of the preprocessor or are converted into tokens for operators and punctuators:

```
prefix-op-or-punc: one of
  { } [ ] # ## ( ) <: : > % > %: %: %: %: ; : ...+ - * / % ^ & |

new delete ? :: :> :% :% ; : ...+-* -> ->* ~ ! + - * / % ^ & |=
== =!= < > <= >= <=> && ||
<< >> <<= >>= ++ -- ,
and or xor not bitand bitor compl
and_eq or_eq xor_eq not_eq
```

Each `prefix-op-or-punc` is converted to a single token in translation phase 7 (5.2).

5.13 Literals

5.13.1 Kinds of literals

There are several kinds of literals.

```
literal:
  integer-literal
  character-literal
  floating-literal
  string-literal
  boolean-literal
  pointer-literal
  user-defined-literal
```

5.13.2 Integer literals

```
integer-literal:
  binary-literal integer-suffix
  octal-literal integer-suffix
  decimal-literal integer-suffix
  hexadecimal-literal integer-suffix

binary-literal:
  0b binary-digit
  0B binary-digit
  binary-literal 'opt binary-digit

octal-literal:
  0 octal-literal 'opt octal-digit

decimal-literal:
  nonzero-digit
  decimal-literal 'opt digit

hexadecimal-literal:
  hexadecimal-prefix hexadecimal-digit-sequence

binary-digit: one of
  0 1

octal-digit: one of
  0 1 2 3 4 5 6 7

nonzero-digit: one of
  1 2 3 4 5 6 7 8 9

hexadecimal-prefix: one of
  0x 0X

hexadecimal-digit-sequence:
  hexadecimal-digit
  hexadecimal-digit-sequence 'opt hexadecimal-digit
```

17) The term “literal” generally designates, in this document, those tokens that are called “constants” in ISO C.
hexadecimal-digit: one of
0 1 2 3 4 5 6 7 8 9
a b c d e f
A B C D E F

integer-suffix:
unsigned-suffix long-suffixopt
unsigned-suffix long-long-suffixopt
long-suffix unsigned-suffixopt
long-long-suffix unsigned-suffixopt

unsigned-suffix: one of
u U

long-suffix: one of
l L

long-long-suffix: one of
ll LL

An integer literal is a sequence of digits that has no period or exponent part, with optional separating single quotes that are ignored when determining its value. An integer literal may have a prefix that specifies its base and a suffix that specifies its type. The lexically first digit of the sequence of digits is the most significant. A binary integer literal (base two) begins with 0b or 0B and consists of a sequence of binary digits. An octal integer literal (base eight) begins with the digit 0 and consists of a sequence of octal digits. A decimal integer literal (base ten) begins with a digit other than 0 and consists of a sequence of decimal digits. A hexadecimal integer literal (base sixteen) begins with 0x or 0X and consists of a sequence of hexadecimal digits, which include the decimal digits and the letters a through f and A through F with decimal values ten through fifteen. [Example: The number twelve can be written 12, 014, 0XC, or 0b1100. The integer literals 1048576, 1’048’576, 0X100000, 0x10’0000, and 0’004’000’000 all have the same value. — end example] The type of an integer literal is the first of the corresponding list in Table 7 in which its value can be represented.

<table>
<thead>
<tr>

<td></td>
</tr>
</tbody>
</table>

If an integer literal cannot be represented by any type in its list and an extended integer type (6.7.1) can represent its value, it may have that extended integer type. If all of the types in the list for the integer literal are signed, the extended integer type shall be signed. If all of the types in the list for the integer literal are unsigned, the extended integer type shall be unsigned. If the list contains both signed and unsigned types,
the extended integer type may be signed or unsigned. A program is ill-formed if one of its translation units contains an integer literal that cannot be represented by any of the allowed types.

5.13.3 Character literals

A character literal is one or more characters enclosed in single quotes, as in 'x', optionally preceded by u8, u, U, or L, as in u8'w', u'x', U'y', or L'z', respectively.

2 A character literal that does not begin with u8, u, U, or L is an ordinary character literal. An ordinary character literal that contains a single c-char representable in the execution character set has type char, with value equal to the numerical value of the encoding of the c-char in the execution character set. An ordinary character literal that contains more than one c-char is a multicharacter literal. A multicharacter literal, or an ordinary character literal containing a single c-char not representable in the execution character set, is conditionally-supported, has type int, and has an implementation-defined value.

3 A character literal that begins with u8, such as u8'w', is a character literal of type char, known as a UTF-8 character literal. The value of a UTF-8 character literal is equal to its ISO/IEC 10646 code point value, provided that the code point value is representable with a single UTF-8 code unit (that is, provided it is in the C0 Controls and Basic Latin Unicode block). If the value is not representable with a single UTF-8 code unit, the program is ill-formed. A UTF-8 character literal containing multiple c-chars is ill-formed.

4 A character literal that begins with the letter u, such as u'x', is a character literal of type char16_t. The value of a char16_t character literal containing a single c-char is equal to its ISO/IEC 10646 code point value, provided that the code point value is representable with a single 16-bit code unit (that is, provided it is in the basic multi-lingual plane). If the value is not representable with a single 16-bit code unit, the program is ill-formed. A char16_t character literal containing multiple c-chars is ill-formed.

5 A character literal that begins with the letter U, such as U'y', is a character literal of type char32_t. The value of a char32_t character literal containing a single c-char is equal to its ISO/IEC 10646 code point value. A char32_t character literal containing multiple c-chars is ill-formed.

6 A character literal that begins with the letter L, such as L'z', is a wide-character literal. A wide-character literal has type wchar_t. The value of a wide-character literal containing a single c-char has value equal to the numerical value of the encoding of the c-char in the execution wide-character set, unless the c-char has no representation in the execution wide-character set, in which case the value is implementation-defined.

1 A character literal is one or more characters enclosed in single quotes, as in 'x', optionally preceded by u8, u, U, or L, as in u8'w', u'x', U'y', or L'z', respectively.

2 A character literal that does not begin with u8, u, U, or L is an ordinary character literal. An ordinary character literal that contains a single c-char representable in the execution character set has type char, with value equal to the numerical value of the encoding of the c-char in the execution character set. An ordinary character literal that contains more than one c-char is a multicharacter literal. A multicharacter literal, or an ordinary character literal containing a single c-char not representable in the execution character set, is conditionally-supported, has type int, and has an implementation-defined value.

3 A character literal that begins with u8, such as u8'w', is a character literal of type char, known as a UTF-8 character literal. The value of a UTF-8 character literal is equal to its ISO/IEC 10646 code point value, provided that the code point value is representable with a single UTF-8 code unit (that is, provided it is in the C0 Controls and Basic Latin Unicode block). If the value is not representable with a single UTF-8 code unit, the program is ill-formed. A UTF-8 character literal containing multiple c-chars is ill-formed.

4 A character literal that begins with the letter u, such as u'x', is a character literal of type char16_t. The value of a char16_t character literal containing a single c-char is equal to its ISO/IEC 10646 code point value, provided that the code point value is representable with a single 16-bit code unit (that is, provided it is in the basic multi-lingual plane). If the value is not representable with a single 16-bit code unit, the program is ill-formed. A char16_t character literal containing multiple c-chars is ill-formed.

5 A character literal that begins with the letter U, such as U'y', is a character literal of type char32_t. The value of a char32_t character literal containing a single c-char is equal to its ISO/IEC 10646 code point value. A char32_t character literal containing multiple c-chars is ill-formed.

6 A character literal that begins with the letter L, such as L'z', is a wide-character literal. A wide-character literal has type wchar_t. The value of a wide-character literal containing a single c-char has value equal to the numerical value of the encoding of the c-char in the execution wide-character set, unless the c-char has no representation in the execution wide-character set, in which case the value is implementation-defined.

19) They are intended for character sets where a character does not fit into a single byte.
© ISO/IEC

N4762

[Note: The type wchar_t is able to represent all members of the execution wide-character set (see 6.7.1). — end note] The value of a wide-character literal containing multiple c-chars is implementation-defined.

7 Certain non-graphic characters, the single quote ’, the double quote “, the question mark ?, and the backslash \, can be represented according to Table 8. The double quote ” and the question mark ?, can be represented as themselves or by the escape sequences \n and \r respectively, but the single quote ’ and the backslash \ shall be represented by the escape sequences \’ and \ respectively. Escape sequences in which the character following the backslash is not listed is Table 8 are conditionally-supported, with implementation-defined semantics. An escape sequence specifies a single character.

Table 8 — Escape sequences

<table>
<thead>
<tr>
<th>Escape</th>
<th>Representation</th>
</tr>
</thead>
<tbody>
<tr>
<td>new-line NL(LF)</td>
<td>\n</td>
</tr>
<tr>
<td>horizontal tab HT</td>
<td>\t</td>
</tr>
<tr>
<td>vertical tab VT</td>
<td>\v</td>
</tr>
<tr>
<td>backspace BS</td>
<td>\b</td>
</tr>
<tr>
<td>carriage return CR</td>
<td>\r</td>
</tr>
<tr>
<td>form feed FF</td>
<td>\f</td>
</tr>
<tr>
<td>alert BEL</td>
<td>\a</td>
</tr>
<tr>
<td>backslash \</td>
<td>\</td>
</tr>
<tr>
<td>question mark ?</td>
<td>?</td>
</tr>
<tr>
<td>single quote ’</td>
<td>’</td>
</tr>
<tr>
<td>double quote ”</td>
<td>”</td>
</tr>
<tr>
<td>octal number ooo</td>
<td>\ooo</td>
</tr>
<tr>
<td>hex number hhh</td>
<td>\xhh</td>
</tr>
</tbody>
</table>

8 The escape \ooo consists of the backslash followed by one, two, or three octal digits that are taken to specify the value of the desired character. The escape \xhhh consists of the backslash followed by x followed by one or more hexadecimal digits that are taken to specify the value of the desired character. There is no limit to the number of digits in a hexadecimal sequence. A sequence of octal or hexadecimal digits is terminated by the first character that is not an octal digit or a hexadecimal digit, respectively. The value of a character literal is implementation-defined if it falls outside of the implementation-defined range defined for char (for character literals with no prefix) or wchar_t (for character literals prefixed by L). [Note: If the value of a character literal prefixed by u, u8, or U is outside the range defined for its type, the program is ill-formed. — end note]

9 A universal-character-name is translated to the encoding, in the appropriate execution character set, of the character named. If there is no such encoding, the universal-character-name is translated to an implementation-defined encoding. [Note: In translation phase 1, a universal-character-name is introduced whenever an actual extended character is encountered in the source text. Therefore, all extended characters are described in terms of universal-character-names. However, the actual compiler implementation may use its own native character set, so long as the same results are obtained. — end note]

5.13.4 Floating literals

floating-literal:
  decimal-floating-literal
  hexadecimal-floating-literal

decimal-floating-literal:
  fractional-constant exponent-partopt floating-suffixopt
  digit-sequence exponent-part floating-suffixopt

hexadecimal-floating-literal:
  hexadecimal-prefix hexadecimal-fractional-constant binary-exponent-part floating-suffixopt
  hexadecimal-prefix hexadecimal-digit-sequence binary-exponent-part floating-suffixopt

fractional-constant:
  digit-sequenceopt . digit-sequence
  digit-sequence
hexadecimal-fractional-constant:
  hexadecimal-digit-sequence opt . hexadecimal-digit-sequence
exponent-part:
  e sign opt digit-sequence
  E sign opt digit-sequence
binary-exponent-part:
  p sign opt digit-sequence
  P sign opt digit-sequence
sign: one of
  + -
digit-sequence:
  digit
digit-sequence ' opt digit
floating-suffix: one of
  f F L

A floating literal consists of an optional prefix specifying a base, an integer part, a radix point, a fraction part, an e, E, p or P, an optionally signed integer exponent, and an optional type suffix. The integer and fraction parts both consist of a sequence of decimal (base ten) digits if there is no prefix, or hexadecimal (base sixteen) digits if the prefix is 0x or 0X. The floating literal is a decimal floating literal in the former case and a hexadecimal floating literal in the latter case. Optional separating single quotes in a digit-sequence or hexadecimal-digit-sequence are ignored when determining its value. [Example: The floating literals 1.602'176'565e-19 and 1.602176565e-19 have the same value. —end example] Either the integer part or the fraction part (not both) can be omitted. Either the radix point or the letter e or E and the exponent (not both) can be omitted from a decimal floating literal. The radix point (but not the exponent) can be omitted from a hexadecimal floating literal. The integer part, the optional radix point, and the optional fraction part, form the significand of the floating literal. In a decimal floating literal, the exponent, if present, indicates the power of 10 by which the significand is to be scaled. In a hexadecimal floating literal, the exponent indicates the power of 2 by which the significand is to be scaled. [Example: The floating literals 49.625 and 0xC.68p+2 have the same value. —end example] If the scaled value is in the range of representable values for its type, the result is the scaled value if representable, else the larger or smaller representable value nearest the scaled value, chosen in an implementation-defined manner. The type of a floating literal is double unless explicitly specified by a suffix. The suffixes f and F specify float, the suffixes l and L specify long double. If the scaled value is not in the range of representable values for its type, the program is ill-formed.

5.13.5 String literals

string-literal:
  encoding-prefix opt " s-char-sequence opt "
  encoding-prefix opt R raw-string
s-char-sequence:
  s-char
  s-char-sequence s-char
s-char:
  any member of the source character set except the double-quote ",", backslash \, or new-line character
  escape-sequence
  universal-character-name
raw-string:
  " d-char-sequence opt ( r-char-sequence opt ) d-char-sequence opt "
r-char-sequence:
  r-char
  r-char-sequence r-char
r-char:
  any member of the source character set, except a right parenthesis ) followed by the initial d-char-sequence (which may be empty) followed by a double quote ".
d-char-sequence:
  d-char
  d-char-sequence d-char
A string-literal is a sequence of characters (as defined in 5.13.3) surrounded by double quotes, optionally prefixed by R, u8, uR, u, UR, L, or LR, as in "...", R"(...)", u8"...", u8R"(...)"**, u"...", ur"(...)"**, U"...", UR"zzz(...)"zzz", L"...", or LR"(...)", respectively.

A string-literal that has an R in the prefix is a raw string literal. The d-char-sequence serves as a delimiter. The terminating d-char-sequence of a raw-string is the same sequence of characters as the initial d-char-sequence. A d-char-sequence shall consist of at most 16 characters.

A string-literal that begins with u8, such as u8"asdf", is a UTF-8 string literal. Ordinary string literals and UTF-8 string literals are also referred to as narrow string literals. A narrow string literal has type “array of n const char”, where n is the size of the string as defined below, and has static storage duration (6.6.4).

For a UTF-8 string literal, each successive element of the object representation (6.7) has the value of the corresponding code unit of the UTF-8 encoding of the string.

A string-literal that begins with u, such as u"asdf", is a char16_t string literal. A char16_t string literal has type “array of n const char16_t”, where n is the size of the string as defined below; it is initialized with the given characters. A single c-char may produce more than one char16_t character in the form of surrogate pairs.

A string-literal that begins with U, such as U"asdf", is a char32_t string literal. A char32_t string literal has type “array of n const char32_t”, where n is the size of the string as defined below; it is initialized with the given characters.

A string-literal that begins with L, such as L"asdf", is a wide string literal. A wide string literal has type “array of n const wchar_t”, where n is the size of the string as defined below; it is initialized with the given characters.

In translation phase 6 (5.2), adjacent string-literals are concatenated. If both string-literals have the same encoding-prefix, the resulting concatenated string literal has that encoding-prefix. If one string-literal has no encoding-prefix, it is treated as a string-literal of the same encoding-prefix as the other operand. If a UTF-8 string literal token is adjacent to a wide string literal token, the program is ill-formed. Any other concatenations are conditionally-supported with implementation-defined behavior. [Note: This concatenation is an interpretation, not a conversion. Because the interpretation happens in translation phase 6 (after each character from a string literal has been translated into a value from the appropriate character set), a
string-literal’s initial rawness has no effect on the interpretation or well-formedness of the concatenation. —end note] Table 9 has some examples of valid concatenations.

Table 9 — String literal concatenations

<table>
<thead>
<tr>
<th>Source</th>
<th>Means</th>
</tr>
</thead>
<tbody>
<tr>
<td>u&quot;a&quot;</td>
<td>u&quot;b&quot;</td>
</tr>
<tr>
<td>U&quot;a&quot;</td>
<td>U&quot;b&quot;</td>
</tr>
<tr>
<td>L&quot;a&quot;</td>
<td>L&quot;b&quot;</td>
</tr>
<tr>
<td>&quot;a&quot;</td>
<td>&quot;b&quot;</td>
</tr>
<tr>
<td>a</td>
<td>b</td>
</tr>
</tbody>
</table>

Characters in concatenated strings are kept distinct.

[Example:
 "\xA" "B"
contains the two characters ' \xA' and 'B' after concatenation (and not the single hexadecimal character ' \xAB'). —end example]

After any necessary concatenation, in translation phase 7 (5.2), '\0' is appended to every string literal so that programs that scan a string can find its end.

Escape sequences and universal-character-names in non-raw string literals have the same meaning as in character literals (5.13.3), except that the single quote ' is representable either by itself or by the escape sequence \', and the double quote " shall be preceded by a \, and except that a universal-character-name in a char16_t string literal may yield a surrogate pair. In a narrow string literal, a universal-character-name may map to more than one char element due to multibyte encoding. The size of a char32_t or wide string literal is the total number of escape sequences, universal-character-names, and other characters, plus one for the terminating U'\0' or L'\0'. The size of a char16_t string literal is the total number of escape sequences, universal-character-names, and other characters, plus one for each character requiring a surrogate pair, plus one for the terminating u'\0'. [Note: The size of a char16_t string literal is the number of code units, not the number of characters. —end note] Within char32_t and char16_t string literals, any universal-character-names shall be within the range 0x00 to 0x10FFFF. The size of a narrow string literal is the total number of escape sequences and other characters, plus at least one for the multibyte encoding of each universal-character-name, plus one for the terminating '\0'.

Evaluating a string-literal results in a string literal object with static storage duration, initialized from the given characters as specified above. Whether all string literals are distinct (that is, are stored in nonoverlapping objects) and whether successive evaluations of a string-literal yield the same or a different object is unspecified. [Note: The effect of attempting to modify a string literal is undefined. —end note]

5.13.6 Boolean literals

boolean-literal:
   false
   true

The Boolean literals are the keywords false and true. Such literals are prvalues and have type bool.

5.13.7 Pointer literals

pointer-literal:
   nullptr

The pointer literal is the keyword nullptr. It is a prvalue of type std::nullptr_t. [Note: std::nullptr_t is a distinct type that is neither a pointer type nor a pointer-to-member type; rather, a prvalue of this type is a null pointer constant and can be converted to a null pointer value or null member pointer value. See 7.3.11 and 7.3.12. —end note]

5.13.8 User-defined literals

user-defined-literal:
   user-defined-integer-literal
   user-defined-floating-literal
   user-defined-string-literal
   user-defined-character-literal

§ 5.13.8
user-defined-integer-literal:
  decimal-literal ud-suffix
  octal-literal ud-suffix
  hexadecimal-literal ud-suffix
  binary-literal ud-suffix

user-defined-floating-literal:
  fractional-constant exponent-part opt ud-suffix
  digit-sequence exponent-part ud-suffix
  hexadecimal-prefix hexadecimal-fractional-constant binary-exponent-part ud-suffix
  hexadecimal-prefix hexadecimal-digit-sequence binary-exponent-part ud-suffix

user-defined-string-literal:
  string-literal ud-suffix

user-defined-character-literal:
  character-literal ud-suffix

ud-suffix:
  identifier

1 If a token matches both user-defined-literal and another literal kind, it is treated as the latter. [Example: 123_km is a user-defined-literal, but 12LL is an integer-literal. —end example] The syntactic non-terminal preceding the ud-suffix in a user-defined-literal is taken to be the longest sequence of characters that could match that non-terminal.

2 A user-defined-literal is treated as a call to a literal operator or literal operator template (11.5.8). To determine the form of this call for a given user-defined-literal L with ud-suffix X, the literal-operator-id whose literal suffix identifier is X is looked up in the context of L using the rules for unqualified name lookup (6.4.1). Let S be the set of declarations found by this lookup. S shall not be empty.

3 If L is a user-defined-integer-literal, let n be the literal without its ud-suffix. If S contains a literal operator with parameter type unsigned long long, the literal L is treated as a call of the form
   \( \text{operator} \ "X(\text{nULL}) \)
   Otherwise, S shall contain a raw literal operator or a numeric literal operator template (11.5.8) but not both. If S contains a raw literal operator, the literal L is treated as a call of the form
   \( \text{operator} \ "X("n") \)
   Otherwise (S contains a numeric literal operator template), L is treated as a call of the form
   \( \text{operator} \ "X<"c_1","c_2","\ldots","c_k">() \)
   where n is the source character sequence \(c_1c_2\ldots c_k\). [Note: The sequence \(c_1c_2\ldots c_k\) can only contain characters from the basic source character set. —end note]

4 If L is a user-defined-floating-literal, let f be the literal without its ud-suffix. If S contains a literal operator with parameter type long double, the literal L is treated as a call of the form
   \( \text{operator} \ "X(fL) \)
   Otherwise, S shall contain a raw literal operator or a numeric literal operator template (11.5.8) but not both. If S contains a raw literal operator, the literal L is treated as a call of the form
   \( \text{operator} \ "X("f") \)
   Otherwise (S contains a numeric literal operator template), L is treated as a call of the form
   \( \text{operator} \ "X<"c_1","c_2","\ldots","c_k">() \)
   where f is the source character sequence \(c_1c_2\ldots c_k\). [Note: The sequence \(c_1c_2\ldots c_k\) can only contain characters from the basic source character set. —end note]

5 If L is a user-defined-string-literal, let str be the literal without its ud-suffix and let len be the number of code units in str (i.e., its length excluding the terminating null character). If S contains a literal operator template with a non-type template parameter for which str is a well-formed template-argument, the literal L is treated as a call of the form
   \( \text{operator} \ "X<str>() \)
   Otherwise, the literal L is treated as a call of the form
   \( \text{operator} \ "X(str, len) \)
If \( L \) is a user-defined-character-literal, let \( ch \) be the literal without its ud-suffix. \( S \) shall contain a literal operator (11.5.8) whose only parameter has the type of \( ch \) and the literal \( L \) is treated as a call of the form
\[
\text{operator } "\ X(ch)
\]

[Example:

```c
long double operator "" _w(long double);
std::string operator "" _w(const char16_t*, std::size_t);
unsigned operator "" _w(const char*);
int main() {
  1.2_w;  // calls operator "" _w(1.2L)
  u"one"_w;  // calls operator "" _w(u"one", 3)
  12_w;  // calls operator "" _w("12")
  "two"_w;  // error: no applicable literal operator
}
```

—end example]

In translation phase 6 (5.2), adjacent string literals are concatenated and user-defined-string-literals are considered string literals for that purpose. During concatenation, ud-suffixes are removed and ignored and the concatenation process occurs as described in 5.13.5. At the end of phase 6, if a string literal is the result of a concatenation involving at least one user-defined-string-literal, all the participating user-defined-string-literals shall have the same ud-suffix and that suffix is applied to the result of the concatenation.

[Example:

```c
int main() {
  L"A" "B" "C",_x;  // OK: same as L"ABC",_x
  "P",_x "Q",_y;  // error: two different ud-suffixes
}
```

—end example]
6 Basics

1 [Note: This Clause presents the basic concepts of the C++ language. It explains the difference between an object and a name and how they relate to the value categories for expressions. It introduces the concepts of a declaration and a definition and presents C++’s notion of type, scope, linkage, and storage duration. The mechanisms for starting and terminating a program are discussed. Finally, this Clause presents the fundamental types of the language and lists the ways of constructing compound types from these. — end note]

2 [Note: This Clause does not cover concepts that affect only a single part of the language. Such concepts are discussed in the relevant Clauses. — end note]

3 An entity is a value, object, reference, structured binding, function, enumerator, type, class member, bit-field, template, template specialization, namespace, or pack.

4 A name is a use of an identifier (5.10), operator-function-id (11.5), literal-operator-id (11.5.8), conversion-function-id (10.3.8.2), or template-id (12.2) that denotes an entity or label (8.6.4, 8.1).

5 Every name that denotes an entity is introduced by a declaration. Every name that denotes a label is introduced either by a goto statement (8.6.4) or a labeled-statement (8.1).

6 A variable is introduced by the declaration of a reference other than a non-static data member or of an object. The variable’s name, if any, denotes the reference or object.

7 A local entity is a variable with automatic storage duration (6.6.4.3), a structured binding (9.5) whose corresponding variable is such an entity, or the *this object (7.5.2).

8 Some names denote types or templates. In general, whenever a name is encountered it is necessary to determine whether that name denotes one of these entities before continuing to parse the program that contains it. The process that determines this is called name lookup (6.4).

9 Two names are the same if

(9.1) — they are identifiers composed of the same character sequence, or
(9.2) — they are operator-function-ids formed with the same operator, or
(9.3) — they are conversion-function-ids formed with the same type, or
(9.4) — they are template-ids that refer to the same class, function, or variable (12.5), or
(9.5) — they are the names of literal operators (11.5.8) formed with the same literal suffix identifier.

10 A name used in more than one translation unit can potentially refer to the same entity in these translation units depending on the linkage (6.5) of the name specified in each translation unit.

6.1 Declarations and definitions

A declaration (Clause 9) may introduce one or more names into a translation unit or redeclare names introduced by previous declarations. If so, the declaration specifies the interpretation and attributes of these names. A declaration may also have effects including:

(1.1) — a static assertion (Clause 9),
(1.2) — controlling template instantiation (12.8.2),
(1.3) — guiding template argument deduction for constructors (12.10),
(1.4) — use of attributes (Clause 9), and
(1.5) — nothing (in the case of an empty-declaration).

Each entity declared by a declaration is also defined by that declaration unless:

(2.1) — it declares a function without specifying the function’s body (9.4),
(2.2) — it contains the extern specifier (9.1.1) or a linkage-specification (9.10) and neither an initializer nor a function-body,

Appearing inside the brace-enclosed declaration-seq in a linkage-specification does not affect whether a declaration is a definition.
— it declares a non-inline static data member in a class definition (10.3, 10.3.9),
— it declares a static data member outside a class definition and the variable was defined within the class with the constexpr specifier (this usage is deprecated; see D.4),
— it is introduced by an elaborated-type-specifier (10.2),
— it is an opaque-enum-declaration (9.6),
— it is a template-parameter (12.1),
— it is a parameter-declaration (9.2.3.5) in a function declarator that is not the declarator of a function-definition,
— it is a typedef declaration (9.1.3),
— it is an alias-declaration (9.1.3),
— it is a using-declaration (9.8),
— it is a deduction-guide (12.10),
— it is a static_assert-declaration (Clause 9),
— it is an attribute-declaration (Clause 9),
— it is an empty-declaration (Clause 9),
— it is an explicit instantiation declaration (12.8.2), or
— it is an explicit specialization (12.8.3) whose declaration is not a definition.

A declaration is said to be a definition of each entity that it defines. [Example: All but one of the following are definitions:

```cpp
int a; // defines a
extern const int c = 1; // defines c
int f(int x) { return x+a; } // defines f and defines x
struct S { int a; int b; }; // defines S, S::a, and S::b
struct X {
    int x; // defines X
    static int y; // declares static data member y
    X(): x(0) {} // defines a constructor of X
};
int X::y = 1; // defines X::y
enum { up, down }; // defines up and down
namespace N { int d; } // defines N and N::d
namespace N1 = N; // defines N1
X anX; // defines anX
```

whereas these are just declarations:

```cpp
extern int a; // declares a
extern const int c; // declares c
int f(int); // declares f
struct S; // declares S
typedef int Int; // declares Int
extern X anotherX; // declares anotherX
using N::d; // declares d
```

—end example]

3 [Note: In some circumstances, C++ implementations implicitly define the default constructor (10.3.4), copy constructor, move constructor (10.3.5), copy assignment operator, move assignment operator (10.3.6), or destructor (10.3.7) member functions. —end note] [Example: Given

```cpp
#include <string>

struct C {
    std::string s; // std::string is the standard library class (Clause 20)
};
```
```c
int main() {
    C a;
    C b = a;
    b = a;
}
```

the implementation will implicitly define functions to make the definition of `C` equivalent to

```c
struct C {
    std::string s;
    C() : s() { }
    C(const C& x): s(x.s) { }
    C(C&& x): s(static_cast<std::string&&>(x.s)) { }
    // : s(std::move(x.s)) { }
    C& operator=(const C& x) { s = x.s; return *this; }
    C& operator=(C&& x) { s = static_cast<std::string&&>(x.s); return *this; }
    // : s(std::move(x.s)); return *this; }
    ~C() { }
};
```

---

4 [Note: A class name can also be implicitly declared by an elaborated-type-specifier (9.1.7.3). — end note]

5 In the definition of an object, the type of that object shall not be an incomplete type (6.7), an abstract class type (10.6.3), or a (possibly multi-dimensional) array thereof.

### 6.2 One-definition rule

No translation unit shall contain more than one definition of any variable, function, class type, enumeration type, or template.

An expression is potentially evaluated unless it is an unevaluated operand (7.2) or a subexpression thereof. The set of potential results of an expression `e` is defined as follows:

1. If `e` is an id-expression (7.5.4), the set contains only `e`.
2. If `e` is a subscripting operation (7.6.1.1) with an array operand, the set contains the potential results of that operand.
3. If `e` is a class member access expression (7.6.1.5), the set contains the potential results of the object expression.
4. If `e` is a pointer-to-member expression (7.6.4) whose second operand is a constant expression, the set contains the potential results of the object expression.
5. If `e` has the form `(e1)`, the set contains the potential results of `e1`.
6. If `e` is a glvalue conditional expression (7.6.16), the set is the union of the sets of potential results of the second and third operands.
7. If `e` is a comma expression (7.6.19), the set contains the potential results of the right operand.
8. Otherwise, the set is empty.

[Note: This set is a (possibly-empty) set of id-expressions, each of which is either `e` or a subexpression of `e`.]

[Example: In the following example, the set of potential results of the initializer of `n` contains the first `S::x` subexpression, but not the second `S::x` subexpression.

```c
struct S { static const int x = 0; }; 
const int &f(const int &r);
int n = b ? (1, S::x) // S::x is not odr-used here
    : f(S::x); // S::x is odr-used here, so a definition is required
```

---

3 A function is named by an expression as follows:

1. A function whose name appears in an expression is named by that expression if it is the unique lookup result or the selected member of a set of overloaded functions (6.4, 11.3, 11.4), unless it is a pure virtual function and either its name is not explicitly qualified or the expression forms a pointer to member (7.6.2.1). [Note: This covers taking the address of functions (7.3.3, 7.6.2.1), calls to named functions (7.6.1.2), operator overloading (Clause 11), user-defined conversions (10.3.8.2),]
allocation functions for placement new-expressions (7.6.2.4), as well as non-default initialization (9.3). A constructor selected to copy or move an object of class type is considered to be named by an expression even if the call is actually elided by the implementation (10.9.5). — end note]

(3.2) — An allocation or deallocation function for a class is named by a new-expression as specified in 7.6.2.4 and 10.11.

(3.3) — A deallocation function for a class is named by a delete expression as specified in 7.6.2.5 and 10.11.

A variable x whose name appears as a potentially-evaluated expression ex is odr-used by ex unless applying the lvalue-to-rvalue conversion (7.3.1) to x yields a constant expression (7.7) that does not invoke any non-trivial functions and, if x is an object, ex is an element of the set of potential results of an expression e, where either the lvalue-to-rvalue conversion (7.3.1) is applied to e, or e is a discarded-value expression (7.2).

A structured binding is odr-used if it appears as a potentially-evaluated expression.

*this is odr-used if this appears as a potentially-evaluated expression (including as the result of the implicit transformation in the body of a non-static member function (10.3.2)).

A virtual member function is odr-used if it is not pure. A function is odr-used if it is named by a potentially-evaluated expression. A non-placement allocation or deallocation function for a class is odr-used by the definition of a constructor of that class. A non-placement deallocation function for a class is odr-used by the definition of the destructor of that class, or by being selected by the lookup at the point of definition of a virtual destructor (10.3.7).

An assignment operator function in a class is odr-used by an implicitly-defined copy-assignment or move-assignment function for another class as specified in 10.3.6. A constructor for a class is odr-used as specified in 9.3. A destructor for a class is odr-used if it is potentially invoked (10.3.7).

A local entity (Clause 6) is odr-usable in a declarative region (6.3.1) if:

(9.1) — the local entity is either not *this, or an enclosing class or non-lambda function parameter scope exists and, if the innermost such scope is a function parameter scope, it corresponds to a non-static member function, and

(9.2) — for each intervening declarative region (6.3.1) between the point at which the entity is introduced and the region (where *this is considered to be introduced within the innermost enclosing class or non-lambda function definition scope), either:

(9.2.1) — the declarative region is a block scope, or

(9.2.2) — the declarative region is the function parameter scope of a lambda-expression that has a simple-capture naming the entity or has a capture-default.

If a local entity is odr-used in a declarative region in which it is not odr-usable, the program is ill-formed.

[Example:

```cpp
void f(int n) {
    [] { n = 1; }; // error, n is not odr-usable due to intervening lambda-expression
    struct A {
        void f() { n = 2; } // error, n is not odr-usable due to intervening function definition scope
    };
    void g(int = n);
    [&] { [n]{ return n; }; }; // OK
}

— end example]

Every program shall contain exactly one definition of every non-inline function or variable that is odr-used in that program outside of a discarded statement (8.4.1); no diagnostic required. The definition can appear explicitly in the program, it can be found in the standard or a user-defined library, or (when appropriate) it is implicitly defined (see 10.3.4, 10.3.7, 10.3.5, and 10.3.6). An inline function or variable shall be defined in every translation unit in which it is odr-used outside of a discarded statement.

Exactly one definition of a class is required in a translation unit if the class is used in a way that requires the class type to be complete. [Example: The following complete translation unit is well-formed, even though it never defines X:]

22) An implementation is not required to call allocation and deallocation functions from constructors or destructors; however, this is a permissible implementation technique.
© ISO/IEC

struct X; // declare X as a struct type
struct X* x1; // use X in pointer formation
X* x2; // use X in pointer formation

— end example] [Note: The rules for declarations and expressions describe in which contexts complete class types are required. A class type T must be complete if:

(11.1) — an object of type T is defined (6.1), or
(11.2) — a non-static class data member of type T is declared (10.3), or
(11.3) — T is used as the allocated type or array element type in a new-expression (7.6.2.4), or
(11.4) — an lvalue-to-rvalue conversion is applied to a glvalue referring to an object of type T (7.3.1), or
(11.5) — an expression is converted (either implicitly or explicitly) to type T (7.3, 7.6.1.3, 7.6.1.7, 7.6.1.9, 7.6.3), or
(11.6) — an expression that is not a null pointer constant, and has type other than cv void*, is converted to the type pointer to T or reference to T using a standard conversion (7.3), a dynamic_cast (7.6.1.7) or a static_cast (7.6.1.9), or
(11.7) — a class member access operator is applied to an expression of type T (7.6.1.5), or
(11.8) — the typeid operator (7.6.1.8) or the sizeof operator (7.6.2.3) is applied to an operand of type T, or
(11.9) — a function with a return type or argument type of type T is defined (6.1) or called (7.6.1.2), or
(11.10) — a class with a base class of type T is defined (10.6), or
(11.11) — an lvalue of type T is assigned to (7.6.18), or
(11.12) — the type T is the subject of an alignof expression (7.6.2.6), or
(11.13) — an exception-declaration has type T, reference to T, or pointer to T (13.3).

— end note]

12 There can be more than one definition of a class type (Clause 10), enumeration type (9.6), inline function with external linkage (9.1.6), inline variable with external linkage (9.1.6), class template (Clause 12), non-static function template (12.6.6), concept (12.6.8), static data member of a class template (12.6.1.3), member function of a class template (12.6.1.1), or template specialization for which some template parameters are not specified (12.8, 12.6.5) in a program provided that each definition appears in a different translation unit, and provided the definitions satisfy the following requirements. Given such an entity named D defined in more than one translation unit, then

(12.1) — each definition of D shall consist of the same sequence of tokens; and
(12.2) — in each definition of D, corresponding names, looked up according to 6.4, shall refer to an entity defined within the definition of D, or shall refer to the same entity, after overload resolution (11.3) and after matching of partial template specialization (12.9.3), except that a name can refer to

(12.2.1) — a non-volatile const object with internal or no linkage if the object
(12.2.1.1) — has the same literal type in all definitions of D,
(12.2.1.2) — is initialized with a constant expression (7.7),
(12.2.1.3) — is not odr-used in any definition of D, and
(12.2.1.4) — has the same value in all definitions of D,

or

(12.2.2) — a reference with internal or no linkage initialized with a constant expression such that the reference refers to the same entity in all definitions of D;

and

(12.3) — in each definition of D, corresponding entities shall have the same language linkage; and
(12.4) — in each definition of D, the overloaded operators referred to, the implicit calls to conversion functions, constructors, operator new functions and operator delete functions, shall refer to the same function, or to a function defined within the definition of D; and
(12.5) — in each definition of D, a default argument used by an (implicit or explicit) function call is treated as if its token sequence were present in the definition of D; that is, the default argument is subject to the
requirements described in this paragraph (and, if the default argument has subexpressions with default arguments, this requirement applies recursively)\(^{23}\); and

(12.6) — if \(D\) invokes a function with a precondition, or is a function that contains an assertion or has a contract condition (9.11.4), it is implementation-defined under which conditions all definitions of \(D\) shall be translated using the same build level and violation continuation mode; and

(12.7) — if \(D\) is a class with an implicitly-declared constructor (10.3.4), it is as if the constructor was implicitly defined in every translation unit where it is odr-used, and the implicit definition in every translation unit shall call the same constructor for a subobject of \(D\). [Example:

// translation unit 1:
struct X {
    X(int, int);
    X(int, int, int);
};
X::X(int, int = 0) { }
class D {
    X x = 0;
};
D d1;       //X(int, int) called by D()

// translation unit 2:
struct X {
    X(int, int);
    X(int, int, int);
};
X::X(int, int = 0, int = 0) { }
class D {
    X x = 0;
};
D d2;       //X(int, int, int) called by D();
//D()'s implicit definition violates the ODR

— end example]

If \(D\) is a template and is defined in more than one translation unit, then the preceding requirements shall apply both to names from the template’s enclosing scope used in the template definition (12.7.3), and also to dependent names at the point of instantiation (12.7.2). If the definitions of \(D\) satisfy all these requirements, then the behavior is as if there were a single definition of \(D\). [Note: The entity is still declared in multiple translation units, and 6.5 still applies to these declarations. In particular, lambda-expressions (7.5.5) appearing in the type of \(D\) may result in the different declarations having distinct types. — end note] If the definitions of \(D\) do not satisfy these requirements, then the behavior is undefined.

6.3 Scope

6.3.1 Declarative regions and scopes

Every name is introduced in some portion of program text called a declarative region, which is the largest part of the program in which that name is valid, that is, in which that name may be used as an unqualified name to refer to the same entity. In general, each particular name is valid only within some possibly contiguous portion of program text called its scope. To determine the scope of a declaration, it is sometimes convenient to refer to the potential scope of a declaration. The scope of a declaration is the same as its potential scope unless the potential scope contains another declaration of the same name. In that case, the potential scope of the declaration in the inner (contained) declarative region is excluded from the scope of the declaration in the outer (containing) declarative region.

[Example: In

\[
\begin{align*}
\text{int } j &= 24; \\
\text{int main()} \{ \\
\text{int } i &= j, j; \\
\text{j} &= 42; \\
\} 
\end{align*}
\]

] 23\) 9.2.3.6 describes how default argument names are looked up.
the identifier \( j \) is declared twice as a name (and used twice). The declarative region of the first \( j \) includes the entire example. The potential scope of the first \( j \) begins immediately after that \( j \) and extends to the end of the program, but its (actual) scope excludes the text between the \{ \) and the \}. The declarative region of the second declaration of \( j \) (the \( j \) immediately before the semicolon) includes all the text between \{ \) and \}, but its potential scope excludes the declaration of \( i \). The scope of the second declaration of \( j \) is the same as its potential scope. —end example

3 The names declared by a declaration are introduced into the scope in which the declaration occurs, except that the presence of a friend specifier (10.8.3), certain uses of the elaborated-type-specifier (9.1.7.3), and using-directives (9.7.3) alter this general behavior.

4 Given a set of declarations in a single declarative region, each of which specifies the same unqualified name, —they shall all refer to the same entity, or all refer to functions and function templates; or
—exactly one declaration shall declare a class name or enumeration name that is not a typedef name and the other declarations shall all refer to the same variable, non-static data member, or enumerator, or all refer to functions and function templates; in this case the class name or enumeration name is hidden (6.3.10). [Note: A namespace name or a class template name must be unique in its declarative region (9.7.2, Clause 12). —end note]

[Note: These restrictions apply to the declarative region into which a name is introduced, which is not necessarily the same as the region in which the declaration occurs. In particular, elaborated-type-specifiers (9.1.7.3) and friend declarations (10.8.3) may introduce a (possibly not visible) name into an enclosing namespace; these restrictions apply to that region. Local extern declarations (6.5) may introduce a name into the declarative region where the declaration appears and also introduce a (possibly not visible) name into an enclosing namespace; these restrictions apply to both regions. —end note]

5 For a given declarative region \( R \) and a point \( P \) outside \( R \), the set of intervening declarative regions between \( P \) and \( R \) comprises all declarative regions that are or enclose \( R \) and do not enclose \( P \).

6 [Note: The name lookup rules are summarized in 6.4. —end note]

6.3.2 Point of declaration [basic.scope.pdecl]

1 The point of declaration for a name is immediately after its complete declarator (9.2) and before its initializer (if any), except as noted below. [Example:

\[
\begin{align*}
\text{unsigned char } \&x = 12; \\
\{ \text{ unsigned char } \&x = x; \} \\
\end{align*}
\]

Here the second \( x \) is initialized with its own (indeterminate) value. —end example]

2 [Note: A name from an outer scope remains visible up to the point of declaration of the name that hides it. [Example:

\[
\begin{align*}
\text{const int } \&i = 2; \\
\{ \text{ int } i[1]; \} \\
\end{align*}
\]

declares a block-scope array of two integers. —end example] —end note]

3 The point of declaration for a class or class template first declared by a class-specifier is immediately after the identifier or simple-template-id (if any) in its class-head (Clause 10). The point of declaration for an enumeration is immediately after the identifier (if any) in either its enum-specifier (9.6) or its first opaque-enum-declaration (9.6), whichever comes first. The point of declaration of an alias or alias template immediately follows the defining-type-id to which the alias refers.

4 The point of declaration of a using-declarator that does not name a constructor is immediately after the using-declarator (9.8).

5 The point of declaration for an enumerator is immediately after its enumerator-definition. [Example:

\[
\begin{align*}
\text{const int } \&x = 12; \\
\{ \text{ enum } \{ x = x \}; \} \\
\end{align*}
\]

Here, the enumerator \( x \) is initialized with the value of the constant \( x \), namely 12. —end example]

6 After the point of declaration of a class member, the member name can be looked up in the scope of its class. [Note: This is true even if the class is an incomplete class. For example,

\[
\begin{align*}
\text{struct X}
\{ \\
\text{ enum E } \{ z = 16 \}; \\
\end{align*}
\]
The point of declaration of a class first declared in an elaborated-type-specifier is as follows:

(7.1) — for a declaration of the form

\[
\text{class-key attribute-specifier-seq\opt identifier ;}
\]

the identifier is declared to be a class-name in the scope that contains the declaration, otherwise

(7.2) — for an elaborated-type-specifier of the form

\[
\text{class-key identifier}
\]

if the elaborated-type-specifier is used in the decl-specifier-seq or parameter-declaration-clause of a function defined in namespace scope, the identifier is declared as a class-name in the namespace that contains the declaration; otherwise, except as a friend declaration, the identifier is declared in the smallest namespace or block scope that contains the declaration. [Note: These rules also apply within templates. —end note] [Note: Other forms of elaborated-type-specifier do not declare a new name, and therefore must refer to an existing type-name. See 6.4.4 and 9.1.7.3. — end note]

The point of declaration for an injected-class-name (Clause 10) is immediately following the opening brace of the class definition.

The point of declaration for a function-local predefined variable (9.4.1) is immediately before the function-body of a function definition.

The point of declaration of a structured binding (9.5) is immediately after the identifier-list of the structured binding declaration.

The point of declaration for the variable or the structured bindings declared in the for-range-declaration of a range-based for statement (8.5.4) is immediately after the for-range-initializer.

The point of declaration for a template parameter is immediately after its complete template-parameter.

[Example:

\[
\begin{align*}
\text{typedef unsigned char T;} \\
\text{template<class T=} T & // lookup finds the typedef name of unsigned char \\
= T & // lookup finds the template parameter \\
\text{N = G> struct A { };}
\end{align*}
\]

—end example]

[Note: Friend declarations refer to functions or classes that are members of the nearest enclosing namespace, but they do not introduce new names into that namespace (9.7.1.2). Function declarations at block scope and variable declarations with the extern specifier at block scope refer to declarations that are members of an enclosing namespace, but they do not introduce new names into that scope. — end note]

[Note: For point of instantiation of a template, see 12.7.4.1. — end note]

6.3.3 Block scope [basic.scope.block]

A name declared in a block (8.3) is local to that block; it has block scope. Its potential scope begins at its point of declaration (6.3.2) and ends at the end of its block. A variable declared at block scope is a local variable.

The name declared in an exception-declaration is local to the handler and shall not be redeclared in the outermost block of the handler.

Names declared in the init-statement, the for-range-declaration, and in the condition of if, while, for, and switch statements are local to the if, while, for, or switch statement (including the controlled statement), and shall not be redeclared in a subsequent condition of that statement nor in the outermost block (or, for the if statement, any of the outermost blocks) of the controlled statement; see 8.4.

6.3.4 Function parameter scope [basic.scope.param]

A function parameter (including one appearing in a lambda-declarator) or function-local predefined variable (9.4) has function parameter scope. The potential scope of a parameter or function-local predefined variable begins at its point of declaration. If the nearest enclosing function declarator is not the declarator of a

§ 6.3.4
function definition, the potential scope ends at the end of that function declarator. Otherwise, if the function has a function-try-block the potential scope ends at the end of the last associated handler. Otherwise the potential scope ends at the end of the outermost block of the function definition. A parameter name shall not be redeclared in the outermost block of the function definition nor in the outermost block of any handler associated with a function-try-block.

6.3.5 Function scope [basic.funscope]

Labels (8.1) have function scope and may be used anywhere in the function in which they are declared. Only labels have function scope.

6.3.6 Namespace scope [basic.scope.namespace]

1 The declarative region of a namespace-definition is its namespace-body. Entities declared in a namespace-body are said to be members of the namespace, and names introduced by these declarations into the declarative region of the namespace are said to be member names of the namespace. A namespace member name has namespace scope. Its potential scope includes its namespace from the name’s point of declaration (6.3.2) onwards; and for each using-directive (9.7.3) that nominates the member’s namespace, the member’s potential scope includes that portion of the potential scope of the using-directive that follows the member’s point of declaration. [Example:

```c
namespace N {
    int i;
    int g(int a) { return a; }
    int j();
    void q();
}
namespace { int l=1; }
// the potential scope of l is from its point of declaration to the end of the translation unit

namespace N {
    int g(char a) { // overloads N::g(int)
        return l+a; // l is from unnamed namespace
    }
    int i; // error: duplicate definition
    int j(); // OK: duplicate function declaration
    int j() { // OK: definition of N::j()
        return g(i); // calls N::g(int)
    }
    int q(); // error: different return type
}
```

—end example]

2 A namespace member can also be referred to after the :: scope resolution operator (7.5.4.2) applied to the name of its namespace or the name of a namespace which nominates the member’s namespace in a using-directive; see 6.4.3.2.

3 The outermost declarative region of a translation unit is also a namespace, called the global namespace. A name declared in the global namespace has global namespace scope (also called global scope). The potential scope of such a name begins at its point of declaration (6.3.2) and ends at the end of the translation unit that is its declarative region. A name with global namespace scope is said to be a global name.

6.3.7 Class scope [basic.scope.class]

1 The potential scope of a name declared in a class consists not only of the declarative region following the name’s point of declaration, but also of all complete-class contexts (10.3) of that class.

2 A name N used in a class S shall refer to the same declaration in its context and when re-evaluated in the completed scope of S. No diagnostic is required for a violation of this rule.

3 A name declared within a member function hides a declaration of the same name whose scope extends to or past the end of the member function’s class.

4 The potential scope of a declaration that extends to or past the end of a class definition also extends to the regions defined by its member definitions, even if the members are defined lexically outside the class (this
includes static data member definitions, nested class definitions, and member function definitions, including
the member function body and any portion of the declarator part of such definitions which follows the
declarator-id, including a parameter-declaration-clause and any default arguments (9.2.3.6)).

5 [Example:
   typedef int c;
   enum { i = 1 };

   class X {
      char v[i];          // error: i refers to ::i but when reevaluated is X::i
      int f() { return sizeof(c); } // OK: X::c
      char c;
      enum { i = 2 };       // error:
   };

   typedef char* T;
   struct Y {
      T a;                 // error: T refers to ::T but when reevaluated is Y::T
      typedef long T;
      T b;
   };

   typedef int I;
   class D {
      typedef I I;         // error, even though no reordering involved
   };
   —end example]

6 The name of a class member shall only be used as follows:

   — in the scope of its class (as described above) or a class derived (10.6) from its class,

   — after the . operator applied to an expression of the type of its class (7.6.1.5) or a class derived from its
     class,

   — after the -> operator applied to a pointer to an object of its class (7.6.1.5) or a class derived from its
     class,

   — after the :: scope resolution operator (7.5.4.2) applied to the name of its class or a class derived from
     its class.

6.3.8 Enumeration scope

1 The name of a scoped enumerator (9.6) has enumeration scope. Its potential scope begins at its point of
declaration and terminates at the end of the enum-specifier.

6.3.9 Template parameter scope

1 The declarative region of the name of a template parameter of a template template-parameter list in which the name was introduced.

2 The declarative region of the name of a template parameter of a template is the smallest template-declaration
   in which the name was introduced. Only template parameter names belong to this declarative region; any
   other kind of name introduced by the declaration of a template-declaration is instead introduced into the
   same declarative region where it would be introduced as a result of a non-template declaration of the same
   name. [Example:
   namespace N {
      template<class T> struct A { }; // #1
      template<class U> void f(U) { }  // #2
      struct B {
         template<class V> friend int g(struct C*); // #3
      };
   }

   The declarative regions of T, U and V are the template-declarations on lines #1, #2, and #3, respectively.
   But the names A, f, g and C all belong to the same declarative region — namely, the namespace-body of N.

§ 6.3.9 33
The potential scope of a template parameter name begins at its point of declaration (6.3.2) and ends at the end of its declarative region. [Note: This implies that a template-parameter can be used in the declaration of subsequent template-parameters and their default arguments but cannot be used in preceding template-parameters or their default arguments. For example,

```cpp
template<class T, T* p, class U = T> class X { /* ... */ }
```

This also implies that a template-parameter can be used in the specification of base classes. For example,

```cpp```
template<class T> class X : public Array<T> { /* ... */ }
template<class T> class Y : public T { /* ... */ }
```cpp```

The use of a template parameter as a base class implies that a class used as a template argument must be defined and not just declared when the class template is instantiated. —end note]

The declarative region of the name of a template parameter is nested within the immediately-enclosing declarative region. [Note: As a result, a template-parameter hides any entity with the same name in an enclosing scope (6.3.10). [Example:

```cpp```
typedef int N;
template<N X, typename N, template<N Y> class T> struct A;
```cpp```

Here, X is a non-type template parameter of type int and Y is a non-type template parameter of the same type as the second template parameter of A. —end example] —end note]

The declarative region of the name of a template parameter is nested within the immediately-enclosing declarative region. [Note: As a result, a template-parameter hides any entity with the same name in an enclosing scope (6.3.10).] —end note]

### 6.3.10 Name hiding

A declaration of a name in a nested declarative region hides a declaration of the same name in an enclosing declarative region; see 6.3.1 and 6.4.1.

If a class name (10.2) or enumeration name (9.6) and a variable, data member, function, or enumerator are declared in the same declarative region (in any order) with the same name (excluding declarations made visible via using-directives (6.4.1)), the class or enumeration name is hidden wherever the variable, data member, function, or enumerator name is visible.

In a member function definition, the declaration of a name at block scope hides the declaration of a member of the class with the same name; see 6.3.7. The declaration of a member in a derived class (10.6) hides the declaration of a member of a base class of the same name; see 10.7.

During the lookup of a name qualified by a namespace name, declarations that would otherwise be made visible by a using-directive can be hidden by declarations with the same name in the namespace containing the using-directive; see 6.4.3.2.

If a name is in scope and is not hidden it is said to be visible.

### 6.4 Name lookup

The name lookup rules apply uniformly to all names (including typedef-names (9.1.3), namespace-names (9.7), and class-names (10.2)) wherever the grammar allows such names in the context discussed by a particular rule. Name lookup associates the use of a name with a set of declarations (6.1) of that name. The declarations found by name lookup shall either all denote the same entity or shall all denote functions or function templates; in the latter case, the declarations are said to form a set of overloaded functions (11.1). Overload resolution (11.3) takes place after name lookup has succeeded. The access rules (10.8) are considered only once name lookup and function overload resolution (if applicable) have succeeded. Only after name lookup, function overload resolution (if applicable) and access checking have succeeded are the attributes introduced by the name’s declaration used further in expression processing (Clause 7).

A name “looked up in the context of an expression” is looked up as an unqualified name in the scope where the expression is found.

The injected-class-name of a class (Clause 10) is also considered to be a member of that class for the purposes of name hiding and lookup.
Note: 6.5 discusses linkage issues. The notions of scope, point of declaration and name hiding are discussed in 6.3. —end note]

6.4.1 Unqualified name lookup [basic.lookup.unqual]

In all the cases listed in 6.4.1, the scopes are searched for a declaration in the order listed in each of the respective categories; name lookup ends as soon as a declaration is found for the name. If no declaration is found, the program is ill-formed.

The declarations from the namespace nominated by a using-directive become visible in a namespace enclosing the using-directive; see 9.7.3. For the purpose of the unqualified name lookup rules described in 6.4.1, the declarations from the namespace nominated by the using-directive are considered members of that enclosing namespace.

The lookup for an unqualified name used as the postfix-expression of a function call is described in 6.4.2. [Note: For purposes of determining (during parsing) whether an expression is a postfix-expression for a function call, the usual name lookup rules apply. In some cases a name followed by < is treated as a template-name even though name lookup did not find a template-name (see 12.2). For example,

```cpp
int h;
void g();
namespace N {
    struct A {
        template <class T> int f(T);
        template <class T> int g(T);
        template <class T> int h(T);
    }

    int x = f<N::A>(N::A()); // OK: lookup of f finds nothing, f treated as template name
    int y = g<N::A>(N::A()); // OK: lookup of g finds a function, g treated as template name
    int z = h<N::A>(N::A()); // error: h< does not begin a template-id
}
```

The rules in 6.4.2 have no effect on the syntactic interpretation of an expression. For example,

```cpp
typedef int f;
namespace N {
    struct A {
        friend void f(A &);
        operator int();
        void g(A a) {
            int i = f(a); // f is the typedef, not the friend function: equivalent to int(a)
        }
    }
}
```

Because the expression is not a function call, the argument-dependent name lookup (6.4.2) does not apply and the friend function f is not found. —end note]

A name used in global scope, outside of any function, class or user-declared namespace, shall be declared before its use in global scope.

A name used in a user-declared namespace outside of the definition of any function or class shall be declared before its use in that namespace or before its use in a namespace enclosing its namespace.

In the definition of a function that is a member of namespace N, a name used after the function’s declarator-id shall be declared before its use in the block in which it is used or in one of its enclosing blocks (8.3) or shall be declared before its use in namespace N or, if N is a nested namespace, shall be declared before its use in one of N’s enclosing namespaces. [Example:

```cpp
namespace A {
    namespace N {
        void f();
    }
}
void A::N::f() {
    i = 5;
}
```

24) This refers to unqualified names that occur, for instance, in a type or default argument in the parameter-declaration-clause or used in the function body.
A name used in the definition of a class \(X\) outside of a complete-class context (10.3) of \(X\) shall be declared in one of the following ways:

- before its use in class \(X\) or be a member of a base class of \(X\) (10.7), or
- if \(X\) is a nested class of class \(Y\) (10.3.11), before the definition of \(X\) in \(Y\), or shall be a member of a base class of \(Y\) (this lookup applies in turn to \(Y\)'s enclosing classes, starting with the innermost enclosing class),
- if \(X\) is a local class (10.5) or is a nested class of a local class, before the definition of class \(X\) in a block enclosing the definition of class \(X\), or
- if \(X\) is a member of namespace \(N\), or is a nested class of a class that is a member of \(N\), or is a local class or a nested class within a local class of a function that is a member of \(N\), before the definition of class \(X\) in namespace \(N\) or in one of \(N\)'s enclosing namespaces.

**Example:**

```cpp
namespace M {
    class B {
    };
}
namespace N {
    class Y : public M::B {
        class X {
            int a[i];
        };
    };
}
```

---

For the members of a class \(X\), a name used in a complete-class context (10.3) of \(X\) or in the definition of a class member outside of the definition of \(X\), following the member's declarator-id (27), shall be declared in one of the following ways:

- before its use in the block in which it is used or in an enclosing block (8.3), or
- shall be a member of class \(X\) or be a member of a base class of \(X\) (10.7), or
- if \(X\) is a nested class of class \(Y\) (10.3.11), shall be a member of \(Y\), or shall be a member of a base class of \(Y\) (this lookup applies in turn to \(Y\)'s enclosing classes, starting with the innermost enclosing class),

---

25) This refers to unqualified names following the class name; such a name may be used in a base-specifier or in the member-specification of the class definition.
26) This lookup applies whether the definition of \(X\) is nested within \(Y\)'s definition or whether \(X\)'s definition appears in a namespace scope enclosing \(Y\)'s definition (10.3.11).
27) That is, an unqualified name that occurs, for instance, in a type in the parameter-declaration-clause or in the noexcept-specifier.
28) This lookup applies whether the member function is defined within the definition of class \(X\) or whether the member function is defined in a namespace scope enclosing \(X\)'s definition.
— if \( X \) is a local class (10.5) or is a nested class of a local class, before the definition of class \( X \) in a block enclosing the definition of class \( X \), or

— if \( X \) is a member of namespace \( N \), or is a nested class of a class that is a member of \( N \), or is a local class or a nested class within a local class of a function that is a member of \( N \), before the use of the name, in namespace \( N \) or in one of \( N \)'s enclosing namespaces.

\[ \text{Example:} \]

```cpp
class B { }
namespace M {
    namespace N {
        class X : public B {
            void f();
        }
    }
}
void M::N::X::f() {
    i = 16;
}
```

// The following scopes are searched for a declaration of \( i \):
// 1) outermost block scope of \( M::N::X::f \), before the use of \( i \)
// 2) scope of class \( M::N::X \)
// 3) scope of \( M::N::X \)'s base class \( B \)
// 4) scope of namespace \( M::N \)
// 5) scope of namespace \( M \)
// 6) global scope, before the definition of \( M::N::X::f \)

— end example \]  

[Note: 10.3.1 and 10.3.9 further describe the restrictions on the use of names in member function definitions. 10.3.11 further describes the restrictions on the use of names in the scope of nested classes. 10.5 further describes the restrictions on the use of names in local class definitions. — end note]

Name lookup for a name used in the definition of a friend function (10.8.3) defined inline in the class granting friendship shall proceed as described for lookup in member function definitions. If the friend function is not defined in the class granting friendship, name lookup in the friend function definition shall proceed as described for lookup in namespace member function definitions.

In a friend declaration naming a member function, a name used in the function declarator and not part of a template-argument in the declarator-id is first looked up in the scope of the member function’s class (10.7). If it is not found, or if the name is part of a template-argument in the declarator-id, the look up is as described for unqualified names in the definition of the class granting friendship. [Example:

```cpp
struct A {
    typedef int AT;
    void f1(AT);
    void f2(float);
    template <class T> void f3();
};
struct B {
    typedef char AT;
    typedef float BT;
    friend void A::f1(AT);    // parameter type is A::AT
    friend void A::f2(BT);    // parameter type is B::BT
    friend void A::f3<AT>();  // template argument is B::AT
};
```

— end example]

During the lookup for a name used as a default argument (9.2.3.6) in a function parameter-declaration-clause or used in the expression of a mem-initializer for a constructor (10.9.2), the function parameter names are visible and hide the names of entities declared in the block, class or namespace scopes containing the function declaration. [Note: 9.2.3.6 further describes the restrictions on the use of names in default arguments. 10.9.2 further describes the restrictions on the use of names in a ctor-initializer. — end note]

During the lookup of a name used in the constant-expression of an enumerator-definition, previously declared enumerators of the enumeration are visible and hide the names of entities declared in the block, class, or namespace scopes containing the enum-specifier.
13 A name used in the definition of a static data member of class \( \text{X} \) (10.3.9.2) (after the qualified-id of the static member) is looked up as if the name was used in a member function of \( \text{X} \). [\textit{Note: 10.3.9.2 further describes the restrictions on the use of names in the definition of a static data member. — end note}]

14 If a variable member of a namespace is defined outside of the scope of its namespace then any name that appears in the definition of the member (after the declarator-id) is looked up as if the definition of the member occurred in its namespace. [\textit{Example:}

\[
\begin{aligned}
\text{namespace N} & \{
\text{int i = 4;}
\text{extern int j;}
\}\n\text{int i = 2;}
\text{int N::j = i;} \quad // \text{N::j == 4}
\end{aligned}
\]

— end example]

15 A name used in the handler for a function-try-block (Clause 13) is looked up as if the name was used in the outermost block of the function definition. In particular, the function parameter names shall not be redeclared in the exception-declaration nor in the outermost block of a handler for the function-try-block. Names declared in the outermost block of the function definition are not found when looked up in the scope of a handler for the function-try-block. [\textit{Note: But function parameter names are found. — end note}]

16 [\textit{Note: The rules for name lookup in template definitions are described in 12.7. — end note}]

### 6.4.2 Argument-dependent name lookup

[\textit{basic.lookup.argdep}]

1 When the postfix-expression in a function call (7.6.1.2) is an unqualified-id, other namespaces not considered during the usual unqualified lookup (6.4.1) may be searched, and in those namespaces, namespace-scope friend function or function template declarations (10.8.3) not otherwise visible may be found. These modifications to the search depend on the types of the arguments (and for template template arguments, the namespace of the template argument). [\textit{Example:}

\[
\begin{aligned}
\text{namespace N} & \{
\text{struct S} & \{}
\text{void f(S);} \\
\text{\}}
\text{void g()} & \{
\text{N::S s;}
\text{f(s);} \quad // \text{OK: calls N::f}
\text{f(a);} \quad // \text{error: N::f not considered; parentheses prevent argument-dependent lookup}
\text{\}}
\end{aligned}
\]

— end example]

2 For each argument type \( T \) in the function call, there is a set of zero or more associated namespaces and a set of zero or more associated classes to be considered. The sets of namespaces and classes are determined entirely by the types of the function arguments (and the namespace of any template template argument). Typedef names and using-declarations used to specify the types do not contribute to this set. The sets of namespaces and classes are determined in the following way:

\[2.1\] — If \( T \) is a fundamental type, its associated sets of namespaces and classes are both empty.

\[2.2\] — If \( T \) is a class type (including unions), its associated classes are: the class itself; the class of which it is a member, if any; and its direct and indirect base classes. Its associated namespaces are the innermost enclosing namespaces of its associated classes. Furthermore, if \( T \) is a class template specialization, its associated namespaces and classes also include: the namespaces and classes associated with the types of the template arguments provided for template type parameters (excluding template template parameters); the namespaces of which any template template arguments are members; and the classes of which any member templates used as template template arguments are members. [\textit{Note: Non-type template arguments do not contribute to the set of associated namespaces. — end note}]

\[2.3\] — If \( T \) is an enumeration type, its associated namespace is the innermost enclosing namespace of its declaration. If it is a class member, its associated class is the member’s class; else it has no associated class.
If \( T \) is a pointer to \( U \) or an array of \( U \), its associated namespaces and classes are those associated with \( U \).

(2.5) If \( T \) is a function type, its associated namespaces and classes are those associated with the function parameter types and those associated with the return type.

(2.6) If \( T \) is a pointer to a member function of a class \( X \), its associated namespaces and classes are those associated with the function parameter types and return type, together with those associated with \( X \).

(2.7) If \( T \) is a pointer to a data member of class \( X \), its associated namespaces and classes are those associated with the member type together with those associated with \( X \).

If an associated namespace is an inline namespace (9.7.1), its enclosing namespace is also included in the set.

If an associated namespace directly contains inline namespaces, those inline namespaces are also included in the set. In addition, if the argument is the name or address of a set of overloaded functions and/or function templates, its associated classes and namespaces are the union of those associated with each of the members of the set, i.e., the classes and namespaces associated with its parameter types and return type. Additionally, if the aforementioned set of overloaded functions is named with a template-id, its associated classes and namespaces also include those of its type template-arguments and its template template-arguments.

Let \( X \) be the lookup set produced by unqualified lookup (6.4.1) and let \( Y \) be the lookup set produced by argument dependent lookup (defined as follows). If \( X \) contains

(3.1) a declaration of a class member, or

(3.2) a block-scope function declaration that is not a using-declaration, or

(3.3) a declaration that is neither a function nor a function template

then \( Y \) is empty. Otherwise \( Y \) is the set of declarations found in the namespaces associated with the argument types as described below. The set of declarations found by the lookup of the name is the union of \( X \) and \( Y \).

[Note: The namespaces and classes associated with the argument types can include namespaces and classes already considered by the ordinary unqualified lookup. — end note] [Example:

```c
namespace NS {
    class T {
    public:
        static int n;
    
    void f(T);
    void g(T, int);
    }
    
    NS::T parm;
    void g(NS::T, float);
}
```

```c
int main() {
    f(parm); // OK: calls NS::f
    extern void g(NS::T, float);
    g(parm, 1); // OK: calls g(NS::T, float)
}
```

— end example]

When considering an associated namespace, the lookup is the same as the lookup performed when the associated namespace is used as a qualifier (6.4.3.2) except that:

(4.1) Any using-directives in the associated namespace are ignored.

(4.2) Any namespace-scope friend functions or friend function templates (10.8.3) declared in associated classes are visible within their respective namespaces even if they are not visible during an ordinary lookup (9.7.1.2).

(4.3) All names except those of (possibly overloaded) functions and function templates are ignored.

6.4.3 Qualified name lookup [basic.lookup.qual]

The name of a class or namespace member or enumerator can be referred to after the :: scope resolution operator (7.5.4.2) applied to a nested-name-specifier that denotes its class, namespace, or enumeration. If a :: scope resolution operator in a nested-name-specifier is not preceded by a decltype-specifier, lookup of the name preceding that :: considers only namespaces, types, and templates whose specializations are types. If the name found does not designate a namespace or a class, enumeration, or dependent type, the program is ill-formed. [Example:

```c
class A {
public:
    static int n;
```
int main() {
    int A;
    A::n = 42;    // OK
    A a;         // ill-formed: a does not name a type
}

— end example] 2 [Note: Multiply qualified names, such as N1::N2::N3::n, can be used to refer to members of nested classes (10.3.11) or members of nested namespaces. — end note]

3 In a declaration in which the declarator-id is a qualified-id, names used before the qualified-id being declared are looked up in the defining namespace scope; names following the qualified-id are looked up in the scope of the member’s class or namespace. [Example:

```c
class X { }
class C {
    class X { }
    static const int number = 50;
    static X arr[number];
};
X C::arr[number];    // ill-formed:
// equivalent to ::X C::arr[C::number];
// and not to C::X C::arr[C::number];
```

— end example] 3

4 A name prefixed by the unary scope operator :: (7.5.4.2) is looked up in global scope, in the translation unit where it is used. The name shall be declared in global namespace scope or shall be a name whose declaration is visible in global scope because of a using-directive (6.4.3.2). The use of :: allows a global name to be referred to even if its identifier has been hidden (6.3.10).

5 A name prefixed by a nested-name-specifier that nominates an enumeration type shall represent an enumerator of that enumeration.

6 If a pseudo-destructor-name (7.6.1.4) contains a nested-name-specifier, the type-names are looked up as types in the scope designated by the nested-name-specifier. Similarly, in a qualified-id of the form:

```
nested-name-specifier opt class-name :: ~ class-name
```
the second class-name is looked up in the same scope as the first. [Example:

```c
struct C {
    typedef int I;
};
typedef int I1, I2;
extern int* p;
extern int* q;
p->C::I::~I();  // I is looked up in the scope of C
q->I1::~I2();   // I2 is looked up in the scope of the postfix-expression
```

— end example] 6 [Note: 6.4.5 describes how name lookup proceeds after the . and -> operators. — end note]

6.4.3.1 Class members [class.qual]

1 If the nested-name-specifier of a qualified-id nominates a class, the name specified after the nested-name-specifier is looked up in the scope of the class (10.7), except for the cases listed below. The name shall represent one or more members of that class or of one of its base classes (10.6). [Note: A class member can be referred to using a qualified-id at any point in its potential scope (6.3.7). — end note] The exceptions to the name lookup rule above are the following:

§ 6.4.3.1 40
(1.1) the lookup for a destructor is as specified in 6.4.3;
(1.2) a conversion-type-id of a conversion-function-id is looked up in the same manner as a conversion-type-id in a class member access (see 6.4.5);
(1.3) the names in a template-argument of a template-id are looked up in the context in which the entire postfix-expression occurs.
(1.4) the lookup for a name specified in a using-declaration (9.8) also finds class or enumeration names hidden within the same scope.

In a lookup in which function names are not ignored and the nested-name-specifier nominates a class C:

(2.1) if the name specified after the nested-name-specifier, when looked up in C, is the injected-class-name of C (Clause 10), or
(2.2) in a using-declarator of a using-declaration (9.8) that is a member-declaration, if the name specified after the nested-name-specifier is the same as the identifier or the simple-template-id’s template-name in the last component of the nested-name-specifier,

the name is instead considered to name the constructor of class C. [Note: For example, the constructor is not an acceptable lookup result in an elaborated-type-specifier so the constructor would not be used in place of the injected-class-name. — end note] Such a constructor name shall be used only in the declarator-id of a declaration that names a constructor or in a using-declaration. [Example:

```cpp
struct A { A(); }
struct B: public A { B(); }

A::A() { }
B::B() { }

B::A ba;  // object of type A
A::A a;   // error, A::A is not a type name
struct A::A a2;  // object of type A
```
—end example]

A class member name hidden by a name in a nested declarative region or by the name of a derived class member can still be found if qualified by the name of its class followed by the :: operator.

### 6.4.3.2 Namespace members

If the nested-name-specifier of a qualified-id nominates a namespace (including the case where the nested-name-specifier is ::; i.e., nominating the global namespace), the name specified after the nested-name-specifier is looked up in the scope of the namespace. The names in a template-argument of a template-id are looked up in the context in which the entire postfix-expression occurs.

For a namespace X and name m, the namespace-qualified lookup set S(X, m) is defined as follows: Let S′(X, m) be the set of all declarations of m in X and the inline namespace set of X (9.7.1). If S′(X, m) is not empty, S(X, m) is S′(X, m); otherwise, S(X, m) is the union of S(Ni, m) for all namespaces Ni nominated by using-directives in X and its inline namespace set.

Given X::m (where X is a user-declared namespace), or given ::m (where X is the global namespace), if S(X, m) is the empty set, the program is ill-formed. Otherwise, if S(X, m) has exactly one member, or if the context of the reference is a using-declaration (9.8), S(X, m) is the required set of declarations of m. Otherwise if the use of m is not one that allows a unique declaration to be chosen from S(X, m), the program is ill-formed. [Example:

```cpp
int x;
namespace Y {
    void f(float);
    void h(int);
}

namespace Z {
    void h(double);
}
```

29) Lookups in which function names are ignored include names appearing in a nested-name-specifier, an elaborated-type-specifier, or a base-specifier.
namespace A {
    using namespace Y;
    void f(int);
    void g(int);
    int i;
}

amespace B {
    using namespace Z;
    void f(char);
    int i;
}

namespace AB {
    using namespace A;
    using namespace B;
    void g();
}

void h() {
    AB::g();  // g is declared directly in AB, therefore S is {AB::g()} and AB::g() is chosen
    AB::f(1);  // f is not declared directly in AB so the rules are applied recursively to A and B;
                // namespace Y is not searched and Y::f(float) is not considered;
                // S is {A::f(int), B::f(char)} and overload resolution chooses A::f(int)
    AB::f('c');  // as above but resolution chooses B::f(char)
    AB::x++;    // x is not declared directly in AB, and is not declared in A or B, so the rules
                // are applied recursively to Y and Z, S is {} so the program is ill-formed
    AB::i++;    // i is not declared directly in AB so the rules are applied recursively to A and B,
                // S is {A::i, B::i} so the use is ambiguous and the program is ill-formed
    AB::h(16.8);  // h is not declared directly in AB and not declared directly in A or B so the rules
                   // are applied recursively to Y and Z, S is {Y::h(int), Z::h(double)} and
                   // overload resolution chooses Z::h(double)
}

—end example] 4

[Note: The same declaration found more than once is not an ambiguity (because it is still a unique declaration).

[Example:

namespace A {
    int a;
}

namespace B {
    using namespace A;
}

namespace C {
    using namespace A;
}

namespace BC {
    using namespace B;
    using namespace C;
}

void f() {
    BC::a++;  // OK: S is {A::a, A::a}
namespace D {
    using A::a;
}

namespace BD {
    using namespace B;
    using namespace D;
}

void g()
{
    BD::a++;
    // OK: S is {A::a, A::a}
}

—end example —end note

5 [Example: Because each referenced namespace is searched at most once, the following is well-defined:

namespace B {
    int b;
}

namespace A {
    using namespace B;
    int a;
}

namespace B {
    using namespace A;
}

void f()
{
    A::a++;
    // OK: a declared directly in A, S is {A::a}
    B::a++;
    // OK: both A and B searched (once), S is {A::a}
    A::b++;
    // OK: both A and B searched (once), S is {B::b}
    B::b++;
    // OK: b declared directly in B, S is {B::b}
}

—end example]}

6 During the lookup of a qualified namespace member name, if the lookup finds more than one declaration of
the member, and if one declaration introduces a class name or enumeration name and the other declarations
either introduce the same variable, the same enumerator or a set of functions, the non-type name hides
the class or enumeration name if and only if the declarations are from the same namespace; otherwise (the
declarations are from different namespaces), the program is ill-formed. [Example:

namespace A {
    struct x {};
    int x;
    int y;
}

namespace B {
    struct y {};
}

namespace C {
    using namespace A;
    using namespace B;
    int i = C::x;  // OK, A::x (of type int)
    int j = C::y;  // ambiguous, A::y or B::y
}

—end example]
In a declaration for a namespace member in which the declarator-id is a qualified-id, given that the qualified-id for the namespace member has the form

\[ \text{qualified-id} \]

the unqualified-id shall name a member of the namespace designated by the \text{nested-name-specifier} or of an element of the inline namespace set (9.7.1) of that namespace. [Example:

```cpp
namespace A {
    namespace B {
        void f1(int);
    }
    using namespace B;
}
void A::f1(int){ }  // ill-formed, f1 is not a member of A
```
— end example] However, in such namespace member declarations, the \text{nested-name-specifier} may rely on using-directives to implicitly provide the initial part of the \text{nested-name-specifier}. [Example:

```cpp
namespace A {
    namespace B {
        void f1(int);
    }
}
namespace C {
    namespace D {
        void f1(int);
    }
}
using namespace A;
using namespace C::D;
void B::f1(int){ }  // OK, defines A::B::f1(int)
```
— end example]

### 6.4.4 Elaborated type specifiers

An elaborated-type-specifier (9.1.7.3) may be used to refer to a previously declared class-name or enum-name even though the name has been hidden by a non-type declaration (6.3.10).

If the elaborated-type-specifier has no nested-name-specifier, and unless the elaborated-type-specifier appears in a declaration with the following form:

\[ \text{class-key} \text{ attribute-specifier-seq}_a \text{opt} \text{ identifier} \]

the identifier is looked up according to 6.4.1 but ignoring any non-type names that have been declared. If the elaborated-type-specifier is introduced by the \text{enum} keyword and this lookup does not find a previously declared type-name, the elaborated-type-specifier is ill-formed. If the elaborated-type-specifier is introduced by the class-key and this lookup does not find a previously declared type-name, or if the elaborated-type-specifier appears in a declaration with the form:

\[ \text{class-key} \text{ attribute-specifier-seq}_a \text{opt} \text{ identifier} \]

the elaborated-type-specifier is a declaration that introduces the class-name as described in 6.3.2.

If the elaborated-type-specifier has a nested-name-specifier, qualified name lookup is performed, as described in 6.4.3, but ignoring any non-type names that have been declared. If the name lookup does not find a previously declared type-name, the elaborated-type-specifier is ill-formed. [Example:

```cpp
struct Node {
    struct Node* Next;  // OK: Refers to Node at global scope
    struct Data* Data;  // OK: Declares type Data at global scope and member Data
};

struct Data {
    struct Node* Node;  // OK: Refers to Node at global scope
    friend struct ::Glob;  // error: Glob is not declared, cannot introduce a qualified type (9.1.7.3)
    friend struct Glob;  // OK: Refers to (as yet) undeclared Glob at global scope.
```
struct Base {
    struct Data; // OK: Declares nested Data
    struct ::Data* thatData; // OK: Refers to ::Data
    struct Base::Data* thisData; // OK: Refers to nested Data
    friend class ::Data; // OK: global Data is a friend
    friend class Data; // OK: nested Data is a friend
    struct Data { /* ... */ }; // Defines nested Data
};

struct Data; // OK: Redeclares Data at global scope
struct ::Data; // error: cannot introduce a qualified type (9.1.7.3)
struct Base::Data; // error: cannot introduce a qualified type (9.1.7.3)
struct Base::Datum; // error: Datum undefined
struct Base::Data* pBase; // OK: refers to nested Data

—end example

6.4.5 Class member access

In a class member access expression (7.6.1.5), if the . or \(-\rightarrow\) token is immediately followed by an identifier followed by a <, the identifier must be looked up to determine whether the < is the beginning of a template argument list (12.2) or a less-than operator. The identifier is first looked up in the class of the object expression. If the identifier is not found, it is then looked up in the context of the entire postfix-expression and shall name a class template.

If the id-expression in a class member access (7.6.1.5) is an unqualified-id, and the type of the object expression is of a class type \(C\), the unqualified-id is looked up in the scope of class \(C\). For a pseudo-destructor call (7.6.1.4), the unqualified-id is looked up in the context of the complete postfix-expression. [Example:

```cpp
struct A { }

struct B {
    struct A { }
    void f(::A* a);
};

void B::f(::A* a) {
    a->A(); // OK: lookup in *a finds the injected-class-name
}
—end example]

If the id-expression in a class member access is a qualified-id of the form

```
class-name-or-namespace-name::...
```

the class-name-or-namespace-name following the . or -> operator is first looked up in the class of the object expression and the name, if found, is used. Otherwise it is looked up in the context of the entire postfix-expression. [Note: See 6.4.3, which describes the lookup of a name before ::, which will only find a type or namespace name. — end note]

If the qualified-id has the form

```
::class-name-or-namespace-name::...
```

the class-name-or-namespace-name is looked up in global scope as a class-name or namespace-name.

If the nested-name-specifier contains a simple-template-id (12.2), the names in its template-arguments are looked up in the context in which the entire postfix-expression occurs.

If the id-expression is a conversion-function-id, its conversion-type-id is first looked up in the class of the object expression and the name, if found, is used. Otherwise it is looked up in the context of the entire
postfix-expression. In each of these lookups, only names that denote types or templates whose specializations are types are considered. [Example:

```
struct A { }
namespace N {
    struct A {
        void g() {}
        template <class T> operator T();
    };
}

int main() {
    N::A a;
    a.operator A(); // calls N::A::operator N::A
}
```
—end example]

6.4.6 Using-directives and namespace aliases

In a using-directive or namespace-alias-definition, during the lookup for a namespace-name or for a name in a nested-name-specifier only namespace names are considered.

6.5 Program and linkage

A program consists of one or more translation units (Clause 5) linked together. A translation unit consists of a sequence of declarations.

```
translation-unit:
    declaration-seqopt
```

A name is said to have linkage when it might denote the same object, reference, function, type, template, namespace or value as a name introduced by a declaration in another scope:

1. When a name has external linkage, the entity it denotes can be referred to by names from scopes of other translation units or from other scopes of the same translation unit.

2. When a name has internal linkage, the entity it denotes can be referred to by names from other scopes in the same translation unit.

3. When a name has no linkage, the entity it denotes cannot be referred to by names from other scopes.

A name having namespace scope (6.3.6) has internal linkage if it is the name of:

1. A variable, function or function template that is explicitly declared static; or,

2. A non-inline variable of non-volatile const-qualified type that is neither explicitly declared extern nor previously declared to have external linkage; or

3. A data member of an anonymous union.

An unnamed namespace or a namespace declared directly or indirectly within an unnamed namespace has internal linkage. All other namespaces have external linkage. A name having namespace scope that has not been given internal linkage above has the same linkage as the enclosing namespace if it is the name of:

1. A variable; or

2. A function; or

3. A named class (Clause 10), or an unnamed class defined in a typedef declaration in which the class has the typedef name for linkage purposes (9.1.3); or

4. A named enumeration (9.6), or an unnamed enumeration defined in a typedef declaration in which the enumeration has the typedef name for linkage purposes (9.1.3); or

5. A template.

In addition, a member function, static data member, a named class or enumeration of class scope, or an unnamed class or enumeration defined in a class-scope typedef declaration such that the class or enumeration has the typedef name for linkage purposes (9.1.3), has the same linkage, if any, as the name of the class of which it is a member.

The name of a function declared in block scope and the name of a variable declared by a block scope extern declaration have linkage. If there is a visible declaration of an entity with linkage having the same name and
type, ignoring entities declared outside the innermost enclosing namespace scope, the block scope declaration declares that same entity and receives the linkage of the previous declaration. If there is more than one such matching entity, the program is ill-formed. Otherwise, if no matching entity is found, the block scope entity receives external linkage. If, within a translation unit, the same entity is declared with both internal and external linkage, the program is ill-formed. [Example:

```c
static void f();
static int i = 0; // #1
void g() {
    extern void f(); // internal linkage
    int i; // #2: i has no linkage
    {
        extern void f(); // internal linkage
        extern int i; // #3: external linkage, ill-formed
    }
}
```

Without the declaration at line #2, the declaration at line #3 would link with the declaration at line #1. Because the declaration with internal linkage is hidden, however, #3 is given external linkage, making the program ill-formed. —end example]

When a block scope declaration of an entity with linkage is not found to refer to some other declaration, then that entity is a member of the innermost enclosing namespace. However such a declaration does not introduce the member name in its namespace scope. [Example:

```c
namespace X {
    void p() {
        q(); // error: q not yet declared
    }
}
void middle() {
    q(); // error: q not yet declared
}
void q() { /* ... */ } // definition of X::q
void q() { /* ... */ } // some other, unrelated q

—end example]

Names not covered by these rules have no linkage. Moreover, except as noted, a name declared at block scope (6.3.3) has no linkage.

A type is said to have linkage if and only if:

1. it is a class or enumeration type that is named (or has a name for linkage purposes (9.1.3)) and the name has linkage; or
2. it is an unnamed class or unnamed enumeration that is a member of a class with linkage; or
3. it is a specialization of a class template (Clause 12)\(^\text{30}\); or
4. it is a fundamental type (6.7.1); or
5. it is a compound type (6.7.2) other than a class or enumeration, compounded exclusively from types that have linkage; or
6. it is a cv-qualified (6.7.3) version of a type that has linkage.

[Note: In other words, a type without linkage contains a class or enumeration that cannot be named outside its translation unit. Classes with linkage may contain members whose types do not have linkage. Typedef names are ignored in the determination of whether a type has linkage. —end note]

[Example:

```c
template <class T> struct B {
    void g(T) {}
}
```

\(^{30}\) A class template has the linkage of the innermost enclosing class or namespace in which it is declared.
void h(T);
friend void i(B, T) { }
);

void f() {
  struct A { int x; }; // no linkage
  A a = { 1 };
  B<A> ba; // declares B<A>::g(A) and B<A>::h(A)
  ba.g(a); // OK
  ba.h(a); // error: B<A>::h(A) not defined; A cannot be named in another translation unit
  i(ba, a); // OK
}
— end example

10 Two names that are the same (Clause 6) and that are declared in different scopes shall denote the same
variable, function, type, template or namespace if

(10.1) — both names have external linkage or else both names have internal linkage and are declared in the same
translaction unit; and

(10.2) — both names refer to members of the same namespace or to members, not by inheritance, of the same
class; and

(10.3) — when both names denote functions, the parameter-type-lists of the functions (9.2.3.5) are identical; and

(10.4) — when both names denote function templates, the signatures (12.6.6.1) are the same.

11 After all adjustments of types (during which typedefs (9.1.3) are replaced by their definitions), the types
specified by all declarations referring to a given variable or function shall be identical, except that declarations
for an array object can specify array types that differ by the presence or absence of a major array bound (9.2.3.4).
A violation of this rule on type identity does not require a diagnostic.

12 [Note: Linkage to non-C++ declarations can be achieved using a linkage-specification (9.10). — end note]

6.6 Memory and objects
6.6.1 Memory model

1 The fundamental storage unit in the C++ memory model is the byte. A byte is at least large enough to contain
any member of the basic execution character set (5.3) and the eight-bit code units of the Unicode UTF-8
encoding form and is composed of a contiguous sequence of bits, the number of which is implementation-
defined. The least significant bit is called the low-order bit; the most significant bit is called the high-order
bit. The memory available to a C++ program consists of one or more sequences of contiguous bytes. Every
byte has a unique address.

2 [Note: The representation of types is described in 6.7. — end note]

3 A memory location is either an object of scalar type or a maximal sequence of adjacent bit-fields all having
nonzero width. [Note: Various features of the language, such as references and virtual functions, might involve
additional memory locations that are not accessible to programs but are managed by the implementation.
— end note] Two or more threads of execution (6.8.2) can access separate memory locations without interfering
with each other.

4 [Note: Thus a bit-field and an adjacent non-bit-field are in separate memory locations, and therefore can be
concurrently updated by two threads of execution without interference. The same applies to two bit-fields,
if one is declared inside a nested struct declaration and the other is not, or if the two are separated by a
zero-length bit-field declaration, or if they are separated by a non-bit-field declaration. It is not safe to
concurrently update two bit-fields in the same struct if all fields between them are also bit-fields of nonzero
width. — end note]

5 [Example: A structure declared as
  struct {
    char a;

31) The number of bits in a byte is reported by the macro CHAR_BIT in the header <climits>.
int b:5,
c:11,
d:8;
struct {int ee:8;} e;
}

contains four separate memory locations: The member a and bit-fields d and e.ee are each separate memory locations, and can be modified concurrently without interfering with each other. The bit-fields b and c together constitute the fourth memory location. The bit-fields b and c cannot be concurrently modified, but b and a, for example, can be. —end example]

6.6.2 Object model

The constructs in a C++ program create, destroy, refer to, access, and manipulate objects. An object is created by a definition (6.1), by a new-expression (7.6.2.4), when implicitly changing the active member of a union (10.4), or when a temporary object is created (7.3.4, 6.6.6). An object occupies a region of storage in its period of construction (10.9.4), throughout its lifetime (6.6.3), and in its period of destruction (10.9.4). [Note: A function is not an object, regardless of whether or not it occupies storage in the way that objects do. — end note] The properties of an object are determined when the object is created. An object can have a name (Clause 6). An object has a storage duration (6.6.4) which influences its lifetime (6.6.3). An object has a type (6.7). Some objects are polymorphic (10.6.2); the implementation generates information associated with each such object that makes it possible to determine that object’s type during program execution. For other objects, the interpretation of the values found therein is determined by the type of the expressions (7.6) used to access them.

Objects can contain other objects, called subobjects. A subobject can be a member subobject (10.3), a base class subobject (10.6), or an array element. An object that is not a subobject of any other object is called a complete object. If an object is created in storage associated with a member subobject or array element e (which may or may not be within its lifetime), the created object is a subobject of e’s containing object if:

(2.1) — the lifetime of e’s containing object has begun and not ended, and
(2.2) — the storage for the new object exactly overlays the storage location associated with e, and
(2.3) — the new object is of the same type as e (ignoring cv-qualification).

[Note: If the subobject contains a reference member or a const subobject, the name of the original subobject cannot be used to access the new object (6.6.3). —end note] [Example:

struct X { const int n; };
union U { X x; float f; };
void tong() {
    U u = {{ 1 }}; // OK, creates new subobject of u (10.4)
    u.f = 5.f;
    X *p = new (ku.x) X {2}; // OK, creates new subobject of u
    assert(p->n == 2); // OK
    assert(*std::launder(&u.x.n) == 2); // OK
    assert(u.x.n == 2); // undefined behavior, u.x does not name new subobject
}
—end example]

If a complete object is created (7.6.2.4) in storage associated with another object e of type “array of N unsigned char” or of type “array of N std::byte” (16.2.1), that array provides storage for the created object if:

(3.1) — the lifetime of e has begun and not ended, and
(3.2) — the storage for the new object fits entirely within e, and
(3.3) — there is no smaller array object that satisfies these constraints.

[Note: If that portion of the array previously provided storage for another object, the lifetime of that object ends because its storage was reused (6.6.3). — end note] [Example:

template<typename ...T>
struct AlignedUnion {
    alignas(T...) unsigned char data[max(sizeof(T)...)];
};
int f() {
    AlignedUnion<int, char> au;
    int *p = new (au.data) int; // OK, au.data provides storage
    char *c = new (au.data) char(); // OK, ends lifetime of *p
    char *d = new (au.data + 1) char();
    return *c + *d; // OK
}

struct A { unsigned char a[32]; }; struct B { unsigned char b[16]; }; A a;
B *b = new (a.a + 8) B; // a.a provides storage for *b
int *p = new (b->b + 4) int; // b->b provides storage for *p
// a.a does not provide storage for *p (directly),
// but *p is nested within a (see below)

/* end example */

4 An object a is nested within another object b if:
   (4.1) a is a subobject of b, or
   (4.2) b provides storage for a, or
   (4.3) there exists an object c where a is nested within c, and c is nested within b.

5 For every object x, there is some object called the complete object of x, determined as follows:
   (5.1) If x is a complete object, then the complete object of x is itself.
   (5.2) Otherwise, the complete object of x is the complete object of the (unique) object that contains x.

6 If a complete object, a data member (10.3), or an array element is of class type, its type is considered the most derived class, to distinguish it from the class type of any base class subobject; an object of a most derived class type or of a non-class type is called a most derived object.

7 A potentially-overlapping subobject is either:
   (7.1) a base class subobject, or
   (7.2) a non-static data member declared with the no_unique_address attribute (9.11.11).

8 An object has nonzero size if it
   (8.1) is not a potentially-overlapping subobject, or
   (8.2) is not of class type, or
   (8.3) is of a class type with virtual member functions or virtual base classes, or
   (8.4) has subobjects of nonzero size or bit-fields of nonzero length.

   Otherwise, if the object is a base class subobject of a standard-layout class type with no non-static data members, it has zero size. Otherwise, the circumstances under which the object has zero size are implementation-defined. Unless it is a bit-field (10.3.10), an object with nonzero size shall occupy one or more bytes of storage, including every byte that is occupied in full or in part by any of its subobjects. An object of trivially copyable or standard-layout type (6.7) shall occupy contiguous bytes of storage.

9 Unless an object is a bit-field or a subobject of zero size, the address of that object is the address of the first byte it occupies. Two objects with overlapping lifetimes that are not bit-fields may have the same address if one is nested within the other, or if at least one is a subobject of zero size and they are of different types; otherwise, they have distinct addresses and occupy disjoint bytes of storage.32 [Example:
   static const char test1 = 'x';
   static const char test2 = 'x';
   const bool b = &test1 != &test2; // always true
   /* end example */ The address of a non-bit-field subobject of zero size is the address of an unspecified byte of storage occupied by the complete object of that subobject.

10 [Note: C++ provides a variety of fundamental types and several ways of composing new types from existing types (6.7). — end note]
6.6.3 Object lifetime

The lifetime of an object or reference is a runtime property of the object or reference. An object is said to have non-vacuous initialization if it is of a class or aggregate type and it or one of its subobjects is initialized by a constructor other than a trivial default constructor. [Note: Initialization by a trivial copy/move constructor is non-vacuous initialization. —end note] The lifetime of an object of type T begins when:

- storage with the proper alignment and size for type T is obtained, and
- if the object has non-vacuous initialization, its initialization is complete,
  except that if the object is a union member or subobject thereof, its lifetime only begins if that union member is the initialized member in the union (9.3.1, 10.9.2), or as described in 10.4. The lifetime of an object o of type T ends when:
  - if T is a class type with a non-trivial destructor (10.3.7), the destructor call starts, or
  - the storage which the object occupies is released, or is reused by an object that is not nested within o (6.6.2).

The lifetime of a reference begins when its initialization is complete. The lifetime of a reference ends as if it were a scalar object.

[Note: 10.9.2 describes the lifetime of base and member subobjects. —end note]

The properties ascribed to objects and references throughout this document apply for a given object or reference only during its lifetime. [Note: In particular, before the lifetime of an object starts and after its lifetime ends there are significant restrictions on the use of the object, as described below, in 10.9.2 and in 10.9.4. Also, the behavior of an object under construction and destruction might not be the same as the behavior of an object whose lifetime has started and not ended. 10.9.2 and 10.9.4 describe the behavior of objects during the construction and destruction phases. —end note]

A program may end the lifetime of any object by reusing the storage which the object occupies or by explicitly calling the destructor for an object of a class type with a non-trivial destructor. For an object of a class type with a non-trivial destructor, the program is not required to call the destructor explicitly before the storage which the object occupies is reused or released; however, if there is no explicit call to the destructor or if a delete-expression (7.6.2.5) is not used to release the storage, the destructor shall not be implicitly called and any program that depends on the side effects produced by the destructor has undefined behavior.

Before the lifetime of an object has started but after the storage which the object will occupy has been allocated or, after the lifetime of an object has ended and before the storage which the object occupied is reused or released, any pointer that represents the address of the storage location where the object will be or was located may be used but only in limited ways. For an object under construction or destruction, see 10.9.4. Otherwise, such a pointer refers to allocated storage (6.6.4.4.1), and using the pointer as if the pointer were of type void*, is well-defined. Indirection through such a pointer is permitted but the resulting value may only be used in limited ways, as described below. The program has undefined behavior if:

- the object will be or was of a class type with a non-trivial destructor and the pointer is used as the operand of a delete-expression,
- the pointer is used to access a non-static data member or call a non-static member function of the object, or
- the pointer is implicitly converted (7.3.11) to a pointer to a virtual base class, or
- the pointer is used as the operand of a static_cast (7.6.1.9), except when the conversion is to pointer to cv void, or to pointer to cv void and subsequently to pointer to cv char, cv unsigned char, or cv std::byte (16.2.1), or
- the pointer is used as the operand of a dynamic_cast (7.6.1.7).

[Example:

```c
#include <cstdlib>

struct B {
    virtual void f();
    void mutate();
```
](33) For example, before the construction of a global object that is initialized via a user-provided constructor (10.9.4).
virtual ~B();
;
struct D1 : B { void f(); };  
struct D2 : B { void f(); };  

void B::mutate() {
    new (this) D2;  // reuses storage — ends the lifetime of *this
    f();  // undefined behavior
    ... = this;  // OK, this points to valid memory
}

void g() {
    void* p = std::malloc(sizeof(D1) + sizeof(D2));
    B* pb = new (p) D1;
    pb->mutate();
    *pb;  // OK: pb points to valid memory
    void* q = pb;  // OK: pb points to valid memory
    pb->f();  // undefined behavior, lifetime of *pb has ended
}

— end example]  

Similarly, before the lifetime of an object has started but after the storage which the object will occupy has been allocated or, after the lifetime of an object has ended and before the storage which the object occupied is reused or released, any glvalue that refers to the original object may be used but only in limited ways. For an object under construction or destruction, see 10.9.4. Otherwise, such a glvalue refers to allocated storage (6.6.4.4.1), and using the properties of the glvalue that do not depend on its value is well-defined. The program has undefined behavior if:

(7.1) — the glvalue is used to access the object, or
(7.2) — the glvalue is used to call a non-static member function of the object, or
(7.3) — the glvalue is bound to a reference to a virtual base class (9.3.3), or
(7.4) — the glvalue is used as the operand of a dynamic_cast (7.6.1.7) or as the operand of typeid.

If, after the lifetime of an object has ended and before the storage which the object occupied is reused or released, a new object is created at the storage location which the original object occupied, a pointer that pointed to the original object, a reference that referred to the original object, or the name of the original object will automatically refer to the new object and, once the lifetime of the new object has started, can be used to manipulate the new object, if:

(8.1) — the storage for the new object exactly overlays the storage location which the original object occupied, and
(8.2) — the new object is of the same type as the original object (ignoring the top-level cv-qualifiers), and
(8.3) — the type of the original object is not const-qualified, and, if a class type, does not contain any non-static data member whose type is const-qualified or a reference type, and
(8.4) — neither the original object nor the new object is a potentially-overlapping subobject (6.6.2).

[Example:
    struct C {
        int i;
        void f();
        const C& operator=( const C& );
    };

    const C& C::operator=( const C& other ) {
        if ( this != &other ) {
            this->~C();  // lifetime of *this ends
            new (this) C(other);  // new object of type C created
            f();  // well-defined
        }
        return *this;
    }

§ 6.6.3
If a program ends the lifetime of an object of type \( T \) with static (6.6.4.1), thread (6.6.4.2), or automatic (6.6.4.3) storage duration and if \( T \) has a non-trivial destructor, the program must ensure that an object of the original type occupies that same storage location when the implicit destructor call takes place; otherwise the behavior of the program is undefined. This is true even if the block is exited with an exception. [Example:

```cpp
class T { };  
struct B {
    ~B();
};

void h() {
    B b;
    new (&b) T;  // undefined behavior at block exit
}
```

—end example] [Note: Therefore, undefined behavior results if an object that is being constructed in one thread is referenced from another thread without adequate synchronization. — end note]

Creating a new object within the storage that a const complete object with static, thread, or automatic storage duration occupies, or within the storage that such a const object used to occupy before its lifetime ended, results in undefined behavior. [Example:

```cpp
struct B {
    B();
    ~B();
};

const B b;

void h() {
    b.~B();
    new (const_cast<B*>(\&b)) const B;  // undefined behavior
}
```

—end example]

In this subclause, “before” and “after” refer to the “happens before” relation (6.8.2). [Note: Therefore, undefined behavior results if an object that is being constructed in one thread is referenced from another thread without adequate synchronization. — end note]

### 6.6.4 Storage duration

The **storage duration** is the property of an object that defines the minimum potential lifetime of the storage containing the object. The storage duration is determined by the construct used to create the object and is one of the following:

1. **static storage duration**
2. **thread storage duration**
3. **automatic storage duration**
4. **dynamic storage duration**

Static, thread, and automatic storage durations are associated with objects introduced by declarations (6.1) and implicitly created by the implementation (6.6.6). The dynamic storage duration is associated with objects created by a `new-expression` (7.6.2.4).

The storage duration categories apply to references as well.

34) That is, an object for which a destructor will be called implicitly—upon exit from the block for an object with automatic storage duration, upon exit from the thread for an object with thread storage duration, or upon exit from the program for an object with static storage duration.
When the end of the duration of a region of storage is reached, the values of all pointers representing the address of any part of that region of storage become invalid pointer values (6.7.2). Indirection through an invalid pointer value and passing an invalid pointer value to a deallocation function have undefined behavior. Any other use of an invalid pointer value has implementation-defined behavior.35

### 6.6.4.1 Static storage duration

1. All variables which do not have dynamic storage duration, do not have thread storage duration, and are not local have static storage duration. The storage for these entities shall last for the duration of the program (6.8.3.2, 6.8.3.4).

2. If a variable with static storage duration has initialization or a destructor with side effects, it shall not be eliminated even if it appears to be unused, except that a class object or its copy/move may be eliminated as specified in 10.9.5.

3. The keyword static can be used to declare a local variable with static storage duration. [Note: 8.7 describes the initialization of local static variables; 6.8.3.4 describes the destruction of local static variables. — end note]

4. The keyword static applied to a class data member in a class definition gives the data member static storage duration.

### 6.6.4.2 Thread storage duration

1. All variables declared with the thread_local keyword have thread storage duration. The storage for these entities shall last for the duration of the thread in which they are created. There is a distinct object or reference per thread, and use of the declared name refers to the entity associated with the current thread.

2. A variable with thread storage duration shall be initialized before its first odr-use (6.2) and, if constructed, shall be destroyed on thread exit.

### 6.6.4.3 Automatic storage duration

1. Block-scope variables not explicitly declared static, thread_local, or extern have automatic storage duration. The storage for these entities lasts until the block in which they are created exits.

2. [Note: These variables are initialized and destroyed as described in 8.7. — end note]

3. If a variable with automatic storage duration has initialization or a destructor with side effects, an implementation shall not destroy it before the end of its block nor eliminate it as an optimization, even if it appears to be unused, except that a class object or its copy/move may be eliminated as specified in 10.9.5.

### 6.6.4.4 Dynamic storage duration

1. Objects can be created dynamically during program execution (6.8.1), using new-expressions (7.6.2.4), and destroyed using delete-expressions (7.6.2.5). A C++ implementation provides access to, and management of, dynamic storage via the global allocation functions operator new and operator new[] and the global deallocation functions operator delete and operator delete[]. [Note: The non-allocating forms described in 16.6.2.3 do not perform allocation or deallocation. — end note]

2. The library provides default definitions for the global allocation and deallocation functions. Some global allocation and deallocation functions are replaceable (16.6.2). A C++ program shall provide at most one definition of a replaceable allocation or deallocation function. Any such function definition replaces the default version provided in the library (15.5.4.6). The following allocation and deallocation functions (16.6) are implicitly declared in global scope in each translation unit of a program.

```cpp
[[nodiscard]] void* operator new(std::size_t);
[[nodiscard]] void* operator new(std::size_t, std::align_val_t);

void operator delete(void*) noexcept;
void operator delete(void*, std::size_t) noexcept;
void operator delete(void*, std::align_val_t) noexcept;
void operator delete(void*, std::size_t, std::align_val_t) noexcept;

[[nodiscard]] void* operator new[](std::size_t);
[[nodiscard]] void* operator new[](std::size_t, std::align_val_t);
```

35 Some implementations might define that copying an invalid pointer value causes a system-generated runtime fault.
An allocation function attempts to allocate the requested amount of storage. If it is successful, it returns the address of the start of a block of storage whose length in bytes is at least as large as the requested size. The order, contiguity, and initial value of storage allocated by successive calls to an allocation function are unspecified. For an allocation function other than a reserved placement allocation function (16.6.2.3), the pointer returned is suitably aligned so that it can be converted to a pointer to any suitable complete object type (16.6.2.1) and then used to access the object or array in the storage allocated (until the storage is explicitly deallocated by a call to a corresponding deallocation function). Even if the size of the space requested is zero, the request can fail. If the request succeeds, the value returned by a replaceable allocation function is a non-null pointer value (7.3.11) different from any previously returned value \( p_0 \), unless that value \( p_1 \) was subsequently passed to a replaceable deallocation function. Furthermore, for the library allocation functions in 16.6.2.1 and 16.6.2.2, \( p_0 \) represents the address of a block of storage disjoint from the storage for any other object accessible to the caller. The effect of indirecting through a pointer returned from a request for zero size is undefined.\(^{36}\)

An allocation function that fails to allocate storage can invoke the currently installed new-handler function (16.6.3.3), if any. \([\textit{Note: A program-supplied allocation function can obtain the address of the currently installed new_handler using the std::get_new_handler function (16.6.3.4). — end note}]\) An allocation function that has a non-throwing exception specification (13.4) indicates failure by returning a null pointer value. Any other allocation function never returns a null pointer value and indicates failure only by throwing an exception (13.1) of a type that would match a handler (13.3) of type std::bad_alloc (16.6.3.1). \([\textit{Note: In particular, a global allocation function is not called to allocate storage for objects with static storage duration (6.6.4.1), for objects or references with thread storage duration (6.6.4.2), for objects of type std::type_info (7.6.1.8), or for an exception object (13.1). — end note}]\)

A global allocation function is only called as the result of a new expression (7.6.2.4), or called directly using a new-expression, delete-expression or function call that refers to one of these functions without including the header <new> is well-formed. However, referring to std or std::size_t or std::align_val_t is ill-formed unless the name has been declared by including the appropriate header. \([\textit{— end note}]\) Allocation and/or deallocation functions may also be declared and defined for any class (10.11).

If the behavior of an allocation or deallocation function does not satisfy the semantic constraints specified in 6.6.4.4.1 and 6.6.4.4.2, the behavior is undefined.

### 6.6.4.4.1 Allocation functions
\([\textit{basic.stc.dynamic.allocation}]\)

1 An allocation function shall be a class member function or a global function; a program is ill-formed if an allocation function is declared in a namespace scope other than global scope or declared static in global scope. The return type shall be \( \text{void*} \). The first parameter shall have type \( \text{std::size_t} \) (16.2). The first parameter shall not have an associated default argument (9.2.3.6). The value of the first parameter is interpreted as the requested size of the allocation. An allocation function can be a function template. Such a template shall declare its return type and first parameter as specified above (that is, template parameter types shall not be used in the return type and first parameter type). Template allocation functions shall have two or more parameters.

2 An allocation function attempts to allocate the requested amount of storage. If it is successful, it returns the address of the start of a block of storage whose length in bytes is at least as large as the requested size. The order, contiguity, and initial value of storage allocated by successive calls to an allocation function are unspecified. For an allocation function other than a reserved placement allocation function (16.6.2.3), the pointer returned is suitably aligned so that it can be converted to a pointer to any suitable complete object type (16.6.2.1) and then used to access the object or array in the storage allocated (until the storage is explicitly deallocated by a call to a corresponding deallocation function). Even if the size of the space requested is zero, the request can fail. If the request succeeds, the value returned by a replaceable allocation function is a non-null pointer value (7.3.11) different from any previously returned value \( p_0 \), unless that value \( p_1 \) was subsequently passed to a replaceable deallocation function. Furthermore, for the library allocation functions in 16.6.2.1 and 16.6.2.2, \( p_0 \) represents the address of a block of storage disjoint from the storage for any other object accessible to the caller. The effect of indirecting through a pointer returned from a request for zero size is undefined.\(^{36}\)

An allocation function that fails to allocate storage can invoke the currently installed new-handler function (16.6.3.3), if any. \([\textit{Note: A program-supplied allocation function can obtain the address of the currently installed new_handler using the std::get_new_handler function (16.6.3.4). — end note}]\) An allocation function that has a non-throwing exception specification (13.4) indicates failure by returning a null pointer value. Any other allocation function never returns a null pointer value and indicates failure only by throwing an exception (13.1) of a type that would match a handler (13.3) of type std::bad_alloc (16.6.3.1). \([\textit{Note: In particular, a global allocation function is not called to allocate storage for objects with static storage duration (6.6.4.1), for objects or references with thread storage duration (6.6.4.2), for objects of type std::type_info (7.6.1.8), or for an exception object (13.1). — end note}]\)

### 6.6.4.4.2 Deallocation functions
\([\textit{basic.stc.dynamic.deallocation}]\)

1 Deallocation functions shall be class member functions or global functions; a program is ill-formed if deallocation functions are declared in a namespace scope other than global scope or declared static in global scope.

2 A deallocation function is a destroying operator delete if it has at least two parameters and its second parameter is of type \( \text{std::destroying_delete_t} \). A destroying operator delete shall be a class member

3 The intent is to have operator new() implementable by calling std::malloc() or std::calloc(), so the rules are substantially the same. C++ differs from C in requiring a zero request to return a non-null pointer.
function named \texttt{operator delete}. \[Note: \text{Array deletion cannot use a destroying operator delete. } — \text{end note}\]

Each deallocation function shall return \texttt{void}. If the function is a destroying \texttt{operator delete} declared in class type \texttt{C}, the type of its first parameter shall be \texttt{C*}; otherwise, the type of its first parameter shall be \texttt{void*}. A deallocation function may have more than one parameter. A \textit{usual deallocation function} is a deallocation function whose parameters after the first are

\begin{enumerate}
\item optionally, a parameter of type \texttt{std::destroying_delete_t}, then
\item optionally, a parameter of type \texttt{std::size_t} \footnote{The global \texttt{operator delete(void*, std::size_t)} precludes use of an allocation function \texttt{void operator new(std::size_t, std::align_val_t)} as a placement allocation function (C.3.2).}, then
\item optionally, a parameter of type \texttt{std::align_val_t}.
\end{enumerate}

A destroying \texttt{operator delete} shall be a usual deallocation function. A deallocation function may be an instance of a function template. Neither the first parameter nor the return type shall depend on a template parameter. A deallocation function template shall have two or more function parameters. A template instance is never a usual deallocation function, regardless of its signature.

If a deallocation function terminates by throwing an exception, the behavior is undefined. The value of the first argument supplied to a deallocation function may be a null pointer value; if so, and if the deallocation function is one supplied in the standard library, the call has no effect.

If the argument given to a deallocation function in the standard library is a pointer that is not the null pointer value (7.3.11), the deallocation function shall deallocate the storage referenced by the pointer, ending the duration of the region of storage.

\subsection*{6.6.4.4.3 Safely-derived pointers} \[\text{[basic.stc.dynamic.safety]}\]

1 A \textit{traceable pointer object} is

\begin{enumerate}
\item an object of an object pointer type (6.7.2), or
\item an object of an integral type that is at least as large as \texttt{std::intptr_t}, or
\item a sequence of elements in an array of narrow character type (6.7.1), where the size and alignment of the sequence match those of some object pointer type.
\end{enumerate}

2 A pointer value is a \textit{safely-derived pointer} to a dynamic object only if it has an object pointer type and it is one of the following:

\begin{enumerate}
\item the value returned by a call to the C++ standard library implementation of \texttt{::operator new(std::size_t)} or \texttt{::operator new(std::size_t, std::align_val_t)}; \footnote{This subclause does not impose restrictions on indirection through pointers to memory not allocated by \texttt{::operator new}. This maintains the ability of many C++ implementations to use binary libraries and components written in other languages. In particular, this applies to C binaries, because indirection through pointers to memory allocated by \texttt{std::malloc} is not restricted.}
\item the result of taking the address of an object (or one of its subobjects) designated by an lvalue resulting from indirectiation through a safely-derived pointer value;
\item the result of well-defined pointer arithmetic (7.6.6) using a safely-derived pointer value;
\item the result of a well-defined pointer conversion (7.3.11, 7.6.3) of a safely-derived pointer value;
\item the result of a \texttt{reinterpret_cast} of a safely-derived pointer value;
\item the result of a \texttt{reinterpret_cast} of an integer representation of a safely-derived pointer value;
\item the value of an object whose value was copied from a traceable pointer object, where at the time of the copy the source object contained a copy of a safely-derived pointer value.
\end{enumerate}

3 An integer value is an \textit{integer representation of a safely-derived pointer} only if its type is at least as large as \texttt{std::intptr_t} and it is one of the following:

\begin{enumerate}
\item the result of a \texttt{reinterpret_cast} of a safely-derived pointer value;
\item the result of a valid conversion of an integer representation of a safely-derived pointer value;
\item the value of an object whose value was copied from a traceable pointer object, where at the time of the copy the source object contained an integer representation of a safely-derived pointer value;
\end{enumerate}
— the result of an additive or bitwise operation, one of whose operands is an integer representation of a safely-derived pointer value P, if that result converted by reinterpret_cast<void*> would compare equal to a safely-derived pointer computable from reinterpret_cast<void*>(P).

An implementation may have relaxed pointer safety, in which case the validity of a pointer value does not depend on whether it is a safely-derived pointer value. Alternatively, an implementation may have strict pointer safety, in which case a pointer value referring to an object with dynamic storage duration that is not a safely-derived pointer value is an invalid pointer value unless the referenced complete object has previously been declared reachable (19.10.5). [Note: The effect of using an invalid pointer value (including passing it to a deallocation function) is undefined, see 6.6.4. This is true even if the unsafely-derived pointer value might compare equal to some safely-derived pointer value. — end note] It is implementation-defined whether an implementation has relaxed or strict pointer safety.

### 6.6.4.5 Duration of subobjects

The storage duration of subobjects and reference members is that of their complete object (6.6.2).

### 6.6.5 Alignment

Object types have alignment requirements (6.7.1, 6.7.2) which place restrictions on the addresses at which an object of that type may be allocated. An alignment is an implementation-defined integer value representing the number of bytes between successive addresses at which a given object can be allocated. An object type imposes an alignment requirement on every object of that type; stricter alignment can be requested using the alignment specifier (9.11.2).

A fundamental alignment is represented by an alignment less than or equal to the greatest alignment supported by the implementation in all contexts, which is equal to `alignof(std::max_align_t)` (16.2). The alignment required for a type might be different when it is used as the type of a complete object and when it is used as the type of a subobject. [Example:

```cpp
struct B { long double d; }
struct D : virtual B { char c; }
```

When `D` is the type of a complete object, it will have a subobject of type `B`, so it must be aligned appropriately for a `long double`. If `D` appears as a subobject of another object that also has `B` as a virtual base class, the `B` subobject might be part of a different subobject, reducing the alignment requirements on the `D` subobject. — end example] The result of the `alignof` operator reflects the alignment requirement of the type in the complete-object case.

An extended alignment is represented by an alignment greater than `alignof(std::max_align_t)`. It is implementation-defined whether any extended alignments are supported and the contexts in which they are supported (9.11.2). A type having an extended alignment requirement is an over-aligned type. [Note: Every over-aligned type is or contains a class type to which extended alignment applies (possibly through a non-static data member). — end note] A new-extended alignment is represented by an alignment greater than `_STDCPP_DEFAULT_NEW_ALIGNMENT_` (14.8).

Alignments are represented as values of the type `std::size_t`. Valid alignments include only those values returned by an `alignof` expression for the fundamental types plus an additional implementation-defined set of values, which may be empty. Every alignment value shall be a non-negative integral power of two.

Alignments have an order from weaker to stronger or stricter alignments. Stricter alignments have larger alignment values. An address that satisfies an alignment requirement also satisfies any weaker valid alignment requirement.

The alignment requirement of a complete type can be queried using an `alignof` expression (7.6.2.6). Furthermore, the narrow character types (6.7.1) shall have the weakest alignment requirement. [Note: This enables the narrow character types to be used as the underlying type for an aligned memory area (9.11.2). — end note]

Comparing alignments is meaningful and provides the obvious results:

1. Two alignments are equal when their numeric values are equal.
2. Two alignments are different when their numeric values are not equal.
3. When an alignment is larger than another it represents a stricter alignment.
8 [Note: The runtime pointer alignment function (19.10.6) can be used to obtain an aligned pointer within a buffer; the aligned-storage templates in the library (19.15.7.6) can be used to obtain aligned storage. — end note]

9 If a request for a specific extended alignment in a specific context is not supported by an implementation, the program is ill-formed.

6.6.6 Temporary objects

Temporary objects are created

- when a prvalue is materialized so that it can be used as a glvalue (7.3.4),
- when needed by the implementation to pass or return an object of trivially-copyable type (see below), and
- when throwing an exception (13.1). [Note: The lifetime of exception objects is described in 13.1. — end note]

Even when the creation of the temporary object is unevaluated (7.2), all the semantic restrictions shall be respected as if the temporary object had been created and later destroyed. [Note: This includes accessibility (10.8) and whether it is deleted, for the constructor selected and for the destructor. However, in the special case of the operand of a decltype-specifier (7.6.1.2), no temporary is introduced, so the foregoing does not apply to such a prvalue. — end note]

2 The materialization of a temporary object is generally delayed as long as possible in order to avoid creating unnecessary temporary objects. [Note: Temporary objects are materialized:

- when binding a reference to a prvalue (9.3.3, 7.6.1.3, 7.6.1.7, 7.6.1.9, 7.6.1.11, 7.6.3),
- when performing member access on a class prvalue (7.6.1.5, 7.6.4),
- when performing an array-to-pointer conversion or subscripting on an array prvalue (7.3.2, 7.6.1.1),
- when initializing an object of type std::initializer_list<T> from a braced-init-list (9.3.4),
- for certain unevaluated operands (7.6.1.8, 7.6.2.3), and
- when a prvalue appears as a discarded-value expression (7.2).

—end note] [Example: Consider the following code:

```cpp
class X {
public:
  X(int);
  X(const X&);
  X& operator=(const X&);
  ~X();
};

class Y {
public:
  Y(int);
  Y(Y&&);
  ~Y();
};

X f(X);
Y g(Y);

void h() {
  X a(1);
  X b = f(X(2));
  Y c = g(Y(3));
  a = f(a);
}
```

X(2) is constructed in the space used to hold f()’s argument and Y(3) is constructed in the space used to hold g()’s argument. Likewise, f()’s result is constructed directly in b and g()’s result is constructed directly in c. On the other hand, the expression a = f(a) requires a temporary for the result of f(a), which is materialized so that the reference parameter of A::operator=(const A&) can bind to it. — end example]
When an object of class type X is passed to or returned from a function, if each copy constructor, move constructor, and destructor of X is either trivial or deleted, and X has at least one non-deleted copy or move constructor, implementations are permitted to create a temporary object to hold the function parameter or result object. The temporary object is constructed from the function argument or return value, respectively, and the function’s parameter or return object is initialized as if by using the non-deleted trivial constructor to copy the temporary (even if that constructor is inaccessible or would not be selected by overload resolution to perform a copy or move of the object). [Note: This latitude is granted to allow objects of class type to be passed to or returned from functions in registers. — end note]

When an implementation introduces a temporary object of a class that has a non-trivial constructor (10.3.4, 10.3.5), it shall ensure that a constructor is called for the temporary object. Similarly, the destructor shall be called for a temporary with a non-trivial destructor (10.3.7). Temporary objects are destroyed as the last step in evaluating the full-expression (6.8.1) that (lexically) contains the point where they were created. This is true even if that evaluation ends in throwing an exception. The value computations and side effects of destroying a temporary object are associated only with the full-expression, not with any specific subexpression.

There are three contexts in which temporaries are destroyed at a different point than the end of the full-expression. The first context is when a default constructor is called to initialize an element of an array with no corresponding initializer (9.3). The second context is when a copy constructor is called to copy an element of an array while the entire array is copied (7.5.5.2, 10.3.5). In either case, if the constructor has one or more default arguments, the destruction of every temporary created in a default argument is sequenced before the construction of the next array element, if any.

The third context is when a reference is bound to a temporary object. The temporary object to which the reference is bound or the temporary object that is the complete object of a subobject to which the reference is bound persists for the lifetime of the reference if the glvalue to which the reference is bound was obtained through one of the following:

- a temporary materialization conversion (7.3.4),
- ( expression ), where expression is one of these expressions,
- subscripting (7.6.1.1) of an array operand, where that operand is one of these expressions,
- a class member access (7.6.1.5) using the . operator where the left operand is one of these expressions and the right operand designates a non-static data member of non-reference type,
- a pointer-to-member operation (7.6.4) using the .* operator where the left operand is one of these expressions and the right operand is a pointer to data member of non-reference type,
- a
  - const_cast (7.6.1.11),
  - static_cast (7.6.1.9),
  - dynamic_cast (7.6.1.7), or
  - reinterpret_cast (7.6.1.10)
  converting, without a user-defined conversion, a glvalue operand that is one of these expressions to a glvalue that refers to the object designated by the operand, or to its complete object or a subobject thereof,
- a conditional expression (7.6.16) that is a glvalue where the second or third operand is one of these expressions, or
- a comma expression (7.6.19) that is a glvalue where the right operand is one of these expressions.

[Example:]

```cpp
template<typename T> using id = T;

int i = 1;
int&& a = id<int[3]>{1, 2, 3}[i]; // temporary array has same lifetime as a
const int& b = static_cast<const int&>(0); // temporary int has same lifetime as b
int&& c = cond ? id<int[3]>{1, 2, 3}[i] : static_cast<int&&>(0);
// exactly one of the two temporaries is lifetime-extended
```

39 The same rules apply to initialization of an initializer_list object (9.3.4) with its underlying temporary array.
The exceptions to this lifetime rule are:

(6.9) — A temporary object bound to a reference parameter in a function call (7.6.1.2) persists until the completion of the full-expression containing the call.

(6.10) — The lifetime of a temporary bound to the returned value in a function return statement (8.6.3) is not extended; the temporary is destroyed at the end of the full-expression in the return statement.

(6.11) — A temporary bound to a reference in a new-initializer (7.6.2.4) persists until the completion of the full-expression containing the new-initializer. [Note: This may introduce a dangling reference. — end note] [Example:]

```cpp
struct S {
    const int& m;
};
const S& s = S(1); // both S and int temporaries have lifetime of s
```

The destruction of a temporary whose lifetime is not extended by being bound to a reference is sequenced before the destruction of every temporary which is constructed earlier in the same full-expression. If the lifetime of two or more temporaries to which references are bound ends at the same point, these temporaries are destroyed at that point in the reverse order of the completion of their construction. In addition, the destruction of temporaries bound to references shall take into account the ordering of destruction of objects with static, thread, or automatic storage duration (6.6.4.1, 6.6.4.2, 6.6.4.3); that is, if `obj1` is an object with the same storage duration as the temporary and created before the temporary is created the temporary shall be destroyed before `obj1` is destroyed; if `obj2` is an object with the same storage duration as the temporary and created after the temporary is created the temporary shall be destroyed after `obj2` is destroyed.

7 [Example:

```cpp
struct S {
    S();
    S(int);
    friend S operator+(const S&, const S&);
    ~S();
};
S obj1;
const S& cr = S(16)+S(23);
S obj2;
```

The expression `S(16) + S(23)` creates three temporaries: a first temporary `T1` to hold the result of the expression `S(16)`, a second temporary `T2` to hold the result of the expression `S(23)`, and a third temporary `T3` to hold the result of the addition of these two expressions. The temporary `T3` is then bound to the reference `cr`. It is unspecified whether `T1` or `T2` is created first. On an implementation where `T1` is created before `T2`, `T2` shall be destroyed before `T1`. The temporaries `T1` and `T2` are bound to the reference parameters of `operator+`; these temporaries are destroyed at the end of the full-expression containing the call to `operator+`. The temporary `T3` bound to the reference `cr` is destroyed at the end of `cr`'s lifetime, that is, at the end of the program. In addition, the order in which `T3` is destroyed takes into account the destruction order of other objects with static storage duration. That is, because `obj1` is constructed before `T3`, and `T3` is constructed before `obj2`, `obj2` shall be destroyed before `T3`, and `T3` shall be destroyed before `obj1`. — end example]

8 [Note: 6.7 and the subclauses thereof impose requirements on implementations regarding the representation of types. There are two kinds of types: fundamental types and compound types. Types describe objects (6.6.2),

6.7 Types [basic.types]
references (9.2.3.2), or functions (9.2.3.5). — end note]

2 For any object (other than a potentially-overlapping subobject) of trivially copyable type T, whether or not the object holds a valid value of type T, the underlying bytes (6.6.1) making up the object can be copied into an array of char, unsigned char, or std::byte (16.2.1). 40 If the content of that array is copied back into the object, the object shall subsequently hold its original value. [Example:

```c
#define N sizeof(T)
char buf[N];
T obj; // obj initialized to its original value
std::memcpy(buf, &obj, N); // between these two calls to std::memcpy, obj might be modified
std::memcpy(&obj, buf, N); // at this point, each subobject of obj of scalar type holds its original value
```
—end example]

3 For any trivially copyable type T, if two pointers to T point to distinct T objects obj1 and obj2, where neither obj1 nor obj2 is a potentially-overlapping subobject, if the underlying bytes (6.6.1) making up obj1 are copied into obj2, 41 obj2 shall subsequently hold the same value as obj1. [Example:

```c
T* t1p;
T* t2p;
// provided that t2p points to an initialized object ...
std::memcpy(t1p, t2p, sizeof(T)); // at this point, every subobject of trivially copyable type in *t1p contains
// the same value as the corresponding subobject in *t2p
```
—end example]

4 The object representation of an object of type T is the sequence of N unsigned char objects taken up by the object of type T, where N equals sizeof(T). The value representation of an object is the set of bits that hold the value of type T. Bits in the object representation that are not part of the value representation are padding bits. For trivially copyable types, the value representation is a set of bits in the object representation that determines a value, which is one discrete element of an implementation-defined set of values. 42

5 A class that has been declared but not defined, an enumeration type in certain contexts (9.6), or an array of unknown bound or of incomplete element type, is an incompletely-defined object type. 43 Incompletely-defined object types and cv void are incomplete types (6.7.1). Objects shall not be defined to have an incomplete type.

6 A class type (such as “class X”) might be incomplete at one point in a translation unit and complete later on; the type “class X” is the same type at both points. The declared type of an array object might be an array of incomplete class type and therefore incomplete; if the class type is completed later on in the translation unit, the array type becomes complete; the array type at those two points is the same type. The declared type of an array object might be an array of unknown bound and therefore be incomplete at one point in a translation unit and complete later on; the array types at those two points (“array of unknown bound of T” and “array of N T”) are different types. The type of a pointer to array of unknown bound, or of a type defined by a typedef declaration to be an array of unknown bound, cannot be completed. [Example:

```c
class X; // X is an incomplete type
extern X* xp; // xp is a pointer to an incomplete type
extern int arr[]; // the type of arr is incomplete
typedef int UNKA[]; // UNKA is an incomplete type
UNKA* arrp; // arrp is a pointer to an incomplete type
UNKA** arrpp;

void foo() {
  xp++; // ill-formed: X is incomplete
  arrp++; // ill-formed: incomplete type
  arrpp++; // OK: sizeof UNKA* is known
}

struct X { int i; }; // now X is a complete type
int arr[10]; // now the type of arr is complete
```

40 By using, for example, the library functions (15.5.1.2) std::memcpy or std::memmove.
41 By using, for example, the library functions (15.5.1.2) std::memcpy or std::memmove.
42 The intent is that the memory model of C++ is compatible with that of ISO/IEC 9899 Programming Language C.
43 The size and layout of an instance of an incompletely-defined object type is unknown.

§ 6.7
X x;

void bar() {
    xp = &x; // OK: type is “pointer to X”
    arrp = &arr; // ill-formed: different types
    xp++;
    // OK: X is complete
    arrp++;
    // ill-formed: UNK can’t be completed
}

—end example]

[Note: The rules for declarations and expressions describe in which contexts incomplete types are prohibited. —end note]

An object type is a (possibly cv-qualified) type that is not a function type, not a reference type, and not `cv void`.

Arithmetic types (6.7.1), enumeration types, pointer types, pointer-to-member types (6.7.2), `std::nullptr_t`, and cv-qualified (6.7.3) versions of these types are collectively called scalar types. Cv-unqualified scalar types, trivially copyable class types (Clause 10), arrays of such types, and cv-qualified versions of these types are collectively called trivially copyable types. Scalar types, trivial class types (Clause 10), arrays of such types and cv-qualified versions of these types are collectively called trivial types. Scalar types, standard-layout class types (Clause 10), arrays of such types and cv-qualified versions of these types are collectively called standard-layout types.

A type is a literal type if it is:

(10.1) — possibly cv-qualified void; or
(10.2) — a scalar type; or
(10.3) — a reference type; or
(10.4) — an array of literal type; or
(10.5) — a possibly cv-qualified class type (Clause 10) that has all of the following properties:

(10.5.1) — it has a trivial destructor,
(10.5.2) — it is either a closure type (7.5.5.1), an aggregate type (9.3.1), or has at least one constexpr constructor or constructor template (possibly inherited (9.8) from a base class) that is not a copy or move constructor,
(10.5.3) — if it is a union, at least one of its non-static data members is of non-volatile literal type, and
(10.5.4) — if it is not a union, all of its non-static data members and base classes are of non-volatile literal types.

[Note: A literal type is one for which it might be possible to create an object within a constant expression. It is not a guarantee that it is possible to create such an object, nor is it a guarantee that any object of that type will be usable in a constant expression. —end note]

Two types `cv1 T1` and `cv2 T2` are layout-compatible types if `T1` and `T2` are the same type, layout-compatible enumeration (9.6), or layout-compatible standard-layout class types (10.3).

6.7.1 Fundamental types

Objects declared as characters (char) shall be large enough to store any member of the implementation’s basic character set. If a character from this set is stored in a character object, the integral value of that character object is equal to the value of the single character literal form of that character. It is implementation-defined whether a `char` object can hold negative values. Characters can be explicitly declared `unsigned` or `signed`. Plain `char`, `signed char`, and `unsigned char` are three distinct types, collectively called narrow character types. A `char`, a `signed char`, and an `unsigned char` occupy the same amount of storage and have the same alignment requirements (6.6.5); that is, they have the same object representation. For narrow character types, all bits of the object representation participate in the value representation. [Note: A bit-field of narrow character type whose length is larger than the number of bits in the object representation of that type has padding bits; see 6.7. —end note] For unsigned narrow character types, each possible bit pattern of the value representation represents a distinct number. These requirements do not hold for other types. In any particular implementation, a plain `char` object can take on either the same values as a `signed char` or an `unsigned char`; which one is implementation-defined. For each value `i` of type `unsigned char` in the range
There are five standard signed integer types: “signed char”, “short int”, “int”, “long int”, and “long long int”. In this list, each type provides at least as much storage as those preceding it in the list. There may also be implementation-defined extended signed integer types. The standard and extended signed integer types are collectively called signed integer types. Plain ints have the natural size suggested by the architecture of the execution environment; the other signed integer types are provided to meet special needs.

For each of the standard signed integer types, there exists a corresponding (but different) standard unsigned integer type: “unsigned char”, “unsigned short int”, “unsigned int”, “unsigned long int”, and “unsigned long long int”, each of which occupies the same amount of storage and has the same alignment requirements as the corresponding signed integer type; that is, each signed integer type has the same object representation as its corresponding unsigned integer type. Likewise, for each of the extended signed integer types there exists a corresponding extended unsigned integer type with the same amount of storage and alignment requirements. The standard and extended unsigned integer types are collectively called unsigned integer types. The range of non-negative values of a signed integer type is a subrange of the corresponding unsigned integer type, the representation of the same value in each of the two types is the same, and the value representation of each corresponding signed/unsigned type shall be the same.

The standard signed integer types and standard unsigned integer types are collectively called the standard integer types, and the extended signed integer types and extended unsigned integer types are collectively called the extended integer types. The signed and unsigned integer types shall satisfy the constraints given in the C standard, subclause 6.2.4.2.1.

Unsigned integers shall obey the laws of arithmetic modulo \(2^n\) where \(n\) is the number of bits in the value representation of that particular size of integer.

Type wchar_t is a distinct type whose values can represent distinct codes for all members of the largest extended character set specified among the supported locales (16.3.1). Type wchar_t shall have the same size, signedness, and alignment requirements (6.6.5) as one of the other integral types, called its underlying type. Types char16_t and char32_t denote distinct types with the same size, signedness, and alignment as uint_least16_t and uint_least32_t, respectively, in <cstdint>, called the underlying types.

Values of type bool are either true or false. [Note: There are no signed, unsigned, short, or long bool types or values. — end note] Values of type bool participate in integral promotions (7.3.6).

Types bool, char, char16_t, char32_t, wchar_t, and the signed and unsigned integer types are collectively called integral types. A synonym for integral type is integer type. The representations of integral types shall define values by use of a pure binary numeration system. [Example: This document permits two’s complement, ones’ complement and signed magnitude representations for integral types. — end example]

There are three floating-point types: float, double, and long double. The type double provides at least as much precision as float, and the type long double provides at least as much precision as double. The set of values of the type float is a subset of the set of values of the type double; the set of values of the type double is a subset of the set of values of the type long double. The value representation of floating-point types is implementation-defined. [Note: This document imposes no requirements on the accuracy of floating-point operations; see also 16.3. — end note] Integral and floating-point types are collectively called arithmetic types. Specializations of the standard library template std::numeric_limits (16.3) shall specify the maximum and minimum values of each arithmetic type for an implementation.

A type cv void is an incomplete type that cannot be completed; such a type has an empty set of values. It is used as the return type for functions that do not return a value. Any expression can be explicitly converted to type cv void (7.6.3). An expression of type cv void shall be used only as an expression statement (8.2),
as an operand of a comma expression (7.6.19), as a second or third operand of ?: (7.6.16), as the operand of typeid, noexcept, or decltype, as the expression in a return statement (8.6.3) for a function with the return type cv::void, or as the operand of an explicit conversion to type cv::void.

10 A value of type std::nullptr_t is a null pointer constant (7.3.11). Such values participate in the pointer and the pointer-to-member conversions (7.3.11, 7.3.12). sizeof(std::nullptr_t) shall be equal to sizeof(void*).

11 The types described in this subclause are called fundamental types. [Note: Even if the implementation defines two or more fundamental types to have the same value representation, they are nevertheless different types. —end note]

6.7.2 Compound types [basic.compound]

1 Compound types can be constructed in the following ways:

(1.1) — arrays of objects of a given type, 9.2.3.4;
(1.2) — functions, which have parameters of given types and return void or references or objects of a given type, 9.2.3.5;
(1.3) — pointers to cv::void or objects or functions (including static members of classes) of a given type, 9.2.3.1;
(1.4) — references to objects or functions of a given type, 9.2.3.2. There are two types of references:
  (1.4.1) — value reference
  (1.4.2) — rvalue reference
(1.5) — classes containing a sequence of objects of various types (Clause 10), a set of types, enumerations and functions for manipulating these objects (10.3.1), and a set of restrictions on the access to these entities (10.8);
(1.6) — unions, which are classes capable of containing objects of different types at different times, 10.4;
(1.7) — enumerations, which comprise a set of named constant values. Each distinct enumeration constitutes a different enumerated type, 9.6;
(1.8) — pointers to non-static class members, which identify members of a given type within objects of a given class, 9.2.3.3. Pointers to data members and pointers to member functions are collectively called pointer-to-member types.

2 These methods of constructing types can be applied recursively; restrictions are mentioned in 9.2.3.1, 9.2.3.4, 9.2.3.5, and 9.2.3.2. Constructing a type such that the number of bytes in its object representation exceeds the maximum value representable in the type std::size_t (16.2) is ill-formed.

3 The type of a pointer to cv::void or a pointer to an object type is called an object pointer type. [Note: A pointer to void does not have a pointer-to-object type, however, because void is not an object type. —end note] The type of a pointer that can designate a function is called a function pointer type. A pointer to objects of type T is referred to as a “pointer to T”. [Example: A pointer to an object of type int is referred to as “pointer to int” and a pointer to an object of class X is called a “pointer to X”. —end example] Except for pointers to static members, text referring to “pointers” does not apply to pointers to members. Pointers to incomplete types are allowed although there are restrictions on what can be done with them (6.6.5). Every value of pointer type is one of the following:

(3.1) — a pointer to an object or function (the pointer is said to point to the object or function), or
(3.2) — a pointer past the end of an object (7.6.6), or
(3.3) — the null pointer value (7.3.11) for that type, or
(3.4) — an invalid pointer value.

A value of a pointer type that is a pointer to or past the end of an object represents the address of the first byte in memory (6.6.1) occupied by the object or the first byte in memory after the end of the storage occupied by the object, respectively. [Note: A pointer past the end of an object (7.6.6) is not considered to point to an unrelated object of the object’s type that might be located at that address. A pointer value becomes invalid when the storage it denotes reaches the end of its storage duration; see 6.6.4. —end note] For purposes of pointer arithmetic (7.6.6) and comparison (7.6.9, 7.6.10), a pointer past the end of the last

50) Static class members are objects or functions, and pointers to them are ordinary pointers to objects or functions.

51) For an object that is not within its lifetime, this is the first byte in memory that it will occupy or used to occupy.
element of an array \( x \) of \( n \) elements is considered to be equivalent to a pointer to a hypothetical element \( x[n] \). The value representation of pointer types is implementation-defined. Pointers to layout-compatible types shall have the same value representation and alignment requirements (6.6.5). [Note: Pointers to over-aligned types (6.6.5) have no special representation, but their range of valid values is restricted by the extended alignment requirement. — end note]

4 Two objects \( a \) and \( b \) are pointer-interconvertible if:

- they are the same object, or
- one is a union object and the other is a non-static data member of that object (10.4), or
- one is a standard-layout class object and the other is the first non-static data member of that object, or, if the object has no non-static data members, any base class subobject of that object (10.3), or
- there exists an object \( c \) such that \( a \) and \( c \) are pointer-interconvertible, and \( c \) and \( b \) are pointer-interconvertible.

If two objects are pointer-interconvertible, then they have the same address, and it is possible to obtain a pointer to one from a pointer to the other via a \texttt{reinterpret_cast} (7.6.1.10). [Note: An array object and its first element are not pointer-interconvertible, even though they have the same address. — end note]

5 A pointer to \texttt{cv}-qualified (6.7.3) or \texttt{cv}-unqualified \texttt{void} can be used to point to objects of unknown type. Such a pointer shall be able to hold any object pointer. An object of type \texttt{cv void*} shall have the same representation and alignment requirements as \texttt{cv char*}.

6.7.3 CV-qualifiers [basic.type.qualifier]

1 A type mentioned in 6.7.1 and 6.7.2 is a \texttt{cv-unqualified type}. Each type which is a \texttt{cv-unqualified complete} or incomplete object type or is \texttt{void} (6.7) has three corresponding \texttt{cv-qualified} versions of its type: a \texttt{const-qualified} version, a \texttt{volatile-qualified} version, and a \texttt{const-volatile-qualified} version. The type of an object (6.6.2) includes the \texttt{cv-qualifiers} specified in the \texttt{decl-specifier-seq} (9.1), \texttt{declarator} (9.2), \texttt{type-id} (9.2.1), or \texttt{new-type-id} (7.6.2.4) when the object is created.

- a \texttt{const object} is an object of type \texttt{const T} or a non-mutable subobject of such an object.
- a \texttt{volatile object} is an object of type \texttt{volatile T}, a subobject of such an object, or a mutable subobject of a \texttt{const volatile object}.
- a \texttt{const volatile object} is an object of type \texttt{const volatile T}, a non-mutable subobject of such an object, a \texttt{const} subobject of a \texttt{volatile} object, or a non-mutable \texttt{volatile} subobject of a \texttt{const} object.

The \texttt{cv-qualified} or \texttt{cv-unqualified} versions of a type are distinct types; however, they shall have the same representation and alignment requirements (6.6.5).

2 A compound type (6.7.2) is not \texttt{cv-qualified} by the \texttt{cv-qualifiers} (if any) of the types from which it is compounded. Any \texttt{cv-qualifiers} applied to an array type affect the array element type (9.2.3.4).

3 See 9.2.3.5 and 10.3.2.1 regarding function types that have \texttt{cv-qualifiers}.

4 There is a partial ordering on \texttt{cv-qualifiers}, so that a type can be said to be more \texttt{cv-qualified} than another. Table 10 shows the relations that constitute this ordering.

<table>
<thead>
<tr>
<th>no cv-qualifier</th>
<th>&lt;</th>
<th>const</th>
</tr>
</thead>
<tbody>
<tr>
<td>no cv-qualifier</td>
<td>&lt;</td>
<td>volatile</td>
</tr>
<tr>
<td>no cv-qualifier</td>
<td>&lt;</td>
<td>const volatile</td>
</tr>
<tr>
<td>const</td>
<td>&lt;</td>
<td>const volatile</td>
</tr>
<tr>
<td>volatile</td>
<td>&lt;</td>
<td>const volatile</td>
</tr>
</tbody>
</table>

5 In this document, the notation \texttt{cv} (or \texttt{cv1}, \texttt{cv2}, etc.), used in the description of types, represents an arbitrary set of \texttt{cv-qualifiers}, i.e., one of \{\texttt{const}\}, \{\texttt{volatile}\}, \{\texttt{const, volatile}\}, or the empty set. For a type \texttt{cv T}, the top-level \texttt{cv-qualifiers} of that type are those denoted by \texttt{cv}. [Example: The type corresponding to the \texttt{type-id const int &} has no top-level \texttt{cv-qualifiers}. The type corresponding to the \texttt{type-id volatile int *} has...]

52) The same representation and alignment requirements are meant to imply interchangeability as arguments to functions, return values from functions, and non-static data members of unions.
6 Cv-qualifiers applied to an array type attach to the underlying element type, so the notation “cv T”, where T is an array type, refers to an array whose elements are so-qualified. An array type whose elements are cv-qualified is also considered to have the same cv-qualifications as its elements. [Example:

typedef char CA[5];
typedef const char CC;
CC arr1[5] = { 0 };
const CA arr2 = { 0 };

The type of both arr1 and arr2 is “array of 5 const char”, and the array type is considered to be const-qualified. —end example]

6.7.4 Integer conversion rank [conv.rank]

1 Every integer type has an integer conversion rank defined as follows:

- (1.1) No two signed integer types other than char and signed char (if char is signed) shall have the same rank, even if they have the same representation.

- (1.2) The rank of a signed integer type shall be greater than the rank of any signed integer type with a smaller size.

- (1.3) The rank of long long int shall be greater than the rank of long int, which shall be greater than the rank of int, which shall be greater than the rank of short int, which shall be greater than the rank of signed char.

- (1.4) The rank of any unsigned integer type shall equal the rank of the corresponding signed integer type.

- (1.5) The rank of any standard integer type shall be greater than the rank of any extended integer type with the same size.

- (1.6) The rank of char shall equal the rank of signed char and unsigned char.

- (1.7) The rank of bool shall be less than the rank of all other standard integer types.

- (1.8) The ranks of char16_t, char32_t, and wchar_t shall equal the ranks of their underlying types (6.7.1).

- (1.9) The rank of any extended signed integer type relative to another extended signed integer type with the same size is implementation-defined, but still subject to the other rules for determining the integer conversion rank.

- (1.10) For all integer types T1, T2, and T3, if T1 has greater rank than T2 and T2 has greater rank than T3, then T1 shall have greater rank than T3.

[Note: The integer conversion rank is used in the definition of the integral promotions (7.3.6) and the usual arithmetic conversions (7.2). —end note]

6.8 Program execution [basic.exec]

6.8.1 Sequential execution [intro.execution]

1 An instance of each object with automatic storage duration (6.6.4.3) is associated with each entry into its block. Such an object exists and retains its last-stored value during the execution of the block and while the block is suspended (by a call of a function or receipt of a signal).

2 A constituent expression is defined as follows:

- (2.1) The constituent expression of an expression is that expression.

- (2.2) The constituent expressions of a braced-init-list or of a (possibly parenthesized) expression-list are the constituent expressions of the elements of the respective list.

- (2.3) The constituent expressions of a brace-or-equal-initializer of the form = initializer-clause are the constituent expressions of the initializer-clause.

[Example:

struct A { int x; };
struct B { int y; struct A a; };
B b = { 5, { 1+1 } };
§ 6.8.1 66
The constituent expressions of the initializer used for the initialization of \( b \) are 5 and \( 1+1 \). — end example

The immediate subexpressions of an expression \( e \) are

1. the constituent expressions of \( e \)'s operands (7.2),
2. any function call that \( e \) implicitly invokes,
3. if \( e \) is a lambda-expression (7.5.5), the initialization of the entities captured by copy and the constituent expressions of the initializer of the init-captures,
4. if \( e \) is a function call (7.6.1.2) or implicitly invokes a function, the constituent expressions of each default argument (9.2.3.6) used in the call, or
5. if \( e \) creates an aggregate object (9.3.1), the constituent expressions of each default member initializer (10.3) used in the initialization.

A subexpression of an expression \( e \) is an immediate subexpression of \( e \) or a subexpression of an immediate subexpression of \( e \). [Note: Expressions appearing in the compound-statement of a lambda-expression are not subexpressions of the lambda-expression. — end note]

A full-expression is

1. an unevaluated operand (7.2),
2. a constant-expression (7.7),
3. an init-declarator (9.2) or a mem-initializer (10.9.2), including the constituent expressions of the initializer,
4. an invocation of a destructor generated at the end of the lifetime of an object other than a temporary object (6.6.6), or
5. an expression that is not a subexpression of another expression and that is not otherwise part of a full-expression.

If a language construct is defined to produce an implicit call of a function, a use of the language construct is considered to be an expression for the purposes of this definition. Conversions applied to the result of an expression in order to satisfy the requirements of the language construct in which the expression appears are also considered to be part of the full-expression. For an initializer, performing the initialization of the entity (including evaluating default member initializers of an aggregate) is also considered part of the full-expression.

[Example:

```c
struct S {
    S(int i): I(i) { } // full-expression is initialization of I
    int& v() { return I; }
    ~S() noexcept(false) {} // full-expression is destruction of I
private:
    int I;
};

S s1(1); // full-expression comprises call of S::S(int)
void f() {
    S s2 = 2; // full-expression comprises call of S::S(int)
    if (s2.v()) // full-expression includes lvalue-to-rvalue and int to bool conversions,
        // performed before temporary is deleted at end of full-expression
    }
    bool b = noexcept(S()); // exception specification of destructor of S considered for noexcept
    ~S() noexcept(false){ } // full-expression is destruction of s2 at end of block
}
struct B {
    B(S = S(0));
};
B b[2] = { B(), B() }; // full-expression is the entire initialization // including the destruction of temporaries

— end example]

[Note: The evaluation of a full-expression can include the evaluation of subexpressions that are not lexically part of the full-expression. For example, subexpressions involved in evaluating default arguments (9.2.3.6)
are considered to be created in the expression that calls the function, not the expression that defines the default argument. —end note

Reading an object designated by a volatile glvalue (7.2.1), modifying an object, calling a library I/O function, or calling a function that does any of those operations are all side effects, which are changes in the state of the execution environment. Evaluation of an expression (or a subexpression) in general includes both value computations (including determining the identity of an object for glvalue evaluation and fetching a value previously assigned to an object for prvalue evaluation) and initiation of side effects. When a call to a library I/O function returns or an access through a volatile glvalue is evaluated the side effect is considered complete, even though some external actions implied by the call (such as the I/O itself) or by the volatile access may not have completed yet.

Sequenced before is an asymmetric, transitive, pair-wise relation between evaluations executed by a single thread (6.8.2), which induces a partial order among those evaluations. Given any two evaluations $A$ and $B$, if $A$ is sequenced before $B$ (or, equivalently, $B$ is sequenced after $A$), then the execution of $A$ shall precede the execution of $B$. If $A$ is not sequenced before $B$ and $B$ is not sequenced before $A$, then $A$ and $B$ are unsequenced. [Note: The execution of unsequenced evaluations can overlap. —end note] Evaluations $A$ and $B$ are indeterminately sequenced when either $A$ is sequenced before $B$ or $B$ is sequenced before $A$, but it is unspecified which. [Note: Indeterminately sequenced evaluations cannot overlap, but either could be executed first. —end note] An expression $X$ is said to be sequenced before an expression $Y$ if every value computation and every side effect associated with the expression $X$ is sequenced before every value computation and every side effect associated with the expression $Y$.

Every value computation and side effect associated with a full-expression is sequenced before every value computation and side effect associated with the next full-expression to be evaluated.\footnote{53}

Except where noted, evaluations of operands of individual operators and of subexpressions of individual expressions are unsequenced. [Note: In an expression that is evaluated more than once during the execution of a program, unsequenced and indeterminately sequenced evaluations of its subexpressions need not be performed consistently in different evaluations. —end note] The value computations of the operands of an operator are sequenced before the value computation of the result of the operator. If a side effect on a memory location (6.6.1) is unsequenced relative to either another side effect on the same memory location or a value computation using the value of any object in the same memory location, and they are not potentially concurrent (6.8.2), the behavior is undefined. [Note: The next subclause imposes similar, but more complex restrictions on potentially concurrent computations. —end note]

[Example:

```c
void g(int i) {
    i = 7, i++, i++;
    // i becomes 9
    i = i++ + i++;
    // the value of i is incremented
    i = i++ + i;
    // the behavior is undefined
    i = i + 1;
    // the value of i is incremented
}

—end example
```

Note\footnote{54}: If $A$ and $B$ would not otherwise be sequenced then they are indeterminately sequenced. —end note] Several contexts in C++ cause evaluation of a function call, even though no corresponding function call syntax appears in the translation unit. [Example: Evaluation of a new-expression invokes one or more allocation and constructor functions; see 7.6.2.4. For another example, invocation of a conversion function (10.3.8.2) can arise in contexts in which no function call syntax appears. —end example] The sequencing constraints on the execution of the called function (as described above) are features of the function calls as evaluated, whatever the syntax of the expression that calls the function might be.

:\footnote{53} As specified in 6.6.6, after a full-expression is evaluated, a sequence of zero or more invocations of destructor functions for temporary objects takes place, usually in reverse order of the construction of each temporary object.

:\footnote{54} In other words, function executions do not interleave with each other.
If a signal handler is executed as a result of a call to the `std::raise` function, then the execution of the handler is sequenced after the invocation of the `std::raise` function and before its return. [Note: When a signal is received for another reason, the execution of the signal handler is usually unsequenced with respect to the rest of the program. — end note]

6.8.2 Multi-threaded executions and data races [intro.multithread]

A thread of execution (also known as a thread) is a single flow of control within a program, including the initial invocation of a top-level function, and recursively including every function invocation subsequently executed by the thread. [Note: When one thread creates another, the initial call to the top-level function of the new thread is executed by the new thread, not by the creating thread. — end note] Every thread in a program can potentially access every object and function in a program. Under a hosted implementation, a C++ program can have more than one thread running concurrently. The execution of each thread proceeds as defined by the remainder of this document. The execution of the entire program consists of an execution of all of its threads. [Note: Usually the execution can be viewed as an interleaving of all its threads. However, some kinds of atomic operations, for example, allow executions inconsistent with a simple interleaving, as described below. — end note] Under a freestanding implementation, it is implementation-defined whether a program can have more than one thread of execution.

For a signal handler that is not executed as a result of a call to the `std::raise` function, it is unspecified which thread of execution contains the signal handler invocation.

6.8.2.1 Data races [intro.races]

The value of an object visible to a thread `T` at a particular point is the initial value of the object, a value assigned to the object by `T`, or a value assigned to the object by another thread, according to the rules below. [Note: In some cases, there may instead be undefined behavior. Much of this subclause is motivated by the desire to support atomic operations with explicit and detailed visibility constraints. However, it also implicitly supports a simpler view for more restricted programs. — end note]

Two expression evaluations conflict if one of them modifies a memory location (6.6.1) and the other one reads or modifies the same memory location.

The library defines a number of atomic operations (Clause 29) and operations on mutexes (Clause 30) that are specially identified as synchronization operations. These operations play a special role in making assignments in one thread visible to another. A synchronization operation on one or more memory locations is either a consume operation, an acquire operation, a release operation, or both an acquire and release operation. A synchronization operation without an associated memory location is a fence and can be either an acquire fence, a release fence, or both an acquire and release fence. In addition, there are relaxed atomic operations, which are not synchronization operations, and atomic read-modify-write operations, which have special characteristics. [Note: For example, a call that acquires a mutex will perform an acquire operation on the locations comprising the mutex. Correspondingly, a call that releases the same mutex will perform a release operation on those same locations. Informally, performing a release operation on `A` forces prior side effects on other memory locations to become visible to other threads that later perform a consume or an acquire operation on `A`. “Relaxed” atomic operations are not synchronization operations even though, like synchronization operations, they cannot contribute to data races. — end note]

All modifications to a particular atomic object `M` occur in some particular total order, called the modification order of `M`. [Note: There is a separate order for each atomic object. There is no requirement that these can be combined into a single total order for all objects. In general this will be impossible since different threads may observe modifications to different objects in inconsistent orders. — end note]

A release sequence headed by a release operation `A` on an atomic object `M` is a maximal contiguous subsequence of side effects in the modification order of `M`, where the first operation is `A`, and every subsequent operation

(5.1) — is performed by the same thread that performed `A`, or
(5.2) — is an atomic read-modify-write operation.

Certain library calls synchronize with other library calls performed by another thread. For example, an atomic store-release synchronizes with a load-acquire that takes its value from the store (29.4). [Note: Except in the specified cases, reading a later value does not necessarily ensure visibility as described below. Such a

55) An object with automatic or thread storage duration (6.6.4) is associated with one specific thread, and can be accessed by a different thread only indirectly through a pointer or reference (6.7.2).
requirement would sometimes interfere with efficient implementation. — end note] [Note: The specifications of the synchronization operations define when one reads the value written by another. For atomic objects, the definition is clear. All operations on a given mutex occur in a single total order. Each mutex acquisition “reads the value written” by the last mutex release. — end note]

7 An evaluation $A$ carries a dependency to an evaluation $B$ if

\[(7.1)\] the value of $A$ is used as an operand of $B$, unless:

\[(7.1.1)\] $B$ is an invocation of any specialization of std::kill_dependency (29.4), or

\[(7.1.2)\] $A$ is the left operand of a built-in logical AND (&&, see 7.6.14) or logical OR (||, see 7.6.15) operator, or

\[(7.1.3)\] $A$ is the left operand of a conditional (?; see 7.6.16) operator, or

\[(7.1.4)\] $A$ is the left operand of the built-in comma (,) operator (7.6.19);

or

\[(7.2)\] $A$ writes a scalar object or bit-field $M$, $B$ reads the value written by $A$ from $M$, and $A$ is sequenced before $B$, or

\[(7.3)\] for some evaluation $X$, $A$ carries a dependency to $X$, and $X$ carries a dependency to $B$.

[Note: “Carries a dependency to” is a subset of “is sequenced before”, and is similarly strictly intra-thread. — end note]

8 An evaluation $A$ is dependency-ordered before an evaluation $B$ if

\[(8.1)\] $A$ performs a release operation on an atomic object $M$, and, in another thread, $B$ performs a consume operation on $M$ and reads a value written by any side effect in the release sequence headed by $A$, or

\[(8.2)\] for some evaluation $X$, $A$ is dependency-ordered before $X$ and $X$ carries a dependency to $B$.

[Note: The relation “is dependency-ordered before” is analogous to “synchronizes with”, but uses release/consume in place of release/acquire. — end note]

9 An evaluation $A$ inter-thread happens before an evaluation $B$ if

\[(9.1)\] $A$ synchronizes with $B$, or

\[(9.2)\] $A$ is dependency-ordered before $B$, or

\[(9.3)\] for some evaluation $X$

\[(9.3.1)\] $A$ synchronizes with $X$ and $X$ is sequenced before $B$, or

\[(9.3.2)\] $A$ is sequenced before $X$ and $X$ inter-thread happens before $B$, or

\[(9.3.3)\] $A$ inter-thread happens before $X$ and $X$ inter-thread happens before $B$.

[Note: The “inter-thread happens before” relation describes arbitrary concatenations of “sequenced before”, “synchronizes with” and “dependency-ordered before” relationships, with two exceptions. The first exception is that a concatenation is not permitted to end with “dependency-ordered before” followed by “sequenced before”. The reason for this limitation is that a consume operation participating in a “dependency-ordered before” relationship provides ordering only with respect to operations to which this consume operation actually carries a dependency. The reason that this limitation applies only to the end of such a concatenation is that any subsequent release operation will provide the required ordering for a prior consume operation. The second exception is that a concatenation is not permitted to consist entirely of “sequenced before”. The reasons for this limitation are (1) to permit “inter-thread happens before” to be transitively closed and (2) the “happens before” relation, defined below, provides for relationships consisting entirely of “sequenced before”. — end note]

10 An evaluation $A$ happens before an evaluation $B$ (or, equivalently, $B$ happens after $A$) if:

\[(10.1)\] $A$ is sequenced before $B$, or

\[(10.2)\] $A$ inter-thread happens before $B$.

The implementation shall ensure that no program execution demonstrates a cycle in the “happens before” relation. [Note: This cycle would otherwise be possible only through the use of consume operations. — end note]

11 An evaluation $A$ strongly happens before an evaluation $B$ if either
If a side effect on an object modifies an object, then the visible side effect on that object shall take its value from a side effect on that object, even if both operations are relaxed loads. This effectively makes the cache coherence guarantee provided by most hardware available to C++ atomic operations. —end note

The four preceding coherence requirements effectively disallow compiler reordering of atomic operations to a single object, even if both operations are relaxed loads. This effectively makes the cache coherence guarantee provided by most hardware available to C++ atomic operations. —end note

Note: The value observed by a load of an atomic depends on the "happens before" relation, which depends on the values observed by loads of atomic. The intended reading is that there must exist an association of atomic loads with modifications they observe that, together with suitably chosen modification orders and the "happens before" relation derived as described above, satisfy the resulting constraints as imposed here. —end note

Two actions are potentially concurrent if

— they are performed by different threads, or
— they are unsequenced, at least one is performed by a signal handler, and they are not both performed by the same signal handler invocation.

The execution of a program contains a data race if it contains two potentially concurrent conflicting actions, at least one of which is not atomic, and neither happens before the other, except for the special case for signal handlers described below. Any such data race results in undefined behavior. [Note: It can be shown that programs that correctly use mutexes and memory_order::seq_cst operations to prevent all data races and use no other synchronization operations behave as if the operations executed by their constituent threads were simply interleaved, with each value computation of an object being taken from the last side effect on that object in that interleaving. This is normally referred to as "sequential consistency". However, this applies only to data-race-free programs, and data-race-free programs cannot observe most program transformations that do not change single-threaded program semantics. In fact, most single-threaded program transformations

§ 6.8.2.1
continue to be allowed, since any program that behaves differently as a result must perform an undefined operation. — end note]

21 Two accesses to the same object of type \texttt{volatile std::sigatomic\_t} do not result in a data race if both occur in the same thread, even if one or more occurs in a signal handler. For each signal handler invocation, evaluations performed by the thread invoking a signal handler can be divided into two groups \emph{A} and \emph{B}, such that no evaluations in \emph{B} happen before evaluations in \emph{A}, and the evaluations of such \texttt{volatile std::sigatomic\_t} objects take values as though all evaluations in \emph{A} happened before the execution of the signal handler and the execution of the signal handler happened before all evaluations in \emph{B}. [Note: Compiler transformations that introduce assignments to a potentially shared memory location that would not be modified by the abstract machine are generally precluded by this document, since such an assignment might overwrite another assignment by a different thread in cases in which an abstract machine execution would not have encountered a data race. This includes implementations of data member assignment that overwrite adjacent members in separate memory locations. Reordering of atomic loads in cases in which the atomicities in question may alias is also generally precluded, since this may violate the coherence rules. — end note]

22 [Note: Transformations that introduce a speculative read of a potentially shared memory location may not preserve the semantics of the \texttt{C++} program as defined in this document, since they potentially introduce a data race. However, they are typically valid in the context of an optimizing compiler that targets a specific machine with well-defined semantics for data races. They would be invalid for a hypothetical machine that is not tolerant of races or provides hardware race detection. — end note]

6.8.2.2 Forward progress 

1 The implementation may assume that any thread will eventually do one of the following:

(1.1) — terminate,
(1.2) — make a call to a library I/O function,
(1.3) — perform an access through a volatile glvalue, or
(1.4) — perform a synchronization operation or an atomic operation.

[Note: This is intended to allow compiler transformations such as removal of empty loops, even when termination cannot be proven. — end note]

2 Executions of atomic functions that are either defined to be lock-free (29.9) or indicated as lock-free (29.5) are lock-free executions.

(2.1) — If there is only one thread that is not blocked (3.6) in a standard library function, a lock-free execution in that thread shall complete. [Note: Concurrently executing threads may prevent progress of a lock-free execution. For example, this situation can occur with load-locked store-conditional implementations. This property is sometimes termed obstruction-free. — end note]

(2.2) — When one or more lock-free executions run concurrently, at least one should complete. [Note: It is difficult for some implementations to provide absolute guarantees to this effect, since repeated and particularly inopportune interference from other threads may prevent forward progress, e.g., by repeatedly stealing a cache line for unrelated purposes between load-locked and store-conditional instructions. Implementations should ensure that such effects cannot indefinitely delay progress under expected operating conditions, and that such anomalies can therefore safely be ignored by programmers. Outside this document, this property is sometimes termed lock-free. — end note]

3 During the execution of a thread of execution, each of the following is termed an execution step:

(3.1) — termination of the thread of execution,
(3.2) — performing an access through a volatile glvalue, or
(3.3) — completion of a call to a library I/O function, a synchronization operation, or an atomic operation.

4 An invocation of a standard library function that blocks (3.6) is considered to continuously execute execution steps while waiting for the condition that it blocks on to be satisfied. [Example: A library I/O function that blocks until the I/O operation is complete can be considered to continuously check whether the operation is complete. Each such check might consist of one or more execution steps, for example using observable behavior of the abstract machine. — end example]
For a thread of execution providing **concurrent forward progress guarantees**, the implementation ensures that the thread will eventually make progress for as long as it has not terminated. [Note: This is required regardless of whether or not other threads of executions (if any) have been or are making progress. To eventually fulfill this requirement means that this will happen in an unspecified but finite amount of time. — end note]

It is implementation-defined whether the implementation-created thread of execution that executes main (6.8.3.1) and the threads of execution created by std::thread (30.3.2) provide concurrent forward progress guarantees. [Note: General-purpose implementations should provide these guarantees. — end note]

For a thread of execution providing **parallel forward progress guarantees**, the implementation is not required to ensure that the thread will eventually make progress if it has not yet executed any execution step; once this thread has executed a step, it provides concurrent forward progress guarantees.

[Note: This does not specify a requirement for when to start this thread of execution, which will typically be specified by the entity that creates this thread of execution. For example, a thread of execution that provides concurrent forward progress guarantees and executes tasks from a set of tasks in an arbitrary order, one after the other, satisfies the requirements of parallel forward progress for these tasks. — end note]

For a thread of execution providing **weakly parallel forward progress guarantees**, the implementation does not ensure that the thread will eventually make progress.

[Note: Threads of execution providing weakly parallel forward progress guarantees cannot be expected to make progress regardless of whether other threads make progress or not; however, blocking with forward progress guarantee delegation, as defined below, can be used to ensure that such threads of execution make progress eventually. — end note]

Concurrent forward progress guarantees are stronger than parallel forward progress guarantees, which in turn are stronger than weakly parallel forward progress guarantees. [Note: For example, some kinds of synchronization between threads of execution may only make progress if the respective threads of execution provide parallel forward progress guarantees, but will fail to make progress under weakly parallel guarantees. — end note]

When a thread of execution \( P \) is specified to **block with forward progress guarantee delegation** on the completion of a set \( S \) of threads of execution, then throughout the whole time of \( P \) being blocked on \( S \), the implementation shall ensure that the forward progress guarantees provided by at least one thread of execution in \( S \) is at least as strong as \( P \)'s forward progress guarantees. [Note: It is unspecified which thread or threads of execution in \( S \) are chosen and for which number of execution steps. The strengthening is not permanent and not necessarily in place for the rest of the lifetime of the affected thread of execution. As long as \( P \) is blocked, the implementation has to eventually select and potentially strengthen a thread of execution in \( S \). — end note] Once a thread of execution in \( S \) terminates, it is removed from \( S \). Once \( S \) is empty, \( P \) is unblocked.

[Note: A thread of execution \( B \) thus can temporarily provide an effectively stronger forward progress guarantee for a certain amount of time, due to a second thread of execution \( A \) being blocked on it with forward progress guarantee delegation. In turn, if \( B \) then blocks with forward progress guarantee delegation on \( C \), this may also temporarily provide a stronger forward progress guarantee to \( C \). — end note]

If all threads of execution in \( S \) finish executing (e.g., they terminate and do not use blocking synchronization incorrectly), then \( P \)'s execution of the operation that blocks with forward progress guarantee delegation will not result in \( P \)'s progress guarantee being effectively weakened. [Note: This does not remove any constraints regarding blocking synchronization for threads of execution providing parallel or weakly parallel forward progress guarantees because the implementation is not required to strengthen a particular thread of execution whose too-weak progress guarantee is preventing overall progress. — end note]

An implementation should ensure that the last value (in modification order) assigned by an atomic or synchronization operation will become visible to all other threads in a finite period of time.
6.8.3 Start and termination

6.8.3.1 main function

A program shall contain a global function called main. Executing a program starts a main thread of execution (6.8.2, 30.3) in which the main function is invoked, and in which variables of static storage duration might be initialized (6.8.3.2) and destroyed (6.8.3.4). It is implementation-defined whether a program in a freestanding environment is required to define a main function.  

Note: In a freestanding environment, start-up and termination is implementation-defined; start-up contains the execution of constructors for objects of namespace scope with static storage duration; termination contains the execution of destructors for objects with static storage duration. — end note

An implementation shall not redefine the main function. This function shall not be overloaded. Its type shall have C++ language linkage and it shall have a declared return type of type int, but otherwise its type is implementation-defined. An implementation shall allow both

(a) a function of () returning int and
(b) a function of (int, pointer to pointer to char) returning int

as the type of main (9.2.3.5). In the latter form, for purposes of exposition, the first function parameter is called argc and the second function parameter is called argv, where argv shall be the number of arguments passed to the program from the environment in which the program is run. If argc is nonzero these arguments shall be supplied in argv[0] through argv[argc-1] as pointers to the initial characters of null-terminated multibyte strings (NTMBS) (15.4.2.1.5.2) and argv[0] shall be the pointer to the initial character of a NTMBS that represents the name used to invoke the program or "". The value of argc shall be non-negative. The value of argv[argc] shall be 0.  

Note: It is recommended that any further (optional) parameters be added after argv. — end note

The function main shall not be used within a program. The linkage (6.5) of main is implementation-defined. A program that defines main as deleted or that declares main to be inline, static, or constexpr is ill-formed. The main function shall not be declared with a linkage-specification (9.10). A program that declares a variable main at global scope or that declares the name main with C language linkage (in any namespace) is ill-formed. The name main is not otherwise reserved.  

Example: Member functions, classes, and enumerations can be called main, as can entities in other namespaces. — end example

Terminating the program without leaving the current block (e.g., by calling the function std::exit(int) (16.5)) does not destroy any objects with automatic storage duration (10.3.7). If std::exit is called to end a program during the destruction of an object with static or thread storage duration, the program has undefined behavior.

A return statement (8.6.3) in main has the effect of leaving the main function (destroying any objects with automatic storage duration) and calling std::exit with the return value as the argument. If control flows off the end of the compound-statement of main, the effect is equivalent to a return with operand 0 (see also 13.3).

6.8.3.2 Static initialization

Variables with static storage duration are initialized as a consequence of program initiation. Variables with thread storage duration are initialized as a consequence of thread execution. Within each of these phases of initiation, initialization occurs as follows.

A constant initializer for a variable or temporary object o is an initializer whose full-expression is a constant expression, except that if o is an object, such an initializer may also invoke constexpr constructors for o and its subobjects even if those objects are of non-literal class types.  

Note: Such a class may have a non-trivial destructor. — end note

Constant initialization is performed if a variable or temporary object with static or thread storage duration is initialized by a constant initializer for the entity. If constant initialization is not performed, a variable with static storage duration (6.6.4.1) or thread storage duration (6.6.4.2) is zero-initialized (9.3). Together, zero-initialization and constant initialization are called static initialization; all other initialization is dynamic initialization. All static initialization strongly happens before (6.8.2.1) any dynamic initialization.  

Note: The dynamic initialization of non-local variables is described in 6.8.3.3; that of local static variables is described in 8.7. — end note

An implementation is permitted to perform the initialization of a variable with static or thread storage duration as a static initialization even if such initialization is not required to be done statically, provided that

(3.1) the dynamic version of the initialization does not change the value of any other object of static or thread storage duration prior to its initialization, and
the static version of the initialization produces the same value in the initialized variable as would be produced by the dynamic initialization if all variables not required to be initialized statically were initialized dynamically.

[Note: As a consequence, if the initialization of an object obj1 refers to an object obj2 of namespace scope potentially requiring dynamic initialization and defined later in the same translation unit, it is unspecified whether the value of obj2 used will be the value of the fully initialized obj2 (because obj2 was statically initialized) or will be the value of obj2 merely zero-initialized. For example,

```
inline double fd() { return 1.0; }
extern double d1;
double d2 = d1;  // unspecified:
    // may be statically initialized to 0.0 or
    // dynamically initialized to 0.0 if d1 is
    // dynamically initialized, or 1.0 otherwise

double d1 = fd();  // may be initialized statically or dynamically to 1.0
```

—end note]

6.8.3.3 Dynamic initialization of non-local variables

1 Dynamic initialization of a non-local variable with static storage duration is unordered if the variable is an implicitly or explicitly instantiated specialization, is partially-ordered if the variable is an inline variable that is not an implicitly or explicitly instantiated specialization, and otherwise is ordered. [Note: An explicitly specialized non-inline static data member or variable template specialization has ordered initialization. — end note]

2 Dynamic initialization of non-local variables V and W with static storage duration are ordered as follows:

(2.1) If V and W have ordered initialization and V is defined before W within a single translation unit, the initialization of V is sequenced before the initialization of W.

(2.2) If V has partially-ordered initialization, W does not have unordered initialization, and V is defined before W in every translation unit in which W is defined, then

(2.2.1) if the program starts a thread (6.8.2) other than the main thread (6.8.3.1), the initialization of V strongly happens before the initialization of W;

(2.2.2) otherwise, the initialization of V is sequenced before the initialization of W.

(2.3) Otherwise, if the program starts a thread other than the main thread before either V or W is initialized, it is unspecified in which threads the initializations of V and W occur; the initializations are unsequenced if they occur in the same thread.

(2.4) Otherwise, the initializations of V and W are indeterminately sequenced.

[Note: This definition permits initialization of a sequence of ordered variables concurrently with another sequence. — end note]

3 A non-initialization odr-use is an odr-use (6.2) not caused directly or indirectly by the initialization of a non-local static or thread storage duration variable.

4 It is implementation-defined whether the dynamic initialization of a non-local non-inline variable with static storage duration is sequenced before the first statement of main or is deferred. If it is deferred, it strongly happens before any non-initialization odr-use of any non-inline function or non-inline variable defined in the same translation unit as the variable to be initialized. It is implementation-defined in which threads and at which points in the program such deferred dynamic initialization occurs. [Note: Such points should be chosen in a way that allows the programmer to avoid deadlocks. — end note] [Example:

```
// - File 1 -
#include "a.h"
#include "b.h"
B b;
A::A(){
    b.Use();
}
```

56) A non-local variable with static storage duration having initialization with side effects is initialized in this case, even if it is not itself odr-used (6.2, 6.6.4.1).
It is implementation-defined whether either a or b is initialized before main is entered or whether the initializations are delayed until a is first odr-used in main. In particular, if a is initialized before main is entered, it is not guaranteed that b will be initialized before it is odr-used by the initialization of a, that is, before A::A is called. If, however, a is initialized at some point after the first statement of main, b will be initialized prior to its use in A::A. —end example

5 It is implementation-defined whether the dynamic initialization of a non-local inline variable with static storage duration is sequenced before the first statement of main or is deferred. If it is deferred, it strongly happens before any non-initialization odr-use of that variable. It is implementation-defined in which threads and at which points in the program such deferred dynamic initialization occurs.

6 It is implementation-defined whether the dynamic initialization of a non-local non-inline variable with thread storage duration is sequenced before the first statement of the initial function of a thread or is deferred. If it is deferred, the initialization associated with the entity for thread t is sequenced before the first non-initialization odr-use by t of any non-inline variable with thread storage duration defined in the same translation unit as the variable to be initialized. It is implementation-defined in which threads and at which points in the program such deferred dynamic initialization occurs.

7 If the initialization of a non-local variable with static or thread storage duration exits via an exception, the function std::terminate is called (13.5.1).

6.8.3.4 Termination

Destructors (10.3.7) for initialized objects (that is, objects whose lifetime (6.6.3) has begun) with static storage duration, and functions registered with std::atexit, are called as part of a call to std::exit (16.5). The call to std::exit is sequenced before the invocations of the destructors and the registered functions. [Note: Returning from main invokes std::exit (6.8.3.1). —end note]

Destructors for initialized objects with thread storage duration within a given thread are called as a result of returning from the initial function of that thread and as a result of that thread calling std::exit. The completions of the destructors for all initialized objects with thread storage duration within that thread strongly happen before the initiation of the destructors of any object with static storage duration.

If the completion of the constructor or dynamic initialization of an object with static storage duration strongly happens before that of another, the completion of the destructor of the second is sequenced before the initiation of the destructor of the first. If the completion of the constructor or dynamic initialization of an object with thread storage duration is sequenced before that of another, the completion of the destructor of the second is sequenced before the initiation of the destructor of the first. If an object is initialized statically, the object is destroyed in the same order as if the object was dynamically initialized. For an object of array or class type, all subobjects of that object are destroyed before any block-scope object with static storage duration initialized during the construction of the subobjects is destroyed. If the destruction of an object with static or thread storage duration exits via an exception, the function std::terminate is called (13.5.1).

If a function contains a block-scope object of static or thread storage duration that has been destroyed and the function is called during the destruction of an object with static or thread storage duration, the program has undefined behavior if the flow of control passes through the definition of the previously destroyed block-scope object. Likewise, the behavior is undefined if the block-scope object is used indirectly (i.e., through a pointer) after its destruction.

If the completion of the initialization of an object with static storage duration strongly happens before a call to std::atexit (see <cstdlib>, 16.5), the call to the function passed to std::atexit is sequenced before...
the call to the destructor for the object. If a call to `std::atexit` strongly happens before the completion of
the initialization of an object with static storage duration, the call to the destructor for the object is sequenced
before the call to the function passed to `std::atexit`. If a call to `std::atexit` strongly happens before
another call to `std::atexit`, the call to the function passed to the second `std::atexit` call is sequenced
before the call to the function passed to the first `std::atexit` call.

6 If there is a use of a standard library object or function not permitted within signal handlers (16.12) that
does not happen before (6.8.2) completion of destruction of objects with static storage duration and execution
of `std::atexit` registered functions (16.5), the program has undefined behavior. [Note: If there is a use of
an object with static storage duration that does not happen before the object’s destruction, the program
has undefined behavior. Terminating every thread before a call to `std::exit` or the exit from `main` is
sufficient, but not necessary, to satisfy these requirements. These requirements permit thread managers as
static-storage-duration objects. — end note]

7 Calling the function `std::abort()` declared in `<cstdlib>` terminates the program without executing any
destructors and without calling the functions passed to `std::atexit()` or `std::at_quick_exit()`.
7 Expressions

7.1 Preamble

[Note: Clause 7 defines the syntax, order of evaluation, and meaning of expressions. An expression is a sequence of operators and operands that specifies a computation. An expression can result in a value and can cause side effects. — end note]

[Note: Operators can be overloaded, that is, given meaning when applied to expressions of class type (Clause 10) or enumeration type (9.6). Uses of overloaded operators are transformed into function calls as described in 11.5. Overloaded operators obey the rules for syntax and evaluation order specified in 7.6, but the requirements of operand type and value category are replaced by the rules for function call. Relations between operators, such as ++a meaning a+=1, are not guaranteed for overloaded operators (11.5). — end note]

Subclause 7.6 defines the effects of operators when applied to types for which they have not been overloaded. Operator overloading shall not modify the rules for the built-in operators, that is, for operators applied to types for which they are defined by this Standard. However, these built-in operators participate in overload resolution, and as part of that process user-defined conversions will be considered where necessary to convert the operands to types appropriate for the built-in operator. If a built-in operator is selected, such conversions will be applied to the operands before the operation is considered further according to the rules in subclause 7.6; see 11.3.1.2, 11.6.

If during the evaluation of an expression, the result is not mathematically defined or not in the range of representable values for its type, the behavior is undefined. [Note: Treatment of division by zero, forming a remainder using a zero divisor, and all floating-point exceptions vary among machines, and is sometimes adjustable by a library function. — end note]

The values of the floating operands and the results of floating expressions may be represented in greater precision and range than that required by the type; the types are not changed thereby.

7.2 Properties of expressions

7.2.1 Value category

Expressions are categorized according to the taxonomy in Figure 1.

expression
  /\  
glvalue  rvalue
  /\  
lvalue  xvalue  prvalue

Figure 1 — Expression category taxonomy

(1.1) — A glvalue is an expression whose evaluation determines the identity of an object, bit-field, or function.
(1.2) — A prvalue is an expression whose evaluation initializes an object or a bit-field, or computes the value of the operand of an operator, as specified by the context in which it appears.
(1.3) — An xvalue is a glvalue that denotes an object or bit-field whose resources can be reused (usually because it is near the end of its lifetime).
(1.4) — An lvalue is a glvalue that is not an xvalue.
(1.5) — An rvalue is a prvalue or an xvalue.

57) The precedence of operators is not directly specified, but it can be derived from the syntax.
58) The cast and assignment operators must still perform their specific conversions as described in 7.6.3, 7.6.1.9 and 7.6.18.
Every expression belongs to exactly one of the fundamental classifications in this taxonomy: lvalue, xvalue, or prvalue. This property of an expression is called its **value category**. [Note: The discussion of each built-in operator in 7.6 indicates the category of the value it yields and the value categories of the operands it expects. For example, the built-in assignment operators expect that the left operand is an lvalue and that the right operand is a prvalue and yield an lvalue as the result. User-defined operators are functions, and the categories of values they expect and yield are determined by their parameter and return types. — end note]

[Note: Historically, lvalues and rvalues were so-called because they could appear on the left- and right-hand side of an assignment (although this is no longer generally true); glvalues are “generalized” lvalues, prvalues are “pure” rvalues, and xvalues are “eXpiring” lvalues. Despite their names, these terms classify expressions, not values. — end note]

An expression is an xvalue if it is:

1. the result of calling a function, whether implicitly or explicitly, whose return type is an rvalue reference to object type (7.6.1.2),
2. a cast to an rvalue reference to object type (7.6.1.7, 7.6.1.9, 7.6.1.10, 7.6.1.11, 7.6.3),
3. a subscripting operation with an xvalue array operand (7.6.1.1),
4. a class member access expression designating a non-static data member of non-reference type in which the object expression is an xvalue (7.6.1.5), or
5. a .* pointer-to-member expression in which the first operand is an xvalue and the second operand is a pointer to data member (7.6.4).

In general, the effect of this rule is that named rvalue references are treated as lvalues and unnamed rvalue references to objects are treated as xvalues; rvalue references to functions are treated as lvalues whether named or not. — end note]

Example:

```cpp
struct A {
    int m;
};
A&& operator+(A, A);
A&& f();
A a;
A&& ar = static_cast<A&&>(a);
```

The expressions f(), f().m, static_cast<A&&>(a), and a + a are xvalues. The expression ar is an lvalue. — end example]

The **result** of a prvalue is the value that the expression stores into its context. A prvalue whose result is the value \( V \) is sometimes said to have or name the value \( V \). The **result object** of a prvalue is the object initialized by the prvalue; a prvalue that is used to compute the value of an operand of an operator or that has type `cv void` has no result object. [Note: Except when the prvalue is the operand of a `decltype-specifier`, a prvalue of class or array type always has a result object. For a discarded prvalue, a temporary object is materialized; see 7.2. — end note] The **result** of a glvalue is the entity denoted by the expression.

Whenever a glvalue appears as an operand of an operator that expects a prvalue for that operand, the lvalue-to-rvalue (7.3.1), array-to-pointer (7.3.2), or function-to-pointer (7.3.3) standard conversions are applied to convert the expression to a prvalue. [Note: An attempt to bind an rvalue reference to an lvalue is not such a context; see 9.3.3. — end note] [Note: Because cv-qualifiers are removed from the type of an expression of non-class type when the expression is converted to a prvalue, an lvalue of type `const int` can, for example, be used where a prvalue of type `int` is required. — end note] [Note: There are no prvalue bit-fields; if a bit-field is converted to a prvalue (7.3.1), a prvalue of the type of the bit-field is created, which might then be promoted (7.3.6). — end note]

Whenever a prvalue appears as an operand of an operator that expects a glvalue for that operand, the temporary materialization conversion (7.3.4) is applied to convert the expression to an xvalue.

The discussion of reference initialization in 9.3.3 and of temporaries in 6.6.6 indicates the behavior of lvalues and rvalues in other significant contexts.

Unless otherwise indicated (9.1.7.2), a prvalue shall always have complete type or the `void` type; if it has a class type or (possibly multi-dimensional) array of class type, that class shall not be an abstract class (10.6.3).
A glvalue shall not have type cv void. [Note: A glvalue may have complete or incomplete non-void type. Class and array prvalues can have cv-qualified types; other prvalues always have cv-unqualified types. See 7.2. — end note]

10 An lvalue is modifiable unless its type is const-qualified or is a function type. [Note: A program that attempts to modify an object through a nonmodifiable lvalue or through an rvalue is ill-formed (7.6.18, 7.6.1.6, 7.6.2.2). — end note]

11 If a program attempts to access the stored value of an object through a glvalue of other than one of the following types the behavior is undefined.

1. the dynamic type of the object,
2. a cv-qualified version of the dynamic type of the object,
3. a type similar (as defined in 7.3.5) to the dynamic type of the object,
4. a type that is the signed or unsigned type corresponding to a cv-qualified version of the dynamic type of the object,
5. an aggregate or union type that includes one of the aforementioned types among its elements or non-static data members (including, recursively, an element or non-static data member of a subaggregate or contained union),
6. a type that is a (possibly cv-qualified) base class type of the dynamic type of the object,
7. a char, unsigned char, or std::byte type.

### 7.2.2 Type

If an expression initially has the type “reference to T” (9.2.3.2, 9.3.3), the type is adjusted to T prior to any further analysis. The expression designates the object or function denoted by the reference, and the expression is an lvalue or an xvalue, depending on the expression. [Note: Before the lifetime of the reference has started or after it has ended, the behavior is undefined (see 6.6.3). — end note]

If a prvalue initially has the type “cv T”, where T is a cv-unqualified non-class, non-array type, the type of the expression is adjusted to T prior to any further analysis.

The cv-combined type of two types T1 and T2 is a type T3 similar to T1 whose cv-qualification signature (7.3.5) is:

1. for every i > 0, cv^i_1 is the union of cv^i_1 and cv^i_2;
2. if the resulting cv^i_1 is different from cv^i_1 or cv^i_2, then const is added to every cv^k_1 for 0 < k < i. [Note: Given similar types T1 and T2, this construction ensures that both can be converted to T3. — end note]

The composite pointer type of two operands p1 and p2 having types T1 and T2, respectively, where at least one is a pointer or pointer-to-member type or std::nullptr_t, is:

1. if both p1 and p2 are null pointer constants, std::nullptr_t;
2. if either p1 or p2 is a null pointer constant, T2 or T1, respectively;
3. if T1 or T2 is “pointer to cv1 void” and the other type is “pointer to cv2 T”, where T is an object type or void, “pointer to cv2 void”, where cv2 is the union of cv1 and cv2;
4. if T1 or T2 is “pointer to noexcept function” and the other type is “pointer to function”, where the function types are otherwise the same, “pointer to function”;
5. if T1 is “pointer to cv1 C1” and T2 is “pointer to cv2 C2”, where C1 is reference-related to C2 or C2 is reference-related to C1 (9.3.3), the cv-combined type of T1 and T2 or the cv-combined type of T2 and T1, respectively;
6. if T1 is “pointer to member of C1 of type cv1 U1” and T2 is “pointer to member of C2 of type cv2 U2” where C1 is reference-related to C2 or C2 is reference-related to C1 (9.3.3), the cv-combined type of T2 and T1 or the cv-combined type of T1 and T2, respectively;
7. if T1 and T2 are similar types (7.3.5), the cv-combined type of T1 and T2;

59) The intent of this list is to specify those circumstances in which an object may or may not be aliased.
— otherwise, a program that necessitates the determination of a composite pointer type is ill-formed.

[Example:
  typedef void *p;
  typedef const int *q;
  typedef int **pi;
  typedef const int **pci;

  The composite pointer type of \( p \) and \( q \) is “pointer to \( \text{const void} \)”;
  the composite pointer type of \( \text{pi} \) and \( \text{pci} \) is “pointer to \( \text{const pointer to const int} \)”. — end example]

7.2.3 Context dependence [expr.context]

1 In some contexts, unevaluated operands appear (7.5.7, 7.6.1.8, 7.6.2.3, 7.6.2.7, 9.1.7.2, Clause 12). An unevaluated operand is not evaluated. [Note: In an unevaluated operand, a non-static class member may be named (7.5.4) and naming of objects or functions does not, by itself, require that a definition be provided (6.2). An unevaluated operand is considered a full-expression (6.8.1). — end note]

2 In some contexts, an expression only appears for its side effects. Such an expression is called a discarded-value expression. The array-to-pointer (7.3.2) and function-to-pointer (7.3.3) standard conversions are not applied. The lvalue-to-rvalue conversion (7.3.1) is applied if and only if the expression is a glvalue of volatile-qualified type and it is one of the following:

(2.1) — (expression), where expression is one of these expressions,

(2.2) — id-expression (7.5.4),

(2.3) — subscripting (7.6.1.1),

(2.4) — class member access (7.6.1.5),

(2.5) — indirection (7.6.2.1),

(2.6) — pointer-to-member operation (7.6.4),

(2.7) — conditional expression (7.6.16) where both the second and the third operands are one of these expressions, or

(2.8) — comma expression (7.6.19) where the right operand is one of these expressions.

[Note: Using an overloaded operator causes a function call; the above covers only operators with built-in meaning. — end note] If the (possibly converted) expression is a prvalue, the temporary materialization conversion (7.3.4) is applied. [Note: If the expression is an lvalue of class type, it must have a volatile copy constructor to initialize the temporary object that is the result object of the lvalue-to-rvalue conversion. — end note] The glvalue expression is evaluated and its value is discarded.

7.3 Standard conversions [conv]

1 Standard conversions are implicit conversions with built-in meaning. 7.3 enumerates the full set of such conversions. A standard conversion sequence is a sequence of standard conversions in the following order:

(1.1) — Zero or one conversion from the following set: lvalue-to-rvalue conversion, array-to-pointer conversion, and function-to-pointer conversion.

(1.2) — Zero or one conversion from the following set: integral promotions, floating-point promotion, integral conversions, floating-point conversions, floating-integral conversions, pointer conversions, pointer-to-member conversions, and boolean conversions.

(1.3) — Zero or one function pointer conversion.

(1.4) — Zero or one qualification conversion.

[Note: A standard conversion sequence can be empty, i.e., it can consist of no conversions. — end note] A standard conversion sequence will be applied to an expression if necessary to convert it to a required destination type.

2 [Note: Expressions with a given type will be implicitly converted to other types in several contexts:

(2.1) — When used as operands of operators. The operator’s requirements for its operands dictate the destination type (7.6).

(2.2) — When used in the condition of an if statement (8.4.1) or iteration statement (8.5). The destination type is bool.
(2.3) When used in the expression of a `switch` statement (8.4.2). The destination type is integral.

(2.4) When used as the source expression for an initialization (which includes use as an argument in a function call and use as the expression in a `return` statement). The type of the entity being initialized is (generally) the destination type. See 9.3, 9.3.3.

— end note

3 An expression e can be implicitly converted to a type T if and only if the declaration `T t = e;` is well-formed, for some invented temporary variable t (9.3).

4 Certain language constructs require that an expression be converted to a Boolean value. An expression e appearing in such a context is said to be contextually converted to bool and is well-formed if and only if the declaration `bool t(e);` is well-formed, for some invented temporary variable t (9.3).

5 Certain language constructs require conversion to a value having one of a specified set of types appropriate to the construct. An expression e of class type E appearing in such a context is said to be contextually implicitly converted to a specified type T and is well-formed if and only if e can be implicitly converted to a type T that is determined as follows: E is searched for non-explicit conversion functions whose return type is cv T or reference to cv T such that T is allowed by the context. There shall be exactly one such T.

6 The effect of any implicit conversion is the same as performing the corresponding declaration and initialization and then using the temporary variable as the result of the conversion. The result is an lvalue if T is an lvalue reference type or an rvalue reference to function type (9.2.3.2), an xvalue if T is an rvalue reference to object type, and a prvalue otherwise. The expression e is used as a glvalue if and only if the initialization uses it as a glvalue.

7 [Note: For class types, user-defined conversions are considered as well; see 10.3.8. In general, an implicit conversion sequence (11.3.3.1) consists of a standard conversion sequence followed by a user-defined conversion followed by another standard conversion sequence. — end note]

8 [Note: There are some contexts where certain conversions are suppressed. For example, the lvalue-to-rvalue conversion is not done on the operand of the unary & operator. Specific exceptions are given in the descriptions of those operators and contexts. — end note]

## 7.3.1 Lvalue-to-rvalue conversion [conv.lval]

1 A glvalue (7.2.1) of a non-function, non-array type T can be converted to a prvalue. If T is an incomplete type, a program that necessitates this conversion is ill-formed. If T is a non-class type, the type of the prvalue is the cv-unqualified version of T. Otherwise, the type of the prvalue is T.

2 When an lvalue-to-rvalue conversion is applied to an expression e, and either

   — e is not potentially evaluated, or

   — the evaluation of e results in the evaluation of a member ex of the set of potential results of e, and ex names a variable x that is not odr-used by ex (6.2),

the value contained in the referenced object is not accessed. [Example:

```
struct S { int n; };
auto f() {
    S x { 1 };
    constexpr S y { 2 };
    return [&](bool b) { return (b ? y : x).n; };
}
auto g = f();
int m = g(false); // undefined behavior due to access of x.n outside its lifetime
int n = g(true);  // OK, does not access y.n
```

— end example]

3 The result of the conversion is determined according to the following rules:

   — If T is `cv std::nullptr_t`, the result is a null pointer constant (7.3.11). [Note: Since no value is fetched from memory, there is no side effect for a volatile access (6.8.1), and an inactive member of a union (10.4) may be accessed. — end note]

---

60) For historical reasons, this conversion is called the “lvalue-to-rvalue” conversion, even though that name does not accurately reflect the taxonomy of expressions described in 7.2.1.

61) In C++ class and array prvalues can have cv-qualified types. This differs from ISO C, in which non-lvalues never have cv-qualified types.
For every

Otherwise, if the object to which the glvalue refers contains an invalid pointer value (6.6.4.4.2, 6.6.4.4.3), the behavior is implementation-defined.

Otherwise, the value contained in the object indicated by the glvalue is the prvalue result.

4 [Note: See also 7.2.1. — end note]

7.3.2  Array-to-pointer conversion

1 An lvalue or rvalue of type “array of N T” or “array of unknown bound of T” can be converted to a prvalue of type “pointer to T”. The temporary materialization conversion (7.3.4) is applied. The result is a pointer to the first element of the array.

7.3.3  Function-to-pointer conversion

1 An lvalue of function type T can be converted to a prvalue of type “pointer to T”. The result is a pointer to the function.

2 [Note: See 11.4 for additional rules for the case where the function is overloaded. — end note]

7.3.4  Temporary materialization conversion

1 A prvalue of type T can be converted to an xvalue of type “pointer to T”. The behavior is implementation-defined.

2 [Note: This conversion never applies to non-static member functions because an lvalue that refers to a non-static member function cannot be obtained.

3 [Note: These rules ensure that const-safety is preserved by the conversion.

Example:

```c
int main() {
    int k = X().n;  // OK, X() prvalue is converted to xvalue
    // #1: not allowed
}
```

---

62) This conversion never applies to non-static member functions because an lvalue that refers to a non-static member function cannot be obtained.

63) These rules ensure that const-safety is preserved by the conversion.
A prvalue of a type other than bool, char16_t, char32_t, or wchar_t whose integer conversion rank (6.7.4) is less than the rank of int can be converted to a prvalue of type int if int can represent all the values of the source type; otherwise, the source prvalue can be converted to a prvalue of type unsigned int.

A prvalue of an unscoped enumeration type whose underlying type is not fixed (9.6) can be converted to a prvalue of the first of the following types that can represent all the values of its underlying type: int, unsigned int, long int, unsigned long int, long long int, or unsigned long long int. If none of the types in that list can represent all the values of the underlying type, a prvalue of type char16_t, char32_t, or wchar_t can be converted to a prvalue of its underlying type.

A prvalue of an unscoped enumeration type whose underlying type is fixed (9.6) can be converted to a prvalue of its underlying type. Moreover, if integral promotion can be applied to its underlying type, a prvalue of an unscoped enumeration type whose underlying type is fixed can also be converted to a prvalue of the promoted underlying type.

A prvalue for an integral bit-field (10.3.10) can be converted to a prvalue of type int if int can represent all the values of the bit-field; otherwise, it can be converted to unsigned int if unsigned int can represent all the values of the bit-field. If the bit-field is larger yet, no integral promotion applies to it. If the bit-field has an enumerated type, it is treated as any other value of that type for promotion purposes.

A prvalue of type bool can be converted to a prvalue of type int, with false becoming zero and true becoming one.

These conversions are called integral promotions.

A prvalue of type float can be converted to a prvalue of type double. The value is unchanged.

This conversion is called floating-point promotion.

A prvalue of an integer type can be converted to a prvalue of another integer type. A prvalue of an unscoped enumeration type can be converted to a prvalue of an integer type.

If the destination type is unsigned, the resulting value is the least unsigned integer congruent to the source integer (modulo 2\(n\) where \(n\) is the number of bits used to represent the unsigned type). [Note: In a two’s complement representation, this conversion is conceptual and there is no change in the bit pattern (if there is no truncation). — end note]

If the destination type is signed, the value is unchanged if it can be represented in the destination type; otherwise, the value is implementation-defined.

If the destination type is bool, see 7.3.14. If the source type is bool, the value false is converted to zero and the value true is converted to one.

§ 7.3.8
A prvalue of an integer type or of an unscoped enumeration type can be converted to a prvalue of a floating-point type. If the source value can be exactly represented in the destination type, the result of the conversion is that exact representation. If the source value is between two adjacent destination values, the result of the conversion is an implementation-defined choice of either of those values. Otherwise, the behavior is undefined.

The conversions allowed as integral promotions are excluded from the set of integral conversions.

### 7.3.9 Floating-point conversions

A prvalue of floating-point type can be converted to a prvalue of another floating-point type. If the conversion of a null pointer constant to a pointer to member of a class type is a single conversion, and not the sequence of a pointer to member conversion followed by a qualification conversion (7.3.5). A null pointer constant of integral type can be converted to a prvalue of type "pointer to member of that type and is distinguishable from every other value of object pointer or function pointer type. Such a conversion is called a null member pointer conversion. Two null member pointer values of the same type shall compare equal. The conversion of a null pointer constant to a pointer to cv-qualified type is a single conversion, and not the sequence of a pointer conversion followed by a qualification conversion (7.3.5). A null pointer constant of integral type can be converted to a prvalue of type std::nullptr_t. [Note: The resulting prvalue is not a null pointer value. — end note]

A prvalue of type “pointer to cv T”, where T is an object type, can be converted to a prvalue of type “pointer to cv void”. The pointer value (6.7.2) is unchanged by this conversion.

A prvalue of type “pointer to cv D”, where D is a class type, can be converted to a prvalue of type “pointer to cv B”, where B is a base class (10.6) of D. If B is an inaccessible (10.8) or ambiguous (10.7) base class of D, a program that necessitates this conversion is ill-formed. The result of the conversion is a pointer to the base class subobject of the derived class object. The null pointer value is converted to the null pointer value of the destination type.

### 7.3.11 Pointer conversions

A null pointer constant (7.3.11) can be converted to a pointer-to-member type; the result is the null member pointer value of that type and is distinguishable from any pointer to member not created from a null pointer constant. Such a conversion is called a null member pointer conversion. Two null member pointer values of the same type shall compare equal. The conversion of a null pointer constant to a pointer to cv-qualified type is a single conversion, and not the sequence of a pointer to member conversion followed by a qualification conversion (7.3.5). A null pointer constant of integral type can be converted to a prvalue of type std::nullptr_t. [Note: The resulting prvalue is not a null pointer value. — end note]

A prvalue of type “pointer to member of B of type cv T”, where B is a class type, can be converted to a prvalue of type “pointer to member of D of type cv T”, where D is a derived class (10.6) of B. If B is an inaccessible (10.8), ambiguous (10.7), or virtual (10.6.1) base class of D, or a base class of a virtual base class of D, a program that necessitates this conversion is ill-formed. The result of the conversion refers to the same member as the pointer to member before the conversion took place, but it refers to the base class member as if it were a member of the derived class. The result refers to the member in D’s instance of B. Since the result has type “pointer to member of D of type cv T”, indirecting through it with a D object is valid. The result is the same as if indirecting through the pointer to member of B with the B subobject of D. The null member pointer value is converted to the null member pointer value of the destination type.\(^{64}\)

---

\(^{64}\) The rule for conversion of pointers to members (from pointer to member of base to pointer to member of derived) appears inverted compared to the rule for pointers to objects (from pointer to derived to pointer to base) (7.3.11, 10.6). This inversion is
7.3.13 Function pointer conversions

A prvalue of type “pointer to noexcept function” can be converted to a prvalue of type “pointer to function”. The result is a pointer to the function. A prvalue of type “pointer to member of type noexcept function” can be converted to a prvalue of type “pointer to member of type function”. The result designates the member function.

[Example:

```c
void (*p)();
void (**pp)() noexcept = &p;  // error: cannot convert to pointer to noexcept function
struct S { typedef void (*p)(); operator p(); };
void (*q)() noexcept = S();  // error: cannot convert to pointer to noexcept function
```

— end example]

7.3.14 Boolean conversions

A prvalue of arithmetic, unscoped enumeration, pointer, or pointer-to-member type can be converted to a prvalue of type `bool`. A zero value, null pointer value, or null member pointer value is converted to `false`; any other value is converted to `true`. For direct-initialization (9.3), a prvalue of type `std::nullptr_t` can be converted to a prvalue of type `bool`; the resulting value is `false`.

7.4 Usual arithmetic conversions

Many binary operators that expect operands of arithmetic or enumeration type cause conversions and yield result types in a similar way. The purpose is to yield a common type, which is also the type of the result. This pattern is called the usual arithmetic conversions, which are defined as follows:

1. If either operand is of scoped enumeration type (9.6), no conversions are performed; if the other operand does not have the same type, the expression is ill-formed.
2. If either operand is of type `long double`, the other shall be converted to `long double`.
3. Otherwise, if either operand is `double`, the other shall be converted to `double`.
4. Otherwise, if either operand is `float`, the other shall be converted to `float`.
5. Otherwise, the integral promotions (7.3.6) shall be performed on both operands. Then the following rules shall be applied to the promoted operands:

1. If both operands have the same type, no further conversion is needed.
2. Otherwise, if both operands have signed integer types or both have unsigned integer types, the operand with the type of lesser integer conversion rank shall be converted to the type of the operand with greater rank.
3. Otherwise, if the operand that has unsigned integer type has rank greater than or equal to the rank of the type of the other operand, the operand with signed integer type shall be converted to the type of the operand with unsigned integer type.
4. Otherwise, if the type of the operand with signed integer type can represent all of the values of the type of the operand with unsigned integer type, the operand with unsigned integer type shall be converted to the type of the operand with signed integer type.
5. Otherwise, both operands shall be converted to the unsigned integer type corresponding to the type of the operand with signed integer type.

If one operand is of enumeration type and the other operand is of a different enumeration type or a floating-point type, this behavior is deprecated (D.1).

---

necessary to ensure type safety. Note that a pointer to member is not an object pointer or a function pointer and the rules for conversions of such pointers do not apply to pointers to members. In particular, a pointer to member cannot be converted to a `void*`.

65) As a consequence, operands of type `bool, char16_t, char32_t, wchar_t, or an enumerated type are converted to some integral type.
7.5 Primary expressions

primary-expression:
literal
this
( expression )
id-expression
fold-expression
lambda-expression
requires-expression

7.5.1 Literals

A literal is a primary expression. Its type depends on its form (5.13). A string literal is an lvalue; all other literals are prvalues.

7.5.2 This

The keyword this names a pointer to the object for which a non-static member function (10.3.2.1) is invoked or a non-static data member’s initializer (10.3) is evaluated.

Otherwise, if a member-declarator declares a non-static data member (10.3) of a class X, the expression this is a prvalue of type “pointer to X”. It shall not appear elsewhere in the member-declarator.

The expression this shall not appear in any other context. [Example:

class Outer {
  int a[sizeof(*this)];
  unsigned int sz = sizeof(*this);
  void f() {
    int b[sizeof(*this)];
    struct Inner {
      int c[sizeof(*this)];
    };
  }
} // error: not inside a member function

— end example]

7.5.3 Parentheses

A parenthesized expression (E) is a primary expression whose type, value, and value category are identical to those of E. The parenthesized expression can be used in exactly the same contexts as those where E can be used, and with the same meaning, except as otherwise indicated.
### 7.5.4 Names

**id-expression:**

- unqualified-id
- qualified-id

1. An *id-expression* is a restricted form of a *primary-expression*. [Note: An *id-expression* can appear after `. and −>` operators (7.6.1.5). — end note]

2. An *id-expression* that denotes a non-static data member or non-static member function of a class can only be used:

   - (2.1) as part of a class member access (7.6.1.5) in which the object expression refers to the member’s class or a class derived from that class, or
   - (2.2) to form a pointer to member (7.6.2.1), or
   - (2.3) if that *id-expression* denotes a non-static data member and it appears in an unevaluated operand. [Example:
     ```
     struct S {
       int m;
     };
     int i = sizeof(S::m);    // OK
     int j = sizeof(S::m + 42); // OK
     ```
     — end example]

3. An *id-expression* that denotes the specialization of a concept (12.6.8) results in a prvalue of type *bool*. The expression is *true* if the concept’s normalized *constraint-expression* (12.4.2) is satisfied (12.4.1) by the specified template arguments and *false* otherwise. [Example:
   ```
   template<typename T> concept C = true;
   static_assert(C<int>);    // OK
   ```
   — end example] [Note: A concept’s constraints are also considered when using a template name (12.2) and during overload resolution (Clause 11), and they are compared during the the partial ordering of constraints (12.4.4). — end note]

4. A program that refers explicitly or implicitly to a function with a trailing *requires-clause* whose *constraint-expression* is not satisfied, other than to declare it, is ill-formed. [Example:
   ```
   void f(int) requires false;
   void g() {
     f(0);                        // error: cannot call f
     void (*p1)(int) = f;         // error: cannot take the address of f
     decltype(f)* p2 = nullptr;  // error: the type decltype(f) is invalid
   }
   ```
   In each case, the constraints of *f* are not satisfied. In the declaration of *p2*, those constraints are required to be satisfied even though *f* is an unevaluated operand (7.2). — end example]

#### 7.5.4.1 Unqualified names

**unqualified-id:**

- identifier
- operator-function-id
- conversion-function-id
- literal-operator-id
- ~ class-name
- ~ decltype-specifier
- template-id

1. An *identifier* is only an *id-expression* if it has been suitably declared (Clause 9) or if it appears as part of a declarator-id (9.2). [Note: For operator-function-ids, see 11.5; for conversion-function-ids, see 10.3.8.2; for literal-operator-ids, see 11.5.8; for template-ids, see 12.2. A class-name or decltype-specifier prefixed by ~ denotes a destructor; see 10.3.7. Within the definition of a non-static member function, an *identifier* that names a non-static member is transformed to a class member access expression (10.3.2). — end note]

---

66) This also applies when the object expression is an implicit (*this*) (10.3.2).
The result is the entity denoted by the identifier. If the entity is a local entity and naming it from outside of an unevaluated operand within the declarative region where the \textit{unqualified-id} appears would result in some intervening \textit{lambda-expression} capturing it by copy (7.5.5.2), the type of the expression is the type of a class member access expression (7.6.1.5) naming the non-static data member that would be declared for such a capture in the closure object of the innermost such intervening \textit{lambda-expression}. \textit{[Note: If that \textit{lambda-expression} is not declared \textit{mutable}, the type of such an identifier will typically be \textit{const} qualified. —end note]} If the entity is a template parameter object for a template parameter of type \textit{T} (12.1), the type of the expression is \textit{const T}. Otherwise, the type of the expression is the type of the result. \textit{[Note: The type will be adjusted as described in 7.2.2 if it is cv-qualified or is a reference type. —end note]} The expression is an lvalue if the entity is a function, variable, structured binding (9.5), data member, or template parameter object and a prvalue otherwise (7.2.1); it is a bit-field if the identifier designates a bit-field. \textit{[Example:}

```cpp
void f() {
  float x, &r = x;
  [&] {
    decltype(x) y1; // y1 has type float
declaype{(x)} y2 = y1; // y2 has type float const& because this lambda
      // is not mutable and x is an lvalue
declaype{(r)} r1 = y1; // r1 has type float
    decltype{(r)} r2 = y2; // r2 has type float const
  }
}
```

\textit{—end example]}

\section*{7.5.4.2 Qualified names}

\textit{qualified-id:}

\textit{nested-name-specifier template_opt unqualified-id}

\textit{nested-name-specifier:}

\begin{itemize}
  \item type-name ::
  \item namespace-name ::
  \item decltype-specifier ::
  \item nested-name-specifier identifier ::
  \item nested-name-specifier template_opt simple-template-id ::
\end{itemize}

1 The type denoted by a \textit{decltype-specifier} in a \textit{nested-name-specifier} shall be a class or enumeration type.

2 A \textit{nested-name-specifier} that denotes a class, optionally followed by the keyword \textit{template} (12.2), and then followed by the name of a member of either that class (10.3) or one of its base classes (10.6), is a \textit{qualified-id}; 6.4.3.1 describes name lookup for class members that appear in \textit{qualified-ids}. The result is the member. The type of the result is the type of the member. The result is an lvalue if the member is a static member function or a data member and a prvalue otherwise. \textit{[Note: A class member can be referred to using a \textit{qualified-id} at any point in its potential scope (6.3.7). —end note]} Where \textit{class-name ::= class-name} is used, the two \textit{class-names} shall refer to the same class; this notation names the destructor (10.3.7). The form \textit{~ decltype-specifier} also denotes the destructor, but it shall not be used as the \textit{unqualified-id} in a \textit{qualified-id}. \textit{[Note: A typedef-name that names a class is a \textit{class-name} (10.2). —end note]}

3 The \textit{nested-name-specifier :::} names the global namespace. A \textit{nested-name-specifier} that names a namespace (9.7), optionally followed by the keyword \textit{template} (12.2), and then followed by the name of a member of that namespace (or the name of a member of a namespace made visible by a \textit{using-directive}), is a \textit{qualified-id}; 6.4.3.2 describes name lookup for namespace members that appear in \textit{qualified-ids}. The result is the member. The type of the result is the type of the member. The result is an lvalue if the member is a function, a variable, or a structured binding (9.5) and a prvalue otherwise.

4 A \textit{nested-name-specifier} that denotes an enumeration (9.6), followed by the name of an enumerator of that enumeration, is a \textit{qualified-id} that refers to the enumerator. The result is the enumerator. The type of the result is the type of the enumeration. The result is a prvalue.

5 In a \textit{qualified-id}, if the \textit{unqualified-id} is a \textit{conversion-function-id}, its \textit{conversion-type-id} shall denote the same type in both the context in which the entire \textit{qualified-id} occurs and in the context of the class denoted by the \textit{nested-name-specifier}. 

\section*{§ 7.5.4.2}

89
7.5.5 Lambda expressions [expr.prim.lambda]

A lambda-expression provides a concise way to create a simple function object. [Example:]

```cpp
#include <algorithm>
#include <cmath>

void abssort(float* x, unsigned N) {
  std::sort(x, x + N, [](float a, float b) { return std::abs(a) < std::abs(b); });
}
```

—end example]

2 A lambda-expression is a prvalue whose result object is called the closure object. [Note: A closure object behaves like a function object (19.14). — end note]

3 In the decl-specifier-seq of the lambda-declarator, each declSpecifier shall either be mutable or constexpr. [Note: The trailing requires-clause is described in 9.2. — end note]

4 If a lambda-expression does not include a lambda-declarator, it is as if the lambda-declarator were (). The lambda return type is auto, which is replaced by the type specified by the trailing-return-type if provided and/or deduced from return statements as described in 9.1.7.4. [Example:]

```cpp
auto x1 = [](int i){ return i; };  // OK: return type is int
auto x2 = [](int i, int j){ return { i, 2 }; };  // error: deducing return type from braced-init-list
int j;
auto x3 = []()->auto&& { return j; };  // OK: return type is int&
```

—end example]

5 A lambda is a generic lambda if the auto type-specifier appears as one of the decl-specifiers in the decl-specifier-seq of a parameter-declaration of the lambda-expression, or if the lambda has a template-parameter-list. [Example:]

```cpp
int i = [](int i, auto a) { return i; }(3, 4);   // OK: a generic lambda
int j = [](class T>(T t, int i){ return i; })(3, 4);  // OK: a generic lambda
```

—end example]

7.5.5.1 Closure types [expr.prim.lambda.closure]

The type of a lambda-expression (which is also the type of the closure object) is a unique, unnamed non-union class type, called the closure type, whose properties are described below.

2 The closure type is declared in the smallest block scope, class scope, or namespace scope that contains the corresponding lambda-expression. [Note: This determines the set of namespaces and classes associated with the closure type (6.4.2). The parameter types of a lambda-declarator do not affect these associated namespaces and classes. — end note] The closure type is not an aggregate type (9.3.1). An implementation may define the closure type differently from what is described below provided this does not alter the observable behavior of the program other than by changing:

(2.1) the size and/or alignment of the closure type,
(2.2) whether the closure type is trivially copyable (Clause 10), or
(2.3) whether the closure type is a standard-layout class (Clause 10).

An implementation shall not add members of rvalue reference type to the closure type.

3 The closure type for a non-generic lambda-expression has a public inline function call operator (11.5.4) whose parameters and return type are described by the lambda-expression’s parameter-declaration-clause.
and trailing-return-type respectively. For a generic lambda, the closure type has a public inline function
call operator member template (12.6.2) whose template-parameter-list consists of the specified template-
parameter-list, if any, to which is appended one invented type template-parameter for each occurrence of
auto in the lambda’s parameter-declaration-clause, in order of appearance. The invented type template-parameter
is a template parameter pack if the corresponding parameter-declaration declares a function
parameter pack (9.2.3.5). The return type and function parameters of the function call operator template
are derived from the lambda-expression’s trailing-return-type and parameter-declaration-clause by replacing
each occurrence of auto in the decl-specifiers of the parameter-declaration-clause with the name of the
corresponding invented template-parameter. The requires-clause of the function call operator template is
the requires-clause immediately following < template-parameter-list >, if any. The trailing requires-clause of
the function call operator or operator template is the requires-clause following the lambda-declarator, if any.

[Example:

```cpp
auto glambda = [] (auto a, auto&& b) { return a < b; }; // OK
bool b = glambda(3, 3.14);
auto vglambda = [](auto printer) {
    return [=](auto&& ... ts) {
        // OK: ts is a function parameter pack
        printer(std::forward<decltype(ts)>(ts)...);
    };
};
auto p = vglambda([](auto v1, auto v2, auto v3) {
    std::cout << v1 << v2 << v3; });
auto q = p(1, 'a', 3.14); // OK: outputs 1a3.14
q(); // OK: outputs 1a3.14
```

—end example]

4 The function call operator or operator template is declared const (10.3.2) if and only if the lambda-expression’s
parameter-declaration-clause is not followed by mutable. It is neither virtual nor declared volatile. Any
noexcept-specifier specified on a lambda-expression applies to the corresponding function call operator or
operator template. An attribute-specifier-seq in a lambda-declarator appertains to the type of the corresponding
function call operator or operator template. The function call operator or any given operator template
specialization is a constexpr function if either the corresponding lambda-expression’s parameter-declaration-
clause is followed by constexpr, or it satisfies the requirements for a constexpr function (9.1.5). [Note:
Names referenced in the lambda-declarator are looked up in the context in which the lambda-expression
appears. —end note] [Example:

```cpp
auto ID = [] (auto a) { return a; }; // OK
static_assert(ID(3) == 3);
// OK

struct NonLiteral {
    NonLiteral(int n) : n(n) { }
    int n;
};
static_assert(ID(NonLiteral{3}).n == 3); // ill-formed
```

—end example]

5 [Example:

```cpp
auto monoid = [] (auto v) { return [=] (return v; ); }; // OK
auto add = [] (auto m1) constexpr {
    auto ret = m1();
    return [=] (auto m2) mutable {
        auto m1val = m1();
        auto plus = [=] (auto m2val) mutable constexpr {
            return m1val += m2val;
        };
        ret = plus(m2());
        return monoid(ret);
    };
};
```

§ 7.5.5.1 91
constexpr auto zero = monoid(0);
constexpr auto one = monoid(1);
static_assert(add(one)(zero)() == one()); // OK

// Since two below is not declared constexpr, an evaluation of its constexpr member function call operator cannot perform an lvalue-to-rvalue conversion on one of its subobjects (that represents its capture) in a constant expression.
auto two = monoid(2);
assert(two() == 2); // OK, not a constant expression.
static_assert(add(one)(one)() == two()); // ill-formed: two() is not a constant expression
static_assert(add(one)(one)() == monoid(2)()); // OK

—end example

6 The function call operator or operator template may be constrained (12.4.2) by a constrained-parameter (12.1), a requires-clause (Clause 12), or a trailing requires-clause (9.2). [Example:

```cpp
template <typename T> concept C1 = /* ... */;
template <std::size_t N> concept C2 = /* ... */;
template <typename A, typename B> concept C3 = /* ... */;

auto f = […]<typename T1, C1 T2> requires C2<sizeof(T1) + sizeof(T2)>
    (T1 a1, T1 b1, T2 a2, auto a3, auto a4) requires C3<decltype(a4), T2> {
    // T2 is a constrained parameter,
    // T1 and T2 are constrained by a requires-clause, and
    // T2 and the type of a4 are constrained by a trailing requires-clause.
};
—end example
```

7 The closure type for a non-generic lambda-expression with no lambda-capture whose constraints (if any) are satisfied has a conversion function to pointer to function with C++ language linkage (9.10) having the same parameter and return types as the closure type’s function call operator. The conversion is to “pointer to noexcept function” if the function call operator has a non-throwing exception specification. The value returned by this conversion function is the address of a function F that, when invoked, has the same effect as invoking the closure type’s function call operator. F is a constexpr function if the function call operator is a constexpr function. For a generic lambda with no lambda-capture, the closure type has a conversion function template to pointer to function. The conversion function template has the same invented template parameter list, and the pointer to function has the same parameter types, as the function call operator template. The return type of the pointer to function shall behave as if it were a decltype-specifier denoting the return type of the corresponding function call operator template specialization.

[Note: If the generic lambda has no trailing-return-type or the trailing-return-type contains a placeholder type, return type deduction of the corresponding function call operator template specialization has to be done. The corresponding specialization is that instantiation of the function call operator template with the same template arguments as those deduced for the conversion function template. Consider the following:

```cpp
auto glambda = []<auto a> { return a; };
int (*fp)(int) = glambda;
```

The behavior of the conversion function of glambda above is like that of the following conversion function:

```cpp
struct Closure {
    template<class T> auto operator()<T t> const { /* ... */ }
    template<class T> static auto lambda_call_operator_invoker(T a) {
        // forwards execution to operator()(a) and therefore has
        // the same return type deduced
        /* ... */
    }
    template<class T> using fptr_t =
        decltype(lambda_call_operator_invoker(declval<T>())) (*)(T);

    template<class T> operator fptr_t<T>() const
        { return &lambda_call_operator_invoker; }
};
—end note

§ 7.5.5.1 92
Example:

```cpp
void f1(int (*)(int)) { }
void f2(char (*)(int)) { }

void g(int (*)(int)) { } // #1
void g(char (*)(char)) { } // #2

void h(int (*)(int)) { } // #3
void h(char (*)(int)) { } // #4

auto glambda = [] (auto a) { return a; }; // OK
f1(glambda);  // OK
f2(glambda); // error: ID is not convertible
g(glambda);  // error: ambiguous
h(glambda);  // OK: calls #3 since it is convertible from ID
int& (*fpi)(int*) = [] (auto* a) -> auto& { return *a; }; // OK
```

The value returned by any given specialization of this conversion function template is the address of a function F that, when invoked, has the same effect as invoking the generic lambda’s corresponding function call operator template specialization. F is a constexpr function if the corresponding specialization is a constexpr function. [Note: This will result in the implicit instantiation of the generic lambda’s body. The instantiated generic lambda’s return type and parameter types shall match the return type and parameter types of the pointer to function. —end note]

Example:

```cpp
auto GL = [] (auto a) { std::cout << a; return a; }; // OK: through conversion function template
int (*GL_int)(int) = GL; // OK: same as GL(3)
```

The conversion function or conversion function template is public, constexpr, non-virtual, non-explicit, const, and has a non-throwing exception specification (13.4). [Example:

```cpp
auto Fwd = [] (int (*fp)(int), auto a) { return fp(a); };
auto C = [] (auto a) { return a; };
static_assert(Fwd(C,3) == 3); // OK

// No specialization of the function call operator template can be constexpr (due to the local static).
auto NC = [] (auto a) { static int s; return a; };
static_assert(Fwd(NC,3) == 3); // ill-formed
```

The lambda-expression’s compound-statement yields the function-body (9.4) of the function call operator, but for purposes of name lookup (6.4), determining the type and value of this (10.3.2.1) and transforming id-expressions referring to non-static class members into class member access expressions using (*this) (10.3.2), the compound-statement is considered in the context of the lambda-expression. [Example:

```cpp
struct S1 {
  int x, y;
  int operator()(int);
  void f() {
    [=]()->int {
      return operator()(this->x + y); // equivalent to S1::operator()(this->x + (*this).y)
      // this has type S1*
    };
  }
};
```

Further, a variable __func__ is implicitly defined at the beginning of the compound-statement of the lambda-expression, with semantics as described in 9.4.1.

The closure type associated with a lambda-expression has no default constructor if the lambda-expression has a lambda-capture and a defaulted default constructor otherwise. It has a defaulted copy constructor and a defaulted move constructor (10.3.5). It has a deleted copy assignment operator if the lambda-expression has
a lambda-capture and defaulted copy and move assignment operators otherwise (10.3.6). [Note: These special
member functions are implicitly defined as usual, and might therefore be defined as deleted. — end note]

13 The closure type associated with a lambda-expression has an implicitly-declared destructor (10.3.7).

14 A member of a closure type shall not be explicitly instantiated (12.8.2), explicitly specialized (12.8.3), or
named in a friend declaration (10.8.3).

7.5.5.2 Captures

lambda-capture:
capture-default
capture-list
capture-default, capture-list
capture-default:
& =
capture-list:
capture
capture-list, capture
capture:
simple-capture . . . opt
. . . opt init-capture
simple-capture:
identifier
& identifier
this
* this
init-capture:
identifier initializer
& identifier initializer

1 The body of a lambda-expression may refer to variables with automatic storage duration and the *this
object (if any) of enclosing block scopes by capturing those entities, as described below.

2 If a lambda-capture includes a capture-default that is &, no identifier in a simple-capture of that lambda-capture
shall be preceded by &. If a lambda-capture includes a capture-default that is =, each simple-capture of
that lambda-capture shall be of the form “& identifier”, “this”, or “* this”. [Note: The form [&, this]
is redundant but accepted for compatibility with ISO C++ 2014. — end note] Ignoring appearances in
initializers of init-captures, an identifier or this shall not appear more than once in a lambda-capture.
[Example:

struct S2 { void f(int i); }
void S2::f(int i) {
    [& , i]{ }; // OK
    [& , this , i]{ }; // OK, equivalent to [& , i]
    [& , &i]{ }; // error: i preceded by & when & is the default
    [= , *this]{ }; // OK
    [= , this]{}; // OK, equivalent to [=]
    [i , i]{}; // error: i repeated
    [this , *this]{}; // error: this appears twice
}
— end example]

3 A lambda-expression shall not have a capture-default or simple-capture in its lambda-introducer unless its
innermost enclosing scope is a block scope (6.3.3) or it appears within a default member initializer and its
innermost enclosing scope is the corresponding class scope (6.3.7).

4 The identifier in a simple-capture is looked up using the usual rules for unqualified name lookup (6.4.1); each
such lookup shall find a local entity. The simple-captures this and * this denote the local entity *this.
An entity that is designated by a simple-capture is said to be explicitly captured.

5 If an identifier in a simple-capture appears as the declarator-id of a parameter of the lambda-declarator’s
parameter-declaration-clause, the program is ill-formed. [Example:
void f() {
    int x = 0;
    auto g = [x](int x) { return 0; }  // error: parameter and simple-capture have the same name
}

— end example

An init-capture behaves as if it declares and explicitly captures a variable of the form “auto init-capture ;” whose declarative region is the lambda-expression’s compound-statement, except that:

(6.1) — if the capture is by copy (see below), the non-static data member declared for the capture and the variable are treated as two different ways of referring to the same object, which has the lifetime of the non-static data member, and no additional copy and destruction is performed, and

(6.2) — if the capture is by reference, the variable’s lifetime ends when the closure object’s lifetime ends.

[Note: This enables an init-capture like “x = std::move(x)”; the second “x” must bind to a declaration in the surrounding context. — end note]  [Example:

    int x = 4;
    auto y = [&r = x, x = x+1]()->int {
        r += 2;
        return x+2;
    }(); // Updates ::x to 6, and initializes y to 7.

    auto z = [a = 42](int a) { return 1; }  // error: parameter and local variable have the same name
    — end example]

For the purposes of lambda capture, an expression potentially references local entities as follows:

(7.1) — An id-expression that names a local entity potentially references that entity; an id-expression that names one or more non-static class members and does not form a pointer to member (7.6.2.1) potentially references *this. [Note: This occurs even if overload resolution selects a static member function for the id-expression. — end note]

(7.2) — A this expression potentially references *this.

(7.3) — A lambda-expression potentially references the local entities named by its simple-captures.

If an expression potentially references a local entity within a declarative region in which it is odr-usable, and the expression would be potentially evaluated if the effect of any enclosing typeid expressions (7.6.1.8) were ignored, the entity is said to be implicitly captured by each intervening lambda-expression with an associated capture-default that does not explicitly capture it. The implicit capture of *this is deprecated when the capture-default is =; see D.2. [Example:

    void f(int, const int (&)[2] = {});  // #1
    void f(const int &, const int (&)[1]);  // #2
    void test() {
        const int x = 17;
        auto g = [](auto a) {
            f(x);  // OK: calls #1, does not capture x
        };

        auto g1 = [=](auto a) {
            f(x);  // OK: calls #1, captures x
        };

        auto g2 = [=](auto a) {
            int selector[sizeof(a) == 1 ? 1 : 2]{};
            f(x, selector);  // OK: captures x, might call #1 or #2
        };

        auto g3 = [=](auto a) {  // captures x regardless of whether a + x is an unevaluated operand
            typeid(a + x);
        };
    }

§ 7.5.5.2
Within g1, an implementation might optimize away the capture of x as it is not odr-used. —end example] [Note: The set of captured entities is determined syntactically, and entities might be implicitly captured even if the expression denoting a local entity is within a discarded statement (8.4.1). [Example:

```c
template<bool B>
void f(int n) {
    [=](auto a) {
        if constexpr (B && sizeof(a) > 4) {
            (void)n;     // captures n regardless of the value of B and sizeof(int)
        }
    }(0);
}
—end example—end note]

An entity is captured if it is captured explicitly or implicitly. An entity captured by a lambda-expression is odr-used (6.2) in the scope containing the lambda-expression. If a lambda-expression explicitly captures an entity that is not odr-usable or captures a structured binding (explicitly or implicitly), the program is ill-formed. [Example:

```c
void f1(int i) {
    int const N = 20;
    auto m1 = [=]{
        int const M = 30;
        auto m2 = [i]{
            int x[N][M];
            x[0][0] = i;
            // OK: i is explicitly captured by m2 and implicitly captured by m1
        };
    };
    struct s1 {
        int f;
        void work(int n) {
            int m = n*n;
            auto m3 = [this,m] {
                auto m4 = [&,j] {
                    int x = n;
                    // error: j not odr-usable due to intervening lambda m3
                    x += m;
                    // error: m is odr-used but not odr-usable due to intervening lambda m3
                    x += i;
                    // error: i is odr-used but not odr-usable
                    // due to intervening function and class scopes
                    x += f;
                    // OK: this captured implicitly by m4 and explicitly by m3
                };
            };
        }
    };
    struct s2 {
        double ohseven = .007;
        auto f() {
            return [this] {
                return [this] {
                    return ohseven;
                    // OK
                }();
            };
        }
    auto g() {
        return [] {
            return [this] {};
            // error: *this not captured by outer lambda-expression
        }();
    }
    —end example] 9
```

A lambda-expression appearing in a default argument shall not implicitly or explicitly capture any entity. [Example:
©ISO/IEC

void f2() {
    int i = 1;
    void g1(int = ([i]{ return i; })());    // ill-formed
    void g2(int = ([i]{ return 0; })());    // ill-formed
    void g3(int = ([=]{ return i; })());    // ill-formed
    void g4(int = ([=]{ return 0; })());    // OK
    void g5(int = ([]{ return sizeof i; })()); // OK
}
— end example]

10 An entity is captured by copy if

(10.1) — it is implicitly captured, the capture-default is =, and the captured entity is not *this, or

(10.2) — it is explicitly captured with a capture that is not of the form this, & identifier, or & identifier initializer.

For each entity captured by copy, an unnamed non-static data member is declared in the closure type. The declaration order of these members is unspecified. The type of such a data member is the referenced type if the entity is a reference to an object, an lvalue reference to the referenced function type if the entity is a reference to a function, or the type of the corresponding captured entity otherwise. A member of an anonymous union shall not be captured by copy.

11 Every id-expression within the compound-statement of a lambda-expression that is an odr-use (6.2) of an entity captured by copy is transformed into an access to the corresponding unnamed data member of the closure type. [Note: An id-expression that is not an odr-use refers to the original entity, never to a member of the closure type. However, such an id-expression can still cause the implicit capture of the entity. — end note] If *this is captured by copy, each expression that odr-uses *this is transformed to instead refer to the corresponding unnamed data member of the closure type. [Example:

    void f(const int*);
    void g() {
        const int N = 10;
        [=] {
            int arr[N]; // OK: not an odr-use, refers to automatic variable
            f(&N); // OK: causes N to be captured; &N points to
                    // the corresponding member of the closure type
        }
    }
— end example]

12 An entity is captured by reference if it is implicitly or explicitly captured but not captured by copy. It is unspecified whether additional unnamed non-static data members are declared in the closure type for entities captured by reference. If declared, such non-static data members shall be of literal type. [Example:

    // The inner closure type must be a literal type regardless of how reference captures are represented.
    static_assert([](int n) { return [n] { return ++n; }(); }((3) == 4));
— end example] A bit-field or a member of an anonymous union shall not be captured by reference.

13 An id-expression within the compound-statement of a lambda-expression that is an odr-use of a reference captured by reference refers to the entity to which the captured reference is bound and not to the captured reference. [Note: The validity of such captures is determined by the lifetime of the object to which the reference refers, not by the lifetime of the reference itself. — end note] [Example:

    auto h(int &r) {
        return [&] {
            ++r; // Valid after h returns if the lifetime of the
                 // object to which r is bound has not ended
        };
    }
— end example]

14 If a lambda-expression m2 captures an entity and that entity is captured by an immediately enclosing lambda-expression m1, then m2’s capture is transformed as follows:

(14.1) — if m1 captures the entity by copy, m2 captures the corresponding non-static data member of m1’s closure type;
if \( m_1 \) captures the entity by reference, \( m_2 \) captures the same entity captured by \( m_1 \).

**Example:** The nested lambda-expressions and invocations below will output 123234.

```cpp
int a = 1, b = 1, c = 1;
auto m1 = [a, &b, &c]() mutable {
  auto m2 = [a, b, &c]() mutable {
    std::cout << a << b << c;
    a = 4; b = 4; c = 4;
  };
  a = 3; b = 3; c = 3;
  m2();
};

a = 2; b = 2; c = 2;
m1();
std::cout << a << b << c;
```

When the lambda-expression is evaluated, the entities that are captured by copy are used to direct-initialize each corresponding non-static data member of the resulting closure object, and the non-static data members corresponding to the init-captures are initialized as indicated by the corresponding initializer (which may be copy- or direct-initialization). (For array members, the array elements are direct-initialized in increasing subscript order.) These initializations are performed in the (unspecified) order in which the non-static data members are declared. [Note: This ensures that the destructions will occur in the reverse order of the constructions. —end note]

[Note: If a non-reference entity is implicitly or explicitly captured by reference, invoking the function call operator of the corresponding lambda-expression after the lifetime of the entity has ended is likely to result in undefined behavior. —end note]

A simple-capture followed by an ellipsis is a pack expansion (12.6.3). An init-capture preceded by an ellipsis is a pack expansion that introduces an init-capture pack (12.6.3) whose declarative region is the lambda-expression's compound-statement. [Example:

```cpp
template<class... Args>
void f(Args... args) {
  auto lm = [&args...]{ return g(args...); };
  lm();

  auto lm2 = [...xs=std::move(args)]{ return g(xs...); };
  lm2();
}
```

—end example]

### 7.5.6 Fold expressions

A fold expression performs a fold of a pack (12.6.3) over a binary operator.

```
fold-expression:
  ( cast-expression fold-operator ... )
  ( ... fold-operator cast-expression )
  ( cast-expression fold-operator ... fold-operator cast-expression )

fold-operator: one of
  + - * / % & ^ | << >>
  += -= *= /= %= &= ^= |= <<= >>= =
```

An expression of the form \((\ldots \ op \ e)\) where \( \op \) is a fold-operator is called a unary left fold. An expression of the form \((e \ op \ \ldots)\) where \( \op \) is a fold-operator is called a unary right fold. Unary left folds and unary right folds are collectively called unary folds. In a unary fold, the cast-expression shall contain an unexpanded pack (12.6.3).

An expression of the form \((e_1 \ op_1 \ldots \ op_2 \ e_2)\) where \( \op_1 \) and \( \op_2 \) are fold-operators is called a binary fold. In a binary fold, \( \op_1 \) and \( \op_2 \) shall be the same fold-operator, and either \( e_1 \) shall contain an unexpanded pack or \( e_2 \) shall contain an unexpanded pack, but not both. If \( e_2 \) contains an unexpanded pack, the expression
is called a binary left fold. If e1 contains an unexpanded pack, the expression is called a binary right fold.

[Example:

```c++
#include <iostream>

int main() {
    bool f(int x, ... y, z) {
        return (true && ... && x); // OK
    }

    bool g(int x, ...) {
        return (x + ... + y); // error: both operands contain unexpanded packs
    }
}
```
—end example]

7.5.7 Requires expressions [expr.prim.req]

A requires-expression provides a concise way to express requirements on template arguments that can be checked by name lookup (6.4) or by checking properties of types and expressions.

```c++
requires-expression:
    requires requirement-parameter-list opt requirement-body

requirement-parameter-list:
    ( parameter-declaration-clause opt )

requirement-body:
    { requirement-seq }

requirement-seq:
    requirement
    requirement-seq requirement

requirement:
    simple-requirement
    type-requirement
    compound-requirement
    nested-requirement
```

2 A requires-expression is a prvalue of type bool whose value is described below. Expressions appearing within a requirement-body are unevaluated operands (7.2).

3 [Example: A common use of requires-expressions is to define requirements in concepts such as the one below:

```c++
template<typename T>
concept R = requires(T i) {
    typename T::type;
    {*i} -> const typename T::type&;
};
```

A requires-expression can also be used in a requires-clause (Clause 12) as a way of writing ad hoc constraints on template arguments such as the one below:

```c++
template<typename T>
requires requires(T x) { x + x; }
T add(T a, T b) { return a + b; }
```

The first requires introduces the requires-clause, and the second introduces the requires-expression. — end example]

4 A requires-expression may introduce local parameters using a parameter-declaration-clause (9.2.3.5). A local parameter of a requires-expression shall not have a default argument. Each name introduced by a local parameter is in scope from the point of its declaration until the closing brace of the requirement-body. These parameters have no linkage, storage, or lifetime; they are only used as notation for the purpose of defining requirements. The parameter-declaration-clause of a requirement-parameter-list shall not terminate with an ellipsis. [Example:

```c++
template<typename T>
concept C = requires(T t, ...) { // error: terminates with an ellipsis
    t;
};
```
The requirement-body contains a sequence of requirements. These requirements may refer to local parameters, template parameters, and any other declarations visible from the enclosing context.

The substitution of template arguments into a requires-expression may result in the formation of invalid types or expressions in its requirements or the violation of the semantic constraints of those requirements. In such cases, the requires-expression evaluates to false; it does not cause the program to be ill-formed. The substitution and semantic constraint checking proceeds in lexical order and stops when a condition that determines the result of the requires-expression is encountered. If substitution (if any) and semantic constraint checking succeed, the requires-expression evaluates to true. [Note: If a requires-expression contains invalid types or expressions in its requirements, and it does not appear within the declaration of a templated entity, then the program is ill-formed. — end note] If the substitution of template arguments into a requirement would always result in a substitution failure, the program is ill-formed; no diagnostic required. [Example:

```cpp
template<typename T> concept C =
  requires {
    new int[-(int)sizeof(T)]; // ill-formed, no diagnostic required
  };
— end example]
```

### 7.5.7.1 Simple requirements

<table>
<thead>
<tr>
<th>Requirement</th>
<th>Expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>simple-requirement</td>
<td>expression</td>
</tr>
</tbody>
</table>

A simple-requirement asserts the validity of an expression. [Note: The enclosing requires-expression will evaluate to false if substitution of template arguments into the expression fails. The expression is an unevaluated operand (7.2). — end note] [Example:

```cpp
template<typename T> concept C =
  requires (T a, T b) {
    a + b; // C<T> is true if a + b is a valid expression
  };
— end example]
```

### 7.5.7.2 Type requirements

<table>
<thead>
<tr>
<th>Requirement</th>
<th>Expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>type-requirement</td>
<td>typename nested-name-specifier_opt type-name ;</td>
</tr>
</tbody>
</table>

A type-requirement asserts the validity of a type. [Note: The enclosing requires-expression will evaluate to false if substitution of template arguments fails. — end note] [Example:

```cpp
template<typename T, typename T::type = 0> struct S;
template<typename T> using Ref = T&;
template<typename T> concept C = requires {
  typename T::inner; // required nested member name
  typename S<T> ; // required class template specialization
  typename Ref<T>; // required alias template substitution, fails if T is void
};
— end example]
```

A type-requirement that names a class template specialization does not require that type to be complete (6.7).

### 7.5.7.3 Compound requirements

<table>
<thead>
<tr>
<th>Requirement</th>
<th>Expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>compound-requirement</td>
<td>{ expression } noexcept_opt return-type-requirement_opt ;</td>
</tr>
</tbody>
</table>

A compound-requirement asserts properties of the expression \( E \). Substitution of template arguments (if any) and verification of semantic properties proceed in the following order:

1. Substitution of template arguments (if any) into the expression is performed.
If the `noexcept` specifier is present, E shall not be a potentially-throwing expression (13.4).

If the `return-type-requirement` is present, then:

1. Substitution of template arguments (if any) into the `return-type-requirement` is performed.
2. If the `return-type-requirement` is a `trailing-return-type`, E is implicitly convertible to the type named by the `trailing-return-type`. If conversion fails, the enclosing `requires-expression` is `false`.
3. If the `return-type-requirement` starts with a `constrained-parameter` (12.1), the expression is deduced against an invented function template F using the rules in 12.9.2.1. F is a `void` function template with a single type template parameter T declared with the `constrained-parameter`. A `cv-qualifier-seq` is formed as the union of `const` and `volatile` specifiers around the `constrained-parameter`. F has a single parameter whose `type-specifier` is `cv T` followed by the `abstract-declarator`. If deduction fails, the enclosing `requires-expression` is `false`.

Example:

```cpp
template<constr T> concept C1 = requires(T x) {
  {x++};
};
```

The `compound-requirement` in C1 requires that `x++` is a valid expression. It is equivalent to the `simple-requirement` `x++`.

```cpp
template<constr T> concept C2 = requires(T x) {
  {*x} -> typename T::inner;
};
```

The `compound-requirement` in C2 requires that `*x` is a valid expression, that `typename T::inner` is a valid type, and that `*x` is implicitly convertible to `typename T::inner`.

```cpp
template<constr T, constr U> concept C3 = requires(T t, U u) {
  t == u;
};
```

The `compound-requirement` requires that `*x` be deduced as an argument for the invented function:

```cpp
template<C3<int> X> void f(X const&);
```

In this case, deduction only succeeds if an expression of the type deduced for `X` can be compared to an `int` with the `==` operator.

```cpp
template<constr T> concept C5 = requires(T x) {
  {g(x)} noexcept;
};
```

The `compound-requirement` in C5 requires that `g(x)` is a valid expression and that `g(x)` is non-throwing.

7.5.7.4 Nested requirements

A `nested-requirement` can be used to specify additional constraints in terms of local parameters. The `constraint-expression` shall be satisfied (12.4.2) by the substituted template arguments, if any. Substitution of template arguments into a `nested-requirement` does not result in substitution into the `constraint-expression` other than as specified in 12.4.2. (Example:

```cpp
template<typename U> concept C = sizeof(U) == 1;
```

```cpp
template<typename T> concept D = requires (T t) {
  requires C<decltype (+t)>;
};
```

D<T> is satisfied if `sizeof(decltype (+t)) == 1` (12.4.1.2). — end example]

A local parameter shall only appear as an unevaluated operand (7.2) within the `constraint-expression`. (Example:
template<typename T> concept C = requires (T a) {
  requires sizeof(a) == 4; // OK
  requires a == 0; // error: evaluation of a constraint variable
}
—end example]}

7.6 Compound expressions  [expr.compound]
7.6.1 Postfix expressions  [expr.post]

Postfix expressions group left-to-right.

postfix-expression:
  primary-expression
  postfix-expression [ expr-or-braced-init-list ]
  postfix-expression ( expression-list_opt )
  simple-type-specifier ( expression-list_opt )
  typename-specifier ( expression-list_opt )
  simple-type-specifier braced-init-list
  typename-specifier braced-init-list
  postfix-expression . template_opt id-expression
  postfix-expression -> template_opt id-expression
  postfix-expression . pseudo-destructor-name
  postfix-expression -> pseudo-destructor-name
  postfix-expression ++
  postfix-expression --
  dynamic_cast < type-id > ( expression )
  static_cast < type-id > ( expression )
  reinterpret_cast < type-id > ( expression )
  const_cast < type-id > ( expression )
  typeid ( expression )
  typeid ( type-id )

expression-list:
  initializer-list

pseudo-destructor-name:
  nested-name-specifier_opt type-name :: ~ type-name
  nested-name-specifier template simple-template-id :: ~ type-name
  ~ type-name
  ~ decltype-specifier

[Note: The > token following the type-id in a dynamic_cast, static_cast, reinterpret_cast, or const_cast may be the product of replacing a >> token by two consecutive > tokens (12.2). — end note]

7.6.1.1 Subscripting  [expr.sub]

A postfix expression followed by an expression in square brackets is a postfix expression. One of the expressions shall be a glvalue of type “array of T” or a prvalue of type “pointer to T” and the other shall be a prvalue of unscoped enumeration or integral type. The result is of type “T”. The type “T” shall be a completely-defined object type. The expression \( E_1[E_2] \) is identical (by definition) to \( *(E_1)+E_2) \), except that in the case of an array operand, the result is an lvalue if that operand is an lvalue and an xvalue otherwise. The expression \( E_1 \) is sequenced before the expression \( E_2 \).

[Note: Despite its asymmetric appearance, subscripting is a commutative operation except for sequencing. See 7.6.2 and 7.6.6 for details of * and + and 9.2.3.4 for details of array types. — end note]

A braced-init-list shall not be used with the built-in subscript operator.

7.6.1.2 Function call  [expr.call]

A function call is a postfix expression followed by parentheses containing a possibly empty, comma-separated list of initializer-clauses which constitute the arguments to the function. The postfix expression shall have function type or function pointer type. For a call to a non-member function or to a static member function, the postfix expression shall be either an lvalue that refers to a function (in which case the function-to-pointer standard conversion (7.3.3) is suppressed on the postfix expression), or it shall have function pointer type.

67) This is true even if the subscript operator is used in the following common idiom: \&x[0].

§ 7.6.1.2  102
For a call to a non-static member function, the postfix expression shall be an implicit (10.3.2, 10.3.9) or explicit class member access (7.6.1.5) whose id-expression is a function member name, or a pointer-to-member expression (7.6.4) selecting a function member; the call is as a member of the class object referred to by the object expression. In the case of an implicit class member access, the implied object is the one pointed to by this. [Note: A member function call of the form f() is interpreted as (*this).f() (see 10.3.2). — end note]

If a function or member function name is used, the appropriate function and the validity of the call are determined according to the rules in 11.3. If the selected function is non-virtual, or if the id-expression in the class member access expression is a qualified-id, that function is called. Otherwise, its final overrider (10.6.2) in the dynamic type of the object expression is called; such a call is referred to as a virtual function call. [Note: The dynamic type is the type of the object referred to by the current value of the object expression. 10.9.4 describes the behavior of virtual function calls when the object expression refers to an object under construction or destruction. — end note]

[Note: If a function or member function name is used, and name lookup (6.4) does not find a declaration of that name, the program is ill-formed. No function is implicitly declared by such a call. — end note]

If the postfix-expression designates a destructor (10.3.7), the type of the function call expression is void; otherwise, the type of the function call expression is the return type of the statically chosen function (i.e., ignoring the virtual keyword), even if the type of the function actually called is different. This return type shall be an object type, a reference type or ce void.

Calling a function through an expression whose function type is different from the function type of the called function’s definition results in undefined behavior (9.10).

When a function is called, each parameter (9.2.3.5) is initialized (9.3, 10.3.5) with its corresponding argument. If there is no corresponding argument, the default argument for the parameter is used; the program is ill-formed if one is not present. [Example:

```cpp
template<typename ...T> int f(int n = 0, T ...t);
int x = f<int>();
// error: no argument for second function parameter
```
—end example] If the function is a non-static member function, the this parameter of the function (10.3.2.1) is initialized with a pointer to the object of the call, converted as if by an explicit type conversion (7.6.3). [Note: There is no access or ambiguity checking on this conversion; the access checking and disambiguation are done as part of the (possibly implicit) class member access operator. See 10.7, 10.8.2, and 7.6.1.5. — end note] When a function is called, the type of any parameter shall not be a class type that is either incomplete or abstract. [Note: This still allows a parameter to be a pointer or reference to such a type. However, it prevents a passed-by-value parameter to have an incomplete or abstract class type. — end note] It is implementation-defined whether the lifetime of a parameter ends when the function in which it is defined returns or at the end of the enclosing full-expression. The initialization and destruction of each parameter occurs within the context of the calling function. [Example: The access of the constructor, conversion functions or destructor is checked at the point of call in the calling function. If a constructor or destructor for a function parameter throws an exception, the search for a handler starts in the scope of the calling function; in particular, if the function called has a function-try-block (Clause 13) with a handler that could handle the exception, this handler is not considered. — end example]

The postfix-expression is sequenced before each expression in the expression-list and any default argument. The initialization of a parameter, including every associated value computation and side effect, is indeterminately sequenced with respect to that of any other parameter. [Note: All side effects of argument evaluations are sequenced before the function is entered (see 6.8.1). — end note] [Example:

```cpp
void f() {
    std::string s = "but I have heard it works even if you don't believe in it";
    s.replace(0, 4, " " ).replace(s.find("even"), 4, "only").replace(s.find(" don't"), 6, " " );
    assert(s == "I have heard it works only if you believe in it"); // OK
}
```
—end example] [Note: If an operator function is invoked using operator notation, argument evaluation is sequenced as specified for the built-in operator; see 11.3.1.2. — end note] [Example:

```cpp
struct S {
    S(int);
};
int operator<(S, int);
int i, j;
```
A function call is an lvalue if the result type is an lvalue reference type or an rvalue reference to function

When there is no parameter for a given argument, the argument is passed in such a way that the receiving

A function can be declared to accept fewer arguments (by declaring default arguments (9.2.3.6)) or more

When there is no parameter for a given argument, the argument is passed in such a way that the receiving

A function can be declared to accept fewer arguments (by declaring default arguments (9.2.3.6)) or more

When there is no parameter for a given argument, the argument is passed in such a way that the receiving

A function can be declared to accept fewer arguments (by declaring default arguments (9.2.3.6)) or more

When there is no parameter for a given argument, the argument is passed in such a way that the receiving

A function can be declared to accept fewer arguments (by declaring default arguments (9.2.3.6)) or more

Recursive calls are permitted, except to the main function (6.8.3.1).

A function call is an lvalue if the result type is an lvalue reference type or an rvalue reference to function

An expression of the form

An expression of the form

An expression of the form

An expression of the form

An expression of the form

An expression of the form

An expression of the form
type and of the type designated by the pseudo-destructor-name shall be the same type. Furthermore, the two type-names in a pseudo-destructor-name of the form

\[
\text{nested-name-specifier}_\text{opt} \text{ type-name} ::\sim \text{ type-name}
\]

shall designate the same scalar type (ignoring cv-qualification).

7.6.1.5 Class member access

1 A postfix expression followed by a dot \( . \) or an arrow \( \rightarrow \), optionally followed by the keyword template (12.2), and then followed by an id-expression, is a postfix expression. The postfix expression before the dot or arrow is evaluated,\(^{68}\) the result of that evaluation, together with the id-expression, determines the result of the entire postfix expression.

2 For the first option (dot) the first expression shall be a glvalue having class type. For the second option (arrow) the first expression shall be a prvalue having pointer to class type. In both cases, the class type shall be complete unless the class member access appears in the definition of that class. [Note: If the class is incomplete, lookup in the complete class type is required to refer to the same declaration (6.3.7). — end note] The expression \( E1\rightarrow E2 \) is converted to the equivalent form *(\( E1 \)).\( E2 \); the remainder of 7.6.1.5 will address only the first option (dot).\(^{69}\) In either case, the id-expression shall name a member of the class or of one of its base classes. [Note: Because the name of a class is inserted in its class scope (Clause 10), the name of a class is also considered a nested member of that class. — end note] [Note: 6.4.5 describes how names are looked up after the . and \( \rightarrow \) operators. — end note]

3 Abbreviating postfix-expression.id-expression as \( E1.E2 \), \( E1 \) is called the object expression. If \( E2 \) is a bit-field, \( E1.E2 \) is a bit-field. The type and value category of \( E1.E2 \) are determined as follows. In the remainder of 7.6.1.5, \( eq \) represents either const or the absence of const and \( vq \) represents either volatile or the absence of volatile. \( cv \) represents an arbitrary set of cv-qualifiers, as defined in 6.7.3.

4 If \( E2 \) is declared to have type “reference to \( T \)”, then \( E1.E2 \) is an lvalue; the type of \( E1.E2 \) is \( T \). Otherwise, one of the following rules applies.

\((4.1)\) — If \( E2 \) is a static data member and the type of \( E2 \) is \( T \), then \( E1.E2 \) is an lvalue; the expression designates the named member of the class. The type of \( E1.E2 \) is \( T \).

\((4.2)\) — If \( E2 \) is a non-static data member and the type of \( E1 \) is “cq1 \( vq1 \) \( X \)”, and the type of \( E2 \) is “cq2 \( vq2 \) \( T \)”, the expression designates the named member of the object designated by the first expression. If \( E1 \) is an lvalue, then \( E1.E2 \) is an lvalue; otherwise \( E1.E2 \) is an xvalue. Let the notation \( vq12 \) stand for the “union” of \( vq1 \) and \( vq2 \); that is, if \( vq1 \) or \( vq2 \) is volatile, then \( vq12 \) is volatile. Similarly, let the notation \( cq12 \) stand for the “union” of \( cq1 \) and \( cq2 \); that is, if \( cq1 \) or \( cq2 \) is const, then \( cq12 \) is const.

\((4.3)\) — If \( E2 \) is declared to have type “function of \( T \)”, and the type of \( E1.E2 \) is “\( vq12 \) \( T \)”. If \( E2 \) is not declared to be a mutable member, then the type of \( E1.E2 \) is “\( cq12 \) \( vq12 \) \( T \)”.

\((4.4)\) — If \( E2 \) is a nested type, the expression \( E1.E2 \) is ill-formed.

\((4.5)\) — If \( E2 \) is a member enumerator and the type of \( E2 \) is \( T \), the expression \( E1.E2 \) is a prvalue. The type of \( E1.E2 \) is \( T \).

5 If \( E2 \) is a non-static data member or a non-static member function, the program is ill-formed if the class of which \( E2 \) is directly a member is an ambiguous base (10.7) of the naming class (10.8.2) of \( E2 \). [Note: The

---

\(^{68}\) If the class member access expression is evaluated, the subexpression evaluation happens even if the result is unnecessary to determine the value of the entire postfix expression, for example if the id-expression denotes a static member.

\(^{69}\) Note that *(\( E1 \)) is an lvalue.
The value of a postfix ++ expression is the value of its operand. [Note: The value obtained is a copy of the original value — end note] The operand shall be a modifiable lvalue. The type of the operand shall be an arithmetic type other than cv bool, or a pointer to a complete object type. The value of the operand object is modified by adding 1 to it. The value computation of the ++ expression is sequenced before the modification of the operand object. With respect to an indeterminately-sequenced function call, the operation of postfix ++ is a single evaluation. [Note: Therefore, a function call shall not intervene between the lvalue-to-rvalue conversion and the side effect associated with any single postfix ++ operator. — end note] The result is a prvalue. The type of the result is the cv-unqualified version of the type of the operand. If the operand is a bit-field that cannot represent the incremented value, the resulting value of the bit-field is implementation-defined. See also 7.6.6 and 7.6.18.

The operand of postfix -- is decremented analogously to the postfix ++ operator. [Note: For prefix increment and decrement, see 7.6.2.2. — end note]

The result of the expression dynamic_cast<T>(v) is the result of converting the expression v to type T. T shall be a pointer or reference to a complete class type, or “pointer to cv void”. The dynamic_cast operator shall not cast away constness (7.6.1.11).

If T is a pointer type, v shall be a prvalue of a pointer to complete class type, and the result is a prvalue of type T. If T is an lvalue reference type, v shall be an lvalue of a complete class type, and the result is an lvalue of the type referred to by T. If T is an rvalue reference type, v shall be a glvalue having a complete class type, and the result is an xvalue of the type referred to by T.

If the type of v is the same as T (ignoring cv-qualifications), the result is v (converted if necessary).

If the value of v is a null pointer value in the pointer case, the result is the null pointer value of type T.

If T is “pointer to cv1 B” and v has type “pointer to cv2 D” such that B is a base class of D, the result is a pointer to the unique B subobject of the D object pointed to by v. Similarly, if T is “reference to cv1 B” and v has type cv2 D such that B is a base class of D, the result is the unique B subobject of the D object referred to by v. 70 In both the pointer and reference cases, the program is ill-formed if B is an inaccessible or ambiguous base class of D. [Example:

```cpp
struct B { };  
struct D : B { };  
void foo(D* dp) { 
  B* bp = dynamic_cast<B*>(dp);  // equivalent to B* bp = dp; 
}
```

— end example]

Otherwise, v shall be a pointer to or a glvalue of a polymorphic type (10.6.2).

If T is “pointer to cv void”, then the result is a pointer to the most derived object pointed to by v. Otherwise, a runtime check is applied to see if the object pointed or referred to by v can be converted to the type pointed or referred to by T.

If C is the class type to which T points or refers, the runtime check logically executes as follows:

1. If, in the most derived object pointed (referred) to by v, v points (refers) to a public base class subobject of a C object, and if only one object of type C is derived from the subobject pointed (referred) to by v the result points (refers) to that C object.

2. Otherwise, if v points (refers) to a public base class subobject of the most derived object, and the type of the most derived object has a base class, of type C, that is unambiguous and public, the result points (refers) to the C subobject of the most derived object.

3. Otherwise, the runtime check fails.

The value of a failed cast to pointer type is the null pointer value of the required result type. A failed cast to reference type throws an exception (13.1) of a type that would match a handler (13.3) of type std::bad_cast (16.7.3).

---

70) The most derived object (6.6.2) pointed or referred to by v can contain other B objects as base classes, but these are ignored.
7.6.1.8 Type identification

The result of a \texttt{typeid} expression is an lvalue of static type \texttt{const std::type\_info} (16.7.2) and dynamic type \texttt{const std::type\_info} or \texttt{const name} where \texttt{name} is an implementation-defined class publicly derived from \texttt{std::type\_info} which preserves the behavior described in 16.7.2.\(^{71}\) The lifetime of the object referred to by the \texttt{typeid} expression extends to the end of the program. Whether or not the destructor is called for the \texttt{std::type\_info} object at the end of the program is unspecified.

When \texttt{typeid} is applied to a glvalue whose type is a polymorphic class type (10.6.2), the result refers to a \texttt{std::type\_info} object representing the type of the most derived object (6.6.2) (that is, the dynamic type) to which the glvalue refers. If the glvalue is obtained by applying the unary \texttt{*} operator to a pointer\(^{72}\) and the pointer is a null pointer value (7.3.11), the \texttt{typeid} expression throws an exception (13.1) of a type that would match a handler of type \texttt{std::bad\_typeid} exception (16.7.4).

When \texttt{typeid} is applied to an expression other than a glvalue of a polymorphic class type, the result refers to a \texttt{std::type\_info} object representing the static type of the expression. Lvalue-to-rvalue (7.3.1), array-to-pointer (7.3.2), and function-to-pointer (7.3.3) conversions are not applied to the expression. If the expression is a prvalue, the temporary materialization conversion (7.3.4) is applied. The expression is an unevaluated operand (7.2).

When \texttt{typeid} is applied to a \texttt{type-id}, the result refers to a \texttt{std::type\_info} object representing the type of the \texttt{type-id}. If the type of the \texttt{type-id} is a reference to a possibly cv-qualified type, the result of the \texttt{typeid} expression refers to a \texttt{std::type\_info} object representing the cv-unqualified referenced type. If the type of the \texttt{type-id} is a class type or a reference to a class type, the class shall be completely-defined.

If the type of the expression or \texttt{type-id} is a cv-qualified type, the result of the \texttt{typeid} expression refers to a \texttt{std::type\_info} object representing the cv-unqualified type. [Example:

```cpp
class D { /* ... */ };  
D d1;  
const D d2;
```

\texttt{typeid(d1) == typeid(d2)}; // yields true
\texttt{typeid(D) == typeid(const D)}; // yields true
\texttt{typeid(D) == typeid(d2)}; // yields true

\(^{71}\) The recommended name for such a class is \texttt{extended\_type\_info}.

\(^{72}\) If \texttt{p} is an expression of pointer type, then \texttt{*p}, \texttt{(*p)}, \texttt{(**p)}, \texttt{(**(p))}, \texttt{(*p)}, and so on all meet this requirement.
 typeid(D) == typeid(const D&); // yields true

—end example]

6 If the header <typeinfo> (16.7.2) is not included prior to a use of typeid, the program is ill-formed.

7 [Note: Subclause 10.9.4 describes the behavior of typeid applied to an object under construction or destruction. —end note]

7.6.1.9 Static cast [expr.static.cast]

1 The result of the expression static_cast<T>(v) is the result of converting the expression v to type T. If T is an lvalue reference type or an rvalue reference to function type, the result is an lvalue; if T is an rvalue reference to object type, the result is an xvalue; otherwise, the result is a prvalue. The static_cast operator shall not cast away constness (7.6.1.11).

2 An lvalue of type “cv1 B”, where B is a class type, can be cast to type “reference to cv2 D”, where D is a class derived (10.6) from B, if cv2 is the same cv-qualification as, or greater cv-qualification than, cv1. If B is a virtual base class of D or a base class of a virtual base class of D, or if no valid standard conversion from “pointer to D” to “pointer to B” exists (7.3.11), the program is ill-formed. An xvalue of type “cv1 B” can be cast to type “rvalue reference to cv2 D” with the same constraints as for an lvalue of type “cv1 B”. If the object of type “cv1 B” is actually a base class subobject of an object of type D, the result refers to the enclosing object of type D. Otherwise, the behavior is undefined. [Example:

    struct B { }; 
    struct D : public B { }; 
    D d; 
    B &br = d; 
    static_cast<D&>(br); // produces lvalue to the original d object

—end example]

3 An lvalue of type “cv1 T1” can be cast to type “rvalue reference to cv2 T2” if “cv2 T2” is reference-compatible with “cv1 T1” (9.3.3). If the value is not a bit-field, the result refers to the object or the specified base class subobject thereof; otherwise, the lvalue-to-rvalue conversion (7.3.1) is applied to the bit-field and the resulting prvalue is used as the expression of the static_cast for the remainder of this subclause. If T2 is an inaccessible (10.8) or ambiguous (10.7) base class of T1, a program that necessitates such a cast is ill-formed.

4 An expression e can be explicitly converted to a type T if there is an implicit conversion sequence (11.3.3.1) from e to T, or if overload resolution for a direct-initialization (9.3) of an object or reference of type T from e would find at least one viable function (11.3.2). If T is a reference type, the effect is the same as performing the declaration and initialization

    T t(e);

for some invented temporary variable t (9.3) and then using the temporary variable as the result of the conversion. Otherwise, the result object is direct-initialized from e. [Note: The conversion is ill-formed when attempting to convert an expression of class type to an inaccessible or ambiguous base class. —end note]

5 Otherwise, the static_cast shall perform one of the conversions listed below. No other conversion shall be performed explicitly using a static_cast.

6 Any expression can be explicitly converted to type cv void, in which case it becomes a discarded-value expression (7.2). [Note: However, if the value is in a temporary object (6.6.6), the destructor for that object is not executed until the usual time, and the value of the object is preserved for the purpose of executing the destructor. —end note]

7 The inverse of any standard conversion sequence (7.3) not containing an lvalue-to-rvalue (7.3.1), array-to-pointer (7.3.2), function-to-pointer (7.3.3), null pointer (7.3.11), null member pointer (7.3.12), boolean (7.3.14), or function pointer (7.3.13) conversion, can be performed explicitly using static_cast. A program is ill-formed if it uses static_cast to perform the inverse of an ill-formed standard conversion sequence. [Example:

    struct B { }; 
    struct D : private B { }; 
    void f() { 
        static_cast<D*>(0); // error: B is a private base of D 
        static_cast<int*>(0); // error: B is a private base of D
    }

§ 7.6.1.9 108
A prvalue of type "pointer to member of

A value of a scoped enumeration type (9.6) can be explicitly converted to an integral type. If the type

A value of integral or enumeration type can be explicitly converted to a complete enumeration type. If the

A prvalue of type “pointer to cv1 B”, where B is a class type, can be converted to a prvalue of type “pointer to
cv2 D”, where D is a class derived (10.6) from B, if cv2 is the same cv-qualification as, or greater cv-qualification than, cv1. If B is a virtual base class of D or a base class of a virtual base class of D, or if no valid standard
conversion from “pointer to D” to “pointer to B” exists (7.3.11), the program is ill-formed. The null pointer
value (7.3.11) is converted to the null pointer value of the destination type. If the prvalue of type “pointer to
cv1 B” points to a B that is actually a subobject of an object of type D, the resulting pointer points to the
enclosing object of type D. Otherwise, the behavior is undefined.

A prvalue of type “pointer to member of D of type cv1 T” can be converted to a prvalue of type “pointer to
member of B of type cv2 T”, where B is a base class (10.6) of D, if cv2 is the same cv-qualification as, or
greater cv-qualification than, cv1. If no valid standard conversion from “pointer to member of B of type T” to
“pointer to member of D of type T” exists (7.3.12), the program is ill-formed. The null member pointer
value (7.3.12) is converted to the null member pointer value of the destination type. If class B contains the
original member, or is a base or derived class of the class containing the original member, the resulting
pointer to member points to the original member. Otherwise, the behavior is undefined. [Note: Although
class B need not contain the original member, the dynamic type of the object with which indirection through
the pointer to member is performed must contain the original member; see 7.6.4. — end note]

A prvalue of type “pointer to cv1 void” can be converted to a prvalue of type “pointer to cv2 T”, where T is
an object type and cv2 is the same cv-qualification as, or greater cv-qualification than, cv1. If the original
pointer value represents the address A of a byte in memory and A does not satisfy the alignment requirement
of T, then the resulting pointer value is unspecified. Otherwise, if the original pointer value points to an
object a, and there is an object b of type T (ignoring cv-qualification) that is pointer-interconvertible (6.7.2)
with a, the result is a pointer to b. Otherwise, the pointer value is unchanged by the conversion. [Example:

```cpp
T* p1 = new T;
const T* p2 = static_cast<const T*>(static_cast<void*>(p1));
bool b = p1 == p2; // b will have the value true.
```
— end example]

7.6.1.10 Reinterpret cast

The result of the expression reinterpret_cast<T>(v) is the result of converting the expression v to type
T. If T is an lvalue reference type or an rvalue reference to function type, the result is an lvalue; if T is
an rvalue reference to object type, the result is an rvalue; otherwise, the result is a prvalue and the
lvalue-to-rvalue (7.3.1), array-to-pointer (7.3.2), and function-to-pointer (7.3.3) standard conversions are
performed on the expression v. Conversions that can be performed explicitly using reinterpret_cast are
listed below. No other conversion can be performed explicitly using reinterpret_cast.

The reinterpret_cast operator shall not cast away constness (7.6.1.11). An expression of integral, enumera-
tion, pointer, or pointer-to-member type can be explicitly converted to its own type; such a cast yields the
value of its operand.

Footnote 73: Function types (including those used in pointer-to-member-function types) are never cv-qualified; see 9.2.3.5.
A prvalue of type "pointer to member of \( T \)" can be converted to an integral type; the conversion has the same meaning and validity as a conversion of \((\text{void}*)0\) to the integral type. \([\text{Note: A reinterpret_cast cannot be used to convert a value of any type to the type std::nullptr_t. — end note}]\)

A value of integral type or enumeration type can be explicitly converted to a pointer. A pointer converted to an integer of sufficient size (if any such exists on the implementation) and back to the same pointer type will have its original value; mappings between pointers and integers are otherwise implementation-defined. \([\text{Note: Except as described in 6.6.4.4.3, the result of such a conversion will not be a safely-derived pointer value. — end note}]\)

A function pointer can be explicitly converted to a function pointer of a different type. \([\text{Note: The effect of calling a function through a pointer to a function type (9.2.3.5) that is not the same as the type used in the definition of the function is undefined. — end note}]\) Except that converting a prvalue of type “pointer to \( T_1 \)” to the type “pointer to \( T_2 \)” (where \( T_1 \) and \( T_2 \) are function types) and back to its original type yields the original pointer value, the result of such a pointer conversion is unspecified. \([\text{Note: See also 7.3.11 for more details of pointer conversions. — end note}]\)

An object pointer can be explicitly converted to an object pointer of a different type.\(^{74}\) When a prvalue \( v \) of object type is converted to the object pointer type “pointer to cv \( T \)” the result is \( \text{static_cast<cv T*>(static_cast<cv void*>(v))} \). \([\text{Note: Converting a prvalue of type “pointer to \( T_1 \)” to the type “pointer to \( T_2 \)” (where \( T_1 \) and \( T_2 \) are object types and where the alignment requirements of \( T_2 \) are no stricter than those of \( T_1 \)) and back to its original type yields the original pointer value. — end note}]\)

Converting a function pointer to an object pointer type or vice versa is conditionally-supported. The meaning of such a conversion is implementation-defined, except that if an implementation supports conversions in both directions, converting a prvalue of one type to the other type and back, possibly with different cv-qualification, shall yield the original pointer value.

The null pointer value (7.3.11) is converted to the null pointer value of the destination type. \([\text{Note: A null pointer constant of type std::nullptr_t cannot be converted to a pointer type, and a null pointer constant of integral type is not necessarily converted to a null pointer value. — end note}]\)

A prvalue of type “pointer to member of \( X \) of type \( T_1 \)” can be explicitly converted to a prvalue of a different type “pointer to member of \( Y \) of type \( T_2 \)” if \( T_1 \) and \( T_2 \) are both function types or both object types.\(^{75}\) The null member pointer value (7.3.12) is converted to the null member pointer value of the destination type. The result of this conversion is unspecified, except in the following cases:

\[(10.1)\] — converting a prvalue of type “pointer to member function” to a different pointer-to-member-function type and back to its original type yields the original pointer-to-member value.

\[(10.2)\] — converting a prvalue of type “pointer to data member of \( X \) of type \( T_1 \)” to the type “pointer to data member of \( Y \) of type \( T_2 \)” (where the alignment requirements of \( T_2 \) are no stricter than those of \( T_1 \)) and back to its original type yields the original pointer-to-member value.

A glvalue of type \( T_1 \), designating an object \( x \), can be cast to the type “reference to \( T_2 \)” if an expression of type “pointer to \( T_1 \)” can be explicitly converted to the type “pointer to \( T_2 \)” using a reinterpret_cast. The result is that of \( \text{reinterpret_cast<T2*(p)} \) where \( p \) is a pointer to \( x \) of type “pointer to \( T_1 \)”. No temporary is created, no copy is made, and no constructors (10.3.4) or conversion functions (10.3.8) are called.\(^{76}\)

### 7.6.1.11 Const cast

The result of the expression \( \text{const cast<T>(v)} \) is of type \( T \). If \( T \) is an lvalue reference to object type, the result is an lvalue; if \( T \) is an lvalue reference to object type, the result is an xvalue; otherwise, the result is a prvalue and the lvalue-to-rvalue (7.3.1), array-to-pointer (7.3.2), and function-to-pointer (7.3.3) rules apply.

\(\text{Note: The types may have different cv-qualifiers, subject to the overall restriction that a reinterpret_cast cannot cast away constness.}\)\(^{74}\)

\(\text{Note: T1 and T2 may have different cv-qualifiers, subject to the overall restriction that a reinterpret_cast cannot cast away constness.}\)\(^{75}\)

\(\text{Note: This is sometimes referred to as a type pun when the result refers to the same object as the source glvalue.}\)\(^{76}\)
standard conversions are performed on the expression \( v \). Conversions that can be performed explicitly using const_cast are listed below. No other conversion shall be performed explicitly using const_cast.

[Note: Subject to the restrictions in this subclause, an expression may be cast to its own type using a const_cast operator. — end note]

For two similar types \( T_1 \) and \( T_2 \) (7.3.5), a prvalue of type \( T_1 \) may be explicitly converted to the type \( T_2 \) using a const_cast. The result of a const_cast refers to the original entity. [Example:

```cpp
typedef int *A[3]; // array of 3 pointer to int
typedef const int *const CA[3]; // array of 3 const pointer to const int

CA &&r = A{}; // OK, reference binds to temporary array object after qualification conversion to type CA
A &&rl = const_cast<A>(CA{}); // error: temporary array decayed to pointer
A &&r2 = const_cast<A&&>(CA{}); // OK
```

— end example]

For two object types \( T_1 \) and \( T_2 \), if a pointer to \( T_1 \) can be explicitly converted to the type “pointer to \( T_2 \)” using a const_cast, then the following conversions can also be made:

1. an lvalue of type \( T_1 \) can be explicitly converted to an lvalue of type \( T_2 \) using the cast const_cast<T2&>;
2. a glvalue of type \( T_1 \) can be explicitly converted to an xvalue of type \( T_2 \) using the cast const_cast<T2&&>;
3. if \( T_1 \) is a class type, a prvalue of type \( T_1 \) can be explicitly converted to an xvalue of type \( T_2 \) using the cast const_cast<T2&&>.

The result of a reference const_cast refers to the original object if the operand is a glvalue and to the result of applying the temporary materialization conversion (7.3.4) otherwise.

A null pointer value (7.3.11) is converted to the null pointer value of the destination type. The null member pointer value (7.3.12) is converted to the null member pointer value of the destination type.

[Note: Depending on the type of the object, a write operation through the pointer, lvalue or pointer to data member resulting from a const_cast that casts away a const-qualifier \(^{77}\) may produce undefined behavior (9.1.7.1). — end note]

A conversion from a type \( T_1 \) to a type \( T_2 \) casts away constness if \( T_1 \) and \( T_2 \) are different, there is a cv-decomposition (7.3.5) of \( T_1 \) yielding \( n \) such that \( T_2 \) has a cv-decomposition of the form

\[
cv_0^2 \ P_0^2 \ cv_1^2 \ P_1^2 \ \cdots \ cv_{n-1}^2 \ P_{n-1}^2 \ cv_n^2 \ U_2,
\]

and there is no qualification conversion that converts \( T_1 \) to

\[
cv_0^1 \ P_0^1 \ cv_1^1 \ P_1^1 \ \cdots \ cv_{n-1}^1 \ P_{n-1}^1 \ cv_n^1 \ U_1.
\]

Casting from an lvalue of type \( T_1 \) to an lvalue of type \( T_2 \) using an lvalue reference cast or casting from an expression of type \( T_1 \) to an xvalue of type \( T_2 \) using an rvalue reference cast casts away constness if a cast from a prvalue of type “pointer to \( T_1 \)” to the type “pointer to \( T_2 \)” casts away constness.

[Note: Some conversions which involve only changes in cv-qualification cannot be done using const_cast. For instance, conversions between pointers to functions are not covered because such conversions lead to values whose use causes undefined behavior. For the same reasons, conversions between pointers to member functions, and in particular, the conversion from a pointer to a const member function to a pointer to a non-const member function, are not covered. — end note]

7.6.2 Unary expressions [expr.unary]

Expressions with unary operators group right-to-left.

\(^{77}\) const_cast is not limited to conversions that cast away a const-qualifier.
7.6.2.1 Unary operators

1 The unary * operator performs indirection: the expression to which it is applied shall be a pointer to an object type, or a pointer to a function type and the result is an lvalue referring to the object or function to which the expression points. If the type of the expression is “pointer to T”, the type of the result is “T”. [Note: Indirection through a pointer to an incomplete type (other than cv void) is valid. The lvalue thus obtained can be used in limited ways (to initialize a reference, for example); this lvalue must not be converted to a prvalue, see 7.3.1. — end note]

2 The result of each of the following unary operators is a prvalue.

3 The result of the unary & operator is a pointer to its operand. The operand shall be an lvalue or a qualified-id. If the operand is a qualified-id naming a non-static or variant member m of some class C with type T, the result has type “pointer to member of class C of type T” and is a prvalue designating C::m. Otherwise, if the type of the expression is T, the result has type “pointer to T” and is a prvalue that is the address of the designated object (6.6.1) or a pointer to the designated function. [Note: In particular, the address of an object of type “cv T” is “pointer to cv T”, with the same cv-qualification. — end note] For purposes of pointer arithmetic (7.6.6) and comparison (7.6.9, 7.6.10), an object that is not an array element whose address is taken in this way is considered to belong to an array with one element of type T. [Example:

```c
struct A { int i; }
struct B : A { }

... &B::i ... // has type int A::*

int a;
int* p1 = &a;
int* p2 = p1 + 1;  // defined behavior
bool b = p2 > p1;  // defined behavior, with value true
```
— end example] [Note: A pointer to member formed from a mutable non-static data member (9.1.1) does not reflect the mutable specifier associated with the non-static data member. — end note]

4 A pointer to member is only formed when an explicit & is used and its operand is a qualified-id not enclosed in parentheses. [Note: That is, the expression & (qualified-id), where the qualified-id is enclosed in parentheses, does not form an expression of type “pointer to member”. Neither does qualified-id, because there is no implicit conversion from a qualified-id for a non-static member function to the type “pointer to member function” as there is from an lvalue of function type to the type “pointer to function” (7.3.3). Nor is & unqualified-id a pointer to member, even within the scope of the unqualified-id’s class. — end note]

5 If & is applied to an lvalue of incomplete class type and the complete type declares operator(), it is unspecified whether the operator has the built-in meaning or the operator function is called. The operand of & shall not be a bit-field.

6 The address of an overloaded function (Clause 11) can be taken only in a context that uniquely determines which version of the overloaded function is referred to (see 11.4). [Note: Since the context might determine whether the operand is a static or non-static member function, the context can also affect whether the expression has type “pointer to function” or “pointer to member function”. — end note]

7 The operand of the unary + operator shall have arithmetic, unscoped enumeration, or pointer type and the result is the value of the argument. Integral promotion is performed on integral or enumeration operands. The type of the result is the type of the promoted operand.
The operand of the unary - operator shall have arithmetic or unscoped enumeration type and the result is the negation of its operand. Integral promotion is performed on integral or enumeration operands. The negative of an unsigned quantity is computed by subtracting its value from \(2^n\), where \(n\) is the number of bits in the promoted operand. The type of the result is the type of the promoted operand.

The operand of the logical negation operator ! is contextually converted to bool (7.3); its value is true if the converted operand is false and false otherwise. The type of the result is bool.

The operand of - shall have integral or unscoped enumeration type; the result is the ones' complement of its operand. Integral promotions are performed. The type of the result is the type of the promoted operand. There is an ambiguity in the grammar when - is followed by a class-name or decltype-specifier. The ambiguity is resolved by treating - as the unary complement operator rather than as the start of an unqualified-id naming a destructor. [Note: Because the grammar does not permit an operator to follow the ., ->, or :: tokens, a - followed by a class-name or decltype-specifier in a member access expression or qualified-id is unambiguously parsed as a destructor name. —end note]

7.6.2.2 Increment and decrement [expr.pre.incr]

The operand of prefix ++ is modified by adding 1. The operand shall be a modifiable lvalue. The type of the operand shall be an arithmetic type other than cv bool, or a pointer to a completely-defined object type. The result is the updated operand; it is an lvalue, and it is a bit-field if the operand is a bit-field. The expression ++x is equivalent to x+=1. [Note: See the discussions of addition (7.6.6) and assignment operators (7.6.18) for information on conversions. —end note]

The operand of prefix -- is modified by subtracting 1. The requirements on the operand of prefix -- and the properties of its result are otherwise the same as those of prefix ++. [Note: For postfix increment and decrement, see 7.6.1.6. —end note]

7.6.2.3 Sizeof [expr.sizeof]

The sizeof operator yields the number of bytes occupied by a non-potentially-overlapping object of the type of its operand. The operand is either an expression, which is an unevaluated operand (7.2), or a parenthesized type-id. The sizeof operator shall not be applied to an expression that has function or incomplete type, to the parenthesized name of such types, or to a gvalue that designates a bit-field. sizeof(char), sizeof(signed char) and sizeof(unsigned char) are 1. The result of sizeof applied to any other fundamental type (6.7.1) is implementation-defined. [Note: In particular, sizeof(bool), sizeof(char16_t), sizeof(char32_t), and sizeof(wchar_t) are implementation-defined. —end note] [Note: See 6.6.1 for the definition of byte and 6.7 for the definition of object representation. —end note]

When applied to a reference or a reference type, the result is the size of the referenced type. When applied to a class, the result is the number of bytes in an object of that class including any padding required for placing objects of that type in an array. The result of applying sizeof to a potentially-overlapping subobject is the size of the type, not the size of the subobject. When applied to an array, the result is the total number of bytes in the array. This implies that the size of an array of \(n\) elements is \(n\) times the size of an element.

The sizeof operator can be applied to a pointer to a function, but shall not be applied directly to a function.

The lvalue-to-rvalue (7.3.1), array-to-pointer (7.3.2), and function-to-pointer (7.3.3) standard conversions are not applied to the operand of sizeof. If the operand is a prvalue, the temporary materialization conversion (7.3.4) is applied.

The identifier in a sizeof... expression shall name a pack. The sizeof... operator yields the number of elements in the pack (12.6.3). A sizeof... expression is a pack expansion (12.6.3). [Example:

```cpp
template<class... Types>
struct count {
    static const std::size_t value = sizeof...(Types);
};

—end example]
```

The result of sizeof and sizeof... is a constant of type std::size_t. [Note: std::size_t is defined in the standard header <cstdlib> (16.2.1, 16.2.4). —end note]

78] sizeof(bool) is not required to be 1.

79] The actual size of a potentially-overlapping subobject may be less than the result of applying sizeof to the subobject, due to virtual base classes and less strict padding requirements on potentially-overlapping subobjects.
7.6.2.4 New

The new-expression attempts to create an object of the type-id (9.2.1) or new-type-id to which it is applied. The type of that object is the allocated type. This type shall be a complete object type, but not an abstract class type or array thereof (6.6.2, 6.7, 10.6.3). [Note: Because references are not objects, references cannot be created by new-expressions. — end note] [Note: The type-id may be a cv-qualified type, in which case the object created by the new-expression has a cv-qualified type. — end note]

new-expression:
::opt new new-placementopt new-type-id new-initializeropt
::opt new new-placementopt ( type-id ) new-initializeropt

new-placement:
( expression-list )

new-type-id:
type-specifier-seq new-declaratoropt

new-declarator:
ptr-operator new-declaratoropt
noptr-new-declarator

noptr-new-declarator:
[ expression ] attribute-specifier-seqopt
noptr-new-declarator [ constant-expression ] attribute-specifier-seqopt

new-initializer:
( expression-listopt )
braced-init-list

Entities created by a new-expression have dynamic storage duration (6.6.4.4). [Note: The lifetime of such an entity is not necessarily restricted to the scope in which it is created. — end note] If the entity is a non-array object, the result of the new-expression is a pointer to the object created. If it is an array, the result of the new-expression is a pointer to the initial element of the array.

If a placeholder type (9.1.7.4) appears in the type-specifier-seq of a new-type-id or type-id of a new-expression, the allocated type is deduced as follows: Let \( \text{init} \) be the new-initializer, if any, and \( T \) be the new-type-id or type-id of the new-expression, then the allocated type is the type deduced for the variable \( x \) in the invented declaration (9.1.7.4):
\[
T \ x \ \text{init} ;
\]

[Example:

new auto(1); // allocated type is int
auto x = new auto(‘a’); // allocated type is char, x is of type char*

template<class T> struct A { A(T, T); }; auto y = new A{1, 2}; // allocated type is A<int>

— end example]

The new-type-id in a new-expression is the longest possible sequence of new-declarators. [Note: This prevents ambiguities between the declarator operators &amp;, &amp;&amp;, *, and [] and their expression counterparts. — end note] [Example:

new int * i; // syntax error: parsed as (new int*) i, not as (new int)*i

The * is the pointer declarator and not the multiplication operator. — end example]

[Note: Parentheses in a new-type-id of a new-expression can have surprising effects. [Example:

new int(*[10])(); // error

is ill-formed because the binding is

(new int) (*[10])(); // error

Instead, the explicitly parenthesized version of the new operator can be used to create objects of compound types (6.7.2):

new (int (*[10])());

allocates an array of 10 pointers to functions (taking no argument and returning int). — end example] — end note]
When the allocated object is an array (that is, the `n0ptr-new-declarator` syntax is used or the `new-type-id` or `type-id` denotes an array type), the `new-expression` yields a pointer to the initial element (if any) of the array.

[Note: Both `new int` and `new int[10]` have type `int*` and the type of `new int[i][10]` is `int (*)[10]` — end note]. The attribute-specifier-seq in a `n0ptr-new-declarator` appertains to the associated array type.

Every `constant-expression` in a `n0ptr-new-declarator` shall be a converted constant expression (7.7) of type `std::size_t` and shall evaluate to a strictly positive value. The `expression` in a `n0ptr-new-declarator` is implicitly converted to `std::size_t`. [Example: Given the definition `int n = 42`, `new float[n][5]` is well-formed (because `n` is the `expression` of a `n0ptr-new-declarator`), but `new float[5][n]` is ill-formed (because `n` is not a constant expression). — end example]

The `expression` in a `n0ptr-new-declarator` is erroneous if:

- the `expression` is of non-class type and its value before converting to `std::size_t` is less than zero;
- the `expression` is of class type and its value before application of the second standard conversion (11.3.3.1.2)\(^{80}\) is less than zero;
- its value is such that the size of the allocated object would exceed the implementation-defined limit (Annex B); or
- the `new-initializer` is a `braced-init-list` and the number of array elements for which initializers are provided (including the terminating ‘\0’ in a string literal (5.13.5)) exceeds the number of elements to initialize.

If the `expression` is erroneous after converting to `std::size_t`:

- if the `expression` is a core constant expression, the program is ill-formed;
- otherwise, an allocation function is not called; instead
  - if the allocation function that would have been called has a non-throwing exception specification (13.4), the value of the `new-expression` is the null pointer value of the required result type;
  - otherwise, the `new-expression` terminates by throwing an exception of a type that would match a handler (13.3) of type `std::bad_array_new_length` (16.6.3.2).

When the value of the `expression` is zero, the allocation function is called to allocate an array with no elements.

A `new-expression` may obtain storage for the object by calling an allocation function (6.6.4.4.1). If the `new-expression` terminates by throwing an exception, it may release storage by calling a deallocation function (6.6.4.4.2). If the allocated type is a non-array type, the allocation function’s name is `operator new` and the deallocation function’s name is `operator delete`. If the allocated type is an array type, the allocation function’s name is `operator new[]` and the deallocation function’s name is `operator delete[]`. [Note: An implementation shall provide default definitions for the global allocation functions (6.6.4.4, 16.6.2.1, 16.6.2.2). A C++ program can provide alternative definitions of these functions (15.5.4.6) and/or class-specific versions (10.11). The set of allocation and deallocation functions that may be called by a `new-expression` may include functions that do not perform allocation or deallocation; for example, see 16.6.2.3. — end note]

If the `new-expression` begins with a unary `::` operator, the allocation function’s name is looked up in the global scope. Otherwise, if the allocated type is a class type `T` or array thereof, the allocation function’s name is looked up in the scope of `T`. If this lookup fails to find the name, or if the allocated type is not a class type, the allocation function’s name is looked up in the global scope.

An implementation is allowed to omit a call to a replaceable global allocation function (16.6.2.1, 16.6.2.2). When it does so, the storage is instead provided by the implementation or provided by extending the allocation of another `new-expression`. The implementation may extend the allocation of a `new-expression` `e1` to provide storage for a `new-expression` `e2` if the following would be true were the allocation not extended:

- the evaluation of `e1` is sequenced before the evaluation of `e2`, and
- `e2` is evaluated whenever `e1` obtains storage, and
- both `e1` and `e2` invoke the same replaceable global allocation function, and
- if the allocation function invoked by `e1` and `e2` is throwing, any exceptions thrown in the evaluation of `e1` or `e2` would be first caught in the same handler, and

\(^{80}\) If the conversion function returns a signed integer type, the second standard conversion converts to the unsigned type `std::size_t` and thus thwarts any attempt to detect a negative value afterwards.
the pointer values produced by e1 and e2 are operands to evaluated delete-expressions, and

the evaluation of e2 is sequenced before the evaluation of the delete-expression whose operand is the pointer value produced by e1.

Example:

```cpp
void mergeable(int x) {
    // These allocations are safe for merging:
    std::unique_ptr<char[]> a{new (std::nothrow) char[8]};
    std::unique_ptr<char[]> b{new (std::nothrow) char[8]};
    std::unique_ptr<char[]> c{new (std::nothrow) char[x]};

    g(a.get(), b.get(), c.get());
}

void unmergeable(int x) {
    std::unique_ptr<char[]> a{new char[8]};
    try {
        // Merging this allocation would change its catch handler.
        std::unique_ptr<char[]> b{new char[x]};
    } catch (const std::bad_alloc& e) {
        std::cerr << "Allocation failed: " << e.what() << std::endl;
        throw;
    }
}
```

—end example

—  When a new-expression calls an allocation function and that allocation has not been extended, the new-expression passes the amount of space requested to the allocation function as the first argument of type `std::size_t`. That argument shall be no less than the size of the object being created; it may be greater than the size of the object being created only if the object is an array. For arrays of `char`, `unsigned char`, and `std::byte`, the difference between the result of the new-expression and the address returned by the allocation function shall be an integral multiple of the strictest fundamental alignment requirement (6.6.5) of any object type whose size is no greater than the size of the array being created. [Note: Because allocation functions are assumed to return pointers to storage that is appropriately aligned for objects of any type with fundamental alignment, this constraint on array allocation overhead permits the common idiom of allocating character arrays into which objects of other types will later be placed. — end note]

—  When a new-expression calls an allocation function and that allocation has been extended, the size argument to the allocation call shall be no greater than the sum of the sizes for the omitted calls as specified above, plus the size for the extended call had it not been extended, plus any padding necessary to align the allocated objects within the allocated memory.

The new-placement syntax is used to supply additional arguments to an allocation function; such an expression is called a placement new-expression.

Overload resolution is performed on a function call created by assembling an argument list. The first argument is the amount of space requested, and has type `std::size_t`. If the type of the allocated object has new-extended alignment, the next argument is the type’s alignment, and has type `std::align_val_t`. If the new-placement syntax is used, the initializer-clauses in its expression-list are the succeeding arguments. If no matching function is found and the allocated object type has new-extended alignment, the alignment argument is removed from the argument list, and overload resolution is performed again again.

Example:

—  new T results in one of the following calls:
```cpp
    operator new(sizeof(T))
    operator new(sizeof(T), std::align_val_t(alignof(T)))
```

—  new(2,f) T results in one of the following calls:
```cpp
    operator new(sizeof(T), 2, f)
    operator new(sizeof(T), std::align_val_t(alignof(T)), 2, f)
```

—  new T[5] results in one of the following calls:
operator new[](sizeof(T) + 5 + x)
operator new[](sizeof(T) + 5 + x, std::align_val_t(alignof(T)))

(15.4) — new(2,f) T[5] results in one of the following calls:
operator new[](sizeof(T) + 5 + x, 2, f)
operator new[](sizeof(T) + 5 + x, std::align_val_t(alignof(T)), 2, f)

Here, each instance of x is a non-negative unspecified value representing array allocation overhead; the result of the new-expression will be offset by this amount from the value returned by operator new[]. This overhead may be applied in all array new-expressions, including those referencing the library function operator new[](std::size_t, void*) and other placement allocation functions. The amount of overhead may vary from one invocation of new to another. — end example]

[Note: Unless an allocation function has a non-throwing exception specification (13.4), it indicates failure to allocate storage by throwing a std::bad_alloc exception (6.6.4.4.1, Clause 13, 16.6.3.1); it returns a non-null pointer otherwise. If the allocation function has a non-throwing exception specification, it returns null to indicate failure to allocate storage and a non-null pointer otherwise. — end note] If the allocation function is a non-allocating form (16.6.2.3) that returns null, the behavior is undefined. Otherwise, if the allocation function returns null, initialization shall not be done, the deallocation function shall not be called, and the value of the new-expression shall be null.

[Note: When the allocation function returns a value other than null, it must be a pointer to a block of storage in which space for the object has been reserved. The block of storage is assumed to be appropriately aligned and of the requested size. The address of the created object will not necessarily be the same as that of the block if the object is an array. — end note]

A new-expression that creates an object of type T initializes that object as follows:

(18.1) — If the new-initializer is omitted, the object is default-initialized (9.3). [Note: If no initialization is performed, the object has an indeterminate value. — end note]
(18.2) — Otherwise, the new-initializer is interpreted according to the initialization rules of 9.3 for direct-initialization.

The invocation of the allocation function is sequenced before the evaluations of expressions in the new-initializer.

Initialization of the allocated object is sequenced before the value computation of the new-expression.

If the new-expression creates an object or an array of objects of class type, access and ambiguity control are done for the allocation function, the deallocation function (10.11), and the constructor (10.3.4). If the new-expression creates an array of objects of class type, the destructor is potentially invoked (10.3.7). If any part of the object initialization described above terminates by throwing an exception and a suitable deallocation function can be found, the deallocation function is called to free the memory in which the object was being constructed, after which the exception continues to propagate in the context of the new-expression.

If no unambiguous matching deallocation function can be found, propagating the exception does not cause the object’s memory to be freed. [Note: This is appropriate when the called allocation function does not allocate memory; otherwise, it is likely to result in a memory leak. — end note]

If the new-expression begins with a unary :: operator, the deallocation function’s name is looked up in the global scope. Otherwise, if the allocated type is a class type T or an array thereof, the deallocation function’s name is looked up in the scope of T. If this lookup fails to find the name, or if the allocated type is not a class type or array thereof, the deallocation function’s name is looked up in the global scope.

A declaration of a placement deallocation function matches the declaration of a placement allocation function if it has the same number of parameters and, after parameter transformations (9.2.3.5), all parameter types except the first are identical. If the lookup finds a single matching deallocation function, that function will be called; otherwise, no deallocation function will be called. If the lookup finds a usual deallocation function with a parameter of type std::size_t (6.6.4.4.2) and that function, considered as a placement deallocation function, would have been selected as a match for the allocation function, the program is ill-formed. For a non-placement allocation function, the normal deallocation function lookup is used to find the matching deallocation function (7.6.2.5) [Example:

```c
struct S {
    // Placement allocation function:
    static void* operator new(std::size_t, std::size_t);
```

81) This may include evaluating a new-initializer and/or calling a constructor.
If the allocation call for the

```cpp
S* p = new (0) S;  // ill-formed: non-placement deallocation function matches
                    // placement allocation function
```

—if a new-expression calls a deallocation function, it passes the value returned from the allocation function call as the first argument of type void*. If a placement deallocation function is called, it is passed the same additional arguments as were passed to the placement allocation function, that is, the same arguments as those specified with the new-placement syntax. If the implementation is allowed to introduce a temporary object or make a copy of any argument as part of the call to the allocation function, it is unspecified whether the same object is used in the call to both the allocation and deallocation functions.

### 7.6.2.5 Delete

The delete-expression operator destroys a most derived object (6.6.2) or array created by a new-expression.

```cpp
delete-expression:
::opt delete cast-expression
::opt delete [ ] cast-expression
```

The first alternative is a single-object delete expression, and the second is an array delete expression. Whenever the delete keyword is immediately followed by empty square brackets, it shall be interpreted as the second alternative.  

If the operand has a class type, the operand is converted to a pointer type by calling the above-mentioned conversion function, and the converted operand is used in place of the original operand for the remainder of this subclause. In a single-object delete expression, the value of the operand of delete may be a null pointer value, a pointer to a non-array object created by a previous new-expression, or a pointer to a subobject (6.6.2) representing a base class of such an object (10.6). If not, the behavior is undefined. In an array delete expression, the value of the operand of delete may be a null pointer value or a pointer value that resulted from a previous array new-expression.  

If not, the behavior is undefined.  

[Note: This means that the syntax of the delete-expression must match the type of the object allocated by new, not the syntax of the new-expression. — end note]  

If the operand is of class type, it is not necessary to cast away the constness (7.6.1.11) of the pointer expression before it is used as the operand of the delete-expression.  

In a single-object delete expression, if the static type of the object to be deleted is different from its dynamic type and the selected deallocation function (see below) is not a destroying operator delete, the static type shall be a base class of the dynamic type of the object to be deleted and the static type shall have a virtual destructor or the behavior is undefined. In an array delete expression, if the dynamic type of the object to be deleted differs from its static type, the behavior is undefined.

The cast-expression in a delete-expression shall be evaluated exactly once.

If the value of the operand of the delete-expression is not a null pointer value and the selected deallocation function (see below) is not a destroying operator delete, the delete-expression will invoke the destructor (if any) for the object or the elements of the array being deleted. In the case of an array, the elements will be destroyed in order of decreasing address (that is, in reverse order of the completion of their constructor; see 10.9.2).

If the value of the operand of the delete-expression is not a null pointer value, then:

- If the allocation call for the new-expression for the object to be deleted was not omitted and the allocation was not extended (7.6.2.4), the delete-expression shall call a deallocation function (6.6.4.4.2).

---

82) A lambda-expression with a lambda-introducer that consists of empty square brackets can follow the delete keyword if the lambda-expression is enclosed in parentheses.

83) This implies that an object cannot be deleted using a pointer of type void* because void is not an object type.

84) For nonzero-length arrays, this is the same as a pointer to the first element of the array created by that new-expression. Zero-length arrays do not have a first element.
The value returned from the allocation call of the `new-expression` shall be passed as the first argument to the deallocation function.

(7.2)   — Otherwise, if the allocation was extended or was provided by extending the allocation of another `new-expression`, and the `delete-expression` for every other pointer value produced by a `new-expression` that had storage provided by the extended `new-expression` has been evaluated, the `delete-expression` shall call a deallocation function. The value returned from the allocation call of the extended `new-expression` shall be passed as the first argument to the deallocation function.

(7.3)   — Otherwise, the `delete-expression` will not call a deallocation function.

[Note: The deallocation function is called regardless of whether the destructor for the object or some element of the array throws an exception. — end note] If the value of the operand of the `delete-expression` is a null pointer value, it is unspecified whether a deallocation function will be called as described above.

8  [Note: An implementation provides default definitions of the global deallocation functions `operator delete` for non-arrays (16.6.2.1) and `operator delete[]` for arrays (16.6.2.2). A C++ program can provide alternative definitions of these functions (15.5.4.6), and/or class-specific versions (10.11). — end note]

9  When the keyword `delete` in a `delete-expression` is preceded by the unary `::` operator, the deallocation function’s name is looked up in global scope. Otherwise, the lookup considers class-specific deallocation functions (10.11). If no class-specific deallocation function is found, the deallocation function’s name is looked up in global scope.

10 If deallocation function lookup finds more than one usual deallocation function, the function to be called is selected as follows:

10.1   — If any of the deallocation functions is a destroying operator delete, all deallocation functions that are not destroying operator deletes are eliminated from further consideration.

10.2   — If the type has new-extended alignment, a function with a parameter of type `std::align_val_t` is preferred; otherwise a function without such a parameter is preferred. If any preferred functions are found, all non-preferred functions are eliminated from further consideration.

10.3   — If exactly one function remains, that function is selected and the selection process terminates.

10.4   — If the deallocation functions have class scope, the one without a parameter of type `std::size_t` is selected.

10.5   — If the type is complete and if, for an array delete expression only, the operand is a pointer to a class type with a non-trivial destructor or a (possibly multi-dimensional) array thereof, the function with a parameter of type `std::size_t` is selected.

10.6   — Otherwise, it is unspecified whether a deallocation function with a parameter of type `std::size_t` is selected.

11 For a single-object delete expression, the deleted object is the object denoted by the operand if its static type does not have a virtual destructor, and its most-derived object otherwise. [Note: If the deallocation function is not a destroying operator delete and the deleted object is not the most derived object in the former case, the behavior is undefined, as stated above. — end note] For an array delete expression, the deleted object is the array object. When a `delete-expression` is executed, the selected deallocation function shall be called with the address of the deleted object in a single-object delete expression, or the address of the deleted object suitably adjusted for the array allocation overhead (7.6.2.4) in an array delete expression, as its first argument. [Note: Any cv-qualifiers in the type of the deleted object are ignored when forming this argument. — end note] If a destroying operator delete is used, an unspecified value is passed as the argument corresponding to the parameter of type `std::destroying_delete_t`. If a deallocation function with a parameter of type `std::align_val_t` is used, the alignment of the type of the deleted object is passed as the corresponding argument. If a deallocation function with a parameter of type `std::size_t` is used, the size of the deleted object in a single-object delete expression, or of the array plus allocation overhead in an array delete expression, is passed as the corresponding argument. [Note: If this results in a call to a replaceable deallocation function, and either the first argument was not the result of a prior call to a replaceable allocation function or the second or third argument was not the corresponding argument in said call, the behavior is undefined (16.6.2.1, 16.6.2.2). — end note]

12 Access and ambiguity control are done for both the deallocation function and the destructor (10.3.7, 10.11).
7.6.2.6 Alignof

An alignof expression yields the alignment requirement of its operand type. The operand shall be a type-id representing a complete object type, or an array thereof, or a reference to one of those types.

The result is an integral constant of type std::size_t.

When alignof is applied to a reference type, the result is the alignment of the referenced type. When alignof is applied to an array type, the result is the alignment of the element type.

7.6.2.7 noexcept operator

The noexcept operator determines whether the evaluation of its operand, which is an unevaluated operand (7.2), can throw an exception (13.1).

The result of the noexcept operator is a constant of type bool and is a prvalue.

The result of the noexcept operator is true unless the expression is potentially-throwing (13.4).

7.6.3 Explicit type conversion (cast notation)

The result of the expression (T) cast-expression is of type T. The result is an lvalue if T is an lvalue reference type or an rvalue reference to function type and an xvalue if T is an rvalue reference to object type; otherwise the result is a prvalue. [Note: If T is a non-class type that is cv-qualified, the cv-qualifiers are discarded when determining the type of the resulting prvalue; see 7.2. — end note]

An explicit type conversion can be expressed using functional notation (7.6.1.3), a type conversion operator (dynamic_cast, static_cast, reinterpret_cast, const_cast), or the cast notation.

cast-expression:
unary-expression ( type-id ) cast-expression

Any type conversion not mentioned below and not explicitly defined by the user (10.3.8) is ill-formed.

The conversions performed by

(4.1) — a const_cast (7.6.1.11),
(4.2) — a static_cast (7.6.1.9),
(4.3) — a static_cast followed by a const_cast,
(4.4) — a reinterpret_cast (7.6.1.10), or
(4.5) — a reinterpret_cast followed by a const_cast,

can be performed using the cast notation of explicit type conversion. The same semantic restrictions and behaviors apply, with the exception that in performing a static_cast in the following situations the conversion is valid even if the base class is inaccessible:

(4.6) — a pointer to an object of derived class type or an lvalue or rvalue of derived class type may be explicitly converted to a pointer or reference to an unambiguous base class type, respectively;
(4.7) — a pointer to member of derived class type may be explicitly converted to a pointer to member of an unambiguous non-virtual base class type;
(4.8) — a pointer to an object of an unambiguous non-virtual base class type, a glvalue of an unambiguous non-virtual base class type, or a pointer to member of an unambiguous non-virtual base class type may be explicitly converted to a pointer, a reference, or a pointer to member of a derived class type, respectively.

If a conversion can be interpreted in more than one of the ways listed above, the interpretation that appears first in the list is used, even if a cast resulting from that interpretation is ill-formed. If a conversion can be interpreted in more than one way as a static_cast followed by a const_cast, the conversion is ill-formed.

[Example:

struct A { }; 
struct I1 : A { }; 
struct I2 : A { }; 
struct D : I1, I2 { };]
The operand of a cast using the cast notation can be a prvalue of type “pointer to incomplete class type”. The destination type of a cast using the cast notation can be “pointer to incomplete class type”. If both the operand and destination types are class types and one or both are incomplete, it is unspecified whether the \texttt{static\_cast} or the \texttt{reinterpret\_cast} interpretation is used, even if there is an inheritance relationship between the two classes. \textit{[Note: For example, if the classes were defined later in the translation unit, a multi-pass compiler would be permitted to interpret a cast between pointers to the classes as if the class types were complete at the point of the cast. —end note]}

7.6.4 Pointer-to-member operators \[expr.mptr.oper\]

1 The pointer-to-member operators \texttt{\rightarrow*} and \texttt{.\*} group left-to-right.

\texttt{pm-expression:}

\texttt{cast-expression pm-expression .\* cast-expression}

\texttt{pm-expression \rightarrow* cast-expression}

2 The binary operator \texttt{.\*} binds its second operand, which shall be of type “pointer to member of \(T\)” to its first operand, which shall be a glvalue of class \(T\) or of a class of which \(T\) is an unambiguous and accessible base class. The result is an object or a function of the type specified by the second operand.

3 The binary operator \texttt{\rightarrow*} binds its second operand, which shall be of type “pointer to member of \(T\)” to its first operand, which shall be of type “pointer to \(U\)” where \(U\) is either \(T\) or a class of which \(T\) is an unambiguous and accessible base class. The expression \(E1\rightarrow*E2\) is converted into the equivalent form \(((\ast(E1)).\ast E2)\).

4 Abbreviating \texttt{pm-expression.\*cast-expression} as \texttt{E1.\*E2}, \(E1\) is called the object expression. If the dynamic type of \(E1\) does not contain the member to which \(E2\) refers, the behavior is undefined. Otherwise, the expression \(E1\) is sequenced before the expression \(E2\).

5 The restrictions on cv-qualification, and the manner in which the cv-qualifiers of the operands are combined to produce the cv-qualifiers of the result, are the same as the rules for \(E1.E2\) given in 7.6.1.5. \textit{[Note: It is not possible to use a pointer to member that refers to a \texttt{mutable} member to modify a \texttt{const} class object. For example,}

\begin{verbatim}
struct S {
    S() : i(0) {} 
    mutable int i;
};
void f()
{
    const S cs;
    int S::* pm = &S::i;  // pm refers to mutable member S::i
    cs.*pm = 88;         // ill-formed: cs is a const object
}
@end note]

6 If the result of \texttt{.\*} or \texttt{\rightarrow*} is a function, then that result can be used only as the operand for the function call operator \(().\) \textit{[Example:}

\begin{verbatim}
(ptr_to_obj->*ptr_to_mfct)(10);
\end{verbatim}

calls the member function denoted by \texttt{ptr\_to\_mfct} for the object pointed to by \texttt{ptr\_to\_obj}. —end example]

In a \texttt{.\*} expression whose object expression is an rvalue, the program is ill-formed if the second operand is a pointer to member function whose \texttt{ref-qualifier} is \&\&, unless its \texttt{cv-qualifier-seq} is \texttt{const}. In a \texttt{.\*} expression whose object expression is an lvalue, the program is ill-formed if the second operand is a pointer to member function whose \texttt{ref-qualifier} is \&\&. The result of a \texttt{.\*} expression whose second operand is a pointer to a data member is an lvalue if the first operand is an lvalue and an xvalue otherwise. The result of a \texttt{.\*} expression whose second operand is a pointer to a member function is a prvalue. If the second operand is the null member pointer value (7.3.12), the behavior is undefined.

\section*{§ 7.6.4}
7.6.5 Multiplicative operators

1 The multiplicative operators *, /, and % group left-to-right.

```
multiplicative-expression:
  pm-expression
  multiplicative-expression * pm-expression
  multiplicative-expression / pm-expression
  multiplicative-expression % pm-expression
```

2 The operands of * and / shall have arithmetic or unscoped enumeration type; the operands of % shall have integral or unscoped enumeration type. The usual arithmetic conversions (7.4) are performed on the operands and determine the type of the result.

3 The binary * operator indicates multiplication.

4 The binary / operator yields the quotient, and the binary % operator yields the remainder from the division of the first expression by the second. If the second operand of / or % is zero the behavior is undefined. For integral operands the / operator yields the algebraic quotient with any fractional part discarded,85 if the quotient a/b is representable in the type of the result, (a/b)*b + a%b is equal to a; otherwise, the behavior of both a/b and a%b is undefined.

7.6.6 Additive operators

1 The additive operators + and - group left-to-right. The usual arithmetic conversions (7.4) are performed for operands of arithmetic or enumeration type.

```
additive-expression:
  multiplicative-expression
  additive-expression + multiplicative-expression
  additive-expression - multiplicative-expression
```

For addition, either both operands shall have arithmetic or unscoped enumeration type, or one operand shall be a pointer to a completely-defined object type and the other shall have integral or unscoped enumeration type.

2 For subtraction, one of the following shall hold:

(2.1) — both operands have arithmetic or unscoped enumeration type; or

(2.2) — both operands are pointers to cv-qualified or cv-unqualified versions of the same completely-defined object type; or

(2.3) — the left operand is a pointer to a completely-defined object type and the right operand has integral or unscoped enumeration type.

3 The result of the binary + operator is the sum of the operands. The result of the binary - operator is the difference resulting from the subtraction of the second operand from the first.

4 When an expression that has integral type is added to or subtracted from a pointer, the result has the type of the pointer operand. If the expression P points to element x[i] of an array object x with n elements,86 the expressions P + J and J + P (where J has the value j) point to the (possibly-hypothetical) element x[i + j] if 0 ≤ i + j ≤ n; otherwise, the behavior is undefined. Likewise, the expression P - J points to the (possibly-hypothetical) element x[i - j] if 0 ≤ i - j ≤ n; otherwise, the behavior is undefined.

5 When two pointers to elements of the same array object are subtracted, the type of the result is an implementation-defined signed integral type; this type shall be the same type that is defined as std::ptrdiff_t in the `<cstdlib>` header (16.2). If the expressions P and Q point to, respectively, elements x[i] and x[j] of the same array object x, the expression P - Q has the value i - j; otherwise, the behavior is undefined. [Note: If the value i - j is not in the range of representable values of type std::ptrdiff_t, the behavior is undefined. — end note]

6 For addition or subtraction, if the expressions P or Q have type “pointer to cv T”, where T and the array element type are not similar (7.3.5), the behavior is undefined. [Note: In particular, a pointer to a base class cannot be used for pointer arithmetic when the array contains objects of a derived class type. — end note]

85) This is often called truncation towards zero.
86) An object that is not an array element is considered to belong to a single-element array for this purpose; see 7.6.2.1. A pointer past the last element of an array x of n elements is considered to be equivalent to a pointer to a hypothetical element x[n] for this purpose; see 6.7.2.
7 If the value 0 is added to or subtracted from a null pointer value, the result is a null pointer value. If two null pointer values are subtracted, the result compares equal to the value 0 converted to the type `std::ptrdiff_t`.

7.6.7 Shift operators

1 The shift operators `<<` and `>>` group left-to-right.

```
shift-expression:
  additive-expression
  shift-expression `<<` additive-expression
  shift-expression `>>` additive-expression
```

The operands shall be of integral or unscoped enumeration type and integral promotions are performed. The type of the result is that of the promoted left operand. The behavior is undefined if the right operand is negative, or greater than or equal to the length in bits of the promoted left operand.

2 The value of `E1 << E2` is `E1` left-shifted `E2` bit positions; vacated bits are zero-filled. If `E1` has an unsigned type, the value of the result is `E1 \times 2^{E2}`, reduced modulo one more than the maximum value representable in the result type. Otherwise, if `E1` has a signed type and non-negative value, and `E1 \times 2^{E2}` is representable in the corresponding unsigned type of the result type, then that value, converted to the result type, is the resulting value; otherwise, the behavior is undefined.

3 The value of `E1 >> E2` is `E1` right-shifted `E2` bit positions. If `E1` has an unsigned type or if `E1` has a signed type and a non-negative value, the value of the result is the integral part of the quotient of `E1 / 2^{E2}`. If `E1` has a signed type and a negative value, the resulting value is implementation-defined.

4 The expression `E1` is sequenced before the expression `E2`.

7.6.8 Three-way comparison operator

1 The three-way comparison operator groups left-to-right.

```
compare-expression:
  shift-expression
  compare-expression `<=>` shift-expression
```

2 The expression `p <=> q` is a prvalue indicating whether `p` is less than, equal to, greater than, or incomparable with `q`.

3 If one of the operands is of type `bool` and the other is not, the program is ill-formed.

4 If both operands have arithmetic types, or one operand has integral type and the other operand has unscoped enumeration type, the usual arithmetic conversions (7.4) are applied to the operands. Then:

   (4.1) If a narrowing conversion (9.3.4) is required, other than from an integral type to a floating point type, the program is ill-formed.

   (4.2) Otherwise, if the operands have integral type, the result is of type `std::strong_ordering`. The result is `std::strong_ordering::equal` if both operands are arithmetically equal, `std::strong_ordering::less` if the first operand is arithmetically less than the second operand, and `std::strong_ordering::greater` otherwise.

   (4.3) Otherwise, the operands have floating-point type, and the result is of type `std::partial_ordering`. The expression `a <=> b` yields `std::partial_ordering::less` if `a` is less than `b`, `std::partial_ordering::greater` if `a` is greater than `b`, `std::partial_ordering::equivalent` if `a` is equivalent to `b`, and `std::partial_ordering::unordered` otherwise.

5 If both operands have the same enumeration type `E`, the operator yields the result of converting the operands to the underlying type of `E`, and applying `==` to the converted operands.

6 If at least one of the operands is of pointer type, array-to-pointer conversions (7.3.2), pointer conversions (7.3.11), function pointer conversions (7.3.13), and qualification conversions (7.3.5) are performed on both operands to bring them to their composite pointer type (7.2.2). If at least one of the operands is of pointer-to-member type, pointer-to-member conversions (7.3.12) and qualification conversions (7.3.5) are performed on both operands to bring them to their composite pointer type (7.2.2). If both operands are null pointer constants, but not both of integer type, pointer conversions (7.3.11) are performed on both operands to bring them to their composite pointer type (7.2.2). In all cases, after the conversions, the operands shall have the same type. [Note: If both of the operands are arrays, array-to-pointer conversions (7.3.2) are not applied. —end note]
If the composite pointer type is a function pointer type, a pointer-to-member type, or `std::nullptr_t`, the result is of type `std::strong_equality`; the result is `std::strong_equality::equal` if the (possibly converted) operands compare equal (7.6.10) and `std::strong_equality::nonequal` if they compare unequal, otherwise the result of the operator is unspecified.

If the composite pointer type is an object pointer type, \( p \mathrel{\lll} q \) is of type `std::strong_ordering`. If two pointer operands \( p \) and \( q \) compare equal (7.6.10), \( p \mathrel{\lll} q \) yields `std::strong_ordering::equal`; if \( p \) and \( q \) compare unequal, \( p \mathrel{\lll} q \) yields `std::strong_ordering::less` if \( q \) compares greater than \( p \) and `std::strong_ordering::greater` if \( p \) compares greater than \( q \) (7.6.9). Otherwise, the result is unspecified.

Otherwise, the program is ill-formed.

The five comparison category types (16.11.2) (the types `std::strong_ordering`, `std::strong_equality`, `std::weak_ordering`, `std::weak_equality`, and `std::partial_ordering`) are not predefined; if the header `<compare>` is not included prior to a use of such a class type – even an implicit use in which the type is not named (e.g., via the `auto` specifier (9.1.7.4) in a defaulted three-way comparison (10.10.2) or use of the built-in operator) – the program is ill-formed.

### 7.6.9 Relational operators

The relational operators group left-to-right. [Example: \( a < b < c \) means \( (a < b) < c \) and not \( (a < b) && (b < c) \). — end example]

The lvalue-to-rvalue (7.3.1), array-to-pointer (7.3.2), and function-to-pointer (7.3.3) standard conversions are performed on the operands. The comparison is deprecated if both operands were of array type prior to these conversions (D.3).

The converted operands shall have arithmetic, enumeration, or pointer type. The operators \(<\) (less than), \(>\) (greater than), \(\leq\) (less than or equal to), and \(\geq\) (greater than or equal to) all yield `false` or `true`. The type of the result is `bool`.

The usual arithmetic conversions (7.4) are performed on operands of arithmetic or enumeration type. If both operands are pointers, pointer conversions (7.3.11) and qualification conversions (7.3.5) are performed to bring them to their composite pointer type (7.2). After conversions, the operands shall have the same type.

The result of comparing unequal pointers to objects\(^{87}\) is defined in terms of a partial order consistent with the following rules:

1. If two pointers point to different elements of the same array, or to subobjects thereof, the pointer to the element with the higher subscript is required to compare greater.
2. If two pointers point to different non-static data members of the same object, or to subobjects of such members, recursively, the pointer to the later declared member is required to compare greater provided the two members have the same access control (10.8), neither member is a subobject of zero size, and their class is not a union.
3. Otherwise, neither pointer is required to compare greater than the other.

If two operands \( p \) and \( q \) compare equal (7.6.10), \( p \mathrel{\lll} q \) and \( p \mathrel{\gg} q \) both yield `true` and \( p \mathrel{<} q \) and \( p \mathrel{>} q \) both yield `false`. Otherwise, if a pointer \( p \) compares greater than a pointer \( q \), \( p \mathrel{>} q \), \( q \mathrel{<} p \), \( q \mathrel{=} p \), \( q \mathrel{=} q \), and \( q \mathrel{=} p \) all yield `true` and \( p \mathrel{\leq} q \), \( p \mathrel{\geq} q \), \( q \mathrel{\leq} p \), \( q \mathrel{\geq} p \), and \( q \mathrel{\geq} q \) all yield `false`. Otherwise, the result of each of the operators is unspecified.

If both operands (after conversions) are of arithmetic or enumeration type, each of the operators shall yield `true` if the specified relationship is true and `false` if it is false.

---

\(^{87}\) An object that is not an array element is considered to belong to a single-element array for this purpose; see 7.6.2.1. A pointer past the last element of an array \( x \) of \( n \) elements is considered to be equivalent to a pointer to a hypothetical element \( x[n] \) for this purpose; see 6.7.2.
7.6.10 Equality operators

equality-expression:
  relational-expression
  equality-expression == relational-expression
  equality-expression != relational-expression

1. The == (equal to) and the != (not equal to) operators group left-to-right. The lvalue-to-rvalue (7.3.1),
array-to-pointer (7.3.2), and function-to-pointer (7.3.3) standard conversions are performed on the operands.
The comparison is deprecated if both operands were of array type prior to these conversions (D.3).

2. The converted operands shall have arithmetic, enumeration, pointer, or pointer-to-member type, or type
std::nullptr_t. The operators == and != both yield true or false, i.e., a result of type bool. In each
case below, the operands shall have the same type after the specified conversions have been applied.

3. If at least one of the operands is a pointer, pointer conversions (7.3.11), function pointer conversions (7.3.13),
and qualification conversions (7.3.5) are performed on both operands to bring them to their composite pointer
type (7.2). Comparing pointers is defined as follows:

(3.1) — If one pointer represents the address of a complete object, and another pointer represents the address
one past the last element of a different complete object, the result of the comparison is unspecified.

(3.2) — Otherwise, if the pointers are both null, both point to the same function, or both represent the same
address (6.7.2), they compare equal.

(3.3) — Otherwise, the pointers compare unequal.

4. If at least one of the operands is a pointer to member, pointer-to-member conversions (7.3.12) and qualification
conversions (7.3.5) are performed on both operands to bring them to their composite pointer type (7.2).
Comparing pointers to members is defined as follows:

(4.1) — If two pointers to members are both the null member pointer value, they compare equal.

(4.2) — If only one of two pointers to members is the null member pointer value, they compare unequal.

(4.3) — If either is a pointer to a virtual member function, the result is unspecified.

(4.4) — If one refers to a member of class C1 and the other refers to a member of a different class C2, where
neither is a base class of the other, the result is unspecified. [Example:

```cpp
struct A {}
struct B : A { int x; }
struct C : A { int x; }

int A::*bx = (int(A::*))&B::x;
int A::*cx = (int(A::*))&C::x;

bool b1 = (bx == cx); // unspecified
```

— end example]

(4.5) — If both refer to (possibly different) members of the same union (10.4), they compare equal.

(4.6) — Otherwise, two pointers to members compare equal if they would refer to the same member of the
same most derived object (6.6.2) or the same subobject if indirection with a hypothetical object of the
associated class type were performed, otherwise they compare unequal. [Example:

```cpp
struct B {
  int f();
};
struct L : B {}
struct R : B {}
struct D : L, R {}

int (B::*pb)() = &B::f;
int (L::*pl)() = pb;
int (R::*pr)() = pb;
int (D::*pdl)() = pl;
int (D::*pdr)() = pr;
bool x = (pdl == pdr); // false
```
bool y = (pb == pl); // true

— end example]

5 Two operands of type `std::nullptr_t` or one operand of type `std::nullptr_t` and the other a null pointer constant compare equal.

6 If two operands compare equal, the result is `true` for the `==` operator and `false` for the `!=` operator. If two operands compare unequal, the result is `false` for the `==` operator and `true` for the `!=` operator. Otherwise, the result of each of the operators is unspecified.

7 If both operands are of arithmetic or enumeration type, the usual arithmetic conversions (7.4) are performed on both operands; each of the operators shall yield `true` if the specified relationship is true and `false` if it is false.

7.6.11 Bitwise AND operator

\[
\text{and-expression:}
\begin{align*}
\text{equality-expression} \\
\text{and-expression} \& \text{equality-expression}
\end{align*}
\]

1 The usual arithmetic conversions (7.4) are performed; the result is the bitwise AND function of the operands. The operator applies only to integral or unscoped enumeration operands.

7.6.12 Bitwise exclusive OR operator

\[
\text{exclusive-or-expression:}
\begin{align*}
\text{and-expression} \\
\text{exclusive-or-expression} \wedge \text{and-expression}
\end{align*}
\]

1 The usual arithmetic conversions (7.4) are performed; the result is the bitwise exclusive OR function of the operands. The operator applies only to integral or unscoped enumeration operands.

7.6.13 Bitwise inclusive OR operator

\[
\text{inclusive-or-expression:}
\begin{align*}
\text{exclusive-or-expression} \\
\text{inclusive-or-expression} \mid \text{exclusive-or-expression}
\end{align*}
\]

1 The usual arithmetic conversions (7.4) are performed; the result is the bitwise inclusive OR function of its operands. The operator applies only to integral or unscoped enumeration operands.

7.6.14 Logical AND operator

\[
\text{logical-and-expression:}
\begin{align*}
\text{inclusive-or-expression} \\
\text{logical-and-expression} \& \text{inclusive-or-expression}
\end{align*}
\]

1 The `&` operator groups left-to-right. The operands are both contextually converted to `bool` (7.3). The result is `true` if both operands are `true` and `false` otherwise. Unlike `&`, `&&` guarantees left-to-right evaluation: the second operand is not evaluated if the first operand is `false`.

2 The result is a `bool`. If the second expression is evaluated, every value computation and side effect associated with the first expression is sequenced before every value computation and side effect associated with the second expression.

7.6.15 Logical OR operator

\[
\text{logical-or-expression:}
\begin{align*}
\text{logical-and-expression} \\
\text{logical-or-expression} \mid \text{logical-and-expression}
\end{align*}
\]

1 The `||` operator groups left-to-right. The operands are both contextually converted to `bool` (7.3). The result is `true` if either of its operands is `true`, and `false` otherwise. Unlike `|`, `||` guarantees left-to-right evaluation; moreover, the second operand is not evaluated if the first operand evaluates to `true`.

2 The result is a `bool`. If the second expression is evaluated, every value computation and side effect associated with the first expression is sequenced before every value computation and side effect associated with the second expression.
7.6.16 Conditional operator

\[ \text{conditional-expression}: \]
\[ \text{logical-or-expression} \]
\[ \text{logical-or-expression} \ ? \ \text{expression} : \ \text{assignment-expression} \]

1 Conditional expressions group right-to-left. The first expression is contextually converted to `bool` (7.3). It is evaluated and if it is `true`, the result of the conditional expression is the value of the second expression, otherwise that of the third expression. Only one of the second and third expressions is evaluated. Every value computation and side effect associated with the first expression is sequenced before every value computation and side effect associated with the second or third expression.

2 If either the second or the third operand has type `void`, one of the following shall hold:

1. If both the second and third operands have type `void`; the result is of type `void` and is a prvalue. [Note: This includes the case where both operands are `throw-expressions`. — end note]

3 Otherwise, if the second and third operand are glvalue bit-fields of the same value category and of types `cv1 T` and `cv2 T`, respectively, the operands are considered to be of type `cv T` for the remainder of this subclause, where `cv` is the union of `cv1` and `cv2`.

4 Otherwise, if the second and third operand have different types and either has (possibly cv-qualified) class type, or if both are glvalues of the same value category and the same type except for cv-qualification, an attempt is made to form an implicit conversion sequence (11.3.3.1) from each of those operands to the type of the other. [Note: Properties such as access, whether an operand is a bit-field, or whether a conversion function is deleted are ignored for that determination. — end note] Attempts are made to form an implicit conversion sequence from an operand expression `E1` of type `T1` to a target type related to the type `T2` of the operand expression `E2` as follows:

4.1 If `E2` is an lvalue, the target type is “lvalue reference to `T2`”, subject to the constraint that in the conversion the reference must bind directly (9.3.3) to a glvalue.

4.2 If `E2` is an xvalue, the target type is “rvalue reference to `T2`”, subject to the constraint that the reference must bind directly.

4.3 If `E2` is a prvalue or if neither of the conversion sequences above can be formed and at least one of the operands has (possibly cv-qualified) class type:

4.3.1 If `T1` and `T2` are the same class type (ignoring cv-qualification) and `T2` is at least as cv-qualified as `T1`, the target type is `T2`.

4.3.2 Otherwise, if `T2` is a base class of `T1`, the target type is `cv1 T2`, where `cv1` denotes the cv-qualifiers of `T1`.

4.3.3 Otherwise, the target type is the type that `E2` would have after applying the lvalue-to-rvalue (7.3.1), array-to-pointer (7.3.2), and function-to-pointer (7.3.3) standard conversions.

Using this process, it is determined whether an implicit conversion sequence can be formed from the second operand to the target type determined for the third operand, and vice versa. If both sequences can be formed, or one can be formed but it is the ambiguous conversion sequence, the program is ill-formed. If no conversion sequence can be formed, the operands are left unchanged and further checking is performed as described below. Otherwise, if exactly one conversion sequence can be formed, that conversion is applied to the chosen operand and the converted operand is used in place of the original operand for the remainder of this subclause. [Note: The conversion might be ill-formed even if an implicit conversion sequence could be formed. — end note]

5 If the second and third operands are glvalues of the same value category and have the same type, the result is of that type and value category and it is a bit-field if the second or the third operand is a bit-field, or if both are bit-fields.

6 Otherwise, the result is a prvalue. If the second and third operands do not have the same type, and either has (possibly cv-qualified) class type, overload resolution is used to determine the conversions (if any) to be applied to the operands (11.3.1.2, 11.6). If the overload resolution fails, the program is ill-formed. Otherwise, the conversions thus determined are applied, and the converted operands are used in place of the original operands for the remainder of this subclause.
Lvalue-to-rvalue (7.3.1), array-to-pointer (7.3.2), and function-to-pointer (7.3.3) standard conversions are performed on the second and third operands. After those conversions, one of the following shall hold:

- The second and third operands have the same type; the result is of that type and the result object is initialized using the selected operand.
- The second and third operands have arithmetic or enumeration type; the usual arithmetic conversions (7.4) are performed to bring them to a common type, and the result is of that type.
- One or both of the second and third operands have pointer type; pointer conversions (7.3.11), function pointer conversions (7.3.13), and qualification conversions (7.3.5) are performed to bring them to their composite pointer type (7.2). The result is of the composite pointer type.
- One or both of the second and third operands have pointer-to-member type; pointer to member conversions (7.3.12) and qualification conversions (7.3.5) are performed to bring them to their composite pointer type (7.2). The result is of the composite pointer type.
- Both the second and third operands have type `std::nullptr_t` or one has that type and the other is a null pointer constant. The result is of type `std::nullptr_t`.

### 7.6.17 Throwing an exception

`throw-expression`:

```
throw assignment-expression opt
```

1. A `throw-expression` is of type `void`.
2. Evaluating a `throw-expression` with an operand throws an exception (13.1); the type of the exception object is determined by removing any top-level `cv-qualifiers` from the static type of the operand and adjusting the type from “array of `T`” or function type `T` to “pointer to `T`”.
3. A `throw-expression` with no operand rethrows the currently handled exception (13.3). The exception is reactivated with the existing exception object; no new exception object is created. The exception is no longer considered to be caught. 

### 7.6.18 Assignment and compound assignment operators

`assignment-expression`:

```
conditional-expression logical-or-expression assignment-operator initializer-clause throw-expression
```

2. In simple assignment (`=`), the object referred to by the left operand is modified by replacing its value with the result of the right operand.
3 If the left operand is not of class type, the expression is implicitly converted (7.3) to the cv-unqualified type of the left operand.

4 If the left operand is of class type, the class shall be complete. Assignment to objects of a class is defined by the copy/move assignment operator (10.3.6, 11.5.3).

[Note: For class objects, assignment is not in general the same as initialization (9.3, 10.3.5, 10.3.6, 10.9). — end note]

5 When the left operand of an assignment operator is a bit-field that cannot represent the value of the expression, the resulting value of the bit-field is implementation-defined.

6 The behavior of an expression of the form \( E_1 \ op = E_2 \) is equivalent to \( E_1 = E_1 \ op E_2 \) except that \( E_1 \) is evaluated only once. In += and -=, \( E_1 \) shall either have arithmetic type or be a pointer to a possibly cv-qualified completely-defined object type. In all other cases, \( E_1 \) shall have arithmetic type.

7 If the value being stored in an object is read via another object that overlaps in any way the storage of the first object, then the overlap shall be exact and the two objects shall have the same type, otherwise the behavior is undefined. [Note: This restriction applies to the relationship between the left and right sides of the assignment operation; it is not a statement about how the target of the assignment may be aliased in general. See 7.2.1. — end note]

8 A braced-init-list may appear on the right-hand side of

(9.1) an assignment to a scalar, in which case the initializer list shall have at most a single element. The meaning of \( x = \{ v \} \), where \( T \) is the scalar type of the expression \( x \), is that of \( x = T\{v\} \). The meaning of \( x = \{} \) is \( x = T\{} \).

(9.2) an assignment to an object of class type, in which case the initializer list is passed as the argument to the assignment operator function selected by overload resolution (11.5.3, 11.3).

[Example:

```c
complex<double> z;
z = { 1, 2 }; // meaning z.operator={1,2})
z += { 1, 2 }; // meaning z.operator+=({1,2})
int a, b;
a = b = { 1 }; // meaning a=b=1;
a = { 1 } = b; // syntax error
```

— end example]

7.6.19 Comma operator [expr.comma]

1 The comma operator groups left-to-right.

```
expression:
assignment-expression
expression, assignment-expression
```

A pair of expressions separated by a comma is evaluated left-to-right; the left expression is a discarded-value expression (7.2). Every value computation and side effect associated with the left expression is sequenced before every value computation and side effect associated with the right expression. The type and value of the result are the type and value of the right operand; the result is of the same value category as its right operand, and is a bit-field if its right operand is a bit-field. If the right operand is a temporary expression (6.6.6), the result is a temporary expression.

2 In contexts where comma is given a special meaning, [Example: in lists of arguments to functions (7.6.1.2) and lists of initializers (9.3) — end example] the comma operator as described in this subclause can appear only in parentheses. [Example:

```c
f(a, (t=3, t+2), c);
```

has three arguments, the second of which has the value 5. — end example]

7.7 Constant expressions [expr.const]

1 Certain contexts require expressions that satisfy additional requirements as detailed in this subclause; other contexts have different semantics depending on whether or not an expression satisfies these requirements. Expressions that satisfy these requirements, assuming that copy elision is performed, are called constant expressions. [Note: Constant expressions can be evaluated during translation. — end note]
constant-expression:
c conditional-expression

An expression \( e \) is a core constant expression unless the evaluation of \( e \), following the rules of the abstract machine (6.8.1), would evaluate one of the following expressions:

1. - **This** (7.5.2), except in a constexpr function or a constexpr constructor that is being evaluated as part of \( e \);
2. - an invocation of a function other than a constexpr constructor for a literal class, a constexpr function, or an implicit invocation of a trivial destructor (10.3.7) [Note: Overload resolution (11.3) is applied as usual — end note] ;
3. - an invocation of an undefined constexpr function or an undefined constexpr constructor;
4. - an invocation of an instantiated constexpr function or constexpr constructor that fails to satisfy the requirements for a constexpr function or constexpr constructor (9.1.5);
5. - an expression that would exceed the implementation-defined limits (see Annex B);
6. - an operation that would have undefined behavior as specified in Clause 4 through Clause 14 of this document [Note: including, for example, signed integer overflow (7.2), certain pointer arithmetic (7.6.6), division by zero (7.6.5), or certain shift operations (7.6.7) — end note] ;
7. - an lvalue-to-rvalue conversion (7.3.1) unless it is applied to
   7.1. - a non-volatile glvalue of integral or enumeration type that refers to a complete non-volatile const object with a preceding initialization, initialized with a constant expression, or
   7.2. - a non-volatile glvalue that refers to a subobject of a string literal (5.13.5), or
   7.3. - a non-volatile glvalue that refers to a non-volatile object defined with constexpr or a template parameter object (12.1), or that refers to a non-mutable subobject of such an object, or
   7.4. - a non-volatile glvalue of literal type that refers to a non-volatile object whose lifetime began within the evaluation of \( e \);
8. - an lvalue-to-rvalue conversion (7.3.1) that is applied to a glvalue that refers to a non-active member of a union or a subobject thereof;
9. - an invocation of an implicitly-defined copy/move constructor or copy/move assignment operator for a union whose active member (if any) is mutable, unless the lifetime of the union object began within the evaluation of \( e \);
10. - an assignment expression (7.6.18) or invocation of an assignment operator (10.3.6) that would change the active member of a union;
11. - an id-expression that refers to a variable or data member of reference type unless the reference has a preceding initialization and either
   11.1. - it is initialized with a constant expression or
   11.2. - its lifetime began within the evaluation of \( e \);
12. - a checked contract (9.11.4) whose predicate evaluates to false;
13. - in a lambda-expression, a reference to this or to a variable with automatic storage duration defined outside that lambda-expression, where the reference would be an odr-use (6.2, 7.5.5): [Example:

```c
void g() {
    const int n = 0;
    [=] {
        constexpr int i = n; // OK, n is not odr-used here
        constexpr int j = *\&n; // ill-formed, \&n would be an odr-use of n
    }
}
```

- end example] [Note: If the odr-use occurs in an invocation of a function call operator of a closure type, it no longer refers to this or to an enclosing automatic variable due to the transformation (7.5.5.2) of the id-expression into an access of the corresponding data member. [Example:

```c
auto monad = [] (auto v) { return [=] { return v; }; };
```
auto bind = [](auto m) {
    return [=](auto fvm) { return fvm(m()); }
};

// OK to have captures to automatic objects created during constant expression evaluation.
static_assert(bind(monad(2))(monad)() == monad(2)());

— end example] — end note]

(2.14) — a conversion from type cv void* to a pointer-to-object type;
(2.15) — a dynamic cast (7.6.1.7);
(2.16) — a reinterpret_cast (7.6.1.10);
(2.17) — a pseudo-destructor call (7.6.1.4);
(2.18) — modification of an object (7.6.18, 7.6.1.6, 7.6.2.2) unless it is applied to a non-volatile lvalue of literal type that refers to a non-volatile object whose lifetime began within the evaluation of e;
(2.19) — a typeid expression (7.6.1.8) whose operand is a glvalue of a polymorphic class type;
(2.20) — a new-expression (7.6.2.4);
(2.21) — a delete-expression (7.6.2.5);
(2.22) — a three-way comparison (7.6.8) comparing pointers that do not point to the same complete object or to any subobject thereof;
(2.23) — a relational (7.6.9) or equality (7.6.10) operator where the result is unspecified;
(2.24) — a throw-expression (7.6.17); or
(2.25) — an invocation of the va_arg macro (16.12.1).

If e satisfies the constraints of a core constant expression, but evaluation of e would evaluate an operation that has undefined behavior as specified in Clause 15 through Clause 30 of this document, or an invocation of the va_start macro (16.12.1), it is unspecified whether e is a core constant expression.

[Example:

    int x;
    // not constant
    struct A {
        constexpr A(bool b) : m(b?42:x) { }
        int m;
    };
    constexpr int v = A(true).m;
    // OK: constructor call initializes m with the value 42
    constexpr int w = A(false).m;
    // error: initializer for m is x, which is non-constant
    constexpr int f1(int k) {
        constexpr int x = k;
        // error: x is not initialized by a constant expression
        // because lifetime of k began outside the initializer of x
        return x;
    }
    constexpr int f2(int k) {
        int x = k;
        // OK: not required to be a constant expression
        // because x is not constexpr
        return x;
    }
    constexpr int incr(int &n) {
        return ++n;
    }
    constexpr int g(int k) {
        constexpr int x = incr(k);
        // error: incr(k) is not a core constant expression
        // because lifetime of k began outside the expression incr(k)
        return x;
    }
    constexpr int h(int k) {
        int x = incr(k);
        // OK: incr(k) is not required to be a core constant expression
3 An integral constant expression is an expression of integral or unscoped enumeration type, implicitly converted to a prvalue, where the converted expression is a core constant expression. [Note: Such expressions may be used as bit-field lengths (10.3.10), as enumerator initializers if the underlying type is not fixed (9.6), and as alignments (9.11.2). — end note]

4 If an expression of literal class type is used in a context where an integral constant expression is required, then that expression is contextually implicitly converted (7.3) to an integral or unscoped enumeration type and the selected conversion function shall be constexpr. [Example:

```cpp
struct A {
    constexpr A(int i) : val(i) { }
    constexpr operator int() const { return val; }
    constexpr operator long() const { return 42; }
private:
    int val;
};
template<int> struct X { }
constexpr A a = alignof(int);
alignas(a) int n;    // error: ambiguous conversion
struct B { int n : a; };    // error: ambiguous conversion
— end example]

5 A converted constant expression of type T is an expression, implicitly converted to type T, where the converted expression is a constant expression and the implicit conversion sequence contains only

(5.1) — user-defined conversions,
(5.2) — lvalue-to-rvalue conversions (7.3.1),
(5.3) — array-to-pointer conversions (7.3.2),
(5.4) — function-to-pointer conversions (7.3.3),
(5.5) — qualification conversions (7.3.5),
(5.6) — integral promotions (7.3.6),
(5.7) — integral conversions (7.3.8) other than narrowing conversions (9.3.4),
(5.8) — null pointer conversions (7.3.11) from std::nullptr_t,
(5.9) — null member pointer conversions (7.3.12) from std::nullptr_t, and
(5.10) — function pointer conversions (7.3.13),

and where the reference binding (if any) binds directly. [Note: Such expressions may be used in new expressions (7.6.2.4), as case expressions (8.4.2), as enumerator initializers if the underlying type is fixed (9.6), as array bounds (9.2.3.4), and as non-type template arguments (12.3). — end note] A contextually converted constant expression of type bool is an expression, contextually converted to bool (7.3), where the converted expression is a constant expression and the conversion sequence contains only the conversions above.

6 A constant expression is either a glvalue core constant expression that refers to an entity that is a permitted result of a constant expression (as defined below), or a prvalue core constant expression whose value satisfies the following constraints:

(6.1) — if the value is an object of class type, each non-static data member of reference type refers to an entity that is a permitted result of a constant expression,
(6.2) — if the value is of pointer type, it contains the address of an object with static storage duration, the address past the end of such an object (7.6.6), the address of a function, or a null pointer value, and
(6.3) — if the value is an object of class or array type, each subobject satisfies these constraints for the value.
An entity is a permitted result of a constant expression if it is an object with static storage duration that is either not a temporary object or is a temporary object whose value satisfies the above constraints, or it is a function.

[Note: Since this document imposes no restrictions on the accuracy of floating-point operations, it is unspecified whether the evaluation of a floating-point expression during translation yields the same result as the evaluation of the same expression (or the same operations on the same values) during program execution.]

[Example:]

```c
bool f() {
    char array[1 + int(1 + 0.2 - 0.1 - 0.1)]; // Must be evaluated during translation
    int size = 1 + int(1 + 0.2 - 0.1 - 0.1); // May be evaluated at runtime
    return sizeof(array) == size;
}
```

It is unspecified whether the value of f() will be true or false. — end example] — end note]

An expression is potentially constant evaluated if it is:

(8.1) — a potentially-evaluated expression (6.2),
(8.2) — a constraint-expression, including one formed from the constraint-logical-or-expression of a requires-clause,
(8.3) — an immediate subexpression of a braced-init-list,
(8.4) — an expression of the form & cast-expression that occurs within a templated entity, or
(8.5) — a subexpression of one of the above that is not a subexpression of a nested unevaluated operand.

A function or variable is needed for constant evaluation if it is:

(8.6) — a constexpr function that is named by an expression (6.2) that is potentially constant evaluated, or
(8.7) — a variable whose name appears as a potentially constant evaluated expression that is either a constexpr variable or is of non-volatile const-qualified integral type or of reference type.

89) Nonetheless, implementations should provide consistent results, irrespective of whether the evaluation was performed during translation and/or during program execution.
90) Constant evaluation may be necessary to determine whether a narrowing conversion is performed (9.3.4).
91) Constant evaluation may be necessary to determine whether such an expression is value-dependent (12.7.2.3).
8 Statements

1 Except as indicated, statements are executed in sequence.

    statement:
        labeled-statement
        attribute-specifier-seq_opt expression-statement
        attribute-specifier-seq_opt compound-statement
        attribute-specifier-seq_opt selection-statement
        attribute-specifier-seq_opt iteration-statement
        attribute-specifier-seq_opt jump-statement
        declaration-statement
        attribute-specifier-seq_opt try-block

    init-statement:
        expression-statement
        simple-declaration

    condition:
        expression
        attribute-specifier-seq_opt decl-specifier-seq declarator brace-or-equal-initializer

The optional attribute-specifier-seq appertains to the respective statement.

2 The rules for conditions apply both to selection-statements and to the for and while statements (8.5). A condition that is not an expression is a declaration (Clause 9). The declarator shall not specify a function or an array. The decl-specifier-seq shall not define a class or enumeration. If the auto type-specifier appears in the decl-specifier-seq, the type of the identifier being declared is deduced from the initializer as described in 9.1.7.4.

3 A name introduced by a declaration in a condition (either introduced by the decl-specifier-seq or the declarator of the condition) is in scope from its point of declaration until the end of the substatements controlled by the condition. If the name is redeclared in the outermost block of a substatement controlled by the condition, the declaration that redeclares the name is ill-formed. [Example:

        if (int x = f()) {
            int x;        // ill-formed, redeclaration of x
        }
        else {
            int x;        // ill-formed, redeclaration of x
        }

        — end example]

4 The value of a condition that is an initialized declaration in a statement other than a switch statement is the value of the declared variable contextually converted to bool (7.3). If that conversion is ill-formed, the program is ill-formed. The value of a condition that is an initialized declaration in a switch statement is the value of the declared variable if it has integral or enumeration type, or of that variable implicitly converted to integral or enumeration type otherwise. The value of a condition that is an expression is the value of the expression, contextually converted to bool for statements other than switch; if that conversion is ill-formed, the program is ill-formed. The value of the condition will be referred to as simply “the condition” where the usage is unambiguous.

5 If a condition can be syntactically resolved as either an expression or the declaration of a block-scope name, it is interpreted as a declaration.

6 In the decl-specifier-seq of a condition, each decl-specifier shall be either a type-specifier or constexpr.

8.1 Labeled statement

1 A statement can be labeled.

    labeled-statement:
        attribute-specifier-seq_opt identifier : statement
        attribute-specifier-seq_opt case constant-expression : statement
        attribute-specifier-seq_opt default : statement
The optional attribute-specifier-seq appertains to the label. An identifier label declares the identifier. The only use of an identifier label is as the target of a goto. The scope of a label is the function in which it appears. Labels shall not be redeclared within a function. A label can be used in a goto statement before its declaration. Labels have their own name space and do not interfere with other identifiers. [Note: A label may have the same name as another declaration in the same scope or a template-parameter from an enclosing scope. Unqualified name lookup (6.4.1) ignores labels. — end note]

2 Case labels and default labels shall occur only in switch statements.

8.2 Expression statement

Expression statements have the form

expression-statement:
expression
opt

The expression is a discarded-value expression (7.2). All side effects from an expression statement are completed before the next statement is executed. An expression statement with the expression missing is called a null statement. [Note: Most statements are expression statements — usually assignments or function calls. A null statement is useful to carry a label just before the } of a compound statement and to supply a null body to an iteration statement such as a while statement (8.5.1). — end note]

8.3 Compound statement or block

So that several statements can be used where one is expected, the compound statement (also, and equivalently, called “block”) is provided.

compound-statement:
{ statement-seq
opt
}
statement-seq:
statement
statement-seq statement

A compound statement defines a block scope (6.3). [Note: A declaration is a statement (8.7). — end note]

8.4 Selection statements

Selection statements choose one of several flows of control.

selection-statement:
if constexpr
opt
( init-statement
opt
condition
) statement
if constexpr
opt
( init-statement
opt
condition
) statement else statement
switch
( init-statement
opt
condition
) statement

See 9.2.3 for the optional attribute-specifier-seq in a condition. [Note: An init-statement ends with a semicolon. — end note] In Clause 8, the term substatement refers to the contained statement or statements that appear in the syntax notation. The substatement in a selection-statement (each substatement, in the else form of the if statement) implicitly defines a block scope (6.3). If the substatement in a selection-statement is a single statement and not a compound-statement, it is as if it was rewritten to be a compound-statement containing the original substatement. [Example:

if (x)
int i;
can be equivalently rewritten as

if (x) {
int i;
}

Thus after the if statement, i is no longer in scope. — end example]

8.4.1 The if statement

If the condition (8.4) yields true the first substatement is executed. If the else part of the selection statement is present and the condition yields false, the second substatement is executed. If the first substatement is reached via a label, the condition is not evaluated and the second substatement is not executed. In the second form of if statement (the one including else), if the first substatement is also an if statement then that inner if statement shall contain an else part.92

92) In other words, the else is associated with the nearest un-elsed if.
If the if statement is of the form if constexpr, the value of the condition shall be a contextually converted constant expression of type bool (7.7); this form is called a constexpr if statement. If the value of the converted condition is false, the first substatement is a discarded statement, otherwise the second substatement, if present, is a discarded statement. During the instantiation of an enclosing templated entity (Clause 12), if the condition is not value-dependent after its instantiation, the discarded substatement (if any) is not instantiated. [Note: Odr-uses (6.2) in a discarded statement do not require an entity to be defined. — end note] A case or default label appearing within such an if statement shall be associated with a switch statement (8.4.2) within the same if statement. A label (8.1) declared in a substatement of a constexpr if statement shall only be referred to by a statement (8.6.4) in the same substatement. [Example:

```
template<typename T, typename ... Rest> void g(T&& p, Rest&& ...rs) {
    // ... handle p
    if constexpr (sizeof...(rs) > 0)
        g(rs...);  // never instantiated with an empty argument list
}
extern int x;  // no definition of x required
```

int f() {
    if constexpr (true)
        return 0;
    else if (x)
        return x;
    else
        return -x;
}
—end example]

An if statement of the form

```c
if constexpr_opt ( init-statement condition ) statement
```

is equivalent to

```c
{  
    init-statement  
    if constexpr_opt ( condition ) statement  
}
```

and an if statement of the form

```c
if constexpr_opt ( init-statement condition ) statement else statement
```

is equivalent to

```c
{  
    init-statement  
    if constexpr_opt ( condition ) statement else statement  
}
```

except that names declared in the init-statement are in the same declarative region as those declared in the condition.

### 8.4.2 The switch statement

The switch statement causes control to be transferred to one of several statements depending on the value of a condition.

The condition shall be of integral type, enumeration type, or class type. If of class type, the condition is contextually implicitly converted (7.3) to an integral or enumeration type. If the (possibly converted) type is subject to integral promotions (7.3.6), the condition is converted to the promoted type. Any statement within the switch statement can be labeled with one or more case labels as follows:

```c
case constant-expression :
```

where the constant-expression shall be a converted constant expression (7.7) of the adjusted type of the switch condition. No two of the case constants in the same switch shall have the same value after conversion.

There shall be at most one label of the form...
Switch statements can be nested; a case or default label is associated with the smallest switch enclosing it.

When the switch statement is executed, its condition is evaluated and compared with each case constant. If one of the case constants is equal to the value of the condition, control is passed to the statement following the matched case label. If no case constant matches the condition, and if there is a default label, control passes to the statement labeled by the default label. If no case matches and if there is no default then none of the statements in the switch is executed.

case and default labels in themselves do not alter the flow of control, which continues unimpeded across such labels. To exit from a switch, see break, 8.6.1. [Note: Usually, the substatement that is the subject of a switch is compound and case and default labels appear on the top-level statements contained within the (compound) substatement, but this is not required. Declarations can appear in the substatement of a switch statement. — end note]

A switch statement of the form

```plaintext
switch ( init-statement condition ) statement
```

is equivalent to

```plaintext
{  
    init-statement  
    switch ( condition ) statement  
}
```

except that names declared in the init-statement are in the same declarative region as those declared in the condition.

### 8.5 Iteration statements

Iteration statements specify looping.

```plaintext
iteration-statement:  
  while ( condition ) statement  
  do statement while ( expression ) ;  
  for ( init-statement conditionopt ; expressionopt ) statement  
  for ( init-statementopt for-range-declaration : for-range-initializer ) statement  

for-range-declaration:  
  attribute-specifier-seqopt decl-specifier-seq declarator  
  attribute-specifier-seqopt decl-specifier-seq ref-qualifieropt [ identifier-list ]  

for-range-initializer:  
  expr-or-braced-init-list
```

See 9.2.3 for the optional attribute-specifier-seq in a for-range-declaration. [Note: An init-statement ends with a semicolon. — end note]

The substatement in an iteration-statement implicitly defines a block scope (6.3) which is entered and exited each time through the loop.

If the substatement in an iteration-statement is a single statement and not a compound-statement, it is as if it was rewritten to be a compound-statement containing the original statement. [Example:

```plaintext
while (--x >= 0)  
  int i;  
```

The substatement in an iteration-statement is a single statement and not a compound-statement, it is as if it was rewritten to be a compound-statement containing the original statement. [Example:

```plaintext
while (--x >= 0) {  
  int i;  
}
```

Thus after the while statement, i is no longer in scope. — end example]

If a name introduced in an init-statement or for-range-declaration is redeclared in the outermost block of the substatement, the program is ill-formed. [Example:

```plaintext
void f() {  
  for (int i = 0; i < 10; ++i)  
    int i = 0;  // error: redeclaration
```

§ 8.5
for (int i : {1, 2, 3})
    int i = 1; // error: redeclaration

—end example]

8.5.1 The while statement [stmt.while]

In the while statement the substatement is executed repeatedly until the value of the condition (8.4) becomes false. The test takes place before each execution of the substatement.

When the condition of a while statement is a declaration, the scope of the variable that is declared extends from its point of declaration (6.3.2) to the end of the while statement. A while statement whose condition is an initialized declaration of some variable t is equivalent to

```
label:
    {  // start of condition scope
        condition ;  // declares t
        if (t) {
            statement
            goto label;
        }
    }  // end of condition scope
```

[Note: The variable created in the condition is destroyed and created with each iteration of the loop. [Example:

```c
struct A {
    int val;
    A(int i) : val(i) { }
    ~A() {}  
    operator bool() { return val != 0; } }

int i = 1;
while (A a = i) {
    // ...
    i = 0;
}
```

In the while-loop, the constructor and destructor are each called twice, once for the condition that succeeds and once for the condition that fails. — end example] — end note]

8.5.2 The do statement [stmt.do]

The expression is contextually converted to bool (7.3); if that conversion is ill-formed, the program is ill-formed.

In the do statement the substatement is executed repeatedly until the value of the expression becomes false. The test takes place after each execution of the statement.

8.5.3 The for statement [stmt.for]

The for statement

```
for ( init-statement conditionopt ; expressionopt ) statement
```

is equivalent to

```
{  
    init-statement
    while ( condition ) {
        statement
        expression ;
    }
}
```

except that names declared in the init-statement are in the same declarative region as those declared in the condition, and except that a continue in statement (not enclosed in another iteration statement) will execute expression before re-evaluating condition. [Note: Thus the first statement specifies initialization for the loop; the condition (8.4) specifies a test, sequenced before each iteration, such that the loop is exited when the condition becomes false; the expression often specifies incrementing that is sequenced after each iteration. — end note]
Either or both of the condition and the expression can be omitted. A missing condition makes the implied while clause equivalent to while(true).

If the init-statement is a declaration, the scope of the name(s) declared extends to the end of the for statement. [Example:

```c
int i = 42;
int a[10];

for (int i = 0; i < 10; i++)
  a[i] = i;

int j = i; // j = 42
```
—end example]

8.5.4 The range-based for statement

The range-based for statement

```c
for ( init-statement_opt for-range-declaration : for-range-initializer ) statement
```

is equivalent to

```c
{  
  auto &&__range = for-range-initializer ;
  auto __begin = begin-exp ;
  auto __end = end-exp ;
  for ( ; __begin != __end; ++__begin ) {
    for-range-declaration = *__begin;
    statement
  }
}
```

where

(1.1) — if the for-range-initializer is an expression, it is regarded as if it were surrounded by parentheses (so that a comma operator cannot be reinterpreted as delimiting two init-declarators);

(1.2) — __range, __begin, and __end are variables defined for exposition only; and

(1.3) — begin-exp and end-exp are determined as follows:

(1.3.1) — if the for-range-initializer is an expression of array type \( R \), begin-exp and end-exp are __range and __range + __bound, respectively, where __bound is the array bound. If \( R \) is an array of unknown bound or an array of incomplete type, the program is ill-formed;

(1.3.2) — if the for-range-initializer is an expression of class type \( C \), the unqualified-ids begin and end are looked up in the scope of \( C \) as if by class member access lookup (6.4.5), and if both find at least one declaration, begin-exp and end-exp are __range.begin() and __range.end(), respectively;

(1.3.3) — otherwise, begin-exp and end-exp are begin(__range) and end(__range), respectively, where begin and end are looked up in the associated namespaces (6.4.2). [Note: Ordinary unqualified lookup (6.4.1) is not performed. —end note]

[Example:

```c
int array[5] = { 1, 2, 3, 4, 5 };
for (int & x : array)
  x *= 2;
```
—end example]

2 In the decl-specifier-seq of a for-range-declaration, each decl-specifier shall be either a type-specifier or constexpr. The decl-specifier-seq shall not define a class or enumeration.

8.6 Jump statements

Jump statements unconditionally transfer control.
jump-statement:
  break ;
  continue ;
  return expr-or-braced-init-listopt ;
  goto identifier ;

2 On exit from a scope (however accomplished), objects with automatic storage duration (6.6.4.3) that have been constructed in that scope are destroyed in the reverse order of their construction. [Note: For temporaries, see 6.6.6. — end note] Transfer out of a loop, out of a block, or back past an initialized variable with automatic storage duration involves the destruction of objects with automatic storage duration that are in scope at the point transferred from but not at the point transferred to. (See 8.7 for transfers into blocks). [Note: However, the program can be terminated (by calling std::exit() or std::abort() (16.5), for example) without destroying class objects with automatic storage duration. — end note]

8.6.1 The break statement

1 The break statement shall occur only in an iteration-statement or a switch statement and causes termination of the smallest enclosing iteration-statement or switch statement; control passes to the statement following the terminated statement, if any.

8.6.2 The continue statement

1 The continue statement shall occur only in an iteration-statement and causes control to pass to the loop-continuation portion of the smallest enclosing iteration-statement, that is, to the end of the loop. More precisely, in each of the statements

```c
while (foo) {
  do {
    // ...
    // ...
  } while (foo);
  contin: ;
}
```

a continue not contained in an enclosed iteration statement is equivalent to goto contin.

8.6.3 The return statement

1 A function returns to its caller by the return statement.

2 The expr-or-braced-init-list of a return statement is called its operand. A return statement with no operand shall be used only in a function whose return type is cv void, a constructor (10.3.4), or a destructor (10.3.7). A return statement with an operand of type void shall be used only in a function whose return type is cv void. A return statement with any other operand shall be used only in a function whose return type is not cv void; the return statement initializes the glvalue result or prvalue result object of the (explicit or implicit) function call by copy-initialization (9.3) from the operand. [Note: A return statement can involve an invocation of a constructor to perform a copy or move of the operand if it is not a prvalue or if its type differs from the return type of the function. A copy operation associated with a return statement may be elided or converted to a move operation if an automatic storage duration variable is returned (10.9.5). — end note] [Example:

```c
std::pair<std::string,int> f(const char* p, int x) {
  return {p,x};
}
```

— end example] Flowing off the end of a constructor, a destructor, or a function with a cv void return type is equivalent to a return with no operand. Otherwise, flowing off the end of a function other than main (6.8.3.1) results in undefined behavior.

3 The copy-initialization of the result of the call is sequenced before the destruction of temporaries at the end of the full-expression established by the operand of the return statement, which, in turn, is sequenced before the destruction of local variables (8.6) of the block enclosing the return statement.

8.6.4 The goto statement

1 The goto statement unconditionally transfers control to the statement labeled by the identifier. The identifier shall be a label (8.1) located in the current function.
8.7 Declaration statement

A declaration statement introduces one or more new identifiers into a block; it has the form

\[
\text{declaration-statement:} \\
\text{block-declaration}
\]

If an identifier introduced by a declaration was previously declared in an outer block, the outer declaration is hidden for the remainder of the block, after which it resumes its force.

Variables with automatic storage duration (6.6.4.3) are initialized each time their declaration-statement is executed. Variables with automatic storage duration declared in the block are destroyed on exit from the block (8.6).

It is possible to transfer into a block, but not in a way that bypasses declarations with initialization (including ones in conditions and init-statements). A program that jumps\(^93\) from a point where a variable with automatic storage duration is not in scope to a point where it is in scope is ill-formed unless the variable has scalar type, class type with a trivial default constructor and a trivial destructor, a cv-qualified version of one of these types, or an array of one of the preceding types and is declared without an initializer (9.3). \[Example:

```c
void f() {
    // ...
    goto lx;     // ill-formed: jump into scope of a
    // ...
    ly:
    X a = 1;
    // ...
    lx:
    goto ly;     // OK, jump implies destructor call for a followed by
    // construction again immediately following label ly
}
```

—end example\]

Dynamic initialization of a block-scope variable with static storage duration (6.6.4.1) or thread storage duration (6.6.4.2) is performed the first time control passes through its declaration; such a variable is considered initialized upon the completion of its initialization. If the initialization exits by throwing an exception, the initialization is not complete, so it will be tried again the next time control enters the declaration. If control enters the declaration concurrently while the variable is being initialized, the concurrent execution shall wait for completion of the initialization.\(^94\) If control re-enters the declaration recursively while the variable is being initialized, the behavior is undefined. \[Example:

```c
int foo(int i) {
    static int s = foo(2*i);     // recursive call - undefined
    return i+1;
}
```

—end example\]

The destructor for a block-scope object with static or thread storage duration will be executed if and only if it was constructed. \[Note: 6.8.3.4 describes the order in which block-scope objects with static and thread storage duration are destroyed. —end note\]

8.8 Ambiguity resolution

There is an ambiguity in the grammar involving expression-statements and declarations: An expression-statement with a function-style explicit type conversion (7.6.1.3) as its leftmost subexpression can be indistinguishable from a declaration where the first declarator starts with a $. In those cases the statement is a declaration.

\[Note: If the statement cannot syntactically be a declaration, there is no ambiguity, so this rule does not apply. The whole statement might need to be examined to determine whether this is the case. This resolves the meaning of many examples. [Example: Assuming T is a simple-type-specifier (9.1.7),

```c
T(a)->m = 7;     // expression-statement
T(a)++;          // expression-statement
T(a,5)<<c;       // expression-statement
```

93 The transfer from the condition of a switch statement to a case label is considered a jump in this respect.

94 The implementation must not introduce any deadlock around execution of the initializer. Deadlocks might still be caused by the program logic; the implementation need only avoid deadlocks due to its own synchronization operations.
T(*d)(int);  // declaration
T(e)[5];      // declaration
T(f) = { 1, 2 };  // declaration
T(*g)(double(3)); // declaration

In the last example above, g, which is a pointer to T, is initialized to double(3). This is of course ill-formed for semantic reasons, but that does not affect the syntactic analysis. — end example

The remaining cases are declarations. [Example:

```cpp
class T {
   // ...
   public:
   T();
   T(int);
   T(int, int);
);
T(a);             // declaration
T(*b)();          // declaration
T(c)=7;           // declaration
T(d),e,f=3;       // declaration
extern int h;
T(g)(h,2);        // declaration

— end example] — end note]

3 The disambiguation is purely syntactic; that is, the meaning of the names occurring in such a statement, beyond whether they are type-names or not, is not generally used in or changed by the disambiguation. Class templates are instantiated as necessary to determine if a qualified name is a type-name. Disambiguation precedes parsing, and a statement disambiguated as a declaration may be an ill-formed declaration. If, during parsing, a name in a template parameter is bound differently than it would be bound during a trial parse, the program is ill-formed. No diagnostic is required. [Note: This can occur only when the name is declared earlier in the declaration. — end note] [Example:

```cpp
struct T1 {
   T1 operator()(int x) { return T1(x); }
   int operator=(int x) { return x; }
   T1(int) { }
};
struct T2 { T2(int){ } }
int a, (**(b)(T2))(int), c, d;

void f() {
   // disambiguation requires this to be parsed as a declaration:
   T1(a) = 3,
   T2(4),
   (**(b)(T2(c)))(int(d));
   // T2 will be declared as a variable of type T1, but this will not
   // allow the last part of the declaration to parse properly,
   // since it depends on T2 being a type-name
}

— end example]
9 Declarations

Declarations generally specify how names are to be interpreted. Declarations have the form

```
declaration-seq:
  declaration
  declaration-seq declaration

declaration:
  block-declaration
  nodeclspec-function-declaration
  function-definition
  template-declaration
  deduction-guide
  explicit-instantiation
  explicit-specialization
  linkage-specification
  namespace-definition
  empty-declaration
  attribute-declaration

block-declaration:
  simple-declaration
  asm-definition
  namespace-alias-definition
  using-declaration
  using-directive
  static_assert-declaration
  alias-declaration
  opaque-enum-declaration

nodeclspec-function-declaration:
  attribute-specifier-seqopt declarator ;

alias-declaration:
  using identifier attribute-specifier-seqopt = defining-type-id ;

simple-declaration:
  decl-specifier-seq init-declarator-listopt ;
  attribute-specifier-seq decl-specifier-seq init-declarator-list ;
  attribute-specifier-seqopt decl-specifier-seq ref-qualifieropt [ identifier-list ] initializer ;

static_assert-declaration:
  static_assert ( constant-expression ) ;
  static_assert ( constant-expression , string-literal ) ;

empty-declaration:
  ;

attribute-declaration:
  attribute-specifier-seq ;
```

[Note: asm-definitions are described in 9.9, and linkage-specifications are described in 9.10; function-definitions are described in 9.4 and template-declarations and deduction-guides are described in Clause 12; namespace-definitions are described in 9.7.1, using-declarations are described in 9.8 and using-directives are described in 9.7.3. — end note]

A simple-declaration or nodeclspec-function-declaration of the form

```
attribute-specifier-seqopt decl-specifier-seqopt init-declarator-listopt ;
```

is divided into three parts. Attributes are described in 9.11. decl-specifiers, the principal components of a decl-specifier-seq, are described in 9.1. declarators, the components of an init-declarator-list, are described in 9.2. The attribute-specifier-seq appertains to each of the entities declared by the declarators of the init-declarator-list. [Note: In the declaration for an entity, attributes appertaining to that entity may appear at the start of the declaration and after the declarator-id for that declaration. — end note] [Example:
Except where otherwise specified, the meaning of an attribute-declaration is implementation-defined.

A declaration occurs in a scope (6.3); the scope rules are summarized in 6.4. A declaration that declares a function or defines a class, namespace, template, or function also has one or more scopes nested within it. These nested scopes, in turn, can have declarations nested within them. Unless otherwise stated, utterances in Clause 9 about components in, of, or contained by a declaration or subcomponent thereof refer only to those components of the declaration that are not nested within scopes nested within the declaration.

In a simple-declaration, the optional init-declarator-list can be omitted only when declaring a class (Clause 10) or enumeration (9.6), that is, when the decl-specifier-seq contains either a class-specifier, an elaborated-type-specifier with a class-key (10.2), or an enum-specifier. In these cases and whenever a class-specifier or enum-specifier is present in the decl-specifier-seq, the identifiers in these specifiers are among the names being declared by the declaration (as class-names, enum-names, or enumerators, depending on the syntax). In such cases, the decl-specifier-seq shall introduce one or more names into the program, or shall redeclare a name introduced by a previous declaration. [Example:

```c
enum { }; // ill-formed
typedef class { }; // ill-formed
```
—end example]

In a static_assert-declaration, the constant-expression shall be a contextually converted constant expression of type bool (7.7). If the value of the expression when so converted is true, the declaration has no effect. Otherwise, the program is ill-formed, and the resulting diagnostic message (4.1) shall include the text of the string-literal, if one is supplied, except that characters not in the basic source character set (5.3) are not required to appear in the diagnostic message. [Example:

```c
static_assert(sizeof(int) == sizeof(void*), "wrong pointer size");
```
—end example]

An empty-declaration has no effect.

A simple-declaration with an identifier-list is called a structured binding declaration (9.5). The decl-specifier-seq shall contain only the type-specifier auto (9.1.7.4) and cv-qualifiers. The initializer shall be of the form “= assignment-expression”, of the form “{ assignment-expression }”, or of the form “( assignment-expression )”, where the assignment-expression is of array or non-union class type.

Each init-declarator in the init-declarator-list contains exactly one declarator-id, which is the name declared by that init-declarator and hence one of the names declared by the declaration. The defining-type-specifiers (9.1.7) in the decl-specifier-seq and the recursive declarator structure of the init-declarator describe a type (9.2.3), which is then associated with the name being declared by the init-declarator.

If the decl-specifier-seq contains the typedef specifier, the declaration is called a typedef declaration and the name of each init-declarator is declared to be a typedef-name, synonymous with its associated type (9.1.3). If the decl-specifier-seq contains no typedef specifier, the declaration is called a function declaration if the type associated with the name is a function type (9.2.3.5) and an object declaration otherwise.

Syntactic components beyond those found in the general form of declaration are added to a function declaration to make a function-definition. An object declaration, however, is also a definition unless it contains the extern specifier and has no initializer (6.1). A definition causes the appropriate amount of storage to be reserved and any appropriate initialization (9.3) to be done.

A nodeclspec-function-declaration shall declare a constructor, destructor, or conversion function. [Note: A nodeclspec-function-declaration can only be used in a template-declaration (Clause 12), explicit-instantiation (12.8.2), or explicit-specialization (12.8.3). —end note]

9.1 Specifiers [dcl.spec]

The specifiers that can be used in a declaration are

---

95) The “implicit int” rule of C is no longer supported.
decl-specifier:
  storage-class-specifier
  defining-type-specifier
  function-specifier
  friend
typedef
constexpr
inline
decl-specifier-seq:
  decl-specifier attribute-specifier-seqopt
  decl-specifier decl-specifier-seq

The optional attribute-specifier-seq in a decl-specifier-seq appertains to the type determined by the preceding decl-specifiers (9.2.3). The attribute-specifier-seq affects the type only for the declaration it appears in, not other declarations involving the same type.

2 Each decl-specifier shall appear at most once in a complete decl-specifier-seq, except that long may appear twice.

3 If a type-name is encountered while parsing a decl-specifier-seq, it is interpreted as part of the decl-specifier-seq if and only if there is no previous defining-type-specifier other than a cv-qualifier in the decl-specifier-seq. The sequence shall be self-consistent as described below. [Example:

```c
typedef char* Pc;
static Pc;
// error: name missing
```

Here, the declaration static Pc is ill-formed because no name was specified for the static variable of type Pc. To get a variable called Pc, a type-specifier (other than const or volatile) has to be present to indicate that the typedef-name Pc is the name being (re)declared, rather than being part of the decl-specifier sequence. For another example,

```c
void f(const Pc);
void g(const int Pc);
```

—end example]

4 [Note: Since signed, unsigned, long, and short by default imply int, a type-name appearing after one of those specifiers is treated as the name being (re)declared. [Example:

```c
void h(unsigned Pc);
void k(unsigned int Pc);
```

—end example] —end note]

9.1.1 Storage class specifiers [decl.stc]

1 The storage class specifiers are

```
storage-class-specifier:
  static
  thread_local
  extern
  mutable
```

At most one storage-class-specifier shall appear in a given decl-specifier-seq, except that thread_local may appear with static or extern. If thread_local appears in any declaration of a variable it shall be present in all declarations of that entity. If a storage-class-specifier appears in a decl-specifier-seq, there can be no typedef specifier in the same decl-specifier-seq and the init-declarator-list or member-declarator-list of the declaration shall not be empty (except for an anonymous union declared in a named namespace or in the global namespace, which shall be declared static (10.4.1)). The storage-class-specifier applies to the name declared by each init-declarator in the list and not to any names declared by other specifiers. A storage-class-specifier other than thread_local shall not be specified in an explicit specialization (12.8.3) or an explicit instantiation (12.8.2) directive.

2 [Note: A variable declared without a storage-class-specifier at block scope or declared as a function parameter has automatic storage duration by default (6.6.4.3). —end note]

3 The thread_local specifier indicates that the named entity has thread storage duration (6.6.4.2). It shall be applied only to the names of variables of namespace or block scope and to the names of static data members.
When `thread_local` is applied to a variable of block scope the `storage-class-specifier static` is implied if no other `storage-class-specifier` appears in the `decl-specifier-seq`.

The `static` specifier can be applied only to names of variables and functions and to anonymous unions (10.4.1). There can be no `static` function declarations within a block, nor any `static` function parameters. A `static` specifier used in the declaration of a variable declares the variable to have static storage duration (6.6.4.1), unless accompanied by the `thread_local` specifier, which declares the variable to have thread storage duration (6.6.4.2). A `static` specifier can be used in declarations of class members; 10.3.9 describes its effect. For the linkage of a name declared with a `static` specifier, see 6.5.

The `extern` specifier can be applied only to the names of variables and functions. The `extern` specifier cannot be used in the declaration of class members or function parameters. For the linkage of a name declared with an `extern` specifier, see 6.5. [Note: The `extern` keyword can also be used in `explicit-instantiations` and `linkage-specifications`, but it is not a `storage-class-specifier` in such contexts. — end note]

The linkages implied by successive declarations for a given entity shall agree. That is, within a given scope, each declaration declaring the same variable name or the same overloading of a function name shall imply the same linkage. Each function in a given set of overloaded functions can have a different linkage, however. [Example:

```c
static char* f(); // f() has internal linkage
char* f()        // f() still has internal linkage
    { /* ... */ }

char* g();      // g() has external linkage
static char* g() // error: inconsistent linkage
    { /* ... */ }

void h();
inline void h(); // external linkage

inline void l(); // external linkage
void l();

inline void m(); // external linkage
extern void m();

static void n();
inline void n(); // internal linkage

static int a;    // a has internal linkage
int a;           // error: two definitions

static int b;    // b has internal linkage
extern int b;    // b still has internal linkage

int c;           // c has external linkage
static int c;    // error: inconsistent linkage

extern int d;    // d has external linkage
static int d;    // error: inconsistent linkage
```

— end example]

The name of a declared but undefined class can be used in an `extern` declaration. Such a declaration can only be used in ways that do not require a complete class type. [Example:

```c
struct S;
extern S a;
extern S f();
extern void g(S);

void h() {
    g(a);    // error: S is incomplete
    f();     // error: S is incomplete
}
```

§ 9.1.1
The `mutable` specifier shall appear only in the declaration of a non-static data member (10.3) whose type is neither const-qualified nor a reference type. [Example:

```cpp
class X {
mutable const int* p;  // OK
mutable int* const q;   // ill-formed
};
```
—end example]

9 The `mutable` specifier on a class data member nullifies a `const` specifier applied to the containing class object and permits modification of the mutable class member even though the rest of the object is `const` (9.1.7.1).

### 9.1.2 Function specifiers

A `function-specifier` can be used only in a function declaration.

```cpp
function-specifier:
virtual
explicit-specifier
```

An `explicit-specifier` shall be used only in the declaration of a constructor or conversion function within its class definition; see 10.3.8.1 and 10.3.8.2.

In an `explicit-specifier`, the `constant-expression`, if supplied, shall be a contextually converted constant expression of type `bool` (7.7). The `explicit-specifier explicit` without a `constant-expression` is equivalent to the `explicit-specifier explicit(true)`. If the constant expression evaluates to `true`, the function is explicit. Otherwise, the function is not explicit. A `(token that follows explicit` is parsed as part of the `explicit-specifier`.

### 9.1.3 The `typedef` specifier

Declarations containing the `decl-specifier typedef` declare identifiers that can be used later for naming fundamental (6.7.1) or compound (6.7.2) types. The `typedef` specifier shall not be combined in a `decl-specifier-seq` with any other kind of specifier except a `defining-type-specifier`, and it shall not be used in the `decl-specifier-seq` of a `parameter-declaration` (9.2.3.5) nor in the `decl-specifier-seq` of a `function-definition` (9.4).

If a `typedef` specifier appears in a declaration without a `declarator`, the program is ill-formed.

A name declared with the `typedef` specifier becomes a `typedef-name`. Within the scope of its declaration, a `typedef-name` is syntactically equivalent to a keyword and names the type associated with the identifier in the way described in 9.2. A `typedef-name` is thus a synonym for another type. A `typedef-name` does not introduce a new type the way a class declaration (10.2) or enum declaration does. [Example: After

```cpp
typedef int MILES, *KLICKSP;
```
the constructions

```cpp
MILES distance;
extern KLICKSP metricp;
```
are all correct declarations; the type of `distance` is `int` and that of `metricp` is “pointer to `int`”. —end example]

A `typedef-name` can also be introduced by an `alias-declaration`. The `identifier` following the `using` keyword becomes a `typedef-name` and the optional `attribute-specifier-seq` following the `identifier` appertains to that `typedef-name`. Such a `typedef-name` has the same semantics as if it were introduced by the `typedef` specifier. In particular, it does not define a new type. [Example:

```cpp
using handler_t = void (*)(int);
extern handler_t ignore;
extern void (*ignore)(int);    // redeclare ignore
```
using cell = pair<void*, cell*>; // ill-formed

—end example] The defining-type-specifier-seq of the defining-type-id shall not define a class or enumeration if the alias-declaration is the declaration of a template-declaration.

In a given non-class scope, a typedef specifier can be used to redefine the name of any type declared in that scope to refer to the type to which it already refers. [Example:

```c
typedef struct s { /* ... */ } s;
typedef int I;
typedef I I;
—end example]
```

In a given class scope, a typedef specifier can be used to redefine any class-name declared in that scope that is not also a typedef-name to refer to the type to which it already refers. [Example:

```c
struct S {
    typedef struct A { } A; // OK
    typedef struct B B; // OK
    typedef A A; // error
};
—end example]
```

If a typedef specifier is used to redefine in a given scope an entity that can be referenced using an elaborated-type-specifier, the entity can continue to be referenced by an elaborated-type-specifier or as an enumeration or class name in an enumeration or class definition respectively. [Example:

```c
struct S;
typedef struct S S;
int main() {
    struct S* p; // OK
}
struct S { }; // OK
—end example]
```

In a given scope, a typedef specifier shall not be used to redefine the name of any type declared in that scope to refer to a different type. [Example:

```c
class complex { /* ... */ };
typedef int complex; // error: redefinition
—end example]
```

Similarly, in a given scope, a class or enumeration shall not be declared with the same name as a typedef-name that is declared in that scope and refers to a type other than the class or enumeration itself. [Example:

```c
typedef int complex;
class complex { /* ... */ }; // error: redefinition
—end example]
```

[Note: A typedef-name that names a class type, or a cv-qualified version thereof, is also a class-name (10.2). If a typedef-name is used to identify the subject of an elaborated-type-specifier (9.1.7.3), a class definition (Clause 10), a constructor declaration (10.3.4), or a destructor declaration (10.3.7), the program is ill-formed. —end note] [Example:

```c
struct S {
    S();
    ~S();
};
typedef struct S T;
S a = T(); // OK
struct T* p; // error
—end example]
```

If the typedef declaration defines an unnamed class (or enum), the first typedef-name declared by the declaration to be that class type (or enum type) is used to denote the class type (or enum type) for linkage
purposes only (6.5). [Note: A typedef declaration involving a lambda-expression does not itself define the associated closure type, and so the closure type is not given a name for linkage purposes. — end note]

[Example:

typedef struct { } *ps, S;   // S is the class name for linkage purposes
typedef decltype(()) C;     // the closure type has no name for linkage purposes
— end example]

9.1.4 The friend specifier

The friend specifier is used to specify access to class members; see 10.8.3.

9.1.5 The constexpr specifier

The constexpr specifier shall be applied only to the definition of a variable or variable template or the declaration of a function or function template. A function or static data member declared with the constexpr specifier is implicitly an inline function or variable (9.1.6). If any declaration of a function or function template has a constexpr specifier, then all its declarations shall contain the constexpr specifier. [Note: An explicit specialization can differ from the template declaration with respect to the constexpr specifier. — end note] [Example:

```c
constexpr void square(int &x);  // OK: declaration
constexpr int bufsz = 1024;     // OK: definition
constexpr struct pixel {
    int x;
    int y;
};
constexpr pixel pixel(int);    // OK: declaration

constexpr pixel::pixel(int a)
    : x(a), y(x)   // OK: definition
{
    square(x); }
constexpr pixel small(2);      // error: square not defined, so small(2)
                               // not constant (7.7) so constexpr not satisfied

customexpr void square(int &x) {
    x *= x; }
```  
— end example]

1 A constexpr specifier used in the declaration of a function that is not a constructor declares that function to be a constexpr function. Similarly, a constexpr specifier used in a constructor declaration declares that constructor to be a constexpr constructor.

2 The definition of a constexpr function shall satisfy the following requirements:

   (3.1) its return type shall be a literal type;
   (3.2) each of its parameter types shall be a literal type;
   (3.3) its function-body shall be = delete, = default, or a compound-statement that does not contain
         (3.3.1) an asm-definition,
         (3.3.2) a goto statement,
         (3.3.3) an identifier label (8.1),
         (3.3.4) a try-block, or
        (3.3.5) a definition of a variable of non-literal type or of static or thread storage duration or for which no initialization is performed.

   [Example:
    ```c
    constexpr int square(int x)
    { return x * x; }   // OK
    ```

   § 9.1.5

   149
4 The definition of a constexpr constructor shall satisfy the following requirements:

- the class shall not have any virtual base classes;
- each of the parameter types shall be a literal type;
- its function-body shall not be a function-try-block.

In addition, either its function-body shall be = delete, or it shall satisfy the following requirements:

- either its function-body shall be = default, or the compound-statement of its function-body shall satisfy the requirements for a function-body of a constexpr function;
- every non-variant non-static data member and base class subobject shall be initialized (10.9.2);
- if the class is a union having variant members (10.4), exactly one of them shall be initialized;
- if the class is a union-like class, but is not a union, for each of its anonymous union members having variant members, exactly one of them shall be initialized;
- for a non-delegating constructor, every constructor selected to initialize non-static data members and base class subobjects shall be a constexpr constructor;
- for a delegating constructor, the target constructor shall be a constexpr constructor.

[Example:

```cpp
struct Length {
    constexpr explicit Length(int i = 0) : val(i) { }
private:
    int val;
};
```

—end example]

5 For a constexpr function or constexpr constructor that is neither defaulted nor a template, if no argument values exist such that an invocation of the function or constructor could be an evaluated subexpression of a core constant expression (7.7), or, for a constructor, a constant initializer for some object (6.8.3.2), the program is ill-formed, no diagnostic required. [Example:

```cpp
constexpr int f(bool b)
{ return b ? throw 0 : 0; }    // OK
constexpr int f() { return f(true); }    // ill-formed, no diagnostic required
```

```cpp
struct B {
    constexpr B(int x) : i(0) { }  // x is unused
```
```cpp
int i;
};

int global;

struct D : B {
    constexpr D() : B(global) { }  // ill-formed, no diagnostic required
    // value-to-value conversion on non-constant global
};
— end example]

6 If the instantiated template specialization of a constexpr function template or member function of a class
    template would fail to satisfy the requirements for a constexpr function or constexpr constructor, that
    specialization is still a constexpr function or constexpr constructor, even though a call to such a function
    cannot appear in a constant expression. If no specialization of the template would satisfy the requirements
    for a constexpr function or constexpr constructor when considered as a non-template function or constructor,
    the template is ill-formed, no diagnostic required.

7 A call to a constexpr function produces the same result as a call to an equivalent non-constexpr function in
    all respects except that
    (7.1) — a call to a constexpr function can appear in a constant expression (7.7) and
    (7.2) — copy elision is mandatory in a constant expression (10.9.5).

8 The constexpr specifier has no effect on the type of a constexpr function or a constexpr constructor.
[Example:
    constexpr int bar(int x, int y)  // OK
        { return x + y + x*y; }
    // ...
    int bar(int x, int y)  // error: redefinition of bar
        { return x * 2 + 3 * y; }
    — end example]

9 A constexpr specifier used in an object declaration declares the object as const. Such an object shall
    have literal type and shall be initialized. In any constexpr variable declaration, the full-expression of the
    initialization shall be a constant expression (7.7). [Example:
    struct pixel {
        int x, y;
    };
    constexpr pixel ur = { 1294, 1024 };  // OK
    constexpr pixel origin;  // error: initializer missing
    — end example]

9.1.6 The inline specifier[inline]

1 The inline specifier can be applied only to the declaration or definition of a variable or function.

2 A function declaration (9.2.3.5, 10.3.1, 10.8.3) with an inline specifier declares an inline function. The
    inline specifier indicates to the implementation that inline substitution of the function body at the point
    of call is to be preferred to the usual function call mechanism. An implementation is not required to perform
    this inline substitution at the point of call; however, even if this inline substitution is omitted, the other rules
    for inline functions specified in this subclause shall still be respected.

3 A variable declaration with an inline specifier declares an inline variable.

4 A function defined within a class definition is an inline function.

5 The inline specifier shall not appear on a block scope declaration. If the inline specifier is used in a
    friend function declaration, that declaration shall be a definition or the function shall have previously been
    declared inline.

6 An inline function or variable shall be defined in every translation unit in which it is odr-used and shall
    have exactly the same definition in every case (6.2). [Note: A call to the inline function or a use of the

96) The inline keyword has no effect on the linkage of a function.

§ 9.1.6

151
inline variable may be encountered before its definition appears in the translation unit. — end note] If the definition of a function or variable appears in a translation unit before its first declaration as inline, the program is ill-formed. If a function or variable with external linkage is declared inline in one translation unit, it shall be declared inline in all translation units in which it appears; no diagnostic is required. An inline function or variable with external linkage shall have the same address in all translation units. [Note: A static local variable in an inline function with external linkage always refers to the same object. A type defined within the body of an inline function with external linkage is the same type in every translation unit. — end note]

9.1.7 Type specifiers

The type-specifiers are

1

type-specifier:

   simple-type-specifier
   elaborated-type-specifier
   typename-specifier
   cv-qualifier

type-specifier-seq:

type-specifier attribute-specifier-seq_opt
type-specifier type-specifier-seq

defining-type-specifier:

type-specifier
   class-specifier
   enum-specifier

defining-type-specifier-seq:

   defining-type-specifier attribute-specifier-seq_opt
defining-type-specifier defining-type-specifier-seq

The optional attribute-specifier-seq in a type-specifier-seq or a defining-type-specifier-seq appertains to the type denoted by the preceding type-specifiers or defining-type-specifiers (9.2.3). The attribute-specifier-seq affects the type only for the declaration it appears in, not other declarations involving the same type.

As a general rule, at most one defining-type-specifier is allowed in the complete decl-specifier-seq of a declaration or in a defining-type-specifier-seq, and at most one type-specifier is allowed in a type-specifier-seq.

The only exceptions to this rule are the following:

(2.1) — const can be combined with any type specifier except itself.

(2.2) — volatile can be combined with any type specifier except itself.

(2.3) — signed or unsigned can be combined with char, long, short, or int.

(2.4) — short or long can be combined with int.

(2.5) — long can be combined with double.

(2.6) — long can be combined with long.

Except in a declaration of a constructor, destructor, or conversion function, at least one defining-type-specifier that is not a cv-qualifier shall appear in a complete type-specifier-seq or a complete decl-specifier-seq.97

[Note: enum-specifiers, class-specifiers, and typename-specifiers are discussed in 9.6, Clause 10, and 12.7, respectively. The remaining type-specifiers are discussed in the rest of this subclause. — end note]

9.1.7.1 The cv-qualifiers

There are two cv-qualifiers, const and volatile. Each cv-qualifier shall appear at most once in a cv-qualifier-seq. If a cv-qualifier appears in a decl-specifier-seq, the init-declarator-list or member-declarator-list of the declaration shall not be empty. [Note: 6.7.3 and 9.2.3.5 describe how cv-qualifiers affect object and function types. — end note] Redundant cv-qualifications are ignored. [Note: For example, these could be introduced by typedefs. — end note]

[Note: Declaring a variable const can affect its linkage (9.1.1) and its usability in constant expressions (7.7). As described in 9.3, the definition of an object or subobject of const-qualified type must specify an initializer or be subject to default-initialization. — end note]

97) There is no special provision for a decl-specifier-seq that lacks a type-specifier or that has a type-specifier that only specifies cv-qualifiers. The “implicit int” rule of C is no longer supported.
A pointer or reference to a cv-qualified type need not actually point or refer to a cv-qualified object, but it is treated as if it does; a const-qualified access path cannot be used to modify an object even if the object referenced is a non-const object and can be modified through some other access path. [Note: Cv-qualifiers are supported by the type system so that they cannot be subverted without casting (7.6.1.11). — end note]

Except that any class member declared mutable (9.1.1) can be modified, any attempt to modify (7.6.18, 7.6.1.6, 7.6.2.2) a const object (6.7.3) during its lifetime (6.6.3) results in undefined behavior. [Example:

```c
const int ci = 3; // cv-qualified (initialized as required)
ci = 4; // ill-formed: attempt to modify const

int i = 2; // not cv-qualified
const int* cip; // pointer to const int
cip = &i; // OK: cv-qualified access path to unqualified
*cip = 4; // ill-formed: attempt to modify through ptr to const

int* ip;
ip = const_cast<int*>(cip); // cast needed to convert const int* to int*
*ip = 4; // defined: *ip points to i, a non-const object

const int* ciq = new const int (3); // initialized as required
int* iq = const_cast<int*>(ciq); // cast required
*iq = 4; // undefined: modifies a const object
```

For another example,

```c
struct X {
    mutable int i;
    int j;
};
struct Y {
    X x;
    Y();
};

const Y y;
y.x.i++; // well-formed: mutable member can be modified
y.x.j++; // ill-formed: const-qualified member modified
Y* p = const_cast<Y*>(&y); // cast away const-ness of y
p->x.i = 99; // well-formed: mutable member can be modified
p->x.j = 99; // undefined: modifies a const subobject
```

— end example]

The semantics of an access through a volatile glvalue are implementation-defined. If an attempt is made to access an object defined with a volatile-qualified type through the use of a non-volatile glvalue, the behavior is undefined.

[Note: volatile is a hint to the implementation to avoid aggressive optimization involving the object because the value of the object might be changed by means undetectable by an implementation. Furthermore, for some implementations, volatile might indicate that special hardware instructions are required to access the object. See 6.8.1 for detailed semantics. In general, the semantics of volatile are intended to be the same in C++ as they are in C. — end note]

9.1.7.2 Simple type specifiers

The simple type specifiers are

§ 9.1.7.2 153
simple-type-specifier:
  nested-name-specifier opt type-name
  nested-name-specifier template simple-template-id
  nested-name-specifier opt template-name
  char
  char16_t
  char32_t
  wchar_t
  bool
  short
  int
  long
  signed
  unsigned
  float
  double
  void
  decltype-specifier

type-name:
  class-name
  enum-name
  typedef-name
  simple-template-id

dcltype-specifier:
  dcltype ( expression )
  dcltype ( auto )

2 The simple-type-specifier auto is a placeholder for a type to be deduced (9.1.7.4). A type-specifier of the form typename opt nested-name-specifier opt template-name is a placeholder for a deduced class type (9.1.7.5). The template-name shall name a class template that is not an injected-class-name. The other simple-type-specifiers specify either a previously-declared type, a type determined from an expression, or one of the fundamental types (6.7.1). Table 11 summarizes the valid combinations of simple-type-specifiers and the types they specify.

3 When multiple simple-type-specifiers are allowed, they can be freely intermixed with other decl-specifiers in any order. [Note: It is implementation-defined whether objects of char type are represented as signed or unsigned quantities. The signed specifier forces char objects to be signed; it is redundant in other contexts. — end note]

4 For an expression e, the type denoted by dcltype(e) is defined as follows:

- (4.1) if e is an unparenthesized id-expression naming a structured binding (9.5), dcltype(e) is the referenced type as given in the specification of the structured binding declaration;

- (4.2) otherwise, if e is an unparenthesized id-expression naming a non-type template-parameter (12.1), dcltype(e) is the type of the template-parameter after performing any necessary type deduction (9.1.7.4, 9.1.7.5);

- (4.3) otherwise, if e is an unparenthesized id-expression or an unparenthesized class member access (7.6.1.5), dcltype(e) is the type of the entity named by e. If there is no such entity, or if e names a set of overloaded functions, the program is ill-formed;

- (4.4) otherwise, if e is an xvalue, dcltype(e) is T&&, where T is the type of e;

- (4.5) otherwise, if e is an lvalue, dcltype(e) is T&, where T is the type of e;

- (4.6) otherwise, dcltype(e) is the type of e.

The operand of the dcltype specifier is an unevaluated operand (7.2).

[Example:
const int&& foo();
int i;
struct A { double x; };
const A* a = new A();
dcltype(foo()) x1 = 17; // type is const int&&
dcltype(i) x2; // type is int

dcltype(a->x) x3;  // type is double

dcltype((a->x)) x4 = x3;  // type is const double*

—end example— [Note: The rules for determining types involving dcltype(auto) are specified in 9.1.7.4.
—end note]

5 If the operand of a dcltype-specifier is a prvalue, the temporary materialization conversion is not applied (7.3.4)
and no result object is provided for the prvalue. The type of the prvalue may be incomplete or an abstract
class type. [Note: As a result, storage is not allocated for the prvalue and it is not destroyed. Thus, a class
type is not instantiated as a result of being the type of a function call in this context. In this context, the
common purpose of writing the expression is merely to refer to its type. In that sense, a dcltype-specifier
is analogous to a use of a typedef-name, so the usual reasons for requiring a complete type do not apply. In
particular, it is not necessary to allocate storage for a temporary object or to enforce the semantic constraints

§ 9.1.7.2
associated with invoking the type’s destructor. — end note] [Note: Unlike the preceding rule, parentheses have no special meaning in this context. — end note] [Example:

```cpp
template<class T> struct A { ~A() = delete; };

template<class T> auto h() -> A<T>; // identity

template<class T> auto i(T) -> T; // #1

// forces completion of A<T> and implicitly uses A<T>::~A()
// for the temporary introduced by the use of h().
// (A temporary is not introduced as a result of the use of i().)

template<class T> auto f(T) -> decltype(i(h<T>())); // #2

// OK: calls #2. (#1 is not a viable candidate: type deduction
// fails (12.9.2) because A<int>::~A() is implicitly used in its
// decltype-specifier)

auto g() -> void {
    f(42);
}

// does not force completion of A<T>; A<T>::~A() is not implicitly
// used within the context of this decltype-specifier

void r() {
    q(42);
    // error: deduction against q succeeds, so overload resolution selects
    // the specialization "q(T) -> decltype((h<T>()))" with T=int;
    // the return type is A<int>, so a temporary is introduced and its
    // destructor is used, so the program is ill-formed
}

— end example]

9.1.7.3 Elaborated type specifiers

[dcl.type.elab]

elaborated-type-specifier:
    class-key attribute-specifier-seq_opt nested-name-specifier_opt identifier
    class-key simple-template-id
    class-key nested-name-specifier template_opt simple-template-id
    enum nested-name-specifier_opt identifier

1 An attribute-specifier-seq shall not appear in an elaborated-type-specifier unless the latter is the sole constituent of a declaration. If an elaborated-type-specifier is the sole constituent of a declaration, the declaration is ill-formed unless it is an explicit specialization (12.8.3), an explicit instantiation (12.8.2) or it has one of the following forms:

    class-key attribute-specifier-seq_opt identifier;
    friend class-key ::opt identifier;
    friend class-key ::opt simple-template-id;
    friend class-key nested-name-specifier identifier;
    friend class-key nested-name-specifier template_opt simple-template-id;

In the first case, the attribute-specifier-seq, if any, appertains to the class being declared; the attributes in the attribute-specifier-seq are thereafter considered attributes of the class whenever it is named.

2 6.4.4 describes how name lookup proceeds for the identifier in an elaborated-type-specifier. If the identifier resolves to a class-name or enum-name, the elaborated-type-specifier introduces it into the declaration the same way a simple-type-specifier introduces its type-name. If the identifier resolves to a typedef-name or the simple-template-id resolves to an alias template specialization, the elaborated-type-specifier is ill-formed. [Note: This implies that, within a class template with a template type-parameter T, the declaration

    friend class T;

is ill-formed. However, the similar declaration friend T; is allowed (10.8.3). — end note]

3 The class-key or enum keyword present in the elaborated-type-specifier shall agree in kind with the declaration to which the name in the elaborated-type-specifier refers. This rule also applies to the form of elaborated-type-specifier that declares a class-name or friend class since it can be construed as referring to the definition of the class. Thus, in any elaborated-type-specifier, the enum keyword shall be used to refer to an enumeration (9.6),
the union class-key shall be used to refer to a union (Clause 10), and either the class or struct class-key shall be used to refer to a class (Clause 10) declared using the class or struct class-key. [Example:

```c
enum class E { a, b }
enum E x = E::a;       // OK
```
—end example]

9.1.7.4 The auto specifier [decl.spec.auto]

1 The auto and decltype(auto) type-specifiers are used to designate a placeholder type that will be replaced later by deduction from an initializer. The auto type-specifier is also used to introduce a function type having a trailing-return-type or to signify that a lambda is a generic lambda (7.5.5). The auto type-specifier is also used to introduce a structured binding declaration (9.5).

2 The placeholder type can appear with a function declarator in the decl-specifier-seq, type-specifier-seq, conversion-function-id, or trailing-return-type, in any context where such a declarator is valid. If the function declarator includes a trailing-return-type (9.2.3.5), that trailing-return-type specifies the declared return type of the function. Otherwise, the function declarator shall declare a function. If the declared return type of the function contains a placeholder type, the return type of the function is deduced from non-discarded return statements, if any, in the body of the function (8.4.1).

3 The type of a variable declared using auto or decltype(auto) is deduced from its initializer. This use is allowed in an initializing declaration (9.3) of a variable. auto or decltype(auto) shall appear as one of the decl-specifiers in the decl-specifier-seq and the decl-specifier-seq shall be followed by one or more declarators, each of which shall be followed by a non-empty initializer. [Example:

```c
auto x = 5;             // OK: x has type int
const auto *v = &x, u = 6;    // OK: v has type const int*, u has type int
static auto y = 0.0;         // OK: y has type double
auto int r;                // error: auto is not a storage-class-specifier
auto f() -> int;            // OK: f returns int
auto g() { return 0.0; }    // OK: g returns double
auto h();                   // OK: h’s return type will be deduced when it is defined
```
—end example]

4 A placeholder type can also be used in the type-specifier-seq in the new-type-id or type-id of a new-expression (7.6.2.4) and as a decl-specifier of the parameter-declaration’s decl-specifier-seq in a template-parameter (12.1).

5 A program that uses auto or decltype(auto) in a context not explicitly allowed in this subclause is ill-formed.

6 If the init-declarator-list contains more than one init-declarator, they shall all form declarations of variables. The type of each declared variable is determined by placeholder type deduction (9.1.7.4.1), and if the type that replaces the placeholder type is not the same in each deduction, the program is ill-formed. [Example:

```c
auto x = 5, *y = &x;        // OK: auto is int
auto a = 5, b = { 1, 2 };   // error: different types for auto
```
—end example]

7 If a function with a declared return type that contains a placeholder type has multiple non-discarded return statements, the return type is deduced for each such return statement. If the type deduced is not the same in each deduction, the program is ill-formed.

8 If a function with a declared return type that uses a placeholder type has no non-discarded return statements, the return type is deduced as though from a return statement with no operand at the closing brace of the function body. [Example:

```c
auto f() { }               // OK, return type is void
auto* g() { }              // error, cannot deduce auto from void()
```
—end example]

9 If the name of an entity with an undeduced placeholder type appears in an expression, the program is ill-formed. Once a non-discarded return statement has been seen in a function, however, the return type
deduced from that statement can be used in the rest of the function, including in other return statements.

Example:

```cpp
auto n = n; // error, n's initializer refers to n
auto f();
void g() { &f; } // error, f's return type is unknown
auto sum(int i) {
    if (i == i)
        return i; // sum's return type is int
    else
        return sum(i-1)+i; // OK, sum's return type has been deduced
}
```

Return type deduction for a function template with a placeholder in its declared type occurs when the definition is instantiated even if the function body contains a return statement with a non-type-dependent operand. [Note: Therefore, any use of a specialization of the function template will cause an implicit instantiation. Any errors that arise from this instantiation are not in the immediate context of the function type and can result in the program being ill-formed (12.9.2). — end note]

Example:

```cpp
template <class T> auto f(T t) { return t; } // return type deduced at instantiation time
typedef decltype(f(1)) fint_t; // instantiates f<int> to deduce return type
template<class T> auto f(T* t) { return *t; }
void g() { int (*p)(int*) = &f; } // instantiates both f's to determine return types, // chooses second
```

Redeclarations or specializations of a function or function template with a declared return type that uses a placeholder type shall also use that placeholder, not a deduced type. Similarly, redeclarations or specializations of a function or function template with a declared return type that does not use a placeholder type shall not use a placeholder. [Example:

```cpp
auto f();
auto f() { return 42; } // return type is int
auto f(); // OK
int f(); // error, cannot be overloaded with auto f()
declaytype(auto) f(); // error, auto and decltype(auto) don't match
template <typename T> auto g(T t) { return t; } // #1
template auto g(int); // OK, return type is int
template char g(char); // error, no matching template
template auto g(double); // OK, forward declaration with unknown return type
template <class T> T g(T t) { return t; } // OK, not functionally equivalent to #1
template char g(char); // OK, now there is a matching template
template auto g(float); // still matches #1
void h() { return g(42); } // error, ambiguous

template <typename T> struct A {
    friend T frf(T);
};
auto frf(int i) { return i; } // not a friend of A<int>
```

A function declared with a return type that uses a placeholder type shall not be virtual (10.6.2).

An explicit instantiation declaration (12.8.2) does not cause the instantiation of an entity declared using a placeholder type, but it also does not prevent that entity from being instantiated as needed to determine its type. [Example:

```cpp
template <typename T> auto f(T t) { return t; }
extern template auto f(int); // does not instantiate f<int>
int (*p)(int) = f; // instantiates f<int> to determine its return type, but an explicit // instantiation definition is still required somewhere in the program
```
9.1.7.4.1 Placeholder type deduction

Placeholder type deduction is the process by which a type containing a placeholder type is replaced by a deduced type.

1 A type T containing a placeholder type, and a corresponding initializer e, are determined as follows:

   (2.1) for a non-discarded return statement that occurs in a function declared with a return type that contains a placeholder type, T is the declared return type and e is the operand of the return statement. If the return statement has no operand, then e is void();

   (2.2) for a variable declared with a type that contains a placeholder type, T is the declared type of the variable and e is the initializer. If the initialization is direct-list-initialization, the initializer shall be a braced-init-list containing only a single assignment-expression and e is the assignment-expression;

   (2.3) for a non-type template parameter declared with a type that contains a placeholder type, T is the declared type of the non-type template parameter and e is the corresponding template argument.

In the case of a return statement with no operand or with an operand of type void, T shall be either decltype(auto) or cv auto.

2 If the deduction is for a return statement and e is a braced-init-list (9.3.4), the program is ill-formed.

3 If the placeholder is the decltype(auto) type-specifier, the deduced type T' replacing T is determined using the rules for template argument deduction. Obtain P from T by replacing the occurrences of auto with either a new invented type template parameter U or, if the initialization is copy-list-initialization, with std::initializer_list<U>. Deduce a value for U using the rules of template argument deduction from a function call (12.9.2.1), where P is a function template parameter type and the corresponding argument is e. If the deduction fails, the declaration is ill-formed. Otherwise, T' is obtained by substituting the deduced U into P. [Example:

```cpp
auto x1 = {1, 2}; // decltype(x1) is std::initializer_list<int>
auto x2 = {1, 2.0}; // error: cannot deduce element type
tax3 = {1, 2}; // error: not a single element
auto x4 = {3}; // decltype(x4) is std::initializer_list<int>
tax5 = {3}; // decltype(x5) is int
```

— end example]

[Example:

```cpp
const auto &i = expr;
```

The type of i is the deduced type of the parameter u in the call f(expr) of the following invented function template:

```cpp
template <class U> void f(const U & u);
```

— end example]

4 If the placeholder is the decltype(auto) type-specifier, T shall be the placeholder alone. The type deduced for T is determined as described in 9.1.7.2, as though e had been the operand of the decltype. [Example:

```cpp
int i;
int & f();
auto x2a(i); // decltype(x2a) is int
decltype(auto) x2d(i); // decltype(x2d) is int
auto x3a = 1; // decltype(x3a) is int
decltype(auto) x3d = 1; // decltype(x3d) is int
auto x4a = (i); // decltype(x4a) is int
decltype(auto) x4d = (i); // decltype(x4d) is int&
auto x5a = f(); // decltype(x5a) is int
decltype(auto) x5d = f(); // decltype(x5d) is int&
auto x6a = {1, 2}; // decltype(x6a) is std::initializer_list<int>
decltype(auto) x6d = {1, 2}; // error, {1, 2} is not an expression
auto *x7a = &i; // decltype(x7a) is int*
decltype(auto)*x7d = &i; // error, declared type is not plain decltype(auto)
```

— end example]
9.1.7.5 Deduced class template specialization types

1 If a placeholder for a deduced class type appears as a decl-specifier in the decl-specifier-seq of an initializing declaration (9.3) of a variable, the placeholder is replaced by the return type of the function selected by overload resolution for class template deduction (11.3.1.8). If the decl-specifier-seq is followed by an init-declarator-list or member-declarator-list containing more than one declarator, the type that replaces the placeholder shall be the same in each deduction.

2 A placeholder for a deduced class type can also be used in the type-specifier-seq in the new-type-id or type-id of a new-expression (7.6.2.4), as the simple-type-specifier in an explicit type conversion (functional notation) (7.6.1.3), or as the type-specifier in the parameter-declaration of a template-parameter (12.1). A placeholder for a deduced class type shall not appear in any other context.

3 [Example:

```c++
    template<class T> struct container {
        container(T t) {}
        template<class Iter> container(Iter beg, Iter end);
    };

    template<class Iter>
    container(Iter b, Iter e) -> container<typename std::iterator_traits<Iter>::value_type>;

    std::vector<double> v = { /* ... */ };
    container c(7); // OK, deduces int for T
    auto d = container(v.begin(), v.end()); // OK, deduces double for T
    container e(5, 6); // error, int is not an iterator

    — end example]
```

9.2 Declarators

1 A declarator declares a single variable, function, or type, within a declaration. The init-declarator-list appearing in a declaration is a comma-separated sequence of declarators, each of which can have an initializer.

   init-declarator-list:
   init-declarator
   init-declarator-list , init-declarator

   init-declarator:
   declarator initializeropt
   declarator requires-clause

2 The three components of a simple-declaration are the attributes (9.11), the specifiers (decl-specifier-seq; 9.1) and the declarators (init-declarator-list). The specifiers indicate the type, storage class or other properties of the entities being declared. The declarators specify the names of these entities and (optionally) modify the type of the specifiers with operators such as * (pointer to) and () (function returning). Initial values can also be specified in a declarator; initializers are discussed in 9.3 and 10.9.

3 Each init-declarator in a declaration is analyzed separately as if it was in a declaration by itself. [Note: A declaration with several declarators is usually equivalent to the corresponding sequence of declarations each with a single declarator. That is

   T D1, D2, ... Dn;

   is usually equivalent to

   T D1; T D2; ... T Dn;

   where T is a decl-specifier-seq and each Di is an init-declarator. One exception is when a name introduced by one of the declarators hides a type name used by the decl-specifiers, so that when the same decl-specifiers are used in a subsequent declaration, they do not have the same meaning, as in

   struct S { /* ... */ }; // declare two instances of struct S

   S S, T;

   which is not equivalent to

   struct S { /* ... */ }; // error
   S S;
   S T;

   Another exception is when T is auto (9.1.7.4), for example:
auto i = 1, j = 2.0;  // error: deduced types for i and j do not match
as opposed to
auto i = 1;       // OK: i deduced to have type int
auto j = 2.0;     // OK: j deduced to have type double
— end note]

The optional requires-clause (Clause 12) in an init-declarator or member-declarator shall not be present when the declarator does not declare a function (9.2.3.5). When present after a declarator, the requires-clause is called the trailing requires-clause. The trailing requires-clause introduces the constraint-expression that results from interpreting its constraint-logical-or-expression as a constraint-expression. [Example:

```c
void f1(int a) requires true;  // OK
auto f2(int a) -> bool requires true;  // OK
auto f3(int a) requires true -> bool;  // error: requires-clause precedes trailing-return-type
void (*pf)() requires true;  // error: constraint on a variable
void g(int (*)() requires true);  // error: constraint on a parameter-declaration
auto* p = new void(*)(char) requires true;  // error: not a function declaration
— end example]

Declarators have the syntax

declarator:
    ptr-declarator
    noptr-declarator parameters-and-qualifiers trailing-return-type
ptr-declarator:
    noptr-declarator
    ptr-operator ptr-declarator
noptr-declarator:
    declarator-id attribute-specifier-seqopt
    noptr-declarator parameters-and-qualifiers
    noptr-declarator [ constant-expressionopt ] attribute-specifier-seqopt
                      ( ptr-declarator )
parameters-and-qualifiers:
    ( parameter-declaration-clause ) cv-qualifier-seqopt
    ref-qualifieropt noexcept-specifieropt attribute-specifier-seqopt
trailing-return-type:
    -> type-id
ptr-operator:
    * attribute-specifier-seqopt cv-qualifier-seqopt
    & attribute-specifier-seqopt
    && attribute-specifier-seqopt
    nested-name-specifier * attribute-specifier-seqopt cv-qualifier-seqopt
cv-qualifier-seq:
    cv-qualifier cv-qualifier-seqopt

9.2.1 Type names

To specify type conversions explicitly, and as an argument of sizeof, alignof, new, or typeid, the name of
a type shall be specified. This can be done with a type-id, which is syntactically a declaration for a variable
or function of that type that omits the name of the entity.
It is possible to identify uniquely the location in the abstract-declarator where the identifier would appear if the construction were a declarator in a declaration. The named type is then the same as the type of the hypothetical identifier. [Example:

```c
int i
int *pi
int *[3]
int (*)(double)
int (*)(int)
int *()
int *([3])
int (*)(double)[3]
int *([3])(double)
```

name respectively the types “int”, “pointer to int”, “array of 3 pointers to int”, “pointer to array of 3 int”, “function of (no parameters) returning pointer to int”, and “pointer to a function of (double) returning int”. — end example]

A type can also be named (often more easily) by using a typedef (9.1.3).

### 9.2.2 Ambiguity resolution

[declambig.res]

The ambiguity arising from the similarity between a function-style cast and a declaration mentioned in 8.8 can also occur in the context of a declaration. In that context, the choice is between a function declaration with a redundant set of parentheses around a parameter name and an object declaration with a function-style cast as the initializer. Just as for the ambiguities mentioned in 8.8, the resolution is to consider any construct that could possibly be a declaration a declaration. [Note: A declaration can be explicitly disambiguated by adding parentheses around the argument. The ambiguity can be avoided by use of copy-initialization or list-initialization syntax, or by use of a non-function-style cast. — end note] [Example:

```c
struct S {
    S(int);
};

void foo(double a) {
    S u(int(a)); // function declaration
    S x(int()); // function declaration
    S y((int(a)));
    // object declaration
    S z = int(a);
    // object declaration
}
```

— end example]
An ambiguity can arise from the similarity between a function-style cast and a type-id. The resolution is that any construct that could possibly be a type-id in its syntactic context shall be considered a type-id. [Example:

```cpp
template <class T> struct X {};  // type-id
template <int N> struct Y {};  // type-id
X<int()> a;  // expression (ill-formed)
X<int(1)> b;  // expression (ill-formed)
Y<int()> c;  // type-id (ill-formed)
Y<int(1)> d;  // expression
```

—end example]

Another ambiguity arises in a parameter-declaration-clause when a type-name is nested in parentheses. In this case, the choice is between the declaration of a parameter of type pointer to function and the declaration of a parameter with redundant parentheses around the declarator-id. The resolution is to consider the type-name as a simple-type-specifier rather than a declarator-id. [Example:

```cpp
class C { };  
void f(int(C)) { }  // void f(int(*fp)(C c)) { }  // not: void f(int C) { }
int g(C);
void foo() {
    f(1);  // error: cannot convert 1 to function pointer
    f(g);  // OK
}
```

For another example,

```cpp
class C { };  
void h(int *(C[10]));  // void h(int *(C _parm[10]));  // not: void h(int *C[10]);
```

—end example]

### 9.2.3 Meaning of declarators

A declarator contains exactly one declarator-id; it names the identifier that is declared. An unqualified-id occurring in a declarator-id shall be a simple identifier except for the declaration of some special functions (10.3.4, 10.3.8, 10.3.7, 11.5) and for the declaration of template specializations or partial specializations (12.8). When the declarator-id is qualified, the declaration shall refer to a previously declared member of the class or namespace to which the qualifier refers (or, in the case of a namespace, an element of the inline namespace set of that namespace (9.7.1)) or to a specialization thereof; the member shall not merely have been introduced by a using-declaration in the scope of the class or namespace nominated by the nested-name-specifier of the declarator-id. The nested-name-specifier of a qualified declarator-id shall not begin with a decltype-specifier.

[Note: If the qualifier is the global :: scope resolution operator, the declarator-id refers to a name declared in the global namespace scope. —end note] The optional attribute-specifier-seq following a declarator-id appertains to the entity that is declared.

A static, thread_local, extern, mutable, friend, inline, virtual, constexpr, or typedef specifier or an explicit-specifier applies directly to each declarator-id in an init-declarator-list or member-declarator-list; the type specified for each declarator-id depends on both the decl-specifier-seq and its declarator.

Thus, a declaration of a particular identifier has the form

```
T D
```
where \( T \) is of the form attribute-specifier-seq_{opt} decl-specifier-seq and \( D \) is a declarator. Following is a recursive procedure for determining the type specified for the contained declarator-id by such a declaration.

4 First, the decl-specifier-seq determines a type. In a declaration

\[
T \ D
\]

the decl-specifier-seq \( T \) determines the type \( T \). [Example: In the declaration

\[
\text{int unsigned i;}
\]

the type specifiers \text{int unsigned} determine the type “unsigned int” (9.1.7.2). — end example]

5 In a declaration attribute-specifier-seq_{opt} \( T \ D \) where \( D \) is an unadorned identifier the type of this identifier is “\( T \)”.

6 In a declaration \( T \ D \) where \( D \) has the form

\[
( \ D1 \ )
\]

the type of the contained declarator-id is the same as that of the contained declarator-id in the declaration

\[
T \ D1
\]

Parentheses do not alter the type of the embedded declarator-id, but they can alter the binding of complex declarators.

9.2.3.1 Pointers

In a declaration \( T \ D \) where \( D \) has the form

\[
* \text{attribute-specifier-seq}_{opt} \text{cv-qualifier-seq}_{opt} \ D1
\]

and the type of the identifier in the declaration \( T \ D1 \) is “derived-declarator-type-list \( T \)”, then the type of the identifier of \( D \) is “derived-declarator-type-list cv-qualifier-seq pointer to \( T \)”. The cv-qualifiers apply to the pointer and not to the object pointed to. Similarly, the optional attribute-specifier-seq (9.11.1) appertains to the pointer and not to the object pointed to.

[Example: The declarations

\[
\text{const int ci = 10, *pc = &ci, *const cpc = pc, **ppc;}
\text{int i, *p, *const cp = &i;}
\]

declare ci, a constant integer; pc, a pointer to a constant integer; cpc, a constant pointer to a constant integer; ppc, a pointer to a pointer to a constant integer; i, an integer; p, a pointer to integer; and cp, a constant pointer to integer. The value of ci, cpc, and cp cannot be changed after initialization. The value of pc can be changed, and so can the object pointed to by cp. Examples of some correct operations are

\[
i = ci; \quad // \text{error}
*cp = ci; \quad // \text{error}
cp++; \quad // \text{error}
pc = cpc; \quad // \text{error}
ppc = p; \quad // \text{error}
ppc = &pc; \quad // \text{error}
\]

Examples of ill-formed operations are

\[
ci = 1; \quad // \text{error}
ci++; \quad // \text{error}
*\text{pc} = 2; \quad // \text{error}
\text{cp} = &\text{ci}; \quad // \text{error}
\text{cpc++}; \quad // \text{error}
\text{p} = \text{pc}; \quad // \text{error}
\text{ppc} = &\text{p}; \quad // \text{error}
\]

Each is unacceptable because it would either change the value of an object declared const or allow it to be changed through a cv-unqualified pointer later, for example:

\[
*\text{ppc} = &\text{ci}; \quad // \text{OK, but would make p point to ci because of previous error}
*\text{p} = 5; \quad // \text{clobber ci}
\]

— end example]

3 See also 7.6.18 and 9.3.
4 [Note: Forming a pointer to reference type is ill-formed; see 9.2.3.2. Forming a function pointer type is ill-formed if the function type has cv-qualifiers or a ref-qualifier; see 9.2.3.5. Since the address of a bit-field (10.3.10) cannot be taken, a pointer can never point to a bit-field. — end note]

9.2.3.2 References

1 In a declaration \( T \ D \) where \( D \) has either of the forms

\[
& \text{attribute-specifier-seq}_\text{opt} \ D_1 \\
&& \text{attribute-specifier-seq}_\text{opt} \ D_1
\]

and the type of the identifier in the declaration \( T \ D_1 \) is “derived-declarator-type-list \( T \)”, then the type of the identifier of \( D \) is “derived-declarator-type-list reference to \( T \)”. The optional attribute-specifier-seq appertains to the reference type. Cv-qualified references are ill-formed except when the cv-qualifiers are introduced through the use of a typedef-name (9.1.3, 12.1) or decltype-specifier (9.1.7.2), in which case the cv-qualifiers are ignored. [Example:

```c
typedef int& A;
const A aref = 3;  // ill-formed; lvalue reference to non-const initialized with rvalue
```

The type of \( \text{aref} \) is “lvalue reference to int”, not “lvalue reference to const int”. — end example] [Note: A reference can be thought of as a name of an object. — end note] A declarator that specifies the type “reference to cv void” is ill-formed.

2 A reference type that is declared using & is called an lvalue reference, and a reference type that is declared using && is called an rvalue reference. Lvalue references and rvalue references are distinct types. Except where explicitly noted, they are semantically equivalent and commonly referred to as references.

3 [Example:

```c
void f(double& a) { a += 3.14; }
// ...
double d = 0;
f(d);
```

declares \( a \) to be a reference parameter of \( f \) so the call \( f(d) \) will add 3.14 to \( d \).

```c
int v[20];
// ...
int& g(int i) { return v[i]; }
// ...
g(3) = 7;
```

declares the function \( g() \) to return a reference to an integer so \( g(3) = 7 \) will assign 7 to the fourth element of the array \( v \). For another example,

```c
struct link {
    link* next;
};

link* first;

void h(link*& p) {  // p is a reference to pointer
    p->next = first;
    first = p;
    p = 0;
}

void k() {
    link* q = new link;
    h(q);
}
```

declares \( p \) to be a reference to a pointer to \( \text{link} \) so \( h(q) \) will leave \( q \) with the value zero. See also 9.3.3. — end example]

4 It is unspecified whether or not a reference requires storage (6.6.4).

5 There shall be no references to references, no arrays of references, and no pointers to references. The declaration of a reference shall contain an initializer (9.3.3) except when the declaration contains an explicit extern specifier (9.1.1), is a class member (10.3) declaration within a class definition, or is the declaration of
a parameter or a return type (9.2.3.5); see 6.1. A reference shall be initialized to refer to a valid object or function. [Note: In particular, a null reference cannot exist in a well-defined program, because the only way to create such a reference would be to bind it to the “object” obtained by indirection through a null pointer, which causes undefined behavior. As described in 10.3.10, a reference cannot be bound directly to a bit-field. —end note]

6 If a typedef-name (9.1.3, 12.1) or a decltype-specifier (9.1.7.2) denotes a type TR that is a reference to a type T, an attempt to create the type “lvalue reference to cv TR” creates the type “lvalue reference to T”, while an attempt to create the type “rvalue reference to cv TR” creates the type TR. [Note: This rule is known as reference collapsing. —end note]

   [Example:
   int i;
typedef int& LRI;
typedef int&& RRI;
   LRI& r1 = i; // r1 has the type int&
   const LRI& r2 = i; // r2 has the type int&
   const LRI&& r3 = i; // r3 has the type int&&
   RRI& r4 = i; // r4 has the type int&
   RRI&& r5 = 5; // r5 has the type int&&
decaytype(r2)& r6 = i; // r6 has the type int&
decaytype(r2)&& r7 = i; // r7 has the type int&
   —end example]

7 [Note: Forming a reference to function type is ill-formed if the function type has cv-qualifiers or a ref-qualifier; see 9.2.3.5. —end note]

9.2.3.3 Pointers to members [dcl.mptr]

1 In a declaration T D where D has the form

   nested-name-specifier * attribute-specifier-seqopt cv-qualifier-seqopt D1

and the nested-name-specifier denotes a class, and the type of the identifier in the declaration T D1 is “derived-declarator-type-list T”, then the type of the identifier of D is “derived-declarator-type-list cv-qualifier-seq pointer to member of class nested-name-specifier of type T”. The optional attribute-specifier-seq (9.11.1) appertains to the pointer-to-member.

2 [Example:
   struct X {
      void f(int);
      int a;
   };
   struct Y;
   int X::* pmi = &X::a;
   void (X::* pmf)(int) = &X::f;
   double X::* pmd;
   char Y::* pmc;

decares pmi, pmf, pmd and pmc to be a pointer to a member of X of type int, a pointer to a member of X of type void(int), a pointer to a member of X of type double and a pointer to a member of Y of type char respectively. The declaration of pmd is well-formed even though X has no members of type double. Similarly, the declaration of pmc is well-formed even though Y is an incomplete type. pmi and pmf can be used like this:

   X obj;
   // ...
   obj.*pmi = 7; // assign 7 to an integer member of obj
   (obj.*pmf)(7); // call a function member of obj with the argument 7
   —end example]

3 A pointer to member shall not point to a static member of a class (10.3.9), a member with reference type, or “cv void”.

§ 9.2.3.3
An array can be constructed from one of the fundamental types (except void). In a declaration
In a declaration $T D$ where $D$ has the form

$$D_1 [ \ [ \begin{array}{l} \text{constant-expression}_{opt} \ \text{attribute-specifier-seq}_{opt} \end{array} \ ] \ ]$$

and the type of the identifier in the declaration $T D_1$ is “derived-declarator-type-list $T$”, then the type of
the identifier of $D$ is an array type; if the type of the identifier of $D$ contains the auto type specifier, the
program is ill-formed. $T$ is called the array element type; this type shall not be a reference type, cv void,
or a function type. If the constant expression (7.7) is present, it shall be a converted constant expression of
type std::size_t and its value shall be greater than zero. The constant expression specifies the bound
(of number of elements in) the array. If the value of the constant expression is $N$, the array has $N$ elements
numbered 0 to $N-1$, and the type of the identifier of $D$ is “derived-declarator-type-list array of $N$ T”. An object
of array type contains a contiguous allocated non-empty set of $N$ subobjects of type $T$. Except as noted
below, if the constant expression is omitted, the type of the identifier of $D$ is “derived-declarator-type-list
array of unknown bound of $T$”, an incomplete object type. The type “derived-declarator-type-list array of
$N$ $T$” is a different type from the type “derived-declarator-type-list array of unknown bound of $T$”, see 6.7. Any
type of the form “cv-qualifier-seq array of $N$ $T$” is adjusted to “array of $N$ cv-qualifier-seq $T$”, and similarly for
“array of unknown bound of $T$”. The optional attribute-specifier-seq appertains to the array. [Example:

```c
typedef int A[5], AA[2][3];
typedef const AA CA;
typedef const AA CAA;
```
—end example] [Note: An “array of $N$ cv-qualifier-seq $T$” has cv-qualified type; see 6.7.3. — end note]

An array can be constructed from one of the fundamental types (except void), from a pointer, from a pointer
to member, from a class, from an enumeration type, or from another array.

When several “array of” specifications are adjacent, a multidimensional array type is created; only the first of
the constant expressions that specify the bounds of the arrays may be omitted. In addition to declarations in
which an incomplete object type is allowed, an array bound may be omitted in some cases in the declaration
of a function parameter (9.2.3.5). An array bound may also be omitted when the declarator is followed by an
initializer (9.3), when a declarator for a static data member is followed by an brace-or-equal-initializer (10.3),
or in an explicit type conversion (7.6.1.3). In these cases, the bound is calculated from the number of initial
elements (say, $N$) supplied (9.3.1), and the type of the identifier of $D$ is “array of $N$ $T$”. Furthermore, if there is
a preceding declaration of the entity in the same scope in which the bound was specified, an omitted array
bound is taken to be the same as in that earlier declaration, and similarly for the definition of a static data
member of a class.

[Example:

```c
float fa[17], *afp[17];
```
declares an array of float numbers and an array of pointers to float numbers. — end example]

[Example:

```c
int x3d[3][5][7];
```
declares an array of three elements, each of which is an array of five elements, each of which is an array
of seven integers. The overall array can be viewed as a three-dimensional array of integers, with rank $3 \times 5 \times 7$.
Any of the expressions $x3d$, $x3d[1]$, $x3d[1][j]$, $x3d[1][j][k]$ can reasonably appear in an expression. The expression
$x3d[1]$ is equivalent to $*(x3d + 1)$; in that expression, $x3d$ is subject to the array-to-pointer conversion (7.3.2) and
is first converted to a pointer to a 2-dimensional array with rank $5 \times 7$ that points to the first element of $x3d$.
Then $i$ is added, which on typical implementations involves multiplying $i$ by the length of the object to which the pointer points, which is sizeof(int)$\times 5 \times 7$. The result of the addition and
indirection is an lvalue denoting the $i^{th}$ array element of $x3d$ (an array of five arrays of seven integers).
If there is another subscript, the same argument applies again, so $x3d[1][j]$ is an lvalue denoting the $j^{th}$
array element of the $i^{th}$ array element of $x3d$ (an array of seven integers), and $x3d[1][j][k]$ is an lvalue
denoting the $k^{th}$ array element of the $j^{th}$ array element of the $i^{th}$ array element of $x3d$ (an integer). — end
example] [Note: The first subscript in the declaration helps determine the amount of storage consumed by
an array but plays no other part in subscript calculations. — end note]
In a declaration $T D$ where $D$ has the form

\[ D1 ( \text{parameter-declaration-clause} ) \text{cv-qualifier-seq}_{\text{opt}} \text{ref-qualifier}_{\text{opt}} \text{noexcept-specifier}_{\text{opt}} \text{attribute-specifier-seq}_{\text{opt}} \]

and the type of the contained declarator-id in the declaration $T D1$ is “derived-declarator-type-list $T$”, the type of the declarator-id in $D$ is “derived-declarator-type-list noexcept$_{\text{opt}}$ function of (parameter-declaration-clause) cv-qualifier-seq$_{\text{opt}}$ ref-qualifier$_{\text{opt}}$ returning $T$”, where the optional noexcept is present if and only if the exception specification (13.4) is non-throwing. The optional attribute-specifier-seq appertains to the function type.

In a declaration $T D$ where $D$ has the form

\[ D1 ( \text{parameter-declaration-clause} ) \text{cv-qualifier-seq}_{\text{opt}} \text{ref-qualifier}_{\text{opt}} \text{noexcept-specifier}_{\text{opt}} \text{attribute-specifier-seq}_{\text{opt}} \text{trailing-return-type} \]

and the type of the contained declarator-id in the declaration $T D1$ is “derived-declarator-type-list $T$”, $T$ shall be the single type-specifier auto. The type of the declarator-id in $D$ is “derived-declarator-type-list noexcept$_{\text{opt}}$ function of (parameter-declaration-clause) cv-qualifier-seq$_{\text{opt}}$ ref-qualifier$_{\text{opt}}$ returning $U$”, where $U$ is the type specified by the trailing-return-type, and where the optional noexcept is present if and only if the exception specification is non-throwing. The optional attribute-specifier-seq appertains to the function type.

A type of either form is a function type.\(^\text{98}\)

\[
\begin{align*}
\text{parameter-declaration-clause:} & \quad \text{parameter-declaration-list}_{\text{opt}} \ldots_{\text{opt}} \\
\text{parameter-declaration-list:} & \quad \text{parameter-declaration} \\
\text{parameter-declaration:} & \quad \text{attribute-specifier-seq}_{\text{opt}} \text{decl-specifier-seq declarator} \\
& \quad \text{attribute-specifier-seq}_{\text{opt}} \text{decl-specifier-seq declarator = initializer-clause} \\
& \quad \text{attribute-specifier-seq}_{\text{opt}} \text{decl-specifier-seq abstract-declarator}_{\text{opt}} \\
& \quad \text{attribute-specifier-seq}_{\text{opt}} \text{decl-specifier-seq abstract-declarator}_{\text{opt}} = \text{initializer-clause}
\end{align*}
\]

The optional attribute-specifier-seq in a parameter-declaration appertains to the parameter.

The parameter-declaration-clause determines the arguments that can be specified, and their processing, when the function is called. [Note: The parameter-declaration-clause is used to convert the arguments specified on the function call; see 7.6.1.2. — end note] If the parameter-declaration-clause is empty, the function takes no arguments. A parameter list consisting of a single unnamed parameter of non-dependent type void is equivalent to an empty parameter list. Except for this special case, a parameter shall not have type cv void. If the parameter-declaration-clause terminates with an ellipsis or a function parameter pack (12.6.3), the

\(^{98}\) As indicated by syntax, cv-qualifiers are a significant component in function return types.
number of arguments shall be equal to or greater than the number of parameters that do not have a default argument and are not function parameter packs. Where syntactically correct and where "..." is not part of an abstract-declarator, "..." is synonymous with "...". [Example: The declaration

```c
int printf(const char*, ...);
```

declares a function that can be called with varying numbers and types of arguments.

```c
printf("hello world");
printf("a=%d b=%d", a, b);
```

However, the first argument must be of a type that can be converted to a `const char*`. — end example] [Note: The standard header `<stdarg>` contains a mechanism for accessing arguments passed using the ellipsis (see 7.6.1.2 and 16.12). — end note]

5 The type of a function is determined using the following rules. The type of each parameter (including function parameter packs) is determined from its own `decl-specifier-seq` and `declarator`. After determining the type of each parameter, any parameter of type "array of T" or of function type T is adjusted to be "pointer to T". After producing the list of parameter types, any top-level `cv-qualifiers` modifying a parameter type are deleted when forming the function type. The resulting list of transformed parameter types and the presence or absence of the ellipsis or a function parameter pack is the function’s `parameter-type-list`. [Note: This transformation does not affect the types of the parameters. For example, `int(*)(const int p, decltype(p)*)` and `int(*)(int, const int*)` are identical types. — end note]

6 A function type with a `cv-qualifier-seq` or a `ref-qualifier` (including a type named by `typedef-name` (9.1.3, 12.1)) shall appear only as:

(6.1) — the function type for a non-static member function,
(6.2) — the function type to which a pointer to member refers,
(6.3) — the top-level function type of a function typedef declaration or `alias-declaration`,
(6.4) — the `type-id` in the default argument of a `type-parameter` (12.1), or
(6.5) — the `type-id` of a `template-argument` for a `type-parameter` (12.3.1).

[Example:

```c
typedef int FIC(int) const;
FIC f;
struct S {
   FIC f;          // ill-formed: does not declare a member function
};
FIC S::*pm = &S::f; // OK
— end example]

7 The effect of a `cv-qualifier-seq` in a function declarator is not the same as adding cv-qualification on top of the function type. In the latter case, the `cv-qualifiers` are ignored. [Note: A function type that has a `cv-qualifier-seq` is not a cv-qualified type; there are no cv-qualified function types. — end note] [Example:

```c
typedef void F();
struct S {
   const F f;          // OK: equivalent to: void f();
};
— end example]

8 The return type, the parameter-type-list, the `ref-qualifier`, the `cv-qualifier-seq`, and the exception specification, but not the default arguments (9.2.3.6) or the trailing `requires-clause` (9.2), are part of the function type. [Note: Function types are checked during the assignments and initializations of pointers to functions, references to functions, and pointers to member functions. — end note]

9 [Example: The declaration

```c
int fseek(FILE*, long, int);
```

declares a function taking three arguments of the specified types, and returning `int` (9.1.7). — end example]

10 A single name can be used for several different functions in a single scope; this is function overloading (Clause 11). All declarations for a function shall have equivalent return types, parameter-type-lists, and `requires-clauses` (12.6.6.1).
Functions shall not have a return type of type array or function, although they may have a return type of type pointer or reference to such things. There shall be no arrays of functions, although there can be arrays of pointers to functions.

Types shall not be defined in return or parameter types.

A typedef of function type may be used to declare a function but shall not be used to define a function (9.4).

Example:
```c
typedef void F();
F fv;    // OK: equivalent to void fv();
F fv{}   // ill-formed
void fv{}; // OK: definition of fv
```

An identifier can optionally be provided as a parameter name; if present in a function definition (9.4), it names a parameter. [Note: In particular, parameter names are also optional in function definitions and names used for a parameter in different declarations and the definition of a function need not be the same. If a parameter name is present in a function declaration that is not a definition, it cannot be used outside of its function declarator because that is the extent of its potential scope (6.3.4). —end note]

Example: The declaration
```c
int i,
  *pi,
  f(),
  *fpi(int),
  (**pif)(const char*, const char*),
  (**fpif(int))(int);
```
declares an integer `i`, a pointer `pi` to an integer, a function `f` taking no arguments and returning an integer, a function `fpi` taking an integer argument and returning a pointer to an integer, a pointer `pif` to a function which takes two pointers to constant characters and returns an integer, a function `fpif` taking an integer argument and returning a pointer to a function that takes an integer argument and returns an integer. It is especially useful to compare `fpi` and `pif`. The binding of `*fpi(int)` is `*(fpi(int))`, so the declaration suggests, and the same construction in an expression requires, the calling of a function `fpi`, and then using indirection through the (pointer) result to yield an integer. In the declaration `(**pif)(const char*, const char*)`, the extra parentheses are necessary to indicate that indirection through a pointer to a function yields a function, which is then called. —end example] [Note: Typedefs and trailing-return-types are sometimes convenient when the return type of a function is complex. For example, the function `fpif` above could have been declared
```c
typedef int IFUNC(int);
IFUNC* fpif(int);
```
or
```c
auto fpif(int)->int(*)(int);
```
A trailing-return-type is most useful for a type that would be more complicated to specify before the declarator-id:
```c
template<class T, class U> auto add(T t, U u) -> decltype(t + u);
```
rather than
```c
template<class T, class U> decltype((*(T*)0) + (*(U*)0)) add(T t, U u);
```
—end note]

A non-template function is a function that is not a function template specialization. [Note: A function template is not a function. —end note]

A declarator-id or abstract-declarator containing an ellipsis shall only be used in a parameter-declaration. When it is part of a parameter-declaration-clause, the parameter-declaration declares a function parameter pack (12.6.3). Otherwise, the parameter-declaration is part of a template-parameter-list and declares a template parameter pack; see 12.1. A function parameter pack is a pack expansion (12.6.3). Example:
```c
template<typename... T> void f(T (...t)(int, int));
```
float subtract(int, int);

void g() {
    f(add, subtract);
}

—end example]

There is a syntactic ambiguity when an ellipsis occurs at the end of a parameter-declaration-clause without a preceding comma. In this case, the ellipsis is parsed as part of the abstract-declarator if the type of the parameter either names a template parameter pack that has not been expanded or contains auto; otherwise, it is parsed as part of the parameter-declaration-clause. 99

9.2.3.6 Default arguments [dcl.fct.default]

1 If an initializer-clause is specified in a parameter-declaration this initializer-clause is used as a default argument. [Note: Default arguments will be used in calls where trailing arguments are missing (7.6.1.2). — end note]

2 [Example: The declaration

      void point(int = 3, int = 4);

declares a function that can be called with zero, one, or two arguments of type int. It can be called in any of these ways:

      point(1,2); point(1); point();

The last two calls are equivalent to point(1,4) and point(3,4), respectively. — end example]

A default argument shall be specified only in the parameter-declaration-clause of a function declaration or lambda-declarator or in a template-parameter (12.1); in the latter case, the initializer-clause shall be an assignment-expression. A default argument shall not be specified for a template parameter pack or a function parameter pack. If it is specified in a parameter-declaration-clause, it shall not occur within a declarator or abstract-declarator of a parameter-declaration. 100

4 For non-template functions, default arguments can be added in later declarations of a function in the same scope. Declarations in different scopes have completely distinct sets of default arguments. That is, declarations in inner scopes do not acquire default arguments from declarations in outer scopes, and vice versa. In a given function declaration, each parameter subsequent to a parameter with a default argument shall have a default argument supplied in this or a previous declaration, unless the parameter was expanded from a parameter pack, or shall be a function parameter pack. A default argument shall not be redefined by a later declaration (not even to the same value). [Example:

      void g(int = 0, ...); // OK, ellipsis is not a parameter so it can follow
      // a parameter with a default argument

      void f(int, int);
      void f(int, int = 7);
      void h() {
          f(3);
          void f(int = 1, int); // error: does not use default from surrounding scope
      }
      void m() {
          void f(int, int); // has no defaults
          f(4); // error: wrong number of arguments
          void f(int, int = 5); // OK
          f(4); // OK, calls f(4, 5);
          void f(int, int = 5); // error: cannot redefine, even to same value
      }
      void n() {
          f(6); // OK, calls f(6, 7)
      }

99) One can explicitly disambiguate the parse either by introducing a comma (so the ellipsis will be parsed as part of the parameter-declaration-clause) or by introducing a name for the parameter (so the ellipsis will be parsed as part of the declarator-id).

100) This means that default arguments cannot appear, for example, in declarations of pointers to functions, references to functions, or typedef declarations.
template<class ... T> struct C {
    void f(int n = 0, T...);
};
C<int> c; // OK, instantiates declaration void C::f(int n = 0, int)

For a given inline function defined in different translation units, the accumulated sets of
default arguments at the end of the translation units shall be the same; see 6.2. If a friend declaration
specifies a default argument expression, that declaration shall be a definition and shall be the only declaration
of the function or function template in the translation unit.

The default argument has the same semantic constraints as the initializer in a declaration of a variable of the
parameter type, using the copy-initialization semantics (9.3). The names in the default argument are bound,
and the semantic constraints are checked, at the point where the default argument appears. Name lookup
and checking of semantic constraints for default arguments in function templates and in member functions of
class templates are performed as described in 12.8.1. [Example: In the following code, g will be called with
the value f(2):

```c++
int a = 1;
int f(int);
int g(int x = f(a)); // default argument: f(::a)
```

void h() {
    a = 2;
    { int a = 3;
    g(); // g(f(::a))
    }
}

—end example] [Note: In member function declarations, names in default arguments are looked up as
described in 6.4.1. Access checking applies to names in default arguments as described in 10.8. —end note]

Except for member functions of class templates, the default arguments in a member function definition that
appears outside of the class definition are added to the set of default arguments provided by the member
function declaration in the class definition; the program is ill-formed if a default constructor (10.3.4), copy or
move constructor (10.3.5), or copy or move assignment operator (10.3.6) is so declared. Default arguments
for a member function of a class template shall be specified on the initial declaration of the member function
within the class template. [Example:

```c++
class C {
    void f(int i = 3);
    void g(int i, int j = 99);
};
void C::f(int i = 3) {}
void C::g(int i = 88, int j) {} // in this translation unit, C::g can be called with no argument

—end example]
```

[Note: A local variable cannot be odr-used (6.2) in a default argument. —end note] [Example:

```c++
void f() {
    int i;
    extern void g(int x = i); // error
    extern void h(int x = sizeof(i)); // OK
    // ...
}

—end example]
```

[Note: The keyword this may not appear in a default argument of a member function; see 7.5.2. [Example:

```c++
class A {
    void f(A* p = this) { }

—end example] —end note]
```

A default argument is evaluated each time the function is called with no argument for the corresponding
parameter. A parameter shall not appear as a potentially-evaluated expression in a default argument.

§ 9.2.3.6
Parameters of a function declared before a default argument are in scope and can hide namespace and class member names. [Example:

```c
int a;
int f(int a, int b = a); // error: parameter a used as default argument
typedef int I;
int g(float I, int b = I(2)); // error: parameter I found
int h(int a, int b = sizeof(a)); // OK, unevaluated operand
```
—end example] A non-static member shall not appear in a default argument unless it appears as the id-expression of a class member access expression (7.6.1.5) or unless it is used to form a pointer to member (7.6.2.1). [Example: The declaration of `X::mem1()` in the following example is ill-formed because no object is supplied for the non-static member `X::a` used as an initializer.

```c
int b;
class X {
  int a;
  int mem1(int i = a); // error: non-static member a used as default argument
  int mem2(int i = b); // OK; use X::b
  static int b;
};
```

The declaration of `X::mem2()` is meaningful, however, since no object is needed to access the static member `X::b`. Classes, objects, and members are described in Clause 10. —end example] A default argument is not part of the type of a function. [Example:

```c
int f(int = 0);
void h() {
  int j = f(1);
  int k = f(); // OK, means f(0)
}
int (*p1)(int) = &f;
int (*p2)() = &f; // error: type mismatch
```
—end example] When a declaration of a function is introduced by way of a using-declaration (9.8), any default argument information associated with the declaration is made known as well. If the function is redeclared thereafter in the namespace with additional default arguments, the additional arguments are also known at any point following the redeclaration where the using-declaration is in scope.

A virtual function call (10.6.2) uses the default arguments in the declaration of the virtual function determined by the static type of the pointer or reference denoting the object. An overriding function in a derived class does not acquire default arguments from the function it overrides. [Example:

```c
struct A {
  virtual void f(int a = 7);
};
struct B : public A {
  void f(int a);
};
void m() {
  B* pb = new B;
  A* pa = pb;
  pa->f(); // OK, calls pa->B::f(7)
  pb->f(); // error: wrong number of arguments for B::f()
}
```
—end example]

9.3 Initializers

[decl.init]

1 The process of initialization described in this subclause applies to all initializations regardless of syntactic context, including the initialization of a function parameter (7.6.1.2), the initialization of a return value (8.6.3), or when an initializer follows a declarator.

```
initializer:
  brace-or-equal-initializer
  (expression-list)
```

§ 9.3 173
brace-or-equal-initializer:
  = initializer-clause
braced-init-list

initializer-clause:
  assignment-expression
braced-init-list

braced-init-list:
  { initializer-list ,opt }
  { designated-initializer-list ,opt }
  
initializer-list:
  initializer-clause ...opt
  initializer-list , initializer-clause ...opt
designated-initializer-list:
  designated-initializer-clause
designated-initializer-list , designated-initializer-clause
designated-initializer-clause:
  designator brace-or-equal-initializer
designator:
  . identifier
expr-or-braced-init-list:
  expression
braced-init-list

[Note: The rules in this subclause apply even if the grammar permits only the brace-or-equal-initializer form of initializer in a given context. —end note]

2 Except for objects declared with the constexpr specifier, for which see 9.1.5, an initializer in the definition of a variable can consist of arbitrary expressions involving literals and previously declared variables and functions, regardless of the variable’s storage duration. [Example:

    int f(int);
    int a = 2;
    int b = f(a);
    int c(b);
  —end example]

3 [Note: Default arguments are more restricted; see 9.2.3.6. —end note]

4 [Note: The order of initialization of variables with static storage duration is described in 6.8.3 and 8.7. —end note]

5 A declaration of a block-scope variable with external or internal linkage that has an initializer is ill-formed.

6 To zero-initialize an object or reference of type T means:

(6.1) — if T is a scalar type (6.7), the object is initialized to the value obtained by converting the integer literal 0 (zero) to T;\(^\text{101}\)

(6.2) — if T is a (possibly cv-qualified) non-union class type, its padding bits (6.7) are initialized to zero bits and each non-static data member, each non-virtual base class subobject, and, if the object is not a base class subobject, each virtual base class subobject is zero-initialized;

(6.3) — if T is a (possibly cv-qualified) union type, its padding bits (6.7) are initialized to zero bits and the object’s first non-static named data member is zero-initialized;

(6.4) — if T is an array type, each element is zero-initialized;

(6.5) — if T is a reference type, no initialization is performed.

7 To default-initialize an object of type T means:

(7.1) — If T is a (possibly cv-qualified) class type (Clause 10), constructors are considered. The applicable constructors are enumerated (11.3.1.3), and the best one for the initializer () is chosen through overload

\(^{101}\) As specified in 7.3.11, converting an integer literal whose value is 0 to a pointer type results in a null pointer value.
resolution (11.3). The constructor thus selected is called, with an empty argument list, to initialize the object.

(7.2) — If \( T \) is an array type, each element is default-initialized.

(7.3) — Otherwise, no initialization is performed.

A class type \( T \) is **const-default-constructible** if default-initialization of \( T \) would invoke a user-provided constructor of \( T \) (not inherited from a base class) or if

(7.4) — each direct non-variant non-static data member \( M \) of \( T \) has a default member initializer or, if \( M \) is of class type \( X \) (or array thereof), \( X \) is const-default-constructible,

(7.5) — if \( T \) is a union with at least one non-static data member, exactly one variant member has a default member initializer,

(7.6) — if \( T \) is not a union, for each anonymous union member with at least one non-static data member (if any), exactly one non-static data member has a default member initializer, and

(7.7) — each potentially constructed base class of \( T \) is const-default-constructible.

If a program calls for the default-initialization of an object of a const-qualified type \( T \), \( T \) shall be a const-default-constructible class type or array thereof.

8 **To value-initialize** an object of type \( T \) means:

(8.1) — if \( T \) is a (possibly cv-qualified) class type (Clause 10) with either no default constructor (10.3.4) or a default constructor that is user-provided or deleted, then the object is default-initialized;

(8.2) — if \( T \) is a (possibly cv-qualified) class type without a user-provided or deleted default constructor, then the object is zero-initialized and the semantic constraints for default-initialization are checked, and if \( T \) has a non-trivial default constructor, the object is default-initialized;

(8.3) — if \( T \) is an array type, then each element is value-initialized;

(8.4) — otherwise, the object is zero-initialized.

9 A program that calls for default-initialization or value-initialization of an entity of reference type is ill-formed.

10 [Note: Every object of static storage duration is zero-initialized at program startup before any other initialization takes place. In some cases, additional initialization is done later. — end note]

11 An object whose initializer is an empty set of parentheses, i.e., \( () \), shall be value-initialized.

[Note: Since \( () \) is not permitted by the syntax for \textit{initializer},

\[ X \ a(); \]

is not the declaration of an object of class \( X \), but the declaration of a function taking no argument and returning an \( X \). The form \( () \) is permitted in certain other initialization contexts (7.6.2.4, 7.6.1.3, 10.9.2). — end note]

12 If no initializer is specified for an object, the object is default-initialized. When storage for an object with automatic or dynamic storage duration is obtained, the object has an indeterminate value, and if no initialization is performed for the object, that object retains an indeterminate value until that value is replaced (7.6.18). [Note: Objects with static or thread storage duration are zero-initialized, see 6.8.3.2. — end note] If an indeterminate value is produced by an evaluation, the behavior is undefined except in the following cases:

(12.1) — If an indeterminate value of unsigned narrow character type (6.7.1) or \texttt{std::byte} type (16.2.1) is produced by the evaluation of:

(12.1.1) — the second or third operand of a conditional expression (7.6.16),

(12.1.2) — the right operand of a comma expression (7.6.19),

(12.1.3) — the operand of a cast or conversion (7.3.8, 7.6.1.3, 7.6.1.9, 7.6.3) to an unsigned narrow character type or \texttt{std::byte} type (16.2.1), or

(12.1.4) — a discarded-value expression (7.2),

then the result of the operation is an indeterminate value.

(12.2) — If an indeterminate value of unsigned narrow character type or \texttt{std::byte} type is produced by the evaluation of the right operand of a simple assignment operator (7.6.18) whose first operand is an value
of unsigned narrow character type or `std::byte` type, an indeterminate value replaces the value of the object referred to by the left operand.

12.3 — If an indeterminate value of unsigned narrow character type is produced by the evaluation of the initialization expression when initializing an object of unsigned narrow character type, that object is initialized to an indeterminate value.

12.4 — If an indeterminate value of unsigned narrow character type or `std::byte` type is produced by the evaluation of the initialization expression when initializing an object of `std::byte` type, that object is initialized to an indeterminate value.

[Example:
```
int f(bool b) {
    unsigned char c;
    unsigned char d = c;  // OK, d has an indeterminate value
    int e = d;           // undefined behavior
    return b ? d : 0;    // undefined behavior if b is true
}
```
— end example]

13 An initializer for a static member is in the scope of the member’s class. [Example:
```
int a;

struct X {
    static int a;
    static int b;
};

int X::a = 1;
int X::b = a;  // X::b = X::a
```
— end example]

14 If the entity being initialized does not have class type, the `expression-list` in a parenthesized initializer shall be a single expression.

15 The initialization that occurs in the `=` form of a brace-or-equal-initializer or condition (8.4), as well as in argument passing, function return, throwing an exception (13.1), handling an exception (13.3), and aggregate member initialization (9.3.1), is called copy-initialization. [Note: Copy-initialization may invoke a move (10.3.5). — end note]

16 The initialization that occurs

16.1 — for an initializer that is a parenthesized `expression-list` or a `braced-init-list`,
16.2 — for a new-initializer (7.6.2.4),
16.3 — in a static_cast expression (7.6.1.9),
16.4 — in a functional notation type conversion (7.6.1.3), and
16.5 — in the `braced-init-list` form of a condition

is called direct-initialization.

17 The semantics of initializers are as follows. The destination type is the type of the object or reference being initialized and the source type is the type of the initializer expression. If the initializer is not a single (possibly parenthesized) expression, the source type is not defined.

17.1 — If the initializer is a (non-parenthesized) `braced-init-list` or is `= braced-init-list`, the object or reference is list-initialized (9.3.4).
17.2 — If the destination type is a reference type, see 9.3.3.
17.3 — If the destination type is an array of characters, an array of char16_t, an array of char32_t, or an array of wchar_t, and the initializer is a string literal, see 9.3.2.
17.4 — If the initializer is `0`, the object is value-initialized.
17.5 — Otherwise, if the destination type is an array, the program is ill-formed.
17.6 — If the destination type is a (possibly cv-qualified) class type:

§ 9.3
— If the initializer expression is a prvalue and the cv-unqualified version of the source type is the same class as the class of the destination, the initializer expression is used to initialize the destination object. [*Example: T x = T(T(T()));* calls the T default constructor to initialize x. — end example]

— Otherwise, if the initialization is direct-initialization, or if it is copy-initialization where the cv-unqualified version of the source type is the same class as, or a derived class of, the class of the destination, constructors are considered. The applicable constructors are enumerated (11.3.1.3), and the best one is chosen through overload resolution (11.3). The constructor so selected is called to initialize the object, with the initializer expression or *expression-list* as its argument(s). If no constructor applies, or the overload resolution is ambiguous, the initialization is ill-formed.

— Otherwise (i.e., for the remaining copy-initialization cases), user-defined conversion sequences that can convert from the source type to the destination type or (when a conversion function is used) to a derived class thereof are enumerated as described in 11.3.1.4, and the best one is chosen through overload resolution (11.3). If the conversion cannot be done or is ambiguous, the initialization is ill-formed. The function selected is called with the initializer expression as its argument; if the function is a constructor, the call is a prvalue of the cv-unqualified version of the destination type whose result object is initialized by the constructor. The call is used to direct-initialize, according to the rules above, the object that is the destination of the copy-initialization.

— Otherwise, if the source type is a (possibly cv-qualified) class type, conversion functions are considered. The applicable conversion functions are enumerated (11.3.1.5), and the best one is chosen through overload resolution (11.3). The user-defined conversion so selected is called to convert the initializer expression into the object being initialized. If the conversion cannot be done or is ambiguous, the initialization is ill-formed.

— Otherwise, the initial value of the object being initialized is the (possibly converted) value of the initializer expression. Standard conversions (7.3) will be used, if necessary, to convert the initializer expression to the cv-unqualified version of the destination type; no user-defined conversions are considered. If the conversion cannot be done, the initialization is ill-formed. When initializing a bit-field with a value that it cannot represent, the resulting value of the bit-field is implementation-defined. [*Note: An expression of type “cv1 T” can initialize an object of type “cv2 T” independently of the cv-qualifiers cv1 and cv2.*]

An *initializer-clause* followed by an ellipsis is a pack expansion (12.6.3).

If the initializer is a parenthesized *expression-list*, the expressions are evaluated in the order specified for function calls (7.6.1.2).

The same *identifier* shall not appear in multiple *designators* of a *designated-initializer-list*.

An object whose initialization has completed is deemed to be constructed, even if no constructor of the object’s class is invoked for the initialization. [*Note: Such an object might have been value-initialized or initialized by aggregate initialization (9.3.1) or by an inherited constructor (10.9.3). — end note*]

A declaration that specifies the initialization of a variable, whether from an explicit initializer or by default-initialization, is called the *initializing declaration* of that variable. [*Note: In most cases this is the defining declaration (6.1) of the variable, but the initializing declaration of a non-inline static data member (10.3.9.2) might be the declaration within the class definition and not the definition at namespace scope. — end note*]

### 9.3.1 Aggregates

An *aggregate* is an array or a class (Clause 10) with

1. **no user-declared or inherited constructors** (10.3.4),
2. **no private or protected non-static data members** (10.8),
3. **no virtual functions** (10.6.2), and
4. **no virtual, private, or protected base classes** (10.6.1).

[Note: Aggregate initialization does not allow accessing protected and private base class’ members or constructors. — end note]
The elements of an aggregate are:

(2.1) — for an array, the array elements in increasing subscript order, or
(2.2) — for a class, the direct base classes in declaration order, followed by the direct non-static data members (10.3) that are not members of an anonymous union, in declaration order.

When an aggregate is initialized by an initializer list as specified in 9.3.4, the elements of the initializer list are taken as initializers for the elements of the aggregate. The explicitly initialized elements of the aggregate are determined as follows:

(3.1) — If the initializer list is a designated-initializer-list, the aggregate shall be of class type, the identifier in each designator shall name a direct non-static data member of the class, and the explicitly initialized elements of the aggregate are the elements that are, or contain, those members.
(3.2) — If the initializer list is an initializer-list, the explicitly initialized elements of the aggregate are the first elements of the aggregate, where is the number of elements in the initializer list.
(3.3) — Otherwise, the initializer list must be {}, and there are no explicitly initialized elements.

For each explicitly initialized element:

(4.1) — If the element is an anonymous union object and the initializer list is a designated-initializer-list, the anonymous union object is initialized by the designated-initializer-list \{ D \}, where D is the designated-initializer-clause naming a member of the anonymous union object. There shall be only one such designated-initializer-clause.
(4.2) — Otherwise, the element is copy-initialized from the corresponding initializer-clause or is initialized with the brace-or-equal-initializer of the corresponding designated-initializer-clause. If that initializer is of the form assignment-expression or = assignment-expression and a narrowing conversion (9.3.4) is required to convert the expression, the program is ill-formed. [Note: If an initializer is itself an initializer list, the element is list-initialized, which will result in a recursive application of the rules in this subclause if the element is an aggregate. — end note]

[Example:

```c
struct A {
    int x;
    struct B {
        int i;
        int j;
    } b;
} a = { 1, { 2, 3 } };
```
initializes a.x with 1, a.b.i with 2, a.b.j with 3.

```c
struct base1 { int b1, b2 = 42; };
struct base2 {
    base2() {
        b3 = 42;
    }
    int b3;
};
struct derived : base1, base2 {
    int d;
};
```

derived d1{{1}, {}, 4};
derived d2{{}, {}, 4};
ishializes d1.b1 with 1, d1.b2 with 2, d1.b3 with 42, d1.d with 4, and d2.b1 with 0, d2.b2 with 42, d2.b3 with 42, d2.d with 4. — end example]

For a non-union aggregate, each element that is not an explicitly initialized element is initialized as follows:

(5.1) — If the element has a default member initializer (10.3), the element is initialized from that initializer.
(5.2) — Otherwise, if the element is not a reference, the element is copy-initialized from an empty initializer list (9.3.4).
(5.3) — Otherwise, the program is ill-formed.
If the aggregate is a union and the initializer list is empty, then

(5.4) — if any variant member has a default member initializer, that member is initialized from its default
member initializer;
(5.5) — otherwise, the first member of the union (if any) is copy-initialized from an empty initializer list.

[Example:

```c
struct S { int a; const char* b; int c; int d = b[a]; };
S ss = { 1, "asdf" };
```
initializes `ss.a` with 1, `ss.b` with "asdf", `ss.c` with the value of an expression of the form `int{}` (that is, 0), and `ss.d` with the value of `ss.b[ss.a]` (that is, 's'), and in

```c
struct X { int i, j, k = 42; };
X a[] = { 1, 2, 3, 4, 5, 6 };
X b[2] = { { 1, 2, 3 }, { 4, 5, 6 } };
```
a and b have the same value

```c
struct A {
    string a;
    int b = 42;
    int c = -1;
};
A{.c=21} has the following steps:

(5.6) — Initialize a with {}
(5.7) — Initialize b with = 42
(5.8) — Initialize c with = 21
 — end example]
```

6 The initializations of the elements of the aggregate are evaluated in the element order. That is, all value
computations and side effects associated with a given element are sequenced before those of any element that
follows it in order.

7 An aggregate that is a class can also be initialized with a single expression not enclosed in braces, as described
in 9.3.

8 The destructor for each element of class type is potentially invoked (10.3.7) from the context where the
aggregate initialization occurs. [Note: This provision ensures that destructors can be called for fully-
constructed subobjects in case an exception is thrown (13.2). — end note]

9 An array of unknown bound initialized with a brace-enclosed `initializer-list` containing `n` `initializer-clauses`,
where `n` shall be greater than zero, is defined as having `n` elements (9.2.3.4). [Example:

```c
int x[] = { 1, 3, 5 };
```
declares and initializes `x` as a one-dimensional array that has three elements since no size was specified
and there are three initializers. — end example] An empty initializer list `{}` shall not be used as the
`initializer-clause` for an array of unknown bound.102 [Note: A default member initializer does not determine
the bound for a member array of unknown bound. Since the default member initializer is ignored if a suitable
`mem-initializer` is present (10.9.2), the default member initializer is not considered to initialize the array of
unknown bound. [Example:

```c
struct S {
    int y[] = { 0 }; // error: non-static data member of incomplete type
};
```
— end example] — end note]

10 [Note: Static data members, non-static data members of anonymous union members, and unnamed bit-fields
are not considered elements of the aggregate. [Example:

```c
struct A {
    int i;
    static int s;
    int j;
```

102) The syntax provides for empty `initializer-lists`, but nonetheless C++ does not have zero length arrays.
int :17;
int k;
} a = { 1, 2, 3 };

Here, the second initializer 2 initializes \( a.j \) and not the static data member \( A::a \), and the third initializer 3 initializes \( a.k \) and not the unnamed bit-field before it. —end example —end note

An initializer-list is ill-formed if the number of initializer-clauses exceeds the number of elements of the aggregate. [Example:

```plaintext
char cv[4] = { 'a', 's', 'd', 'f', 0 }; // error
```

is ill-formed. —end example]

If a reference member is initialized from its default member initializer and a potentially-evaluated subexpression thereof is an aggregate initialization that would use that default member initializer, the program is ill-formed. [Example:

```plaintext
struct A;
extern A a;
struct A {
    const A& a1 { A(a, a) };  // OK
    const A& a2 { A() };     // error
};
a a(a, a);               // OK
```

—end example]

If an aggregate class \( C \) contains a subaggregate element \( e \) with no elements, the initializer-clause for \( e \) shall not be omitted from an initializer-list for an object of type \( C \) unless the initializer-clauses for all elements of \( C \) following \( e \) are also omitted. [Example:

```plaintext
struct S { } s;
struct A {
    S s1;
    int i1;
    S s2;
    int i2;
    S s3;
    int i3;
} a = {
    { },                         // Required initialization
    0,
    s,                               // Required initialization
    0
};                               // Initialization not required for A::s3 because A::i3 is also not initialized
```

—end example]

When initializing a multi-dimensional array, the initializer-clauses initialize the elements with the last (rightmost) index of the array varying the fastest (9.2.3.4). [Example:

```plaintext
int x[2][2] = { 3, 1, 4, 2 };
```

initializes \( x[0][0] \) to 3, \( x[0][1] \) to 1, \( x[1][0] \) to 4, and \( x[1][1] \) to 2. On the other hand,

```plaintext
float y[4][3] = {
    { 1 },
    { 2 },
    { 3 },
    { 4 }
};
```

initializes the first column of \( y \) (regarded as a two-dimensional array) and leaves the rest zero. —end example]

Braces can be elided in an initializer-list as follows. If the initializer-list begins with a left brace, then the succeeding comma-separated list of initializer-clauses initializes the elements of a subaggregate; it is erroneous for there to be more initializer-clauses than elements. If, however, the initializer-list for a subaggregate does not begin with a left brace, then only enough initializer-clauses from the list are taken to initialize the elements of the subaggregate; any remaining initializer-clauses are left to initialize the next element of the aggregate of which the current subaggregate is an element. [Example:

```plaintext
float y[4][3] = {
    { 1, 3, 5 }
};
```
is a completely-braced initialization: 1, 3, and 5 initialize the first row of the array \( y[0] \), namely \( y[0][0] \), \( y[0][1] \), and \( y[0][2] \). Likewise the next two lines initialize \( y[1] \) and \( y[2] \). The initializer ends early and therefore \( y[3] \)‘s elements are initialized as if explicitly initialized with an expression of the form float(), that is, are initialized with 0.0. In the following example, braces in the initializer-list are elided; however the initializer-list has the same effect as the completely-braced initializer-list of the above example,

```c
float \( y[4][3] = \{
    1, 3, 5, 2, 4, 6, 3, 5, 7
\};
```

The initializer for \( y \) begins with a left brace, but the one for \( y[0] \) does not, therefore three elements from the list are used. Likewise the next three are taken successively for \( y[1] \) and \( y[2] \). —end example]

All implicit type conversions (7.3) are considered when initializing the element with an assignment-expression. If the assignment-expression can initialize an element, the element is initialized. Otherwise, if the element is itself a subaggregate, brace elision is assumed and the assignment-expression is considered for the initialization of the first element of the subaggregate. [Note: As specified above, brace elision cannot apply to subaggregates with no elements; an initializer-clause for the entire subobject is required. —end note]

[Example:
```
struct A {
    int i;
    operator int();
};
struct B {
    A a1, a2;
    int z;
};
A a;
B b = { 4, a, a };
```

Braces are elided around the initializer-clause for \( b.a1.i \). \( b.a1.i \) is initialized with 4, \( b.a2 \) is initialized with \( a \), \( b.z \) is initialized with whatever \( a.operator \text{int}() \) returns. —end example]

[Note: An aggregate array or an aggregate class may contain elements of a class type with a user-declared constructor (10.3.4). Initialization of these aggregate objects is described in 10.9.1. —end note]

[Note: Whether the initialization of aggregates with static storage duration is static or dynamic is specified in 6.8.3.2, 6.8.3.3, and 8.7. —end note]

When a union is initialized with an initializer list, there shall not be more than one explicitly initialized element. [Example:
```
union u { int a; const char* b; }
    u a = { 1 };
    u b = a;
    u c = 1;  // error
    u d = { 0, "asdf" };  // error
    u e = { "asdf" };  // error
    u f = { .b = "asdf" };  // error
    u g = { .a = 1, .b = "asdf" };  // error
```

—end example]

[Note: As described above, the braces around the initializer-clause for a union member can be omitted if the union is a member of another aggregate. —end note]

### 9.3.2 Character arrays

An array of narrow character type (6.7.1), char16_t array, char32_t array, or wchar_t array can be initialized by a narrow string literal, char16_t string literal, char32_t string literal, or wide string literal, respectively, or by an appropriately-typed string literal enclosed in braces (5.13.5). Successive characters of the value of the string literal initialize the elements of the array. [Example:

```
    char \text{msg[]} = "Syntax error on line %s\n";
```

§ 9.3.2 181
shows a character array whose members are initialized with a string-literal. Note that because ‘\n’ is a single character and because a trailing ‘\0’ is appended, sizeof(msg) is 25. —end example

There shall not be more initializers than there are array elements. [Example:

```c
char cv[4] = "asdf";  // error
```

is ill-formed since there is no space for the implied trailing ‘\0’. —end example]

If there are fewer initializers than there are array elements, each element not explicitly initialized shall be zero-initialized (9.3).

9.3.3 References
[decl.init.ref]

A variable whose declared type is “reference to type T” (9.2.3.2) shall be initialized. [Example:

```c
int g(int) noexcept;
void f() {
    int i;
    int& r = i;  // r refers to i
    r = 1;  // the value of i becomes 1
    int* p = &r;  // p points to i
    int& rr = r;  // rr refers to what r refers to, that is, to i
    int (freg)(int) = g;  // freg refers to the function g
    rg(i);  // calls function g
    int a[3];
    int (*ra)[3] = a;  // ra refers to the array a
    ra[1] = i;  // modifies a[1]
}
—end example]

A reference cannot be changed to refer to another object after initialization. [Note: Assignment to a reference assigns to the object referred to by the reference (7.6.18). —end note] Argument passing (7.6.1.2) and function value return (8.6.3) are initializations.

The initializer can be omitted for a reference only in a parameter declaration (9.2.3.5), in the declaration of a function return type, in the declaration of a class member within its class definition (10.3), and where the extern specifier is explicitly used. [Example:

```c
int& r1;
extern int& r2;  // error: initializer missing
// OK
—end example]

Given types “cv1 T1” and “cv2 T2”, “cv1 T1” is reference-related to “cv2 T2” if T1 is the same type as T2, or T1 is a base class of T2. “cv1 T1” is reference-compatible with “cv2 T2” if

(4.1) — T1 is reference-related to T2, or
(4.2) — T2 is “noexcept” function and T1 is “function”, where the function types are otherwise the same, and cv1 is the same cv-qualification as, or greater cv-qualification than, cv2. In all cases where the reference-related or reference-compatible relationship of two types is used to establish the validity of a reference binding, and T1 is a base class of T2, a program that necessitates such a binding is ill-formed if T1 is an inaccessible (10.8) or ambiguous (10.7) base class of T2.

A reference to type “cv1 T1” is initialized by an expression of type “cv2 T2” as follows:

(5.1) — If the reference is an lvalue reference and the initializer expression
(5.1.1) — is an lvalue (but is not a bit-field), and “cv1 T1” is reference-compatible with “cv2 T2”, or
(5.1.2) — has a class type (i.e., T2 is a class type), where T1 is not reference-related to T2, and can be converted to an lvalue of type “cv3 T3”, where “cv1 T1” is reference-compatible with “cv3 T3”, this conversion is selected by enumerating the applicable conversion functions (11.3.1.6) and choosing the best one through overload resolution (11.3), then the reference is bound to the initializer expression lvalue in the first case and to the lvalue result of the conversion in the second case (or, in either case, to the appropriate base class subobject of the object). [Note: The usual lvalue-to-rvalue (7.3.1), array-to-pointer (7.3.2), and function-to-pointer (7.3.3)

103) This requires a conversion function (10.3.8.2) returning a reference type.
standard conversions are not needed, and therefore are suppressed, when such direct bindings to lvalues are done. — end note]

[Example:

```cpp
double d = 2.0;
double& rd = d; // rd refers to d
const double& rcd = d; // rcd refers to d

struct A { }; struct B : A { operator int&() } b;
A& ra = b; // ra refers to A subobject in b
const A& rca = b; // rca refers to A subobject in b
int& ir = B(); // ir refers to the result of B::operator int&
```

— end example]

(5.2) — Otherwise, if the reference is an lvalue reference to a type that is not const-qualified or is volatile-qualified, the program is ill-formed. [Example:

```cpp
double& rd2 = 2.0; // error: not an lvalue and reference not const
int i = 2;
double& rd3 = i; // error: type mismatch and reference not const
```

— end example]

(5.3) — Otherwise, if the initializer expression

(5.3.1) — is an rvalue (but not a bit-field) or function lvalue and "cv1 T1" is reference-compatible with "cv2 T2", or

(5.3.2) — has a class type (i.e., T2 is a class type), where T1 is not reference-related to T2, and can be converted to an rvalue or function value of type "cv3 T3", where "cv1 T1" is reference-compatible with "cv3 T3" (see 11.3.1.6),

then the value of the initializer expression in the first case and the result of the conversion in the second case is called the converted initializer. If the converted initializer is a prvalue, its type T4 is adjusted to type "cv1 T4" (7.3.5) and the temporary materialization conversion (7.3.4) is applied. In any case, the reference is bound to the resulting glvalue (or to an appropriate base class subobject).

[Example:

```cpp
struct A { }; struct B : A { } b; extern B f();
const A& rca2 = f(); // bound to the A subobject of the B rvalue.
A& rra = f(); // same as above
struct X {
    operator B();
    operator int&();
} x;
const A& r = x; // bound to the A subobject of the result of the conversion
int i2 = 42;
int& rri = static_cast<int&>(i2); // bound directly to i2
B& rrb = x; // bound directly to the result of operator B
```

— end example]

(5.4) — Otherwise:

(5.4.1) — If T1 or T2 is a class type and T1 is not reference-related to T2, user-defined conversions are considered using the rules for copy-initialization of an object of type "cv1 T1" by user-defined conversion (9.3, 11.3.1.4, 11.3.1.5); the program is ill-formed if the corresponding non-reference copy-initialization would be ill-formed. The result of the call to the conversion function, as described for the non-reference copy-initialization, is then used to direct-initialize the reference. For this direct-initialization, user-defined conversions are not considered.

(5.4.2) — Otherwise, the initializer expression is implicitly converted to a prvalue of type "cv1 T1". The temporary materialization conversion is applied and the reference is bound to the result.

If T1 is reference-related to T2:

§ 9.3.3
— cv1 shall be the same cv-qualification as, or greater cv-qualification than, cv2; and
— if the reference is an rvalue reference, the initializer expression shall not be an lvalue.

[Example:
```
struct Banana { }
struct Enigma { operator const Banana(); }
struct Alaska { operator Banana&(); }
void enigmatic() {
  typedef const Banana ConstBanana;
  Banana &&banana1 = ConstBanana(); // ill-formed
  Banana &&banana2 = Enigma(); // ill-formed
  Banana &&banana3 = Alaska(); // ill-formed
}

const double& rcd2 = 2; // rcd2 refers to temporary with value 2.0
double&& rrd = 2; // rrd refers to temporary with value 2.0
const volatile int cvi = 1;
const int r2 = cvi; // error: cv-qualification dropped
struct A { operator volatile int&(); } a;
const int r3 = a; // error: cv-qualification dropped
  // from result of conversion function
double d2 = 1.0;
double&& rrd2 = d2; // error: initializer is lvalue of related type
struct X { operator int&(); };
  int&& rri2 = X(); // error: result of conversion function is lvalue of related type
int i3 = 2;
double&& rrd3 = i3; // rrd3 refers to temporary with value 2.0
  // end example]
```

In all cases except the last (i.e., implicitly converting the initializer expression to the referenced type), the reference is said to bind directly to the initializer expression.

6 [Note: 6.6.6 describes the lifetime of temporaries bound to references. — end note]

9.3.4 List-initialization [dcl.init.list]

List-initialization is initialization of an object or reference from a braced-init-list. Such an initializer is called an initializer list, and the comma-separated initializer-clauses of the initializer-list or designated-initializer-clauses of the designated-initializer-list are called the elements of the initializer list. An initializer list may be empty. List-initialization can occur in direct-initialization or copy-initialization contexts; list-initialization in a direct-initialization context is called direct-list-initialization and list-initialization in a copy-initialization context is called copy-list-initialization. [Note: List-initialization can be used

(1.1) — as the initializer in a variable definition (9.3)
(1.2) — as the initializer in a new-expression (7.6.2.4)
(1.3) — in a return statement (8.6.3)
(1.4) — as a for-range-initializer (8.5)
(1.5) — as a function argument (7.6.1.2)
(1.6) — as a subscript (7.6.1.1)
(1.7) — as an argument to a constructor invocation (9.3, 7.6.1.3)
(1.8) — as an initializer for a non-static data member (10.3)
(1.9) — in a mem-initializer (10.9.2)
(1.10) — on the right-hand side of an assignment (7.6.18)

[Example:
```
int a = {1};
std::complex<double> z({1,2});
new std::vector<std::string> { "once", "upon", "a", "time" }; // 4 string elements
f({ "Nicholas", "Annemarie" }); // pass list of two elements
return { "Norah" }; // return list of one element
```

§ 9.3.4 184
A constructor is an **initializer-list constructor** if its first parameter is of type `std::initializer_list<E>` or reference to possibly cv-qualified `std::initializer_list<E>` for some type `E`, and either there are no other parameters or else all other parameters have default arguments (9.2.3.6). [Note: Initializer-list constructors are favored over other constructors in list-initialization (11.3.1.7). Passing an initializer list as the argument to the constructor template `template<class T> C(T)` of a class `C` does not create an initializer-list constructor, because an initializer list argument causes the corresponding parameter to be a non-deduced context (12.9.2.1). —end note] The template `std::initializer_list` is not predefined; if the header `<initializer_list>` is not included prior to a use of `std::initializer_list` — even an implicit use in which the type is not named (9.1.7.4) — the program is ill-formed.

List-initialization of an object or reference of type `T` is defined as follows:

(3.1) — If the **braced-init-list** contains a **designated-initializer-list**, `T` shall be an aggregate class. The ordered identifiers in the **designators** of the **designated-initializer-list** shall form a subsequence of the ordered identifiers in the direct non-static data members of `T`. Aggregate initialization is performed (9.3.1). [Example:

```cpp
struct A { int x; int y; int z; };  
A a1 { .y = 2, .x = 1};  // error: designator order does not match declaration order  
A b1 { .x = 1, .z = 2};  // OK, b.y initialized to 0  
— end example]
```

(3.2) — If `T` is an aggregate class and the initializer list has a single element of type `cv U`, where `U` is `T` or a class derived from `T`, the object is initialized from that element (by copy-initialization for copy-list-initialization, or by direct-initialization for direct-list-initialization).

(3.3) — Otherwise, if `T` is a character array and the initializer list has a single element that is an appropriately-typed string literal (9.3.2), initialization is performed as described in that subclause.

(3.4) — Otherwise, if `T` is an aggregate, aggregate initialization is performed (9.3.1). [Example:

```cpp
double ad[] = { 1, 2.0 };  // OK  
int ai[] = { 1, 2.0 };  // error: narrowing

struct S2  
{  
    int m1;  
    double m2, m3;  
};  
S2 s21 = { 1, 2, 3.0 };  // OK  
S2 s22 { 1.0, 2, 3 };  // error: narrowing  
S2 s23 {};  // OK: default to 0,0,0  
— end example]
```

(3.5) — Otherwise, if the initializer list has no elements and `T` is a class type with a default constructor, the object is value-initialized.

(3.6) — Otherwise, if `T` is a specialization of `std::initializer_list<E>`, the object is constructed as described below.

(3.7) — Otherwise, if `T` is a class type, constructors are considered. The applicable constructors are enumerated and the best one is chosen through overload resolution (11.3, 11.3.1.7). If a narrowing conversion (see below) is required to convert any of the arguments, the program is ill-formed. [Example:

```cpp
struct S  
{  
    S(std::initializer_list<double>);  // #1  
    S(std::initializer_list<int>);  // #2  
    S();  // #3  
    // ...
};
```
S s1 = { 1.0, 2.0, 3.0 }; // invoke #1
S s2 = { 1, 2, 3 }; // invoke #2
S s3 = { }; // invoke #3
— end example

[Example:

```cpp
struct Map {
    Map(std::initializer_list<std::pair<std::string, int>>);  // #1
    Map(); // #2
};
Map ship = {"Sophie", 14}, {"Surprise", 28};
— end example
```

— end example

Example:

```cpp
struct S {
    // no initializer-list constructors
    S(int, double, double); // #1
    S(); // #2
    // ... );
    S s1 = { 1, 2, 3.0 }; // OK: invoke #1
    S s2 { 1.0, 2, 3 }; // error: narrowing
    S s3 { }; // OK: invoke #2

— end example
```

— (3.8) Otherwise, if \( T \) is an enumeration with a fixed underlying type (9.6), the initializer-list has a single element \( v \), and the initialization is direct-list-initialization, the object is initialized with the value \( T(v) \) (7.6.1.3); if a narrowing conversion is required to convert \( v \) to the underlying type of \( T \), the program is ill-formed. [Example:

```cpp
enum byte : unsigned char { }; byte b { 42 }; // OK
byte c = { 42 }; // error
byte d = byte( 42 ); // OK; same value as b
byte e { -1 }; // error
```

struct A { byte b; }; A a1 = { { 42 } }; // error
A a2 = { byte{ 42 } }; // OK
void f(byte); f({ 42 }); // error
enum class Handle : uint32_t { Invalid = 0 }; Handle h { 42 }; // OK
— end example

— (3.9) Otherwise, if the initializer list has a single element of type \( E \) and either \( T \) is not a reference type or its referenced type is reference-related to \( E \), the object or reference is initialized from that element (by copy-initialization for copy-list-initialization, or by direct-initialization for direct-list-initialization); if a narrowing conversion (see below) is required to convert \( v \) to the underlying type of \( T \), the program is ill-formed. [Example:

```cpp
int x1 {2}; // OK
int x2 {2.0}; // error: narrowing
— end example
```

— (3.10) Otherwise, if \( T \) is a reference type, a prvalue of the type referenced by \( T \) is generated. The prvalue initializes its result object by copy-list-initialization or direct-list-initialization, depending on the kind of initialization for the reference. The prvalue is then used to direct-initialize the reference. [Note: As usual, the binding will fail and the program is ill-formed if the reference type is an lvalue reference to a non-const type. — end note]

[Example:
struct S {
    S(std::initializer_list<double>); // #1
    S(const std::string&); // #2
    // ...
};
const S& r1 = { 1, 2, 3.0 }; // OK: invoke #1
const S& r2 { "Spinach" }; // OK: invoke #2
S& r3 = { 1, 2, 3 }; // error: initializer is not an lvalue
const int& i1 = { 1 }; // OK
const int& i2 = { 1.1 }; // error: narrowing
const int (&iar)[2] = { 1, 2 }; // OK: iar is bound to temporary array
@end example
(3.11) Otherwise, if the initializer list has no elements, the object is value-initialized.

[Example:
  int** pp {}; // initialized to null pointer
@end example]
(3.12) Otherwise, the program is ill-formed.

[Example:
  struct A { int i; int j; }
  A a1 { 1, 2 }; // aggregate initialization
  A a2 { 1.2 }; // error: narrowing
  struct B {
      B(std::initializer_list<int>);
  };
  B b1 { 1, 2 }; // creates std::initializer_list<int> and calls constructor
  B b2 { 1, 2.0 }; // error: narrowing
  struct C {
      C(int i, double j);
  };
  C c1 = { 1, 2.2 }; // calls constructor with arguments (1, 2.2)
  C c2 = { 1.1, 2 }; // error: narrowing
  int j { 1 }; // initialize to 1
  int k { }; // initialize to 0
@end example]

4 Within the initializer-list of a braced-init-list, the initializer-clauses, including any that result from pack expansions (12.6.3), are evaluated in the order in which they appear. That is, every value computation and side effect associated with a given initializer-clause is sequenced before every value computation and side effect associated with any initializer-clause that follows it in the comma-separated list of the initializer-list. [Note: This evaluation ordering holds regardless of the semantics of the initialization; for example, it applies when the elements of the initializer-list are interpreted as arguments of a constructor call, even though ordinarily there are no sequencing constraints on the arguments of a call. —end note]

5 An object of type std::initializer_list<E> is constructed from an initializer list as if the implementation generated and materialized (7.3.4) a prvalue of type “array of \(N\) const E", where \(N\) is the number of elements in the initializer list. Each element of that array is copy-initialized with the corresponding element of the initializer list, and the std::initializer_list<E> object is constructed to refer to that array. [Note: A constructor or conversion function selected for the copy shall be accessible (10.8) in the context of the initializer list. —end note] If a narrowing conversion is required to initialize any of the elements, the program is ill-formed. [Example:
  struct X {
      X(std::initializer_list<double> v);
  };
  X x{ 1, 2, 3 };
  The initialization will be implemented in a way roughly equivalent to this:
  const double __a[3] = {double{1}, double{2}, double{3}};
  X x(std::initializer_list<double>(__a, __a+3));
assuming that the implementation can construct an *initializer_list* object with a pair of pointers. — end example]

6 The array has the same lifetime as any other temporary object (6.6.6), except that initializing an *initializer_list* object from the array extends the lifetime of the array exactly like binding a reference to a temporary. [Example:

```c++
typedef std::complex<double> cmplx;
std::vector<cmplx> v1 = { 1, 2, 3 };

void f()
{
    std::vector<cmplx> v2{ 1, 2, 3 };  // does not work
    std::initializer_list<int> i3 = { 1, 2, 3 };  // does not work
}

struct A
{
    std::initializer_list<int> i4;
    A() : i4{ 1, 2, 3 } {}  // ill-formed, would create a dangling reference
};
```

For `v1` and `v2`, the *initializer_list* object is a parameter in a function call, so the array created for `{ 1, 2, 3 }` has full-expression lifetime. For `i3`, the *initializer_list* object is a variable, so the array persists for the lifetime of the variable. For `i4`, the *initializer_list* object is initialized in the constructor’s `ctor-initializer` as if by binding a temporary array to a reference member, so the program is ill-formed (10.9.2). — end example] [Note: The implementation is free to allocate the array in read-only memory if an explicit array with the same initializer could be so allocated. — end note]

7 A *narrowing conversion* is an implicit conversion

(7.1) — from a floating-point type to an integer type, or

(7.2) — from `long double` to `double` or `float`, or from `double` to `float`, except where the source is a constant expression and the actual value after conversion is within the range of values that can be represented (even if it cannot be represented exactly), or

(7.3) — from an integer type or unscoped enumeration type to a floating-point type, except where the source is a constant expression and the actual value after conversion will fit into the target type and will produce the original value when converted back to the original type, or

(7.4) — from an integer type or unscoped enumeration type to an integer type that cannot represent all the values of the original type, except where the source is a constant expression whose value after integral promotions will fit into the target type.

[Note: As indicated above, such conversions are not allowed at the top level in list-initializations. — end note] [Example:

```c++
int x = 999;  // x is not a constant expression
const int y = 999;
const int z = 99;
char c1 = x;  // OK, though it might narrow (in this case, it does narrow)
char c2(x);  // error: might narrow
char c3(y);  // error: narrows (assuming char is 8 bits)
char c4(z);  // OK: no narrowing needed
unsigned char uc1 = {5};  // OK: no narrowing needed
unsigned char uc2 = {-1};  // error: narrows
unsigned int ui1 = {-1};  // error: narrows
signed int si1 = { (unsigned int)-1 };  // error: narrows
int ii1 = {2.0};  // error: narrows
float f1 { x };  // error: might narrow
float f2 { 7 };  // OK: 7 be exactly represented as a float
int f(int);
int a[] = { 2, f(2), f(2.0) };  // OK: the double-to-int conversion is not at the top level
```

— end example]
9.4 Function definitions

9.4.1 In general

Function definitions have the form

```
function-definition:
  attribute-specifier-seq_opt decl-specifier-seq_opt declarator virt-specifier-seq_opt function-body
  attribute-specifier-seq_opt decl-specifier-seq_opt declarator requires-clause function-body

function-body:
  ctor-initializer_opt compound-statement
  function-try-block
  = default ;
  = delete ;
```

Any informal reference to the body of a function should be interpreted as a reference to the non-terminal function-body. The optional attribute-specifier-seq in a function-definition appertains to the function. A virt-specifier-seq can be part of a function-definition only if it is a member-declaration (10.3).

In a function-definition, either void declarator; or declarator; shall be a well-formed function declaration as described in 9.2.3.5. A function shall be defined only in namespace or class scope. The type of a parameter or the return type for a function definition shall not be an incomplete or abstract (possibly cv-qualified) class type in the context of the function definition unless the function is deleted (9.4.3).

[Example: A simple example of a complete function definition is]

```
int max(int a, int b, int c) {
  int m = (a > b) ? a : b;
  return (m > c) ? m : c;
}
```

Here int is the decl-specifier-seq; max(int a, int b, int c) is the declarator; { /* ... */ } is the function-body. —end example]

A ctor-initializer is used only in a constructor; see 10.3.4 and 10.9.

[Note: A cv-qualifier-seq affects the type of this in the body of a member function; see 9.2.3.2. —end note]

[Note: Unused parameters need not be named. For example,]

```
void print(int a, int) {
  std::printf("a = %d
",a);
}
```

—end note]

In the function-body, a function-local predefined variable denotes a block-scope object of static storage duration that is implicitly defined (see 6.3.3).

The function-local predefined variable __func__ is defined as if a definition of the form

```
static const char __func__[] = "function-name";
```

had been provided, where function-name is an implementation-defined string. It is unspecified whether such a variable has an address distinct from that of any other object in the program.104 [Example:

```
struct S {
  S() : s(__func__) {} // OK
  const char* s;
};
void f(const char* s = __func__); // error: __func__ is undeclared
```

—end example]

9.4.2 Explicitly-defaulted functions

A function definition whose function-body is of the form = default ; is called an explicitly-defaulted definition. A function that is explicitly defaulted shall

(1.1) — be a special member function or a comparison operator (7.6.8, 7.6.9, 7.6.10), and
(1.2) — not have default arguments.

104) Implementations are permitted to provide additional predefined variables with names that are reserved to the implementation (5.10). If a predefined variable is not odr-used (6.2), its string value need not be present in the program image.
The type $T_1$ of an explicitly defaulted function $F$ is allowed to differ from the type $T_2$ it would have had if it were implicitly declared, as follows:

1. $T_1$ and $T_2$ may have differing *ref-qualifiers*; and
2. if $T_2$ has a parameter of type `const C&`, the corresponding parameter of $T_1$ may be of type `C&`.

If $T_1$ differs from $T_2$ in any other way, then:

3. if $F$ is an assignment operator, and the return type of $T_1$ differs from the return type of $T_2$ or $T_1$’s parameter type is not a reference, the program is ill-formed;
4. otherwise, if $F$ is explicitly defaulted on its first declaration, it is defined as deleted;
5. otherwise, the program is ill-formed.

An explicitly-defaulted function that is not defined as deleted may be declared `constexpr` only if it would have been implicitly declared as `constexpr`. If a function is explicitly defaulted on its first declaration, it is implicitly considered to be `constexpr` if the implicit declaration would be.

[Example:

```cpp
struct S {
    constexpr S() = default; // ill-formed: implicit S() is not constexpr
    S(int a = 0) = default; // ill-formed: default argument
    void operator=(const S&) = default; // ill-formed: non-matching return type
    ~S() noexcept(false) = default; // deleted: exception specification does not match
private:
    int i;
    S(S&); // OK: private copy constructor
};
S::S(S&) = default; // OK: defines copy constructor
```

Explicitly-defaulted functions and implicitly-declared functions are collectively called *defaulted functions*, and the implementation shall provide implicit definitions for them (10.3.4 10.3.7, 10.3.5, 10.3.6), which might mean defining them as deleted. A function is *user-provided* if it is user-declared and not explicitly defaulted or deleted on its first declaration. A user-provided explicitly-defaulted function (i.e., explicitly defaulted after its first declaration) is defined at the point where it is explicitly defaulted; if such a function is implicitly defined as deleted, the program is ill-formed. [Note: Declaring a function as defaulted after its first declaration can provide efficient execution and concise definition while enabling a stable binary interface to an evolving code base. —end note]

[Example:

```cpp
struct trivial {
    trivial() = default;
    trivial(const trivial&) = default;
    trivial(trivial&&) = default;
    trivial& operator=(const trivial&) = default;
    trivial& operator=(trivial&&) = default;
    ~trivial() = default;
};

struct nontrivial1 {
    nontrivial1();
};
nontrivial1::nontrivial1() = default; // not first declaration
```

---

9.4.3 Deleted definitions  [dcl.fct.def.delete]

A function definition whose *function-body* is of the form `= delete` is called a *deleted definition*. A function with a deleted definition is also called a *deleted function*.

A program that refers to a deleted function implicitly or explicitly, other than to declare it, is ill-formed. [Note: This includes calling the function implicitly or explicitly and forming a pointer or pointer-to-member to the function. It applies even for references in expressions that are not potentially-evaluated. If a function
is overloaded, it is referenced only if the function is selected by overload resolution. The implicit odr-use (6.2) of a virtual function does not, by itself, constitute a reference. — end note

3 Example: One can prevent default initialization and initialization by non-doubles with

```cpp
struct onlydouble {
    onlydouble() = delete; // OK, but redundant
    template<class T>
        onlydouble(T) = delete;
    onlydouble(double);
};
— end example
```

Example: One can prevent use of a class in certain new-expressions by using deleted definitions of a user-declared operator new for that class.

```cpp
struct sometype {
    void* operator new(std::size_t) = delete;
    void* operator new[](std::size_t) = delete;
};
sometype* p = new sometype; // error, deleted class operator new
sometype* q = new sometype[3]; // error, deleted class operator new[]
— end example
```

Example: One can make a class uncopyable, i.e., move-only, by using deleted definitions of the copy constructor and copy assignment operator, and then providing defaulted definitions of the move constructor and move assignment operator.

```cpp
struct moveonly {
    moveonly() = default;
    moveonly(const moveonly&) = delete;
    moveonly(moveonly&&) = default;
    moveonly& operator=(const moveonly&) = delete;
    moveonly& operator=(moveonly&&) = default;
    ~moveonly() = default;
};
moveonly* p;
moveonly q(*p); // error, deleted copy constructor
— end example
```

4 A deleted function is implicitly an inline function (9.1.6). [Note: The one-definition rule (6.2) applies to deleted definitions. — end note] A deleted definition of a function shall be the first declaration of the function or, for an explicit specialization of a function template, the first declaration of that specialization. An implicitly declared allocation or deallocation function (6.6.4.4) shall not be defined as deleted. [Example:

```cpp
struct sometype {
    sometype();
};
sometype::sometype() = delete; // ill-formed; not first declaration
— end example
```

9.5 Structured binding declarations [decl.struct.bind]

1 A structured binding declaration introduces the identifiers \(v_0, v_1, v_2, \ldots\) of the identifier-list as names (6.3.1) of structured bindings. Let \(cv\) denote the cv-qualifiers in the decl-specifier-seq. First, a variable with a unique name \(e\) is introduced. If the assignment-expression in the initializer has array type \(A\) and no ref-qualifier is present, \(e\) has type \(cv\ A\) and each element is copy-initialized or direct-initialized from the corresponding element of the assignment-expression as specified by the form of the initializer. Otherwise, \(e\) is defined as-if by

```cpp
attribute-specifier-seq_opt decl-specifier-seq ref-qualifier_opt e initializer ;
```

where the declaration is never interpreted as a function declaration and the parts of the declaration other than the declarator:id are taken from the corresponding structured binding declaration. The type of the id-expression \(e\) is called \(E\). [Note: \(E\) is never a reference type (7.2). — end note]
If the initializer refers to one of the names introduced by the structured binding declaration, the program is ill-formed.

If E is an array type with element type T, the number of elements in the identifier-list shall be equal to the number of elements of E. Each vi is the name of an lvalue that refers to the element i of the array and whose type is T; the referenced type is T. [Note: The top-level cv-qualifiers of T are cv. — end note] [Example:

```cpp
auto f() -> int(&)[2];
auto [x, y] = f(); // x and y refer to elements in a copy of the array return value
auto& [xr, yr] = f(); // xr and yr refer to elements in the array referred to by f's return value
```
—end example]

Otherwise, if the qualified-id std::tuple_size<E> names a complete type, the expression std::tuple_size<E>::value shall be a well-formed integral constant expression and the number of elements in the identifier-list shall be equal to the value of that expression. Let i be an index prvalue of type std::size_t corresponding to vi. The unqualified-id get is looked up in the scope of E by class member access lookup (6.4.5), and if that finds at least one declaration that is a function template whose first template parameter is a non-type parameter, the initializer is e.get<i>(). Otherwise, the initializer is get<i>(e), where get is looked up in the associated namespaces (6.4.2). In either case, get<i> is interpreted as a template-id. [Note: Ordinary unqualified lookup (6.4.1) is not performed. — end note] In either case, e is an lvalue if the type of the entity e is an lvalue reference and an xvalue otherwise. Given the type Ti designated by std::tuple_element<i, E>::type, variables are introduced with unique names ri of type "reference to Ti" initialized with the initializer (9.3.3), where the reference is an lvalue reference if the initializer is an lvalue and an rvalue reference otherwise. Each vi is the name of an lvalue of type Ti that refers to the object bound to ri; the referenced type is Ti. [Example:

```cpp
struct S { int x1: 2; volatile double y1; };
S f();
const auto [x, y] = f();
```
—end example]

Otherwise, all of E's non-static data members shall be direct members of E or of the same base class of E, well-formed when named as e.name in the context of the structured binding. E shall not have an anonymous union member, and the number of elements in the identifier-list shall be equal to the number of non-static data members of E. Designating the non-static data members of E as m0, m1, m2, ... (in declaration order), each vi is the name of an lvalue that refers to the member mi of e and whose type is cv Ti, where Ti is the declared type of that member; the referenced type is cv Ti. The lvalue is a bit-field if that member is a bit-field. [Example:

```cpp
   struct S { int x1: 2; volatile double y1; };
   S f();
   const auto [x, y] = f();
```
—end example]

9.6 Enumeration declarations [dcl.enum]

An enumeration is a distinct type (6.7.2) with named constants. Its name becomes an enum-name within its scope.

```cpp
enum-name:
   identifier

enum-specifier:
   enum-head { enumerator-listopt }
   enum-head { enumerator-list , }

enum-head:
   enum-key attribute-specifier-seqopt enum-head-nameopt enum-baseopt

enum-head-name:
   nested-name-specifieropt identifier

opaque-enum-declaration:
   enum-key attribute-specifier-seqopt nested-name-specifieropt identifier enum-baseopt;

enum-key:
   enum
   enum class
   enum struct

enum-base:
   : type-specifier-seq
```

§ 9.6
The optional attribute-specifier-seq in the enum-head and the opaque-enum-declaration appertains to the enumeration; the attributes in that attribute-specifier-seq are thereafter considered attributes of the enumeration whenever it is named. A : following "enum nested-name-specifier_opt identifier" within the decl-specifier-seq of a member-declaration is parsed as part of an enum-base. \[Note: This resolves a potential ambiguity between the declaration of an enumeration with an enum-base and the declaration of an unnamed bit-field of enumeration type. \] Example:

```c
struct S {
    enum E : int {};  // error: redeclaration of enumeration
    enum E : int {};  
};
```

— end example] — end note] If an opaque-enum-declaration contains a nested-name-specifier, the declaration shall be an explicit specialization (12.8.3).

The enumeration type declared with an enum-key of only enum is an unscoped enumeration, and its enumerators are unscoped enumerators. The enum-keys enum class and enum struct are semantically equivalent; an enumeration type declared with one of these is a scoped enumeration, and its enumerators are scoped enumerators. The optional identifier shall not be omitted in the declaration of a scoped enumeration. The type-specifier-seq of an enum-base shall name an integral type; any cv-qualification is ignored. An opaque-enum-declaration declaring an unscoped enumeration shall not omit the enum-base. The identifiers in an enumerator-list are declared as constants, and can appear wherever constants are required. An enumerator-definition with = gives the associated enumerator the value indicated by the constant-expression. If the first enumerator has no initializer, the value of the corresponding constant is zero. An enumerator-definition without an initializer gives the enumerator the value obtained by increasing the value of the previous enumerator by one. [Example:

```c
enum { a, b, c=0 };  
enum { d, e, f=e+2 }; 
```

defines a, c, and d to be zero, b and e to be 1, and f to be 3. — end example] The optional attribute-specifier-seq in an enumerator appertains to that enumerator.

An opaque-enum-declaration is either a redeclaration of an enumeration in the current scope or a declaration of a new enumeration. \[Note: An enumeration declared by an opaque-enum-declaration has a fixed underlying type and is a complete type. The list of enumerators can be provided in a later redeclaration with an enum-specifier. \] — end note] A scoped enumeration shall not be later redeclared as unscoped or with a different underlying type. An unscoped enumeration shall not be later redeclared as scoped and each redeclaration shall include an enum-base specifying the same underlying type as in the original declaration. If the enum-key is followed by a nested-name-specifier, the enum-specifier shall refer to an enumeration that was previously declared directly in the class or namespace to which the nested-name-specifier refers (i.e., neither inherited nor introduced by a using-declaration), and the enum-specifier shall appear in a namespace enclosing the previous declaration.

Each enumeration defines a type that is different from all other types. Each enumeration also has an underlying type. The underlying type can be explicitly specified using an enum-base. For a scoped enumeration type, the underlying type is int if it is not explicitly specified. In both of these cases, the underlying type is said to be fixed. Following the closing brace of an enum-specifier, each enumerator has the type of its enumeration. If the underlying type is fixed, the type of each enumerator prior to the closing brace is the underlying type and the constant-expression in the enumerator-definition shall be a converted constant expression of the underlying type (7.7). If the underlying type is not fixed, the type of each enumerator prior to the closing brace is determined as follows:

§ 9.6
If an initializer is specified for an enumerator, the constant-expression shall be an integral constant expression (7.7). If the expression has unscoped enumeration type, the enumerator has the underlying type of that enumeration type, otherwise it has the same type as the expression.

If no initializer is specified for the first enumerator, its type is an unspecified signed integral type.

Otherwise the type of the enumerator is the same as that of the preceding enumerator unless the incremented value is not representable in that type, in which case the type is an unspecified integral type sufficient to contain the incremented value. If no such type exists, the program is ill-formed.

An enumeration whose underlying type is fixed is an incomplete type from its point of declaration (6.3.2) to immediately after its enum-base (if any), at which point it becomes a complete type. An enumeration whose underlying type is not fixed is not fixed is an incomplete type from its point of declaration to immediately after the closing } of its enum-specifier, at which point it becomes a complete type.

For an enumeration whose underlying type is not fixed, the underlying type is an integral type that can represent all the enumerator values defined in the enumeration. If no integral type can represent all the enumerator values, the enumeration is ill-formed. It is implementation-defined which integral type is used as the underlying type except that the underlying type shall not be larger than int unless the value of an enumerator cannot fit in an int or unsigned int. If the enumerator-list is empty, the underlying type is as if the enumeration had a single enumerator with value 0.

For an enumeration whose underlying type is fixed, the values of the enumeration are the values of the underlying type. Otherwise, for an enumeration where \( e_{\text{min}} \) is the smallest enumerator and \( e_{\text{max}} \) is the largest, the values of the enumeration are the values in the range \( b_{\text{min}} \) to \( b_{\text{max}} \), defined as follows: Let \( K \) be 1 for a two’s complement representation and 0 for a ones’ complement or sign-magnitude representation. \( b_{\text{max}} \) is the smallest value greater than or equal to \( \max[(e_{\text{min}} - K, e_{\text{max}})] \) and equal to \( 2^M - 1 \), where \( M \) is a non-negative integer. \( b_{\text{min}} \) is zero if \( e_{\text{min}} \) is non-negative and \( -(b_{\text{max}} + K) \) otherwise. The size of the smallest bit-field large enough to hold all the values of the enumeration type is \( \max(M, 1) \) if \( b_{\text{min}} \) is zero and \( M + 1 \) otherwise. It is possible to define an enumeration that has values not defined by any of its enumerators. If the enumerator-list is empty, the values of the enumeration are as if the enumeration had a single enumerator with value 0.

Two enumeration types are layout-compatible enumerations if they have the same underlying type.

The value of an enumerator or an object of an unscoped enumeration type is converted to an integer by integral promotion (7.3.6). [Example:

```
enum color { red, yellow, green=20, blue };
color col = red;
color* cp = &col;
if (*cp == blue) // ...
```

makes color a type describing various colors, and then declares col as an object of that type, and cp as a pointer to an object of that type. The possible values of an object of type color are red, yellow, green, blue; these values can be converted to the integral values 0, 1, 20, and 21. Since enumerations are distinct types, objects of type color can be assigned only values of type color.

```
color c = 1; // error: type mismatch, no conversion from int to color
int i = yellow; // OK: yellow converted to integral value 1, integral promotion
```

Note that this implicit enum to int conversion is not provided for a scoped enumeration:

```
enum class Col { red, yellow, green }
int x = Col::red; // error: no Col to int conversion
Col y = Col::red;
if (y) { } // error: no Col to bool conversion
```

§ 9.6

Each enum-name and each unscoped enumerator is declared in the scope that immediately contains the enum-specifier. Each scoped enumerator is declared in the scope of the enumeration. These names obey the scope rules defined for all names in 6.3 and 6.4. [Example:

```
enum direction { left='l', right='r' }
```
void g() {
  direction d;  // OK
  d = left;    // OK
  d = direction::right;  // OK
}

direction d;
// OK

enum class altitude { high='h', low='l' };  

void h() {
  altitude a;       // OK
  a = high;         // error: high not in scope
  a = altitude::low;  // OK
}

— end example] An enumerator declared in class scope can be referred to using the class member access operators (::, . (dot) and -> (arrow)), see 7.6.1.5. [Example:

struct X {
  enum direction { left='l', right='r' };  
  int f(int i) { return i==left ? 0 : i==right ? 1 : 2; }
};

void g(X* p) {  
  direction d;       // error: direction not in scope
  int i;           
  i = p->f(left);   // error: left not in scope
  i = p->f(X::right);  // OK
  i = p->f(p->left);  // OK
  // ...
}

— end example]  

12 If an enum-head contains a nested-name-specifier, the enum-specifier shall refer to an enumeration that was previously declared directly in the class or namespace to which the nested-name-specifier refers, or in an element of the inline namespace set (9.7.1) of that namespace (i.e., not merely inherited or introduced by a using-declaration), and the enum-specifier shall appear in a namespace enclosing the previous declaration. In such cases, the nested-name-specifier of the enum-head of the definition shall not begin with a decltype-specifier.

9.7 Namespaces  

A namespace is an optionally-named declarative region. The name of a namespace can be used to access entities declared in that namespace; that is, the members of the namespace. Unlike other declarative regions, the definition of a namespace can be split over several parts of one or more translation units.

2 The outermost declarative region of a translation unit is a namespace; see 6.3.6.

9.7.1 Namespace definition  

namespace-name:
  identifier

namespace-alias

namespace-definition:
  named-namespace-definition
  unnamed-namespace-definition
  nested-namespace-definition

named-namespace-definition:
  inline_opt namespace attribute-specifier-seqopt identifier { namespace-body }

unnamed-namespace-definition:
  inline_opt namespace attribute-specifier-seqopt { namespace-body }

nested-namespace-definition:
  namespace enclosing-namespase-specifier :: identifier { namespace-body }

enclosing-namespase-specifier:
  identifier
  enclosing-namespase-specifier :: identifier
Every namespace-definition shall appear in the global scope or in a namespace scope (6.3.6).

In a named-namespace-definition, the identifier is the name of the namespace. If the identifier, when looked up (6.4.1), refers to a namespace-name (but not a namespace-alias) that was introduced in the namespace in which the named-namespace-definition appears or that was introduced in a member of the inline namespace set of that namespace, the namespace-definition extends the previously-declared namespace. Otherwise, the identifier is introduced as a namespace-name into the declarative region in which the named-namespace-definition appears.

Because a namespace-definition contains declarations in its namespace-body and a namespace-definition is itself a declaration, it follows that namespace definitions can be nested. [Example:

```cpp
namespace Outer {
    int i;
    namespace Inner {
        void f() { i++; } // Outer::i
        int i;
        void g() { i++; } // Inner::i
    }
}
```
—end example]

The enclosing namespaces of a declaration are those namespaces in which the declaration lexically appears, except for a redeclaration of a namespace member outside its original namespace (e.g., a definition as specified in 9.7.1.2). Such a redeclaration has the same enclosing namespaces as the original declaration. [Example:

```cpp
namespace Q {
    namespace V {
        void f(); // enclosing namespaces are the global namespace, Q, and Q::V
        class C { void m(); };}
    void V::f() { // enclosing namespaces are the global namespace, Q, and Q::V
        extern void h(); // ... so this declares Q::V::h
    }
    void V::C::m() { // enclosing namespaces are the global namespace, Q, and Q::V
}
}
```
—end example]

If the optional initial inline keyword appears in a namespace-definition for a particular namespace, that namespace is declared to be an inline namespace. The inline keyword may be used on a namespace-definition that extends a namespace only if it was previously used on the namespace-definition that initially declared the namespace-name for that namespace.

The optional attribute-specifier-seq in a named-namespace-definition appertains to the namespace being defined or extended.

Members of an inline namespace can be used in most respects as though they were members of the enclosing namespace. Specifically, the inline namespace and its enclosing namespace are both added to the set of associated namespaces used in argument-dependent lookup (6.4.2) whenever one of them is, and a using-directive (9.7.3) that names the inline namespace is implicitly inserted into the enclosing namespace as for an unnamed namespace (9.7.1.1). Furthermore, each member of the inline namespace can subsequently be partially specialized (12.6.5), explicitly instantiated (12.8.2), or explicitly specialized (12.8.3) as though it were a member of the enclosing namespace. Finally, looking up a name in the enclosing namespace via explicit qualification (6.4.3.2) will include members of the inline namespace brought in by the using-directive even if there are declarations of that name in the enclosing namespace.

These properties are transitive: if a namespace N contains an inline namespace M, which in turn contains an inline namespace O, then the members of O can be used as though they were members of M or N. The inline namespace set of N is the transitive closure of all inline namespaces in N. The enclosing namespace set of O is the set of namespaces consisting of the innermost non-inline namespace enclosing an inline namespace O, together with any intervening inline namespaces.
A nested-namespace-definition with an enclosing-namespace-specifier E, identifier I and namespace-body B is equivalent to

```
namespace E { namespace I { B } }
```

[Example:
```
namespace A::B::C {
  int i;
}
```
]
The above has the same effect as:

```
namespace A {
  namespace B {
    namespace C {
      int i;
    }
  }
}
```

—end example]

### 9.7.1.1 Unnamed namespaces

An unnamed-namespace-definition behaves as if it were replaced by

```
inline_opt namespace unique { /* empty body */ }
using namespace unique;
namespace unique { namespace-body }
```

where inline appears if and only if it appears in the unnamed-namespace-definition and all occurrences of unique in a translation unit are replaced by the same identifier, and this identifier differs from all other identifiers in the translation unit. The optional attribute-specifier-seq in the unnamed-namespace-definition appertains to unique. [Example:
```
namespace { int i; } // unique::i
void f() { i++; } // unique::i++
namespace A {
  namespace {
    int i; // A::unique::i
    int j; // A::unique::j
    void g() { i++; } // A::unique::i++
  }
}
using namespace A;
void h() {
  i++; // error: unique::i or A::unique::i
  A::i++; // A::unique::i
  j++; // A::unique::j
}
```
—end example]

### 9.7.1.2 Namespace member definitions

A declaration in a namespace N (excluding declarations in nested scopes) whose declarator-id is an unqualified-id (9.2.3), whose class-head-name (Clause 10) or enum-head-name (9.6) is an identifier, or whose elaborated-type-specifier is of the form class-key attribute-specifier-seq_opt identifier (9.1.7.3), or that is an opaque-enum-declaration, declares (or redeclares) its unqualified-id or identifier as a member of N. [Note: An explicit instantiation (12.8.2) or explicit specialization (12.8.3) of a template does not introduce a name and thus may be declared using an unqualified-id in a member of the enclosing namespace set, if the primary template is declared in an inline namespace. — end note] [Example:
```
namespace X {
  void f() { /* ... */ } // OK: introduces X::f()
```
namespace M {
    void g();        // OK: introduces X::M::g()
}
using M::g;
void g();        // error: conflicts with X::M::g()
}  

— end example]

Members of a named namespace can also be defined outside that namespace by explicit qualification (6.4.3.2) of the name being defined, provided that the entity being defined was already declared in the namespace and the definition appears after the point of declaration in a namespace that encloses the declaration’s namespace. [Example:

namespace Q {
    namespace V {
        void f();
    }
    void V::f() { /* ... */ }  // OK
    void V::g() { /* ... */ }  // error: g() is not yet a member of V
    namespace V {
        void g();
    }
}

namespace R {
    void Q::V::g() { /* ... */ }  // error: R doesn't enclose Q
}

— end example]

If a friend declaration in a non-local class first declares a class, function, class template or function template the friend is a member of the innermost enclosing namespace. The friend declaration does not by itself make the name visible to unqualified lookup (6.4.1) or qualified lookup (6.4.3). [Note: The name of the friend will be visible in its namespace if a matching declaration is provided at namespace scope (either before or after the class definition granting friendship). — end note] If a friend function or function template is called, its name may be found by the name lookup that considers functions from namespaces and classes associated with the types of the function arguments (6.4.2). If the name in a friend declaration is neither qualified nor a template-id and the declaration is a function or an elaborated-type-specifier, the lookup to determine whether the entity has been previously declared shall not consider any scopes outside the innermost enclosing namespace. [Note: The other forms of friend declarations cannot declare a new member of the innermost enclosing namespace and thus follow the usual lookup rules. — end note] [Example:

// Assume f and g have not yet been declared.
void h(int);
template <class T> void f2(T);
namespace A {
    class X {
        friend void f(X);        // A::f(X) is a friend
    class Y {
        friend void g();        // A::g is a friend
        friend void h(int);     // A::h is a friend
            friend void f2<> (int);  // ::f2<> (int) is a friend
    }
};

// A::f, A::g and A::h are not visible here
X x;
void g() { f(x); }        // definition of A::g
void f(X) { /* ... */ }  // definition of A::f
void h(int) { /* ... */ }  // definition of A::h
// A::f, A::g and A::h are visible here and known to be friends

106) this implies that the name of the class or function is unqualified.

§ 9.7.1.2
using A::x;

void h() {
    A::f(x);
    A::X::f(x); // error: f is not a member of A::X
    A::X::Y::g(); // error: g is not a member of A::X::Y
}

—end example

9.7.2 Namespace alias

A namespace-alias-definition declares an alternate name for a namespace according to the following grammar:

namespace-alias-definition:
    namespace-alias:
        identifier

namespace-alias:
    namespace-alias-definition:
        namespace identifier = qualified-name-specifier;

qualified-name-specifier:
    nested-name-specifier opt namespace-name

1 The identifier in a namespace-alias-definition is a synonym for the name of the namespace denoted by the qualified-name-specifier and becomes a namespace-alias. [Note: When looking up a namespace-name in a namespace-alias-definition, only namespace names are considered, see 6.4.6. — end note]

2 In a declarative region, a namespace-alias-definition can be used to redefine a namespace-alias declared in that declarative region to refer only to the namespace to which it already refers. [Example: The following declarations are well-formed:

```cpp
namespace Company_with_very_long_name { /* ... */ }
namespace CWVLN = Company_with_very_long_name;
namespace CWVLN = Company_with_very_long_name;  // OK: duplicate
namespace CWVLN = CWVLN;
```

—end example]

9.7.3 Using directive

using-directive:
    attribute-specifier-seq opt using namespace nested-name-specifier opt namespace-name;

1 A using-directive shall not appear in class scope, but may appear in namespace scope or in block scope. [Note: When looking up a namespace-name in a using-directive, only namespace names are considered, see 6.4.6. — end note] The optional attribute-specifier-seq appertains to the using-directive.

2 A using-directive specifies that the names in the nominated namespace can be used in the scope in which the using-directive appears after the using-directive. During unqualified name lookup (6.4.1), the names appear as if they were declared in the nearest enclosing namespace which contains both the using-directive and the nominated namespace. [Note: In this context, “contains” means “contains directly or indirectly”. — end note]

3 A using-directive does not add any members to the declarative region in which it appears. [Example:

```cpp
namespace A {
    int i;
    namespace B {
        namespace C {
            int i;
        }
        using namespace A::B::C;
        void f1() {
            i = 5;    // OK, C::i visible in B and hides A::i
        }
    }
    namespace D {
        using namespace B;
        using namespace C;
        void f2() {
            i = 5;    // ambiguous, B::C::i or A::i?
```
For unqualified lookup (6.4.1), the using-directive is transitive: if a scope contains a using-directive that
nominates a second namespace that itself contains using-directives, the effect is as if the using-directives
from the second namespace also appeared in the first. [Note: For qualified lookup, see 6.4.3.2. — end note]
[Example:

```cpp
namespace M {
  int i;
}

namespace N {
  int i;
  using namespace M;
}

void f() {
  using namespace N;
  i = 7;  // error: both M::i and N::i are visible
}
```

For another example,

```cpp
namespace A {
  int i;
}

namespace B {
  int i;
  int j;
  namespace C {
    namespace D {
      using namespace A;
      int j;
      int k;
      int a = i;  // B::i hides A::i
    }
    using namespace D;
    int k = 89;  // no problem yet
    int l = k;   // ambiguous: C::k or D::k
    int m = i;   // B::i hides A::i
    int n = j;   // D::j hides B::j
  }
}
```

— end example]

5 If a namespace is extended (9.7.1) after a using-directive for that namespace is given, the additional members
of the extended namespace and the members of namespaces nominated by using-directives in the extending
namespace-definition can be used after the extending namespace-definition.

[Note: If name lookup finds a declaration for a name in two different namespaces, and the declarations
do not declare the same entity and do not declare functions or function templates, the use of the name is
ill-formed (6.4). In particular, the name of a variable, function or enumerator does not hide the name of a
class or enumeration declared in a different namespace. For example,

```cpp
namespace A {
  class X { };  
  extern "C"  int g();
}
```
extern "C++" int h();
}
namespace B {
    void X(int);
    extern "C" int g();
    extern "C++" int h(int);
}
using namespace A;
using namespace B;

void f() {
    X(1);  // error: name X found in two namespaces
    g();   // OK: name g refers to the same entity
    h();   // OK: overload resolution selects A::h
}

—end note[7]

During overload resolution, all functions from the transitive search are considered for argument matching. The set of declarations found by the transitive search is unordered. [Note: In particular, the order in which namespaces were considered and the relationships among the namespaces implied by the using-directives do not cause preference to be given to any of the declarations found by the search. —end note] An ambiguity exists if the best match finds two functions with the same signature, even if one is in a namespace reachable through using-directives in the namespace of the other. [Example:

namespace D {
    int d1;
    void f(char);
}
using namespace D;

int d1;  // OK: no conflict with D::d1

namespace E {
    int e;
    void f(int);
}
namespace D {  // namespace extension
    int d2;
    using namespace E;
    void f(int);
} 

void f() {
    d1++;  // error: ambiguous ::d1 or D::d1?
    ::d1++; // OK
    D::d1++; // OK
    d2++;  // OK: D::d2
    e++;   // OK: E::e
    f('a'); // error: ambiguous: D::f(int) or E::f(int)?
    f('a'); // OK: D::f(char)
}

—end example]

9.8 The using declaration

using-declaration:
    using using-declarator-list;

using-declarator-list:
    using-declarator ...opt
    using-declarator-list , using-declarator ...opt

[namespace.udecl]

107) During name lookup in a class hierarchy, some ambiguities may be resolved by considering whether one member hides the other along some paths (10.7). There is no such disambiguation when considering the set of names found as a result of following using-directives.
Each using-declarator in a using-declaration\(^{108}\) introduces a set of declarations into the declarative region in which the using-declaration appears. The set of declarations introduced by the using-declarator is found by performing qualified name lookup (6.4.3, 10.7) for the name in the using-declarator, excluding functions that are hidden as described below. If the using-declarator does not name a constructor, the unqualified-id is declared in the declarative region in which the using-declaration appears as a synonym for each declaration introduced by the using-declarator. [Note: Only the specified name is so declared; specifying an enumeration name in a using-declaration does not declare its enumerators in the using-declaration’s declarative region. — end note] If the using-declarator names a constructor, it declares that the class inherits the set of constructor declarations introduced by the using-declarator from the nominated base class.

Every using-declaration is a declaration and a member-declaration and can therefore be used in a class definition. [Example:]

```cpp
struct B {
    void f(char);
    void g(char);
    enum E { e };
    union { int x; };
};

struct D : B {
    using B::f;
    void f(int) { f('c'); } // calls B::f(char)
    void g(int) { g('c'); } // recursively calls D::g(int)
};
```

—end example]

In a using-declaration used as a member-declaration, each using-declarator’s nested-name-specifier shall name a base class of the class being defined. If a using-declarator names a constructor, its nested-name-specifier shall name a direct base class of the class being defined. [Example:]

```cpp
template <typename... bases>
struct X : bases... {
    using bases::g...;
};

X<B, D> x; // OK: B::g and D::g introduced
```

—end example] [Example:]

```cpp
class C {
    int g();
};

class D2 : public B {
    using B::f; // OK: B is a base of D2
    using B::e; // OK: e is an enumerator of base B
    using B::x; // OK: x is a union member of base B
    using C::g; // error: C isn’t a base of D2
};
```

—end example]

[Note: Since destructors do not have names, a using-declaration cannot refer to a destructor for a base class. Since specializations of member templates for conversion functions are not found by name lookup, they are not considered when a using-declaration specifies a conversion function (12.6.2). — end note] If a constructor or assignment operator brought from a base class into a derived class has the signature of a copy/move constructor or assignment operator for the derived class (10.3.5, 10.3.6), the using-declaration does not by itself suppress the implicit declaration of the derived class member; the member from the base class is hidden or overridden by the implicitly-declared copy/move constructor or assignment operator of the derived class, as described below.

\(^{108}\) A using-declaration with more than one using-declarator is equivalent to a corresponding sequence of using-declarations with one using-declarator each.
5 A using-declaration shall not name a template-id. [Example:

```c
struct A {
    template <class T> void f(T);
    template <class T> struct X { };
};
struct B : A {
    using A::f<double>;  // ill-formed
    using A::X<int>;     // ill-formed
};
@end example]
```

6 A using-declaration shall not name a namespace.

7 A using-declaration shall not name a scoped enumerator.

8 A using-declaration that names a class member shall be a member-declaration. [Example:

```c
struct X {
    int i;
    static int s;
};
void f() {
    using X::i;           // error: X::i is a class member and this is not a member declaration.
    using X::s;           // error: X::s is a class member and this is not a member declaration.
}
@end example]
```

9 Members declared by a using-declaration can be referred to by explicit qualification just like other member names (6.4.3.2). [Example:

```c
void f();
namespace A {
    void g();
}
namespace X {
    using ::f;            // global f
    using A::g;          // A's g
}
void h() {
    X::f();              // calls ::f
    X::g();              // calls A::g
}
@end example]
```

10 A using-declaration is a declaration and can therefore be used repeatedly where (and only where) multiple declarations are allowed. [Example:

```c
namespace A {
    int i;
}
namespace A1 {
    using A::i, A::i;    // OK: double declaration
}
struct B {
    int i;
};
```
struct X : B {
    using B::i, B::i; // error: double member declaration
};
—end example]

[Note: For a using-declaration whose nested-name-specifier names a namespace, members added to the namespace after the using-declaration are not in the set of introduced declarations, so they are not considered when a use of the name is made. Thus, additional overloads added after the using-declaration are ignored, but default function arguments (9.2.3.6), default template arguments (12.1), and template specializations (12.6.5, 12.8.3) are considered. —end note] [Example:

namespace A {
    void f(int);
}

using A::f; // f is a synonym for A::f; that is, for A::f(int).
namespace A {
    void f(char);
}

void foo() {
    f('a'); // calls f(int), even though f(char) exists.
}

void bar() {
    using A::f; // f is a synonym for A::f; that is, for A::f(int) and A::f(char).
    f('a'); // calls f(char)
}
—end example]

[Note: Partial specializations of class templates are found by looking up the primary class template and then considering all partial specializations of that template. If a using-declaration names a class template, partial specializations introduced after the using-declaration are effectively visible because the primary template is visible (12.6.5). —end note]

Since a using-declaration is a declaration, the restrictions on declarations of the same name in the same declarative region (6.3) also apply to using-declarations. [Example:

namespace A {
    int x;
}

namespace B {
    int i;
    struct g { }; struct x { }; void f(int), void f(double);
    void g(char); // OK: hides struct g
}

void func() {
    int i;
    using B::i; // error: i declared twice
    void f(char);
    using B::f; // OK: each f is a function
    f(3.5); // calls B::f(double)
    using B::g;
    g('a'); // calls B::g(char)
    struct g g1; // g1 has class type B::g
    using B::x;
    using A::x; // OK: hides struct B::x
    x = 99; // assigns to A::x
    struct x x1; // x1 has class type B::x
}
If a function declaration in namespace scope or block scope has the same name and the same parameter-type-list (9.2.3.5) as a function introduced by a using-declaration, and the declarations do not declare the same function, the program is ill-formed. If a function template declaration in namespace scope has the same name, parameter-type-list, return type, and template parameter list as a function template introduced by a using-declaration, the program is ill-formed. [Note: Two using-declarations may introduce functions with the same name and the same parameter-type-list. If, for a call to an unqualified function name, function overload resolution selects the functions introduced by such using-declarations, the function call is ill-formed. ]

Example:

```cpp
namespace B {
    void f(int);
    void f(double);
}
namespace C {
    void f(int);
    void f(double);
    void f(char);
}
void h() {
    using B::f; // B::f(int) and B::f(double)
    using C::f; // C::f(int), C::f(double), and C::f(char)
    f('h'); // calls C::f(char)
    f(1); // error: ambiguous: B::f(int) or C::f(int) ?
    using int f; // error: f(int) conflicts with C::f(int) and B::f(int)
}
```

When a using-declarator brings declarations from a base class into a derived class, member functions and member function templates in the derived class override and/or hide member functions and member function templates with the same name, parameter-type-list (9.2.3.5), cv-qualification, and ref-qualifier (if any) in a base class (rather than conflicting). Such hidden or overridden declarations are excluded from the set of declarations introduced by the using-declarator. [Example:

```cpp
struct B {
    virtual void f(int);
    virtual void f(char);
    void g(int);
    void h(int);
};

struct D : B {
    using B::f;
    void f(int); // OK: D::f(int) overrides B::f(int);

    using B::g;
    void g(char); // OK

    using B::h;
    void h(int); // OK: D::h(int) hides B::h(int)
};

void k(D* p) {
    p->f(1); // calls D::f(int)
    p->f('a'); // calls B::f(char)
    p->g(1); // calls B::g(int)
    p->g('a'); // calls D::g(char)
}

struct B1 {
    B1(int);
};
```
struct B2 {
    B2(int);
};

struct D1 : B1, B2 {
    using B1::B1;
    using B2::B2;
};
D1 d1(0);  // ill-formed: ambiguous

struct D2 : B1, B2 {
    using B1::B1;
    using B2::B2;
    D2(int);  // OK: D2::D2(int) hides B1::B1(int) and B2::B2(int)
};
D2 d2(0);  // calls D2::D2(int)

—end example

[Note: For the purpose of forming a set of candidates during overload resolution, the functions that are introduced by a using-declaration into a derived class are treated as though they were members of the derived class (10.7). In particular, the implicit object parameter is treated as if it were a reference to the derived class rather than to the base class (11.3.1). This has no effect on the type of the function, and in all other respects the function remains a member of the base class. — end note]

Constructors that are introduced by a using-declaration are treated as though they were constructors of the derived class when looking up the constructors of the derived class (6.4.3.1) or forming a set of overload candidates (11.3.1.3, 11.3.1.4, 11.3.1.7). [Note: If such a constructor is selected to perform the initialization of an object of class type, all subobjects other than the base class from which the constructor originated are implicitly initialized (10.9.3). A constructor of a derived class is sometimes preferred to a constructor of a base class if they would otherwise be ambiguous (11.3.3). — end note]

In a using-declarator that does not name a constructor, all members of the set of introduced declarations shall be accessible. In a using-declarator that names a constructor, no access check is performed. In particular, if a derived class uses a using-declarator to access a member of a base class, the member name shall be accessible. If the name is that of an overloaded member function, then all functions named shall be accessible. The base class members mentioned by a using-declarator shall be visible in the scope of at least one of the direct base classes of the class where the using-declarator is specified.

[Note: Because a using-declarator designates a base class member (and not a member subobject or a member function of a base class subobject), a using-declarator cannot be used to resolve inherited member ambiguities. [Example:

```c
struct A { int x(); };  
struct B : A { };  
struct C : A {
    using A::x;
    int x(int);
};

struct D : B, C {
    using C::x;
    int x(double);
};

int f(B* d) {
    return d->x();  // error: overload resolution selects A::x, but A is an ambiguous base class
}
```
—end example] — end note]

A synonym created by a using-declaration has the usual accessibility for a member-declaration. A using-declarator that names a constructor does not create a synonym; instead, the additional constructors are accessible if they would be accessible when used to construct an object of the corresponding base class, and the accessibility of the using-declaration is ignored. [Example:
9.9 The `asm` declaration

An `asm` declaration has the form

```
asm-definition:
  attribute-specifier-seq_opt asm ( string-literal ) ;
```

The `asm` declaration is conditionally-supported; its meaning is implementation-defined. The optional `attribute-specifier-seq` in an `asm-definition` appertains to the `asm` declaration. [Note: Typically it is used to pass information through the implementation to an assembler. — end note]

9.10 Linkage specifications

All function types, function names with external linkage, and variable names with external linkage have a language linkage. [Note: Some of the properties associated with an entity with language linkage are specific to each implementation and are not described here. For example, a particular language linkage may be associated with a particular form of representing names of objects and functions with external linkage, or with a particular calling convention, etc. — end note] The default language linkage of all function types, function names, and variable names is C++ language linkage. Two function types with different language linkages are distinct types even if they are otherwise identical.

Linkage (6.5) between C++ and non-C++ code fragments can be achieved using a `linkage-specification`:

```
linkage-specification:
  extern string-literal { declaration-seq_opt }
  extern string-literal declaration
```

The `string-literal` indicates the required language linkage. This document specifies the semantics for the `string-literals"C" and "C++". Use of a `string-literal` other than "C" or "C++" is conditionally-supported, with implementation-defined semantics. [Note: Therefore, a linkage-specification with a `string-literal` that is unknown to the implementation requires a diagnostic. — end note] [Note: It is recommended that the spelling of the `string-literal` be taken from the document defining that language. For example, Ada (not ADA) and Fortran or FORTRAN, depending on the vintage. — end note]

Every implementation shall provide for linkage to functions written in the C programming language, "C", and linkage to C++ functions, "C++". [Example:

```
complex sqrt(complex); // C++ linkage by default
extern "C" {
  double sqrt(double); // C linkage
}
```

— end example]

Linkage specifications nest. When linkage specifications nest, the innermost one determines the language linkage. A linkage specification does not establish a scope. A `linkage-specification` shall occur only in namespace scope (6.3). In a `linkage-specification`, the specified language linkage applies to the function types of all function declarators, function names with external linkage, and variable names with external linkage declared within the `linkage-specification`. [Example:
extern "C" void f1(void(*)(int)); // the name f1 and its function type have C language linkage; 
// pf is a pointer to a C function

extern "C" typedef void FUNC();   // the name f2 has C++ language linkage and the 
// function's type has C language linkage
FUNC f2;

extern "C" typedef void FUNC_c();  // the name f3 has C++ language linkage and the function's type have C language linkage
class C {
    void mf1(FUNC_c*);    // the name of the function mf1 and the member function's type have 
    // C++ language linkage; the parameter has type "pointer to C function"
    void mf2(void(*)(int));   // the name of function f3 and the function's type have C language linkage
    static FUNC_c* q;    // the name of variable pf2 has C++ linkage and the type 
    // of pf2 is "pointer to C++ function that takes one parameter of type 
    // pointer to C function"
};

extern "C" {
    extern void f4();    // OK: Name linkage (internal) and function type linkage (C language linkage) 
    // obtained from previous declaration.
    extern void f4();    // OK: Name linkage (internal) and function type linkage (C language linkage) 
    // obtained from previous declaration.
    void f5() {     // OK: Name linkage (internal) and function type linkage (C language linkage) 
        extern void f4();    // OK: Name linkage (internal) and function type linkage (C language linkage) 
        // obtained from previous declaration.
        void f6() {
            extern void f4();    // OK: Name linkage (internal) and function type linkage (C language linkage) 
            // obtained from previous declaration.
        }
    }
}

—end example] A C language linkage is ignored in determining the language linkage of the names of class members and the function type of class member functions. [Example:

extern "C" typedef void FUNC_c();   

class C {
    void mf1(FUNC_c*);    // the name of the function mf1 and the member function's type have 
    // C++ language linkage; the parameter has type "pointer to C function"
    void mf2(void(*)(int));    // the name of function f3 and the function's type have C language linkage
    static FUNC_c* q;    // the name of the data member q has C++ language linkage and 
    // the data member's type is "pointer to C function"
};

extern "C" {
    class X {
        void mf();    // the name of the function mf and the member function's type have 
        // C++ language linkage
        void mf2(void(*)(int));    // the name of the function mf2 has C++ language linkage;
        // the parameter has type "pointer to C function"
    };
}

—end example]

5 If two declarations declare functions with the same name and parameter-type-list (9.2.3.5) to be members of the same namespace or declare objects with the same name to be members of the same namespace and the declarations give the names different language linkages, the program is ill-formed; no diagnostic is required if the declarations appear in different translation units. Except for functions with C++ linkage, a function declaration without a linkage specification shall not precede the first linkage specification for that function. A function can be declared without a linkage specification after an explicit linkage specification has been seen; the linkage explicitly specified in the earlier declaration is not affected by such a function declaration.

§ 9.10 208
At most one function with a particular name can have C language linkage. Two declarations for a function with C language linkage with the same function name (ignoring the namespace names that qualify it) that appear in different namespace scopes refer to the same function. Two declarations for a variable with C language linkage with the same name (ignoring the namespace names that qualify it) that appear in different namespace scopes refer to the same variable. An entity with C language linkage shall not be declared with the same name as a variable in global scope, unless both declarations denote the same entity; no diagnostic is required if the declarations appear in different translation units. A variable with C language linkage shall not be declared with the same name as a function with C language linkage (ignoring the namespace names that qualify the respective names); no diagnostic is required if the declarations appear in different translation units. [Note: Only one definition for an entity with a given name with C language linkage may appear in the program (see 6.2); this implies that such an entity must not be defined in more than one namespace scope.—end note] [Example:

```c
int x;
namespace A {
    extern "C" int f();
    extern "C" int g() { return 1; }
    extern "C" int h();
    extern "C" int x(); // ill-formed: same name as global-space object x
}
namespace B {
    extern "C" int f(); // A::f and B::f refer to the same function
    extern "C" int g() { return 1; } // ill-formed, the function g with C language linkage has two definitions
}
int A::f() { return 98; } // definition for the function f with C language linkage
extern "C" int h() { return 97; } // A::h and ::h refer to the same function
```
—end example]

A declaration directly contained in a `linkage-specification` is treated as if it contains the `extern` specifier (9.1.1) for the purpose of determining the linkage of the declared name and whether it is a definition. Such a declaration shall not specify a storage class. [Example:

```c
extern "C" double f();
static double f(); // error
extern "C" int i; // declaration
extern "C" {
    int i; // definition
}
extern "C" static void g(); // error
```
—end example]

[Note: Because the language linkage is part of a function type, when indirecting through a pointer to C function, the function to which the resulting lvalue refers is considered a C function. — end note]

Linkage from C++ to objects defined in other languages and to objects defined in C++ from other languages is implementation-defined and language-dependent. Only where the object layout strategies of two language implementations are similar enough can such linkage be achieved.

9.11 Attributes

9.11.1 Attribute syntax and semantics

Attributes specify additional information for various source constructs such as types, variables, names, blocks, or translation units.

```c
attribute-specifier-seq:
    attribute-specifier-seqopt attribute-specifier
attribute-specifier:
    [ [ attribute-using-prefixopt attribute-list ] ]
    contract-attribute-specifier
    alignment-specifier
```

§ 9.11.1
alignment-specifier:
  alignas ( type-id ...opt )
  alignas ( constant-expression ...opt )

attribute-using-prefix:
  using attribute-namespace :

attribute-list:
  attributeopt
  attribute-list , attributeopt
  attribute ... 
  attribute-list , attribute ...

attribute:
  attribute-token attribute-argument-clauseopt

attribute-token:
  identifier
  attribute-scoped-token

attribute-scoped-token:
  attribute-namespace :: identifier

attribute-namespace:
  identifier

attribute-argument-clause:
  ( balanced-token-seqopt )

balanced-token-seq:
  balanced-token
  balanced-token-seq balanced-token

balanced-token:
  ( balanced-token-seqopt )
  [ balanced-token-seqopt ]
  { balanced-token-seqopt }
  any token other than a parenthesis, a bracket, or a brace

2 If an attribute-specifier contains an attribute-using-prefix, the attribute-list following that attribute-using-prefix shall not contain an attribute-scoped-token and every attribute-token in that attribute-list is treated as if its identifier were prefixed with N::, where N is the attribute-namespace specified in the attribute-using-prefix. [Note: This rule imposes no constraints on how an attribute-using-prefix affects the tokens in an attribute-argument-clause. — end note] [Example:
[[using CC: opt(1), debug]] // same as [[CC::opt(1), CC::debug]]
void f() {} // error: cannot combine using and scoped attribute token
[[using CC: opt(1)]] [[CC::debug]] // same as [[CC::opt(1)]] [[CC::debug]]
void g() {} // error: cannot combine using and scoped attribute token
[[using CC: CC::opt(1)]]
void h() {} // error: cannot combine using and scoped attribute token
— end example]

3 [Note: For each individual attribute, the form of the balanced-token-seq will be specified. — end note]

4 In an attribute-list, an ellipsis may appear only if that attribute's specification permits it. An attribute followed by an ellipsis is a pack expansion (12.6.3). An attribute-specifier that contains no attributes has no effect. The order in which the attribute-tokens appear in an attribute-list is not significant. If a keyword (5.11) or an alternative token (5.5) that satisfies the syntactic requirements of an identifier (5.10) is contained in an attribute-token, it is considered an identifier. No name lookup (6.4) is performed on any of the identifiers contained in an attribute-token. The attribute-token determines additional requirements on the attribute-argument-clause (if any).

5 Each attribute-specifier-seq is said to appertain to some entity or statement, identified by the syntactic context where it appears (Clause 8, Clause 9, 9.2). If an attribute-specifier-seq that appertains to some entity or statement contains an attribute or alignment-specifier that is not allowed to apply to that entity or statement, the program is ill-formed. If an attribute-specifier-seq appertains to a friend declaration (10.8.3), that declaration shall be a definition. No attribute-specifier-seq shall appertain to an explicit instantiation (12.8.2).

6 For an attribute-token (including an attribute-scoped-token) not specified in this document, the behavior is implementation-defined. Any attribute-token that is not recognized by the implementation is ignored. [Note:
Each implementation should choose a distinctive name for the *attribute-namespace* in an *attribute-scoped-token.*

—end note

7 Two consecutive left square bracket tokens shall appear only when introducing an *attribute-specifier* or within the *balanced-token-seq* of an *attribute-argument-clause.* [Note: If two consecutive left square brackets appear where an *attribute-specifier* is not allowed, the program is ill-formed even if the brackets match an alternative grammar production. —end note] [Example:

```c
int p[10];
void f() {
    int x = 42, y[5];
    int(p[[x] { return x; }()]); /* error: invalid attribute on a nested declarator-id and
    // not a function-style cast of an element of p. */
    y[[] { return 2; }() = 2; /* error even though attributes are not allowed in this context. */
    int i [{vendor::attr([[]])]}; // well-formed implementation-defined attribute.
}
```
—end example]

9.11.2 Alignment specifier

An *alignment-specifier* may be applied to a variable or to a class data member, but it shall not be applied to a bit-field, a function parameter, or an *exception-declaration* (13.3). An *alignment-specifier* may also be applied to the declaration or definition of a class (in an *elaborated-type-specifier* (9.1.7.3) or *class-head* (Clause 10), respectively) and to the declaration or definition of an enumeration (in an *opaque-enum-declaration* or *enum-head*, respectively (9.6)). An *alignment-specifier* with an ellipsis is a pack expansion (12.6.3).

2 When the *alignment-specifier* is of the form `alignas( constant-expression ):`

(2.1) — the *constant-expression* shall be an integral constant expression

(2.2) — if the constant expression does not evaluate to an alignment value (6.6.5), or evaluates to an extended alignment and the implementation does not support that alignment in the context of the declaration, the program is ill-formed.

3 An *alignment-specifier* of the form `alignas( type-id )` has the same effect as `alignas(alignof( type-id ))` (7.6.2.6).

4 The alignment requirement of an entity is the strictest nonzero alignment specified by its *alignment-specifiers*, if any; otherwise, the *alignment-specifiers* have no effect.

5 The combined effect of all *alignment-specifiers* in a declaration shall not specify an alignment that is less strict than the alignment that would be required for the entity being declared if all *alignment-specifiers* appertaining to that entity were omitted. [Example:

```c
struct alignas(8) S {};
struct alignas(1) U {
    S s;
}; // error: U specifies an alignment that is less strict than if the alignas(1) were omitted.
```
—end example]

6 If the defining declaration of an entity has an *alignment-specifier*, any non-defining declaration of that entity shall either specify equivalent alignment or have no *alignment-specifier*. Conversely, if any declaration of an entity has an *alignment-specifier*, every defining declaration of that entity shall specify an equivalent alignment. No diagnostic is required if declarations of an entity have different *alignment-specifiers* in different translation units. [Example:

```c
// Translation unit #1:
struct S { int x; } s, *p = &s;

// Translation unit #2:
struct alignas(16) S; // error: definition of S lacks alignment, no diagnostic required
extern S* p;
```
—end example]

7 [Example: An aligned buffer with an alignment requirement of A and holding N elements of type T can be declared as:

```c
alignas(T) alignas(A) T buffer[N];
```
Specifying `alignas(T)` ensures that the final requested alignment will not be weaker than `alignof(T)`, and therefore the program will not be ill-formed. — end example]

```
alignas(double) void f();                      // error: alignment applied to function
alignas(double) unsigned char c[sizeof(double)]; // array of characters, suitably aligned for a double
extern unsigned char c[sizeof(double)];       // no alignas necessary
alignas(float)
   extern unsigned char c[sizeof(double)];    // error: different alignment in declaration
— end example]
```

### 9.11.3 Carries dependency attribute

The `attribute-token` `carries_dependency` specifies dependency propagation into and out of functions. It shall appear at most once in each `attribute-list` and no `attribute-argument-clause` shall be present. The attribute may be applied to the `declarator-id` of a `parameter-declaration` in a function declaration or lambda, in which case it specifies that the initialization of the parameter carries a dependency to (6.8.2) each `lvalue-to-rvalue conversion (7.3.1)` of that object. The attribute may also be applied to the `declarator-id` of a function declaration, in which case it specifies that the return value, if any, carries a dependency to the evaluation of the function call expression.

The first declaration of a function shall specify the `carries_dependency` attribute for its `declarator-id` if any declaration of the function specifies the `carries_dependency` attribute. Furthermore, the first declaration of a function shall specify the `carries_dependency` attribute for a parameter if any declaration of that function specifies the `carries_dependency` attribute for that parameter. If a function or one of its parameters is declared with the `carries_dependency` attribute in its first declaration in one translation unit and the same function or one of its parameters is declared without the `carries_dependency` attribute in its first declaration in another translation unit, the program is ill-formed, no diagnostic required.

[Note: The `carries_dependency` attribute does not change the meaning of the program, but may result in generation of more efficient code. — end note]

```
/* Translation unit A. */

struct foo { int* a; int* b; };
std::atomic<struct foo *> foo_head[10];
int foo_array[10][10];

[[carries_dependency]] struct foo* f(int i) {
   return foo_head[i].load(memory_order::consume);
}
int g(int* x, int* y [[carries_dependency]]) {
   return kill_dependency(foo_array[*x][*y]);
}

/* Translation unit B. */

[[carries_dependency]] struct foo* f(int i);
int g(int* x, int* y [[carries_dependency]]);
int c = 3;

void h(int i) {
   struct foo* p;
   p = f(i);
   do_something_with(g(&c, p->a));
   do_something_with(g(p->a, &c));
}
```

The `carries_dependency` attribute on function `f` means that the return value carries a dependency out of `f`, so that the implementation need not constrain ordering upon return from `f`. Implementations of `f` and
its caller may choose to preserve dependencies instead of emitting hardware memory ordering instructions (a.k.a. fences). Function g’s second parameter has a carries_dependency attribute, but its first parameter does not. Therefore, function h’s first call to g carries a dependency into g, but its second call does not. The implementation might need to insert a fence prior to the second call to g. —end example

9.11.4 Contract attributes

9.11.4.1 Syntax

Contract attributes are used to specify preconditions, postconditions, and assertions for functions.

contract-attribute-specifier:
  [ [ expects contract-levelopt : conditional-expression ] ]
  [ [ ensures contract-levelopt identifieropt : conditional-expression ] ]
  [ [ assert contract-levelopt : conditional-expression ] ]
  contract-level:
    default
    audit
    axiom

An ambiguity between a contract-level and an identifier is resolved in favor of contract-level.

A contract-attribute-specifier using expects is a precondition. It expresses a function’s expectation on its arguments and/or the state of other objects using a predicate that is intended to hold upon entry into the function. The attribute may be applied to the function type of a function declaration.

A contract-attribute-specifier using ensures is a postcondition. It expresses a condition that a function should ensure for the return value and/or the state of objects using a predicate that is intended to hold upon exit from the function. The attribute may be applied to the function type of a function declaration. A postcondition may introduce an identifier to represent the glvalue result or the prvalue result object of the function. [Example:

```cpp
int f(char * c)
[ [ ensures res: res > 0 && c != nullptr ] ];
```

```cpp
int g(double * p)
[ [ ensures audit res: res != 0 && p != nullptr && *p <= 0.0 ] ];
```

—end example]

A contract-attribute-specifier using assert is an assertion. It expresses a condition that is intended to be satisfied where it appears in a function body. The attribute may be applied to a null statement (8.2). An assertion is checked by evaluating its predicate as part of the evaluation of the null statement it applies to.

Preconditions, postconditions, and assertions are collectively called contracts. The conditional-expression in a contract is contextually converted to bool (7.3); the converted expression is called the predicate of the contract. [Note: The predicate of a contract is potentially evaluated (6.2). —end note]

The only side effects of a predicate that are allowed in a contract-attribute-specifier are modifications of non-volatile objects whose lifetime began and ended within the evaluation of the predicate. An evaluation of a predicate that exits via an exception invokes the function std::terminate (13.5.1). The behavior of any other side effect is undefined. [Example:

```cpp
void push(int x, queue & q)
[ [ expects: !q.full() ] ]
[ [ ensures: !q.empty() ] ]
{
  /* ... */
  [ [ assert: q.is_valid() ] ];
  /* ... */
}
```

```cpp
int min = -42;
constexpr int max = 42;
```
constexpr int g(int x)
[[expects: min <= x]]  // error
[[expects: x < max]]  // OK
{
  // ... *
  [[assert: 2*x < max]];
  [[assert: ++min > 0]];
  // undefined behavior
  // ... *
}

—end example

9.11.4.2 Contract conditions

A contract condition is a precondition or a postcondition. The first declaration of a function shall specify all contract conditions (if any) of the function. Subsequent declarations shall either specify no contract conditions or the same list of contract conditions; no diagnostic is required if corresponding conditions will always evaluate to the same value. The list of contract conditions of a function shall be the same if the declarations of that function appear in different translation units; no diagnostic required. If a friend declaration is the first declaration of the function in a translation unit and has a contract condition, the declaration shall be a definition and shall be the only declaration of the function in the translation unit.

Two lists of contract conditions are the same if they consist of the same contract conditions in the same order. Two contract conditions are the same if their contract levels are the same and their predicates are the same. Two predicates contained in contract-attribute-specifiers are the same if they would satisfy the one-definition rule (6.2) were they to appear in function definitions, except for renaming of parameters, return value identifiers (if any), and template parameters.

[Note: A function pointer cannot include contract conditions. [Example:

typedef int (*fpt)() [[ensures r: r != 0]];  // error: contract condition not on a function declaration

int g(int x)
[[expects: x >= 0]]
[[ensures r: r > x]]
{
  return x+1;
}

int (*pf)(int) = g;  // OK
int x = pf(5);  // contract conditions of g are checked

—end example] —end note]

The predicate of a contract condition has the same semantic restrictions as if it appeared as the first expression-statement in the body of the function it applies to. Additional access restrictions apply to names appearing in a contract condition of a member function of class C:

(4.1) — Friendship is not considered (10.8.3).

(4.2) — For a contract condition of a public member function, no member of C or of an enclosing class of C is accessible unless it is a public member of C, or a member of a base class accessible as a public member of C (10.8.2).

(4.3) — For a contract condition of a protected member function, no member of C or of an enclosing class of C is accessible unless it is a public or protected member of C, or a member of a base class accessible as a public or protected member of C.

For names appearing in a contract condition of a non-member function, friendship is not considered. [Example:

class X {
public:
  int v() const;
  void f() [[expects: x > 0]];  // error: x is private
  void g() [[expects: v() > 0]];  // OK
  friend void r(int z) [[expects: z > 0]];  // OK
  friend void s(int z) [[expects: z > x]];  // error: x is private
protected:
  int w();

§ 9.11.4.2 214
void h() [[expects: x > 0]]; // error: x is private
void i() [[ensures: y > 0]]; // OK
void j() [[ensures: w() > 0]]; // OK
int y;
private:
  void k() [[expects: x > 0]]; // OK
  int x;
};

class Y : public X {
  public:
    void a() [[expects: v() > 0]]; // OK
    void b() [[ensures: w() > 0]]; // error: w is protected
  protected:
    void c() [[expects: w() > 0]]; // OK
};

A precondition is checked by evaluating its predicate immediately before starting evaluation of the function body. [Note: The function body includes the function-try-block (Clause 13) and the ctor-initializer (10.9.2). — end note] A postcondition is checked by evaluating its predicate immediately before returning control to the caller of the function. [Note: The lifetime of local variables and temporaries has ended. Exiting via an exception or via longjmp (16.12.2) is not considered returning control to the caller of the function. — end note]

If a function has multiple preconditions, their evaluation (if any) will be performed in the order they appear lexically. If a function has multiple postconditions, their evaluation (if any) will be performed in the order they appear lexically. [Example:

```c
void f(int * p)
  [[expects: p != nullptr]] // #1
  [[ensures: *p == 1]] // #3
  [[expects: *p == 0]] // #2
{
  *p = 1;
}
```

— end example]

If a postcondition odr-uses (6.2) a parameter in its predicate and the function body makes direct or indirect modifications of the value of that parameter, the behavior is undefined. [Example:

```c
int f(int x)
  [[ensures r: r == x]]
{
  return ++x; // undefined behavior
}

int g(int * p)
  [[ensures r: p != nullptr]]
{
  *p = 42; // OK, p is not modified
}

int h(int x)
  [[ensures r: r == x]]
{
  potentially_modify(x); // undefined behavior if x is modified
  return x;
}
```

— end example]

9.11.4.3 Checking contracts [dcl.attr.contract.check]

If the contract-level of a contract-attribute-specifier is absent, it is assumed to be default. [Note: A default contract-level is expected to be used for those contracts where the cost of run-time checking is assumed to be
small (or at least not expensive) compared to the cost of executing the function. An audit contract-level is expected to be used for those contracts where the cost of run-time checking is assumed to be large (or at least significant) compared to the cost of executing the function. An axiom contract-level is expected to be used for those contracts that are formal comments and are not evaluated at run-time. — end note]

[Note: Multiple contract conditions may be applied to a function type with the same or different contract-levels. [Example:

```cpp
int z;

bool is_prime(int k);

void f(int x)
    [[expects: x > 0]]
    [[expects audit: is_prime(x)]]
    [[ensures: z > 10]]
{
    /* ... */
}
— end example] — end note]

3 A translation may be performed with one of the following build levels: off, default, or audit. A translation with build level set to off performs no checking for any contract. A translation with build level set to default performs checking for default contracts. A translation with build level set to audit performs checking for default and audit contracts. If no build level is explicitly selected, the build level is default. The mechanism for selecting the build level is implementation-defined. The translation of a program consisting of translation units where the build level is not the same in all translation units is conditionally-supported. There should be no programmatic way of setting, modifying, or querying the build level of a translation unit.

4 During constant expression evaluation (7.7), only predicates of checked contracts are evaluated. In other contexts, it is unspecified whether the predicate for a contract that is not checked under the current build level is evaluated; if the predicate of such a contract would evaluate to false, the behavior is undefined.

5 The violation handler of a program is a function of type “`noexcept opt function of (lvalue reference to const std::contract_violation) returning void`”, and is specified in an implementation-defined manner. The violation handler is invoked when the predicate of a checked contract evaluates to false (called a contract violation). There should be no programmatic way of setting or modifying the violation handler. It is implementation-defined how the violation handler is established for a program and how the std::contractViolation (16.8.2) argument value is set, except as specified below. If a precondition is violated, the source location of the violation is implementation-defined. [Note: Implementations are encouraged but not required to report the caller site. — end note] If a postcondition is violated, the source location of the violation is the source location of the function definition. If an assertion is violated, the source location of the violation is the source location of the statement to which the assertion is applied.

6 If a user-provided violation handler exits by throwing an exception and a contract is violated on a call to a function with a non-throwing exception specification, then the behavior is as if the exception escaped the function body. [Note: The function std::terminate is invoked (13.5.1). — end note] [Example:

```cpp
void f(int x) [[expects: x > 0]];

void g() {
    f(0);
    /* ... */
}                      // std::terminate() if violation handler throws
— end example]

7 A translation may be performed with one of the following violation continuation modes: off or on. A translation with violation continuation mode set to off terminates execution by invoking the function std::terminate (13.5.1) after completing the execution of the violation handler. A translation with a violation continuation mode set to on continues execution after completing the execution of the violation handler. If no continuation mode is explicitly selected, the default continuation mode is off. [Note: A continuation mode set to on provides the opportunity to install a logging handler to instrument a pre-existing code base and fix errors before enforcing checks. — end note] [Example:

```cpp
void f(int x) [[expects: x > 0]];

§ 9.11.4.3 216

```c
void g() {
    f(0); // std::terminate() after handler if continuation mode is off;
    /* ... */
}

— end example]
```

### § 9.11.5 Deprecated attribute

The attribute-token `deprecated` can be used to mark names and entities whose use is still allowed, but is discouraged for some reason. [Note: In particular, `deprecated` is appropriate for names and entities that are deemed obsolescent or unsafe. — end note] It shall appear at most once in each `attribute-list`. An `attribute-argument-clause` may be present and, if present, it shall have the form:

```
( string-literal )
```

[Note: The `string-literal` in the `attribute-argument-clause` could be used to explain the rationale for deprecation and/or to suggest a replacing entity. — end note]

The attribute may be applied to the declaration of a class, a `typedef-name`, a variable, a non-static data member, a function, a namespace, an enumeration, an enumerator, or a template specialization.

A name or entity declared without the `deprecated` attribute can later be redeclared with the attribute and vice-versa. [Note: Thus, an entity initially declared without the attribute can be marked as deprecated by a subsequent redeclaration. However, after an entity is marked as deprecated, later redeclarations do not un-deprecate the entity. — end note] Redeclarations using different forms of the attribute (with or without the `attribute-argument-clause` or with different `attribute-argument-clauses`) are allowed.

[Note: Implementations may use the `deprecated` attribute to produce a diagnostic message in case the program refers to a name or entity other than to declare it, after a declaration that specifies the attribute. The diagnostic message may include the text provided within the `attribute-argument-clause` of any `deprecated` attribute applied to the name or entity. — end note]

### § 9.11.6 Fallthrough attribute

The attribute-token `fallthrough` may be applied to a null statement (8.2); such a statement is a fallthrough statement. The attribute-token `fallthrough` shall appear at most once in each `attribute-list` and no `attribute-argument-clause` shall be present. A fallthrough statement may only appear within an enclosing `switch` statement (8.4.2). The next statement that would be executed after a fallthrough statement shall be a labeled statement whose label is a case label or default label for the same `switch` statement. The program is ill-formed if there is no such statement.

[Note: The use of a fallthrough statement is intended to suppress a warning that an implementation might otherwise issue for a case or default label that is reachable from another case or default label along some path of execution. Implementations should issue a warning if a fallthrough statement is not dynamically reachable. — end note]

[Example:

```c
void f(int n) {
    void g(), h(), i();
    switch (n) {
        case 1:
        case 2:
            g();
            [[fallthrough]]; // warning on fallthrough discouraged
            h();
        case 3:
            // implementation may warn on fallthrough
            i();
            [[fallthrough]]; // ill-formed
        }
    }

— end example]
```
9.11.7 Likelihood attributes

The attribute-tokens likely and unlikely may be applied to labels or statements. The attribute-tokens likely and unlikely shall appear at most once in each attribute-list and no attribute-argument-clause shall be present. The attribute-token likely shall not appear in an attribute-specifier-seq that contains the attribute-token unlikely.

[Note: The use of the likely attribute is intended to allow implementations to optimize for the case where paths of execution including it are arbitrarily more likely than any alternative path of execution that does not include such an attribute on a statement or label. The use of the unlikely attribute is intended to allow implementations to optimize for the case where paths of execution including it are arbitrarily more unlikely than any alternative path of execution that does not include such an attribute on a statement or label. A path of execution includes a label if and only if it contains a jump to that label. Excessive usage of either of these attributes is liable to result in performance degradation. — end note]

Example:

```c
void g(int);
int f(int n) {
    if (n > 5) [[unlikely]] {
        // n > 5 is considered to be arbitrarily unlikely
        g(0);
        return n * 2 + 1;
    }

    switch (n) {
        case 1:
            g(1);
            [[fallthrough]];
        [[likely]]
        case 2:  // n == 2 is considered to be arbitrarily more
            g(2);  // likely than any other value of n
            break;
    }
    return 3;
}
```

9.11.8 Maybe unused attribute

The attribute-token maybe_unused indicates that a name or entity is possibly intentionally unused. It shall appear at most once in each attribute-list and no attribute-argument-clause shall be present.

The attribute may be applied to the declaration of a class, a typedef-name, a variable, a non-static data member, a function, an enumeration, or an enumerator.

[Note: For an entity marked maybe_unused, implementations should not emit a warning that the entity is unused, or that the entity is used despite the presence of the attribute. — end note]

A name or entity declared without the maybe_unused attribute can later be redeclared with the attribute and vice versa. An entity is considered marked after the first declaration that marks it.

Example:

```c
[[maybe_unused]] void f([[maybe_unused]] bool thing1,  
                        [[maybe_unused]] bool thing2) {
    [[maybe_unused]] bool b = thing1 && thing2;
    assert(b);
}
```

Implementations should not warn that b is unused, whether or not NDEBUG is defined. — end example]

9.11.9 Nodiscard attribute

The attribute-token nodiscard may be applied to the declarator-id in a function declaration or to the declaration of a class or enumeration. It shall appear at most once in each attribute-list and no attribute-argument-clause shall be present.

[Note: A nodiscard call is a function call expression that calls a function previously declared nodiscard, or whose return type is a possibly cv-qualified class or enumeration type marked nodiscard. Appearance of
a `nodiscard` call as a potentially-evaluated discarded-value expression (7.2) is discouraged unless explicitly cast to `void`. Implementations should issue a warning in such cases. This is typically because discarding the return value of a `nodiscard` call has surprising consequences. —end note]

3 [Example:

```c
struct [[nodiscard]] error_info { /* ... */ };
error_info enable_missile_safety_mode();
void launch_missiles();
void test_missiles()
    { enable_missile_safety_mode(); // warning encouraged
      launch_missiles();
    }
error_info &foo();
void f() { foo(); } // warning not encouraged: not a `nodiscard` call, because neither
// the (reference) return type nor the function is declared `nodiscard`
```
—end example]

9.11.10 Noreturn attribute

1 The attribute-token `noreturn` specifies that a function does not return. It shall appear at most once in each attribute-list and no attribute-argument-clause shall be present. The attribute may be applied to the declarator-id in a function declaration. The first declaration of a function shall specify the `noreturn` attribute if any declaration of that function specifies the `noreturn` attribute. If a function is declared with the `noreturn` attribute in one translation unit and the same function is declared without the `noreturn` attribute in another translation unit, the program is ill-formed, no diagnostic required.

2 If a function `f` is called where `f` was previously declared with the `noreturn` attribute and `f` eventually returns, the behavior is undefined. [Note: The function may terminate by throwing an exception. —end note] [Note: Implementations should issue a warning if a function marked `[[noreturn]]` might return. —end note]

3 [Example:

```c
[[ noreturn ]] void f() {
    throw "error"; // OK
}

[[ noreturn ]] void q(int i) {
    // behavior is undefined if called with an argument <= 0
    if (i > 0)
        throw "positive";
}
```
—end example]

9.11.11 No unique address attribute

1 The attribute-token `no_unique_address` specifies that a non-static data member is a potentially-overlapping subobject (6.6.2). It shall appear at most once in each attribute-list and no attribute-argument-clause shall be present. The attribute may appertain to a non-static data member other than a bit-field.

2 [Note: The non-static data member can share the address of another non-static data member or that of a base class, and any padding that would normally be inserted at the end of the object can be reused as storage for other members. —end note] [Example:

```c
template<typename Key, typename Value,
         typename Hash, typename Pred, typename Allocator>
class hash_map {
    [[no_unique_address]] Hash hasher;
    [[no_unique_address]] Pred pred;
    [[no_unique_address]] Allocator alloc;
    Bucket *buckets;
    // ...
    public:
    // ...
};
```

Here, `hasher`, `pred`, and `alloc` could have the same address as `buckets` if their respective types are all empty. —end example]
10 Classes

1 A class is a type. Its name becomes a class-name (10.2) within its scope.

   class-name:
     identifier
     simple-template-id

A class-specifier or an elaborated-type-specifier (9.1.7.3) is used to make a class-name. An object of a class consists of a (possibly empty) sequence of members and base class objects.

   class-specifier:
     class-head { member-specification_opt }

   class-head:
     class-key attribute-specifier-seq_opt class-head-name class-virt-specifier_opt base-clause_opt
     class-key attribute-specifier-seq_opt base-clause_opt

   class-head-name:
     nested-name-specifier_opt class-name

   class-virt-specifier:
     final

   class-key:
     class
     struct
     union

A class declaration where the class-name in the class-head-name is a simple-template-id shall be an explicit specialization (12.8.3) or a partial specialization (12.6.5). A class-specifier whose class-head omits the class-head-name defines an unnamed class. [Note: An unnamed class thus can’t be final. —end note]

2 A class-name is inserted into the scope in which it is declared immediately after the class-name is seen. The class-name is also inserted into the scope of the class itself; this is known as the injected-class-name. For purposes of access checking, the injected-class-name is treated as if it were a public member name. A class-specifier is commonly referred to as a class definition. A class is considered defined after the closing brace of its class-specifier has been seen even though its member functions are in general not yet defined. The optional attribute-specifier-seq appertains to the class; the attributes in the attribute-specifier-seq are thereafter considered attributes of the class whenever it is named.

3 If a class-head-name contains a nested-name-specifier, the class-specifier shall refer to a class that was previously declared directly in the class or namespace to which the nested-name-specifier refers, or in an element of the inline namespace set (9.7.1) of that namespace (i.e., not merely inherited or introduced by a using-declaration), and the class-specifier shall appear in a namespace enclosing the previous declaration. In such cases, the nested-name-specifier of the class-head-name of the definition shall not begin with a decltype-specifier.

4 If a class is marked with the class-virt-specifier final and it appears as a class-or-decltype in a base-clause (10.6), the program is ill-formed. Whenever a class-key is followed by a class-head-name, the identifier final, and a colon or left brace, final is interpreted as a class-virt-specifier. [Example:

   struct A;
   struct A final {}; // OK: definition of struct A,
                      // not value-initialization of variable final

   struct X {
     struct C { constexpr operator int() { return 5; } };  // OK: definition of nested class B
     struct B final : C{};                                 // not declaration of a bit-field member final
   };
   —end example]

5 [Note: Complete objects of class type have nonzero size. Base class subobjects and members declared with the no_unique_address attribute (9.11.11) are not so constrained. —end note]
[Note: Class objects can be assigned (7.6.18, 11.5.3, 10.3.6), passed as arguments to functions (9.3, 10.3.5), and returned by functions (except objects of classes for which copying or moving has been restricted; see 9.4.3 and 10.8). Other plausible operators, such as equality comparison, can be defined by the user; see 11.5. — end note]

A union is a class defined with the class-key union; it holds at most one data member at a time (10.4). [Note: Aggregates of class type are described in 9.3.1. — end note]

10.1 Properties of classes

A trivially copyable class is a class:

(1.1) where each copy constructor, move constructor, copy assignment operator, and move assignment operator (10.3.5, 10.3.6) is either deleted or trivial,

(1.2) that has at least one non-deleted copy constructor, move constructor, copy assignment operator, or move assignment operator, and

(1.3) that has a trivial, non-deleted destructor (10.3.7).

A trivial class is a class that is trivially copyable and has one or more default constructors (10.3.4), all of which are either trivial or deleted and at least one of which is not deleted. [Note: In particular, a trivially copyable or trivial class does not have virtual functions or virtual base classes. — end note]

A class $S$ is a standard-layout class if it:

(3.1) has no non-static data members of type non-standard-layout class (or array of such types) or reference,

(3.2) has no virtual functions (10.6.2) and no virtual base classes (10.6.1),

(3.3) has the same access control (10.8) for all non-static data members,

(3.4) has no non-standard-layout base classes,

(3.5) has at most one base class subobject of any given type,

(3.6) has all non-static data members and bit-fields in the class and its base classes first declared in the same class, and

(3.7) has no element of the set $M(S)$ of types as a base class, where for any type $X$, $M(X)$ is defined as follows.\[109\] [Note: $M(X)$ is the set of the types of all non-base-class subobjects that may be at a zero offset in $X$. — end note]

(3.7.1) If $X$ is a non-union class type with no (possibly inherited (10.6)) non-static data members, the set $M(X)$ is empty.

(3.7.2) If $X$ is a non-union class type with a non-static data member of type $X_0$ that is either of zero size or is the first non-static data member of $X$ (where said member may be an anonymous union), the set $M(X)$ consists of $X_0$ and the elements of $M(X_0)$.

(3.7.3) If $X$ is a union type, the set $M(X)$ is the union of all $M(U_i)$ and the set containing all $U_i$, where each $U_i$ is the type of the $i$th non-static data member of $X$.

(3.7.4) If $X$ is an array type with element type $X_e$, the set $M(X)$ consists of $X_e$ and the elements of $M(X_e)$.

(3.7.5) If $X$ is a non-class, non-array type, the set $M(X)$ is empty.

[Example:

```cpp
struct B { int i; }; // standard-layout class
struct C : B { }; // standard-layout class
struct D : C { }; // standard-layout class
struct E : D { char : 4; }; // not a standard-layout class
struct Q {}
struct S : Q { }
struct T : Q { }
struct U : S, T { } // not a standard-layout class
```

— end example]

\[109\) This ensures that two subobjects that have the same class type and that belong to the same most derived object are not allocated at the same address (7.6.10).
A **standard-layout struct** is a standard-layout class defined with the **class-key struct** or the **class-key class**. A **standard-layout union** is a standard-layout class defined with the **class-key union**.

[Note: Standard-layout classes are useful for communicating with code written in other programming languages. Their layout is specified in 10.3. — end note]

[Example:

```cpp
struct N {  // neither trivial nor standard-layout
    int i;
    int j;
    virtual ~N();
};

struct T {  // trivial but not standard-layout
    int i;
    private:
        int j;
};

struct SL {  // standard-layout but not trivial
    int i;
    int j;
    ~SL();
};

struct POD {  // both trivial and standard-layout
    int i;
    int j;
};
```
—end example]

### 10.2 Class names

A class definition introduces a new type. **[Example:**

```cpp
struct X { int a; };
struct Y { int a; };
X a1;
Y a2;
int a3;
```
declares three variables of three different types. This implies that

```cpp
a1 = a2;  // error: Y assigned to X
a1 = a3;  // error: int assigned to X
```
are type mismatches, and that

```cpp
int f(X);
int f(Y);
```
declare an overloaded (Clause 11) function f() and not simply a single function f() twice. For the same reason,

```cpp
struct S { int a; };
struct S { int a; };  // error, double definition
```
is ill-formed because it defines S twice. —end example]

A class declaration introduces the class name into the scope where it is declared and hides any class, variable, function, or other declaration of that name in an enclosing scope (6.3). If a class name is declared in a scope where a variable, function, or enumerator of the same name is also declared, then when both declarations are in scope, the class can be referred to only using an **elaborated-type-specifier** (6.4.4). **[Example:**

```cpp
struct stat {
    // ...
};

stat gstat;  // use plain stat to define variable
```
int stat(struct stat*);  // redeclare stat as function

void f() {
    struct stat* ps;   // struct prefix needed to name struct stat
    stat(ps);         // call stat()
}

— end example] A declaration consisting solely of class-key identifier; is either a redeclaration of the name in
the current scope or a forward declaration of the identifier as a class name. It introduces the class name into
the current scope. [Example:

    struct s { int a; };

    void g() {
        struct s;     // hide global struct s with a block-scope declaration
        s* p;         // refer to local struct s
        struct s { char* p; };
        struct s;    // redeclaration, has no effect
    }

— end example] [Note: Such declarations allow definition of classes that refer to each other. [Example:

class Vector;

class Matrix {
    // ...
    friend Vector operator*(const Matrix&, const Vector&);
};

class Vector {
    // ...
    friend Vector operator*(const Matrix&, const Vector&);
};

Declaration of friends is described in 10.8.3, operator functions in 11.5. — end example] — end note]

3 [Note: An elaborated-type-specifier (9.1.7.3) can also be used as a type-specifier as part of a declaration. It
differs from a class declaration in that if a class of the elaborated name is in scope the elaborated name will
refer to it. — end note] [Example:

    struct s { int a; };

    void g(int s) {
        struct s* p = new struct s;  // global s
        p->a = s;                     // parameter s
    }

— end example]

4 [Note: The declaration of a class name takes effect immediately after the identifier is seen in the class
definition or elaborated-type-specifier. For example,

class A * A;

first specifies A to be the name of a class and then redefines it as the name of a pointer to an object of that
class. This means that the elaborated form class A must be used to refer to the class. Such artistry with
names can be confusing and is best avoided. — end note]

5 A typedef-name (9.1.3) that names a class type, or a cv-qualified version thereof, is also a class-name. If a
typedef-name that names a cv-qualified class type is used where a class-name is required, the cv-qualifiers are
ignored. A typedef-name shall not be used as the identifier in a class-head.

10.3 Class members

member-specification:
    member-declaration member-specification_opt
    access-specifier : member-specification_opt

§ 10.3
The member-specification in a class definition declares the full set of members of the class; no member can be added elsewhere. A direct member of a class X is a member of X that was first declared within the member-specification of X, including anonymous union objects (10.4.1) and direct members thereof. Members of a class are data members, member functions (10.3.1), nested types, enumerators, and member templates (12.6.2) and specializations thereof. [Note: A specialization of a static data member template is a static data member. A specialization of a member function template is a member function. A specialization of a member class template is a nested class. —end note]

A member-declaration does not declare new members of the class if it is

(2.1) — a friend declaration (10.8.3),
(2.2) — a static_assert-declaration,
(2.3) — a using-declaration (9.8), or
(2.4) — an empty-declaration.

For any other member-declaration, each declared entity that is not an unnamed bit-field (10.3.10) is a member of the class, and each such member-declaration shall either declare at least one member name of the class or declare at least one unnamed bit-field.

A data member is a non-function member introduced by a member-declarator. A member function is a member that is a function. Nested types are classes (10.2, 10.3.11) and enumerations (9.6) declared in the class and arbitrary types declared as members by use of a typedef declaration (9.1.3) or alias-declaration. The enumerators of an unscoped enumeration (9.6) defined in the class are members of the class.

A data member or member function may be declared static in its member-declaration, in which case it is a static member (see 10.3.9) (a static data member (10.3.9.2) or static member function (10.3.9.1), respectively) of the class. Any other data member or member function is a non-static member (a non-static data member or non-static member function (10.3.2), respectively). [Note: A non-static data member of non-reference type is a member subobject of a class object (6.6.2). —end note]

A member shall not be declared twice in the member-specification, except that

(5.1) — a nested class or member class template can be declared and then later defined, and
(5.2) — an enumeration can be introduced with an opaque-enum-declaration and later redeclared with an enum-specifier.
A single name can denote several member functions provided their types are sufficiently different (Clause 11). — end note

A complete-class context of a class is a

1. function body (9.4.1),
2. default argument (9.2.3.6),
3. noexcept-specifier (13.4),
4. contract condition (9.11.4), or
5. default member initializer

within the member-specification of the class. [Note: A complete-class context of a nested class is also a complete-class context of any enclosing class, if the nested class is defined within the member-specification of the enclosing class. — end note]

A class is considered a completely-defined object type (6.7) (or complete type) at the closing } of the class-specifier. The class is regarded as complete within its complete-class contexts; otherwise it is regarded as incomplete within its own class member-specification.

In a member-declarator, an = immediately following the declarator is interpreted as introducing a pure-specifier if the declarator-id has function type, otherwise it is interpreted as introducing a brace-or-equal-initializer. [Example:

```cpp
struct S {
    using T = void();
    T * p = 0; // OK: brace-or-equal-initializer
    virtual T f = 0; // OK: pure-specifier
};
— end example]
```

In a member-declarator for a bit-field, the constant-expression is parsed as the longest sequence of tokens that could syntactically form a constant-expression. [Example:

```cpp
int a;
const int b = 0;
struct S {
    int x1 : 8 = 42; // OK, "= 42" is brace-or-equal-initializer
    int x2 : 8 { 42 }; // OK, "{ 42 }" is brace-or-equal-initializer
    int y1 : true ? 8 : a = 42; // OK, brace-or-equal-initializer is absent
    int y2 : true ? 8 : b = 42; // error: cannot assign to const int
    int y3 : (true ? 8 : b) = 42; // OK, "= 42" is brace-or-equal-initializer
    int z : 1 || new int { 0 }; // OK, brace-or-equal-initializer is absent
};
— end example]
```

A brace-or-equal-initializer shall appear only in the declaration of a data member. (For static data members, see 10.3.9.2; for non-static data members, see 10.9.2 and 9.3.1). A brace-or-equal-initializer for a non-static data member specifies a default member initializer for the member, and shall not directly or indirectly cause the implicit definition of a defaulted default constructor for the enclosing class or the exception specification of that constructor.

A member shall not be declared with the extern storage-class-specifier. Within a class definition, a member shall not be declared with the thread_local storage-class-specifier unless also declared static.

The decl-specifier-seq may be omitted in constructor, destructor, and conversion function declarations only; when declaring another kind of member the decl-specifier-seq shall contain a type-specifier that is not a cv-qualifier. The member-declarator-list can be omitted only after a class-specifier or an enum-specifier or in a friend declaration (10.8.3). A pure-specifier shall be used only in the declaration of a virtual function (10.6.2) that is not a friend declaration.

The optional attribute-specifier-seq in a member-declaration appertains to each of the entities declared by the member-declarators; it shall not appear if the optional member-declarator-list is omitted.

A virt-specifier-seq shall contain at most one of each virt-specifier. A virt-specifier-seq shall appear only in the first declaration of a virtual member function (10.6.2).
The type of a non-static data member shall not be an incomplete type (6.7), an abstract class type (10.6.3), or a (possibly multi-dimensional) array thereof. [Note: In particular, a class \( C \) cannot contain a non-static member of class \( C \), but it can contain a pointer or reference to an object of class \( C \). — end note]

[Note: See 7.5.4 for restrictions on the use of non-static data members and non-static member functions. — end note]

[Note: The type of a non-static member function is an ordinary function type, and the type of a non-static data member is an ordinary object type. There are no special member function types or data member types. — end note]

[Example: A simple example of a class definition is

```c
struct tnode {
    char tword[20];
    int count;
    tnode* left;
    tnode* right;
};
```

which contains an array of twenty characters, an integer, and two pointers to objects of the same type. Once this definition has been given, the declaration

```c
tnode s, *sp;
```

declares \( s \) to be a \( tnode \) and \( sp \) to be a pointer to a \( tnode \). With these declarations, \( sp->count \) refers to the \( count \) member of the object to which \( sp \) points; \( s.left \) refers to the \( left \) subtree pointer of the object \( s \); and \( s.right->tword[0] \) refers to the initial character of the \( tword \) member of the \( right \) subtree of \( s \). — end example]

Non-static data members of a (non-union) class with the same access control (10.8) are allocated so that later members have higher addresses within a class object. The order of allocation of non-static data members with different access control is unspecified (10.8). Implementation alignment requirements might cause two adjacent members not to be allocated immediately after each other; so might requirements for space for managing virtual functions (10.6.2) and virtual base classes (10.6.1).

If \( T \) is the name of a class, then each of the following shall have a name different from \( T \):

(20.1) — every static data member of class \( T \);

(20.2) — every member function of class \( T \) [Note: This restriction does not apply to constructors, which do not have names (10.3.4) — end note] ;

(20.3) — every member of class \( T \) that is itself a type;

(20.4) — every member template of class \( T \);

(20.5) — every enumerator of every member of class \( T \) that is an unscoped enumerated type; and

(20.6) — every member of every anonymous union that is a member of class \( T \).

In addition, if class \( T \) has a user-declared constructor (10.3.4), every non-static data member of class \( T \) shall have a name different from \( T \).

The common initial sequence of two standard-layout struct (Clause 10) types is the longest sequence of non-static data members and bit-fields in declaration order, starting with the first such entity in each of the structs, such that corresponding entities have layout-compatible types, either both entities are declared with the no_unique_address attribute (9.11.11) or neither is, and either both entities are bit-fields with the same width or neither is a bit-field. [Example:

```c
struct A { int a; char b; };
struct B { const int b1; volatile char b2; };
struct C { int c; unsigned : 0; char b; };
struct D { int d; char b : 4; };
struct E { unsigned int e; char b; };
```

The common initial sequence of \( A \) and \( B \) comprises all members of either class. The common initial sequence of \( A \) and \( C \) and of \( A \) and \( D \) comprises the first member in each case. The common initial sequence of \( A \) and \( E \) is empty. — end example]

Two standard-layout struct (Clause 10) types are layout-compatible classes if their common initial sequence comprises all members and bit-fields of both classes (6.7).
Two standard-layout unions are layout-compatible if they have the same number of non-static data members and corresponding non-static data members (in any order) have layout-compatible types (6.7).

In a standard-layout union with an active member (10.4) of struct type $T_1$, it is permitted to read a non-static data member $m$ of another union member of struct type $T_2$ provided $m$ is part of the common initial sequence of $T_1$ and $T_2$; the behavior is as if the corresponding member of $T_1$ were nominated. [Example:

```c
struct T1 { int a, b; }
struct T2 { int c; double d; }
union U { T1 t1; T2 t2; }
int f() {
  U u = { { 1, 2 } }; // active member is t1
  return u.t2.c; // OK, as if u.t1.a were nominated
}
```

—end example] [Note: Reading a volatile object through a glvalue of non-volatile type has undefined behavior (9.1.7.1). —end note]

If a standard-layout class object has any non-static data members, its address is the same as the address of its first non-static data member if that member is not a bit-field. Its address is also the same as the address of each of its base class subobjects. [Note: There might therefore be unnamed padding within a standard-layout struct object inserted by an implementation, but not at its beginning, as necessary to achieve appropriate alignment. —end note] [Note: The object and its first subobject are pointer-interconvertible (6.7.2, 7.6.1.9). —end note]

10.3.1 Member functions

A member function may be defined (9.4) in its class definition, in which case it is an inline member function (9.1.6), or it may be defined outside of its class definition if it has already been declared but not defined in its class definition. A member function definition that appears outside of the class definition shall appear in a namespace scope enclosing the class definition. Except for member function definitions that appear outside of a class definition, and except for explicit specializations of member functions of class templates and member function templates (12.8) appearing outside of the class definition, a member function shall not be redeclared.

An inline member function (whether static or non-static) may also be defined outside of its class definition provided either its declaration in the class definition or its definition outside of the class definition declares the function as `inline` or `constexpr`. [Note: Member functions of a class in namespace scope have the linkage of that class. Member functions of a local class (10.5) have no linkage. See 6.5. —end note]

[Note: There can be at most one definition of a non-inline member function in a program. There may be more than one inline member function definition in a program. See 6.2 and 9.1.6. —end note]

If the definition of a member function is lexically outside its class definition, the member function name shall be qualified by its class name using the `::` operator. [Note: A name used in a member function definition (that is, in the parameter-declaration-clause including the default arguments (9.2.3.6) or in the member function body) is looked up as described in 6.4. —end note] [Example:

```c
struct X {
  typedef int T;
  static T count;
  void f(T);
};
void X::f(T t = count) {
```

The member function $f$ of class $X$ is defined in global scope; the notation $X::f$ specifies that the function $f$ is a member of class $X$ and in the scope of class $X$. In the function definition, the parameter type $T$ refers to the typedef member $T$ declared in class $X$ and the default argument $count$ refers to the static data member $count$ declared in class $X$. —end example]

[Note: A static local variable or local type in a member function always refers to the same entity, whether or not the member function is inline. —end note]

Previously declared member functions may be mentioned in friend declarations.

Member functions of a local class shall be defined inline in their class definition, if they are defined at all.
A member function can be declared (but not defined) using a typedef for a function type. The resulting member function has exactly the same type as it would have if the function declarator were provided explicitly, see 9.2.3.5. For example,

```cpp
typedef void fv();
typedef void fvc() const;
struct S {
    fv memfunc1; // equivalent to: void memfunc1();
    void memfunc2();
    fvc memfunc3; // equivalent to: void memfunc3() const;
};
fv S::* pmfv1 = &S::memfunc1;
fv S::* pmfv2 = &S::memfunc2;
fvc S::* pmfv3 = &S::memfunc3;
```

Also see 12.3. — end note]

### 10.3.2 Non-static member functions

A non-static member function may be called for an object of its class type, or for an object of a class derived (10.6) from its class type, using the class member access syntax (7.6.1.5, 11.3.1.1). A non-static member function may also be called directly using the function call syntax (7.6.1.2, 11.3.1.1) from within the body of a member function of its class or of a class derived from its class.

If a non-static member function of a class \( X \) is called for an object that is not of type \( X \), or of a type derived from \( X \), the behavior is undefined.

When an *id-expression* (7.5.4) that is not part of a class member access syntax (7.6.1.5) and not used to form a pointer to member (7.6.2.1) is used in a member of class \( X \) in a context where this can be used (7.5.2), if name lookup (6.4) resolves the name in the *id-expression* to a non-static non-type member of some class \( C \), and if either the *id-expression* is potentially evaluated or \( C \) is \( X \) or a base class of \( X \), the *id-expression* is transformed into a class member access expression (7.6.1.5) using \((\ast \text{this}) \ (10.3.2.1)\) as the postfix-expression to the left of the . operator. [Note: If \( C \) is not \( X \) or a base class of \( X \), the class member access expression is ill-formed. — end note] Similarly during name lookup, when an *unqualified-id* (7.5.4.1) used in the definition of a member function for class \( X \) resolves to a static member, an enumerator or a nested type of class \( X \) or of a base class of \( X \), the *unqualified-id* is transformed into a *qualified-id* (7.5.4.2) in which the *nested-name-specifier* names the class of the member function. These transformations do not apply in the template definition context (12.7.2.1). [Example:

```cpp
struct tnode {
    char tword[20];
    int count;
    tnode* left;
    tnode* right;
    void set(const char*, tnode* l, tnode* r);
};

void tnode::set(const char* w, tnode* l, tnode* r) {
    count = strlen(w)+1;
    if (sizeof(tword)<=count)
        perror("tnode string too long");
    strcpy(tword,w);
    left = l;
    right = r;
}

void f(tnode n1, tnode n2) {
    n1.set("abc",\&n2,0);
    n2.set("def",0,0);
}
```

In the body of the member function `tnode::set`, the member names `tword`, `count`, `left`, and `right` refer to members of the object for which the function is called. Thus, in the call `n1.set("abc",\&n2,0)`, `tword` refers...
to n1.tword, and in the call n2.set("def",0,0), it refers to n2.tword. The functions strlen, perror, and strcpy are not members of the class tnode and should be declared elsewhere. — end example]

4 A non-static member function may be declared const, volatile, or const volatile. These cv-qualifiers affect the type of the this pointer (10.3.2.1). They also affect the function type (9.2.3.5) of the member function; a member function declared const is a const member function, a member function declared volatile is a volatile member function and a member function declared const volatile is a const volatile member function. [Example:

```c
struct X {
  void g() const;
  void h() const volatile;
};
X::g is a const member function and X::h is a const volatile member function. — end example]
```

5 A non-static member function may be declared with a ref-qualifier (9.2.3.5); see 11.3.1.

6 A non-static member function may be declared virtual (10.6.2) or pure virtual (10.6.3).

10.3.2.1 The this pointer [class.this]

1 In the body of a non-static (10.3.1) member function, the keyword this is a prvalue whose value is the address of the object for which the function is called. The type of this in a member function of a class X is X*. If the member function is declared const, the type of this is const X*, if the member function is declared volatile, the type of this is volatile X*, and if the member function is declared const volatile, the type of this is const volatile X*. [Note: Thus in a const member function, the object for which the function is called is accessed through a const access path. — end note] [Example:

```c
struct s {
  int a;
  int f() const;
  int g() { return a++; } // error
  int h() const { return a++; }
};
int s::f() const { return a; }
```

The a++ in the body of s::h is ill-formed because it tries to modify (a part of) the object for which s::h() is called. This is not allowed in a const member function because this is a pointer to const; that is, *this has const type. — end example]

2 Similarly, volatile semantics (9.1.7.1) apply in volatile member functions when accessing the object and its non-static data members.

3 A cv-qualified member function can be called on an object-expression (7.6.1.5) only if the object-expression is as cv-qualified or less-cv-qualified than the member function. [Example:

```c
void k(s& x, const s& y) {
  x.f();
  x.g();
  y.f();
  y.g(); // error
}
```

The call y.g() is ill-formed because y is const and s::g() is a non-const member function, that is, s::g() is less-qualified than the object-expression y. — end example]

4 Constructors (10.3.4) and destructors (10.3.7) shall not be declared const, volatile or const volatile. [Note: However, these functions can be invoked to create and destroy objects with cv-qualified types, see 10.3.4 and 10.3.7. — end note]

10.3.3 Special member functions [special]

1 The default constructor (10.3.4), copy constructor, move constructor (10.3.5), copy assignment operator, move assignment operator (10.3.6), and destructor (10.3.7) are special member functions. [Note: The implementation will implicitly declare these member functions for some class types when the program does not explicitly declare them. The implementation will implicitly define them if they are odr-used (6.2) or

110) See, for example, <cstring> (20.5).
needed for constant evaluation (7.7). —end note] An implicitly-declared special member function is declared at the closing } of the class-specifier. Programs shall not define implicitly-declared special member functions.

2 Programs may explicitly refer to implicitly-declared special member functions. [Example: A program may explicitly call or form a pointer to member to an implicitly-declared special member function.

```
struct A {};
// implicitly declared A::operator=
struct B : A {
    B& operator=(const B &);
};
B& B::operator=(const B & s) {
    this->A::operator=(s);
    // well-formed
    return *this;
}
```

—end example]

3 [Note: The special member functions affect the way objects of class type are created, copied, moved, and destroyed, and how values can be converted to values of other types. Often such special member functions are called implicitly. —end note]

4 Special member functions obey the usual access rules (10.8). [Example: Declaring a constructor protected ensures that only derived classes and friends can create objects using it. —end example]

5 For a class, its non-static data members, its non-virtual direct base classes, and, if the class is not abstract (10.6.3), its virtual base classes are called its potentially constructed subobjects.

10.3.4 Constructors [class.ctor]

1 Constructors do not have names. In a declaration of a constructor, the declarator is a function declarator (9.2.3.5) of the form

```
ptr-declarator ( parameter-declaration-clause ) noexcept-specifier_opt attribute-specifier-seq_opt
```

where the ptr-declarator consists solely of an id-expression, an optional attribute-specifier-seq, and optional surrounding parentheses, and the id-expression has one of the following forms:

1.1 — in a member-declaration that belongs to the member-specification of a class or class template but is not a friend declaration (10.8.3), the id-expression is the injected-class-name (Clause 10) of the immediately-enclosing entity or

1.2 — in a declaration at namespace scope or in a friend declaration, the id-expression is a qualified-id that names a constructor (6.4.3.1).

The class-name shall not be a typedef-name. In a constructor declaration, each decl-specifier in the optional decl-specifier-seq shall be friend, inline, constexpr, or an explicit-specifier. [Example:

```
struct S {
    S(); // declares the constructor
};
S::S() {} // defines the constructor
```

—end example]

2 A constructor is used to initialize objects of its class type. Because constructors do not have names, they are never found during name lookup; however an explicit type conversion using the functional notation (7.6.1.3) will cause a constructor to be called to initialize an object. [Note: For initialization of objects of class type see 10.9. —end note]

3 A constructor can be invoked for a const, volatile or const volatile object. const and volatile semantics (9.1.7.1) are not applied on an object under construction. They come into effect when the constructor for the most derived object (6.6.2) ends.

4 A default constructor for a class X is a constructor of class X for which each parameter that is not a function parameter pack has a default argument (including the case of a constructor with no parameters). If there is no user-declared constructor for class X, a non-explicit constructor having no parameters is implicitly declared as defaulted (9.4). An implicitly-declared default constructor is an inline public member of its class.

5 A defaulted default constructor for class X is defined as deleted if:
5.1 — X is a union that has a variant member with a non-trivial default constructor and no variant member of X has a default member initializer,

5.2 — X is a non-union class that has a variant member M with a non-trivial default constructor and no variant member of the anonymous union containing M has a default member initializer,

5.3 — any non-static data member with no default member initializer (10.3) is of reference type,

5.4 — any non-variant non-static data member of const-qualified type (or array thereof) with no brace-or-equal-initializer does not have a user-provided default constructor,

5.5 — X is a union and all of its variant members are of const-qualified type (or array thereof),

5.6 — X is a non-union class and all members of any anonymous union member are of const-qualified type (or array thereof),

5.7 — any potentially constructed subobject, except for a non-static data member with a brace-or-equal-initializer, has class type M (or array thereof) and either M has no default constructor or overload resolution (11.3) as applied to find M’s corresponding constructor results in an ambiguity or in a function that is deleted or inaccessible from the defaulted default constructor, or

5.8 — any potentially constructed subobject has a type with a destructor that is deleted or inaccessible from the defaulted default constructor.

A default constructor is **trivial** if it is not user-provided and:

6.1 — its class has no virtual functions (10.6.2) and no virtual base classes (10.6.1), and

6.2 — no non-static data member of its class has a default member initializer (10.3), and

6.3 — all the direct base classes of its class have trivial default constructors, and

6.4 — for all the non-static data members of its class that are of class type (or array thereof), each such class has a trivial default constructor.

Otherwise, the default constructor is **non-trivial**.

7 A default constructor that is defaulted and not defined as deleted is *implicitly defined* when it is odr-used (6.2) to create an object of its class type (6.6.2), when it is needed for constant evaluation (7.7), or when it is explicitly defaulted after its first declaration. The implicitly-defined default constructor performs the set of initializations of the class that would be performed by a user-written default constructor for that class with no ctor-initializer (10.9.2) and an empty compound-statement. If that user-written default constructor would be ill-formed, the program is ill-formed. If that user-written default constructor would satisfy the requirements of a constexpr constructor (9.1.5), the implicitly-defined default constructor is constexpr. Before the defaulted default constructor for a class is implicitly defined, all the non-user-provided default constructors for its base classes and its non-static data members shall have been implicitly defined. [Note: An implicitly-declared default constructor has an exception specification (13.4). An explicitly-defaulted definition might have an implicit exception specification, see 9.4. — end note]

8 Default constructors are called implicitly to create class objects of static, thread, or automatic storage duration (6.6.4.1, 6.6.4.2, 6.6.4.3) defined without an initializer (9.3), are called to create class objects of dynamic storage duration (6.6.4.4) created by a new-expression in which the new-initializer is omitted (7.6.2.4), or are called when the explicit type conversion syntax (7.6.1.3) is used. A program is ill-formed if the default constructor for an object is implicitly used and the constructor is not accessible (10.8).

9 [Note: 10.9.2 describes the order in which constructors for base classes and non-static data members are called and describes how arguments can be specified for the calls to these constructors. — end note]

10 A return statement in the body of a constructor shall not specify a return value. The address of a constructor shall not be taken.

11 A functional notation type conversion (7.6.1.3) can be used to create new objects of its type. [Note: The syntax looks like an explicit call of the constructor. — end note] [Example:

```cpp
complex zz = complex(1,2.3);
cprint( complex(7.8,1.2) );
```

— end example]

12 An object created in this way is unnamed. [Note: 6.6.6 describes the lifetime of temporary objects. — end note] [Note: Explicit constructor calls do not yield lvalues, see 7.2.1. — end note]
During the construction of an object, if the value of the object or any of its subobjects is accessed through a glvalue that is not obtained, directly or indirectly, from the constructor’s this pointer, the value of the object or subobject thus obtained is unspecified. [Example:

```cpp
struct C;
void no_opt(C*);

C c;
C c() { no_opt(this); }

C cobj;
C c(C* cptr) { cptr->c = 1; cout << cobj.c * 100; }

extern struct D d;
D d = D(1);
```]

### 10.3.5 Copy/move constructors

1. A non-template constructor for class \( X \) is a copy constructor if its first parameter is of type \( X&, \) const \( X& \), volatile \( X& \) or const volatile \( X& \), and either there are no other parameters or else all other parameters have default arguments (9.2.3.6). [Example: \( X::X(const X&) \) and \( X::X(X&, int=1) \) are copy constructors.]

```cpp
struct X {
    X(int);
    X(const X&, int = 1);
};
X a(1); // calls X(int);
X b(a, 0); // calls X(const X&, int);
X c = b; // calls X(const X&, int);
```

2. A non-template constructor for class \( X \) is a move constructor if its first parameter is of type \( X&& \), const \( X&& \), volatile \( X&& \), or const volatile \( X&& \), and either there are no other parameters or else all other parameters have default arguments (9.2.3.6). [Example: \( Y::Y(Y&&) \) is a move constructor.]

```cpp
struct Y {
    Y(const Y&);
    Y(Y&&);
};
Y f(int);
Y d(f(1)); // calls Y(Y&&)
Y e = d; // calls Y(const Y&)
```

3. [Note: All forms of copy/move constructor may be declared for a class. [Example:

```cpp
struct X {
    X(const X&);
    X(X&); // OK
    X(X&&);
```]
X(const X&); // OK, but possibly not sensible

—end example] — end note]

4 [Note: If a class X only has a copy constructor with a parameter of type X&, an initializer of type const X or volatile X cannot initialize an object of type (possibly cv-qualified) X. [Example:

    struct X {
        X(); // default constructor
        X(X&); // copy constructor with a non-const parameter
    };
    const X cx;
    X x = cx; // error: X::X(X&) cannot copy cx into x

—end example] — end note]

5 A declaration of a constructor for a class X is ill-formed if its first parameter is of type (optionally cv-qualified) X and either there are no other parameters or else all other parameters have default arguments. A member function template is never instantiated to produce such a constructor signature. [Example:

    struct S {
        template<typename T> S(T);
        S();
    };
    S g;

    void h() {
        S a(g); // does not instantiate the member template to produce S::S<T>(T);
        // uses the implicitly declared copy constructor
    }

—end example]

6 If the class definition does not explicitly declare a copy constructor, a non-explicit one is declared implicitly. If the class definition declares a move constructor or move assignment operator, the implicitly declared copy constructor is defined as deleted; otherwise, it is defined as defaulted (9.4). The latter case is deprecated if the class has a user-declared copy assignment operator or a user-declared destructor.

7 The implicitly-declared copy constructor for a class X will have the form

    X::X(const X&)

if each potentially constructed subobject of a class type M (or array thereof) has a copy constructor whose first parameter is of type const M& or const volatile M&.111 Otherwise, the implicitly-declared copy constructor will have the form

    X::X(X&)

8 If the definition of a class X does not explicitly declare a move constructor, a non-explicit one will be implicitly declared as defaulted if and only if

8.1 — X does not have a user-declared copy constructor,
8.2 — X does not have a user-declared copy assignment operator,
8.3 — X does not have a user-declared move assignment operator, and
8.4 — X does not have a user-declared destructor.

[Note: When the move constructor is not implicitly declared or explicitly supplied, expressions that otherwise would have invoked the move constructor may instead invoke a copy constructor. — end note]

9 The implicitly-declared move constructor for class X will have the form

    X::X(X&&)

10 An implicitly-declared copy/move constructor is an inline public member of its class. A defaulted copy/move constructor for a class X is defined as deleted (9.4.3) if X has:

111) This implies that the reference parameter of the implicitly-declared copy constructor cannot bind to a volatile lvalue; see C.1.9.
— a potentially constructed subobject type $M$ (or array thereof) that cannot be copied/moved because overload resolution (11.3), as applied to find $M$'s corresponding constructor, results in an ambiguity or a function that is deleted or inaccessible from the defaulted constructor,

— a variant member whose corresponding constructor as selected by overload resolution is non-trivial,

— any potentially constructed subobject of a type with a deconstructor that is deleted or inaccessible from the defaulted constructor, or,

— for the copy constructor, a non-static data member of rvalue reference type.

A defaulted move constructor that is defined as deleted is ignored by overload resolution (11.3, 11.4). [Note: A deleted move constructor would otherwise interfere with initialization from an rvalue which can use the copy constructor instead. — end note]

11 A copy/move constructor for class $X$ is trivial if it is not user-provided and if:

11.1 — class $X$ has no virtual functions (10.6.2) and no virtual base classes (10.6.1), and

11.2 — the constructor selected to copy/move each direct base class subobject is trivial, and

11.3 — for each non-static data member of $X$ that is of class type (or array thereof), the constructor selected to copy/move that member is trivial;

otherwise the copy/move constructor is non-trivial.

12 A copy/move constructor that is defaulted and not defined as deleted is implicitly defined when it is odr-used (6.2), when it is needed for constant evaluation (7.7), or when it is explicitly defaulted after its first declaration. [Note: The copy/move constructor is implicitly defined even if the implementation elided its odr-use (6.2, 6.6.6). — end note] If the implicitly-defined constructor would satisfy the requirements of a constexpr constructor (9.1.5), the implicitly-defined constructor is constexpr.

13 Before the defaulted copy/move constructor for a class is implicitly defined, all non-user-provided copy/move constructors for its potentially constructed subobjects shall have been implicitly defined. [Note: An implicitly-declared copy/move constructor has an implied exception specification (13.4). — end note]

14 The implicitly-defined copy/move constructor for a non-union class $X$ performs a memberwise copy/move of its bases and members. [Note: Default member initializers of non-static data members are ignored. See also the example in 10.9.2. — end note] The order of initialization is the same as the order of initialization of bases and members in a user-defined constructor (see 10.9.2). Let $x$ be either the parameter of the constructor or, for the move constructor, an xvalue referring to the parameter. Each base or non-static data member is copied/moved in the manner appropriate to its type:

14.1 — if the member is an array, each element is direct-initialized with the corresponding subobject of $x$;

14.2 — if a member $m$ has rvalue reference type $T&&$, it is direct-initialized with $\text{static\_cast}<T&&(x.m)$;

14.3 — otherwise, the base or member is direct-initialized with the corresponding base or member of $x$.

Virtual base class subobjects shall be initialized only once by the implicitly-defined copy/move constructor (see 10.9.2).

15 The implicitly-defined copy/move constructor for a union $X$ copies the object representation (6.7) of $X$.

### 10.3.6 Copy/move assignment operator

A user-declared copy assignment operator $X::\text{operator=}\$ is a non-static non-template member function of class $X$ with exactly one parameter of type $X$, $X&$, const $X&$, volatile $X&$ or const volatile $X&$.112 [Note: An overloaded assignment operator must be declared to have only one parameter; see 11.5.3. — end note] [Note: More than one form of copy assignment operator may be declared for a class. — end note] [Note: If a class $X$ only has a copy assignment operator with a parameter of type $X&$, an expression of type const $X$ cannot be assigned to an object of type $X$. [Example:

```
struct X {
  X();
  X& operator=(X&);
};
```

112) Because a template assignment operator or an assignment operator taking an rvalue reference parameter is never a copy assignment operator, the presence of such an assignment operator does not suppress the implicit declaration of a copy assignment operator. Such assignment operators participate in overload resolution with other assignment operators, including copy assignment operators, and, if selected, will be used to assign an object.

§ 10.3.6
2 If the class definition does not explicitly declare a copy assignment operator, one is declared implicitly.
If the class definition declares a move constructor or move assignment operator, the implicitly declared
copy assignment operator is defined as deleted; otherwise, it is defined as defaulted (9.4). The latter
case is deprecated if the class has a user-declared copy constructor or a user-declared destructor. The
implicitly-declared copy assignment operator for a class \( X \) will have the form

\[
X& X::operator=(\text{const} \ X&) \quad \text{if}
\]

(2.1) — each direct base class \( B \) of \( X \) has a copy assignment operator whose parameter is of type \text{const} \( B\& \),
\text{const volatile} \( B\& \) or \( B \), and

(2.2) — for all the non-static data members of \( X \) that are of a class type \( M \) (or array thereof), each such class
type has a copy assignment operator whose parameter is of type \text{const} \( M\& \), \text{const volatile} \( M\& \) or \( M \).

Otherwise, the implicitly-declared copy assignment operator will have the form

\[
X& X::operator=(\text{X&})
\]

3 A user-declared move assignment operator \( X::operator= \) is a non-static non-template member function of
class \( X \) with exactly one parameter of type \( X&& \), \text{const} \( X&& \), \text{volatile} \( X&& \), or \text{const volatile} \( X&& \). [Note:
An overloaded assignment operator must be declared to have only one parameter; see 11.5.3. — end note]
[Note: More than one form of move assignment operator may be declared for a class. — end note]

4 If the definition of a class \( X \) does not explicitly declare a move assignment operator, one will be implicitly
declared as defaulted if and only if

(4.1) — \( X \) does not have a user-declared copy constructor,

(4.2) — \( X \) does not have a user-declared move constructor,

(4.3) — \( X \) does not have a user-declared copy assignment operator, and

(4.4) — \( X \) does not have a user-declared destructor.

[Example: The class definition

```c
struct S {
    int a;
    S& operator=(const S&) = default;
};
```

will not have a default move assignment operator implicitly declared because the copy assignment operator
has been user-declared. The move assignment operator may be explicitly defaulted.

```c
struct S {
    int a;
    S& operator=(const S&) = default;
    S& operator=(S&&) = default;
};
```

— end example]

5 The implicitly-declared move assignment operator for a class \( X \) will have the form

\[
X& X::operator=(X&&);
\]

6 The implicitly-declared copy/move assignment operator for class \( X \) has the return type \( X& \); it returns
the object for which the assignment operator is invoked, that is, the object assigned to. An implicitly-declared
copy/move assignment operator is an inline public member of its class.

7 A defaulted copy/move assignment operator for class \( X \) is defined as deleted if \( X \) has:

(7.1) — a variant member with a non-trivial corresponding assignment operator and \( X \) is a union-like class, or

113) This implies that the reference parameter of the implicitly-declared copy assignment operator cannot bind to a \text{volatile}
value; see C.4.9.
A non-static data member of `const` non-class type (or array thereof), or

A non-static data member of reference type, or

A direct non-static data member of class type `M` (or array thereof) or a direct base class `M` that cannot be copied/moved because overload resolution (11.3), as applied to find `M`'s corresponding assignment operator, results in an ambiguity or a function that is deleted or inaccessible from the defaulted assignment operator.

A defaulted move assignment operator that is defined as deleted is ignored by overload resolution (11.3, 11.4).

Because a copy/move assignment operator is implicitly declared for a class if not declared by the user, a base class copy/move assignment operator is always hidden by the corresponding assignment operator of a derived class (11.5.3). A `using-declaration` (9.8) that brings in from a base class an assignment operator with a parameter type that could be that of a copy/move assignment operator for the derived class is not considered an explicit declaration of such an operator and does not suppress the implicit declaration of the derived class operator; the operator introduced by the `using-declaration` is hidden by the implicitly-declared operator in the derived class.

A copy/move assignment operator for class `X` is trivial if it is not user-provided and if:

1. `X` has no virtual functions (10.6.2) and no virtual base classes (10.6.1), and
2. the assignment operator selected to copy/move each direct base class subobject is trivial, and
3. for each non-static data member of `X` that is of class type (or array thereof), the assignment operator selected to copy/move that member is trivial; otherwise the copy/move assignment operator is non-trivial.

A copy/move assignment operator for a class `X` that is defaulted and not defined as deleted is implicitly defined when it is odr-used (6.2) (e.g., when it is selected by overload resolution to assign to an object of its class type), when it is needed for constant evaluation (7.7), or when it is explicitly defaulted after its first declaration. The implicitly-defined copy/move assignment operator is `constexpr` if:

1. `X` is a literal type, and
2. the assignment operator selected to copy/move each direct base class subobject is a `constexpr` function, and
3. for each non-static data member of `X` that is of class type (or array thereof), the assignment operator selected to copy/move that member is a `constexpr` function.

Before the defaulted copy/move assignment operator for a class is implicitly defined, all non-user-provided copy/move assignment operators for its direct base classes and its non-static data members shall have been implicitly defined. [Note: An implicitly-declared copy/move assignment operator has an implied exception specification (13.4). — end note]

The implicitly-defined copy/move assignment operator for a non-union class `X` performs memberwise copy/move assignment of its subobjects. The direct base classes of `X` are assigned first, in the order of their declaration in the `base-specifier-list`, and then the immediate non-static data members of `X` are assigned, in the order in which they were declared in the class definition. Let `x` be either the parameter of the function or, for the move operator, an `xvalue` referring to the parameter. Each subobject is assigned in the manner appropriate to its type:

1. if the subobject is of class type, as if by a call to `operator=` with the subobject as the object expression and the corresponding subobject of `x` as a single function argument (as if by explicit qualification; that is, ignoring any possible virtual overriding functions in more derived classes);
2. if the subobject is an array, each element is assigned, in the manner appropriate to the element type;
3. if the subobject is of scalar type, the built-in assignment operator is used.

It is unspecified whether subobjects representing virtual base classes are assigned more than once by the implicitly-defined copy/move assignment operator. [Example:

```c
struct V { }
struct A : virtual V { }
struct B : virtual V { }
struct C : B, A { }
```
It is unspecified whether the virtual base class subobject $V$ is assigned twice by the implicitly-defined copy/move assignment operator for $C$. —end example]

The implicitly-defined copy assignment operator for a union $X$ copies the object representation (6.7) of $X$.

10.3.7 Destructors

1 In a declaration of a destructor, the declarator is a function declarator (9.2.3.5) of the form

\[ \text{ptr-declarator ( parameter-declaration-clause ) noexcept-specifier_opt attribute-specifier-seq_opt} \]

where the ptr-declarator consists solely of an id-expression, an optional attribute-specifier-seq, and optional surrounding parentheses, and the id-expression has one of the following forms:

(1.1) — in a member-declaration that belongs to the member-specification of a class or class template but is not a friend declaration (10.8.3), the id-expression is ~class-name and the class-name is the injected-class-name (Clause 10) of the immediately-enclosing entity or

(1.2) — in a declaration at namespace scope or in a friend declaration, the id-expression is nested-name-specifier ~class-name and the class-name names the same class as the nested-name-specifier.

The class-name shall not be a typedef-name. A destructor shall take no arguments (9.2.3.5). Each decl-specifier of the decl-specifier-seq of a destructor declaration (if any) shall be friend, inline, or virtual.

2 A destructor is used to destroy objects of its class type. The address of a destructor shall not be taken. A destructor can be invoked for a const, volatile or const volatile object. const and volatile semantics (9.1.7.1) are not applied on an object under destruction. They stop being in effect when the destructor for the most derived object (6.6.2) starts.

3 [Note: A declaration of a destructor that does not have a noexcept-specifier has the same exception specification as if it had been implicitly declared (13.4). —end note]

4 If a class has no user-declared destructor, a destructor is implicitly declared as defaulted (9.4). An implicitly-declared destructor is an inline public member of its class.

5 A defaulted destructor for a class $X$ is defined as deleted if:

(5.1) — $X$ is a union-like class that has a variant member with a non-trivial destructor,

(5.2) — any potentially constructed subobject has class type $M$ (or array thereof) and $M$ has a deleted destructor or a destructor that is inaccessible from the defaulted destructor,

(5.3) — or, for a virtual destructor, lookup of the non-array deallocation function results in an ambiguity or in a function that is deleted or inaccessible from the defaulted destructor.

6 A destructor is trivial if it is not user-provided and if:

(6.1) — the destructor is not virtual,

(6.2) — all of the direct base classes of its class have trivial destructors, and

(6.3) — for all of the non-static data members of its class that are of class type (or array thereof), each such class has a trivial destructor.

Otherwise, the destructor is non-trivial.

7 A destructor that is defaulted and not defined as deleted is implicitly defined when it is odr-used (6.2) or when it is explicitly defaulted after its first declaration.

8 Before the defaulted destructor for a class is implicitly defined, all the non-user-provided destructors for its base classes and its non-static data members shall have been implicitly defined.

9 After executing the body of the destructor and destroying any automatic objects allocated within the body, a destructor for class $X$ calls the destructors for $X$'s direct non-variant non-static data members, the destructors for $X$'s non-virtual direct base classes and, if $X$ is the type of the most derived class (10.9.2), its destructor calls the destructors for $X$'s virtual base classes. All destructors are called as if they were referenced with a qualified name, that is, ignoring any possible virtual overriding destructors in more derived classes. Bases and members are destroyed in the reverse order of the completion of their constructor (see 10.9.2). A return statement (8.6.3) in a destructor might not directly return to the caller; before transferring control to the caller, the destructors for the members and bases are called. Destructors for elements of an array are called in reverse order of their construction (see 10.9).
A destructor can be declared virtual (10.6.2) or pure virtual (10.6.3); if any objects of that class or any derived class are created in the program, the destructor shall be defined. If a class has a base class with a virtual destructor, its destructor (whether user- or implicitly-declared) is virtual.

A destructor is invoked implicitly

- for a constructed object with static storage duration (6.6.4.1) at program termination (6.8.3.4),
- for a constructed object with thread storage duration (6.6.4.2) at thread exit,
- for a constructed object with automatic storage duration (6.6.4.3) when the block in which an object is created exits (8.7),
- for a constructed temporary object when its lifetime ends (7.3.4, 6.6.6).

In each case, the context of the invocation is the context of the construction of the object. A destructor may also be invoked implicitly through use of a delete-expression (7.6.2.5) for a constructed object allocated by a new-expression (7.6.2.4); the context of the invocation is the delete-expression. [Note: An array of class type contains several subobjects for each of which the destructor is invoked. — end note] A destructor can also be invoked explicitly. A destructor is potentially invoked if it is invoked or as specified in 7.6.2.4, 9.3.1, 10.9.2, and 13.1. A program is ill-formed if a destructor that is potentially invoked is deleted or not accessible from the context of the invocation.

At the point of definition of a virtual destructor (including an implicit definition (10.3.7)), the non-array deallocation function is determined as if for the expression delete this appearing in a non-virtual destructor of the destructor’s class (see 7.6.2.5). If the lookup fails or if the deallocation function has a deleted definition (9.4), the program is ill-formed. [Note: This assures that a deallocation function corresponding to the dynamic type of an object is available for the delete-expression (10.11). — end note]

In an explicit destructor call, the destructor is specified by a ~ followed by a type-name or decltype-specifier that denotes the destructor’s class type. The invocation of a destructor is subject to the usual rules for member functions (10.3.1); that is, if the object is not of the destructor’s class type and not of a class derived from the destructor’s class type (including when the destructor is invoked via a null pointer value), the program has undefined behavior. [Note: Invoking delete on a null pointer does not call the destructor; see 7.6.2.5. — end note] [Example:

```c
struct B {
  virtual ~B() { }
};
struct D : B {
  ~D() { }
};
D D_object;
typedef B B_alias;
B* B_ptr = &D_object;

void f() {
  D_object.B::~B();       // calls B’s destructor
  B_ptr->~B();            // calls D’s destructor
  B_ptr->~B_alias();      // calls D’s destructor
  B_ptr->B_alias::~B();   // calls B’s destructor
  B_ptr->B_alias::~B_alias(); // calls B’s destructor
}
```

— end example] [Note: An explicit destructor call must always be written using a member access operator (7.6.1.5) or a qualified-id (7.5.4.2); in particular, the unary-expression ~X() in a member function is not an explicit destructor call (7.6.2.1). — end note]

[Note: Explicit calls of destructors are rarely needed. One use of such calls is for objects placed at specific addresses using a placement new-expression. Such use of explicit placement and destruction of objects can be necessary to cope with dedicated hardware resources and for writing memory management facilities. For example,

```c
void* operator new(std::size_t, void* p) { return p; }
```
struct X {
    X(int);  
    ~X();  
};

void f(X* p);

void g() {
    // rare, specialized use:
    char* buf = new char[sizeof(X)];
    X* p = new(buf) X(222);   // use buf[] and initialize
    f(p);
    p->X::~X();  // cleanup
}

—end note

16 Once a destructor is invoked for an object, the object no longer exists; the behavior is undefined if the
destructor is invoked for an object whose lifetime has ended (6.6.3). [Example: If the destructor for an
automatic object is explicitly invoked, and the block is subsequently left in a manner that would ordinarily
invoke implicit destruction of the object, the behavior is undefined. — end example]

17 [Note: The notation for explicit call of a destructor can be used for any scalar type name (7.6.1.4). Allowing
this makes it possible to write code without having to know if a destructor exists for a given type. For
example:

```c
typedef int I;
I* p;
p->I::~I();
—end note
```

10.3.8 Conversions

[class.conv]

1 Type conversions of class objects can be specified by constructors and by conversion functions. These
conversions are called user-defined conversions and are used for implicit type conversions (7.3), for initialization
(9.3), and for explicit type conversions (7.6.3, 7.6.1.9).

2 User-defined conversions are applied only where they are unambiguous (10.7, 10.3.8.2). Conversions obey the
access control rules (10.8). Access control is applied after ambiguity resolution (6.4).

3 [Note: See 11.3 for a discussion of the use of conversions in function calls as well as examples below. — end
note]

4 At most one user-defined conversion (constructor or conversion function) is implicitly applied to a single
value. [Example:

 ```c
 struct X {
     operator int();
 };

 struct Y {
     operator X();
 };

 Y a;
 int b = a;  // error, a.operator X().operator int() not tried
 int c = X(a);  // OK: a.operator X().operator int()
 —end example
 ```

5 User-defined conversions are used implicitly only if they are unambiguous. A conversion function in a derived
class does not hide a conversion function in a base class unless the two functions convert to the same type.
Function overload resolution (11.3.3) selects the best conversion function to perform the conversion. [Example:

 ```c
 struct X {
     operator int();
 };

 struct Y : X {
     operator char();
 };
 ```

§ 10.3.8
void f(Y& a) {
    if (a) { // ill-formed: X::operator int() or Y::operator char()
    }
}
—end example]

10.3.8.1 Conversion by constructor [class.convctor]

A constructor that is not explicit (9.1.2) specifies a conversion from the types of its parameters (if any) to
the type of its class. Such a constructor is called a converting constructor. [Example:

```c
struct X {
    X(int);
    X(const char*, int =0);
    X(int, int);
};

void f(X arg) {
    X a = 1;       // a = X(1)
    X b = "Jessie";// b = X("Jessie",0)
    a = 2;         // a = X(2)
    f(3);          // f(X(3))
    f(1, 2));      // f(X(1,2))
}
—end example]
```

2 [Note: An explicit constructor constructs objects just like non-explicit constructors, but does so only where the
direct-initialization syntax (9.3) or where casts (7.6.1.9, 7.6.3) are explicitly used; see also 11.3.1.4. A default
constructor may be an explicit constructor; such a constructor will be used to perform default-initialization
or value-initialization (9.3).] [Example:

```c
struct Z {
    explicit Z();
    explicit Z(int);
    explicit Z(int, int);
};

Z a;       // OK: default-initialization performed
Z b();     // OK: direct initialization syntax used
Z c = {};  // error: copy-list-initialization
Z a1 = 1;  // error: no implicit conversion
Z a3 = Z(1);  // OK: direct initialization syntax used
Z aZ(1);   // OK: direct initialization syntax used
Z* p = new Z(1); // OK: explicit cast used
Z a5 = static_cast<Z>(1); // OK: explicit cast used
Z a6 = { 3, 4 }; // error: no implicit conversion
—end example] — end note]

3 A non-explicit copy/move constructor (10.3.5) is a converting constructor. [Note: An implicitly-declared
copy/move constructor is not an explicit constructor; it may be called for implicit type conversions. — end
note]

10.3.8.2 Conversion functions [class.conv.fct]

A member function of a class X having no parameters with a name of the form

```
conversion-function-id:
    operator conversion-type-id
```

```
conversion-type-id:
    type-specifier-seq conversion-declarator
```

```
conversion-declarator:
    ptr-operator conversion-declarator
```
specifies a conversion from X to the type specified by the conversion-type-id. Such functions are called
conversion functions. A decl-specifier in the decl-specifier-seq of a conversion function (if any) shall be
neither a defining-type-specifier nor static. The type of the conversion function (9.2.3.5) is “function taking no parameter returning conversion-type-id”. A conversion function is never used to convert a (possibly cv-qualified) object to the (possibly cv-qualified) same object type (or a reference to it), to a (possibly cv-qualified) base class of that type (or a reference to it), or to (possibly cv-qualified) void.\footnote{These conversions are considered as standard conversions for the purposes of overload resolution (11.3.3.1, 11.3.3.1.4) and therefore initialization (9.3) and explicit casts (7.6.1.9). A conversion to void does not invoke any conversion function (7.6.1.9). Even though never directly called to perform a conversion, such conversion functions can be declared and can potentially be reached through a call to a virtual conversion function in a base class.} [Example:

```c
struct X {
    operator int();
    operator auto() -> short;    // error: trailing return type
};

void f(X a) {
    int i = int(a);
    i = (int)a;
    i = a;
}
```

In all three cases the value assigned will be converted by `X::operator int()`. —end example]\  

\footnote{A conversion function may be explicit (9.1.2), in which case it is only considered as a user-defined conversion for direct-initialization (9.3). Otherwise, user-defined conversions are not restricted to use in assignments and initializations. [Example:

```c
class Y { }
struct Z {
    explicit operator Y() const;
};

void h(Z z) {
    Y y1(z);    // OK: direct-initialization
    Y y2 = z;   // ill-formed: copy-initialization
    Y y3 = (Y)z; // OK: cast notation
}

void g(X a, X b) {
    int i = (a) ? 1+a : 0;
    int j = (a&&b) ? a+b : i;
    if (a) {
    }
}
```

—end example]  

The conversion-type-id shall not represent a function type nor an array type. The conversion-type-id in a conversion-function-id is the longest sequence of tokens that could possibly form a conversion-type-id. [Note: This prevents ambiguities between the declarator operator * and its expression counterparts. [Example:

```c
&ac.operator int*1; // syntax error:
// parsed as: &(ac.operator int *)&1
// not as: &ac.operator int*1
```

The * is the pointer declarator and not the multiplication operator. —end example] This rule also prevents ambiguities for attributes. [Example:

```c
operator int [[noreturn]] () ;    // error: noreturn attribute applied to a type
```

—end example] —end note]  

Conversion functions are inherited.

Conversion functions can be virtual.

A conversion function template shall not have a deduced return type (9.1.7.4). [Example:

```c
struct S {
    operator auto() const { return 10; }    // OK
```
10.3.9 Static members

A static member \( s \) of class \( X \) may be referred to using the `qualified-id` expression \( X::s \); it is not necessary to use the class member access syntax (7.6.1.5) to refer to a static member. A static member may be referred to using the class member access syntax, in which case the object expression is evaluated. [Example:

```cpp
struct process {
    static void reschedule();
};

process& g();

void f() {
    process::reschedule(); // OK: no object necessary
    g().reschedule();      // g() is called
}
```
—end example]

A static member may be referred to directly in the scope of its class or in the scope of a class derived (10.6) from its class; in this case, the static member is referred to as if a `qualified-id` expression was used, with the `nested-name-specifier` of the `qualified-id` naming the class scope from which the static member is referenced. [Example:

```cpp
int g();
struct X {
    static int g();
};
struct Y : X {
    static int i;
};
int Y::i = g(); // equivalent to Y::g();
```
—end example]

If an `unqualified-id` (7.5.4.1) is used in the definition of a static member following the member’s `declarator-id`, and name lookup (6.4.1) finds that the `unqualified-id` refers to a static member, enumerator, or nested type of the member’s class (or of a base class of the member’s class), the `unqualified-id` is transformed into a `qualified-id` expression in which the `nested-name-specifier` names the class scope from which the member is referenced. [Note: See 7.5.4 for restrictions on the use of non-static data members and non-static member functions. —end note]

Static members obey the usual class member access rules (10.8). When used in the declaration of a class member, the `static` specifier shall only be used in the member declarations that appear within the `member-specification` of the class definition. [Note: It cannot be specified in member declarations that appear in namespace scope. —end note]

10.3.9.1 Static member functions

[Note: The rules described in 10.3.1 apply to static member functions. —end note]

[Note: A static member function does not have a `this` pointer (10.3.2.1). —end note] A static member function shall not be `virtual`. There shall not be a static and a non-static member function with the same name and the same parameter types (11.1). A static member function shall not be declared `const`, `volatile`, or `const volatile`.

10.3.9.2 Static data members

[Note: A static data member is not part of the subobjects of a class. If a static data member is declared `thread-local` there is one copy of the member per thread. If a static data member is not declared `thread_local` there is one copy of the data member that is shared by all the objects of the class.

The declaration of a non-inline static data member in its class definition is not a definition and may be of an incomplete type other than `cv void`. The definition for a static data member that is not defined inline
in the class definition shall appear in a namespace scope enclosing the member’s class definition. In the
definition at namespace scope, the name of the static data member shall be qualified by its class name using
the :: operator. The initializer expression in the definition of a static data member is in the scope of its
class (6.3.7). [Example:

```cpp
class process {
    static process* run_chain;
    static process* running;
};
```

```cpp```

process* process::running = get_main();
process* process::run_chain = running;
```cpp```

The static data member `run_chain` of class `process` is defined in global scope; the notation `process::run_-
chain` specifies that the member `run_chain` is a member of class `process` and in the scope of class `process`. In
the static data member definition, the initializer expression refers to the static data member `running` of
class `process`. —end example]

[Note: Once the static data member has been defined, it exists even if no objects of its class have been
created. [Example: In the example above, `run_chain` and `running` exist even if no objects of class `process`
are created by the program. —end example] —end note]

3 If a non-volatile non-inline `const` static data member is of integral or enumeration type, its declaration
in the class definition can specify a `brace-or-equal-initializer` in which every `initializer-clause` that is an
assignment-expression is a constant expression (7.7). The member shall still be defined in a namespace scope
if it is odr-used (6.2) in the program and the namespace scope definition shall not contain an initializer. An
inline static data member may be defined in the class definition and may specify a `brace-or-equal-initializer`.
If the member is declared with the `constexpr` specifier, it may be redeclared in namespace scope with no
initializer (this usage is deprecated; see D.4). Declarations of other static data members shall not specify a
`brace-or-equal-initializer`.

4 [Note: There shall be exactly one definition of a static data member that is odr-used (6.2) in a program; no
diagnostic is required. —end note] Unnamed classes and classes contained directly or indirectly within
unnamed classes shall not contain static data members.

5 [Note: Static data members of a class in namespace scope have the linkage of that class (6.5). A local class
cannot have static data members (10.5). —end note]

6 Static data members are initialized and destroyed exactly like non-local variables (6.8.3.2, 6.8.3.3, 6.8.3.4).

7 A static data member shall not be `mutable` (9.1.1).

10.3.10 Bit-fields [class.bit]

A `member-declarator` of the form

```
identifier_opt attribute-specifier-seq_opt : constant-expression brace-or-equal-initializer_opt
```

specifies a bit-field; its length is set off from the bit-field name by a colon. The optional `attribute-specifier-seq`
appertains to the entity being declared. The bit-field attribute is not part of the type of the class member.
The `constant-expression` shall be an integral constant expression with a value greater than or equal to
zero. The value of the integral constant expression may be larger than the number of bits in the object
representation (6.7) of the bit-field’s type; in such cases the extra bits are padding bits (6.7). Allocation of
bit-fields within a class object is implementation-defined. Alignment of bit-fields is implementation-defined.
Bit-fields are packed into some addressable allocation unit. [Note: Bit-fields straddle allocation units on some
machines and not on others. Bit-fields are assigned right-to-left on some machines, left-to-right on others.
—end note]

2 A declaration for a bit-field that omits the `identifier` declares an `unnamed bit-field`. Unnamed bit-fields are
not members and cannot be initialized. An unnamed bit-field shall not be declared with a cv-qualified type.
[Note: An unnamed bit-field is useful for padding to conform to externally-imposed layouts. —end note]
As a special case, an unnamed bit-field with a width of zero specifies alignment of the next bit-field at an
allocation unit boundary. Only when declaring an unnamed bit-field may the value of the `constant-expression`
be equal to zero.

3 A bit-field shall not be a static member. A bit-field shall have integral or enumeration type (6.7.1). A `bool`
value can successfully be stored in a bit-field of any nonzero size. The `address-of` operator `&` shall not be
applied to a bit-field, so there are no pointers to bit-fields. A non-const reference shall not be bound to a
bit-field (9.3.3). [Note: If the initializer for a reference of type const T& is an lvalue that refers to a bit-field, the reference is bound to a temporary initialized to hold the value of the bit-field; the reference is not bound to the bit-field directly. See 9.3.3. — end note]

If the value true or false is stored into a bit-field of type bool of any size (including a one bit bit-field), the original bool value and the value of the bit-field shall compare equal. If the value of an enumerator is stored into a bit-field of the same enumeration type and the number of bits in the bit-field is large enough to hold all the values of that enumeration type (9.6), the original enumerator value and the value of the bit-field shall compare equal. [Example:

```c
enum BOOL { FALSE=0, TRUE=1 }; 
struct A {
  BOOL b:1;
};
A a;
void f() {
  a.b = TRUE;
  if (a.b == TRUE) // yields true
    { /* ... */ }
}
```

—end example]

10.3.11 Nested class declarations [class.nest]

A class can be declared within another class. A class declared within another is called a nested class. The name of a nested class is local to its enclosing class. The nested class is in the scope of its enclosing class. [Note: See 7.5.4 for restrictions on the use of non-static data members and non-static member functions. — end note]

[Example:

```c
int x;
int y;

struct enclose {
  int x;
  static int s;

  struct inner {
    void f(int i) {
      int a = sizeof(x); // OK: operand of sizeof is an unevaluated operand
      x = i; // error: assign to enclose::x
      s = i; // OK: assign to enclose::s
      ::x = i; // OK: assign to global x
      y = i; // OK: assign to global y
    }
    void g(enclose* p, int i) {
      p->x = i; // OK: assign to enclose::x
    }
  };

  inner* p = 0; // error: inner not in scope
};
```

—end example]

Member functions and static data members of a nested class can be defined in a namespace scope enclosing the definition of their class. [Example:

```c
struct enclose {
  struct inner {
    static int x;
    void f(int i);
  };

  int enclose::inner::x = 1;
};
```
If class \( X \) is defined in a namespace scope, a nested class \( Y \) may be declared in class \( X \) and later defined in the definition of class \( X \) or be later defined in a namespace scope enclosing the definition of class \( X \). [Example:

```cpp
class E {
    class I1; // forward declaration of nested class
    class I2;
    class I1 {}; // definition of nested class
};
class E::I2 {}; // definition of nested class
```
—end example]

Like a member function, a friend function (10.8.3) defined within a nested class is in the lexical scope of that class; it obeys the same rules for name binding as a static member function of that class (10.3.9), but it has no special access rights to members of an enclosing class.

### 10.3.12 Nested type names

Type names obey exactly the same scope rules as other names. In particular, type names defined within a class definition cannot be used outside their class without qualification. [Example:

```cpp
struct X {
    typedef int I;
    class Y { /* ... */ }; // forward declaration of nested class
    I a;
};
I b; // error
Y c; // error
X::Y d; // OK
X::I e; // OK
```
—end example]

### 10.4 Unions

In a union, a non-static data member is active if its name refers to an object whose lifetime has begun and has not ended (6.6.3). At most one of the non-static data members of an object of union type can be active at any time, that is, the value of at most one of the non-static data members can be stored in a union at any time. [Note: One special guarantee is made in order to simplify the use of unions: If a standard-layout union contains several standard-layout structs that share a common initial sequence (10.3), and if a non-static data member of an object of this standard-layout union type is active and is one of the standard-layout structs, it is permitted to inspect the common initial sequence of any of the standard-layout struct members; see 10.3. —end note]

The size of a union is sufficient to contain the largest of its non-static data members. Each non-static data member is allocated as if it were the sole member of a struct. [Note: A union object and its non-static data members are pointer-interconvertible (6.7.2, 7.6.1.9). As a consequence, all non-static data members of a union object have the same address. —end note]

A union can have member functions (including constructors and destructors), but it shall not have virtual (10.6.2) functions. A union shall not have base classes. A union shall not be used as a base class. If a union contains a non-static data member of reference type the program is ill-formed. [Note: Absent default member initializers (10.3), if any non-static data member of a union has a non-trivial default constructor (10.3.4), copy constructor, move constructor (10.3.5), copy assignment operator, move assignment operator (10.3.6), or destructor (10.3.7), the corresponding member function of the union must be user-provided or it will be implicitly deleted (9.4.3) for the union. —end note]

[Example: Consider the following union:

```cpp
union U {
    int i;
    float f;
    std::string s;
};
```
Since `std::string` (20.3) declares non-trivial versions of all of the special member functions, \( U \) will have an implicitly deleted default constructor, copy/move constructor, copy/move assignment operator, and destructor. To use \( U \), some or all of these member functions must be user-provided. — end example

5 When the left operand of an assignment operator involves a member access expression (7.6.1.5) that nominates a union member, it may begin the lifetime of that union member, as described below. For an expression \( E \), define the set \( S(E) \) of subexpressions of \( E \) as follows:

(5.1) — If \( E \) is of the form \( A.B \), \( S(E) \) contains the elements of \( S(A) \), and also contains \( A.B \) if \( B \) names a union member of a non-class, non-array type, or of a class type with a trivial default constructor that is not deleted, or an array of such types.

(5.2) — If \( E \) is of the form \( A[B] \) and is interpreted as a built-in array subscripting operator, \( S(E) \) is \( S(A) \) if \( A \) is of array type, \( S(B) \) if \( B \) is of array type, and empty otherwise.

(5.3) — Otherwise, \( S(E) \) is empty.

In an assignment expression of the form \( E_1 = E_2 \) that uses either the built-in assignment operator (7.6.18) or a trivial assignment operator (10.3.6), for each element \( X \) of \( S(E_1) \), if modification of \( X \) would have undefined behavior under 6.6.3, an object of the type of \( X \) is implicitly created in the nominated storage; no initialization is performed and the beginning of its lifetime is sequenced after the value computation of the left and right operands and before the assignment. [Note: This ends the lifetime of the previously-active member of the union, if any (6.6.3). — end note]

Example:

```c
union A { int x; int y[4]; };
struct B { A a; };
union C { B b; int k; };
int f()
{
  C c;  // does not start lifetime of any union member
  c.b.a.y[3] = 4;  // OK: S(c.b.a.y[3]) contains c.b and c.b.a.y;
  // creates objects to hold union members c.b and c.b.a.y
  return c.b.a.y[3];  // OK: c.b.a.y refers to newly created object (see 6.6.3)
}
```

Example:

```c
struct X { const int a; int b; };
union Y { X x; int k; };
void g()
{
  Y y = { { 1, 2 } };  // OK, y.x is active union member (10.3)
  int n = y.x.a;
  y.k = 4;  // OK: ends lifetime of y.x, y.k is active member of union
  y.x.b = n;
  // undefined behavior: y.x.b modified outside its lifetime,
  // S(y.x.b) is empty because X's default constructor is deleted,
  // so union member y.x's lifetime does not implicitly start
}
```

— end example

6 [Note: In general, one must use explicit destructor calls and placement new-expression to change the active member of a union. — end note] [Example: Consider an object \( u \) of a union type \( U \) having non-static data members \( m \) of type \( M \) and \( n \) of type \( N \). If \( M \) has a non-trivial destructor and \( N \) has a non-trivial constructor (for instance, if they declare or inherit virtual functions), the active member of \( u \) can be safely switched from \( m \) to \( n \) using the destructor and placement new-expression as follows:

```c
u.m.-~M();
new (&u.n) N;
```

— end example

### 10.4.1 Anonymous unions

A union of the form

```c
union { member-specification } ;
```

is called an anonymous union; it defines an unnamed type and an unnamed object of that type called an anonymous union object. Each member-declaration in the member-specification of an anonymous union shall either define a non-static data member or be a static_assert-declaration. [Note: Nested types, anonymous unions, and functions cannot be declared within an anonymous union. — end note] The names of the members of an anonymous union shall be distinct from the names of any other entity in the scope in which

§ 10.4.1  246
the anonymous union is declared. For the purpose of name lookup, after the anonymous union definition, the members of the anonymous union are considered to have been defined in the scope in which the anonymous union is declared. [Example:

```c
void f() {
  union { int a; const char* p; };  
  a = 1;  
  p = "Jennifer";  
}
```

Here `a` and `p` are used like ordinary (non-member) variables, but since they are union members they have the same address. — end example]

2 Anonymous unions declared in a named namespace or in the global namespace shall be declared static. Anonymous unions declared at block scope shall be declared with any storage class allowed for a block-scope variable, or with no storage class. A storage class is not allowed in a declaration of an anonymous union in a class scope. An anonymous union shall not have private or protected members (10.8). An anonymous union shall not have member functions.

3 A union for which objects, pointers, or references are declared is not an anonymous union. [Example:

```c
void f() {
  union { int aa; char* p; } obj, *ptr = &obj;  
  aa = 1;  
  // error  
  ptr->aa = 1;  
  // OK  
}
```

The assignment to plain `aa` is ill-formed since the member name is not visible outside the union, and even if it were visible, it is not associated with any particular object. — end example] [Note: Initialization of unions with no user-declared constructors is described in 9.3.1. — end note]

4 A union-like class is a union or a class that has an anonymous union as a direct member. A union-like class `X` has a set of variant members. If `X` is a union, a non-static data member of `X` that is not an anonymous union is a variant member of `X`. In addition, a non-static data member of an anonymous union that is a member of `X` is also a variant member of `X`. At most one variant member of a union may have a default member initializer. [Example:

```c
union U {  
  int x = 0;  
  union { int k;  
  };  
  union {  
  int z;  
  int y = 1;  
  // error: initialization for second variant member of U  
  };  
};
```

— end example]

10.5 Local class declarations [class.local]

1 A class can be declared within a function definition; such a class is called a local class. The name of a local class is local to its enclosing scope. The local class is in the scope of the enclosing scope, and has the same access to names outside the function as does the enclosing function. [Note: A declaration in a local class cannot odr-use (6.2) a local entity from an enclosing scope. — end note] [Example:

```c
int x;  
void f() {  
  static int s;  
  int x;  
  const int N = 5;  
  extern int q();  
  int arr[2];  
  auto [y, z] = arr;  

  struct local {  
  int g() { return x; }  
  // error: odr-use of non-odr-usable variable x  
  };
```
int h() { return s; }  // OK
int k() { return ::x; }  // OK
int l() { return q(); }  // OK
int m() { return N; }  // OK: not an odr-use
int* n() { return &N; }  // error: odr-use of non-odr-usable variable N
int p() { return y; }   // error: odr-use of non-odr-usable structured binding y
};

local* p = 0;        // error: local not in scope

—end example]

2 An enclosing function has no special access to members of the local class; it obeys the usual access rules (10.8). Member functions of a local class shall be defined within their class definition, if they are defined at all.

3 If class X is a local class a nested class Y may be declared in class X and later defined in the definition of class X or be later defined in the same scope as the definition of class X. A class nested within a local class is a local class.

4 A local class shall not have static data members.

### 10.6 Derived classes

A list of base classes can be specified in a class definition using the notation:

base-clause:
  : base-specifier-list
base-specifier-list:
  base-specifier ..opt
  base-specifier-list , base-specifier ..opt
base-specifier:
  attribute-specifier-seqopt class-or-decltype
  attribute-specifier-seqopt virtual access-specifieropt class-or-decltype
  attribute-specifier-seqopt access-specifier virtualopt class-or-decltype
class-or-decltype:
  nested-name-specifieropt class-name
decltype-specifier
access-specifier:
private
protected
public

The optional attribute-specifier-seq appertains to the base-specifier.

2 A class-or-decltype shall denote a class type that is not an incompletely defined class (Clause 10). The class denoted by the class-or-decltype of a base-specifier is called a direct base class for the class being defined. During the lookup for a base class name, non-type names are ignored (6.3.10). If the name found is not a class-name, the program is ill-formed. A class B is a base class of a class D if it is a direct base class of D or a direct base class of one of D's base classes. A class is an indirect base class of another if it is a base class but not a direct base class. A class is said to be (directly or indirectly) derived from its (direct or indirect) base classes. [Note: See 10.8 for the meaning of access-specifier. —end note] Unless redeclared in the derived class, members of a base class are also considered to be members of the derived class. Members of a base class other than constructors are said to be inherited by the derived class. Constructors of a base class can also be inherited as described in 9.8. Inherited members can be referred to in expressions in the same manner as other members of the derived class, unless their names are hidden or ambiguous (10.7). [Note: The scope resolution operator :: (7.5.4.2) can be used to refer to a direct or indirect base member explicitly. This allows access to a name that has been redeclared in the derived class. A derived class can itself serve as a base class subject to access control; see 10.8.2. A pointer to a derived class can be implicitly converted to a pointer to an accessible unambiguous base class (7.3.11). An lvalue of a derived class type can be bound to a reference to an accessible unambiguous base class (9.3.3). —end note]

3 The base-specifier-list specifies the type of the base class subobjects contained in an object of the derived class type. [Example:
struct Base {
    int a, b, c;
};
struct Derived : Base {
    int b;
};
struct Derived2 : Derived {
    int c;
};

Here, an object of class Derived2 will have a subobject of class Derived which in turn will have a subobject of class Base. — end example

4 A base-specifier followed by an ellipsis is a pack expansion (12.6.3).

5 The order in which the base class subobjects are allocated in the most derived object (6.6.2) is unspecified. [Note: A derived class and its base class subobjects can be represented by a directed acyclic graph (DAG) where an arrow means “directly derived from”. An arrow need not have a physical representation in memory. A DAG of subobjects is often referred to as a “subobject lattice”.

Base

↑

Derived1

↑

Derived2

Figure 2 — Directed acyclic graph

— end note]

6 [Note: Initialization of objects representing base classes can be specified in constructors; see 10.9.2. — end note]

7 [Note: A base class subobject might have a layout (6.6.4) different from the layout of a most derived object of the same type. A base class subobject might have a polymorphic behavior (10.9.4) different from the polymorphic behavior of a most derived object of the same type. A base class subobject may be of zero size (Clause 10); however, two subobjects that have the same class type and that belong to the same most derived object must not be allocated at the same address (7.6.10). — end note]

10.6.1 Multiple base classes [class.mi]

1 A class can be derived from any number of base classes. [Note: The use of more than one direct base class is often called multiple inheritance. — end note] [Example:

class A { /* ... */ };
class B { /* ... */ };
class C { /* ... */ };
class D : public A, public B, public C { /* ... */ };
— end example]

2 [Note: The order of derivation is not significant except as specified by the semantics of initialization by constructor (10.9.2), cleanup (10.3.7), and storage layout (10.3, 10.8.1). — end note]

3 A class shall not be specified as a direct base class of a derived class more than once. [Note: A class can be an indirect base class more than once and can be a direct and an indirect base class. There are limited things that can be done with such a class. The non-static data members and member functions of the direct base class cannot be referred to in the scope of the derived class. However, the static members, enumerations and types can be unambiguously referred to. — end note] [Example:

class X { /* ... */ };
class Y : public X, public X { /* ... */ };
// ill-formed

§ 10.6.1 249
class L { public: int next; /* ... */;
    class A : public L { /* ... */;
    class B : public L { /* ... */;
    class C : public A, public B { void f(); /* ... */; } // well-formed
    class D : public A, public L { void f(); /* ... */; } // well-formed

—end example

4 A base class specifier that does not contain the keyword virtual specifies a non-virtual base class. A base class specifier that contains the keyword virtual specifies a virtual base class. For each distinct occurrence of a non-virtual base class in the class lattice of the most derived class, the most derived object (6.6.2) shall contain a corresponding distinct base class subobject of that type. For each distinct base class that is specified virtual, the most derived object shall contain a single base class subobject of that type.

5 [Note: For an object of class type C, each distinct occurrence of a (non-virtual) base class L in the class lattice of C corresponds one-to-one with a distinct L subobject within the object of type C. Given the class C defined above, an object of class C will have two subobjects of class L as shown in Figure 3.

![Figure 3 — Non-virtual base](image)

In such lattices, explicit qualification can be used to specify which subobject is meant. The body of function C::f could refer to the member next of each L subobject:

```c
void C::f() { A::next = B::next; } // well-formed
```

Without the A:: or B:: qualifiers, the definition of C::f above would be ill-formed because of ambiguity (10.7).
—end note

6 [Note: In contrast, consider the case with a virtual base class:

```c
class V { /* ... */;
    class A : virtual public V { /* ... */;
    class B : virtual public V { /* ... */;
    class C : public A, public B { /* ... */;
```

![Figure 4 — Virtual base](image)

For an object c of class type C, a single subobject of type V is shared by every base class subobject of c that has a virtual base class of type V. Given the class C defined above, an object of class C will have one subobject of class V, as shown in Figure 4. —end note

7 [Note: A class can have both virtual and non-virtual base classes of a given type.

```c
class B { /* ... */;
    class X : virtual public B { /* ... */;
    class Y : virtual public B { /* ... */;
    class Z : public B { /* ... */;
    class AA : public X, public Y, public Z { /* ... */;
```
For an object of class AA, all virtual occurrences of base class B in the class lattice of AA correspond to a single B subobject within the object of type AA, and every other occurrence of a (non-virtual) base class B in the class lattice of AA corresponds one-to-one with a distinct B subobject within the object of type AA. Given the class AA defined above, class AA has two subobjects of class B: Z’s B and the virtual B shared by X and Y, as shown in Figure 5.

--- end note

10.6.2 Virtual functions  

[Note: Virtual functions support dynamic binding and object-oriented programming. — end note] A class that declares or inherits a virtual function is called a polymorphic class.

If a virtual member function vf is declared in a class Base and in a class Derived, derived directly or indirectly from Base, a member function vf with the same name, parameter-type-list (9.2.3.5), cv-qualification, and ref-qualifier (or absence of same) as Base::vf is declared, then Derived::vf is also virtual (whether or not it is so declared) and it overrides Base::vf. For convenience we say that any virtual function overrides itself. A virtual member function C::vf of a class object S is a final overrider unless the most derived class (6.6.2) of which S is a base class subobject (if any) declares or inherits another member function that overrides vf. In a derived class, if a virtual member function of a base class subobject has more than one final overrider the program is ill-formed. [Example:

```c
struct A {
    virtual void f();
};
struct B : virtual A {
    virtual void f();
};
struct C : B, virtual A {
    using A::f;
};

void foo() {
    C c;
    c.f(); // calls B::f, the final overrider
    c.C::f(); // calls A::f because of the using-declaration
}
```

— end example]

[Example:

```c
struct A { virtual void f(); };
struct B : A { };
struct C : A { void f(); };
struct D : B, C { }; // OK: A::f and C::f are the final overrides
                    // for the B and C subobjects, respectively
```

— end example]

3 [Note: A virtual member function does not have to be visible to be overridden, for example,

---

115) A function with the same name but a different parameter list (Clause 11) as a virtual function is not necessarily virtual and does not override. The use of the virtual specifier in the declaration of an overriding function is legal but redundant (has empty semantics). Access control (10.8) is not considered in determining overriding.
struct B {
    virtual void f();
};
struct D : B {
    void f(int);
};
struct D2 : D {
    void f();
};

the function f(int) in class D hides the virtual function f() in its base class B; D::f(int) is not a virtual function. However, f() declared in class D2 has the same name and the same parameter list as B::f(), and therefore is a virtual function that overrides the function B::f() even though B::f() is not visible in class D2. —end note]

4 If a virtual function f in some class B is marked with the virt-specifier final and in a class D derived from B a function D::f overrides B::f, the program is ill-formed. [Example:

struct B {
    virtual void f() const final;
};
struct D : B {
    void f() const; // error: D::f attempts to override final B::f
};
—end example]

5 If a virtual function is marked with the virt-specifier override and does not override a member function of a base class, the program is ill-formed. [Example:

struct B {
    virtual void f(int);
};
struct D : B {
    virtual void f(long) override; // error: wrong signature overriding B::f
    virtual void f(int) override; // OK
};
—end example]

6 A virtual function shall not have a trailing requires-clause (9.2). [Example:

struct A {
    virtual void f() requires true; // error: virtual function cannot be constrained (12.4.2)
};
—end example]

7 Even though destructors are not inherited, a destructor in a derived class overrides a base class destructor declared virtual; see 10.3.7 and 10.11.

8 The return type of an overriding function shall be either identical to the return type of the overridden function or covariant with the classes of the functions. If a function D::f overrides a function B::f, the return types of the functions are covariant if they satisfy the following criteria:

(8.1) — both are pointers to classes, both are lvalue references to classes, or both are rvalue references to classes

(8.2) — the class in the return type of B::f is the same class as the class in the return type of D::f, or is an unambiguous and accessible direct or indirect base class of the class in the return type of D::f

(8.3) — both pointers or references have the same cv-qualification and the class type in the return type of D::f has the same cv-qualification as or less cv-qualification than the class type in the return type of B::f.

9 If the class type in the covariant return type of D::f differs from that of B::f, the class type in the return type of D::f shall be complete at the point of declaration of D::f or shall be the class type D. When the

116) Multi-level pointers to classes or references to multi-level pointers to classes are not allowed.
overriding function is called as the final overrider of the overridden function, its result is converted to the type returned by the (statically chosen) overridden function (7.6.1.2). [Example:

```cpp
class B { }
class D : private B { friend class Derived; }
struct Base {
    virtual void vf1();
    virtual void vf2();
    virtual void vf3();
    virtual B* vf4();
    virtual B* vf5();
    void f();
};

struct No_good : public Base {
    D* vf4(); // error: B (base class of D) inaccessible
};

class A;
struct Derived : public Base {
    void vf1(); // virtual and overrides Base::vf1
    void vf2(int); // not virtual, hides Base::vf2
    char vf3(); // error: invalid difference in return type only
    D* vf4(); // OK: returns pointer to derived class
    A* vf5(); // error: returns pointer to incomplete class
    void f();
};

void g() {
    Derived d;
    Base* bp = &d; // standard conversion:
        // Derived* to Base*
    bp->vf1(); // calls Derived::vf1()
    bp->vf2(); // calls Base::vf2()
    bp->f(); // calls Base::f() (not virtual)
    B* p = bp->vf4(); // calls Derived::vf4() and converts the
        // result to B*
    Derived* dp = &d;
    D* q = dp->vf4(); // calls Derived::vf4() and does not
        // convert the result to B*
    dp->vf2(); // ill-formed: argument mismatch
}
```

--- end example]

[10] Note: The interpretation of the call of a virtual function depends on the type of the object for which it is called (the dynamic type), whereas the interpretation of a call of a non-virtual member function depends only on the type of the pointer or reference denoting that object (the static type) (7.6.1.2). — end note

[11] Note: The virtual specifier implies membership, so a virtual function cannot be a non-member (9.1.2) function. Nor can a virtual function be a static member, since a virtual function call relies on a specific object for determining which function to invoke. A virtual function declared in one class can be declared a friend (10.8.3) in another class. — end note

A virtual function declared in a class shall be defined, or declared pure (10.6.3) in that class, or both; no diagnostic is required (6.2).

[Example: Here are some uses of virtual functions with multiple base classes:

```cpp
struct A {
    virtual void f();
}

struct B1 : A {
    // note non-virtual derivation
    void f();
}
```

§ 10.6.2
struct B2 : A {
    void f();
};

struct D : B1, B2 { // D has two separate A subobjects
};

void foo() {
    D d;
    // A* ap = &d; // would be ill-formed: ambiguous
    B1* bip = &d;
    A* ap = bip;
    D* dp = &d;
    ap->f(); // calls D::B1::f
    dp->f(); // ill-formed: ambiguous
}

In class D above there are two occurrences of class A and hence two occurrences of the virtual member function A::f. The final overrider of B1::A::f is B1::f and the final overrider of B2::A::f is B2::f. —end example]

14 [Example: The following example shows a function that does not have a unique final overrider:

struct A {
    virtual void f();
};

struct VB1 : virtual A { // note virtual derivation
    void f();
};

struct VB2 : virtual A {
    void f();
};

struct Error : VB1, VB2 { // ill-formed
};

struct Okay : VB1, VB2 {
    void f();
};

Both VB1::f and VB2::f override A::f but there is no overrider of both of them in class Error. This example is therefore ill-formed. Class Okay is well-formed, however, because Okay::f is a final overrider. —end example]

15 [Example: The following example uses the well-formed classes from above.

struct VB1a : virtual A { // does not declare f
};

struct Da : VB1a, VB2 {
};

void foe() {
    VB1a* vblap = new Da;
    vblap->f(); // calls VB2::f
}

—end example]

16 Explicit qualification with the scope operator (7.5.4.2) suppresses the virtual call mechanism. [Example:

class B { public: virtual void f();
};
class D : public B { public: void f();
};

void D::f() { /* ... */ B::f();
}

Here, the function call in D::f really does call B::f and not D::f. —end example]
A function with a deleted definition (9.4) shall not override a function that does not have a deleted definition. Likewise, a function that does not have a deleted definition shall not override a function with a deleted definition.

If an overriding function specifies contract conditions (9.11.4), it shall specify the same list of contract conditions as its overridden functions; no diagnostic is required if corresponding conditions will always evaluate to the same value. Otherwise, it is considered to have the list of contract conditions from one of its overridden functions; the names in the contract conditions are bound, and the semantic constraints are checked, at the point where the contract conditions appear. Given a virtual function \( f \) with a contract condition that odr-uses \(*this\) (6.2), the class of which \( f \) is a direct member shall be be an unambiguous and accessible base class of any class in which \( f \) is overridden. If a function overrides more than one function, all of the overridden functions shall have the same list of contract conditions (9.11.4); no diagnostic is required if corresponding conditions will always evaluate to the same value. [Example:

```cpp
struct A {
    virtual void g() [[expects: x == 0]];
    int x = 42;
};

int x = 42;
struct B {
    virtual void g() [[expects: x == 0]];
}

struct C : A, B {
    virtual void g();  // error: preconditions of overridden functions are not the same
};

—end example]

10.6.3 Abstract classes
[Note: The abstract class mechanism supports the notion of a general concept, such as a shape, of which only more concrete variants, such as circle and square, can actually be used. An abstract class can also be used to define an interface for which derived classes provide a variety of implementations. —end note]

A virtual function is specified as a pure virtual function by using a pure-specifier (10.3) in the function declaration in the class definition. [Note: Such a function might be inherited: see below. —end note] A class is an abstract class if it has at least one pure virtual function. [Note: An abstract class can be used only as a base class of some other class; no objects of an abstract class can be created except as subobjects of a class derived from it (6.1, 10.3). —end note] A pure virtual function need be defined only if called with, or as if with (10.3.7), the qualified-id syntax (7.5.4.2). [Example:

```cpp
class point { /* ... */ }
class shape {
    // abstract class
    point center;
    public:
        point where() { return center; }
        void move(point p) { center=p; draw(); }
        virtual void rotate(int) = 0; // pure virtual
        virtual void draw() = 0; // pure virtual
    }
    —end example] [Note: A function declaration cannot provide both a pure-specifier and a definition — end note] [Example:

```cpp
struct C {
    virtual void f() = 0 { }  // ill-formed
};

—end example]

3 [Note: An abstract class type cannot be used as a parameter or return type of a function being defined (9.2.3.5) or called (7.6.1.2), except as specified in 9.1.7.2. Further, an abstract class type cannot be used as the type of an explicit type conversion (7.6.1.9, 7.6.1.10, 7.6.1.11), because the resulting prvalue would be of abstract class type (7.2.1). However, pointers and references to abstract class types can appear in such contexts. —end note]
A class is abstract if it contains or inherits at least one pure virtual function for which the final overrider is pure virtual. [Example:

```cpp
class ab_circle : public shape {
   int radius;
   public:
      void rotate(int) { }
      // ab_circle::draw() is a pure virtual
};
```

Since `shape::draw()` is a pure virtual function `ab_circle::draw()` is a pure virtual by default. The alternative declaration,

```cpp
class circle : public shape {
   int radius;
   public:
      void rotate(int) { }
      void draw();
      // a definition is required somewhere
};
```

would make class `circle` non-abstract and a definition of `circle::draw()` must be provided. — end example]

[Note: An abstract class can be derived from a class that is not abstract, and a pure virtual function may override a virtual function which is not pure. — end note]

Member functions can be called from a constructor (or destructor) of an abstract class; the effect of making a virtual call (10.6.2) to a pure virtual function directly or indirectly for the object being created (or destroyed) from such a constructor (or destructor) is undefined.

### 10.7 Member name lookup

Member name lookup determines the meaning of a name (*id-expression*) in a class scope (6.3.7). Name lookup can result in an *ambiguity*, in which case the program is ill-formed. For an *id-expression*, name lookup begins in the class scope of `this`; for a *qualified-id*, name lookup begins in the scope of the *nested-name-specifier*. Name lookup takes place before access control (6.4, 10.8).

The following steps define the result of name lookup for a member name *f* in a class scope `C`.

The *lookup set* for *f* in `C`, called `S(f,C)`, consists of two component sets: the *declaration set*, a set of members named *f*; and the *subobject set*, a set of subobjects where declarations of these members (possibly including *using-declarations*) were found. In the declaration set, *using-declarations* are replaced by the set of designated members that are not hidden or overridden by members of the derived class (9.8), and type declarations (including injected-class-names) are replaced by the types they designate. `S(f,C)` is calculated as follows:

If `C` contains a declaration of the name *f*, the declaration set contains every declaration of *f* declared in `C` that satisfies the requirements of the language construct in which the lookup occurs. [Note: Looking up a name in an *elaborated-type-specifier* (6.4.4) or *base-specifier* (10.6), for instance, ignores all non-type declarations, while looking up a name in a *nested-name-specifier* (6.4.3) ignores function, variable, and enumerator declarations. As another example, looking up a name in a *using-declaration* (9.8) includes the declaration of a class or enumeration that would ordinarily be hidden by another declaration of that name in the same scope. — end note] If the resulting declaration set is not empty, the subobject set contains `C` itself, and calculation is complete.

Otherwise (i.e., `C` does not contain a declaration of *f* or the resulting declaration set is empty), `S(f,C)` is initially empty. If `C` has base classes, calculate the lookup set for *f* in each direct base class subobject `B_i`, and merge each such lookup set `S(f,B_i)` into `S(f,C)`.

The following steps define the result of merging lookup set `S(f,B_i)` into the intermediate `S(f,C)`:

1. If each of the subobject members of `S(f,B_i)` is a base class subobject of at least one of the subobject members of `S(f,C)`, or if `S(f,B_i)` is empty, `S(f,C)` is unchanged and the merge is complete. Conversely, if each of the subobject members of `S(f,C)` is a base class subobject of at least one of the subobject members of `S(f,B_i)`, or if `S(f,C)` is empty, the new `S(f,C)` is a copy of `S(f,B_i)`.

2. Otherwise, if the declaration sets of `S(f,B_i)` and `S(f,C)` differ, the merge is ambiguous: the new `S(f,C)` is a lookup set with an invalid declaration set and the union of the subobject sets. In subsequent merges, an invalid declaration set is considered different from any other.
Otherwise, the new $S(f,C)$ is a lookup set with the shared set of declarations and the union of the subobject sets.

7 The result of name lookup for $f$ in $C$ is the declaration set of $S(f,C)$. If it is an invalid set, the program is ill-formed. [Example:

```c
struct A { int x; };       // S(x,A) = { { A::x }, { A } }
struct B { float x; };     // S(x,B) = { { B::x }, { B } }
struct C: public A, public B { };  // S(x,C) = { invalid, { A in C, B in C } }
struct D: public virtual C { };  // S(x,D) = S(x,C)
struct E: public virtual C { char x; }; // S(x,E) = { { E::x }, { E } }
struct F: public D, public E { };  // S(x,F) = S(x,E)

int main() {
    F f;
    f.x = 0;       // OK, lookup finds E::x
}
```

$S(x,F)$ is unambiguous because the $A$ and $B$ base class subobjects of $D$ are also base class subobjects of $E$, so $S(x,D)$ is discarded in the first merge step. —end example]

8 If the name of an overloaded function is unambiguously found, overload resolution (11.3) also takes place before access control. Ambiguities can often be resolved by qualifying a name with its class name. [Example:

```c
struct A {
    int f();
};
struct B {
    int f();
};
struct C : A, B {
    int f() { return A::f() + B::f(); }
};
```

—end example]

9 [Note: A static member, a nested type or an enumerator defined in a base class $T$ can unambiguously be found even if an object has more than one base class subobject of type $T$. Two base class subobjects share the non-static member subobjects of their common virtual base classes. —end note] [Example:

```c
struct V {
    int v;
};
struct A {
    int a;
    static int s;
    enum { e };
};
struct B : A, virtual V { }
struct C : A, virtual V { }
struct D : B, C { }

void f(D* pd) {
    pd->v++;       // OK: only one v (virtual)
    pd->s++;       // OK: only one s (static)
    int i = pd->e; // OK: only one e (enumerator)
    pd->a++;       // error, ambiguous: two a's in D
}
```

—end example]

10 [Note: When virtual base classes are used, a hidden declaration can be reached along a path through the subobject lattice that does not pass through the hiding declaration. This is not an ambiguity. The identical use with non-virtual base classes is an ambiguity; in that case there is no unique instance of the name that hides all the others. —end note] [Example:

```c
struct V { int f(); int x; }
struct W { int g(); int y; }
```
struct B : virtual V, W {
    int f(); int x;
    int g(); int y;
};
struct C : virtual V, W {
};
struct D : B, C {
    void glorp();
};

Figure 6 — Name lookup

The names declared in V and the left-hand instance of W are hidden by those in B, but the names declared in
the right-hand instance of W are not hidden at all.

void D::glorp() {
    x++;
    // OK: B::x hides V::x
    f();
    // OK: B::f() hides V::f()
    y++;
    // error: B::y and C's W::y
    g();
    // error: B::g() and C's W::g()
}

—end example]

11 An explicit or implicit conversion from a pointer to or an expression designating an object of a derived class
to a pointer or reference to one of its base classes shall unambiguously refer to a unique object representing
the base class. [Example:

struct V {
};
struct A {
};
struct B : A, virtual V {
};
struct C : A, virtual V {
};
struct D : B, C {
};

void g() {
    D d;
    B* pb = &d;
    A* pa = &d;         // error, ambiguous: C's A or B's A?
    V* pv = &d;        // OK: only one V subobject
}

—end example]

12 [Note: Even if the result of name lookup is unambiguous, use of a name found in multiple subobjects might
still be ambiguous (7.3.12, 7.6.1.5, 10.8.2). — end note] [Example:

struct B1 {
    void f();
    static void f(int);
    int i;
};
struct B2 {
    void f(double);
};
struct I1: B1 {
};
struct I2: B1 {
};
struct D: I1, I2, B2 {
    using B1::f;

§ 10.7
using B2::f;
void g() {  
  f();          // Ambiguous conversion of this
  f();          // Unambiguous (static)
  f(0.0);       // Unambiguous (only one B2)
  int B1::* mpB1 = &D::i;     // Unambiguous
  int D::* mpD = &D::i;        // Ambiguous conversion
}
};

—end example

10.8  Member access control  

A member of a class can be

(1.1) — private; that is, its name can be used only by members and friends of the class in which it is declared.

(1.2) — protected; that is, its name can be used only by members and friends of the class in which it is declared, by classes derived from that class, and by their friends (see 10.8.4).

(1.3) — public; that is, its name can be used anywhere without access restriction.

A member of a class can also access all the names to which the class has access. A local class of a member function may access the same names that the member function itself may access.\(^\text{117}\)

Members of a class defined with the keyword class are private by default. Members of a class defined with the keywords struct or union are public by default. [Example:

class X {
  int a;  
  // X::a is private by default
};

struct S {
  int a;  
  // S::a is public by default
};

—end example]

Access control is applied uniformly to all names, whether the names are referred to from declarations or expressions. [Note: Access control applies to names nominated by friend declarations (10.8.3) and using-declarations (9.8). — end note] In the case of overloaded function names, access control is applied to the function selected by overload resolution. [Note: Because access control applies to names, if access control is applied to a typedef name, only the accessibility of the typedef name itself is considered. The accessibility of the entity referred to by the typedef is not considered. For example,

class A {
  class B {  
    public:
    typedef B BB;
  };

  void f() {
    A::BB x;     // OK, typedef name A::BB is public
    A::B y;      // access error, A::B is private
  }

  —end note]

[Note: Access to members and base classes is controlled, not their visibility (6.3.10). Names of members are still visible, and implicit conversions to base classes are still considered, when those members and base classes are inaccessible. — end note] The interpretation of a given construct is established without regard to access control. If the interpretation established makes use of inaccessible member names or base classes, the construct is ill-formed.

All access controls in 10.8 affect the ability to access a class member name from the declaration of a particular entity, including parts of the declaration preceding the name of the entity being declared and, if the entity is

\(^{117}\) Access permissions are thus transitive and cumulative to nested and local classes.
a class, the definitions of members of the class appearing outside the class’s member-specification. [Note: This access also applies to implicit references to constructors, conversion functions, and destructors. — end note]

7 [Example:

```cpp
class A {
    typedef int I;  // private member
    I f();
    friend I g(I);
    static I x;
    template<int> struct Q;
    template<int> friend struct R;
    protected:
        struct B { };
};
```

```cpp
A::I A::f() { return 0; }
A::I g(A::I p = A::x);
A::I g(A::I p) { return 0; }
A::I A::x = 0;
template<A::I> struct A::Q { };
template<A::I> struct R { };

struct D: A::B, A { };
```

Here, all the uses of A::I are well-formed because A::f, A::x, and A::Q are members of class A and g and R are friends of class A. This implies, for example, that access checking on the first use of A::I must be deferred until it is determined that this use of A::I is as the return type of a member of class A. Similarly, the use of A::B as a base-specifier is well-formed because D is derived from A, so checking of base-specifiers must be deferred until the entire base-specifier-list has been seen. —end example]

8 The names in a default argument (9.2.3.6) are bound at the point of declaration, and access is checked at that point rather than at any points of use of the default argument. Access checking for default arguments in function templates and in member functions of class templates is performed as described in 12.8.1.

9 The names in a default template-argument (12.1) have their access checked in the context in which they appear rather than at any points of use of the default template-argument. [Example:

```cpp
class B { };
template <class T> class C {
    protected:
        typedef T TT;
};
template <class U, class V = typename U::TT> class D : public U { };

D <C<B> >* d;  // access error, C::TT is protected
```

—end example]

10.8.1 Access specifiers [class.access.spec]

1 Member declarations can be labeled by an access-specifier (10.6):

```
access-specifier : member-specification_opt
```

An access-specifier specifies the access rules for members following it until the end of the class or until another access-specifier is encountered. [Example:

```cpp
class X {
    int a;  // X::a is private by default: class used
    public:
        int b;  // X::b is public
        int c;  // X::c is public
};
```

—end example]

2 Any number of access specifiers is allowed and no particular order is required. [Example:
struct S {
    int a;        // S::a is public by default: struct used
protected:
    int b;        // S::b is protected
private:
    int c;        // S::c is private
public:
    int d;        // S::d is public
};

—end example]

3 [Note: The effect of access control on the order of allocation of data members is described in 10.3. — end note]

4 When a member is redeclared within its class definition, the access specified at its redeclaration shall be the same as at its initial declaration. [Example:

struct S {
    class A;
    enum E : int;
private:
    class A { };  // error: cannot change access
    enum E: int { e0 }; // error: cannot change access
};

—end example]

5 [Note: In a derived class, the lookup of a base class name will find the injected-class-name instead of the name of the base class in the scope in which it was declared. The injected-class-name might be less accessible than the name of the base class in the scope in which it was declared. — end note]

[Example:

class A { };
class B : private A { };
class C : public B {
    A* p;  // error: injected-class-name A is inaccessible
    ::A* q;  // OK
};

—end example]

10.8.2 Accessibility of base classes and base class members [class.access.base]

1 If a class is declared to be a base class (10.6) for another class using the public access specifier, the public members of the base class are accessible as public members of the derived class and protected members of the base class are accessible as protected members of the derived class. If a class is declared to be a base class for another class using the protected access specifier, the public and protected members of the base class are accessible as protected members of the derived class. If a class is declared to be a base class for another class using the private access specifier, the public and protected members of the base class are accessible as private members of the derived class.\footnote{118}

2 In the absence of an access-specifier for a base class, public is assumed when the derived class is defined with the class-key struct and private is assumed when the class is defined with the class-key class. [Example:

class B { /* ... */ };
class D1 : private B { /* ... */ };
class D2 : public B { /* ... */ };
class D3 : B { /* ... */ }; // B private by default
struct D4 : public B { /* ... */ };
struct D5 : private B { /* ... */ };
struct D6 : B { /* ... */ }; // B public by default
class D7 : protected B { /* ... */ };
struct D8 : protected B { /* ... */ };

118) As specified previously in 10.8, private members of a base class remain inaccessible even to derived classes unless friend declarations within the base class definition are used to grant access explicitly.
Here B is a public base of D2, D4, and D6, a private base of D1, D3, and D5, and a protected base of D7 and D8. — end example]

3 [Note: A member of a private base class might be inaccessible as an inherited member name, but accessible directly. Because of the rules on pointer conversions (7.3.11) and explicit casts (7.6.3), a conversion from a pointer to a derived class to a pointer to an inaccessible base class might be ill-formed if an implicit conversion is used, but well-formed if an explicit cast is used. For example,

```cpp
class B {
public:
    int mi;  // non-static member
    static int si; // static member
};
class D : private B {
};
class DD : public D {
    void f();
};

void DD::f() {
    mi = 3;    // error: mi is private in D
    si = 3;    // error: si is private in D
    ::B b;
    b.mi = 3;  // OK (b.mi is different from this->mi)
    b.si = 3;  // OK (b.si is different from this->si)
    ::B::si = 3; // OK
    ::B* bp1 = this; // error: B is a private base class
    ::B* bp2 = (::B*)this; // OK with cast
    bp2->mi = 3; // OK: access through a pointer to B.
}

— end note]

4 A base class B of N is accessible at R, if

(4.1) — an invented public member of B would be a public member of N, or
(4.2) — R occurs in a member or friend of class N, and an invented public member of B would be a private or protected member of N, or
(4.3) — R occurs in a member or friend of a class P derived from N, and an invented public member of B would be a private or protected member of P, or
(4.4) — there exists a class S such that B is a base class of S accessible at R and S is a base class of N accessible at R.

[Example:

```cpp
class B {
public:
    int m;
};
class S: private B {
    friend class N;
};
class N: private S {
    void f() {
        B* p = this;  // OK because class S satisfies the fourth condition above: B is a base class of N
        // accessible in f() because B is an accessible base class of S and S is an accessible base class of N.
    }
};

— end example]

5 If a base class is accessible, one can implicitly convert a pointer to a derived class to a pointer to that base class (7.3.11, 7.3.12). [Note: It follows that members and friends of a class X can implicitly convert an X* to a
pointer to a private or protected immediate base class of X. — end note] The access to a member is affected by the class in which the member is named. This naming class is the class in which the member name was looked up and found. [Note: This class can be explicit, e.g., when a qualified-id is used, or implicit, e.g., when a class member access operator (7.6.1.5) is used (including cases where an implicit “this->” is added). If both a class member access operator and a qualified-id are used to name the member (as in p->T::m), the class naming the member is the class denoted by the nested-name-specifier of the qualified-id (that is, T). — end note] A member m is accessible at the point R when named in class N if

(5.1) — m as a member of N is public, or
(5.2) — m as a member of N is private, and R occurs in a member or friend of class N, or
(5.3) — m as a member of N is protected, and R occurs in a member or friend of class N, or in a member of a class P derived from N, where m as a member of P is public, private, or protected, or
(5.4) — there exists a base class B of N that is accessible at R, and m is accessible at R when named in class B.

[Example:
    class B;
    class A {
      private:
        int i;
        friend void f(B*);
    };
    class B : public A {
    }
    void f(B* p) {
      p->i = 1;  // OK: B* can be implicitly converted to A*, and f has access to i in A
    }

    — end example] 6

If a class member access operator, including an implicit “this->”, is used to access a non-static data member or non-static member function, the reference is ill-formed if the left operand (considered as a pointer in the “.” operator case) cannot be implicitly converted to a pointer to the naming class of the right operand. [Note: This requirement is in addition to the requirement that the member be accessible as named. — end note]

10.8.3 Friends [class.friend]

A friend of a class is a function or class that is given permission to use the private and protected member names from the class. A class specifies its friends, if any, by way of friend declarations. Such declarations give special access rights to the friends, but they do not make the nominated friends members of the befriending class. [Example: The following example illustrates the differences between members and friends:

    class X {
      int a;
      friend void friend_set(X*, int);
    public:
      void member_set(int);
    };

    void friend_set(X* p, int i) { p->a = i; }
    void X::member_set(int i) { a = i; }

    void f() {
      X obj;
      friend_set(&obj,10);
      obj.member_set(10);
    }

    — end example]

Declaring a class to be a friend implies that the names of private and protected members from the class granting friendship can be accessed in the base-specifiers and member declarations of the befriended class. [Example:

    class A {
      class B {
      }
      friend class X;
    };

    — end example]

§ 10.8.3 263
A class shall not be defined in a friend declaration. [Example:

```cpp
class A {
friend class B { };
// error: cannot define class in friend declaration
};
```
]

A friend declaration that does not declare a function shall have one of the following forms:

```
friend elaborated-type-specifier;
friend simple-type-specifier;
friend typename-specifier;
```

[Note: A friend declaration may be the declaration in a template-declaration (Clause 12, 12.6.4). — end note]

If the type specifier in a friend declaration designates a (possibly cv-qualified) class type, that class is declared as a friend; otherwise, the friend declaration is ignored. [Example:

```cpp
class C;
typedef C Ct;

class X1 {
    friend C;
    // OK: class C is a friend
};

class X2 {
    friend Ct;
    friend D;
    // error: no type-name D in scope
    friend class D;
    // OK: elaborated-type-specifier declares new class
};

template <typename T> class R {
    friend T;
};

R<C> rc;  // class C is a friend of R<C>
R<int> Rl;  // OK: "friend int;" is ignored
```
]

A function first declared in a friend declaration has the linkage of the namespace of which it is a member (6.5). Otherwise, the function retains its previous linkage (9.1.1).

When a friend declaration refers to an overloaded name or operator, only the function specified by the parameter types becomes a friend. A member function of a class X can be a friend of a class Y. [Example:

```cpp
struct X : A::B {
    // OK: A::B accessible to friend
    A::B mx;
    // OK: A::B accessible to member of friend

class Y {
    A::B my;
    // OK: A::B accessible to nested member of friend
};
```
]

—end example] [Example:

```cpp
class X {
    enum { a=100 };
    friend class Y;
};

class Y {
    int v[X::a];  // OK, Y is a friend of X
};

class Z {
    int v[X::a];  // error: X::a is private
};
```
]
class Y {
friend char* X::foo(int);
friend X::X(char);  // constructors can be friends
friend X::~X();    // destructors can be friends
};

—end example]

A function can be defined in a friend declaration of a class if and only if the class is a non-local class (10.5), the function name is unqualified, and the function has namespace scope. [Example:

```cpp
class M {
friend void f() { }  // definition of global f, a friend of M,
                      // not the definition of a member function
};

—end example]

Such a function is implicitly an inline function (9.1.6). A friend function defined in a class is in the (lexical) scope of the class in which it is defined. A friend function defined outside the class is not (6.4.1).

No storage-class-specifier shall appear in the decl-specifier-seq of a friend declaration.

A name nominated by a friend declaration shall be accessible in the scope of the class containing the friend declaration. The meaning of the friend declaration is the same whether the friend declaration appears in the private, protected, or public (10.3) portion of the class member-specification.

Friendship is neither inherited nor transitive. [Example:

```cpp
class A {
friend class B;
int a;
};

class B {
friend class C;
};

class C {
void f(A* p) {
    p->a++;  // error: C is not a friend of A despite being a friend of a friend
}
};

class D : public B {
void f(A* p) {
    p->a++;  // error: D is not a friend of A despite being derived from a friend
}
};

—end example]

If a friend declaration appears in a local class (10.5) and the name specified is an unqualified name, a prior declaration is looked up without considering scopes that are outside the innermost enclosing non-class scope. For a friend function declaration, if there is no prior declaration, the program is ill-formed. For a friend class declaration, if there is no prior declaration, the class that is specified belongs to the innermost enclosing non-class scope, but if it is subsequently referenced, its name is not found by name lookup until a matching declaration is provided in the innermost enclosing non-class scope. [Example:

```cpp
class X;
void a();
void f() {
    class Y;
    extern void b();
    class A {
friend class X;  // OK, but X is a local class, not ::X
friend class Y;  // OK
friend class Z;  // OK, introduces local class Z
friend void a(); // error, ::a is not considered
```

§ 10.8.3
friend void b(); // OK
friend void c(); // error
};
X* px;       // OK, but ::X is found
Z* pz;      // error, no Z is found
}

— end example

10.8.4 Protected member access

An additional access check beyond those described earlier in 10.8 is applied when a non-static data member
or non-static member function is a protected member of its naming class (10.8.2). As described earlier,
access to a protected member is granted because the reference occurs in a friend or member of some class C.
If the access is to form a pointer to member (7.6.2.1), the nested-name-specifier shall denote C or a class
derived from C. All other accesses involve a (possibly implicit) object expression (7.6.1.5). In this case, the
class of the object expression shall be C or a class derived from C. [Example:

```cpp
class B {
  protected:
    int i;
    static int j;
};
class D1 : public B {
};
class D2 : public B {
  friend void fr(B*, D1*, D2*);
  void mem(B*, D1*);
};
void fr(B* pb, D1* p1, D2* p2) {
  pb->i = 1;   // ill-formed
  p1->i = 2;   // ill-formed
  p2->i = 3;   // OK (access through a D2)
  p2->B::i = 4; // OK (access through a D2, even though naming class is B)
  int B::* pmi_B = &B::i;   // ill-formed
  int B::* pmi_B2 = &D2::i;  // OK (type of &D2::i is int B::*
  B::j = 5;    // ill-formed (not a friend of naming class B)
  D2::j = 6;   // OK (because refers to static member)
}
void D2::mem(B* pb, D1* p1) {
  pb->i = 1;   // ill-formed
  p1->i = 2;   // ill-formed
  i = 3;       // OK (access through this)
  B::i = 4;    // OK (access through this, qualification ignored)
  int B::* pmi_B = &B::i;   // ill-formed
  int B::* pmi_B2 = &D2::i;  // OK
  j = 5;       // OK (because j refers to static member)
  B::j = 6;    // OK (because B::j refers to static member)
}
void g(B* pb, D1* p1, D2* p2) {
  pb->i = 1;   // ill-formed
  p1->i = 2;   // ill-formed
  p2->i = 3;   // ill-formed
}
— end example]
```

119) This additional check does not apply to other members, e.g., static data members or enumerator member constants.
10.8.5 Access to virtual functions

The access rules (10.8) for a virtual function are determined by its declaration and are not affected by the rules for a function that later overrides it. [Example:

```cpp
class B {
public:
  virtual int f();
};

class D : public B {
private:
  int f();
};

void f() {
  D d;
  B* pb = &d;
  D* pd = &d;

  pb->f(); // OK: B::f() is public, D::f() is invoked
  pd->f(); // error: D::f() is private
}
```
—end example]

Access is checked at the call point using the type of the expression used to denote the object for which the member function is called (B* in the example above). The access of the member function in the class in which it was defined (D in the example above) is in general not known.

10.8.6 Multiple access

If a name can be reached by several paths through a multiple inheritance graph, the access is that of the path that gives most access. [Example:

```cpp
class W { public: void f(); }; 
class A : private virtual W { }; 
class B : public virtual W { }; 
class C : public A, public B {
  void f() { W::f(); } // OK
};
```

Since W::f() is available to C::f() along the public path through B, access is allowed. —end example]

10.8.7 Nested classes

A nested class is a member and as such has the same access rights as any other member. The members of an enclosing class have no special access to members of a nested class; the usual access rules (10.8) shall be obeyed. [Example:

```cpp
class E {
  int x;
  class B { }

  class I {
    B b;
    int y;
    void f(E* p, int i) {
      p->x = i; // OK: E::I can access E::x
    }
  }

  int g(I* p) {
    return p->y; // error: I::y is private
  }
};
```
—end example]
10.9 Initialization

1. When no initializer is specified for an object of (possibly cv-qualified) class type (or array thereof), or the
   initializer has the form (), the object is initialized as specified in 9.3.

2. An object of class type (or array thereof) can be explicitly initialized; see 10.9.1 and 10.9.2.

3. When an array of class objects is initialized (either explicitly or implicitly) and the elements are initialized
   by constructor, the constructor shall be called for each element of the array, following the subscript order;
   see 9.2.3.4. [Note: Destructors for the array elements are called in reverse order of their construction. — end
   note]

10.9.1 Explicit initialization

1. An object of class type can be initialized with a parenthesized expression-list, where the expression-list
   is construed as an argument list for a constructor that is called to initialize the object. Alternatively, a
   single assignment-expression can be specified as an initializer using the = form of initialization. Either
   direct-initialization semantics or copy-initialization semantics apply; see 9.3. [Example:

   ```
   struct complex {
   complex();
   complex(double);
   complex(double,double);
   }

   complex sqrt(complex,complex);

   complex a(1);
   complex b = a;
   complex c = complex(1,2);
   complex d = sqrt(b,c);
   complex e;
   complex f = 3;
   complex g = { 1, 2 };
   ```

   // initialized by calling complex(double) with argument 1
   // initialized as a copy of a
   // initialized by calling complex(double, double) with arguments 1 and 2
   // initialized by calling sqrt(complex, complex) with d as its result object
   // initialized by calling complex()
   // initialized by calling complex(double) with argument 3
   // initialized by calling complex(double, double) with arguments 1 and 2

   —end example] [Note: Overloading of the assignment operator (11.5.3) has no effect on initialization. — end
   note]

2. An object of class type can also be initialized by a braced-init-list. List-initialization semantics apply; see 9.3
   and 9.3.4. [Example:

   ```
   complex v[6] = { 1, complex(1,2), complex(), 2 };
   ```

   Here, complex::complex(double) is called for the initialization of v[0] and v[3], complex::complex(double,
   double) is called for the initialization of v[1], complex::complex() is called for the initialization
   v[2], v[4], and v[5]. For another example,

   ```
   struct X {
   int i;
   float f;
   complex c;
   } x = { 99, 88.8, 77.7 };
   ```

   Here, x.i is initialized with 99, x.f is initialized with 88.8, and complex::complex(double) is called for
   the initialization of x.c. — end example] [Note: Braces can be elided in the initializer-list for any aggregate,
   even if the aggregate has members of a class type with user-defined type conversions; see 9.3.1. — end note]

3. [Note: If T is a class type with no default constructor, any declaration of an object of type T (or array thereof)
   is ill-formed if no initializer is explicitly specified (see 10.9 and 9.3). — end note]

4. [Note: The order in which objects with static or thread storage duration are initialized is described in 6.8.3.3
   and 8.7. — end note]

10.9.2 Initializing bases and members

1. In the definition of a constructor for a class, initializers for direct and virtual base class subobjects and
   non-static data members can be specified by a ctor-initializer, which has the form

   ```
   ctor-initializer:
   : mem-initializer-list
   ```
In a `mem-initializer-id` an initial unqualified `identifier` is looked up in the scope of the constructor’s class and, if not found in that scope, it is looked up in the scope containing the constructor’s definition. [Note: If the constructor’s class contains a member with the same name as a direct or virtual base class of the class, a `mem-initializer-id` naming the member or base class and composed of a single identifier refers to the class member. A `mem-initializer-id` for the hidden base class may be specified using a qualified name. —end note] Unless the `mem-initializer-id` names the constructor’s class, a non-static data member of the constructor’s class, or a direct or virtual base of that class, the `mem-initializer` is ill-formed.

A `mem-initializer-list` can initialize a base class using any `class-or-decltype` that denotes that base class type. [Example:

```c
struct A { A(); }; typedef A global_A;
struct B { }; struct C: public A, public B { C(); };
C::C(): global_A() {} // mem-initializer for base A
```
—end example]

If a `mem-initializer-id` is ambiguous because it designates both a direct non-virtual base class and an inherited virtual base class, the `mem-initializer` is ill-formed. [Example:

```c
struct A { A(); }; struct B: public virtual A { }; struct C: public A, public B { C(); };
C::C(): A() {} // ill-formed: which A?
```
—end example]

A `ctor-initializer` may initialize a variant member of the constructor’s class. If a `ctor-initializer` specifies more than one `mem-initializer` for the same member or for the same base class, the `ctor-initializer` is ill-formed.

A `mem-initializer-list` can delegate to another constructor of the constructor’s class using any `class-or-decltype` that denotes the constructor’s class itself. If a `mem-initializer-id` designates the constructor’s class, it shall be the only `mem-initializer`; the constructor is a `delegating constructor`, and the constructor selected by the `mem-initializer` is the `target constructor`. The target constructor is selected by overload resolution. Once the target constructor returns, the body of the delegating constructor is executed. If a constructor delegates to itself directly or indirectly, the program is ill-formed, no diagnostic required. [Example:

```c
struct C {
 C( int ) {} // #1: non-delegating constructor
 C( C42 ) {} // #2: delegates to #1
 C( char c ) : C(C42.0) {} // #3: ill-formed due to recursion with #4
 C( double d ) : C(‘a’) {} // #4: ill-formed due to recursion with #3
};
```
—end example]

The `expression-list` or `braced-init-list` in a `mem-initializer` is used to initialize the designated subobject (or, in the case of a delegating constructor, the complete class object) according to the initialization rules of 9.3 for direct-initialization. [Example:

```c
struct B1 { B1(int); /* ... */ }; struct B2 { B2(int); /* ... */ }; struct D : B1, B2 {
 D(int);
 B1 b;
 const int c;
};
```
D::D(int a) : B2(a+1), B1(a+2), c(a+3), b(a+4) { /* ... */ }
D d(10);

—end example] [Note: The initialization performed by each mem-initializer constitutes a full-expression (6.8.1). Any expression in a mem-initializer is evaluated as part of the full-expression that performs the initialization. — end note] A mem-initializer where the mem-initializer-id denotes a virtual base class is ignored during execution of a constructor of any class that is not the most derived class.  

8 A temporary expression bound to a reference member in a mem-initializer is ill-formed. [Example:

```c
struct A {
    A() : v(42) { } // error
    const int& v;
};
—end example]
```

9 In a non-delegating constructor, if a given potentially constructed subobject is not designated by a mem-initializer-id (including the case where there is no mem-initializer-list because the constructor has no ctor-initializer), then

(9.1) — if the entity is a non-static data member that has a default member initializer (10.3) and either

(9.1.1) — the constructor’s class is a union (10.4), and no other variant member of that union is designated by a mem-initializer-id or

(9.1.2) — the constructor’s class is not a union, and, if the entity is a member of an anonymous union, no other member of that union is designated by a mem-initializer-id,

the entity is initialized from its default member initializer as specified in 9.3;

(9.2) — otherwise, if the entity is an anonymous union or a variant member (10.4.1), no initialization is performed;

(9.3) — otherwise, the entity is default-initialized (9.3).

[Note: An abstract class (10.6.3) is never a most derived class, thus its constructors never initialize virtual base classes, therefore the corresponding mem-initializers may be omitted. — end note] An attempt to initialize more than one non-static data member of a union renders the program ill-formed. [Note: After the call to a constructor for class X for an object with automatic or dynamic storage duration has completed, if the constructor was not invoked as part of value-initialization and a member of X is neither initialized nor given a value during execution of the compound-statement of the body of the constructor, the member has an indeterminate value. — end note] [Example:

```c
struct A {
    A();
};

struct B {
    B(int);
};

struct C {
    C() { }
    // initializes members as follows:
    A a;        // OK: calls A::A()
    const B b; // error: B has no default constructor
    int i;      // OK: i has indeterminate value
    int j = 5;  // OK: j has the value 5
};
—end example]
```

10 If a given non-static data member has both a default member initializer and a mem-initializer, the initialization specified by the mem-initializer is performed, and the non-static data member’s default member initializer is ignored. [Example: Given

```c
struct A {
    int i = /* some integer expression with side effects */;
    A(int arg) : i(arg) { }
    // ...
};
```

§ 10.9.2 270
the \texttt{A(int)} constructor will simply initialize \texttt{i} to the value of \texttt{arg}, and the side effects in \texttt{i}'s default member initializer will not take place. — end example]

11 A temporary expression bound to a reference member from a default member initializer is ill-formed. [Example:

\begin{verbatim}
struct A {
    A() = default;       // OK
    A(int v) : v(v) {}    // OK
    const int& v = 42;    // OK
};
A a1;                 // error: ill-formed binding of temporary to reference
A a2(1);              // OK, unfortunately
\end{verbatim}

— end example]

12 In a non-delegating constructor, the destructor for each potentially constructed subobject of class type is potentially invoked (10.3.7). [Note: This provision ensures that destructors can be called for fully-constructed subobjects in case an exception is thrown (13.2). — end note]

13 In a non-delegating constructor, initialization proceeds in the following order:

\begin{itemize}
\item [(13.1)] First, and only for the constructor of the most derived class (6.6.2), virtual base classes are initialized in the order they appear on a depth-first left-to-right traversal of the directed acyclic graph of base classes, where "left-to-right" is the order of appearance of the base classes in the derived class base-specifier-list.
\item [(13.2)] Then, direct base classes are initialized in declaration order as they appear in the base-specifier-list (regardless of the order of the mem-initializers).
\item [(13.3)] Then, non-static data members are initialized in the order they were declared in the class definition (again regardless of the order of the mem-initializers).
\item [(13.4)] Finally, the compound-statement of the constructor body is executed.
\end{itemize}

[Note: The declaration order is mandated to ensure that base and member subobjects are destroyed in the reverse order of initialization. — end note]

14 [Example:

\begin{verbatim}
struct V {
    V();
    V(int);
};

struct A : virtual V {
    A();
    A(int);
};

struct B : virtual V {
    B();
    B(int);
};

struct C : A, B, virtual V {
    C();
    C(int);
};

A::A(int i) : V(i) { /* ... */ }
B::B(int i) { /* ... */ }
C::C(int i) { /* ... */ }

V v(1);       // use V(int)
A a(2);       // use V(int)
B b(3);       // use V()
C c(4);       // use V()
\end{verbatim}

— end example]
Names in the expression-list or braced-init-list of a mem-initializer are evaluated in the scope of the constructor for which the mem-initializer is specified. [Example:

```cpp
class X {
    int a;
    int b;
    int i;
    int j;
public:
    const int& r;
    X(int i) : r(a), b(i), i(i), j(this->i) {}  
};
```

initializes X::r to refer to X::a, initializes X::b with the value of the constructor parameter i, initializes X::i with the value of the constructor parameter i, and initializes X::j with the value of X::i; this takes place each time an object of class X is created. —end example] [Note: Because the mem-initializer are evaluated in the scope of the constructor, the this pointer can be used in the expression-list of a mem-initializer to refer to the object being initialized. —end note]

16 Member functions (including virtual member functions, 10.6.2) can be called for an object under construction. Similarly, an object under construction can be the operand of the typeid operator (7.6.1.8) or of a dynamic_cast (7.6.1.7). However, if these operations are performed in a ctor-initializer (or in a function called directly or indirectly from a ctor-initializer) before all the mem-initializers for base classes have completed, the program has undefined behavior. [Example:

```cpp
class A {
public:
    A(int);
};

class B : public A {
    int j;
public:
    int f();
    B() : A(f()), j(f()) { }  // undefined: calls member function but base A not yet initialized
};
class C {
public:
    C(int);
};
class D : public B, C {
    int i;
public:
    D() : C(f()), i(f()) { }  // undefined: calls member function but base C not yet initialized
};
```

—end example]

17 [Note: 10.9.4 describes the result of virtual function calls, typeid and dynamic_casts during construction for the well-defined cases; that is, describes the polymorphic behavior of an object under construction. —end note]

18 A mem-initializer followed by an ellipsis is a pack expansion (12.6.3) that initializes the base classes specified by a pack expansion in the base-specifier-list for the class. [Example:

```cpp
template<class... Mixins>
class X : public Mixins... {
public:
    X(const Mixins&... mixins) : Mixins(mixins)... {
};
```

—end example]
10.9.3 Initialization by inherited constructor

When a constructor for type B is invoked to initialize an object of a different type D (that is, when the constructor was inherited (9.8)), initialization proceeds as if a defaulted default constructor were used to initialize the D object and each base class subobject from which the constructor was inherited, except that the B subobject is initialized by the invocation of the inherited constructor. The complete initialization is considered to be a single function call; in particular, the initialization of the inherited constructor’s parameters is sequenced before the initialization of any part of the D object. [Example:

```cpp
struct B1 {
    B1(int, ...) { }
};

struct B2 {
    B2(double) { }
};

int get();

struct D1 : B1 {
    using B1::B1; // inherits B1(int, ...)
    int x;
    int y = get();
};

void test() {
    D1 d(2, 3, 4); // OK: B1 is initialized by calling B1(2, 3, 4),
    // then d.x is default-initialized (no initialization is performed),
    // then d.y is initialized by calling get()
    D1 e; // error: D1 has a deleted default constructor
}

struct D2 : B2 {
    using B2::B2;
    B1 b;
};

D2 f(1.0); // error: B1 has a deleted default constructor
```

] 2

If the constructor was inherited from multiple base class subobjects of type B, the program is ill-formed.

[Example:

```cpp
struct A { A(int); }; struct B : A { using A::A; }; struct C1 : B { using B::B; }; struct C2 : B { using B::B; }

struct D1 : C1, C2 {
    using C1::C1;
    using C2::C2;
};
```

] 2

§ 10.9.3
struct V1 : virtual B { using B::B; }

struct V2 : virtual B { using B::B; }

struct D2 : V1, V2 {
    using V1::V1;
    using V2::V2;
};

D1 d1(0);  // ill-formed: ambiguous
D2 d2(0);  // OK: initializes virtual B base class, which initializes the A base class
            // then initializes the V1 and V2 base classes as if by a defaulted default constructor

struct M { M(); M(int); };  
struct N : M { using M::M; };  
struct O : M {};  
struct P : N, O { using N::N; using O::O; };  
P p(0);  // OK: use M(O) to initialize N’s base class,  
          // use M() to initialize O’s base class

—end example]  

3 When an object is initialized by an inherited constructor, initialization of the object is complete when the  
initialization of all subobjects is complete.

10.9.4 Construction and destruction  

1 For an object with a non-trivial constructor, referring to any non-static member or base class of the object  
before the constructor begins execution results in undefined behavior. For an object with a non-trivial  
destructor, referring to any non-static member or base class of the object after the destructor finishes execution  
results in undefined behavior. [Example:

struct X { int i; };  
struct Y : X { Y(); };  // non-trivial
struct A { int a; };  
struct B : public A { int j; Y y; };  // non-trivial

extern B bobj;
B* pb = &bobj;  // OK
int* p1 = &bobj.a;  // undefined, refers to base class member
int* p2 = &bobj.y.i;  // undefined, refers to member’s member

A* pa = &bobj;  // undefined, upcast to a base class type
B bobj; // definition of bobj

extern X xobj;
int* p3 = &xobj.i; // OK, X is a trivial class
X xobj;

For another example,

struct W { int j; };  
struct X : public virtual W { };  
struct Y {  
    int* p;
    X x;
    Y() : p(0) { // undefined, x is not yet constructed
}
};

—end example]

2 To explicitly or implicitly convert a pointer (a glvalue) referring to an object of class X to a pointer (reference)  
to a direct or indirect base class B of X, the construction of X and the construction of all of its direct or  
indirect bases that directly or indirectly derive from B shall have started and the destruction of these classes  
shall not have completed, otherwise the conversion results in undefined behavior. To form a pointer to (or  
access the value of) a direct non-static member of an object obj, the construction of obj shall have started
and its destruction shall not have completed, otherwise the computation of the pointer value (or accessing
the member value) results in undefined behavior. [Example:

```c
struct A {
};
struct B : virtual A {
};
struct C : B {
};
struct D : virtual A {
    D(A*);
};
struct X {
    X(A*);
};

struct E : C, D, X {
    E() : D(this),
        // undefined: upcast from E* to A* might use path E* → D* → A*
        // but D is not constructed
        // “D((C*)this)” would be defined: E* → C* is defined because E() has started,
        // and C* → A* is defined because C is fully constructed
    X(this) {} // defined: upon construction of X, C/B/D/A sublattice is fully constructed
};
```
—end example]

Member functions, including virtual functions (10.6.2), can be called during construction or destruction (10.9.2).
When a virtual function is called directly or indirectly from a constructor or from a destructor, including
during the construction or destruction of the class’s non-static data members, and the object to which the
call applies is the object (call it x) under construction or destruction, the function called is the final overrider
in the constructor’s or destructor’s class and not one overriding it in a more-derived class. If the virtual
function call uses an explicit class member access (7.6.1.5) and the object expression refers to the complete
object of x or one of that object’s base class subobjects but not x or one of its base class subobjects, the
behavior is undefined. [Example:

```c
struct V {
    virtual void f();
    virtual void g();
};

struct A : virtual V {
    virtual void f();
};

struct B : virtual V {
    virtual void g();
    B(V*, A*);
};

struct D : A, B {
    virtual void f();
    virtual void g();
    D() : B((A*)this, this) {}
};

B::B(V* v, A* a) {
    f(); // calls V::f, not A::f
    g(); // calls B::g, not D::g
    v->g(); // v is base of B, the call is well-defined, calls B::g
    a->f(); // undefined behavior, a’s type not a base of B
}
```
—end example]

The typeid operator (7.6.1.8) can be used during construction or destruction (10.9.2). When typeid
is used in a constructor (including the mem-initializer or default member initializer (10.3) for a non-static
data member) or in a destructor, or used in a function called (directly or indirectly) from a constructor or
destructor, if the operand of typeid refers to the object under construction or destruction, typeid yields the
std::type_info object representing the constructor or destructor’s class. If the operand of typeid refers to
the object under construction or destruction and the static type of the operand is neither the constructor or
destructor’s class nor one of its bases, the behavior is undefined.

§ 10.9.4
**dynamic_casts** (7.6.1.7) can be used during construction or destruction (10.9.2). When a **dynamic_cast** is used in a constructor (including the *mem-initializer* or default member initializer for a non-static data member) or in a destructor, or used in a function called (directly or indirectly) from a constructor or destructor, if the operand of the **dynamic_cast** refers to the object under construction or destruction, this object is considered to be a most derived object that has the type of the constructor or destructor’s class. If the operand of the **dynamic_cast** refers to the object under construction or destruction and the static type of the operand is not a pointer to or object of the constructor or destructor’s own class or one of its bases, the **dynamic_cast** results in undefined behavior. [Example:

```
struct V {
    virtual void f();
};

struct A : virtual V {
};

struct B : virtual V {
    B(V*, A*);
};

struct D : A, B {
    D() : B((A*)this, this) { }
};

B::B(V* v, A* a) {
    typeid(*this); // well-formed: *v has type V, a base of B yields type_info for B.
    typeid(*v);    // undefined behavior: type A not a base of B.
    dynamic_cast<B*>(v); // well-formed: v of type V*, V base of B results in B*.
    dynamic_cast<B*>(a); // undefined behavior, a has type A*, A not a base of B.
}
```

—end example]

### 10.9.5 Copy/move elision

When certain criteria are met, an implementation is allowed to omit the copy/move construction of a class object, even if the constructor selected for the copy/move operation and/or the destructor for the object have side effects. In such cases, the implementation treats the source and target of the omitted copy/move operation as simply two different ways of referring to the same object. If the first parameter of the selected constructor is an rvalue reference to the object’s type, the destruction of that object occurs when the target would have been destroyed; otherwise, the destruction occurs at the later of the times when the two objects would have been destroyed without the optimization. 

This elision of copy/move operations, called *copy elision*, is permitted in the following circumstances (which may be combined to eliminate multiple copies):

1. **in a return statement** in a function with a class return type, when the *expression* is the name of a non-volatile automatic object (other than a function parameter or a variable introduced by the *exception-declaration* of a *handler* (13.3)) with the same type (ignoring cv-qualification) as the function return type, the copy/move operation can be omitted by constructing the automatic object directly into the function call’s return object

2. **in a throw-expression** (7.6.17), when the operand is the name of a non-volatile automatic object (other than a function or catch-clause parameter) whose scope does not extend beyond the end of the innermost enclosing *try-block* (if there is one), the copy/move operation from the operand to the exception object (13.1) can be omitted by constructing the automatic object directly into the exception object

3. **when the exception-declaration** of an exception handler (Clause 13) declares an object of the same type (except for cv-qualification) as the exception object (13.1), the copy operation can be omitted by treating the *exception-declaration* as an alias for the exception object if the meaning of the program will be unchanged except for the execution of constructors and destructors for the object declared by the *exception-declaration*. [Note: There cannot be a move from the exception object because it is always an lvalue. —end note]

---

120) Because only one object is destroyed instead of two, and one copy/move constructor is not executed, there is still one object destroyed for each one constructed.
Copy elision is required where an expression is evaluated in a context requiring a constant expression (7.7) and in constant initialization (6.8.3.2). [Note: Copy elision might not be performed if the same expression is evaluated in another context. — end note]

2 [Example:

```cpp
class Thing {
public:
    Thing();
    ~Thing();
    Thing(const Thing&);
};

Thing t() {
    Thing t;
    return t;
}

Thing t2 = t();
```

```cpp
struct A {
    void *p;
    constexpr A(): p(this) {} // well-formed, a.p points to a
};

constexpr A g() {
    A a;
    return a;
}

constexpr A a; // well-formed, a.p points to a
constexpr A b = g(); // well-formed, b.p points to b

void h() {
    A c = g(); // well-formed, c.p may point to c or to an ephemeral temporary
}
```

Here the criteria for elision can eliminate the copying of the local automatic object `t` into the result object for the function call `t()`, which is the global object `t2`. Effectively, the construction of the local object `t` can be viewed as directly initializing the global object `t2`, and that object’s destruction will occur at program exit. Adding a move constructor to `Thing` has the same effect, but it is the move construction from the local automatic object to `t2` that is elided. — end example]

3 In the following copy-initialization contexts, a move operation might be used instead of a copy operation:

(3.1) — If the expression in a return statement (8.6.3) is a (possibly parenthesized) id-expression that names an object with automatic storage duration declared in the body or parameter-declaration-clause of the innermost enclosing function or lambda-expression, or

(3.2) — if the operand of a throw-expression (7.6.17) is the name of a non-volatile automatic object (other than a function or catch-clause parameter) whose scope does not extend beyond the end of the innermost enclosing try-block (if there is one),

overload resolution to select the constructor for the copy is first performed as if the object were designated by an rvalue. If the first overload resolution fails or was not performed, or if the type of the first parameter of the selected constructor is not an rvalue reference to the object’s type (possibly cv-qualified), overload resolution is performed again, considering the object as an lvalue. [Note: This two-stage overload resolution must be performed regardless of whether copy elision will occur. It determines the constructor to be called if elision is not performed, and the selected constructor must be accessible even if the call is elided. — end note]

4 [Example:

```cpp
class Thing {
public:
    Thing();
    ~Thing();
```
Thing(Thing&&);
private:
  Thing(const Thing&);
};

Thing f(bool b) {
  Thing t;
  if (b)
    throw t;  // OK: Thing(Thing&&) used (or elided) to throw t
  return t;  // OK: Thing(Thing&&) used (or elided) to return t
}

Thing t2 = f(false);  // OK: no extra copy/move performed, t2 constructed by call to f

struct Weird {
  Weird();
  Weird(Weird&);
};

Weird g() {
  Weird w;
  return w;  // OK: first overload resolution fails, second overload resolution selects Weird(Weird&)
}

— end example]

10.10 Comparisons [class.compare]

10.10.1 Defaulted comparison operator functions [class.compare.default]

A defaulted comparison operator function (7.6.8, 7.6.9, 7.6.10) for some class C shall be a non-template function declared in the member-specification of C that is

(1.1) — a non-static member of C having one parameter of type const C&, or

(1.2) — a friend of C having two parameters of type const C&.

2 A three-way comparison operator for a class type C is a structural comparison operator if it is defined as defaulted in the definition of C, and all three-way comparison operators it invokes are structural comparison operators. A type T has strong structural equality if, for a glvalue x of type const T, x <=> x is a valid expression of type std::strong_ordering or std::strong_equality and either does not invoke a three-way comparison operator or invokes a structural comparison operator.

10.10.2 Three-way comparison [class.spaceship]

The direct base class subobjects of C, in the order of their declaration in the base-specifier-list of C, followed by the non-static data members of C, in the order of their declaration in the member-specification of C, form a list of subobjects. In that list, any subobject of array type is recursively expanded to the sequence of its elements, in the order of increasing subscript. Let \( x_i \) be an lvalue denoting the \( i^{th} \) element in the expanded list of subobjects for an object \( x \) (of length \( n \)), where \( x_i \) is formed by a sequence of derived-to-base conversions (11.3.3.1), class member access expressions (7.6.1.5), and array subscript expressions (7.6.1.1) applied to \( x \). The type of the expression \( x_i <=> x_i \) is denoted by \( R_i \). It is unspecified whether virtual base class subobjects are compared more than once.

2 If the declared return type of a defaulted three-way comparison operator function is auto, then the return type is deduced as the common comparison type (see below) of \( R_0, R_1, \ldots, R_{n-1} \). [Note: Otherwise, the program will be ill-formed if the expression \( x_i <=> x_i \) is not implicitly convertible to the declared return type for any \( i \). — end note] If the return type is deduced as void, the operator function is defined as deleted.

3 The return value \( V \) of type R of the defaulted three-way comparison operator function with parameters \( x \) and \( y \) of the same type is determined by comparing corresponding elements \( x_i \) and \( y_i \) in the expanded lists of subobjects for \( x \) and \( y \) until the first index \( i \) where \( x_i <=> y_i \) yields a result value \( v_i \), where \( v_i != 0 \), contextually converted to bool, yields true; \( V \) is \( v_i \) converted to R. If no such index exists, \( V \) is std::strong_ordering::equal converted to R.

4 The common comparison type U of a possibly-empty list of \( n \) types \( T_0, T_1, \ldots, T_{n-1} \) is defined as follows:

(4.1) — If any \( T_i \) is not a comparison category type (16.11.2), U is void.
Otherwise, if at least one \( T_i \) is `std::weak_equality`, or at least one \( T_i \) is `std::strong_equality` and at least one \( T_j \) is `std::partial_ordering` or `std::weak_ordering`, \( U \) is `std::weak_equality` (16.11.2.2).

— Otherwise, if at least one \( T_i \) is `std::strong_equality`, \( U \) is `std::strong_equality` (16.11.2.3).

— Otherwise, if at least one \( T_i \) is `std::partial_ordering`, \( U \) is `std::partial_ordering` (16.11.2.4).

— Otherwise, if at least one \( T_i \) is `std::weak_ordering`, \( U \) is `std::weak_ordering` (16.11.2.5).

— Otherwise, \( U \) is `std::strong_ordering` (16.11.2.6). [Note: In particular, this is the result when \( n \) is 0. —end note]

### 10.10.3 Other comparison operators

[class.rel.eq]

1 A defaulted relational (7.6.9) or equality (7.6.10) operator function for some operator \@ shall have a declared return type `bool`.

2 The operator function with parameters \( x \) and \( y \) is defined as deleted if

— overload resolution (11.3), as applied to \( x \Leftrightarrow y \) (also considering synthesized candidates with reversed order of parameters (11.3.1.2)), results in an ambiguity or a function that is deleted or inaccessible from the operator function, or

— the operator \@ cannot be applied to the return type of \( x \Leftrightarrow y \) or \( y \Leftrightarrow x \).

Otherwise, the operator function yields \( x \Leftrightarrow y \@ 0 \) if an operator\( \Leftrightarrow \) with the original order of parameters was selected, or \( 0 \@ y \Leftrightarrow x \) otherwise.

3 [Example:

```cpp
struct C {
	friend std::strong_equality operator<(const C&, const C&);
	nfriend bool operator==(const C& x, const C& y) = default; // OK, returns x \Leftrightarrow y == 0
	nfriend bool operator<(const C& x, const C& y) = default; // OK, function is deleted
};
—end example]

### 10.11 Free store

[class.free]

1 Any allocation function for a class \( T \) is a static member (even if not explicitly declared `static`).

2 [Example:

```cpp
class Arena;
struct B {
	void* operator new(std::size_t, Arena*);
};
struct D1 : B {
};

Arena* ap;
void foo(int i) {
	new (ap) D1; // calls B::operator new(std::size_t, Arena*)
	new D1[i]; // calls ::operator new[](std::size_t)
	new D1; // ill-formed: ::operator new(std::size_t) hidden
}
—end example]

3 When an object is deleted with a `delete-expression` (7.6.2.5), a deallocation function (operator `delete()` for non-array objects or `operator delete[]` for arrays) is (implicitly) called to reclaim the storage occupied by the object (6.6.4.4.2).

4 Class-specific deallocation function lookup is a part of general deallocation function lookup (7.6.2.5) and occurs as follows. If the `delete-expression` is used to deallocate a class object whose static type has a virtual destructor, the deallocation function is the one selected at the point of definition of the dynamic type’s virtual destructor (10.3.7). Otherwise, if the `delete-expression` is used to deallocate an object of class \( T \) or array thereof, the deallocation function’s name is looked up in the scope of \( T \). If this lookup fails to find the

121) A similar provision is not needed for the array version of `operator delete` because 7.6.2.5 requires that in this situation, the static type of the object to be deleted be the same as its dynamic type.

§ 10.11 279
name, general deallocation function lookup (7.6.2.5) continues. If the result of the lookup is ambiguous or inaccessible, or if the lookup selects a placement deallocation function, the program is ill-formed.

5 Any deallocation function for a class \(X\) is a static member (even if not explicitly declared \texttt{static}). [\textit{Example:}]

```cpp
class X {
    void operator delete(void*);
    void operator delete[](void*, std::size_t);
};

class Y {
    void operator delete(void*, std::size_t);
    void operator delete[](void*);
};
—end example]
```

6 Since member allocation and deallocation functions are \texttt{static} they cannot be virtual. [\textit{Note:} However, when the \texttt{cast-expression} of a \texttt{delete-expression} refers to an object of class type, because the deallocation function actually called is looked up in the scope of the class that is the dynamic type of the object if the destructor is virtual, the effect is the same in that case. For example,

```cpp
struct B {
    virtual ~B();
    void operator delete(void*, std::size_t);
};

struct D : B {
    void operator delete(void*);
};

struct E : B {
    void log_deletion();
    void operator delete(E* p, std::destroying_delete_t) {
        p->log_deletion();
        p->~E();
        ::operator delete(p);
    }
};

void f() {
    B* bp = new D;
    delete bp; // 1: uses \texttt{D::operator delete(void*)}
    bp = new E;
    delete bp; // 2: uses \texttt{E::operator delete(E*, std::destroying_delete_t)}
}
```

Here, storage for the object of class \(D\) is deallocated by \texttt{D::operator delete()}, and the object of class \(E\) is destroyed and its storage is deallocated by \texttt{E::operator delete()}, due to the virtual destructor. —end note] [\textit{Note:} Virtual destructors have no effect on the deallocation function actually called when the \texttt{cast-expression} of a \texttt{delete-expression} refers to an array of objects of class type. For example,

```cpp
struct B {
    virtual ~B();
    void operator delete[](void*, std::size_t);
};

struct D : B {
    void operator delete[](void*, std::size_t);
};

void f(int i) {
    D* dp = new D[i];
    delete [] dp; // uses \texttt{D::operator delete[](void*, std::size_t)}
    B* bp = new D[i];
    delete[] bp; // undefined behavior
}
Access to the deallocation function is checked statically. Hence, even though a different one might actually be executed, the statically visible deallocation function is required to be accessible. [Example: For the call on line “// 1” above, if $B::operator \text{ delete}()$ had been private, the delete expression would have been ill-formed. —end example]

[Note: If a deallocation function has no explicit `noexcept-specifier`, it has a non-throwing exception specification (13.4). —end note]
11 Overloading

1 When two or more different declarations are specified for a single name in the same scope, that name is said to be overloaded, and the declarations are called overloaded declarations. Only function and function template declarations can be overloaded; variable and type declarations cannot be overloaded.

2 When a function name is used in a call, which function declaration is being referenced and the validity of the call are determined by comparing the types of the arguments at the point of use with the types of the parameters in the declarations that are visible at the point of use. This function selection process is called overload resolution and is defined in 11.3. [Example:

\[
\begin{align*}
\text{double} & \quad \text{abs(double);} \\
\text{int} & \quad \text{abs(int);} \\
\text{abs(1);} & \quad \text{// calls abs(int);} \\
\text{abs(1.0);} & \quad \text{// calls abs(double);} \\
\end{align*}
\]

—end example]

11.1 Overloadable declarations

1 Not all function declarations can be overloaded. Those that cannot be overloaded are specified here. A program is ill-formed if it contains two such non-overloadable declarations in the same scope. [Note: This restriction applies to explicit declarations in a scope, and between such declarations and declarations made through a using-declaration (9.8). It does not apply to sets of functions fabricated as a result of name lookup (e.g., because of using-directives) or overload resolution (e.g., for operator functions). —end note]

2 Certain function declarations cannot be overloaded:

(2.1) — Function declarations that differ only in the return type, the exception specification (13.4), or both cannot be overloaded.

(2.2) — Member function declarations with the same name and the same parameter-type-list (9.2.3.5) cannot be overloaded if any of them is a static member function declaration (10.3.9). Likewise, member function template declarations with the same name, the same parameter-type-list, and the same template parameter lists cannot be overloaded if any of them is a static member function template declaration. The types of the implicit object parameters constructed for the member functions for the purpose of overload resolution (11.3.1) are not considered when comparing parameter-type-lists for enforcement of this rule. In contrast, if there is no static member function declaration among a set of member function declarations with the same name and the same parameter-type-list, then these member function declarations can be overloaded if they differ in the type of their implicit object parameter. [Example: The following illustrates this distinction:

\[
\begin{align*}
\text{class X} \{ \\
\quad \text{static void f();} \\
\quad \text{void f();} & \quad \text{// ill-formed} \\
\quad \text{void f() const;} & \quad \text{// ill-formed} \\
\quad \text{void f() const volatile;} & \quad \text{// ill-formed} \\
\quad \text{void g();} \\
\quad \text{void g() const;} & \quad \text{// OK: no static g} \\
\quad \text{void g() const volatile;} & \quad \text{// OK: no static g} \\
\}; \\
\end{align*}
\]

—end example]

(2.3) — Member function declarations with the same name and the same parameter-type-list (9.2.3.5) as well as member function template declarations with the same name, the same parameter-type-list, and the same template parameter lists cannot be overloaded if any of them, but not all, have a ref-qualifier (9.2.3.5). [Example:

\[
\begin{align*}
\text{class Y} \{ \\
\quad \text{void h() &;} \\
\quad \text{void h() const &;} & \quad \text{// OK} \\
\quad \text{void h() &&;} & \quad \text{// OK, all declarations have a ref-qualifier} \\
\end{align*}
\]
void i() &;  // ill-formed, prior declaration of i
    // has a ref-qualifier
};

— end example

3 [Note: As specified in 9.2.3.5, function declarations that have equivalent parameter declarations and requires-clauses, if any (12.4.2), declare the same function and therefore cannot be overloaded:

(3.1) — Parameter declarations that differ only in the use of equivalent typedef “types” are equivalent. A typedef is not a separate type, but only a synonym for another type (9.1.3). [Example:

    typedef int Int;
    void f(int i);
    void f(Int i);    // OK: redeclaration of f(int)
    void f(int i) { /* ... */ }
    void f(Int i) { /* ... */ }    // error: redefinition of f(int)

— end example]

Enumerations, on the other hand, are distinct types and can be used to distinguish overloaded function declarations. [Example:

    enum E { a };
    void f(int i) { /* ... */ }
    void f(E i) { /* ... */ }

— end example]

(3.2) — Parameter declarations that differ only in a pointer * versus an array [] are equivalent. That is, the array declaration is adjusted to become a pointer declaration (9.2.3.5). Only the second and subsequent array dimensions are significant in parameter types (9.2.3.4). [Example:

    int f(char[]);
    int f(char[]);    // same as f(char*)
    int f(char[7]);    // same as f(char*)
    int f(char[9]);    // same as f(char*)

    int g(char(*)(10));
    int g(char[5][10]);    // same as g(char(*)(10))
    int g(char[7][10]);    // same as g(char(*)(10))
    int g(char(*)(20));    // different from g(char(*)(10))

— end example]

(3.3) — Parameter declarations that differ only in that one is a function type and the other is a pointer to the same function type are equivalent. That is, the function type is adjusted to become a pointer to function type (9.2.3.5). [Example:

    void h(int());
    void h(int (*)());    // redeclaration of h(int())
    void h(int x()); { }    // definition of h(int())
    void h(int (*)(x)) { }    // ill-formed: redefinition of h(int())

— end example]

(3.4) — Parameter declarations that differ only in the presence or absence of const and/or volatile are equivalent. That is, the const and volatile type-specifiers for each parameter type are ignored when determining which function is being declared, defined, or called. [Example:

    typedef const int cInt;

    int f (int);
    int f (const int);    // redeclaration of f(int)
    int f (int) { /* ... */ }    // definition of f(int)
    int f (cInt) { /* ... */ }    // error: redefinition of f(int)

— end example]

§ 11.1 283
Only the `const` and `volatile` type-specifiers at the outermost level of the parameter type specification are ignored in this fashion; `const` and `volatile` type-specifiers buried within a parameter type specification are significant and can be used to distinguish overloaded function declarations.\(^{122}\) In particular, for any type \(T\), “pointer to \(T\)”, “pointer to \(const\ T\)”, and “pointer to \(volatile\ T\)” are considered distinct parameter types, as are “reference to \(T\)”, “reference to \(const\ T\)”, and “reference to \(volatile\ T\)”.

(3.5) — Two parameter declarations that differ only in their default arguments are equivalent. [Example: Consider the following:

```c
void f (int i, int j);
void f (int i, int j = 99); // OK: redeclaration of f(int, int)
void f (int i = 88, int j); // OK: redeclaration of f(int, int)
void f (); // OK: overloaded declaration of f

void prog () {
  f (1, 2); // OK: call f(int, int)
  f (1); // OK: call f(int, int)
  f (); // error: f(int, int) or f()?  
}
— end example]
— end note]

11.2 Declaration matching [over.dcl]
1 Two function declarations of the same name refer to the same function if they are in the same scope and have equivalent parameter declarations (11.1) and equivalent trailing `requires-clauses`, if any (9.2). A function member of a derived class is not in the same scope as a function member of the same name in a base class. [Example:

```c
struct B {
  int f(int);
};

struct D : B {
  int f(const char *);
};

Here D::f(const char*) hides B::f(int) rather than overloading it.

void h(D* pd) {
  pd->f(1); // error: D::f(const char*) hides B::f(int)
  pd->B::f(1); // OK
  pd->f("Ben"); // OK, calls D::f
}
— end example]

2 A locally declared function is not in the same scope as a function in a containing scope. [Example:

```c
void f(const char*);
void g() {
  extern void f(int);
  f("asdf"); // error: f(int) hides f(const char*)
  // so there is no f(const char*) in this scope
}

void caller () {
  extern void callee(int, int);
  {
    extern void callee(int); // hides callee(int, int)
    callee(88, 99); // error: only callee(int) in scope
  }
```

\(^{122}\) When a parameter type includes a function type, such as in the case of a parameter type that is a pointer to function, the `const` and `volatile` type-specifiers at the outermost level of the parameter type specifications for the inner function type are also ignored.
Different versions of an overloaded member function can be given different access rules. [Example:]

```cpp
class buffer {
private:
  char* p;
  int size;
protected:
  buffer(int s, char* store) { size = s; p = store; }
public:
  buffer(int s) { p = new char[size = s]; }
};
```

11.3 Overload resolution [over.match]

Overload resolution is a mechanism for selecting the best function to call given a list of expressions that are to be the arguments of the call and a set of candidate functions that can be called based on the context of the call. The selection criteria for the best function are the number of arguments, how well the arguments match the parameter-type-list of the candidate function, how well (for non-static member functions) the object matches the implicit object parameter, and certain other properties of the candidate function. [Note: The function selected by overload resolution is not guaranteed to be appropriate for the context. Other restrictions, such as the accessibility of the function, can make its use in the calling context ill-formed. — end note]

Overload resolution selects the function to call in seven distinct contexts within the language:

1. invocation of a function named in the function call syntax (11.3.1.1.1);
2. invocation of a function call operator, a pointer-to-function conversion function, a reference-to-pointer-to-function conversion function, or a reference-to-function conversion function on a class object named in the function call syntax (11.3.1.1.2);
3. invocation of the operator referenced in an expression (11.3.1.2);
4. invocation of a constructor for default- or direct-initialization (9.3) of a class object (11.3.1.3);
5. invocation of a user-defined conversion for copy-initialization (9.3) of a class object (11.3.1.4);
6. invocation of a conversion function for initialization of an object of a non-class type from an expression of class type (11.3.1.5); and
7. invocation of a conversion function for conversion in which a reference (9.3.3) will be directly bound (11.3.1.6).

Each of these contexts defines the set of candidate functions and the list of arguments in its own unique way. But, once the candidate functions and argument lists have been identified, the selection of the best function is the same in all cases:

1. First, a subset of the candidate functions (those that have the proper number of arguments and meet certain other conditions) is selected to form a set of viable functions (11.3.2).
2. Then the best viable function is selected based on the implicit conversion sequences (11.3.3.1) needed to match each argument to the corresponding parameter of each viable function.

If a best viable function exists and is unique, overload resolution succeeds and produces it as the result. Otherwise overload resolution fails and the invocation is ill-formed. When overload resolution succeeds, and the best viable function is not accessible (10.8) in the context in which it is used, the program is ill-formed.

11.3.1 Candidate functions and argument lists [over.match.funcs]

The subclauses of 11.3.1 describe the set of candidate functions and the argument list submitted to overload resolution in each context in which overload resolution is used. The source transformations and constructions defined in these subclauses are only for the purpose of describing the overload resolution process. An implementation is not required to use such transformations and constructions.
The set of candidate functions can contain both member and non-member functions to be resolved against the same argument list. So that argument and parameter lists are comparable within this heterogeneous set, a member function is considered to have an extra first parameter, called the **implicit object parameter**, which represents the object for which the member function has been called. For the purposes of overload resolution, both static and non-static member functions have an implicit object parameter, but constructors do not.

Similarly, when appropriate, the context can construct an argument list that contains an **implied object argument** as the first argument in the list to denote the object to be operated on.

For non-static member functions, the type of the implicit object parameter is

(4.1) — “lvalue reference to `cv X`” for functions declared without a `ref-qualifier` or with the `&` ref-qualifier

(4.2) — “rvalue reference to `cv X`” for functions declared with the `&&` ref-qualifier

where X is the class of which the function is a member and cv is the cv-qualification on the member function declaration. [Example: For a `const` member function of class X, the extra parameter is assumed to have type “reference to `const X`”. — end example] For conversion functions, the function is considered to be a member of the class of the implied object argument for the purpose of defining the type of the implicit object parameter. For non-conversion functions introduced by a `using-declaration` into a derived class, the function is considered to be a member of the derived class for the purpose of defining the type of the implicit object parameter. For static member functions, the implicit object parameter is considered to match any object (since if the function is selected, the object is discarded). [Note: No actual type is established for the implicit object parameter of a static member function, and no attempt will be made to determine a conversion sequence for that parameter (11.3.3). — end note]

During overload resolution, the implied object argument is indistinguishable from other arguments. The implicit object parameter, however, retains its identity since no user-defined conversions can be applied to achieve a type match with it. For non-static member functions declared without a `ref-qualifier`, an additional rule applies:

(5.1) — even if the implicit object parameter is not const-qualified, an rvalue can be bound to the parameter as long as in all other respects the argument can be converted to the type of the implicit object parameter. [Note: The fact that such an argument is an rvalue does not affect the ranking of implicit conversion sequences (11.3.3.2). — end note]

Because other than in list-initialization only one user-defined conversion is allowed in an implicit conversion sequence, special rules apply when selecting the best user-defined conversion (11.3.3, 11.3.3.1). [Example:

```cpp
class T {
    public:
    T();
};

class C : T {
    public:
    C(int);
};
T a = 1; // ill-formed: T(C(1)) not tried
```

— end example]

In each case where a candidate is a function template, candidate function template specializations are generated using template argument deduction (12.9.3, 12.9.2). If a constructor template or conversion function template has an `explicit-specifier` whose `constant-expression` is value-dependent (12.7.2), template argument deduction is performed first and then, if the context requires a candidate that is not explicit and the generated specialization is explicit (9.1.2), it will be removed from the candidate set. Those candidates are then handled as candidate functions in the usual way. A given name can refer to one or more function templates and also to a set of overloaded non-template functions. In such a case, the candidate functions generated from each function template are combined with the set of non-template candidate functions.

A defaulted move special function (10.3.5, 10.3.6) that is defined as deleted is excluded from the set of candidate functions in all contexts. A constructor inherited from class type C (10.9.3) that has a first
parameter of type “reference to cv1 P” (including such a constructor instantiated from a template) is excluded from the set of candidate functions when constructing an object of type cv2 D if the argument list has exactly one argument and C is reference-related to P and P is reference-related to D. [Example:

```cpp
struct A {
    A();
    A(A &&); // #1
    template<typename T> A(T &&); // #2
};
struct B : A {
    using A::A;
    B(const B &); // #3
    B(B &&) = default; // #4, implicitly deleted
    struct X { X(X &&) = delete; } x;
};
extern B b1;
B b2 = static_cast<B&&>(b1); // calls #3: #1, #2, and #4 are not viable
struct C { operator B&&(); }; // calls #3
struct C { operator B&&(); } x;
```
—end example]

### 11.3.1.1 Function call syntax

In a function call (7.6.1.2):

```
postfix-expression ( expression-list_opt )
```

If the `postfix-expression` denotes a set of overloaded functions and/or function templates, overload resolution is applied as specified in 11.3.1.1.1. If the `postfix-expression` denotes an object of class type, overload resolution is applied as specified in 11.3.1.1.2.

If the `postfix-expression` denotes the address of a set of overloaded functions and/or function templates, overload resolution is applied using that set as described above. If the function selected by overload resolution is a non-static member function, the program is ill-formed. [Note: The resolution of the address of an overload set in other contexts is described in 11.4. — end note]

### 11.3.1.1.1 Call to named function

Of interest in 11.3.1.1 are only those function calls in which the `postfix-expression` ultimately contains a name that denotes one or more functions that might be called. Such a `postfix-expression`, perhaps nested arbitrarily deep in parentheses, has one of the following forms:

```
postfix-expression:
    postfix-expression . id-expression
    postfix-expression -> id-expression
    primary-expression
```

These represent two syntactic subcategories of function calls: qualified function calls and unqualified function calls.

In qualified function calls, the name to be resolved is an `id-expression` and is preceded by an `->` or `. ` operator. Since the construct `A->B` is generally equivalent to `(*A).B`, the rest of Clause 11 assumes, without loss of generality, that all member function calls have been normalized to the form that uses an object and the `. ` operator. Furthermore, Clause 11 assumes that the `postfix-expression` that is the left operand of the `. ` operator has type “cv T” where T denotes a class. Under this assumption, the `id-expression` in the call is looked up as a member function of T following the rules for looking up names in classes (10.7). The function declarations found by that lookup constitute the set of candidate functions. The argument list is the `expression-list` in the call augmented by the addition of the left operand of the `. ` operator in the normalized member function call as the implied object argument (11.3.1).

In unqualified function calls, the name is not qualified by an `->` or `. ` operator and has the more general form of a `primary-expression`. The name is looked up in the context of the function call following the normal rules for name lookup in function calls (6.4). The function declarations found by that lookup constitute the set of candidate functions. Because of the rules for name lookup, the set of candidate functions consists

---

124) Note that cv-qualifiers on the type of objects are significant in overload resolution for both glvalue and class prvalue objects.
(1) entirely of non-member functions or (2) entirely of member functions of some class T. In case (1), the argument list is the same as the expression-list in the call. In case (2), the argument list is the expression-list in the call augmented by the addition of an implied object argument as in a qualified function call. If the keyword `this` (10.3.2.1) is in scope and refers to class T, or a derived class of T, then the implied object argument is `(*this)`. If the keyword `this` is not in scope or refers to another class, then a contrived object of type T becomes the implied object argument.\(^2\) If the argument list is augmented by a contrived object and overload resolution selects one of the non-static member functions of T, the call is ill-formed.

### 11.3.1.2 Call to object of class type

If the postfix-expression \(E\) in the function call syntax evaluates to a class object of type “\(cv\ T\)”, then the set of candidate functions includes at least the function call operators of T. The function call operators of T are obtained by ordinary lookup of the name \(\text{operator()}\) in the context of \((E) . \text{operator()}\).

In addition, for each non-explicit conversion function declared in T of the form

\[
\text{operator conversion-type-id ( ) cv-qualifier ref-qualifier opt noexcept-specifier opt attribute-specifier-seqopt ;}
\]

where cv-qualifier is the same cv-qualification as, or a greater cv-qualification than, cv, and where conversion-type-id denotes the type “pointer to function of \((P_1, \ldots, P_n)\) returning \(R\)”, or the type “reference to pointer to function of \((P_1, \ldots, P_n)\) returning \(R\)”, or the type “reference to function of \((P_1, \ldots, P_n)\) returning \(R\)”, a surrogate call function with the unique name call-function and having the form

\[
R \text{ call-function ( conversion-type-id } F, P_1 a_1, \ldots, P_n a_n) \{ \text{ return } F (a_1, \ldots, a_n); \}
\]

is also considered as a candidate function. Similarly, surrogate call functions are added to the set of candidate functions for each non-explicit conversion function declared in a base class of T provided the function is not hidden within T by another intervening declaration.\(^3\)

If such a surrogate call function is selected by overload resolution, the corresponding conversion function will be called to convert \(E\) to the appropriate function pointer or reference, and the function will then be invoked with the arguments of the call. If the conversion function cannot be called (e.g., because of an ambiguity), the program is ill-formed.

The argument list submitted to overload resolution consists of the argument expressions present in the function call syntax preceded by the implied object argument \((E)\). \([\text{Note: When comparing the call against the function call operators, the implied object argument is compared against the implicit object parameter of the function call operator. When comparing the call against a surrogate call function, the implied object argument is compared against the first parameter of the surrogate call function. The conversion function from which the surrogate call function was derived will be used in the conversion sequence for that parameter since it converts the implied object argument to the appropriate function pointer or reference required by that first parameter. — end note}]\) \([\text{Example:}\)

```c
int f1(int); 
int f2(float); 
typedef int (*fp1)(int); 
typedef int (*fp2)(float); 
struct A {
    operator fp1() { return f1; }
    operator fp2() { return f2; }
} a; 
int i = a(1); // calls f1 via pointer returned from conversion function
```

### 11.3.1.2 Operators in expressions

If no operand of an operator in an expression has a type that is a class or an enumeration, the operator is assumed to be a built-in operator and interpreted according to 7.6. \([\text{Note: Because } \ldots . *, \text{ and } :: \text{ cannot be overloaded, these operators are always built-in operators interpreted according to 7.6. } :: \text{ cannot be overloaded, but the rules in this subclause are used to determine the conversions to be applied to the second and third operands when they have class or enumeration type (7.6.16). — end note}]\) \([\text{Example:}\)

\[^{125}\text{An implied object argument must be contrived to correspond to the implicit object parameter attributed to member functions during overload resolution. It is not used in the call to the selected function. Since the member functions all have the same implicit object parameter, the contrived object will not be the cause to select or reject a function.}\]

\[^{126}\text{Note that this construction can yield candidate call functions that cannot be differentiated one from the other by overload resolution because they have identical declarations or differ only in their return type. The call will be ambiguous if overload resolution cannot select a match to the call that is uniquely better than such undifferentiable functions.}\]
struct String {
    String (const String&);
    String (const char*);
    operator const char* () const;
};
String operator + (const String&, const String&);

void f() {
    const char* p = "one" + "two";  // ill-formed because neither operand has class or enumeration type
    int I = 1 + 1;  // always evaluates to 2 even if class or enumeration types exist
    // that would perform the operation.
}

—end example

If either operand has a type that is a class or an enumeration, a user-defined operator function might be declared that implements this operator or a user-defined conversion can be necessary to convert the operand to a type that is appropriate for a built-in operator. In this case, overload resolution is used to determine which operator function or built-in operator is to be invoked to implement the operator. Therefore, the operator notation is first transformed to the equivalent function-call notation as summarized in Table 12 (where @ denotes one of the operators covered in the specified subclause). However, the operands are sequenced in the order prescribed for the built-in operator (7.6).

Table 12 — Relationship between operator and function call notation

For a unary operator % with an operand of a type whose cv-unqualified version is T1, and for a binary operator @ with a left operand of a type whose cv-unqualified version is T1 and a right operand of a type whose cv-unqualified version is T2, four sets of candidate functions, designated member candidates, non-member candidates, built-in candidates, and rewritten candidates, are constructed as follows:

(3.1) If T1 is a complete class type or a class currently being defined, the set of member candidates is the result of the qualified lookup of T1::operator% (11.3.1.1.1); otherwise, the set of member candidates is empty.

(3.2) The set of non-member candidates is the result of the unqualified lookup of operator% in the context of the expression according to the usual rules for name lookup in unqualified function calls (6.4.2) except that all member functions are ignored. However, if no operand has a class type, only those non-member functions in the lookup set that have a first parameter of type T1 or “reference to cv T1”, when T1 is an enumeration type, or (if there is a right operand) a second parameter of type T2 or “reference to cv T2”, when T2 is an enumeration type, are candidate functions.

(3.3) For the operator , the unary operator & or the operator ->, the built-in candidates set is empty. For all other operators, the built-in candidates include all of the candidate operator functions defined in 11.6 that, compared to the given operator,

(3.3.1) have the same operator name, and

(3.3.2) accept the same number of operands, and

(3.3.3) accept operand types to which the given operand or operands can be converted according to 11.3.3.1, and

(3.3.4) do not have the same parameter-type-list as any non-member candidate that is not a function template specialization.

(3.4) For the relational (7.6.9) and equality (7.6.10) operators, the rewritten candidates include all member, non-member, and built-in candidates for the operator <=> for which the rewritten expression (x <=> y)
© ISO/IEC N4762

@@ 0 is well-formed using that operator\(\Rightarrow\). For the relational (7.6.9), equality (7.6.10), and three-way comparison (7.6.8) operators, the rewritten candidates also include a synthesized candidate, with the order of the two parameters reversed, for each member, non-member, and built-in candidate for the operator \(\Rightarrow\) for which the rewritten expression 0 @ (y \(\Rightarrow\) x) is well-formed using that operator\(\Rightarrow\). [Note: A candidate synthesized from a member candidate has its implicit object parameter as the second parameter, thus implicit conversions are considered for the first, but not for the second, parameter. — end note] In each case, rewritten candidates are not considered in the context of the rewritten expression. For all other operators, the rewritten candidate set is empty.

4 For the built-in assignment operators, conversions of the left operand are restricted as follows:
   (4.1) — no temporaries are introduced to hold the left operand, and
   (4.2) — no user-defined conversions are applied to the left operand to achieve a type match with the left-most parameter of a built-in candidate.

5 For all other operators, no such restrictions apply.

6 The set of candidate functions for overload resolution for some operator \(\oplus\) is the union of the member candidates, the non-member candidates, the built-in candidates, and the rewritten candidates for that operator \(\oplus\).

7 The argument list contains all of the operands of the operator. The best function from the set of candidate functions is selected according to 11.3.2 and 11.3.3. [Example:
   ```c
   struct A {
       operator int();
   };
   A operator+(const A&, const A&);
   void m() {
       A a, b;
       a + b; // operator+(a, b) chosen over int(a) + int(b)
   }
   — end example]

8 If a rewritten candidate is selected by overload resolution for an operator \(\oplus\), x \(\oplus\) y is interpreted as the rewritten expression: 0 \(\oplus\) (y \(\Rightarrow\) x) if the selected candidate is a synthesized candidate with reversed order of parameters, or (x \(\Rightarrow\) y) \(\oplus\) 0 otherwise, using the selected rewritten operator\(\Rightarrow\) candidate.

9 If a built-in candidate is selected by overload resolution, the operands of class type are converted to the types of the corresponding parameters of the selected operation function, except that the second standard conversion sequence of a user-defined conversion sequence (11.3.3.1.2) is not applied. Then the operator is treated as the corresponding built-in operator and interpreted according to 7.6. [Example:
   ```c
   struct X {
       operator double();
   };
   struct Y {
       operator int*();
   };
   int *a = Y() + 100.0; // error: pointer arithmetic requires integral operand
   int *b = Y() + X(); // error: pointer arithmetic requires integral operand
   — end example]

10 The second operand of operator \(\Rightarrow\) is ignored in selecting an operator\(\Rightarrow\) function, and is not an argument when the operator\(\Rightarrow\) function is called. When operator\(\Rightarrow\) returns, the operator \(\Rightarrow\) is applied to the value returned, with the original second operand.128

11 If the operator is the operator ,, the unary operator & or the operator \(\Rightarrow\), and there are no viable functions, then the operator is assumed to be the built-in operator and interpreted according to 7.6.

12 [Note: The lookup rules for operators in expressions are different than the lookup rules for operator function names in a function call, as shown in the following example:

127) If the set of candidate functions is empty, overload resolution is unsuccessful.
128) If the value returned by the operator\(\Rightarrow\) function has class type, this may result in selecting and calling another operator\(\Rightarrow\) function. The process repeats until an operator\(\Rightarrow\) function returns a value of non-class type.
struct A {
};
void operator + (A, A);

struct B {
    void operator + (B);
    void f ();
};
A a;

void B::f() {
    operator+ (a,a); // error: global operator hidden by member
    a + a; // OK: calls global operator+
}

11.3.1.3 Initialization by constructor

When objects of class type are direct-initialized (9.3), copy-initialized from an expression of the same or a derived class type (9.3), or default-initialized (9.3), overload resolution selects the constructor. For direct-initialization or default-initialization that is not in the context of copy-initialization, the candidate functions are all the constructors of the class of the object being initialized. For copy-initialization (including default initialization in the context of copy-initialization), the candidate functions are all the converting constructors (10.3.8.1) of that class. The argument list is the expression-list or assignment-expression of the initializer.

11.3.1.4 Copy-initialization of class by user-defined conversion

Under the conditions specified in 9.3, as part of a copy-initialization of an object of class type, a user-defined conversion can be invoked to convert an initializer expression to the type of the object being initialized. Overload resolution is used to select the user-defined conversion to be invoked. [Note: The conversion performed for indirect binding to a reference to a possibly cv-qualified class type is determined in terms of a corresponding non-reference copy-initialization. — end note] Assuming that “cv1 T” is the type of the object being initialized, with T a class type, the candidate functions are selected as follows:

1. The converting constructors (10.3.8.1) of T are candidate functions.
2. When the type of the initializer expression is a class type “cv S”, the non-explicit conversion functions of S and its base classes are considered. When initializing a temporary object (10.3) to be bound to the first parameter of a constructor where the parameter is of type “reference to possibly cv-qualified T” and the constructor is called with a single argument in the context of direct-initialization of an object of type “cv2 T”, explicit conversion functions are also considered. Those that are not hidden within S and yield a type whose cv-unqualified version is the same type as T or is a derived class thereof are candidate functions. A call to a conversion function returning “reference to X” is a glvalue of type X, and such a conversion function is therefore considered to yield X for this process of selecting candidate functions.

In both cases, the argument list has one argument, which is the initializer expression. [Note: This argument will be compared against the first parameter of the constructors and against the implicit object parameter of the conversion functions. — end note]

11.3.1.5 Initialization by conversion function

Under the conditions specified in 9.3, as part of an initialization of an object of non-class type, a conversion function can be invoked to convert an initializer expression of class type to the type of the object being initialized. Overload resolution is used to select the conversion function to be invoked. Assuming that “cv1 T” is the type of the object being initialized, and “cv S” is the type of the initializer expression, with S a class type, the candidate functions are selected as follows:

1. The conversion functions of S and its base classes are considered. Those non-explicit conversion functions that are not hidden within S and yield type T or a type that can be converted to type T via a standard conversion sequence (11.3.3.1.1) are candidate functions. For direct-initialization, those explicit conversion functions that are not hidden within S and yield type T or a type that can be converted to type T with a qualification conversion (7.3.5) are also candidate functions. Conversion functions that return a cv-qualified type are considered to yield the cv-unqualified version of that type.
for this process of selecting candidate functions. A call to a conversion function returning “reference to X” is a glvalue of type X, and such a conversion function is therefore considered to yield X for this process of selecting candidate functions.

2 The argument list has one argument, which is the initializer expression. [Note: This argument will be compared against the implicit object parameter of the conversion functions. —end note]

11.3.1.6 Initialization by conversion function for direct reference binding [over.match.ref]

Under the conditions specified in 9.3.3, a reference can be bound directly to the result of applying a conversion function to an initializer expression. Overload resolution is used to select the conversion function to be invoked. Assuming that “reference to cvl T” is the type of the reference being initialized, and “cv S” is the type of the initializer expression, with S a class type, the candidate functions are selected as follows:

(1.1) — The conversion functions of S and its base classes are considered. Those non-explicit conversion functions that are not hidden within S and yield type “lvalue reference to cv2 T2” (when initializing an lvalue reference or an rvalue reference to function) or “cv2 T2” or “rvalue reference to cv2 T2” (when initializing an rvalue reference or an lvalue reference to function), where “cv1 T” is reference-compatible (9.3.3) with “cv2 T2”, are candidate functions. For direct-initialization, those explicit conversion functions that are not hidden within S and yield type “lvalue reference to cv2 T2” or “cv2 T2” or “rvalue reference to cv2 T2”, respectively, where T2 is the same type as T or can be converted to type T with a qualification conversion (7.3.5), are also candidate functions.

2 The argument list has one argument, which is the initializer expression. [Note: This argument will be compared against the implicit object parameter of the conversion functions. —end note]

11.3.1.7 Initialization by list-initialization [over.match.list]

When objects of non-aggregate class type T are list-initialized such that 9.3.4 specifies that overload resolution is performed according to the rules in this subclause, overload resolution selects the constructor in two phases:

(1.1) — Initially, the candidate functions are the initializer-list constructors (9.3.4) of the class T and the argument list consists of the initializer list as a single argument.

(1.2) — If no viable initializer-list constructor is found, overload resolution is performed again, where the candidate functions are all the constructors of the class T and the argument list consists of the elements of the initializer list.

If the initializer list has no elements and T has a default constructor, the first phase is omitted. In copy-list-initialization, if an explicit constructor is chosen, the initialization is ill-formed. [Note: This differs from other situations (11.3.1.3, 11.3.1.4), where only converting constructors are considered for copy-initialization. This restriction only applies if this initialization is part of the final result of overload resolution. —end note]

11.3.1.8 Class template argument deduction [over.match.class.deduct]

When resolving a placeholder for a deduced class type (9.1.7.5) where the template-name names a primary class template C, a set of functions and function templates is formed comprising:

(1.1) — If C is defined, for each constructor of C, a function template with the following properties:

(1.1.1) — The template parameters are the template parameters of C followed by the template parameters (including default template arguments) of the constructor, if any.

(1.1.2) — The types of the function parameters are those of the constructor.

(1.1.3) — The return type is the class template specialization designated by C and template arguments corresponding to the template parameters of C.

(1.2) — If C is not defined or does not declare any constructors, an additional function template derived as above from a hypothetical constructor C().

(1.3) — An additional function template derived as above from a hypothetical constructor C(C()), called the copy deduction candidate.

(1.4) — For each deduction-guide, a function or function template with the following properties:

(1.4.1) — The template parameters, if any, and function parameters are those of the deduction-guide.

(1.4.2) — The return type is the simple-template-id of the deduction-guide.

2 Initialization and overload resolution are performed as described in 9.3 and 11.3.1.3, 11.3.1.4, or 11.3.1.7 (as appropriate for the type of initialization performed) for an object of a hypothetical class type, where the
selected functions and function templates are considered to be the constructors of that class type for the purpose of forming an overload set, and the initializer is provided by the context in which class template argument deduction was performed. As an exception, the first phase in 11.3.1.7 (considering initializer-list constructors) is omitted if the initializer list consists of a single expression of type \( cv\ U\), where \( U\) is a specialization of \( C\) or a class derived from a specialization of \( C\). If the function or function template was generated from a constructor or deduction-guide that had an explicit-specifier, each such notional constructor is considered to have that same explicit-specifier. All such notional constructors are considered to be public members of the hypothetical class type.

[Example:

```cpp
template <class T> struct A {
    explicit A(const T& , ...) noexcept;  // #1
    A(T&& , ...);                       // #2
};

int i;
A a1 = { i, i }; // error: explicit constructor #1 selected in copy-list-initialization during deduction,
                  // cannot deduce from non-forwarding real value reference in #2

A a2(i, i);     // OK, #1 deduces to A<int> and also initializes
A a3(0, i);     // OK, #2 deduces to A<int> and also initializes
A a4 = {0, i};  // OK, #2 deduces to A<int> and also initializes

template <class T> A(const T& , const T&) -> A<T&>; // #3

template <class T> explicit A(T&& , T&&) -> A<T>; // #4

A a5 = {0, 1}; // error: explicit deduction guide #4 selected in copy-list-initialization during deduction
A a6(0,1);     // OK, #4 deductes to A<int> and #2 initializes
A a7 = {0, 1}; // error: #3 deduces to A<int&>, #1 and #2 declare same constructor
A a8(0,1);     // error: #3 deduces to A<int&>, #1 and #2 declare same constructor

template <class T> struct B {
    template <class U> using TA = T;
    template <class U> B(U, TA<U>);
};

B b((int*)0, (char*)0); // OK, deduces B<char>
```

— end example]

11.3.2 Viable functions

From the set of candidate functions constructed for a given context (11.3.1), a set of viable functions is chosen, from which the best function will be selected by comparing argument conversion sequences and associated constraints (12.4.2) for the best fit (11.3.3). The selection of viable functions considers associated constraints, if any, and relationships between arguments and function parameters other than the ranking of conversion sequences.

First, to be a viable function, a candidate function shall have enough parameters to agree in number with the arguments in the list.

1. If there are \( m\) arguments in the list, all candidate functions having exactly \( m\) parameters are viable.
2. A candidate function having fewer than \( m\) parameters is viable only if it has an ellipsis in its parameter list (9.2.3.5). For the purposes of overload resolution, any argument for which there is no corresponding parameter is considered to “match the ellipsis” (11.3.3.1.3).
3. A candidate function having more than \( m\) parameters is viable only if the \((m+1)^{st}\) parameter has a default argument (9.2.3.6). For the purposes of overload resolution, the parameter list is truncated on the right, so that there are exactly \( m\) parameters.

Second, for a function to be viable, if it has associated constraints (12.4.2), those constraints shall be satisfied (12.4.1).

129) According to 9.2.3.6, parameters following the \((m+1)^{st}\) parameter must also have default arguments.
Third, for \( F \) to be a viable function, there shall exist for each argument an implicit conversion sequence (11.3.3.1) that converts that argument to the corresponding parameter of \( F \). If the parameter has reference type, the implicit conversion sequence includes the operation of binding the reference, and the fact that an lvalue reference to non-\( \text{const} \) cannot be bound to an rvalue and that an rvalue reference cannot be bound to an lvalue can affect the viability of the function (see 11.3.3.1.4).

### 11.3.3 Best viable function

1. Define \( \text{ICS}(F) \) as follows:

   (1.1) — If \( F \) is a static member function, \( \text{ICS}(F) \) is defined such that \( \text{ICS}(F) \) is neither better nor worse than \( \text{ICS}(G) \) for any function \( G \), and, symmetrically, \( \text{ICS}(G) \) is neither better nor worse than \( \text{ICS}(F) \); otherwise,

   (1.2) — let \( \text{ICS}(F) \) denote the implicit conversion sequence that converts the \( i \)-th argument in the list to the type of the \( i \)-th parameter of viable function \( F \). 11.3.3.1 defines the implicit conversion sequences and 11.3.3.2 defines what it means for one implicit conversion sequence to be a better conversion sequence or worse conversion sequence than another.

Given these definitions, a viable function \( F_1 \) is defined to be a better function than another viable function \( F_2 \) if for all arguments \( i \), \( \text{ICS}(F_1) \) is not a worse conversion sequence than \( \text{ICS}(F_2) \), and then

(1.3) — for some argument \( j \), \( \text{ICS}(F_1) \) is a better conversion sequence than \( \text{ICS}(F_2) \), or, if not that,

(1.4) — the context is an initialization by user-defined conversion (see 9.3, 11.3.1.5, and 11.3.1.6) and the standard conversion sequence from the return type of \( F_1 \) to the destination type (i.e., the type of the entity being initialized) is a better conversion sequence than the standard conversion sequence from the return type of \( F_2 \) to the destination type [Example:

```cpp
struct A {
    A();
    operator int();
    operator double();
} a;
int i = a;  // a.operator int() followed by no conversion is better than
            // a.operator double() followed by a conversion to int
float x = a; // ambiguous: both possibilities require conversions,
              // and neither is better than the other
```

— end example] or, if not that,

(1.5) — the context is an initialization by conversion function for direct reference binding (11.3.1.6) of a reference to function type, the return type of \( F_1 \) is the same kind of reference (lvalue or rvalue) as the reference being initialized, and the return type of \( F_2 \) is not [Example:

```cpp
template <class T> struct A {
    operator T&();  // #1
    operator T&&(); // #2
};
typedef int Fn();
A<Fn> a;
Fn& lf = a;  // calls #1
Fn&& rf = a; // calls #2
```

— end example] or, if not that,

(1.6) — \( F_1 \) is not a function template specialization and \( F_2 \) is a function template specialization, or, if not that,

(1.7) — \( F_1 \) and \( F_2 \) are function template specializations, and the function template for \( F_1 \) is more specialized than the template for \( F_2 \) according to the partial ordering rules described in 12.6.6.2, or, if not that,

(1.8) — \( F_1 \) and \( F_2 \) are non-template functions with the same parameter-type-lists, and \( F_1 \) is more constrained than \( F_2 \) according to the partial ordering of constraints described in 12.4.4, or if not that,

(1.9) — \( F_1 \) is a constructor for a class \( D \), \( F_2 \) is a constructor for a base class \( B \) of \( D \), and for all arguments the corresponding parameters of \( F_1 \) and \( F_2 \) have the same type. [Example:

---

130) If a function is a static member function, this definition means that the first argument, the implied object argument, has no effect in the determination of whether the function is better or worse than any other function.
struct A {
    A(int = 0);
};

struct B: A {
    using A::A;
    B();
};

int main() {
    B b;  // OK, B::B()
}

— end example] or, if not that,

— F2 is a rewritten candidate (11.3.1.2) and F1 is not [Example:

    struct S {
        auto operator<=>(const S&, const S&) = default; // #1
        bool operator<(const S&, const S&); // #2
    };
    bool b = S() < S(); // calls #2
— end example] or, if not that,

— F1 and F2 are rewritten candidates, and F2 is a synthesized candidate with reversed order of parameters and F1 is not [Example:

    struct S {
        std::weak_ordering operator<=>(const S&, int); // #1
        std::weak_ordering operator<=>(int, const S&); // #2
    };
    bool b = 1 < S(); // calls #2
— end example] or, if not that

— F1 is generated from a deduction-guide (11.3.1.8) and F2 is not, or, if not that,

— F1 is the copy deduction candidate (11.3.1.8) and F2 is not, or, if not that,

— F1 is generated from a non-template constructor and F2 is generated from a constructor template. [Example:

    template <class T> struct A {
        using value_type = T;
        A(value_type); // #1
        A(const A&); // #2
        A(T, T, int); // #3
        template<class U>
        A(int, T, U); // #4
        // #5 is the copy deduction candidate, A(A)
    };

    A x(1, 2, 3);  // uses #3, generated from a non-template constructor

    template <class T>
    A(T) -> A<T>; // #6, less specialized than #5

    A a(42); // uses #6 to deduce A<int> and #1 to initialize
    A b = a; // uses #5 to deduce A<int> and #2 to initialize

    template <class T>
    A(A<T>) -> A<A<T>>; // #7, as specialized as #5

    A b2 = a; // uses #7 to deduce A<A<int>> and #1 to initialize
— end example]
If there is exactly one viable function that is a better function than all other viable functions, then it is the one selected by overload resolution; otherwise the call is ill-formed.  

Example:

```c
void Fcn(const int*, short);
void Fcn(int*, int);

int i;
short s = 0;

void f() {
 Fcn(&i, s); // is ambiguous because &i → int* is better than &i → const int*
   // but s → short is also better than s → int
 Fcn(&i, 1L); // calls Fcn(int*, int), because &i → int* is better than &i → const int*
   // and 1L → short and 1L → int are indistinguishable
 Fcn(&i, 'c'); // calls Fcn(int*, int), because &i → int* is better than &i → const int*
   // and c → int is better than c → short
}

— end example
```

If the best viable function resolves to a function for which multiple declarations were found, and if at least two of these declarations — or the declarations they refer to in the case of using-declarations — specify a default argument that made the function viable, the program is ill-formed.  

Example:

```c
namespace A {
 extern "C" void f(int = 5);
}
namespace B {
 extern "C" void f(int = 5);
}
using A::f;
using B::f;

void use() {
 f(3); // OK, default argument was not used for viability
 f(); // error: found default argument twice
}

— end example
```

### 11.3.3.1 Implicit conversion sequences

An implicit conversion sequence is a sequence of conversions used to convert an argument in a function call to the type of the corresponding parameter of the function being called. The sequence of conversions is an implicit conversion as defined in 7.3, which means it is governed by the rules for initialization of an object or reference by a single expression (9.3, 9.3.3).

Implicit conversion sequences are concerned only with the type, cv-qualification, and value category of the argument and how these are converted to match the corresponding properties of the parameter. Other properties, such as the lifetime, storage class, alignment, accessibility of the argument, whether the argument is a bit-field, and whether a function is deleted (9.4.3), are ignored. So, although an implicit conversion sequence can be defined for a given argument-parameter pair, the conversion from the argument to the parameter might still be ill-formed in the final analysis.

A well-formed implicit conversion sequence is one of the following forms:

1. a standard conversion sequence (11.3.3.1.1),
2. a user-defined conversion sequence (11.3.3.1.2), or
3. an ellipsis conversion sequence (11.3.3.1.3).

The algorithm for selecting the best viable function is linear in the number of viable functions. Run a simple tournament to find a function \( W \) that is not worse than any opponent it faced. Although another function \( F \) that \( W \) did not face might be at least as good as \( W \), \( F \) cannot be the best function because at some point in the tournament \( F \) encountered another function \( G \) such that \( F \) was not better than \( G \). Hence, \( W \) is either the best function or there is no best function. So, make a second pass over the viable functions to verify that \( W \) is better than all other functions.
However, if the target is

- the first parameter of a constructor or
- the implicit object parameter of a user-defined conversion function

and the constructor or user-defined conversion function is a candidate by

- 11.3.1.3, when the argument is the temporary in the second step of a class copy-initialization,
- 11.3.1.4, 11.3.1.5, or 11.3.1.6 (in all cases), or
- the second phase of 11.3.1.7 when the initializer list has exactly one element that is itself an initializer list, and the target is the first parameter of a constructor of class $X$, and the conversion is to $X$ or reference to $cvX$,

user-defined conversion sequences are not considered. [Note: These rules prevent more than one user-defined conversion from being applied during overload resolution, thereby avoiding infinite recursion. —end note] [Example:

```c
struct Y { Y(int); };  
struct A { operator int(); };  
Y y1 = A(); // error: A::operator int() is not a candidate

struct X { X(); };  
struct B { operator X(); };  
B b;  
X x{(b)}; // error: B::operator X() is not a candidate
```
—end example]

For the case where the parameter type is a reference, see 11.3.3.1.4.

When the parameter type is not a reference, the implicit conversion sequence models a copy-initialization of the parameter from the argument expression. The implicit conversion sequence is the one required to convert the argument expression to a prvalue of the type of the parameter. [Note: When the parameter has a class type, this is a conceptual conversion defined for the purposes of Clause 11; the actual initialization is defined in terms of constructors and is not a conversion. —end note] Any difference in top-level cv-qualification is subsumed by the initialization itself and does not constitute a conversion. [Example: A parameter of type $A$ can be initialized from an argument of type $const A$. The implicit conversion sequence for that case is the identity sequence; it contains no “conversion” from $const A$ to $A$. —end example] When the parameter has a class type and the argument expression has the same type, the implicit conversion sequence is an identity conversion. When the parameter has a class type and the argument expression has a derived class type, the implicit conversion sequence is a derived-to-base conversion from the derived class to the base class. [Note: There is no such standard conversion; this derived-to-base conversion exists only in the description of implicit conversion sequences. —end note] A derived-to-base conversion has Conversion rank (11.3.3.1.1).

In all contexts, when converting to the implicit object parameter or when converting to the left operand of an assignment operation only standard conversion sequences are allowed.

If no conversions are required to match an argument to a parameter type, the implicit conversion sequence is the standard conversion sequence consisting of the identity conversion (11.3.3.1.1).

If no sequence of conversions can be found to convert an argument to a parameter type, an implicit conversion sequence cannot be formed.

If several different sequences of conversions exist that each convert the argument to the parameter type, the implicit conversion sequence associated with the parameter is defined to be the unique conversion sequence designated the *ambiguous conversion sequence*. For the purpose of ranking implicit conversion sequences as described in 11.3.3.2, the ambiguous conversion sequence is treated as a user-defined conversion sequence that is indistinguishable from any other user-defined conversion sequence. [Note: This rule prevents a function from becoming non-viable because of an ambiguous conversion sequence for one of its parameters. [Example:

```c
class B;  
class A { A (B&);};  
class B { operator A () ; };  
class C { C (B&); };  
void f(A) { }  
void f(C) { }  
B b;
```

§ 11.3.3.1
f(b);  // ill-formed: ambiguous because there is a conversion b → C (via constructor)
// and an (ambiguous) conversion b → A (via constructor or conversion function)
void f(B) { }
f(b);  // OK, unambiguous

— end example — end note] If a function that uses the ambiguous conversion sequence is selected as the best viable function, the call will be ill-formed because the conversion of one of the arguments in the call is ambiguous.

11 The three forms of implicit conversion sequences mentioned above are defined in the following subclauses.

11.3.3.1.1 Standard conversion sequences

Table 13 summarizes the conversions defined in 7.3 and partitions them into four disjoint categories: Lvalue Transformation, Qualification Adjustment, Promotion, and Conversion. [Note: These categories are orthogonal with respect to value category, cv-qualification, and data representation: the Lvalue Transformations do not change the cv-qualification or data representation of the type; the Qualification Adjustments do not change the value category or data representation of the type; and the Promotions and Conversions do not change the value category or cv-qualification of the type. — end note]

[Note: As described in 7.3, a standard conversion sequence is either the Identity conversion by itself (that is, no conversion) or consists of one to three conversions from the other four categories. If there are two or more conversions in the sequence, the conversions are applied in the canonical order: Lvalue Transformation, Promotion or Conversion, Qualification Adjustment. — end note]

Each conversion in Table 13 also has an associated rank (Exact Match, Promotion, or Conversion). These are used to rank standard conversion sequences (11.3.3.2). The rank of a conversion sequence is determined by considering the rank of each conversion in the sequence and the rank of any reference binding (11.3.3.1.4). If any of those has Conversion rank, the sequence has Conversion rank; otherwise, if any of those has Promotion rank, the sequence has Promotion rank; otherwise, the sequence has Exact Match rank.

</table>

11.3.3.1.2 User-defined conversion sequences

1 A user-defined conversion sequence consists of an initial standard conversion sequence followed by a user-defined conversion (10.3.8) followed by a second standard conversion sequence. If the user-defined conversion is specified by a constructor (10.3.8.1), the initial standard conversion sequence converts the source type to the type required by the argument of the constructor. If the user-defined conversion is specified by a conversion function (10.3.8.2), the initial standard conversion sequence converts the source type to the implicit object parameter of the conversion function.

2 The second standard conversion sequence converts the result of the user-defined conversion to the target type for the sequence. Since an implicit conversion sequence is an initialization, the special rules for initialization by user-defined conversion apply when selecting the best user-defined conversion for a user-defined conversion sequence (see 11.3.3 and 11.3.3.1).
3 If the user-defined conversion is specified by a specialization of a conversion function template, the second standard conversion sequence shall have exact match rank.

4 A conversion of an expression of class type to the same class type is given Exact Match rank, and a conversion of an expression of class type to a base class of that type is given Conversion rank, in spite of the fact that a constructor (i.e., a user-defined conversion function) is called for those cases.

11.3.3.1.3 Ellipsis conversion sequences

An ellipsis conversion sequence occurs when an argument in a function call is matched with the ellipsis parameter specification of the function called (see 7.6.1.2).

11.3.3.1.4 Reference binding

When a parameter of reference type binds directly (9.3.3) to an argument expression, the implicit conversion sequence is the identity conversion, unless the argument expression has a type that is a derived class of the parameter type, in which case the implicit conversion sequence is a derived-to-base Conversion (11.3.3.1).

Example:

```c
struct A { int x, y; }
struct B : public A { } b;
int f(A&);  // calls f(B&), an exact match, rather than f(A&), a conversion
int i = f(b);
```

If the parameter binds directly to the result of applying a conversion function to the argument expression, the implicit conversion sequence is a user-defined conversion sequence (11.3.3.1.2), with the second standard conversion sequence either an identity conversion or, if the conversion function returns an entity of a type that is a derived class of the parameter type, a derived-to-base conversion.

2 When a parameter of reference type is not bound directly to an argument expression, the conversion sequence is the one required to convert the argument expression to the referenced type according to 11.3.3.1. Conceptually, this conversion sequence corresponds to copy-initializing a temporary of the referenced type with the argument expression. Any difference in top-level cv-qualification is subsumed by the initialization itself and does not constitute a conversion.

3 Except for an implicit object parameter, for which see 11.3.1, a standard conversion sequence cannot be formed if it requires binding an lvalue reference other than a reference to a non-volatile const type to an rvalue or binding an lvalue reference to an rvalue other than a function rvalue. [Note: This means, for example, that a candidate function cannot be a viable function if it has a non-const lvalue reference parameter (other than the implicit object parameter) and the corresponding argument would require a temporary to be created to initialize the rvalue reference (see 9.3.3). — end note]

4 Other restrictions on binding a reference to a particular argument that are not based on the types of the reference and the argument do not affect the formation of a standard conversion sequence, however. [Example: A function with an “lvalue reference to int” parameter can be a viable candidate even if the corresponding argument is an int bit-field. The formation of implicit conversion sequences treats the int bit-field as an int lvalue and finds an exact match with the parameter. If the function is selected by overload resolution, the call will nonetheless be ill-formed because of the prohibition on binding a non-const lvalue reference to a bit-field (9.3.3). — end example]

11.3.3.1.5 List-initialization sequence

When an argument is an initializer list (9.3.4), it is not an expression and special rules apply for converting it to a parameter type.

2 If the initializer list is a designated-initializer-list, a conversion is only possible if the parameter has an aggregate type that can be initialized from the initializer list according to the rules for aggregate initialization (9.3.1), in which case the implicit conversion sequence is a user-defined conversion sequence whose second standard conversion sequence is an identity conversion. [Note: Aggregate initialization does not require that the members are declared in designation order. If, after overload resolution, the order does not match for the selected overload, the initialization of the parameter will be ill-formed (9.3.4). [Example:
Otherwise, if the parameter type is an aggregate class \( X \) and the initializer list has a single element of type \( cv U \), where \( U \) is \( X \) or a class derived from \( X \), the implicit conversion sequence is the one required to convert the element to the parameter type.

Otherwise, if the parameter type is a character array\(^{132}\) and the initializer list has a single element that is an appropriately-typed string literal (9.3.2), the implicit conversion sequence is the identity conversion.

Otherwise, if the parameter type is \( \text{std::initializer_list}<X> \) and all the elements of the initializer list can be implicitly converted to \( X \), the implicit conversion sequence is the worst conversion necessary to convert an element of the list to \( X \), or if the initializer list has no elements, the identity conversion. This conversion can be a user-defined conversion even in the context of a call to an initializer-list constructor. [Example:

```c
struct A {
    A(std::initializer_list<double>); // #1
    A(std::initializer_list<complex<double>>); // #2
    A(std::initializer_list<std::string>); // #3
};
A a{ 1.0, 2.0 }; // OK, uses #1
```

```c
void g(A);
g({"foo", "bar" }); // OK, uses #3
```

```c
typedef int IA[3];
void h(const IA&);
h({ 1, 2, 3 }); // OK: identity conversion
```

—end example—end note]  

\(^7\) Otherwise, if the parameter type is a non-aggregate class \( X \) and overload resolution per 11.3.1.7 chooses a single best constructor \( C \) of \( X \) to perform the initialization of an object of type \( X \) from the argument initializer list:

\(\begin{align*}
(7.1) & \quad \text{If } C \text{ is not an initializer-list constructor and the initializer list has a single element of type } cv U, \text{ where } U \text{ is } X \text{ or a class derived from } X, \text{ the implicit conversion sequence has Exact Match rank if } U \text{ is } X, \text{ or Conversion rank if } U \text{ is derived from } X.
(7.2) & \quad \text{Otherwise, the implicit conversion sequence is a user-defined conversion sequence with the second standard conversion sequence an identity conversion.}
\end{align*}\)

If multiple constructors are viable but none is better than the others, the implicit conversion sequence is the ambiguous conversion sequence. User-defined conversions are allowed for conversion of the initializer list elements to the constructor parameter types except as noted in 11.3.3.1. [Example:

```c
struct A {
    A(std::initializer_list<int>);  // #1
};
A a(1,2,3); // OK: f(A(std::initializer_list<int>)) user-defined conversion
```

\[^{132}\] Since there are no parameters of array type, this will only occur as the referenced type of a reference parameter.
struct B {
  B(int, double);
};
void g(B);
g( {'a', 'b'} ); // OK: g(B(int, double)) user-defined conversion
g( {1.0, 1.0} );  // error: narrowing

void f(B);
f( {'a', 'b'} );  // error: ambiguous f(A) or f(B)

struct C {
  C(std::string);
};
void h(C);
h( "foo" );      // OK: h(C(std::string("foo")))

struct D {
  D(A, C);
};
void i(D);
i( {1,2}, {"bar"} ); // OK: i(D(A(std::initializer_list<int>{1,2}), C(std::string("bar"))))
— end example]

Otherwise, if the parameter has an aggregate type which can be initialized from the initializer list according to the rules for aggregate initialization (9.3.1), the implicit conversion sequence is a user-defined conversion sequence with the second standard conversion sequence an identity conversion. [Example:

    struct A {
      int m1;
      double m2;
    };

    void f(A);
f( {'a', 'b'} ); // OK: f(A(int,double)) user-defined conversion
f( {1.0} );     // error: narrowing
— end example]

Otherwise, if the parameter is a reference, see 11.3.3.1.4. [Note: The rules in this subclause will apply for initializing the underlying temporary for the reference. — end note] [Example:

    struct A {
      int m1;
      double m2;
    };

    void f(const A&);
f( {'a', 'b'} ); // OK: f(A(int,double)) user-defined conversion
f( {1.0} );    // error: narrowing

    void g(const double &);
g(111);          // same conversion as int to double
— end example]

Otherwise, if the parameter type is not a class:

— if the initializer list has one element that is not itself an initializer list, the implicit conversion sequence is the one required to convert the element to the parameter type; [Example:

    void f(int);
f( 'a' );        // OK: same conversion as char to int
f( {1.0} );       // error: narrowing
— end example]

— if the initializer list has no elements, the implicit conversion sequence is the identity conversion. [Example:
void f(int);
f( { } ); // OK: identity conversion
— end example]

11 In all cases other than those enumerated above, no conversion is possible.

11.3.3.2 Ranking implicit conversion sequences
[over.ics.rank]

1 This subclause defines a partial ordering of implicit conversion sequences based on the relationships better conversion sequence and better conversion. If an implicit conversion sequence S1 is defined by these rules to be a better conversion sequence than S2, then it is also the case that S2 is a worse conversion sequence than S1. If conversion sequence S1 is neither better than nor worse than conversion sequence S2, S1 and S2 are said to be indistinguishable conversion sequences.

2 When comparing the basic forms of implicit conversion sequences (as defined in 11.3.3.1)

(2.1) — a standard conversion sequence (11.3.3.1.1) is a better conversion sequence than a user-defined conversion sequence or an ellipsis conversion sequence, and

(2.2) — a user-defined conversion sequence (11.3.3.1.2) is a better conversion sequence than an ellipsis conversion sequence (11.3.3.1.3).

3 Two implicit conversion sequences of the same form are indistinguishable conversion sequences unless one of the following rules applies:

(3.1) — List-initialization sequence L1 is a better conversion sequence than list-initialization sequence L2 if

(3.1.1) — L1 converts to \texttt{std::initializer\_list<X>} for some X and L2 does not, or, if not that,

(3.1.2) — L1 converts to type “array of \(N1\) T”, L2 converts to type “array of \(N2\) T”, and \(N1\) is smaller than \(N2\), even if one of the other rules in this paragraph would otherwise apply. [Example:

```cpp
void f1(int);
void f1(std::initializer\_list<long>);
void g1() { f1({42}); } // chooses #2

void f2(std::initializer\_list<std::string>); // #4
void g2() { f2("foo","bar"); } // chooses #4

— end example]
```

(3.2) — Standard conversion sequence S1 is a better conversion sequence than standard conversion sequence S2 if

(3.2.1) — S1 is a proper subsequence of S2 (comparing the conversion sequences in the canonical form defined by 11.3.3.1.1, excluding any Lvalue Transformation; the identity conversion sequence is considered to be a subsequence of any non-identity conversion sequence) or, if not that,

(3.2.2) — the rank of S1 is better than the rank of S2, or S1 and S2 have the same rank and are distinguishable by the rules in the paragraph below, or, if not that,

(3.2.3) — S1 and S2 are reference bindings (9.3.3) and neither refers to an implicit object parameter of a non-static member function declared without a ref-qualifier, and S1 binds an rvalue reference to an rvalue and S2 binds an lvalue reference [Example:

```cpp
int i;
int f1();
int\&\& f2();
int g(const int\&);
int g(const int\&\&);
int j = g(i); // calls g(const int&)
int k = g(f1()); // calls g(const int\&\&)
int l = g(f2()); // calls g(const int\&\&)

struct A {
    \&\& operator<<(int);
    void p();
    void p(\&\&);
};
```
A& operator<<(A&&, char);
A() << 1; // calls A::operator<<(int)
A() << 'c'; // calls operator<<(A&, char)
A a;
a << 1; // calls A::operator<<(int)
a << 'c'; // calls A::operator<<(int)
A().p(); // calls A::p()&
a.p(); // calls A::p()

@end example] or, if not that,

(3.2.4) — S1 and S2 are reference bindings (9.3.3) and S1 binds an lvalue reference to a function lvalue and S2 binds an rvalue reference to a function lvalue [Example:

int f(void&()); // #1
int f(void&&()); // #2
void g();
int i1 = f(g); // calls #1

@end example] or, if not that,

(3.2.5) — S1 and S2 differ only in their qualification conversion and yield similar types T1 and T2 (7.3.5), respectively, and the cv-qualification signature of type T1 is a proper subset of the cv-qualification signature of type T2 [Example:

int f(const volatile int*);
int f(const int*);
void g();
int j = f(g); // calls f(const int*)

@end example] or, if not that,

(3.2.6) — S1 and S2 are reference bindings (9.3.3), and the types to which the references refer are the same type except for top-level cv-qualifiers, and the type to which the reference initialized by S2 refers is more cv-qualified than the type to which the reference initialized by S1 refers. [Example:

int f(const int&);
int f(int&);
int g(const int&);
int g(int);

int i;
int j = f(i); // calls f(int&)
int k = g(i); // ambiguous

struct X {
  void f() const;
  void f();
};
void g(const X& a, X b) {
a.f(); // calls X::f() const
b.f(); // calls X::f()
}

@end example]

(3.3) — User-defined conversion sequence U1 is a better conversion sequence than another user-defined conversion sequence U2 if they contain the same user-defined conversion function or constructor or they initialize the same class in an aggregate initialization and in either case the second standard conversion sequence of U1 is better than the second standard conversion sequence of U2. [Example:

struct A {
  operator short();
} a;
int f(int);
int f(float);
int i = f(a); // calls f(int), because short → int is
// better than short → float.

@end example]
Standard conversion sequences are ordered by their ranks: an Exact Match is a better conversion than a Promotion, which is a better conversion than a Conversion. Two conversion sequences with the same rank are indistinguishable unless one of the following rules applies:

(4.1) — A conversion that does not convert a pointer, a pointer to member, or std::nullptr_t to bool is better than one that does.

(4.2) — A conversion that promotes an enumeration whose underlying type is fixed to its underlying type is better than one that promotes to the promoted underlying type, if the two are different.

(4.3) — If class B is derived directly or indirectly from class A, conversion of B* to A* is better than conversion of B* to void*, and conversion of A* to void* is better than conversion of B* to void*.

(4.4) — If class B is derived directly or indirectly from class A and class C is derived directly or indirectly from B,

(4.4.1) — conversion of C* to B* is better than conversion of C* to A*, [Example:

```
struct A {}
struct B : public A {}
struct C : public B {}
C* pc;
int f(A*);
int f(B*);
int i = f(pc); // calls f(B*)
```

— end example]

(4.4.2) — binding of an expression of type C to a reference to type B is better than binding an expression of type C to a reference to type A,

(4.4.3) — conversion of A::* to B::* is better than conversion of A::* to C::*,

(4.4.4) — conversion of C to B is better than conversion of C to A,

(4.4.5) — conversion of B* to A* is better than conversion of C* to A*.

(4.4.6) — binding of an expression of type B to a reference to type A is better than binding an expression of type C to a reference to type A,

(4.4.7) — conversion of B::* to C::* is better than conversion of A::* to C::* and

(4.4.8) — conversion of B to A is better than conversion of C to A.

[Note: Compared conversion sequences will have different source types only in the context of comparing the second standard conversion sequence of an initialization by user-defined conversion (see 11.3.3); in all other contexts, the source types will be the same and the target types will be different. — end note]

### 11.4 Address of overloaded function

1 A use of an overloaded function name without arguments is resolved in certain contexts to a function, a pointer to function or a pointer to member function for a specific function from the overload set. A function template name is considered to name a set of overloaded functions in such contexts. A function with type F is selected for the function type FT of the target type required in the context if F (after possibly applying the function pointer conversion (7.3.13)) is identical to FT. [Note: That is, the class of which the function is a member is ignored when matching a pointer-to-member-function type. — end note] The target can be

(1.1) — an object or reference being initialized (9.3, 9.3.3, 9.3.4),

(1.2) — the left side of an assignment (7.6.18),

(1.3) — a parameter of a function (7.6.1.2),

(1.4) — a parameter of a user-defined operator (11.5),

(1.5) — the return value of a function, operator function, or conversion (8.6.3),

(1.6) — an explicit type conversion (7.6.1.3, 7.6.1.9, 7.6.3), or

(1.7) — a non-type template-parameter (12.3.2).

The overloaded function name can be preceded by the & operator. An overloaded function name shall not be used without arguments in contexts other than those listed. [Note: Any redundant set of parentheses surrounding the overloaded function name is ignored (7.5.3). — end note]
If the name is a function template, template argument deduction is done (12.9.2.2), and if the argument deduction succeeds, the resulting template argument list is used to generate a single function template specialization, which is added to the set of overloaded functions considered. [Note: As described in 12.9.1, if deduction fails and the function template name is followed by an explicit template argument list, the template-id is then examined to see whether it identifies a single function template specialization. If it does, the template-id is considered to be an lvalue for that function template specialization. The target type is not used in that determination. — end note]

Non-member functions and static member functions match targets of function pointer type or reference to function type. Non-static member functions match targets of pointer-to-member-function type. If a non-static member function is selected, the reference to the overloaded function name is required to have the form of a pointer to member as described in 7.6.2.1.

All functions with associated constraints that are not satisfied (12.4.2) are eliminated from the set of selected functions. If more than one function in the set remains, all function template specializations in the set are eliminated if the set also contains a function that is not a function template specialization. Any given non-template function F0 is eliminated if the set contains a second non-template function that is more constrained than F0 according to the partial ordering rules of 12.4.4. Any given function template specialization F1 is eliminated if the set contains a second function template specialization whose function template is more specialized than the function template of F1 according to the partial ordering rules of 12.6.6.2. After such eliminations, if any, there shall remain exactly one selected function.

[Example:

```c
int f(double);
int f(int);
int (*pf1)(double) = &f; // selects f(double)
int (*pf2)(int) = &f; // selects f(int)
int (*pf3)(...) = &f; // error: type mismatch
int (&rf1)(int) = f; // selects f(int)
int (&rf2)(double) = f; // selects f(double)
void g() {
    (int (*)(int))&f; // cast expression as selector
}
```

The initialization of pfe is ill-formed because no f() with type int(...) has been declared, and not because of any ambiguity. For another example,

```c
struct X {
    int f(int);
    static int f(long);
};

int (X::*p1)(int) = &X::f; // OK
int (X::*p2)(int) = &X::f; // error: mismatch
int (X::*p3)(long) = &X::f; // OK
int (X::*p4)(long) = &X::f; // error: mismatch
int (X::*p5)(int) = &X::f; // error: wrong syntax for
    // pointer to member
int (X::*p6)(long) = &X::f; // OK

— end example]

[Note: If f() and g() are both overloaded functions, the cross product of possibilities must be considered to resolve f(&g), or the equivalent expression f(g). — end note]

[Note: Even if B is a public base of D, we have

```c
D* f();
B* (*p1)() = &f; // error
void g(D*);
void (*p2)(B*) = &g; // error
— end note]

§ 11.4 305
11.5 Overloaded operators

A function declaration having one of the following operator-function-ids as its name declares an operator function. A function template declaration having one of the following operator-function-ids as its name declares an operator function template. A specialization of an operator function template is also an operator function. An operator function is said to implement the operator named in its operator-function-id.

operator-function-id:
  operator: one of
    new   delete new[] delete[] () [] --> -* -
    ! + - * / % ^ & |
    == != < > <= >= <=> && ||
    << >> <<= >>= ++ -- ,

[Note: The operators new[], delete[], (), and [] are formed from more than one token. The latter two operators are function call (7.6.1.2) and subscripting (7.6.1.1). —end note]

Both the unary and binary forms of

+ - * &

can be overloaded.

The following operators cannot be overloaded:

. .* :: ?:

nor can the preprocessing symbols # and ## (Clause 14).

Operator functions are usually not called directly; instead they are invoked to evaluate the operators they implement (11.5.1 – 11.5.7). They can be explicitly called, however, using the operator-function-id as the name of the function in the function call syntax (7.6.1.2). [Example:

    complex z = a.operator+(b); // complex z = a+b;
    void* p = operator new(sizeof(int)*n);

  —end example]

The allocation and deallocation functions, operator new, operator new[], operator delete and operator delete[], are described completely in 6.6.4.4. The attributes and restrictions found in the rest of this subclause do not apply to them unless explicitly stated in 6.6.4.4.

An operator function shall either be a non-static member function or be a non-member function that has at least one parameter whose type is a class, a reference to a class, an enumeration, or a reference to an enumeration. It is not possible to change the precedence, grouping, or number of operands of operators. The meaning of the operators =, (unary) & and , (comma), predefined for each type, can be changed for specific class and enumeration types by defining operator functions that implement these operators. Operator functions are inherited in the same manner as other base class functions.

The identities among certain predefined operators applied to basic types (for example, ++a ≡ a+=1) need not hold for operator functions. Some predefined operators, such as +, require an operand to be an lvalue when applied to basic types; this is not required by operator functions.

An operator function cannot have default arguments (9.2.3.6), except where explicitly stated below. Operator functions cannot have more or fewer parameters than the number required for the corresponding operator, as described in the rest of this subclause.

Operators not mentioned explicitly in subclauses 11.5.3 through 11.5.7 act as ordinary unary and binary operators obeying the rules of 11.5.1 or 11.5.2.

11.5.1 Unary operators

A prefix unary operator shall be implemented by a non-static member function (10.3.1) with no parameters or a non-member function with one parameter. Thus, for any prefix unary operator @, @x can be interpreted as either x.operator@() or operator@<x>. If both forms of the operator function have been declared, the rules in 11.3.1.2 determine which, if any, interpretation is used. See 11.5.7 for an explanation of the postfix unary operators ++ and --.
The unary and binary forms of the same operator are considered to have the same name. [Note: Consequently, a unary operator can hide a binary operator from an enclosing scope, and vice versa. —end note]

11.5.2 Binary operators

A binary operator shall be implemented either by a non-static member function (10.3.1) with one parameter or by a non-member function with two parameters. Thus, for any binary operator \( \ast \), \( x \ast y \) can be interpreted as either \( x \operatorname{operator}\ast(y) \) or \( \operatorname{operator}\ast(x,y) \). If both forms of the operator function have been declared, the rules in 11.3.1.2 determine which, if any, interpretation is used.

11.5.3 Assignment

An assignment operator shall be implemented by a non-static member function with exactly one parameter. Because a copy assignment operator \( \operatorname{operator=} \) is implicitly declared for a class if not declared by the user (10.3.6), a base class assignment operator is always hidden by the copy assignment operator of the derived class.

Any assignment operator, even the copy and move assignment operators, can be virtual. [Note: For a derived class \( D \) with a base class \( B \) for which a virtual copy/move assignment has been declared, the copy/move assignment operator in \( D \) does not override \( B \)'s virtual copy/move assignment operator. —end example—end note]

11.5.4 Function call

\( \operatorname{operator()} \) shall be a non-static member function with an arbitrary number of parameters. It can have default arguments. It implements the function call syntax

\[
\text{postfix-expression} \ (\text{expression-list}_{\text{opt}})
\]

where the \text{postfix-expression} evaluates to a class object and the possibly empty \text{expression-list} matches the parameter list of an \( \operatorname{operator()} \) member function of the class. Thus, a call \( x(\arg_1, \ldots) \) is interpreted as \( x.\operatorname{operator}()(\arg_1, \ldots) \) for a class object \( x \) of type \( T \) if \( T::\operatorname{operator}()(T_1, T_2, T_3) \) exists and if the operator is selected as the best match function by the overload resolution mechanism (11.3.3).

11.5.5 Subscripting

\( \operatorname{operator}[] \) shall be a non-static member function with exactly one parameter. It implements the subscripting syntax

\[
\text{postfix-expression} \ [\text{expr-or-braced-init-list}]
\]

Thus, a subscripting expression \( x[y] \) is interpreted as \( x.\operatorname{operator}[](y) \) for a class object \( x \) of type \( T \) if \( T::\operatorname{operator}[](T_1) \) exists and if the operator is selected as the best match function by the overload resolution mechanism (11.3.3). [Example:

```cpp
struct X {
  Z operator[](std::initializer_list<int>);
};
```
11.5.6 Class member access

operator-> shall be a non-static member function taking no parameters. It implements the class member
access syntax that uses \texttt{->}.

\[
\text{postfix-expression} \rightarrow \text{template}\text{opt id-expression} \\
\text{postfix-expression} \rightarrow \text{pseudo-destructor-name}
\]

An expression \texttt{x->m} is interpreted as \texttt{(x.operator->())->m} for a class object \texttt{x} of type \texttt{T} if \texttt{T::operator->()} exists and if the operator is selected as the best match function by the overload resolution mechanism (11.3).

11.5.7 Increment and decrement

The user-defined function called \texttt{operator++} implements the prefix and postfix ++ operator. If this function is a non-static member function with no parameters, or a non-member function with one parameter, it defines
the prefix increment operator ++ for objects of that type. If the function is a non-static member function
with one parameter (which shall be of type \texttt{int}) or a non-member function with two parameters (the second
of which shall be of type \texttt{int}), it defines the postfix increment operator ++ for objects of that type. When
the postfix increment is called as a result of using the ++ operator, the \texttt{int} argument will have value zero.\footnote{Calling \texttt{operator++} explicitly, as in expressions like \texttt{a.operator++(2)}, has no special properties: The argument to \texttt{operator++} is 2.}

\[\text{Example:}\]
\[\text{struct X \{\}
  \text{X& operator++();} \quad // \text{prefix }++a \\
  \text{X operator++(int);} \quad // \text{postfix }a++
\text{\};}\]
\[\text{struct Y \{\}
  \text{Y& operator++(Y&);} \quad // \text{prefix }++b \\
  \text{Y operator++(Y&, int);} \quad // \text{postfix }b++
\text{\};}\]
\[\text{void f(X a, Y b) \{\}
  \text{++a;} \quad // \text{a.operator++();} \\
  \text{a++;} \quad // \text{a.operator++(0);} \\
  \text{++b;} \quad // \text{operator++(b);} \\
  \text{b++;} \quad // \text{operator++(b, 0);} \\
  \text{a.operator++();} \quad // \text{explicit call: like }++a; \\
  \text{a.operator++(0);} \quad // \text{explicit call: like }a++; \\
  \text{operator++(b);} \quad // \text{explicit call: like }++b; \\
  \text{operator++(b, 0);} \quad // \text{explicit call: like }b++; \\
\text{\};}\]

\[\text{-- end example}\]

The prefix and postfix decrement operators -- are handled analogously.

11.5.8 User-defined literals

\[\text{literal-operator-id:}\]
\[\text{operator string-literal identifier}\]
\[\text{operator user-defined-string-literal}\]

The \texttt{string-literal} or \texttt{user-defined-string-literal} in a \texttt{literal-operator-id} shall have no \texttt{encoding-prefix} and shall contain no characters other than the implicit terminating \texttt{'}\texttt{\textbackslash 0}'\texttt{'.} The \texttt{ud-suffix} of the \texttt{user-defined-string-literal} or the \texttt{identifier} in a \texttt{literal-operator-id} is called a \texttt{literal suffix identifier}. Some literal suffix identifiers are reserved for future standardization; see 15.5.4.3.5. A declaration whose \texttt{literal-operator-id} uses such a literal suffix identifier is ill-formed, no diagnostic required.
A declaration whose *declarator-id* is a *literal-operator-id* shall be a declaration of a namespace-scope function or function template (it could be a friend function (10.8.3)), an explicit instantiation or specialization of a function template, or a *using-declaration* (9.8). A function declared with a *literal-operator-id* is a *literal operator*. A function template declared with a *literal-operator-id* is a *literal operator template*.

The declaration of a literal operator shall have a *parameter-declaration-clause* equivalent to one of the following:

- `const char*`
- `unsigned long long int`
- `long double`
- `char`
- `wchar_t`
- `char16_t`
- `char32_t`
- `const char*, std::size_t`
- `const wchar_t*, std::size_t`
- `const char16_t*, std::size_t`
- `const char32_t*, std::size_t`

If a parameter has a default argument (9.2.3.6), the program is ill-formed.

A *raw literal operator* is a literal operator with a single parameter whose type is `const char*`.

A *numeric literal operator template* is a literal operator template whose *template-parameter-list* has a single *template-parameter* that is a non-type template parameter pack (12.6.3) with element type `char`. A *string literal operator template* is a literal operator template whose *template-parameter-list* comprises a single non-type *template-parameter* of class type. The declaration of a literal operator template shall have an empty *parameter-declaration-clause* and shall declare either a numeric literal operator template or a string literal operator template.

Literal operators and literal operator templates shall not have C language linkage.

[Note: Literal operators and literal operator templates are usually invoked implicitly through user-defined literals (5.13.8). However, except for the constraints described above, they are ordinary namespace-scope functions and function templates. In particular, they are looked up like ordinary functions and function templates and they follow the same overload resolution rules. Also, they can be declared *inline* or *constexpr*, they may have internal or external linkage, they can be called explicitly, their addresses can be taken, etc. —end note]

[Example:

```c
void operator "\_km(long double); // OK
string operator "\_i18n(const char*, std::size_t); // OK
template <char...> double operator "\_\_u03c0(); // OK: UCN for lowercase pi
float operator "\_e(const char*); // OK
float operator "\_E(const char*); // error: reserved literal suffix (15.5.4.3.5, 5.13.8)
double operator "\_Bq(long double); // OK: does not use the reserved identifier _Bq (5.10)
double operator "\_Bq(long double); // uses the reserved identifier _Bq (5.10)
float operator "\_Bq(const char*); // error: non-empty string-literal
string operator "\_5X(const char*, std::size_t); // error: invalid literal suffix identifier
double operator "\_miles(double); // error: invalid parameter-declaration-clause
template <char...> int operator "\_j(const char*); // error: invalid parameter-declaration-clause
extern "C" void operator "\_m(long double); // error: C language linkage
```

—end example]

§ 11.6  Built-in operators

The candidate operator functions that represent the built-in operators defined in 7.6 are specified in this subclause. These candidate functions participate in the operator overload resolution process as described in 11.3.1.2 and are used for no other purpose. [Note: Because built-in operators take only operands with non-class type, and operator overload resolution occurs only when an operand expression originally has class or enumeration type, operator overload resolution can resolve to a built-in operator only when an operand has a class type that has a user-defined conversion to a non-class type appropriate for the operator, or when an operand has an enumeration type that can be converted to a type appropriate for the operator. Also note that some of the candidate operator functions given in this subclause are more permissive than the built-in operators themselves. As described in 11.3.1.2, after a built-in operator is selected by overload resolution...
the expression is subject to the requirements for the built-in operator given in 7.6, and therefore to any additional semantic constraints given there. If there is a user-written candidate with the same name and parameter types as a built-in candidate operator function, the built-in operator function is hidden and is not included in the set of candidate functions. — end note]

2 In this subclause, the term **promoted integral type** is used to refer to those integral types which are preserved by integral promotion (7.3.6) (including e.g. int and long but excluding e.g. char). Similarly, the term **promoted arithmetic type** refers to floating-point types plus promoted integral types. [Note: In all cases where a promoted integral type or promoted arithmetic type is required, an operand of enumeration type will be acceptable by way of the integral promotions. — end note]

3 In the remainder of this subclause, \textit{vq} represents either \texttt{volatile} or no cv-qualifier.

4 For every pair \((T, vq)\), where \(T\) is an arithmetic type other than \texttt{bool}, there exist candidate operator functions of the form
\[
 vq T \& \texttt{operator++}(vq T\&);
 T \texttt{operator++}(vq T, \texttt{int});
\]

5 For every pair \((T, vq)\), where \(T\) is an arithmetic type other than \texttt{bool}, there exist candidate operator functions of the form
\[
 vq T \& \texttt{operator--}(vq T\&);
 T \texttt{operator--}(vq T, \texttt{int});
\]

6 For every pair \((T, vq)\), where \(T\) is a cv-qualified or cv-unqualified object type, there exist candidate operator functions of the form
\[
 T* vq \& \texttt{operator++}(T* vq\&);
 T* vq \& \texttt{operator--}(T* vq\&);
 T* \texttt{operator++}(T* vq, \texttt{int});
 T* \texttt{operator--}(T* vq, \texttt{int});
\]

7 For every cv-qualified or cv-unqualified object type \(T\), there exist candidate operator functions of the form
\[
 T \& \texttt{operator*}(T*);
\]

8 For every function type \(T\) that does not have cv-qualifiers or a \texttt{ref-qualifier}, there exist candidate operator functions of the form
\[
 T \& \texttt{operator*}(T*);
\]

9 For every type \(T\) there exist candidate operator functions of the form
\[
 T* \texttt{operator*}(T*);
\]

10 For every promoted arithmetic type \(T\), there exist candidate operator functions of the form
\[
 T \texttt{operator+}(T);
 T \texttt{operator-}(T);
\]

11 For every promoted integral type \(T\), there exist candidate operator functions of the form
\[
 T \texttt{operator~}(T);
\]

12 For every quintuple \((C1, C2, T, cv1, cv2)\), where \(C2\) is a class type, \(C1\) is the same type as \(C2\) or is a derived class of \(C2\), and \(T\) is an object type or a function type, there exist candidate operator functions of the form
\[
 cv12 T \& \texttt{operator->*}(cv1 C1*, cv2 T C2::*);
\]
where \textit{cv12} is the union of \textit{cv1} and \textit{cv2}. The return type is shown for exposition only; see 7.6.4 for the determination of the operator’s result type.

13 For every pair of promoted arithmetic types \(L\) and \(R\), there exist candidate operator functions of the form
\[
 LR \texttt{operator*}(L, R);
 LR \texttt{operator/}(L, R);
 LR \texttt{operator+}(L, R);
 LR \texttt{operator-}(L, R);
\]

\texttt{bool} \texttt{operator==}(L, R);
\texttt{bool} \texttt{operator!=}(L, R);
\texttt{bool} \texttt{operator<}(L, R);
\texttt{bool} \texttt{operator>}(L, R);
\texttt{bool} \texttt{operator<=}(L, R);
\texttt{bool} \texttt{operator=>}(L, R);
where \( LR \) is the result of the usual arithmetic conversions (7.4) between types \( L \) and \( R \).

14 For every integral type \( T \) there exists a candidate operator function of the form
\[
\text{std:strong\_ordering \ operator<=>(T, T);}
\]

15 For every pair of floating-point types \( L \) and \( R \), there exists a candidate operator function of the form
\[
\text{std:partial\_ordering \ operator<=>(L, R);}
\]

16 For every cv-qualified or cv-unqualified object type \( T \) there exist candidate operator functions of the form
\[
\begin{align*}
T* & \quad \text{operator+}(T*, \text{std:ptrdiff\_t}); \\
T& & \text{operator[]}(T*, \text{std:ptrdiff\_t}); \\
T* & \quad \text{operator-}(T*, \text{std:ptrdiff\_t}); \\
T* & \quad \text{operator+}((\text{std:ptrdiff\_t, T})); \\
T& & \text{operator[]}((\text{std:ptrdiff\_t, T}));
\end{align*}
\]

17 For every \( T \), where \( T \) is a pointer to object type, there exist candidate operator functions of the form
\[
\text{std::ptrdiff\_t \ operator-}(T, T);
\]

18 For every \( T \), where \( T \) is an enumeration type or a pointer type, there exist candidate operator functions of the form
\[
\begin{align*}
\text{bool} & \quad \text{operator==}(T, T); \\
\text{bool} & \quad \text{operator!=}(T, T); \\
\text{bool} & \quad \text{operator<}(T, T); \\
\text{bool} & \quad \text{operator>}(T, T); \\
\text{bool} & \quad \text{operator<=>}(T, T); \\
R & \quad \text{operator<=>}(T, T);
\end{align*}
\]

where \( R \) is the result type specified in 7.6.8.

19 For every \( T \), where \( T \) is a pointer-to-member type or \text{std::nullptr\_t}, there exist candidate operator functions of the form
\[
\begin{align*}
\text{bool} & \quad \text{operator==}(T, T); \\
\text{bool} & \quad \text{operator!=}(T, T); \\
\text{std::strong\_equality \ operator<=>}(T, T);
\end{align*}
\]

20 For every pair of promoted integral types \( L \) and \( R \), there exist candidate operator functions of the form
\[
\begin{align*}
LR & \quad \text{operator%}(L, R); \\
LR & \quad \text{operator\&}(L, R); \\
LR & \quad \text{operator\^~}(L, R); \\
LR & \quad \text{operator\O}(L, R); \\
L & \quad \text{operator<}(L, R); \\
L & \quad \text{operator>}(L, R);
\end{align*}
\]

where \( LR \) is the result of the usual arithmetic conversions (7.4) between types \( L \) and \( R \).

21 For every triple \((L, vq, R)\), where \( L \) is an arithmetic type, and \( R \) is a promoted arithmetic type, there exist candidate operator functions of the form
\[
\begin{align*}
vq L& & \text{operator=(vq Lk, R)}; \\
vq L& & \text{operator*=(vq Lk, R)}; \\
vq L& & \text{operator/=(vq Lk, R)}; \\
vq L& & \text{operator+=(vq Lk, R)}; \\
vq L& & \text{operator-=(vq Lk, R)};
\end{align*}
\]

22 For every pair \((T, vq)\), where \( T \) is any type, there exist candidate operator functions of the form
\[
T*vq& & \text{operator=(T*vq\&, T*)};
\]

23 For every pair \((T, vq)\), where \( T \) is an enumeration or pointer-to-member type, there exist candidate operator functions of the form
\[
\begin{align*}
vq T& & \text{operator=(vq Tk, T)};
\end{align*}
\]

24 For every pair \((T, vq)\), where \( T \) is a cv-qualified or cv-unqualified object type, there exist candidate operator functions of the form
\[
\begin{align*}
T*vq& & \text{operator+=}(T*vq\&, \text{std:ptrdiff\_t}); \\
T*vq& & \text{operator-=(T*vq\&, \text{std:ptrdiff\_t});}
\end{align*}
\]

\section*{§ 11.6 311}
For every triple \((L, vq, R)\), where \(L\) is an integral type, and \(R\) is a promoted integral type, there exist candidate operator functions of the form

\[
\begin{align*}
vq L & \text{ operator} %= (vq L, R); \\
vq L & \text{ operator} <<= (vq L, R); \\
vq L & \text{ operator} >>= (vq L, R); \\
vq L & \text{ operator} &= (vq L, R); \\
vq L & \text{ operator} ^= (vq L, R); \\
vq L & \text{ operator} |= (vq L, R);
\end{align*}
\]

There also exist candidate operator functions of the form

\[
\begin{align*}
\text{bool} & \text{ operator}! (\text{bool}); \\
\text{bool} & \text{ operator}&& (\text{bool}, \text{bool}); \\
\text{bool} & \text{ operator}|| (\text{bool}, \text{bool});
\end{align*}
\]

For every pair of promoted arithmetic types \(L\) and \(R\), there exist candidate operator functions of the form

\[
LR \text{ operator}?: (\text{bool}, L, R);
\]

where \(LR\) is the result of the usual arithmetic conversions (7.4) between types \(L\) and \(R\). [Note: As with all these descriptions of candidate functions, this declaration serves only to describe the built-in operator for purposes of overload resolution. The operator “?:” cannot be overloaded. — end note]

For every type \(T\), where \(T\) is a pointer, pointer-to-member, or scoped enumeration type, there exist candidate operator functions of the form

\[
T \text{ operator}?: (\text{bool}, T, T);
\]
12 Templates

1 A *template* defines a family of classes, functions, or variables, an alias for a family of types, or a concept.

   template-declaration:
   template-head declaration
   template-head concept-definition

   template-head:
   template < template-parameter-list > requires-clause_opt

   template-parameter-list:
   template-parameter
   template-parameter-list , template-parameter

   requires-clause:
   requires constraint-logical-or-expression

   constraint-logical-or-expression:
   constraint-logical-and-expression
   | constraint-logical-and-expression

   constraint-logical-and-expression:
   primary-expression
   constraint-logical-and-expression && primary-expression

   concept-definition:
   concept concept-name = constraint-expression ;

   concept-name:
   identifier

   [Note: The > token following the template-parameter-list of a template-declaration may be the product of replacing a >> token by two consecutive > tokens (12.2). — end note]

2 The declaration in a template-declaration (if any) shall

   (2.1) — declare or define a function, a class, or a variable, or
   (2.2) — define a member function, a member class, a member enumeration, or a static data member of a class
   template or of a class nested within a class template, or
   (2.3) — define a member template of a class or class template, or
   (2.4) — be a deduction-guide, or
   (2.5) — be an alias-declaration.

3 A template-declaration is a declaration. A template-declaration is also a definition if its template-head is followed by either a concept-definition or a declaration that defines a function, a class, a variable, or a static data member. A declaration introduced by a template declaration of a variable is a variable template. A variable template at class scope is a static data member template.

   [Example:

   
   template<class T>
   constexpr T pi = T(3.1415926535897932385L);
   template<class T>
   T circular_area(T r) {
   return pi<T> * r * r;
   }
   struct matrix_constants {
   template<class T>
   using pauli = hermitian_matrix<T, 2>;
   template<class T>
   constexpr pauli<T> sigma1 = { { 0, 1 }, { 1, 0 } };
   template<class T>
   constexpr pauli<T> sigma2 = { { 0, -1i }, { 1i, 0 } };
A template-declaration can appear only as a namespace scope or class scope declaration. In a function template declaration, the last component of the declarator-id shall not be a template-id. [Note: That last component may be an identifier, an operator-function-id, a conversion-function-id, or a literal-operator-id. In a class template declaration, if the class name is a simple-template-id, the declaration declares a class template partial specialization (12.6.5). — end note]

In a template-declaration, explicit specialization, or explicit instantiation the init-declarator-list in the declaration shall contain at most one declarator. When such a declaration is used to declare a class template, no declarator is permitted.

A template name has linkage (6.5). Specializations (explicit or implicit) of a template that has internal linkage are distinct from all specializations in other translation units. A template, a template explicit specialization (12.8.3), and a class template partial specialization shall not have C linkage. Use of a linkage specification other than "C" or "C++" with any of these constructs is conditionally-supported, with implementation-defined semantics. Template definitions shall obey the one-definition rule (6.2). [Note: Default arguments for function templates and for member functions of class templates are considered definitions for the purpose of template instantiation (12.6) and must also obey the one-definition rule. — end note]

A class template shall not have the same name as any other template, class, function, variable, enumeration, enumerator, namespace, or type in the same scope (6.3), except as specified in 12.6.5. Except that a function template can be overloaded either by non-template functions (9.2.3.5) with the same name or by other function templates with the same name (12.9.3), a template name declared in namespace scope or in class scope shall be unique in that scope.

A templated entity is

— a template,
— an entity defined (6.1) or created (6.6.6) in a templated entity,
— a member of a templated entity,
— an enumerator for an enumeration that is a templated entity, or
— the closure type of a lambda-expression (7.5.5.1) appearing in the declaration of a templated entity.

[Note: A local class, a local variable, or a friend function defined in a templated entity is a templated entity. — end note]

A template-declaration is written in terms of its template parameters. The optional requires-clause following a template-parameter-list allows the specification of constraints (12.4.2) on template arguments (12.3). The requires-clause introduces the constraint-expression that results from interpreting the constraint-logical-or-expression as a constraint-expression. The constraint-logical-or-expression of a requires-clause is an unevaluated operand (Clause 7). [Note: The expression in a requires-clause uses a restricted grammar to avoid ambiguities. Parentheses can be used to specify arbitrary expressions in a requires-clause. [Example:

```c
template<int N> requires N == sizeof new unsigned short
int f(); // error: parentheses required around == expression
```

— end example] — end note]

A function template, member function of a class template, variable template, or static data member of a class template shall be defined in every translation unit in which it is implicitly instantiated (12.8.1) unless the corresponding specialization is explicitly instantiated (12.8.2) in some translation unit; no diagnostic is required.

12.1 Template parameters

The syntax for template-parameters is:

```c
template-parameter:
  type-parameter
  parameter-declaration
  constrained-parameter
```

§ 12.1 314
type-parameter:
  type-parameter-key ...opt identifieropt
  template-head type-parameter-key ...opt identifieropt
  template-head type-parameter-key identifieropt = type-id

type-parameter-key:
  class
typename

constrained-parameter:
  qualified-concept-name ... identifieropt
  qualified-concept-name identifieropt default-template-argumentopt

qualified-concept-name:
  nested-name-specifieropt concept-name
  nested-name-specifieropt partial-concept-id

partial-concept-id:
  concept-name < template-argument-listopt >

default-template-argument:
  = type-id
  = id-expression
  = initializer-clause

[Note: The > token following the template-parameter-list of a type-parameter may be the product of replacing a >> token by two consecutive > tokens (12.2). — end note]

2 There is no semantic difference between class and typename in a type-parameter-key. typename followed by an unqualified-id names a template type parameter. typename followed by a qualified-id denotes the type in a non-type\textsuperscript{134} parameter-declaration. A template-parameter of the form class identifier is a type-parameter.

[Example:
  
  class T { /* ... */ };
  int i;

  template<class T, T i> void f(T t) {
    T t1 = i;  // template-parameters T and i
    ::T t2 = ::i;  // global namespace members T and i
  }

  Here, the template f has a type-parameter called T, rather than an unnamed non-type template-parameter of class T. — end example] A storage class shall not be specified in a template-parameter declaration. Types shall not be defined in a template-parameter declaration.

3 A type-parameter whose identifier does not follow an ellipsis defines its identifier to be a typedef-name (if declared without template) or template-name (if declared with template) in the scope of the template declaration. [Note: A template argument may be a class template or alias template. For example,

  template<class T> class myarray { /* ... */ };

  template<class K, class V, template<class T> class C = myarray>
  class Map {
    C<K> key;
    C<V> value;
  };

  — end note]

4 A non-type template-parameter shall have one of the following (optionally cv-qualified) types:

  (4.1) — a type that is literal, has strong structural equality (10.10.1), has no mutable or volatile subobjects, and in which if there is a defaulted member operator\textless\textgreater, then it is declared public,

  (4.2) — an lvalue reference type,

  (4.3) — a type that contains a placeholder type (9.1.7.4), or

  (4.4) — a placeholder for a deduced class type (9.1.7.5).

\textsuperscript{134}) Since template template-parameters and template template-arguments are treated as types for descriptive purposes, the terms non-type parameter and non-type argument are used to refer to non-type, non-template parameters and arguments.
5 [Note: Other types are disallowed either explicitly below or implicitly by the rules governing the form of template-arguments (12.3). — end note] The top-level cv-qualifiers on the template-parameter are ignored when determining its type.

6 When a non-type template-parameter of non-reference and non-class type is used as an initializer for a reference, a temporary is always used. An id-expression naming a non-type template-parameter of class type T denotes a static storage duration object of type const T, known as a template parameter object, whose value is that of the corresponding template argument after it has been converted to the type of the template-parameter. All such template parameters in the program of the same type with the same value denote the same template parameter object. [Note: If an id-expression names a non-type non-reference template-parameter, then it is a prvalue if it has non-class type. Otherwise, if it is of class type T, it is an lvalue and has type const T (7.5.4.1). — end note]

7 A non-type template-parameter shall not be declared to have floating-point, class, or void type. [Example:

```
template<double d> class X;
// error
```

`template<double* pd> class Y;` OK

`template<double& rd> class Z;` OK

—end example]

8 A non-type template-parameter of type “array of T” or of function type T is adjusted to be of type “pointer to T”. [Example:

```
template<int* a> struct R { /* ... */};
template<int b[5]> struct S { /* ... */};
```

`int p;` // OK

`R<&p> w;` // OK due to parameter adjustment

`S<&p> x;` // OK due to implicit argument conversion

`int v[5];`

`R<&v> y;` // OK due to both adjustment and conversion

`S<&v> z;` // OK due to both adjustment and conversion

—end example]

9 A partial-concept-id is a concept-name followed by a sequence of template-arguments. These template arguments are used to form a constraint-expression as described below.

10 A constrained-parameter declares a template parameter whose kind (type, non-type, template) and type match that of the prototype parameter (12.6.8) of the concept designated by the qualified-concept-name in the constrained-parameter. Let X be the prototype parameter of the designated concept. The declared template parameter is determined by the kind of X (type, non-type, template) and the optional ellipsis in the constrained-parameter as follows.

10.1 — If X is a type template-parameter, the declared parameter is a type template-parameter.

10.2 — If X is a non-type template-parameter, the declared parameter is a non-type template-parameter having the same type as X.

10.3 — If X is a template template-parameter, the declared parameter is a template template-parameter having the same template-parameter-list as X, excluding default template arguments.

10.4 — If the qualified-concept-name is followed by an ellipsis, then the declared parameter is a template parameter pack (12.6.3).

[Example:
template<typename T> concept C1 = true;
template<template<typename> class X> concept C2 = true;
template<int N> concept C3 = true;
template<typename... Ts> concept C4 = true;
template<char... Cs> concept C5 = true;

— end example

11 A constrained-parameter introduces a constraint-expression (12.4.2). The expression is derived from the qualified-concept-name Q in the constrained-parameter, its designated concept C, and the declared template parameter P.

11.1 — First, a template argument A is formed from P. If P declares a template parameter pack (12.6.3) and C is a variadic concept (12.6.8), then A is the pack expansion P... Otherwise, A is the id-expression P.

11.2 — Then, an id-expression E is formed as follows. If Q is a concept-name, then E is C<A>. Otherwise, Q is a partial-concept-id of the form C<A1, A2, ..., An>, and E is C<A, A1, A2, ..., An>.

11.3 — Finally, if P declares a template parameter pack and C is not a variadic concept, E is adjusted to be the fold-expression (E && ...) (7.5.6).

E is the introduced constraint-expression. [Example:

template<typename T> concept C1 = true;
template<typename... Ts> concept C2 = true;
template<typename T, typename U> concept C3 = true;

template<C1 T> struct s1; // associates C1<T>
template<C1... T> struct s2; // associates (C1<T> && ...)
template<C2... T> struct s3; // associates C2<T...>
template<C3<int> T> struct s4; // associates C3<T, int>

— end example]

12 A default template-argument is a template-argument (12.3) specified after = in a template-parameter. A default template-argument may be specified for any kind of template-parameter (type, non-type, template) that is not a template parameter pack (12.6.3). A default template-argument may be specified in a template declaration. A default template-argument shall not be specified in the template-parameter-lists of the definition of a member of a class template that appears outside of the member’s class. A default template-argument shall not be specified in a friend class template declaration. If a friend function template declaration specifies a default template-argument, that declaration shall be a definition and shall be the only declaration of the function template in the translation unit.

13 The default template-argument of a constrained-parameter shall match the kind (type, non-type, template) of the declared template parameter. [Example:

template<typename T> concept C1 = true;
template<int N> concept C2 = true;
template<template<typename> class X> concept C3 = true;

template<typename T> struct S0;

template<C1 T = int> struct S1; // OK
template<C2 N = 0> struct S2; // OK
template<C3 X = S0> struct S3; // OK
template<C1 T = 0> struct S4; // error: default argument is not a type

— end example]

14 The set of default template-arguments available for use is obtained by merging the default arguments from all prior declarations of the template in the same way default function arguments are (9.2.3.6). [Example:

template<class T1, class T2 = int> class A;
template<class T1 = int, class T2> class A;

is equivalent to

template<class T1 = int, class T2 = int> class A;

—end example

If a template-parameter of a class template, variable template, or alias template has a default template-argument, each subsequent template-parameter shall either have a default template-argument supplied or be a template parameter pack. If a template-parameter of a primary class template, primary variable template, or alias template is a template parameter pack, it shall be the last template-parameter. A template parameter pack of a function template shall not be followed by another template parameter unless that template parameter can be deduced from the parameter-type-list (9.2.3.5) of the function template or has a default argument (12.9.2). A template parameter of a deduction guide template (12.10) that does not have a default argument shall be deducible from the parameter-type-list of the deduction guide template. [Example:

```
template<class T1 = int, class T2> class B;
// error
```

```
// U can be neither deduced from the parameter-type-list nor specified
template<class... T, class... U> void f() { } // error
```

—end example

A template-parameter shall not be given default arguments by two different declarations in the same scope. [Example:

```
template<class T = int> class X;
template<class T = int> class X { /* ... */ }; // error
```

—end example

When parsing a default template-argument for a non-type template-parameter, the first non-nested > is taken as the end of the template-parameter-list rather than a greater-than operator. [Example:

```
template<int i = 3 > 4 >
// syntax error
class X { /* ... */ }; // error
```

```
template<int i = (3 > 4) >
// OK
```

—end example

A template-parameter of a template template-parameter is permitted to have a default template-argument. When such default arguments are specified, they apply to the template template-parameter in the scope of the template template-parameter. [Example:

```
template <class T = float> struct B {};
template <template <class TT = float> class T> struct A {
inline void f();
inline void g();
};
template <template <class TT> class T> void A<T>::f() {
T<> t; // error: TT has no default template argument
}
template <template <class TT = char> class T> void A<T>::g() {
T<> t; // OK, T<char>
}
```

—end example

If a template-parameter is a type-parameter with an ellipsis prior to its optional identifier or is a parameter-declaration that declares a pack (9.2.3.5), then the template-parameter is a template parameter pack (12.6.3). A template parameter pack that is a parameter-declaration whose type contains one or more unexpanded packs is a pack expansion. Similarly, a template parameter pack that is a type-parameter with a template-parameter-list containing one or more unexpanded packs is a pack expansion. A template parameter pack that is a pack expansion shall not expand a template parameter pack declared in the same template-parameter-list. [Example:

```
template <class... Types>
class Tuple; // Types is a template type parameter pack
// but not a pack expansion
```
template <class T, int... Dims>  // Dims is a non-type template parameter pack
struct multi_array;  // but not a pack expansion

template <class... T>
struct value_holder {
    template <T... Values> struct apply {};  // Values is a non-type template parameter pack
};  // and a pack expansion

template <class... T, T... Values>  // error: Values expands template type parameter
struct static_array;  // pack T within the same template parameter list

— end example]

12.2 Names of template specializations [temp.names]

A template specialization (12.8) can be referred to by a template-id:

simple-template-id:
    template-name < template-argument-list_opt >

template-id:
    simple-template-id
    operator-function-id < template-argument-list_opt >
    literal-operator-id < template-argument-list_opt >

template-name:
    identifier

template-argument-list:
    template-argument ...opt
    template-argument-list , template-argument ...opt

template-argument:
    constant-expression
    type-id
    id-expression

[Note: The name lookup rules (6.4) are used to associate the use of a name with a template declaration; that is, to identify a name as a template-name. — end note]

For a template-name to be explicitly qualified by the template arguments, the name must be considered to refer to a template. [Note: Whether a name actually refers to a template cannot be known in some cases until after argument dependent lookup is done (6.4.2). — end note] A name is considered to refer to a template if name lookup finds a template-name or an overload set that contains a function template. A name is also considered to refer to a template if it is an unqualified-id followed by a < and name lookup finds either one or more functions or finds nothing.

When a name is considered to be a template-name, and it is followed by a <, the < is always taken as the delimiter of a template-argument-list and never as the less-than operator. When parsing a template-argument-list, the first non-nested >> is treated as two consecutive but distinct > tokens, the first of which is taken as the end of the template-argument-list and completes the template-id. [Note: The second > token produced by this replacement rule may terminate an enclosing template-id construct or it may be part of a different construct (e.g., a cast). — end note] [Example:

    template< int i> class X { /* ... */ };  
    X< 1>2 > x1;  // syntax error
    X<(1>2)> x2;  // OK

    template<class T> class Y { /* ... */ };  
    Y<X<1>> x3;  // OK, same as Y<X<1>> x3;
    Y<X<6>>1>> x4;  // syntax error
    Y<X<(6>>1)>> x5;  // OK
    — end example]

135) A > that encloses the type-id of a dynamic_cast, static_cast, reinterpret_cast or const_cast, or which encloses the template-arguments of a subsequent template-id, is considered nested for the purpose of this description.
The keyword `template` is said to appear at the top level in a qualified-id if it appears outside of a template-argument-list or decltype-specifier. In a qualified-id of a declarator-id or in a qualified-id formed by a class-head-name (Clause 10) or enum-head-name (9.6), the keyword `template` shall not appear at the top level. In a qualified-id used as the name in a typename-specifier (12.7), elaborated-type-specifier (9.1.7.3), using-declaration (9.8), or class-or-decltype (10.6), an optional keyword `template` appearing at the top level is ignored. In these contexts, a `<` token is always assumed to introduce a template-argument-list. In all other contexts, when naming a template specialization of a member of an unknown specialization (12.7.2.1), the member template name shall be prefixed by the keyword `template`. [Example:

```c
struct X {
    template<std::size_t> X* alloc();
    template<std::size_t> static X* adjust();
};
template<class T> void f(T* p) {
    T* p1 = p->alloc<200>(); // ill-formed: < means less than
    T* p2 = p->template alloc<200>(); // OK: < starts template argument list
    T::adjust<100>(); // ill-formed: < means less than
    T::template adjust<100>(); // OK: < starts template argument list
}
@end example]

5 A name prefixed by the keyword `template` shall be a template-id or the name shall refer to a class template or an alias template. [Note: The keyword `template` may not be applied to non-template members of class templates. —end note] [Note: As is the case with the typename prefix, the `template` prefix is allowed in cases where it is not strictly necessary; i.e., when the nested-name-specifier or the expression on the left of the -> or . is not dependent on a template-parameter, or the use does not appear in the scope of a template. —end note] [Example:

```c
template <class T> struct A {
    void f(int);
    template <class U> void f(U);
};

template <class T> void f(T t) {
    A<T> a;
    a.template f<>(t); // OK: calls template
    a.template f(t); // error: not a template-id
}
```[Example]

```c
template <class T> struct B {
    template <class T2> struct C { }
};

// OK: T::template C names a class template:
template <class T, template <class X> class TT = T::template C> struct D {
} D<int> db;
@end example]

6 A simple-template-id that names a class template specialization is a class-name (Clause 10).

7 A template-id that names an alias template specialization is a type-name.

8 A template-id is valid if

(8.1) there are at most as many arguments as there are parameters or a parameter is a template parameter pack (12.6.3),

(8.2) there is an argument for each non-deducible non-pack parameter that does not have a default template-argument,

(8.3) each template-argument matches the corresponding template-parameter (12.3),

(8.4) substitution of each template argument into the following template parameters (if any) succeeds, and

(8.5) if the template-id is non-dependent, the associated constraints are satisfied as specified in the next paragraph.

A simple-template-id shall be valid unless it names a function template specialization (12.9.2). [Example:
template<class T, T::type n = 0> class X;
struct S {
    using type = int;
};
using T1 = X<S, int, int>; // error: too many arguments
using T2 = X<>; // error: no default argument for first template parameter
using T3 = X<int>; // error: value 1 does not match type-parameter
using T4 = X<int>; // error: substitution failure for second template parameter
using T5 = X<S>; // OK
— end example

9 When the template-name of a simple-template-id names a constrained non-function template or a constrained template template-parameter, but not a member template that is a member of an unknown specialization (12.7), and all template-arguments in the simple-template-id are non-dependent (12.7.2.4), the associated constraints (12.4.2) of the constrained template shall be satisfied (12.4.1). [Example:

```cpp
template<typename T> concept C1 = sizeof(T) != sizeof(int);

template<C1 T> struct S1 { }

template<C1 T> using Ptr = T*;
S1<int>* p; // error: constraints not satisfied
Ptr<int> p; // error: constraints not satisfied

template<typename T>
struct S2 { Ptr<int> x; }
// error, no diagnostic required

template<typename T>
struct S3 { Ptr<T> x; }
// OK, satisfaction is not required

template<typename T>
struct S4 { S3<T> x; }
// error, no diagnostic required

template<typename T> concept C2 = sizeof(T) == 1;

template struct S<char[2]>; // error: constraints not satisfied

template<>
— end example
```

12.3 Template arguments [temp.arg]

There are three forms of template-argument, corresponding to the three forms of template-parameter: type, non-type and template. The type and form of each template-argument specified in a template-id shall match the type and form specified for the corresponding parameter declared by the template in its template-parameter-list. When the parameter declared by the template is a template parameter pack (12.6.3), it will correspond to zero or more template-arguments. [Example:

```cpp
template<class T> class Array {
    T* v;
    int sz;
public:
    explicit Array(int);
    T& operator[](int i) { return v[i]; }
};

Array<int> v1(20);
typedef std::complex<double> dcomplex; // std::complex is a standard library template
Array<dcomplex> v2(30);
```
Array<dcomplex> v3(40);
void bar() {
  v1[3] = 7;
  v2[3] = v3.elem(4) = dcomplex(7,8);
}
— end example

In a template-argument, an ambiguity between a type-id and an expression is resolved to a type-id, regardless of the form of the corresponding template-parameter.\textsuperscript{136} [Example:

```
template<class T> void f();
```

```c
void g() {
  f<int>()(); // int() is a type-id: call the first f()
}
— end example
```

The name of a template-argument shall be accessible at the point where it is used as a template-argument. [Note: If the name of the template-argument is accessible at the point where it is used as a template-argument, there is no further access restriction in the resulting instantiation where the corresponding template-parameter name is used. — end note] [Example:

```
template<class T> class X {
  static T t;
};

class Y {
  private:
    struct S { /* ... */ };
    X<S> x; // OK: S is accessible
    // X<Y::S> has a static member of type Y::S
    // OK: even though Y::S is private
};
X<Y::S> y; // error: S not accessible
— end example
```

For a template-argument that is a class type or a class template, the template definition has no special access rights to the members of the template-argument. [Example:

```
template <template <class TT> class T> class A {
  typename T<int>::S s;
};
```  

```c
B* b; // ill-formed: A has no access to B::S
— end example
```

When template argument packs or default template-arguments are used, a template-argument list can be empty. In that case the empty <> brackets shall still be used as the template-argument-list. [Example:

```
template<class T = char> class String;
String<>* p; // OK: String<char>
String* q; // syntax error
```  

```
template<class ... Elements> class Tuple;
Tuple<>* t; // OK: Elements is empty
Tuple* u; // syntax error
— end example
```

\textsuperscript{136} There is no such ambiguity in a default template-argument because the form of the template-parameter determines the allowable forms of the template-argument.

\section{12.3}
An explicit destructor call (10.3.7) for an object that has a type that is a class template specialization may explicitly specify the template-arguments. [Example:

```c++
#include <typeinfo>

template<class T> struct A {
    ~A();
};
void f(A<int>*, A<int>*) { 
    p->A<int>::~A(); // OK: destructor call
    q->A<int>::~A<int>(); // OK: destructor call
}
```

—end example]

6 If the use of a template-argument gives rise to an ill-formed construct in the instantiation of a template specialization, the program is ill-formed.

7 When name lookup for the name in a template-id finds an overload set, both non-template functions in the overload set and function templates in the overload set for which the template-arguments do not match the template-parameters are ignored. If none of the function templates have matching template-parameters, the program is ill-formed.

8 When a simple-template-id does not name a function, a default template-argument is implicitly instantiated (12.8.1) when the value of that default argument is needed. [Example:

```c++
#include <typeinfo>

template<typename T, typename U = int> struct S { 
};
S<bool>** p; // the type of p is S<bool, int>*
```

The default argument for U is instantiated to form the type S<bool, int>*. —end example]

9 A template-argument followed by an ellipsis is a pack expansion (12.6.3).

### 12.3.1 Template type arguments

A template-argument for a template-parameter which is a type shall be a type-id.

[Example:

```c++
#include <typeinfo>

template <class T> class X { 
};
template <class T> void f(T t) { }
struct { } unnamed_obj;
void f() {
    struct A { 
        enum { e1 }; 
        typedef struct { } B;
        B b;
        X<A> x1; // OK
        X<A> x2; // OK
        X<B> x3; // OK
        f(e1); // OK
        f(unnamed_obj); // OK
        f(b); // OK
    }
}
```

—end example] [Note: A template type argument may be an incomplete type (6.7). —end note]

### 12.3.2 Template non-type arguments

If the type T of a template-parameter (12.1) contains a placeholder type (9.1.7.4) or a placeholder for a deduced class type (9.1.7.5), the type of the parameter is the type deduced for the variable x in the invented declaration

```
T x = template-argument ;
```

If a deduced parameter type is not permitted for a template-parameter declaration (12.1), the program is ill-formed.

A template-argument for a non-type template-parameter shall be a converted constant expression (7.7) of the type of the template-parameter. For a non-type template-parameter of reference or pointer type, or for each non-static data member of reference or pointer type in a non-type template-parameter of class type or subobject thereof, the reference or pointer value shall not refer to or be the address of (respectively):
— a subobject (6.6.2),
— a temporary object (6.6.6),
— a string literal (5.13.5),
— the result of a typeid expression (7.6.1.8), or
— a predefined __func__ variable (9.4.1).

[Note: If the template-argument represents a set of overloaded functions (or a pointer or member pointer to such), the matching function is selected from the set (11.4). — end note]

3 [Example:

```cpp
template<const int* pci> struct X { /* ... */ };  
int ai[10];  
X<ai> x;  // array to pointer and qualification conversions

struct Y { /* ... */ };  
template<const Y& b> struct Z { /* ... */ };  
Y y;  
Z<y> z;  // no conversion, but note extra cv-qualification

template<int (&pa)[5]> struct W { /* ... */ };  
int b[5];  
W<b> w;  // no conversion

void f(char);  
void f(int);

template<void (*pf)(int)> struct A { /* ... */ };  
A<&f> a;  // selects f(int)

template<auto n> struct B { /* ... */ };  
B<5> b1;  // OK: template parameter type is int  
B<'a'> b2;  // OK: template parameter type is char  
B<2.5> b3;  // error: template parameter type cannot be double

— end example]
```

4 [Note: A string literal (5.13.5) is not an acceptable template-argument for a template-parameter of non-class type. [Example:

```cpp
template<class T, T p> class X { /* ... */ };  
X<const char*, "Studebaker"> x;  // error: string literal as template-argument

const char p[] = "Vivisectionist";  
X<const char*, p> y;  // OK

class A {  
    constexpr A(const char*) {}  
    auto operator<(A, A) = default;
};  

X<A, "Pyrophoricity"> z;  // OK, string literal is a constructor argument to A

— end example]  — end note]
```

5 [Note: The address of an array element or non-static data member is not an acceptable template-argument. [Example:

```cpp
template<int* p> class X { };  

int a[10];  
struct S { int m; static int s; } s;
```
X<&a[2]> x3; // error: address of array element
X<&a.m> x4; // error: address of non-static member
X<&s.s> x5; // OK: address of static member
X<&S::s> x6; // OK: address of static member
—end example] —end note]

6 [Note: A temporary object is not an acceptable template-argument when the corresponding template-parameter has reference type. [Example:

```cpp
template<const int& CRI> struct B { /* ... */ };  
B<1> b2; // error: temporary would be required for template argument
int c = 1; 
B<c> b1; // OK
—end example] —end note]

12.3.3 Template template arguments [temp.arg.template]

1 A template-argument for a template template-parameter shall be the name of a class template or an alias template, expressed as id-expression. When the template-argument names a class template, only primary class templates are considered when matching the template template argument with the corresponding parameter; partial specializations are not considered even if their parameter lists match that of the template template parameter.

2 Any partial specializations (12.6.5) associated with the primary class template or primary variable template are considered when a specialization based on the template template-parameter is instantiated. If a specialization is not visible at the point of instantiation, and it would have been selected had it been visible, the program is ill-formed, no diagnostic required. [Example:

```cpp
template<class T> class A { /* ... */ }; 
template<class T, class U = T> class B { /* ... */ }; 
template<class ... Types> class C { /* ... */ }; 
template<auto n> class D { /* ... */ }; 
template<template<class> class P> class X { /* ... */ }; 
template<template<class ...> class Q> class Y { /* ... */ }; 
template<template<int> class R> class Z { /* ... */ }; 
```

§ 12.3.3 325

3 A template-argument matches a template template-parameter P when P is at least as specialized as the template-argument A. If P contains a template parameter pack, then A also matches P if each of A’s template parameters matches the corresponding template parameter in the template-head of P. Two template parameters match if they are of the same kind (type, non-type, template), for non-type template-parameters, their types are equivalent (12.6.6.1), and for template template-parameters, each of their corresponding template-parameters matches, recursively. When P’s template-head contains a template parameter pack (12.6.3), the template parameter pack will match zero or more template parameters or template parameter packs in the template-head of A with the same type and form as the template parameter pack in P (ignoring whether those template parameters are template parameter packs). [Example:

```cpp
template<class T> class A { /* ... */ };  
template<class T, class U = T> class B { /* ... */ };  
template<class ... Types> class C { /* ... */ };  
template<auto n> class D { /* ... */ };  
template<template<class> class P> class X { /* ... */ };  
template<template<class ...> class Q> class Y { /* ... */ };  
template<template<int> class R> class Z { /* ... */ };  
```
A template template-parameter P is at least as specialized as a template template-argument A if, given the following rewrite to two function templates, the function template corresponding to P is at least as specialized as the function template corresponding to A according to the partial ordering rules for function templates (12.6.6.2). Given an invented class template X with the template-head of A (including default arguments and requires-clause, if any):

1. Each of the two function templates has the same template parameters and requires-clause (if any), respectively, as P or A.
2. Each function template has a single function parameter whose type is a specialization of X with template arguments corresponding to the template parameters from the respective function template where, for each template parameter PP in the template-head of the function template, a corresponding template argument AA is formed. If PP declares a template parameter pack, then AA is the id-expression PP. . . (12.6.3); otherwise, AA is the id-expression PP.

If the rewrite produces an invalid type, then P is not at least as specialized as A.

12.4 Template constraints

[Note: This subclause defines the meaning of constraints on template arguments. The abstract syntax and satisfaction rules are defined in 12.4.1. Constraints are associated with declarations in 12.4.2. Declarations are partially ordered by their associated constraints (12.4.4). — end note]
12.4.1 Constraints

A constraint is a sequence of logical operations and operands that specifies requirements on template arguments. The operands of a logical operation are constraints. There are three different kinds of constraints:

- (1.1) conjunctions (12.4.1.1),
- (1.2) disjunctions (12.4.1.1), and
- (1.3) atomic constraints (12.4.1.2)

In order for a constrained template to be instantiated (12.8), its associated constraints (12.4.2) shall be satisfied as described in the following subclauses. [Note: Forming the name of a specialization of a class template, a variable template, or an alias template (12.2) requires the satisfaction of its constraints. Overload resolution (11.3.2) requires the satisfaction of constraints on functions and function templates. —end note]

12.4.1.1 Logical operations

There are two binary logical operations on constraints: conjunction and disjunction. [Note: These logical operations have no corresponding C++ syntax. For the purpose of exposition, conjunction is spelled using the symbol ∧ and disjunction is spelled using the symbol ∨. The operands of these operations are called the left and right operands. In the constraint $A \land B$, $A$ is the left operand, and $B$ is the right operand. —end note]

A conjunction is a constraint taking two operands. To determine if a conjunction is satisfied, the satisfaction of the first operand is checked. If that is not satisfied, the conjunction is not satisfied. Otherwise, the conjunction is satisfied if and only if the second operand is satisfied.

A disjunction is a constraint taking two operands. To determine if a disjunction is satisfied, the satisfaction of the first operand is checked. If that is not satisfied, the conjunction is not satisfied. Otherwise, the disjunction is satisfied if and only if the second operand is satisfied.

Example:

```cpp
template<typename T>
constexpr bool get_value() { return T::value; }

template<typename T>
requires (sizeof(T) > 1) && get_value<T>()
void f(T);

f('a'); // OK: calls f(int)
```

In the satisfaction of the associated constraints (12.4.2) of f, the constraint $\text{sizeof(char)} > 1$ is not satisfied; the second operand is not checked for satisfaction. —end example]

12.4.1.2 Atomic constraints

An atomic constraint is formed from an expression E and a mapping from the template parameters that appear within E to template arguments involving the template parameters of the constrained entity, called the parameter mapping (12.4.2). [Note: Atomic constraints are formed by constraint normalization (12.4.3). E is never a logical AND expression (7.6.14) nor a logical OR expression (7.6.15). —end note]

Two atomic constraints are identical if they are formed from the same expression and the targets of the parameter mappings are equivalent according to the rules for expressions described in 12.6.6.1.

To determine if an atomic constraint is satisfied, the parameter mapping and template arguments are first substituted into its expression. If substitution results in an invalid type or expression, the constraint is not satisfied. Otherwise, the lvalue-to-rvalue conversion (7.3.1) is performed if necessary, and E shall be a constant expression of type bool. The constraint is satisfied if and only if evaluation of E results in true. [Example:

```cpp
template<typename T> concept C =
    sizeof(T) == 4 && !true; // requires atomic constraints sizeof(T) == 4 and !true

template<typename T> struct S {
    constexpr operator bool() const { return true; }
};
```
template<typename T> requires (S<T>{})
void f(T);  // #1
void f(int);  // #2

void g() {
    f(0);  // error: expression S<int>{} does not have type bool
    // while checking satisfaction of deduced arguments of #1;
    // call is ill-formed even though #2 is a better match
}

— end example]

12.4.2 Constrained declarations

A template declaration (Clause 12) or function declaration (9.2.3.5) can be constrained by the use of a requires-clause. This allows the specification of constraints for that declaration as an expression:

\[
\text{constraint-expression} = \text{logical-or-expression}
\]

Constraints can also be associated with a declaration through the use of constrained-parameters in a template-parameter-list. Each of these forms introduces additional constraint-expressions that are used to constrain the declaration.

A template’s associated constraints are defined as follows:

(3.1) — If there are no introduced constraint-expressions, the declaration has no associated constraints.
(3.2) — Otherwise, if there is a single introduced constraint-expression, the associated constraints are the normal form (12.4.3) of that expression.
(3.3) — Otherwise, the associated constraints are the normal form of a logical AND expression (7.6.14) whose operands are in the following order:

(3.3.1) — the constraint-expression introduced by each constrained-parameter (12.1) in the declaration’s template-parameter-list, in order of appearance, and
(3.3.2) — the constraint-expression introduced by a requires-clause following a template-parameter-list (Clause 12), and
(3.3.3) — the constraint-expression introduced by a trailing requires-clause (9.2) of a function declaration (9.2.3.5).

The formation of the associated constraints establishes the order in which constraints are instantiated when checking for satisfaction (12.4.1). [Example:

```
template<typename T> concept C = true;
template<C T> void f1(T);
template<typename T> requires C<T> void f2(T);
template<typename T> void f3(T) requires C<T>;
```

The functions f1, f2, and f3 have the associated constraint C<T>.

```
template<typename T> concept C1 = true;
template<typename T> concept C2 = sizeof(T) > 0;
```

The associated constraints of f4 and f5 are C1<T> \&\& C2<T>.

```
template<C1 T> void f4(T) requires C2<T>;
template<typename T> requires C1<T> \&\& C2<T> void f5(T);
```

The associated constraints of f6 and f7 are C1<T> \&\& C2<T>, and those of f7 are C2<T> \&\& C1<T>. — end example]

12.4.3 Constraint normalization

The normal form of an expression E is a constraint (12.4.1) that is defined as follows:

(1.1) — The normal form of an expression ( E ) is the normal form of E.
(1.2) — The normal form of an expression E1 \| E2 is the disjunction (12.4.1.1) of the normal forms of E1 and E2.

§ 12.4.3 328
The normal form of an expression $E_1 \&\& E_2$ is the conjunction of the normal forms of $E_1$ and $E_2$.

The normal form of an id-expression of the form $C<A_1, A_2, \ldots, A_n>$, where $C$ names a concept, is the normal form of the constraint-expression of $C$, after substituting $A_1, A_2, \ldots, A_n$ for $C$’s respective template parameters in the parameter mappings in each atomic constraint. If any such substitution results in an invalid type or expression, the program is ill-formed; no diagnostic is required. [Example:

```cpp
template<typename T> concept C1 = sizeof(T) == 1;
template<typename T> concept C2 = C1<T>() && 1 == 2;
template<typename T> concept C3 = requires { typename T::type; };
template<typename T> concept C4 = requires (T x) { ++x; };
```

Normalization of $B$’s constraint-expression is valid and results in $T::\text{value}$ (with the mapping $T \mapsto U*$) $\lor$ true (with an empty mapping), despite the expression $T::\text{value}$ being ill-formed for a pointer type $T$. Normalization of $C$’s constraint-expression results in the program being ill-formed, because it would form the invalid type $T&*$ in the parameter mapping. —end example]

The normal form of any other expression $E$ is the atomic constraint whose expression is $E$ and whose parameter mapping is the identity mapping.

The process of obtaining the normal form of a constraint-expression is called normalization. [Note: Normalization of constraint-expressions is performed when determining the associated constraints (12.4.1) of a declaration and when evaluating the value of an id-expression that names a concept specialization (7.5.4). —end note]

[Example:

```cpp
template<typename T> concept C1 = sizeof(T) == 1;
template<typename T> concept C2 = C1<T>() && 1 == 2;
template<typename T> concept C3 = requires { typename T::type; };
template<typename T> concept C4 = requires (T x) { ++x; }
```

The associated constraints of #1 are $\text{sizeof}(T) == 1$ (with mapping $T \mapsto U$) $\land$ 1 == 2.
The associated constraints of #2 are $\text{requires} \{ \text{typename } T::\text{type}; \}$ (with mapping $T \mapsto U$).
The associated constraints of #3 are $\text{requires} \{ \text{typename } T::\text{type}; \}$ (with mapping $T \mapsto U$). —end example]

### 12.4.4 Partial ordering by constraints

A constraint $P$ subsumes a constraint $Q$ if and only if, for every disjunctive clause $P_i$ in the disjunctive normal form $^{137}$ of $P$, $P_i$ subsumes every conjunctive clause $Q_j$ in the conjunctive normal form $^{138}$ of $Q$, where

[(1.1)]
- a disjunctive clause $P_i$ subsumes a conjunctive clause $Q_j$ if and only if there exists an atomic constraint $P_{ia}$ in $P_i$ for which there exists an atomic constraint $Q_{jb}$ in $Q_j$ such that $P_{ia}$ subsumes $Q_{jb}$, and

[(1.2)]
- an atomic constraint $A$ subsumes another atomic constraint $B$ if and only if the $A$ and $B$ are identical using the rules described in 12.4.1.2.

[Example: Let $A$ and $B$ be atomic constraints (12.4.1.2). The constraint $A \land B$ subsumes $A$, but $A$ does not subsume $A \land B$. The constraint $A$ subsumes $A \lor B$, but $A \lor B$ does not subsume $A$. Also note that every constraint subsumes itself. —end example]

[Note: The subsumption relation defines a partial ordering on constraints. This partial ordering is used to determine

[(2.1)]
- the best viable candidate of non-template functions (11.3.3),

[(2.2)]
- the address of a non-template function (11.4),

[(2.3)]
- the matching of template template arguments (12.3.3),

[(2.4)]
- the partial ordering of class template specializations (12.6.5.2), and

[(2.5)]
- the partial ordering of function templates (12.6.6.2).

---

137 A constraint is in disjunctive normal form when it is a disjunction of clauses where each clause is a conjunction of atomic constraints. [Example: For atomic constraints $A$, $B$, and $C$, the disjunctive normal form of the constraint $A \land (B \lor C)$ is $(A \land B) \lor (A \land C)$. Its disjunctive clauses are $(A \land B)$ and $(A \land C)$. —end example]

138 A constraint is in conjunctive normal form when it is a conjunction of clauses where each clause is a disjunction of atomic constraints. [Example: For atomic constraints $A$, $B$, and $C$, the constraint $A \land (B \lor C)$ is in conjunctive normal form. Its conjunctive clauses are $A$ and $(B \lor C)$. —end example]

§ 12.4.4
A declaration \( D_1 \) is at least as constrained as a declaration \( D_2 \) if

1. \( D_1 \) and \( D_2 \) are both constrained declarations and \( D_1 \)'s associated constraints subsume those of \( D_2 \); or
2. \( D_2 \) has no associated constraints.

A declaration \( D_1 \) is more constrained than another declaration \( D_2 \) when \( D_1 \) is at least as constrained as \( D_2 \), and \( D_2 \) is not at least as constrained as \( D_1 \). [Example:

```cpp
template<typename T> concept C1 = requires(T t) { --t; };
template<typename T> concept C2 = C1<T> && requires(T t) { *t; };

template<C1 T> void f(T); // #1
template<C2 T> void f(T); // #2
template<typename T> void g(T); // #3
template<C1 T> void g(T); // #4
```

\( f(0); \) // selects #1
\( f((int*)0); \) // selects #2
\( g(true); \) // selects #3 because \( C1<\text{bool}> \) is not satisfied
\( g(0); \) // selects #4

— end example]

### 12.5 Type equivalence

Two template-ids refer to the same class, function, or variable if

1. their template-names, operator-function-ids, or literal-operator-ids refer to the same template and
2. their corresponding type template-arguments are the same type and
3. their corresponding non-type template-arguments of pointer-to-member type refer to the same class
   member or are both the null member pointer value and
4. their corresponding non-type template-arguments of reference type refer to the same object or function
5. their remaining corresponding non-type template-arguments have the same type and value after
   conversion to the type of the template-parameter, where they are considered to have the same value if
   they compare equal with operator<=>, and
6. their corresponding template template-arguments refer to the same template.

[Example:

```cpp
template<class E, int size> class buffer { /* ... */ };  
buffer<char,2*512> x;  
buffer<char,1024> y;  
```

declares \( x \) and \( y \) to be of the same type, and

```cpp
template<class T, void(*err_fct)()> class list { /* ... */ };  
list<int,&error_handler1> x1;  
list<int,&error_handler2> x2;  
list<int,&error_handler2> x3;  
list<char,&error_handler2> x4;  
```

declares \( x_2 \) and \( x_3 \) to be of the same type. Their type differs from the types of \( x_1 \) and \( x_4 \).
12.6 Template declarations [temp.decls]

1 A template-id, that is, the template-name followed by a template-argument-list shall not be specified in the declaration of a primary template declaration. [Example:

```c
template<class T1, class T2, int I> class A<T1, T2, I> { }; // error
template<class T1, int I> void sort<T1, I>(T1 data[I]); // error
```
—end example] [Note: However, this syntax is allowed in class template partial specializations (12.6.5). —end note]

2 For purposes of name lookup and instantiation, default arguments, partial-concept-ids, requires-clause(s) (Clause 12), and noexcept-specifiers of function templates and of member functions of class templates are considered definitions; each default argument, partial-concept-ids, requires-clause, or noexcept-specifier is a separate definition which is unrelated to the templated function definition or to any other default arguments partial-concept-ids, requires-clauses, or noexcept-specifiers. For the purpose of instantiation, the substatements of a constexpr if statement (8.4.1) are considered definitions.

3 Because an alias-declaration cannot declare a template-id, it is not possible to partially or explicitly specialize an alias template.

12.6.1 Class templates [temp.class]

1 A class template defines the layout and operations for an unbounded set of related types.

2 [Example: A single class template List might provide an unbounded set of class definitions: one class List<T> for every type T, each describing a linked list of elements of type T. Similarly, a class template Array describing a contiguous, dynamic array might be defined like this:

```c
template<class T> class Array {
    T* v;
    int sz;
public:
    explicit Array(int);
    T& operator[](int i);  // return v[i];
};
```

The prefix template<class T> specifies that a template is being declared and that a type-name T may be used in the declaration. In other words, Array is a parameterized type with T as its parameter. —end example]

3 When a member function, a member class, a member enumeration, a static data member or a member template of a class template is defined outside of the class template definition, the member definition is defined as a template definition in which the template-head is equivalent to that of the class template (12.6.6.1). The names of the template parameters used in the definition of the member may be different from the template parameter names used in the class template definition. The template argument list following the class template name in the member definition shall name the parameters in the same order as the one used in the template parameter list of the member. Each template parameter pack shall be expanded with an ellipsis in the template argument list. [Example:

```c
template<class T1, class T2> struct A {
    void f1();
    void f2();
};
```

```c
template<class T2, class T1> struct A<T1,T2> {
    void f1();
}; // OK
```

```c
template<class T2, class T1> void A<T1,T2>::f1() { } // error
```

```c
template<class ... Types> struct B {
    void f3();
    void f4();
};
```

```c
template<class ... Types> void B<Types ...>::f3() { } // OK
```

```c
template<class ... Types> void B<Types>::f4() { } // error
```

```c
template<typename T> concept C = true;
```

```c
template<typename T> concept D = true;
```

§ 12.6.1 331
In a redeclaration, partial specialization, explicit specialization or explicit instantiation of a class template, the class-key shall agree in kind with the original class template declaration (9.1.7.3).

12.6.1.1 Member functions of class templates

A member function of a class template may be defined outside of the class template definition in which it is declared. [Example:

```cpp
template<class T> class Array {
  T* v;
  int sz;
public:
  explicit Array(int);
  T& operator[](int i) { return v[i]; }
};
```

declares three function templates. The subscript function might be defined like this:

```cpp
template<class T> T& Array<T>::operator[](int i) {
  if (i<0 || sz<=i) error("Array: range error");
  return v[i];
}
```

A constrained member function can be defined out of line:

```cpp
template<typename T> concept C = requires {
  typename T::type;
};

template<typename T> struct S {
  void f() requires C<T>;
  void g() requires C<T>;
};
```

```cpp
template<typename T>
void S<T>::f() requires C<T> { }
// OK
```

```cpp
template<typename T>
void S<T>::g() { }
// error: no matching function in S<T>
```

—end example]
12.6.1.2 Member classes of class templates

A member class of a class template may be defined outside the class template definition in which it is declared. [Note: The member class must be defined before its first use that requires an instantiation (12.8.1). For example,]

```cpp
template<class T> struct A {
  class B;
};
A<int>::B* b1;  // OK: requires A to be defined but not A::B
template<class T> class A<T>::B { };  // OK: requires A::B to be defined

—end note]
```

12.6.1.3 Static data members of class templates

A definition for a static data member or static data member template may be provided in a namespace scope enclosing the definition of the static member’s class template. [Example:]

```cpp
template<class T> class X {
  static T s;
};
template<class T> T X<T>::s = 0;
struct limits {
  template<class T>
    static const T min;  // declaration
};
template<class T>
  const T limits::min = { };  // definition

—end example]
```

An explicit specialization of a static data member declared as an array of unknown bound can have a different bound from its definition, if any. [Example:]

```cpp
template <class T> struct A {
  static int i[];
};
template <class T> int A<T>::i[4];  // 4 elements
template <> int A<int>::i[] = { 1 };  // OK: 1 element
—end example]
```

12.6.1.4 Enumeration members of class templates

An enumeration member of a class template may be defined outside the class template definition. [Example:]

```cpp
template<class T> struct A {
  enum E : T;
};
template<class T> enum A<T>::E : T { e1, e2 };
template<> E e = A<int>::e1;
—end example]
```

12.6.2 Member templates

A template can be declared within a class or class template; such a template is called a member template. A member template can be defined within or outside its class definition or class template definition. A member template of a class template that is defined outside of its class template definition shall be specified with a `template-head` equivalent to that of the class template followed by a `template-head` equivalent to that of the member template (12.6.6.1). [Example:]

```cpp
template<class T> struct string {
  template<class T2> int compare(const T2&);
};
```
template<class T2> string(const string<T2>& s) { /* ... */ }

};

template<class T> template<class T2> int string<T>::compare(const T2& s) {
—end example [Example:
  template<typename T> concept C1 = true;
  template<typename T> concept C2 = sizeof(T) <= 4;

  template<C1 T> struct S {
    template<C2 U> void f(U);
    template<C2 U> void g(U);
  };

  template<C1 T> template<C2 U>
  void S<T>::f(U) { } // OK
  template<C1 T> template<typename U>
  void S<T>::g(U) { } // error: no matching function in S<T>
  —end example]

  A local class of non-closure type shall not have member templates. Access control rules (10.8) apply to member
  template names. A destructor shall not be a member template. A non-template member function (9.2.3.5)
  with a given name and type and a member function template of the same name, which could be used to
generate a specialization of the same type, can both be declared in a class. When both exist, a use of that
name and type refers to the non-template member unless an explicit template argument list is supplied.
[Example:

  template <class T> struct A {
    void f(int);
    template <class T2> void f(T2);
  };

  template <> void A<int>::f(int) { } // non-template member function
  template <> template <> void A<int>::f<>(int) { } // member function template specialization

  int main() {
    A<char> ac;
    ac.f(1); // non-template
    ac.f('c'); // template
    ac.f<>(1); // template
  }
  —end example]

  A member function template shall not be virtual. [Example:

  template <class T> struct AA {
    template <class C> virtual void g(C);
    virtual void f(); // OK
  };
  —end example]

  A specialization of a member function template does not override a virtual function from a base class.
[Example:

  class B {
    virtual void f(int);
  };

  class D : public B {
    template <class T> void f(T); // does not override B::f(int)
    void f(int i) { f<>(i); } // overriding function that calls the template instantiation
  };
  —end example]
A specialization of a conversion function template is referenced in the same way as a non-template conversion function that converts to the same type. [Example:

```cpp
struct A {
    template <class T> operator T*();
};
template <class T> A::operator T*(){ return 0; } // specialization
template A::operator void*(); // explicit instantiation

int main() {
    A a;
    int* ip;
    ip = a.operator int*(); // explicit call to template operator A::operator int()  
}
```
—end example] [Note: There is no syntax to form a template-id (12.2) by providing an explicit template argument list (12.9.1) for a conversion function template (10.3.8.2). —end note]

A specialization of a conversion function template is not found by name lookup. Instead, any conversion function templates visible in the context of the use are considered. For each such operator, if argument deduction succeeds (12.9.2.3), the resulting specialization is used as if found by name lookup.

A using-declaration in a derived class cannot refer to a specialization of a conversion function template in a base class.

Overload resolution (11.3.3.2) and partial ordering (12.6.6.2) are used to select the best conversion function among multiple specializations of conversion function templates and/or non-template conversion functions.

### 12.6.3 Variadic templates [temp.variadic]

1. A template parameter pack is a template parameter that accepts zero or more template arguments. [Example:

```cpp
template<class ... Types> struct Tuple {  
};
Tuple<> t0; // Types contains no arguments
Tuple<int> t1; // Types contains one argument: int
Tuple<int, float> t2; // Types contains two arguments: int and float
Tuple<0> error; // error: 0 is not a type
```
—end example]

2. A function parameter pack is a function parameter that accepts zero or more function arguments. [Example:

```cpp
template<class ... Types> void f(Types ... args);

f(); // args contains no arguments
f(1); // args contains one argument: int
f(2, 1.0); // args contains two arguments: int and double
```
—end example]

3. An init-capture pack is a lambda capture that introduces an init-capture for each of the elements in the pack expansion of its initializer. [Example:

```cpp
template <typename... Args>
void foo(Args... args) {
    [...]xs=args[
        bar(xs...); // xs is an init-capture pack
    ];
}

foo(); // xs contains zero init-captures
foo(1); // xs contains one init-capture
```
—end example]

4. A pack is a template parameter pack, a function parameter pack, or an init-capture pack. The number of elements of a template parameter pack or a function parameter pack is the number of arguments provided for the parameter pack. The number of elements of an init-capture pack is the number of elements in the pack expansion of its initializer.

§ 12.6.3
A pack expansion consists of a pattern and an ellipsis, the instantiation of which produces zero or more instantiations of the pattern in a list (described below). The form of the pattern depends on the context in which the expansion occurs. Pack expansions can occur in the following contexts:

- In a function parameter pack (9.2.3.5); the pattern is the parameter-declaration without the ellipsis.
- In a using-declaration (9.8); the pattern is a using-declarator.
- In a template parameter pack that is a pack expansion (12.1):
  - if the template parameter pack is a parameter-declaration; the pattern is the parameter-declaration without the ellipsis;
  - if the template parameter pack is a type-parameter with a template-parameter-list; the pattern is the corresponding type-parameter without the ellipsis.
- In an initializer-list (9.3); the pattern is an initializer-clause.
- In a base-specifier-list (10.6); the pattern is a base-specifier.
- In a mem-initializer-list (10.9.2) for a mem-initializer whose mem-initializer-id denotes a base class; the pattern is the mem-initializer.
- In a template-argument-list (12.3); the pattern is a template-argument.
- In an attribute-list (9.11.1); the pattern is an attribute.
- In an alignment-specifier (9.11.2); the pattern is the alignment-specifier without the ellipsis.
- In a capture-list (7.5.5); the pattern is a capture.
- In a sizeof... expression (7.6.2.3); the pattern is an identifier.
- In a fold-expression (7.5.6); the pattern is the cast-expression that contains an unexpanded pack.

[Example:
  template<class ... Types> void f(Types ... rest);
  template<class ... Types> void g(Types ... rest) {
    f(&rest ...);
    // “&rest ...” is a pack expansion; “&rest” is its pattern
  }

  — end example]

For the purpose of determining whether a pack satisfies a rule regarding entities other than packs, the pack is considered to be the entity that would result from an instantiation of the pattern in which it appears.

A pack whose name appears within the pattern of a pack expansion is expanded by that pack expansion. An appearance of the name of a pack is only expanded by the innermost enclosing pack expansion. The pattern of a pack expansion shall name one or more packs that are not expanded by a nested pack expansion; such packs are called unexpanded packs in the pattern. All of the packs expanded by a pack expansion shall have the same number of arguments specified. An appearance of a name of a pack that is not expanded is ill-formed. [Example:

  template<
typename...> struct Tuple {};
  template<
typename T1, typename T2> struct Pair {};

  template<class ... Args1> struct zip {
    template<class ... Args2> struct with {
      typedef Tuple<Pair<Args1, Args2> ... > type;
    };
  };

typedef zip<short, int>::with<unsigned short, unsigned>::type T1;
  // T1 is Tuple<Pair<short, unsigned short>, Pair<int, unsigned>>
typedef zip<short>::with<unsigned short, unsigned>::type T2;
  // error: different number of arguments specified for Args1 and Args2

  template<class ... Args>
    void g(Args ... args) { // OK: Args is expanded by the function parameter pack args
    f(const_cast<const Args*>(&args)...); // OK: “Args” and “args” are expanded
    f(5 ...); // error: pattern does not contain any packs
    f(args); // error: pack “args” is not expanded

    — end example]
The instantiation of a pack expansion that is neither a \texttt{sizeof...} expression nor a \texttt{fold-expression} produces a list of elements \( E_1, E_2, \ldots, E_N \), where \( N \) is the number of elements in the pack expansion parameters. Each \( E_i \) is generated by instantiating the pattern and replacing each pack expansion parameter with its \( i \)th element. Such an element, in the context of the instantiation, is interpreted as follows:

\begin{enumerate}
\item[(8.1)] if the pack is a template parameter pack, the element is a template parameter \((12.1)\) of the corresponding kind (type or non-type) designating the \( i \)th corresponding type or value template argument;
\item[(8.2)] if the pack is a function parameter pack, the element is an \texttt{id-expression} designating the \( i \)th function parameter that resulted from instantiation of the function parameter pack declaration; otherwise
\item[(8.3)] if the pack is an \texttt{init-capture} pack, the element is an \texttt{id-expression} designating the variable introduced by the \( i \)th \texttt{init-capture} that resulted from instantiation of the \texttt{init-capture} pack.
\end{enumerate}

All of the \( E_i \) become items in the enclosing list. [\textit{Note:} The variety of list varies with the context: \texttt{expression-list, base-specifier-list, template-argument-list}, etc. — end note] When \( N \) is zero, the instantiation of the expansion produces an empty list. Such an instantiation does not alter the syntactic interpretation of the enclosing construct, even in cases where omitting the list entirely would otherwise be ill-formed or would result in an ambiguity in the grammar. [\textit{Example:}]

\begin{verbatim}
template<class... T> struct X : T... { };
template<class... T> void f(T... values) {
    X<T...> x(values...);
}

template void f<>(); // OK: X<> has no base classes
// x is a variable of type X<> that is value-initialized
\end{verbatim}

— end example]

The instantiation of a \texttt{sizeof...} expression \((7.6.2.3)\) produces an integral constant containing the number of elements in the pack it expands.

\begin{enumerate}
\item[(10.1)] \((E_1 \ op \ E_2) \ op \ \cdots \ op \ E_N\) for a unary left fold,
\item[(10.2)] \(E_1 \ op \ (\cdots \ op \ (E_{N-1} \ op \ E_N))\) for a unary right fold,
\item[(10.3)] \(((E \ op \ E_1) \ op \ E_2) \ op \ \cdots \ op \ E_N\) for a binary left fold, and
\item[(10.4)] \(E_1 \ op \ (\cdots \ op \ (E_{N-1} \ op \ (E_N \ op \ E)))\) for a binary right fold.
\end{enumerate}

In each case, \( op \) is the \texttt{fold-operator}, \( N \) is the number of elements in the pack expansion parameters, and each \( E_i \) is generated by instantiating the pattern and replacing each pack expansion parameter with its \( i \)th element. For a binary fold-expression, \( E \) is generated by instantiating the \texttt{cast-expression} that did not contain an unexpanded pack. [\textit{Example:}]

\begin{verbatim}
template<typename ...Args>
bool all(Args ...args) { return (... && args); }

bool b = all(true, true, true, false);
\end{verbatim}

Within the instantiation of \texttt{all}, the returned expression expands to \(((true \ &\& true) \ &\& true) \ &\& false\), which evaluates to \texttt{false}. — end example] If \( N \) is zero for a unary fold-expression, the value of the expression is shown in Table 14; if the operator is not listed in Table 14, the instantiation is ill-formed.

\begin{table}[ht]
\centering
\caption{Value of folding empty sequences}
\begin{tabular}{|c|c|}
\hline
\textbf{Operator} & \textbf{Value when pack is empty} \\
\hline
\&\& & true \\
\|
 & false \\
, & void() \\
\hline
\end{tabular}
\end{table}
12.6.4 Friends [temp.friend]

A friend of a class or class template can be a function template or class template, a specialization of a function template or class template, or a non-template function or class. For a friend function declaration that is not a template declaration:

1. if the name of the friend is a qualified or unqualified template-id, the friend declaration refers to a specialization of a function template, otherwise,
2. if the name of the friend is a qualified-id and a matching non-template function is found in the specified class or namespace, the friend declaration refers to that function, otherwise,
3. if the name of the friend is a qualified-id and a matching function template is found in the specified class or namespace, the friend declaration refers to the deduced specialization of that function template (12.9.2.6), otherwise,
4. the name shall be an unqualified-id that declares (or redeclares) a non-template function.

[Example:

```cpp
template<class T> class task;
template<class T> task<T>* preempt(task<T>);

template<class T> class task {
  friend void next_time();
  friend void process(task<T>*);
  friend task<T>* preempt<T>(task<T>*);
  template<class C> friend int func(C);
  friend class task<int>;
  template<class P> friend class frd;
};
```

Here, each specialization of the task class template has the function next_time as a friend; because process does not have explicit template-arguments, each specialization of the task class template has an appropriately typed function process as a friend, and this friend is not a function template specialization; because the friend preempt has an explicit template-argument T, each specialization of the task class template has the appropriate specialization of the function template preempt as a friend; and each specialization of the task class template has all specializations of the function template func as friends. Similarly, each specialization of the task class template has the class template specialization task<int> as a friend, and has all specializations of the class template frd as friends. —end example]

A friend template may be declared within a class or class template. A friend function template may be defined within a class or class template, but a friend class template may not be defined in a class or class template. In these cases, all specializations of the friend class or friend function template are friends of the class or class template granting friendship. [Example:

```cpp
class A {
  template<class T> friend class B; // OK
  template<class T> friend void f(T){ /* ... */ } // OK
};
```

—end example]

A template friend declaration specifies that all specializations of that template, whether they are implicitly instantiated (12.8.1), partially specialized (12.6.5) or explicitly specialized (12.8.3), are friends of the class containing the template friend declaration. [Example:

```cpp
class X {
  template<class T> friend struct A;
  class Y { }; // OK
};
```

—end example]

A template friend declaration may declare a member of a dependent type to be a friend. The friend declaration shall declare a function or specify a type with an elaborated-type-specifier, in either case with a
nested-name-specifier ending with a simple-template-id, \( C \), whose template-name names a class template. The template parameters of the template friend declaration shall be deducible from \( C \) (12.9.2.5). In this case, a member of a specialization \( S \) of the class template is a friend of the class granting friendship if deduction of the template parameters of \( C \) from \( S \) succeeds, and substituting the deduced template arguments into the friend declaration produces a declaration that would be a valid redeclaration of the member of the specialization. [Example:

```cpp
template<class T> struct A {
    struct B {
    }
    void f();
    struct D {
        void g();
    }
    T h();
    template<T U> T i();
};
template<> struct A<int> {
    struct B {
    }
    int f();
    struct D {
        void g();
    }
    template<int U> int i();
};
template<> struct A<float*> {
    int *h();
};

class C {
    template<class T> friend struct A<T>::B; // grants friendship to A<int>::B even though
    // it is not a specialization of A<T>::B
    template<class T> friend void A<T>::f(); // does not grant friendship to A<int>::f()
    // because its return type does not match
    template<class T> friend void A<T>::D::g(); // ill-formed: A<T>::D does not end with
    // a simple-template-id
    template<class T> friend int *A<T*>::h(); // grants friendship to A<int*>::h() and A<float*>::h()
    template<class T> template<T U> friend T A<T>::i(); // grants friendship to instantiations of A<T>::i() and
    // to A<int>::i(), and thereby to all specializations
    // of those function templates
};
```
—end example]

5 [Note: A friend declaration may first declare a member of an enclosing namespace scope (12.7.5). —end note]

6 A friend template shall not be declared in a local class.

7 Friend declarations shall not declare partial specializations. [Example:

```cpp
template<class T> class A {
};
class X {
    template<class T> friend class A<T*>;
};
```
—end example]

8 When a friend declaration refers to a specialization of a function template, the function parameter declarations shall not include default arguments, nor shall the inline specifier be used in such a declaration.

9 A non-template friend declaration shall not have a requires-clause.

### 12.6.5 Class template partial specializations [temp.class.spec]

1 A primary class template declaration is one in which the class template name is an identifier. A template declaration in which the class template name is a simple-template-id is a partial specialization of the class template named in the simple-template-id. A partial specialization of a class template provides an alternative definition of the template that is used instead of the primary definition when the arguments in a specialization match those given in the partial specialization (12.6.5.1). The primary template shall be declared before
any specializations of that template. A partial specialization shall be declared before the first use of a class
template specialization that would make use of the partial specialization as the result of an implicit or explicit
instantiation in every translation unit in which such a use occurs; no diagnostic is required.

2 Each class template partial specialization is a distinct template and definitions shall be provided for the
members of a template partial specialization (12.6.5.3).

3 [Example:

```cpp
template<class T1, class T2, int I> class A
{ };  // primary template
template<class T, int I> class A<T, T*, I> { };  // partial specialization
```

The first declaration declares the primary (unspecialized) class template. The second and subsequent
declarations declare partial specializations of the primary template. —end example]

4 A class template partial specialization may be constrained (Clause 12). [Example:

```cpp
template<typename T> concept C = true;
template<typename T> struct X { };  // #1
```

Both partial specializations are more specialized than the primary template. #1 is more specialized because
the deduction of its template arguments from the template argument list of the class template specialization
succeeds, while the reverse does not. #2 is more specialized because the template arguments are equivalent,
but the partial specialization is more constrained (12.4.4). —end example]

5 The template parameters are specified in the angle bracket enclosed list that immediately follows the keyword
`template`. For partial specializations, the template argument list is explicitly written immediately following
the class template name. For primary templates, this list is implicitly described by the template parameter
list. Specifically, the order of the template arguments is the sequence in which they appear in the template
parameter list. [Example: The template argument list for the primary template in the example above is
<T1, T2, I>. —end example] [Note: The template argument list shall not be specified in the primary template
declaration. For example,

```cpp
template<class T1, class T2, int I>
class A<T1, T2, I> { };  // error
```

—end note]

6 A class template partial specialization may be declared in any scope in which the corresponding primary
template may be defined (9.7.1.2, 10.3, 12.6.2). [Example:

```cpp
template<class T> struct A {

    struct C {
        template<class T2> struct B { };  // partial specialization #1
        template<class T2> struct B<T2*> { };  // partial specialization #2
    };

    template<class T2> template<class T2>

    template<class T2, int I> struct A<T1, T2, I> { };  // primary template
```

—end example]

7 Partial specialization declarations themselves are not found by name lookup. Rather, when the primary
template name is used, any previously-declared partial specializations of the primary template are also
considered. One consequence is that a using-declaration which refers to a class template does not restrict the
set of partial specializations which may be found through the using-declaration. [Example:

```cpp
namespace N {
    template<class T1, class T2> class A { };  // primary template
}
```
using N::A;

namespace N {
    template<class T> class A<T, T*> {};  // partial specialization
}

A<int, int*> a;  // uses the partial specialization, which is found through the using-declaration

— end example]

A non-type argument is non-specialized if it is the name of a non-type parameter. All other non-type arguments are specialized.

Within the argument list of a class template partial specialization, the following restrictions apply:

(9.1) — The type of a template parameter corresponding to a specialized non-type argument shall not be dependent on a parameter of the specialization. [Example:

    template <class T, T t> struct C {}
    template <class T> struct C<T, 1>;  // error
    template< int X, int (*array_ptr)[X] > class A {};
    int array[5];
    template< int X > class A<X,&array> {};  // error

— end example]

(9.2) — The specialization shall be more specialized than the primary template (12.6.5.2).

(9.3) — The template parameter list of a specialization shall not contain default template argument values.

(9.4) — An argument shall not contain an unexpanded pack. If an argument is a pack expansion (12.6.3), it shall be the last argument in the template argument list.

The usual access checking rules do not apply to non-dependent names used to specify template arguments of the simple-template-id of the partial specialization. [Note: The template arguments may be private types or objects that would normally not be accessible. Dependent names cannot be checked when declaring the partial specialization, but will be checked when substituting into the partial specialization. — end note]

12.6.5.1 Matching of class template partial specializations [temp.class.spec.match]

When a class template is used in a context that requires an instantiation of the class, it is necessary to determine whether the instantiation is to be generated using the primary template or one of the partial specializations. This is done by matching the template arguments of the class template specialization with the template argument lists of the partial specializations.

(1.1) — If exactly one matching specialization is found, the instantiation is generated from that specialization.

(1.2) — If more than one matching specialization is found, the partial order rules (12.6.5.2) are used to determine whether one of the specializations is more specialized than the others. If none of the specializations is more specialized than all of the other matching specializations, then the use of the class template is ambiguous and the program is ill-formed.

(1.3) — If no matches are found, the instantiation is generated from the primary template.

A partial specialization matches a given actual template argument list if the template arguments of the partial specialization can be deduced from the actual template argument list (12.9.2), and the deduced template arguments satisfy the associated constraints of the partial specialization, if any (12.4.2). [Example:

    template<class T1, class T2, int I> class A {};  // #1
    template<class T, int I>    class A<T, T*, I> {};  // #2
    template<class T1, class T2, int I> class A<T1*, T2, I> {};  // #3
    template<class T>          class A<int, T*, 5> {};  // #4
    template<class T1, class T2, int I> class A<T1, T2, I> {};  // #5

    A<int, int, 1> a1;  // uses #1
    A<int, int*, 1> a2;  // uses #2, T is int, I is 1
    A<int, char*, 5> a3;  // uses #4, T is char

139) There is no way in which they could be used.
A<int, char*, 1> a4; // uses #5, T1 is int, T2 is char, I is 1
A<int*, int*, 2> a5; // ambiguous: matches #3 and #5

— end example] [Example:

template< typename T> concept C = requires (T t) { t.f(); };

template< typename T> struct S { }; // #1

template< C T> struct S<T> { }; // #2

struct Arg { void f(); }; // uses #1; the constraints of #2 are not satisfied
S<int> s1; // uses #1; the constraints of #2 are not satisfied
S<Arg> s2; // uses #2; both constraints are satisfied but #2 is more specialized

— end example

3 If the template arguments of a partial specialization cannot be deduced because of the structure of its
template-parameter-list and the template-id, the program is ill-formed. [Example:

template <int I, int J> struct A {}; // error

template <int I> struct A<I+5, I*2> {}; // OK

template <int I, int J, int K> struct B {}; // OK

template <int I> struct B<I, I*2, 2>; // OK

— end example

4 In a type name that refers to a class template specialization, (e.g., A<int, int, 1>) the argument list shall
match the template parameter list of the primary template. The template arguments of a specialization are
deduced from the arguments of the primary template.

12.6.5.2 Partial ordering of class template specializations [temp.class.order]

1 For two class template partial specializations, the first is more specialized than the second if, given the
following rewrite to two function templates, the first function template is more specialized than the second
according to the ordering rules for function templates (12.6.6.2):

(1.1) — Each of the two function templates has the same template parameters and associated constraints (12.4.2)
as the corresponding partial specialization.

(1.2) — Each function template has a single function parameter whose type is a class template specialization
where the template arguments are the corresponding template parameters from the function template
for each template argument in the template-argument-list of the simple-template-id of the partial
specialization.

2 [Example:

template< int I, int J, class T> class X { }; // #1

template< int I> class X<I, J, int> { }; // #1

template< int I> class X<I, I, int> { }; // #2

template< int I0, int J0> void f(X<I0, J0, int>); // A

template< int I0> void f(X<I0, I0, int>); // B

template <auto v> class Y { }; // #3

template <auto* p> class Y<p> { }; // #3

template <auto** pp> class Y<pp> { }; // #4

template <auto* p0> void g(Y<p0>); // C

template <auto** pp0> void g(Y<pp0>); // D

According to the ordering rules for function templates, the function template B is more specialized than
the function template A and the function template D is more specialized than the function template C.
Therefore, the partial specialization #2 is more specialized than the partial specialization #1 and the partial
specialization #4 is more specialized than the partial specialization #3. — end example] [Example:

template<typename T> concept C = requires (T t) { t.f(); };

template<typename T> concept D = C<T> && requires (T t) { t.f(); };

§ 12.6.5.2 342
template<typename T> class S { }; 

template<
 typename T>
 class S { }; // #1 

template<
 C T>
 class S<T> { }; // #2 

The partial specialization #2 is more specialized than #1 because B is more specialized than A. — end example]

12.6.5.3 Members of class template specializations [temp.class.spec.mfunc]

The template parameter list of a member of a class template partial specialization shall match the template parameter list of the class template partial specialization. The template argument list of a member of a class template partial specialization shall match the template argument list of the class template partial specialization. A class template specialization is a distinct template. The members of the class template partial specialization are unrelated to the members of the primary template. Class template partial specialization members that are used in a way that requires a definition shall be defined; the definitions of members of the primary template are never used as definitions for members of a class template partial specialization. An explicit specialization of a member of a class template partial specialization is declared in the same way as an explicit specialization of the primary template. [Example:

```cpp
// primary class template
template<class T, int I> struct A {
    void f();
};

// member of primary class template
template<class T, int I> void A<T,I>::f() { }

// class template partial specialization
template<class T> struct A<T,2> {
    void f();
    void g();
    void h();
};

// member of class template partial specialization
template<class T> void A<T,2>::g() { }

// explicit specialization
template<> void A<char,2>::h() { }
```

```cpp
int main() {
    A<char,0> a0;
    A<char,2> a2;
    a0.f(); // OK, uses definition of primary template’s member
    a2.g(); // OK, uses definition of partial specialization’s member
    a2.h(); // OK, uses definition of explicit specialization’s member
    a2.f(); // ill-formed, no definition of f for A<T,2>; the primary template is not used here
}
```

— end example]

2 If a member template of a class template is partially specialized, the member template partial specializations are member templates of the enclosing class template; if the enclosing class template is instantiated (12.8.1, 12.8.2), a declaration for every member template partial specialization is also instantiated as part of creating the members of the class template specialization. If the primary member template is explicitly specialized for a given (implicit) specialization of the enclosing class template, the partial specializations of the member template are ignored for this specialization of the enclosing class template. If a partial specialization of the member template is explicitly specialized for a given (implicit) specialization of the enclosing class template, the primary member template and its other partial specializations are still considered for this specialization of the enclosing class template. [Example:

```cpp
template<class T> struct A {
    template<class T2> struct B {}; // #1
```
12.6.6 Function templates

A function template defines an unbounded set of related functions. [Example: A family of sort functions might be declared like this:

```cpp
template<class T> class Array { }
template<class T> void sort(Array<T>&);
```

—end example]

2

A function template can be overloaded with other function templates and with non-template functions (9.2.3.5). A non-template function is not related to a function template (i.e., it is never considered to be a specialization), even if it has the same name and type as a potentially generated function template specialization.140

12.6.6.1 Function template overloading

1 It is possible to overload function templates so that two different function template specializations have the same type. [Example:

```cpp
// translation unit 1:
template<class T>
void f(T*);
void g(int* p) {
    f(p); // calls f<int*>(int*)
}
```

// translation unit 2:
```cpp
template<class T>
void f(T);
void h(int* p) {
    f(p); // calls f<int*>(int*)
}
```

—end example]

2 Such specializations are distinct functions and do not violate the one-definition rule (6.2).

3 The signature of a function template is defined in Clause 3. The names of the template parameters are significant only for establishing the relationship between the template parameters and the rest of the signature. [Note: Two distinct function templates may have identical function return types and function parameter lists, even if overload resolution alone cannot distinguish them.

```cpp
template<class T> void f();
template<int I> void f(); // OK: overloads the first template
```

—end note]

4 When an expression that references a template parameter is used in the function parameter list or the return type in the declaration of a function template, the expression that references the template parameter is part of the signature of the function template. This is necessary to permit a declaration of a function template in one translation unit to be linked with another declaration of the function template in another translation unit and, conversely, to ensure that function templates that are intended to be distinct are not linked with one another. [Example:

```cpp
template <int I, int J> A<I+J> f(A<I>, A<J>); // #1
```
Two expressions involving template parameters are considered equivalent if two function definitions containing the expressions would satisfy the one-definition rule (6.2), except that the tokens used to name the template parameters may differ as long as a token used to name a template parameter in one expression is replaced by another token that names the same template parameter in the other expression. Two lambda-expressions are never considered equivalent. [Note: The intent is to avoid lambda-expressions appearing in the signature of a function template with external linkage. — end note] For determining whether two dependent names (12.7.2) are equivalent, only the name itself is considered, not the result of name lookup in the context of the template. If multiple declarations of the same function template differ in the result of this name lookup, the result for the first declaration is used. [Example:

```cpp
// #1
template <int I, int J> void f(A<i+J>);  
// same as #1
template <class T> decltype(g(T())) h();
int g(int);

// redeclaration of h() uses the earlier lookup...
template <class T> decltype(g(T())) h() {
  return g(T()); }
// ... although the lookup here does find g(int)
int i = h<int>();
// template argument substitution fails; g(int)
// was not in scope at the first declaration of h()
```

Two expressions involving template parameters that are not equivalent are functionally equivalent if, for any given set of template arguments, the evaluation of the expression results in the same value.

Two template-heads are equivalent if their template-parameter-lists have the same length, corresponding template-parameters are equivalent, and if either has a requires-clause, they both have requires-clauses and the corresponding constraint-expressions are equivalent. Two template-parameters are equivalent under the following conditions:

- (6.1) they declare template parameters of the same kind,
- (6.2) if either declares a template parameter pack, they both do,
- (6.3) if they declare non-type template parameters, they have equivalent types,
- (6.4) if they declare template template parameters, their template parameters are equivalent, and
- (6.5) if either is declared with a qualified-concept-name, they both are, and the qualified-concept-names are equivalent.

When determining whether types or qualified-concept-names are equivalent, the rules above are used to compare expressions involving template parameters. Two template-heads are functionally equivalent if they accept and are satisfied by (12.4.1) the same set of template argument lists.

Two function templates are equivalent if they are declared in the same scope, have the same name, have equivalent template-heads, and have return types, parameter lists, and trailing requires-clauses (if any) that are equivalent using the rules described above to compare expressions involving template parameters. Two function templates are functionally equivalent if they are declared in the same scope, have the same name, accept and are satisfied by the same set of template argument lists, and have return types and parameter lists that are functionally equivalent using the rules described above to compare expressions involving template parameters. If the validity or meaning of the program depends on whether two constructs are equivalent, and they are functionally equivalent but not equivalent, the program is ill-formed, no diagnostic required.

[Note: This rule guarantees that equivalent declarations will be linked with one another, while not requiring implementations to use heroic efforts to guarantee that functionally equivalent declarations will be treated as distinct. For example, the last two declarations are functionally equivalent and would cause a program to be ill-formed:

```cpp
// guaranteed to be the same
template <int I> void f(A<i>, A<i+10>);
```
template <int I> void f(A<I>, A<I+10>);

// guaranteed to be different
template <int I> void f(A<I>, A<I+10>);
template <int I> void f(A<I>, A<I+11>);

// ill-formed, no diagnostic required
template <int I> void f(A<I>, A<I+10>);
template <int I> void f(A<I>, A<I+1+2+3+4>);

— end note

12.6.6.2 Partial ordering of function templates

1 If a function template is overloaded, the use of a function template specialization might be ambiguous because template argument deduction (12.9.2) may associate the function template specialization with more than one function template declaration. Partial ordering of overloaded function template declarations is used in the following contexts to select the function template to which a function template specialization refers:

(1.1) — during overload resolution for a call to a function template specialization (11.3.3);
(1.2) — when the address of a function template specialization is taken;
(1.3) — when a placement operator delete that is a function template specialization is selected to match a placement operator new (6.6.4.4.2, 7.6.2.4);
(1.4) — when a friend function declaration (12.6.4), an explicit instantiation (12.8.2) or an explicit specialization (12.8.3) refers to a function template specialization.

2 Partial ordering selects which of two function templates is more specialized than the other by transforming each template in turn (see next paragraph) and performing template argument deduction using the function type. The deduction process determines whether one of the templates is more specialized than the other. If so, the more specialized template is the one chosen by the partial ordering process. If both deductions succeed, the partial ordering selects the more constrained template as described by the rules in 12.4.4.

3 To produce the transformed template, for each type, non-type, or template template parameter (including template parameter packs (12.6.3) thereof) synthesize a unique type, value, or class template respectively and substitute it for each occurrence of that parameter in the function type of the template. [Note: The type replacing the placeholder in the type of the value synthesized for a non-type template parameter is also a unique synthesized type. — end note] If only one of the function templates \( M \) is a non-static member of some class \( A \), \( M \) is considered to have a new first parameter inserted in its function parameter list. Given \( cv \) as the \( cv \)-qualifiers of \( M \) (if any), the new parameter is of type “rvalue reference to \( cv \ A \)” if the optional \( ref-qualifier \) of \( M \) is \&\& or if \( M \) has no \( ref-qualifier \) and the first parameter of the other template has rvalue reference type. Otherwise, the new parameter is of type “lvalue reference to \( cv \ A \)” [Note: This allows a non-static member to be ordered with respect to a non-member function and for the results to be equivalent to the ordering of two equivalent non-members. — end note] [Example:

```cpp
struct A { };  

section<class T> struct B {  
   template<class R> int operator*(R&);  // #1  
};  

template<class T, class R> int operator*(T&, R&);  // #2  

// The declaration of B::operator* is transformed into the equivalent of  
// template<class R> int operator*(B&A>&, R&);  // #1a

int main() {  
   A a;  
   B<A> b;  
   b * a;  // calls #1a  
}

— end example]

4 Using the transformed function template’s function type, perform type deduction against the other template as described in 12.9.2.4.

[Example:
template<class T> struct A { A();
};

template<class T> void f(T);
template<class T> void f(T*);
template<class T> void f(const T*);

template<class T> void g(T);
template<class T> void g(T&);

template<class T> void h(const T&);
template<class T> void h(A<T>&);

void m() {
    const int* p;
    f(p);  // f(const T*) is more specialized than f(T) or f(T*)
    float x;
    g(x);  // ambiguous: g(T) or g(T&)
    A<int> z;
    h(z);  // overload resolution selects h(A<T>&)
    const A<int> z2;
    h(z2);  // h(const T&) is called because h(A<T>&) is not callable
}

—end example

Note: Since partial ordering in a call context considers only parameters for which there are explicit
call arguments, some parameters are ignored (namely, function parameter packs, parameters with default
arguments, and ellipsis parameters). [Example:

template<class T> void f(T); // #1
template<class T> void f(T*, int=1); // #2

template<class T> void g(T); // #3
template<class T> void g(T*, ...); // #4

int main() {
    int* ip;
    f(ip);  // calls #2
    g(ip);  // calls #4
}

—end example] [Example:

template<class T, class U> struct A {);

template<class T, class U> void f(U, A<T, U>* p = 0); // #1
template<class T, class U> void f(U, A<T, U>* p = 0); // #2

template<class T, class U> void g(T, T = T()); // #3

template<class T, class U> void g(T, U...); // #4

void h() {
    f<int>(42, (A<int, int>*))0); // calls #2
    f<int>(42); // error: ambiguous
    g(42); // error: ambiguous
}

—end example] [Example:

template<class T, class U> void f(T, U...); // #1

template<class T> void f(T); // #2

template<class T, class U> void g(T, U...); // #3

template<class T> void g(T); // #4

void h(int i) {
    f(&i);  // error: ambiguous
    g(&i);  // OK; calls #3
}

—end example] — end note]
12.6.7 Alias templates

1 A template-declaration in which the declaration is an alias-declaration (Clause 9) declares the identifier to be an alias template. An alias template is a name for a family of types. The name of the alias template is a template-name.

2 When a template-id refers to the specialization of an alias template, it is equivalent to the associated type obtained by substitution of its template-arguments for the template-parameters in the type-id of the alias template. [Note: An alias template name is never deduced. — end note] [Example:

```cpp
template<class T> struct Alloc { /* ... */
};
template<class T> using Vec = vector<T, Alloc<T>>;
Vec<int> v; // same as vector<int, Alloc<int>> v;
```

```cpp
template<class T>
void process(Vec<T>& v)
{ /* ... */
}
```

```cpp
template<class T>
void process(vector<T, Alloc<T>>& w)
{ /* ... */ // error: redefinition

f(v);
// error: Vec not deduced
```

```cpp
template<template<class> class TT>
void f(TT<int>);
f(v);
// error: Vec not deduced
```  

3 However, if the template-id is dependent, subsequent template argument substitution still applies to the template-id. [Example:

```cpp
template<typename...> using void_t = void;
template<typename T> void_t<typename T::foo> f();
f<int>(); // error, int does not have a nested type foo
```

— end example]

4 The type-id in an alias template declaration shall not refer to the alias template being declared. The type produced by an alias template specialization shall not directly or indirectly make use of that specialization. [Example:

```cpp
template <class T> struct A;
template <class T> using B = typename A<T>::U;
template <class T> struct A {
    typedef B<T> U;
};
B<short> b; // error: instantiation of B<short> uses own type via A<short>::U
```

— end example]

5 The type of a lambda-expression appearing in an alias template declaration is different between instantiations of that template, even when the lambda-expression is not dependent. [Example:

```cpp
template <class T>
using A = decltype([] { }); // A<int> and A<char> refer to different closure types
```

— end example]

12.6.8 Concept definitions

1 A concept is a template that defines constraints on its template arguments.

2 A concept-definition declares a concept. Its identifier becomes a concept-name referring to that concept within its scope. [Example:
template<typename T>
concept C = requires(T x) {
    { x == x } -> bool;
};

template<typename T>
    requires C<T>    // C constrains f1(T) in constraint-expression
T f1(T x) { return x; }

template<C T>
    // C constrains f2(T) as a constrained-parameter
T f2(T x) { return x; }
— end example

A concept-definition shall appear at namespace scope (6.3.6).

A concept shall not have associated constraints (12.4.2).

A concept is not instantiated (12.8). [Note: An id-expression that denotes a concept specialization is evaluated as an expression (7.5.4). A concept cannot be explicitly instantiated (12.8.2), explicitly specialized (12.8.3), or partially specialized. — end note]

The first declared template parameter of a concept definition is its prototype parameter. A variadic concept is a concept whose prototype parameter is a template parameter pack.

12.7 Name resolution

Three kinds of names can be used within a template definition:

(1.1) — The name of the template itself, and names declared within the template itself.
(1.2) — Names dependent on a template-parameter (12.7.2).
(1.3) — Names from scopes which are visible within the template definition.

A name used in a template declaration or definition and that is dependent on a template-parameter is assumed not to name a type unless the applicable name lookup finds a type name or the name is qualified by the keyword typename. [Example:

// no B declared here
class X;

template<class T> class Y {
    class Z;
    // forward declaration of member class
    void f() {
        X* a1;    // declare pointer to X
        T* a2;    // declare pointer to T
        Y* a3;    // declare pointer to Y<T>
        Z* a4;    // declare pointer to Z
        typedef typename T::A TA;
        TA* a5;    // declare pointer to T's A
        typename T::A* a6;    // declare pointer to T's A
        T::A* a7;    // T::A is not a type name:
                        // multiplication of T::A by a7; ill-formed, no visible declaration of a7
        B* a8;     // B is not a type name:
                        // multiplication of B by a8; ill-formed, no visible declarations of B and a8
    }
};
— end example]

A typename-specifier denotes the type or class template denoted by the simple-type-specifier (9.1.7.2) formed by omitting the keyword typename. The usual qualified name lookup (6.4.3) is used to find the qualified-id even in the presence of typename. [Example:
struct A {
    struct X { }
    int X;
};
struct B {
    struct X { }
};
template<class T> void f(T t) {
    typename T::X x;
}
void foo() {
    A a;
    B b;
    f(b); // OK: T::X refers to B::X
    f(a); // error: T::X refers to the data member A::X not the struct A::X
}

—end example

4 A qualified name used as the name in a class-or-decltype (10.6) or an elaborated-type-specifier is implicitly assumed to name a type, without the use of the typename keyword. In a nested-name-specifier that immediately contains a nested-name-specifier that depends on a template parameter, the identifier or simple-template-id is implicitly assumed to name a type, without the use of the typename keyword. [Note: The typename keyword is not permitted by the syntax of these constructs. —end note]

5 A qualified-id is assumed to name a type if

(5.1) it is a qualified name in a type-id-only context (see below), or
(5.2) it is a decl-specifier of the decl-specifier-seq of a
(5.2.1) simple-declaration or a function-definition in namespace scope,
(5.2.2) member-declaration,
(5.2.3) parameter-declaration in a member-declaration\(^{141}\), unless that parameter-declaration appears in a default argument,
(5.2.4) parameter-declaration in a declarator of a function or function template declaration whose declarator-id is qualified, unless that parameter-declaration appears in a default argument,
(5.2.5) parameter-declaration in a lambda-declarator, unless that parameter-declaration appears in a default argument, or
(5.2.6) parameter-declaration of a (non-type) template-parameter.

A qualified name is said to be in a type-id-only context if it appears in a type-id, new-type-id, or defining-type-id and the smallest enclosing type-id, new-type-id, or defining-type-id is a new-type-id, defining-type-id, trailing-return-type, default argument of a type-parameter of a template, or type-id of a static_cast, const_cast, reinterpret_cast, or dynamic_cast. [Example:

```c
template<
    class T> T::R f(); // OK, return type of a function declaration at global scope

template<class T> void f(T::R); // ill-formed (no diagnostic required), attempt to declare a void variable template
```

```c
template<class T> struct S {  
    using PTr = PTrTraits<T>::Ptr;
    T::R f(T::P p) {  
        return static_cast<T::R>(p);
    }
    auto g() -> S<T*>::Ptr;
};
```

```c
template<typename T> void f() {  
    void (*pf)(T::X);  
    void g(T::X);  
    // variable pf of type void* initialized with T::X
    // error: T::X at block scope does not denote a type
    // (attempt to declare a void variable)
}
```

—end example]

\(^{141}\) This includes friend function declarations.
A qualified-id that refers to a member of an unknown specialization, that is not prefixed by typename, and that is not otherwise assumed to name a type (see above) denotes a non-type. [Example:

```cpp
template <class T> void f(int i) {
    T::x * i; // expression, not the declaration of a variable i
}
```

```cpp
struct Foo {
    typedef int x;
};
```

```cpp
struct Bar {
    static int const x = 5;
};
```

```cpp
int main() {
    f<Bar>(1); // OK
    f<Foo>(1); // error: Foo::x is a type
}
```

— end example

Within the definition of a class template or within the definition of a member of a class template following the declarator-id, the keyword typename is not required when referring to a member of the current instantiation (12.7.2.1). [Example:

```cpp
template<class T> struct A {
    typedef int B;
    B b; // OK, no typename required
};
```

— end example

The validity of a template may be checked prior to any instantiation. [Note: Knowing which names are type names allows the syntax of every template to be checked in this way. — end note] The program is ill-formed, no diagnostic required, if:

1. no valid specialization can be generated for a template or a substatement of a constexpr if statement (8.4.1) within a template and the template is not instantiated, or
2. no substitution of template arguments into a partial-concept-id or requires-clause would result in a valid expression, or
3. every valid specialization of a variadic template requires an empty template parameter pack, or
4. a hypothetical instantiation of a template immediately following its definition would be ill-formed due to a construct that does not depend on a template parameter, or
5. the interpretation of such a construct in the hypothetical instantiation is different from the interpretation of the corresponding construct in any actual instantiation of the template. [Note: This can happen in situations including the following:

1. a type used in a non-dependent name is incomplete at the point at which a template is defined but is complete at the point at which an instantiation is performed, or
2. lookup for a name in the template definition found a using-declaration, but the lookup in the corresponding scope in the instantiation does not find any declarations because the using-declaration was a pack expansion and the corresponding pack is empty, or
3. an instantiation uses a default argument or default template argument that had not been defined at the point at which the template was defined, or
4. constant expression evaluation (7.7) within the template instantiation uses
   1. the value of a const object of integral or unscoped enumeration type or
   2. the value of a constexpr object or
   3. the value of a reference or
   4. the definition of a constexpr function,
   and that entity was not defined when the template was defined, or

§ 12.7 351
— a class template specialization or variable template specialization that is specified by a non-
dependent simple-template-id is used by the template, and either it is instantiated from a partial
specialization that was not defined when the template was defined or it names an explicit
specialization that was not declared when the template was defined.

— end note]

Otherwise, no diagnostic shall be issued for a template for which a valid specialization can be generated.
[Note: If a template is instantiated, errors will be diagnosed according to the other rules in this document.
Exactly when these errors are diagnosed is a quality of implementation issue. — end note] [Example:

```cpp
int j;
template<class T> class X {
  void f(T t, int i, char* p) {
    t = i;  // diagnosed if X::f is instantiated, and the assignment to t is an error
    p = i;  // may be diagnosed even if X::f is not instantiated
    p = j;  // may be diagnosed even if X::f is not instantiated
  }
  void g(T t) {
    // may be diagnosed even if X::g is not instantiated
  }
};
template<class... T> struct A {
  void operator++(int, T... t);  // error: too many parameters
};
template<class... T> struct A : T... { };   // error: duplicate base class
—end example]

9 When looking for the declaration of a name used in a template definition, the usual lookup rules (6.4.1, 6.4.2)
are used for non-dependent names. The lookup of names dependent on the template parameters is postponed
until the actual template argument is known (12.7.2). [Example:

```cpp
#include <iostream>
using namespace std;
template<class T> class Set {
  T* p;
  int cnt;
public:
  Set();
  Set(const Set<T>&);
  void printall() {
    for (int i = 0; i<cnt; i++)
      cout << p[i] << 'n';
  }
};

In the example, i is the local variable i declared in printall, cnt is the member cnt declared in Set, and
cout is the standard output stream declared in iostream. However, not every declaration can be found this
way; the resolution of some names must be postponed until the actual template-arguments are known. For
example, even though the name operator<< is known within the definition of printall() and a declaration
of it can be found in <iostream>, the actual declaration of operator<< needed to print p[i] cannot be
known until it is known what type T is (12.7.2). — end example]

10 If a name does not depend on a template-parameter (as defined in 12.7.2), a declaration (or set of declarations)
for that name shall be in scope at the point where the name appears in the template definition; the name is
bound to the declaration (or declarations) found at that point and this binding is not affected by declarations
that are visible at the point of instantiation. [Example:

```cpp
void f(char);
template<class T> void g(T t) {
  f(t);  // f(char)
  f(T(t));  // dependent
```
f(t); // dependent
dd++; // not dependent; error: declaration for dd not found

enum E { e }
void f(E);

double dd;
void h() {
g(e); // will cause one call of f(char) followed by two calls of f(E)
g('a'); // will cause three calls of f(char)
}

—end example

11 [Note: For purposes of name lookup, default arguments and noexcept-specifiers of function templates and default arguments and noexcept-specifiers of member functions of class templates are considered definitions (12.6). — end note]

12.7.1 Locally declared names [temp.local]

Like normal (non-template) classes, class templates have an injected-class-name (Clause 10). The injected-class-name can be used as a template-name or a type-name. When it is used with a template-argument-list, as a template-argument for a template template-parameter, or as the final identifier in the elaborated-type-specifier of a friend class template declaration, it refers to the class template itself. Otherwise, it is equivalent to the template-name followed by the template-parameters of the class template enclosed in <>.

Within the scope of a class template specialization or partial specialization, when the injected-class-name is used as a type-name, it is equivalent to the template-name followed by the template-arguments of the class template specialization or partial specialization enclosed in <>.

Example:

```
template<template<class> class T> class A {);
template<class T> class Y;
template> class Y<int> {
Y* p; // meaning Y<int>
Y<char>* q; // meaning Y<char>
A<Y>* a; // meaning A<::Y>
class B {
    template<class> friend class Y; // meaning ::Y
};
};
—end example
```

The injected-class-name of a class template or class template specialization can be used either as a template-name or a type-name wherever it is in scope. [Example:

```
template <class T> struct Base { Base* p; };

template <class T> struct Derived: public Base<T> { typename Derived::Base* p; // meaning Derived::Base<T>
};

template<class T, template<class> class U = T::template Base> struct Third { }; Third<Derived<int>> t; // OK: default argument uses injected-class-name as a template
—end example
```

A lookup that finds an injected-class-name (10.7) can result in an ambiguity in certain cases (for example, if it is found in more than one base class). If all of the injected-class-names that are found refer to specializations of the same class template, and if the name is used as a template-name, the reference refers to the class template itself and not a specialization thereof, and is not ambiguous. [Example:

```
template <class T> struct Base { };
template <class T> struct Derived: Base<int>, Base<char> { typename Derived::Base b; // error: ambiguous
```

§ 12.7.1 353
5 When the normal name of the template (i.e., the name from the enclosing scope, not the injected-class-name) is used, it always refers to the class template itself and not a specialization of the template. [Example:

```cpp
template<class T> class X {
    X* p;
    X<T>* p2;
    X<int>* p3;
    ::X* p4; // error: missing template argument list
};
```

—end example]

6 A template-parameter shall not be redeclared within its scope (including nested scopes). A template-parameter shall not have the same name as the template name. [Example:

```cpp
template<class T, int i> class Y {
    int T; // error: template-parameter redeclared
    void f() {
        char T; // error: template-parameter redeclared
    }
};
```

```cpp
template<class X> class X; // error: template-parameter redeclared
```

—end example]

7 In the definition of a member of a class template that appears outside of the class template definition, the name of a member of the class template hides the name of a template-parameter of any enclosing class templates (but not a template-parameter of the member if the member is a class or function template). [Example:

```cpp
template<class T> struct A {
    struct B { /* ... */ }; typedef void C;
    void f();
    template<class U> void g(U);
};
```

```cpp
template<class B> void A<B>::f() {
    B b; // A's B, not the template parameter
}
```

```cpp
template<class B> template<class C> void A<B>::g(C) {
    B b; // A's B, not the template parameter
    C c; // the template parameter C, not A's C
}
```

—end example]

8 In the definition of a member of a class template that appears outside of the namespace containing the class template definition, the name of a template-parameter hides the name of a member of this namespace. [Example:

```cpp
namespace N {
    class C { }
    template<class T> class B {
        void f(T);
    }
};
```

```cpp
template<class C> void N::B::f(C) {
    C b; // C is the template parameter, not N::C
}
```

—end example]

§ 12.7.1 354
In the definition of a class template or in the definition of a member of such a template that appears outside of the template definition, for each non-dependent base class (12.7.2.1), if the name of the base class or the name of a member of the base class is the same as the name of a template-parameter, the base class name or member name hides the template-parameter name (6.3.10). [Example:

```cpp
struct A {
    struct B { /* ... */ };  
    int a;
    int Y;
};

template<class B, class a> struct X : A {
    B b;                  // A's B
    a b;                  // error: A's a isn't a type name
};
—end example]

12.7.2 Dependent names [temp.dep]

Inside a template, some constructs have semantics which may differ from one instantiation to another. Such a construct depends on the template parameters. In particular, types and expressions may depend on the type and/or value of template parameters (as determined by the template arguments) and this determines the context for name lookup for certain names. An expression may be type-dependent (that is, its type may depend on a template parameter) or value-dependent (that is, its value when evaluated as a constant expression (7.7) may depend on a template parameter) as described in this subclause. In an expression of the form:

postfix-expression ( expression-list )

where the postfix-expression is an unqualified-id, the unqualified-id denotes a dependent name if

(1.1) — any of the expressions in the expression-list is a pack expansion (12.6.3),
(1.2) — any of the expressions or braced-init-lists in the expression-list is type-dependent (12.7.2.2), or
(1.3) — the unqualified-id is a template-id in which any of the template arguments depends on a template parameter.

If an operand of an operator is a type-dependent expression, the operator also denotes a dependent name. Such names are unbound and are looked up at the point of the template instantiation (12.7.4.1) in both the context of the template definition and the context of the point of instantiation.

[Example:

```cpp
template<class T> struct X : B<T> {
    typename T::A* pa;
    void f(B<T>* pb) {
        static int i = B<T>::i;
        pb->j++;
    }
};
```

The base class name B<T>, the type name T::A, the names B<T>::i and pb->j explicitly depend on the template-parameter. —end example]

3 In the definition of a class or class template, the scope of a dependent base class (12.7.2.1) is not examined during unqualified name lookup either at the point of definition of the class template or member or during an instantiation of the class template or member. [Example:

```cpp
typedef double A;
template<class T> class B {
    typedef int A;
};
template<class T> struct X : B<T> {
    A a;                  // a has type double
};
```

The type name A in the definition of X<T> binds to the typedef name defined in the global namespace scope, not to the typedef name defined in the base class B<T>. —end example] [Example:

§ 12.7.2 355
struct A {
    struct B { /* ... */};
    int a;
    int Y;
};

int a;

template<class T> struct Y : T {
    struct B { /* ... */};
    B b;              // The B defined in Y
    void f(int i) { a = i; }  // ::a
    Y* p;            // Y<T>
};

Y< A> ya;

The members A::B, A::a, and A::Y of the template argument A do not affect the binding of names in Y< A>.

end example]

12.7.2.1 Dependent types

1 A name refers to the current instantiation if it is
   (1.1) in the definition of a class template, a nested class of a class template, a member of a class template, or
   a member of a nested class of a class template, the injected-class-name (Clause 10) of the class template
   or nested class,
   (1.2) in the definition of a primary class template or a member of a primary class template, the name of
   the class template followed by the template argument list of the primary template (as described below)
   enclosed in <> (or an equivalent template alias specialization),
   (1.3) in the definition of a nested class of a class template, the name of the nested class referenced as a
   member of the current instantiation, or
   (1.4) in the definition of a partial specialization or a member of a partial specialization, the name of
   the class template followed by the template argument list of the partial specialization enclosed in <> (or an
   equivalent template alias specialization). If the nth template parameter is a template parameter pack,
   the nth template argument is a pack expansion (12.6.3) whose pattern is the name of the template
   parameter pack.

2 The template argument list of a primary template is a template argument list in which the nth template
   argument has the value of the nth template parameter of the class template. If the nth template parameter
   is a template parameter pack (12.6.3), the nth template argument is a pack expansion (12.6.3) whose pattern
   is the name of the template parameter pack.

3 A template argument that is equivalent to a template parameter can be used in place of that template
   parameter in a reference to the current instantiation. For a template type-parameter, a template argument
   is equivalent to a template parameter if it denotes the same type. For a non-type template parameter, a
   template argument is equivalent to a template parameter if it is an identifier that names a variable that is
   equivalent to the template parameter. A variable is equivalent to a template parameter if
   (3.1) it has the same type as the template parameter (ignoring cv-qualification) and
   (3.2) its initializer consists of a single identifier that names the template parameter or, recursively, such a
   variable.

[Note: Using a parenthesized variable name breaks the equivalence. — end note] [Example:

    template <class T> class A {
    A* p1;          // A is the current instantiation
    A<T>* p2;       // A<T> is the current instantiation
    A<T> p3;        // A<T> is not the current instantiation
    ::A<T>* p4;     // ::A<T> is the current instantiation
    class B {
    B* p1;          // B is the current instantiation
    A<T>::B* p2;    // A<T>::B is the current instantiation
    typename A<T>::B* p3; // A<T>::B is not the current instantiation
    }
template <class T> class A<T*> {
    A<T*>* p1; // T* is the current instantiation
    A<T>* p2; // T is not the current instantiation
};

template <class T1, class T2, int I> struct B {
    B<T1, T2, I>* b1; // refers to the current instantiation
    B<T2, T1, I>* b2; // not the current instantiation
    typedef T1 my_T1;
    static const int my_I = I;
    static const int my_I2 = I+0;
    static const long my_I4 = I;
    static const int my_I5 = (I);
    B<my_T1, T2, my_I3>* b3; // refers to the current instantiation
    B<my_T1, T2, my_I2>* b4; // not the current instantiation
    B<my_T1, T2, my_I4>* b5; // refers to the current instantiation
    B<my_T1, T2, my_I5>* b6; // not the current instantiation
};

— end example

4 A dependent base class is a base class that is a dependent type and is not the current instantiation. [Note: A base class can be the current instantiation in the case of a nested class naming an enclosing class as a base.]

[Example:

template<class T> struct A {
    typedef int M;
    struct B {
        typedef void M;
        struct C;
    };
};

template<class T> struct A<T>::B::C : A<T> {
    M m; // OK, A<T>::M
};

— end example] — end note]

5 A name is a member of the current instantiation if it is
(5.1) — An unqualified name that, when looked up, refers to at least one member of a class that is the current instantiation or a non-dependent base class thereof. [Note: This can only occur when looking up a name in a scope enclosed by the definition of a class template. — end note]

(5.2) — A qualified-id in which the nested-name-specifier refers to the current instantiation and that, when looked up, refers to at least one member of a class that is the current instantiation or a non-dependent base class thereof. [Note: If no such member is found, and the current instantiation has any dependent base classes, then the qualified-id is a member of an unknown specialization; see below. — end note]

(5.3) — An id-expression denoting the member in a class member access expression (7.6.1.5) for which the type of the object expression is the current instantiation, and the id-expression, when looked up (6.4.5), refers to at least one member of a class that is the current instantiation or a non-dependent base class thereof. [Note: If no such member is found, and the current instantiation has any dependent base classes, then the id-expression is a member of an unknown specialization; see below. — end note]

[Example:

template <class T> class A {
    static const int i = 5;
    int n1[i]; // i refers to a member of the current instantiation
    int n2[A::i]; // A::i refers to a member of the current instantiation
    int n3[A<T>::i]; // A<T>::i refers to a member of the current instantiation

§ 12.7.2.1

357
int f();
;

template <class T> int A<T>::f() {
    return i;    // i refers to a member of the current instantiation
}
— end example]

A name is a dependent member of the current instantiation if it is a member of the current instantiation that, when looked up, refers to at least one member of a class that is the current instantiation.

A name is a member of an unknown specialization if it is

1. A qualified-id in which the nested-name-specifier names a dependent type that is not the current instantiation.
2. A qualified-id in which the nested-name-specifier refers to the current instantiation, the current instantiation has at least one dependent base class, and name lookup of the qualified-id does not find any member of a class that is the current instantiation or a non-dependent base class thereof.
3. An id-expression denoting the member in a class member access expression (7.6.1.5) in which either
   1. the type of the object expression is dependent, and is not the current instantiation.

If a qualified-id in which the nested-name-specifier refers to the current instantiation is not a member of the current instantiation or a member of an unknown specialization, the program is ill-formed even if the template containing the qualified-id is not instantiated; no diagnostic required. Similarly, if the id-expression in a class member access expression for which the type of the object expression is the current instantiation does not refer to a member of the current instantiation or a member of an unknown specialization, the program is ill-formed even if the template containing the member access expression is not instantiated; no diagnostic required. [Example:

```cpp
template<class T> class A {
    typedef int type;
    void f() {    // OK: refers to a member of the current instantiation
        A<T>::type i;
        // error: neither a member of the current instantiation nor
        typename A<T>::other j;    // a member of an unknown specialization
    }
};
— end example]
```

If, for a given set of template arguments, a specialization of a template is instantiated that refers to a member of the current instantiation with a qualified-id or class member access expression, the name in the qualified-id or class member access expression is looked up in the template instantiation context. If the result of this lookup differs from the result of name lookup in the template definition context, name lookup is ambiguous. [Example:

```cpp
struct A {
    int m;
};

struct B {
    int m;
};

template<typename T>
struct C : A, T {
    int f() { return this->m; }    // finds A::m in the template definition context
    int g() { return m; }          // finds A::m in the template definition context
};

template int C<B>::f();    // error: finds both A::m and B::m
```
A type is dependent if it is

- a template parameter,
- a member of an unknown specialization,
- a nested class or enumeration that is a dependent member of the current instantiation,
- a cv-qualified type where the cv-unqualified type is dependent,
- a compound type constructed from any dependent type,
- an array type whose element type is dependent or whose bound (if any) is value-dependent,
- a function type whose exception specification is value-dependent,
- denoted by a `simple-template-id` in which either the template name is a template parameter or any of the template arguments is a dependent type or an expression that is type-dependent or value-dependent or is a pack expansion [Note: This includes an injected-class-name (Clause 10) of a class template used without a `template-argument-list`. —end note], or
- denoted by `decltype(expression)`, where `expression` is type-dependent (12.7.2.2).

[Note: Because typedefs do not introduce new types, but instead simply refer to other types, a name that refers to a typedef that is a member of the current instantiation is dependent only if the type referred to is dependent. —end note]

### 12.7.2.2 Type-dependent expressions

Except as described below, an expression is type-dependent if any subexpression is type-dependent.

This is type-dependent if the class type of the enclosing member function is dependent (12.7.2.1).

An id-expression is type-dependent if it contains

- an identifier associated by name lookup with one or more declarations declared with a dependent type,
- an identifier associated by name lookup with a non-type `template-parameter` declared with a type that contains a placeholder type (9.1.7.4),
- an identifier associated by name lookup with a variable declared with a type that contains a placeholder type (9.1.7.4) where the initializer is type-dependent,
- an identifier associated by name lookup with one or more declarations of member functions of the current instantiation declared with a return type that contains a placeholder type,
- an identifier associated by name lookup with a structured binding declaration (9.5) whose `brace-or-equal-initializer` is type-dependent,
- the identifier `__func__` (9.4.1), where any enclosing function is a template, a member of a class template, or a generic lambda,
- a `template-id` that is dependent,
- a `conversion-function-id` that specifies a dependent type, or
- a nested-name-specifier or a qualified-id that names a member of an unknown specialization;

or if it names a dependent member of the current instantiation that is a static data member of type “array of unknown bound of T” for some T (12.6.1.3). Expressions of the following forms are type-dependent only if the type specified by the `type-id`, `simple-type-specifier` or `new-type-id` is dependent, even if any subexpression is type-dependent:

- `simple-type-specifier ( expression-list_opt )`
- `::opt new new-placement_opt new-type-id new-initializer_opt`
- `::opt new new-placement_opt ( type-id ) new-initializer_opt`
- `dynamic_cast < type-id > ( expression )`
- `static_cast < type-id > ( expression )`
- `const_cast < type-id > ( expression )`
- `reinterpret_cast < type-id > ( expression )`
- `[ type-id ] cast-expression`
Expressions of the following forms are never type-dependent (because the type of the expression cannot be dependent):

```
literal
postfix-expression . pseudo-destructor-name
postfix-expression -> pseudo-destructor-name
sizeof unary-expression
sizeof ( type-id )
sizeof ... ( identifier )
offsetof ( type-id )
typeid ( expression )
typeid ( type-id )
::opt delete cast-expression
::opt delete [ ] cast-expression
throw assignment-expression_opt
```  

[Note: For the standard library macro offsetof, see 16.2. — end note]

A class member access expression (7.6.1.5) is type-dependent if the expression refers to a member of the current instantiation and the type of the referenced member is dependent, or the class member access expression refers to a member of an unknown specialization. [Note: In an expression of the form x.y or xp->y the type of the expression is usually the type of the member y of the class of x (or the class pointed to by xp). However, if x or xp refers to a dependent type that is not the current instantiation, the type of y is always dependent. If x or xp refers to a non-dependent type or refers to the current instantiation, the type of y is the type of the class member access expression. — end note]

A `braced-init-list` is type-dependent if any element is type-dependent or is a pack expansion.

A `fold-expression` is type-dependent.

### 12.7.2.3 Value-dependent expressions

[temp.dep constexpr]

Except as described below, an expression used in a context where a constant expression is required is value-dependent if any subexpression is value-dependent.

An `id-expression` is value-dependent if:

1. it is type-dependent,
2. it is the name of a non-type template parameter,
3. it names a static data member that is a dependent member of the current instantiation and is not initialized in a `member-declarator`,
4. it names a static member function that is a dependent member of the current instantiation, or
5. it is a constant with literal type and is initialized with an expression that is value-dependent.

Expressions of the following form are value-dependent if the `unary-expression` or `expression` is type-dependent or the `type-id` is dependent:

```
ssizeof unary-expression
sizeof ( type-id )
typeid ( expression )
typeid ( type-id )
offsetof ( type-id )
nexcept ( expression )
```  

[Note: For the standard library macro offsetof, see 16.2. — end note]

Expressions of the following form are value-dependent if either the `type-id` or `simple-type-specifier` is dependent or the `expression` or `cast-expression` is value-dependent:

```
simple-type-specifier ( expression-list_opt )
static_cast < type-id > ( expression )
const_cast < type-id > ( expression )
reinterpret_cast < type-id > ( expression )
( type-id ) cast-expression
```  

Expressions of the following form are value-dependent:
An expression of the form `&qualified-id` where the `qualified-id` names a dependent member of the current instantiation is value-dependent. An expression of the form `&cast-expression` is also value-dependent if evaluating `cast-expression` as a core constant expression (7.7) succeeds and the result of the evaluation refers to a templated entity that is an object with static or thread storage duration or a member function.

### 12.7.2.4 Dependent template arguments

1. A type `template-argument` is dependent if the type it specifies is dependent.

2. A non-type `template-argument` is dependent if its type is dependent or the constant expression it specifies is value-dependent.

3. Furthermore, a non-type `template-argument` is dependent if the corresponding non-type `template-parameter` is of reference or pointer type and the `template-argument` designates or points to a member of the current instantiation or a member of a dependent type.

4. A template `template-argument` is dependent if it names a `template-parameter` or is a `qualified-id` that refers to a member of an unknown specialization.

### 12.7.3 Non-dependent names

1. Non-dependent names used in a template definition are found using the usual name lookup and bound at the point they are used. [Example:

```cpp
void g(double);
void h();

template<class T> class Z {
public:
  void f() { // calls g(double)
    g(1);  // ill-formed: cannot increment function; this could be diagnosed
    h++;  // either here or at the point of instantiation
  }
};

void g(int);  // not in scope at the point of the template definition, not considered for the call g(1)
```
— end example]

### 12.7.4 Dependent name resolution

1. In resolving dependent names, names from the following sources are considered:

   (1.1) — Declarations that are visible at the point of definition of the template.

   (1.2) — Declarations from namespaces associated with the types of the function arguments both from the instantiation context (12.7.4.1) and from the definition context.

#### 12.7.4.1 Point of instantiation

1. For a function template specialization, a member function template specialization, or a specialization for a member function or static data member of a class template, if the specialization is implicitly instantiated because it is referenced from within another template specialization and the context from which it is referenced depends on a template parameter, the point of instantiation of the specialization is the point of instantiation of the enclosing specialization. Otherwise, the point of instantiation for such a specialization immediately follows the namespace scope declaration or definition that refers to the specialization.

2. If a function template or member function of a class template is called in a way which uses the definition of a default argument of that function template or member function, the point of instantiation of the default argument is the point of instantiation of the function template or member function specialization.

3. For a `noexcept-specifier` of a function template specialization or specialization of a member function of a class template, if the `noexcept-specifier` is implicitly instantiated because it is needed by another template specialization and the context that requires it depends on a template parameter, the point of instantiation of the `noexcept-specifier` is the point of instantiation of the specialization that requires it. Otherwise, the
point of instantiation for such a \texttt{noexcept-specifier} immediately follows the namespace scope declaration or definition that requires the \texttt{noexcept-specifier}.

4 For a class template specialization, a class member template specialization, or a specialization for a class member of a class template, if the specialization is implicitly instantiated because it is referenced from within another template specialization, if the context from which the specialization is referenced depends on a template parameter, and if the specialization is not instantiated previous to the instantiation of the enclosing template, the point of instantiation is immediately before the point of instantiation of the enclosing template. Otherwise, the point of instantiation for such a specialization immediately precedes the namespace scope declaration or definition that refers to the specialization.

5 If a virtual function is implicitly instantiated, its point of instantiation is immediately following the point of instantiation of its enclosing class template specialization.

6 An explicit instantiation definition is an instantiation point for the specialization or specializations specified by the explicit instantiation.

7 The instantiation context of an expression that depends on the template arguments is the set of declarations with external linkage declared prior to the point of instantiation of the template specialization in the same translation unit.

8 A specialization for a function template, a member function template, or of a member function or static data member of a class template may have multiple points of instantiations within a translation unit, and in addition to the points of instantiation described above, for any such specialization that has a point of instantiation within the translation unit, the end of the translation unit is also considered a point of instantiation. A specialization for a class template has at most one point of instantiation within a translation unit. A specialization for any template may have points of instantiation in multiple translation units. If two different points of instantiation give a template specialization different meanings according to the one-definition rule (6.2), the program is ill-formed, no diagnostic required.

12.7.4.2 Candidate functions \[\text{[temp.dep.candidate]}\]

1 For a function call where the \texttt{postfix-expression} is a dependent name, the candidate functions are found using the usual lookup rules (6.4.1, 6.4.2) except that:

(1.1) — For the part of the lookup using unqualified name lookup (6.4.1), only function declarations from the template definition context are found.

(1.2) — For the part of the lookup using associated namespaces (6.4.2), only function declarations found in either the template definition context or the template instantiation context are found.

If the call would be ill-formed or would find a better match had the lookup within the associated namespaces considered all the function declarations with external linkage introduced in those namespaces in all translation units, not just considering those declarations found in the template definition and template instantiation contexts, then the program has undefined behavior.

12.7.5 Friend names declared within a class template \[\text{[temp.inject]}\]

1 Friend classes or functions can be declared within a class template. When a template is instantiated, the names of its friends are treated as if the specialization had been explicitly declared at its point of instantiation.

2 As with non-template classes, the names of namespace-scope friend functions of a class template specialization are not visible during an ordinary lookup unless explicitly declared at namespace scope (10.8.3). Such names may be found under the rules for associated classes (6.4.2).  \textit{Example:}

\begin{verbatim}
template<typename T> struct number {
    number(int);  // finds gcd because number<double> is an associated class,
    friend number gcd(number x, number y) { return 0; };  // making gcd visible in its namespace (global scope)
};

void g() {
    number<double> a(3), b(4);
    a = gcd(a, b);  // ill-formed; gcd is not visible
    b = gcd(3, 4);  // finds gcd because number<double> is an associated class,
}
\end{verbatim}

142 Friend declarations do not introduce new names into any scope, either when the template is declared or when it is instantiated.

§ 12.7.5
Template instantiation and specialization

The act of instantiating a function, a class, a member of a class template or a member template is referred to as template instantiation.

A function instantiated from a function template is called an instantiated function. A class instantiated from a class template is called an instantiated class. A member function, a member class, a member enumeration, or a static data member of a class template instantiated from the member definition of the class template is called, respectively, an instantiated member function, member class, member enumeration, or static data member. A member function instantiated from a member function template is called an instantiated member function. A member class instantiated from a member class template is called an instantiated member class. A variable instantiated from a variable template is called an instantiated variable. A static data member instantiated from a static data member template is called an instantiated static data member.

An explicit specialization may be declared for a function template, a class template, a member of a class template or a member template. An explicit specialization declaration is introduced by $\text{template<}$. In an explicit specialization declaration for a class template, a member of a class template or a class member template, the name of the class that is explicitly specialized shall be a simple-template-id. In the explicit specialization declaration for a function template or a member function template, the name of the function or member function explicitly specialized may be a template-id. [Example:

```c
template<class T = int> struct A {
    static int x;
};
template<class U> void g(U) { }

template<> struct A<double> { }; // specialize for T == double
template<> void g(char) { } // specialize for U == char

template<> void g<int>(int) { } // specialize for U == int

template<> int A<char>::x = 0; // specialize for T == char
```

An instantiated template specialization can be either implicitly instantiated (12.8.1) for a given argument list or be explicitly instantiated (12.8.2). A specialization is a class, function, or class member that is either instantiated or explicitly specialized (12.8.3).

For a given template and a given set of template-arguments,

- an explicit specialization shall be defined at most once in a program, as specified in 6.2, and
- both an explicit instantiation and a declaration of an explicit specialization shall not appear in a program unless the explicit instantiation follows a declaration of the explicit specialization.

An implementation is not required to diagnose a violation of this rule.

The usual access checking rules do not apply to names in a declaration of an explicit instantiation or explicit specialization, with the exception of names appearing in a function body, default argument, base-clause, member-specification, enumerator-list, or static data member or variable template initializer. [Note: In particular, the template arguments and names used in the function declarator (including parameter types, return types and exception specifications) may be private types or objects that would normally not be accessible. — end note]

Each class template specialization instantiated from a template has its own copy of any static members. [Example:
template<class T> class X {
    static T s;
};
template<class T> T X<T>::s = 0;
X<int> aa;
X<char*> bb;

X<int> has a static member s of type int and X<char*> has a static member s of type char*. — end example

If a function declaration acquired its function type through a dependent type (12.7.2.1) without using the syntactic form of a function declarator, the program is ill-formed. [Example:

    template<class T> struct A {
        static T t;
    };  
typedef int function();
A<function> a;  // ill-formed: would declare A<function>::t as a static member function
— end example]

12.8.1 Implicit instantiation [temp.inst]

1 Unless a class template specialization has been explicitly instantiated (12.8.2) or explicitly specialized (12.8.3), the class template specialization is implicitly instantiated when the specialization is referenced in a context that requires a completely-defined object type or when the completeness of the class type affects the semantics of the program. [Note: In particular, if the semantics of an expression depend on the member or base class lists of a class template specialization, the class template specialization is implicitly generated. For instance, deleting a pointer to class type depends on whether or not the class declares a destructor, and a conversion between pointers to class type depends on the inheritance relationship between the two classes involved. — end note] [Example:

    template<class T> class B { /* ... */ }
    template<class T> class D : public B<T> { /* ... */ }
    void f(void*);
    void f(B<int>*);
    void g(D<int>* p, D<char>* pp, D<double>* ppp) {
        f(p);                                  // instantiation of D<int> required: call f(B<int>*)
        B<char>* q = pp;                      // instantiation of D<char> required: convert D<char>* to B<char>*
        delete ppp;                          // instantiation of D<double> required
    }
— end example] If a class template has been declared, but not defined, at the point of instantiation (12.7.4.1), the instantiation yields an incomplete class type (6.7). [Example:

    template<class T> class X;
    X<char> ch;                          // error: incomplete type X<char>
— end example] [Note: Within a template declaration, a local class (10.5) or enumeration and the members of a local class are never considered to be entities that can be separately instantiated (this includes their default arguments, noexcept-specifiers, and non-static data member initializers, if any, but not their partial-concept-ids or requires-clauses). As a result, the dependent names are looked up, the semantic constraints are checked, and any templates used are instantiated as part of the instantiation of the entity within which the local class or enumeration is declared. — end note]

2 The implicit instantiation of a class template specialization causes

(2.1) — the implicit instantiation of the declarations, but not of the definitions, of the non-deleted class member functions, member classes, scoped member enumerations, static data members, member templates, and friends; and

(2.2) — the implicit instantiation of the definitions of deleted member functions, unscoped member enumerations, and member anonymous unions.

The implicit instantiation of a class template specialization does not cause the implicit instantiation of default arguments or noexcept-specifiers of the class member functions. [Example:
template<class T>
struct C {
  void f() { T x; }
  void g() = delete;
};
C<void> c; // OK, definition of C<void>::f is not instantiated at this point
template<> void C<int>::g() { } // error: redefinition of C<int>::g

—end example—

However, for the purpose of determining whether an instantiated redeclaration is valid according to 6.2 and 10.3, a declaration that corresponds to a definition in the template is considered to be a definition. [Example:

template<class T, class U>
struct Outer {
  template<class X, class Y> struct Inner;
  template<class Y> struct Inner<T, Y> { }; // #1a
  template<class Y> struct Inner<U, Y> { }; // #2
};
Outer<int, int> outer; // error at #2
Outer<int, int>::Inner<int, Y> is redeclared at #1b. (It is not defined but noted as being associated with a definition in Outer<T, U>.) #2 is also a redeclaration of #1a. It is noted as associated with a definition, so it is an invalid redeclaration of the same partial specialization.

template<typename T> struct Friendly {
  template<typename U> friend int f(U) { return sizeof(T); }
};
Friendly<char> fc;
Friendly<float> ff; // ill-formed: produces second definition of f(U)

—end example—

3 Unless a member of a class template or a member template has been explicitly instantiated or explicitly specialized, the specialization of the member is implicitly instantiated when the specialization is referenced in a context that requires the member definition to exist or if the existence of the definition of the member affects the semantics of the program; in particular, the initialization (and any associated side effects) of a static data member does not occur unless the static data member is itself used in a way that requires the definition of the static data member to exist.

4 Unless a function template specialization has been explicitly instantiated or explicitly specialized, the function template specialization is implicitly instantiated when the specialization is referenced in a context that requires a function definition to exist or if the existence of the definition affects the semantics of the program. A function whose declaration was instantiated from a friend function definition is implicitly instantiated when it is referenced in a context that requires a function definition to exist or if the existence of the definition affects the semantics of the program. Unless a call is to a function template explicit specialization or to a member function of an explicitly specialized class template, a default argument for a function template or a member function of a class template is implicitly instantiated when the function is called in a context that requires the value of the default argument.

5 [Example:

template<class T> struct Z {
  void f();
  void g();
};

void h() {
  Z<int> a; // instantiation of class Z<int> required
  Z<char>** p; // instantiation of class Z<char> not required
  Z<double>** q; // instantiation of class Z<double> not required
  a.f(); // instantiation of Z<int>::f() required
  p->g(); // instantiation of class Z<char> required, and
           // instantiation of Z<char>::g() required
}
Nothing in this example requires `class Z<double>`, `Z<int>::g()`, or `Z<char>::f()` to be implicitly instantiated.  

6 Unless a variable template specialization has been explicitly instantiated or explicitly specialized, the variable template specialization is implicitly instantiated when it is referenced in a context that requires a variable definition to exist or if the existence of the definition affects the semantics of the program. A default template argument for a variable template is implicitly instantiated when the variable template is referenced in a context that requires the value of the default argument.

7 The existence of a definition of a variable or function is considered to affect the semantics of the program if the variable or function is needed for constant evaluation by an expression (7.7), even if constant evaluation of the expression is not required or if constant expression evaluation does not use the definition.

[Example:

```cpp
class Z { };
template<typename T> class Z { };

template<typename T> constexpr int f() { return T::value; }

int main() {
    Z<int> z;
    z.f();
    return 0;
}
```  

—end example]

6 If the function selected by overload resolution (11.3) can be determined without instantiating a class template definition, it is unspecified whether that instantiation actually takes place. [Example:

```cpp
namespace N {
    template<class T> struct S {
        operator int();
    };

template <class T> struct S {
    operator int();
};

void f(int);
void f(S<int>&);
void f(S<float>);

void g(S<int>& sr) {
    f(sr);  // instantiation of S<int> allowed but not required
    fo(sr); // instantiation of S<float> allowed but not required
}
}
```  

—end example]

8 If a function template or a member function template specialization is used in a way that involves overload resolution, a declaration of the specialization is implicitly instantiated (12.9.3).

9 An implementation shall not implicitly instantiate a function template, a variable template, a member template, a non-virtual member function, a member class, a static data member of a class template, or a substatement of a constexpr if statement (8.4.1), unless such instantiation is required. [Note: The instantiation of a generic lambda does not require instantiation of substatements of a constexpr if statement unless the call operator template is instantiated. —end note] It is unspecified whether or not an implementation implicitly instantiates a virtual member function of a class template if the virtual member function would not otherwise be instantiated. The use of a template specialization in a default argument shall not cause the template to be implicitly instantiated except that a class template may be instantiated where its complete type is needed to determine the correctness of the default argument. The use of a default argument in a function call causes specializations in the default argument to be implicitly instantiated.

10 Implicitly instantiated class, function, and variable template specializations are placed in the namespace where the template is defined. Implicitly instantiated specializations for members of a class template are placed in the namespace where the enclosing class template is defined. Implicitly instantiated member templates are placed in the namespace where the enclosing class or class template is defined. [Example:

```cpp
namespace N {
    template<class T> class List {
```  

§ 12.8.1 366
public:
  T* get();
};

} // end class Map

} // end namespace N

template<class K, class V> class Map {
public:
  N::List<V> lt;
  V get(K);
};

void g(Map<const char*,int>& m) {
  int i = m.get("Nicholas");
}

A call of lt.get() from Map<const char*,int>::get() would place List<int>::get() in the namespace N rather than in the global namespace. —end example—

If a function template f is called in a way that requires a default argument to be used, the dependent names are looked up, the semantics constraints are checked, and the instantiation of any template used in the default argument is done as if the default argument had been an initializer used in a function template specialization with the same scope, the same template parameters and the same access as that of the function template f used at that point, except that the scope in which a closure type is declared (7.5.5.1) – and therefore its associated namespaces – remain as determined from the context of the definition for the default argument. This analysis is called default argument instantiation. The instantiated default argument is then used as the argument of f.

Each default argument is instantiated independently. [Example:

```cpp
template<class T> void f(T x, T y = ydef(T()), T z = zdef(T()));

class A {
};

A zdef(A);

void g(A a, A b, A c) {
  f(a, b, c);   // no default argument instantiation
  f(a, b);     // default argument z = zdef(T()) instantiated
  f(a);        // ill-formed; ydef is not declared
}
@end example
```

The noexcept-specifier of a function template specialization is not instantiated along with the function declaration; it is instantiated when needed (13.4). If such an noexcept-specifier is needed but has not yet been instantiated, the dependent names are looked up, the semantics constraints are checked, and the instantiation of any template used in the noexcept-specifier is done as if it were being done as part of instantiating the declaration of the specialization at that point. [Note: 12.7.4.1 defines the point of instantiation of a template specialization. —end note]

There is an implementation-defined quantity that specifies the limit on the total depth of recursive instantiations (Annex B), which could involve more than one template. The result of an infinite recursion in instantiation is undefined. [Example:

```cpp
template<class T> class X {
  X<T>* p;      // OK
  X<T*> a;       // implicit generation of X<T> requires
                 // the implicit instantiation of X<T*>
                 // which requires
                 // the implicit instantiation of X<T**> which ...
};
@end example
```

The partial-concept-ids and requires-clause of a template specialization or member function are not instantiated along with the specialization or function itself, even for a member function of a local class; substitution into the atomic constraints formed from them is instead performed as specified in 12.4.2 and 12.4.1.2 when
determining whether the constraints are satisfied. [Note: The satisfaction of constraints is determined during name lookup or overload resolution (11.3). — end note] [Example:

```cpp
template<typename T> concept C = sizeof(T) > 2;
template<typename T> concept D = C<T> && sizeof(T) > 4;

template<typename T> struct S {
    S() requires C<T> { } // #1
    S() requires D<T> { } // #2
};
```

```cpp
S<char> s1; // error: no matching constructor
S<char[8]> s2; // OK, calls #2
```

When S<char> is instantiated, both constructors are part of the specialization. Their constraints are not satisfied, and they suppress the implicit declaration of a default constructor for S<char> (10.3.4), so there is no viable constructor for s1. — end example]

```cpp
example:
template<typename T> struct S1 {
    template<typename U>
    requires false
    struct Inner1;
    // ill-formed, no diagnostic required
};
template<typename T> struct S2 {
    template<typename U>
    requires (sizeof(T[-(int)sizeof(T)]) > 1)
    struct Inner2;
    // ill-formed, no diagnostic required
};
```

The class S1<T>::Inner1 is ill-formed, no diagnostic required, because it has no valid specializations. S2 is ill-formed, no diagnostic required, since no substitution into the constraints of its Inner2 template would result in a valid expression. — end example]

12.8.2 Explicit instantiation

A class, function, variable, or member template specialization can be explicitly instantiated from its template. A member function, member class or static data member of a class template can be explicitly instantiated from the member definition associated with its class template. An explicit instantiation of a function template, member function of a class template, or variable template shall not use the `inline` or `constexpr` specifiers. [Note: The declaration may declare a `qualified-id`, in which case the `unqualified-id` of the `qualified-id` must be a `template-id`. — end note] If the explicit instantiation is for a class or member class, the `elaborated-type-specifier` in the `declaration` shall include a `simple-template-id`; otherwise, the `declaration` shall be a `simple-declaration` whose `init-declarator-list` comprises a single `init-declarator` that does not have an `initializer`. If the explicit instantiation is for a function or member function, the `unqualified-id` in the `declarator` shall be either a `template-id` or, where all template arguments can be deduced, a `template-name` or `operator-function-id`. [Note: The declaration may declare a `qualified-id`, in which case the `unqualified-id` of the `qualified-id` must be a `template-id`. — end note] If the explicit instantiation is for a member function, a member class or a static data member of a class template specialization, the name of the class template specialization in the `qualified-id` for the member name shall be a `simple-template-id`. If the explicit instantiation is for a variable template specialization, the `unqualified-id` in the `declarator` shall be a `simple-template-id`. An explicit instantiation shall appear in an enclosing namespace of its template. If the name declared in the explicit instantiation is an unqualified name, the explicit instantiation shall appear in the namespace where its template is declared or, if that namespace is inline (9.7.1), any namespace from its enclosing namespace set. [Note: Regarding qualified names in declarators, see 9.2.3. — end note] [Example:

```cpp
template<class T> class Array { void mf(); ;
```

```cpp
template class Array<char>;
template void Array<int>::mf();
```
A declaration of a function template, a variable template, a member function or static data member of a class template, or a member function template of a class or class template shall precede an explicit instantiation of that entity. A definition of a class template, a member class of a class template, or a member class template of a class or class template shall precede an explicit instantiation of that entity unless the explicit instantiation is preceded by an explicit specialization of the entity with the same template arguments. If the declaration of the explicit instantiation names an implicitly-declared special member function (10.3.3), the program is ill-formed.

The declaration in an explicit-instantiation and the declaration produced by the corresponding substitution into the templated function, variable, or class are two declarations of the same entity. [Note: These declarations are required to have matching types as specified in 6.5, except as specified in 13.4. [Example:]

    template<typename T> T var = {};  // OK, instantiated variable has type T
    template float var<float>;        // OK, instantiated variable has type float
    template int var<int[16]>::[];    // OK, absence of major array bound is permitted
    template int *var<int>;           // error: instantiated variable has type int

    template<typename T> auto av = T();    // OK, variable with type int can be redeclared with type auto
    template int av<int>;                // OK, variable with type int can be redeclared with type int

    template<typename T> auto f() {}      // error: function with deduced return type
    template void f<int>();              // redeclared with non-deduced return type (9.1.7.4)

— end example] — end note] Despite its syntactic form, the declaration in an explicit-instantiation for a variable is not itself a definition and does not conflict with the definition instantiated by an explicit instantiation definition for that variable.

For a given set of template arguments, if an explicit instantiation of a template appears after a declaration of an explicit specialization for that template, the explicit instantiation has no effect. Otherwise, for an explicit instantiation definition the definition of a function template, a variable template, a member function template, or a member function or static data member of a class template shall be present in every translation unit in which it is explicitly instantiated.

An explicit instantiation of a class, function template, or variable template specialization is placed in the namespace in which the template is defined. An explicit instantiation for a member of a class template is placed in the namespace where the enclosing class template is defined. An explicit instantiation for a member template is placed in the namespace where the enclosing class or class template is defined. [Example:

    namespace N {
        template<class T> class Y { void mf() { } };
    }

    template class Y<int>;                  // error: class template Y not visible in the global namespace
    using N::Y;
    template class Y<int>;                  // error: explicit instantiation outside of the namespace of the template

    template class N::Y<char*>;             // OK: explicit instantiation in namespace N
    template void N::Y<double>::mf();       // OK: explicit instantiation in namespace N

— end example]

A trailing template-argument can be left unspecified in an explicit instantiation of a function template specialization or of a member function template specialization provided it can be deduced from the type of a function parameter (12.9.2). [Example:

    template<class T> class Array { /* ... */ };
template<class T> void sort(Array<T>& v) { /* ... */ }

// instantiate 
// template-argument deduced
template void sort<>(Array<int>&);

[Note: An explicit instantiation of a constrained template shall satisfy that template’s associated constraints (12.4.2). The satisfaction of constraints is determined when forming the template name of an explicit instantiation in which all template arguments are specified (12.2), or, for explicit instantiations of function templates, during template argument deduction (12.9.2.6) when one or more trailing template arguments are left unspecified. — end note]

An explicit instantiation that names a class template specialization is also an explicit instantiation of the same kind (declaration or definition) of each of its members (not including members inherited from base classes and members that are templates) that has not been previously explicitly specialized in the translation unit containing the explicit instantiation, provided that the associated constraints, if any, of that member are satisfied by the template arguments of the explicit instantiation (12.4.2, 12.4.1), except as described below.  

[Note: In addition, it will typically be an explicit instantiation of certain implementation-dependent data about the class. — end note]

An explicit instantiation definition that names a class template specialization explicitly instantiates the class template specialization and is an explicit instantiation definition of only those members that have been defined at the point of instantiation.

Except for inline functions and variables, declarations with types deduced from their initializer or return value (9.1.7.4), const variables of literal types, variables of reference types, and class template specializations, explicit instantiation declarations have the effect of suppressing the implicit instantiation of the definition of the entity to which they refer. [Note: The intent is that an inline function that is the subject of an explicit instantiation declaration will still be implicitly instantiated when odr-used (6.2) so that the body can be considered for inlining, but that no out-of-line copy of the inline function would be generated in the translation unit. — end note]

If an entity is the subject of both an explicit instantiation declaration and an explicit instantiation definition in the same translation unit, the definition shall follow the declaration. An entity that is the subject of an explicit instantiation declaration and that is also used in a way that would otherwise cause an implicit instantiation (12.8.1) in the translation unit shall be the subject of an explicit instantiation definition somewhere in the program; otherwise the program is ill-formed, no diagnostic required. [Note: This rule does apply to inline functions even though an explicit instantiation declaration of such an entity has no other normative effect. This is needed to ensure that if the address of an inline function is taken in a translation unit in which the implementation chose to suppress the out-of-line body, another translation unit will supply the body. — end note] An explicit instantiation declaration shall not name a specialization of a template with internal linkage.

An explicit instantiation does not constitute a use of a default argument, so default argument instantiation is not done. [Example:

    char* p = 0;
    template<class T> T g(T x = &p) { return x; }
    template int g<int>(int); // OK even though &p isn’t an int.

— end example]

12.8.3 Explicit specialization [temp.expl.spec]

1 An explicit specialization of any of the following:

(1.1) — function template
(1.2) — class template
(1.3) — variable template
(1.4) — member function of a class template
(1.5) — static data member of a class template
(1.6) — member class of a class template
(1.7) — member enumeration of a class template

§ 12.8.3 370
(1.8) — member class template of a class or class template

(1.9) — member function template of a class or class template

can be declared by a declaration introduced by `template<>`; that is:

```cpp
explicit-specialization:
    template <> declaration
```

[Example:
```
template<class T> class stream;
\[ Example:
```
```
template<class T> class stream<char> { /* ... */ };
```
```
template<class T> class Array { /* ... */ };
template<class T> void sort(Array<T>& v) { /* ... */ }
```
```
template<> void sort<char*>(Array<char*>&);
```

Given these declarations, `stream<char>` will be used as the definition of streams of `chars`; other streams will be handled by class template specializations instantiated from the class template. Similarly, `sort<char*>` will be used as the sort function for arguments of type `Array<char*>`; other `Array` types will be sorted by functions generated from the template. — end example]

2 An explicit specialization may be declared in any scope in which the corresponding primary template may be defined (9.7.1.2, 10.3, 12.6.2).

3 A declaration of a function template, class template, or variable template being explicitly specialized shall precede the declaration of the explicit specialization. [Note: A declaration, but not a definition of the template is required. — end note] The definition of a class or class template shall precede the declaration of an explicit specialization for a member template of the class or class template. [Example:
```
template<> class X<int> { /* ... */ };
```
```
// error: X not a template
```
```
template<class T> class X;
```
```
template<> class X<char*> { /* ... */ };
```
```
// OK: X is a template
```
— end example]

4 A member function, a member function template, a member class, a member enumeration, a member class template, a static data member, or a static data member template of a class template may be explicitly specialized for a class specialization that is implicitly instantiated; in this case, the definition of the class template shall precede the explicit specialization for the member of the class template. If such an explicit specialization for the member of a class template names an implicitly-declared special member function (10.3.3), the program is ill-formed.

5 A member of an explicitly specialized class is not implicitly instantiated from the member declaration of the class template; instead, the member of the class template specialization shall itself be explicitly defined if its definition is required. In this case, the definition of the class template explicit specialization shall be in scope at the point at which the member is defined. The definition of an explicitly specialized class is unrelated to the definition of a generated specialization. That is, its members need not have the same names, types, etc. as the members of a generated specialization. Members of an explicitly specialized class template are defined in the same manner as members of normal classes, and not using the `template<>` syntax. The same is true when defining a member of an explicitly specialized member class. However, `template<>` is used in defining a member of an explicitly specialized member class template that is specialized as a class template. [Example:
```
template<class T> struct A {
  struct B { }
  template<class U> struct C { }; };
```
```
template<> struct A<int> {
  void f(int);
};
```
```
void h() {
  A<int> a;
```
a.f(16); // A<int>::f must be defined somewhere
}

// template<> not used for a member of an explicitly specialized class template
void A<int>::f(int) { /* ... */ }

template<> struct A<char>::B {
    void f();
}; // template<> also not used when defining a member of an explicitly specialized member class
void A<char>::B::f() { /* ... */ }

template<> template<class U> struct A<char>::C {
    void f();
}; // template<> is used when defining a member of an explicitly specialized member class
// specialized as a class template
template<class U> void A<char>::C<U>::f() { /* ... */ }

template<> struct A<short>::B {
    void f();
};
template<> void A<short>::B::f() { /* ... */ } // error: template<> not permitted

// template<> template<class U> struct A<short>::C {
    void f();
};
template<> template<class U> void A<short>::C<U>::f() { /* ... */ } // error: template<> required

—end example]  

6 If a template, a member template or a member of a class template is explicitly specialized then that
specialization shall be declared before the first use of that specialization that would cause an implicit
instantiation to take place, in every translation unit in which such a use occurs; no diagnostic is required. If
the program does not provide a definition for an explicit specialization and either the specialization is used in
a way that would cause an implicit instantiation to take place or the member is a virtual member function,
the program is ill-formed, no diagnostic required. An implicit instantiation is never generated for an explicit
specialization that is declared but not defined. [Example:
class String { };
template<class T> class Array { /* ... */ };
template<class T> void sort(Array<T>& v) { /* ... */ }

void f(Array<String>& v) {
    sort(v); // use primary template sort(Array<T>&), T is String
}

template<> void sort<String>(Array<String>& v); // error: specialization after use of primary template
template<> void sort<Array<char>& v); // OK: sort<char*> not yet used

template<class T> struct A {  
    enum E : T;
    enum class S : T;
};
template<> enum A<int>::E : int { eint }; // OK
template<> enum class A<int>::S : int { sint }; // OK
template<class T> enum A<T>::E : T { eT }; // ill-formed, A<char>::E was instantiated
when A<char> was instantiated
template<class T> enum class A<T>::S : T { sT };
template<> enum A<char>::E : char { echar }; // OK

—end example]

7 The placement of explicit specialization declarations for function templates, class templates, variable templates,
member functions of class templates, static data members of class templates, member classes of class templates,
member enumerations of class templates, member class templates of class templates, member function templates of class templates, static data member templates of class templates, member functions of member templates of class templates, member functions of member templates of non-template classes, static data member templates of non-template classes, member function templates of member classes of class templates, etc., and the placement of partial specialization declarations of class templates, variable templates, member class templates of non-template classes, static data member templates of non-template classes, member class templates of class templates, etc., can affect whether a program is well-formed according to the relative positioning of the explicit specialization declarations and their points of instantiation in the translation unit as specified above and below. When writing a specialization, be careful about its location; or to make it compile will be such a trial as to kindle its self-immolation.

8 A template explicit specialization is in the scope of the namespace in which the template was defined. [Example:

```cpp
namespace N {
    template<class T> class X { /* ... */ }; // OK: specialization in same namespace
    template<class T> class Y { /* ... */ }; // forward-declare intent to specialize for double

    template<class X<int> { /* ... */ }; // OK: specialization in same namespace
    template<class Y<double>; // OK: specialization in same namespace

    template<class N::Y<double> { /* ... */ }; // OK: specialization in enclosing namespace
    template<class N::Y<short> { /* ... */ }; // OK: specialization in enclosing namespace
}
```

—end example]

9 A simple-template-id that names a class template explicit specialization that has been declared but not defined can be used exactly like the names of other incompletely-defined classes (6.7). [Example:

```cpp
template<class T> class X; // X is a class template

template<class T> void f(T) { /* ... */ }

template<class T> inline T g(T) { /* ... */ } // with deduced template-argument of type int

template<> inline void f<>(int) { /* ... */ } // OK: inline

—end example]

10 A trailing template-argument can be left unspecified in the template-id naming an explicit function template specialization provided it can be deduced from the function argument type. [Example:

```cpp
template<class T> void f(T) { /* ... */ }

template<class T> void sort(Array<T>& v);

// explicit specialization for sort(Array<int>&)
// with deduced template-argument of type int

template<> void sort(Array<int>&); // OK: inline

template<> int g<>(int) { /* ... */ } // OK: not inline
```

—end example]

11 [Note: An explicit specialization of a constrained template shall satisfy that template’s associated constraints (12.4.2). The satisfaction of constraints is determined when forming the template name of an explicit specialization in which all template arguments are specified (12.2), or, for explicit specializations of function templates, during template argument deduction (12.9.2.6) when one or more trailing template arguments are left unspecified. —end note]

12 A function with the same name as a template and a type that exactly matches that of a template specialization is not an explicit specialization (12.6.6).

13 An explicit specialization of a function or variable template is inline only if it is declared with the inline specifier or defined as deleted, and independently of whether its function or variable template is inline. [Example:

```cpp
template<class T> void f(T) { /* ... */ }

template<class T> inline T g(T) { /* ... */ }

template<> inline void f<>(int) { /* ... */ } // OK: inline

template<> int g<>(int) { /* ... */ } // OK: not inline
```

—end example]
An explicit specialization of a static data member of a template or an explicit specialization of a static data member template is a definition if the declaration includes an initializer; otherwise, it is a declaration. [Note: The definition of a static data member of a template that requires default-initialization must use a braced-init-list:]

```cpp
template<> X Q<int>::x;   // declaration
template<> X Q<int>::x (); // error: declares a function
template<> X Q<int>::x {}; // definition
```

—end note

A member or a member template of a class template may be explicitly specialized for a given implicit instantiation of the class template, even if the member or member template is defined in the class template definition. An explicit specialization of a member or member template is specified using the syntax for explicit specialization. [Example:]

```cpp
template<class T> struct A {
    void f(T);
    template<class X1> void g1(T, X1);
    template<class X2> void g2(T, X2);
    void h(T) { }
};

// specialization
template<> void A<int>::f(int);

// out of class member template definition
template<class T> template<class X1> void A<T>::g1(T, X1) { }

// member template specialization
template<class X1> void A<int>::g1(int, X1);

// member template specialization
template<> template<class X1> void A<int>::g1(int, char); // X1 deduced as char
template<> template<> void A<char>::B<char>::mf();  // X2 specified as char

// member specialization even if defined in class definition
template<> template<> void A<int>::h(int) { }
```

—end example

A member or a member template may be nested within many enclosing class templates. In an explicit specialization for such a member, the member declaration shall be preceded by a `template<>` for each enclosing class template that is explicitly specialized. [Example:]

```cpp
template<class T1> class A {
    template<class T2> class B {
        void mf();
    };
};
template<> template<> class A<int>::B<double>;
template<> template<> void A<char>::B<char>::mf();
```

—end example

In an explicit specialization declaration for a member of a class template or a member template that appears in namespace scope, the member template and some of its enclosing class templates may remain unspecialized, except that the declaration shall not explicitly specialize a class member template if its enclosing class templates are not explicitly specialized as well. In such explicit specialization declaration, the keyword `template` followed by a `template-parameter-list` shall be provided instead of the `template<>` preceding the explicit specialization declaration of the member. The types of the `template-parameters` in the `template-parameter-list` shall be the same as those specified in the primary template definition. [Example:
template <class T1> class A {
    template<class T2> class B {
        template<class T3> void mf1(T3);
        void mf2();
    };
    template <> template <class X> class A<int>::B {
        template <class T> void mf1(T);
    };
    template <> template <> template <class T> void A<int>::B<double>::mf1(T t) {
    }
    template <class Y> template <>
    void A<Y>::B<double>::mf2() { } // ill-formed; B<double> is specialized but
    // its enclosing class template A is not
}

— end example] 19

A specialization of a member function template, member class template, or static data member template of a non-specialized class template is itself a template.

20 An explicit specialization declaration shall not be a friend declaration.

21 Default function arguments shall not be specified in a declaration or a definition for one of the following explicit specializations:

(21.1) — the explicit specialization of a function template;

(21.2) — the explicit specialization of a member function template;

(21.3) — the explicit specialization of a member function of a class template where the class template specialization to which the member function specialization belongs is implicitly instantiated. [Note: Default function arguments may be specified in the declaration or definition of a member function of a class template specialization that is explicitly specialized. — end note]

12.9 Function template specializations [temp.fct.spec] 1

A function instantiated from a function template is called a function template specialization; so is an explicit specialization of a function template. Template arguments can be explicitly specified when naming the function template specialization, deduced from the context (e.g., deduced from the function arguments in a call to the function template specialization, see 12.9.2), or obtained from default template arguments.

2 Each function template specialization instantiated from a template has its own copy of any static variable. [Example:

    template<class T> void f(T* p) {
        static T s;
    };

    void g(int a, char* b) {
        f(&a); // calls f<int>(int*)
        f(&b); // calls f<char*>(char**)
    }

Here f<int>(int*) has a static variable s of type int and f<char*>(char**) has a static variable s of type char*. — end example]

12.9.1 Explicit template argument specification [temp.arg.explicit] 1

Template arguments can be specified when referring to a function template specialization by qualifying the function template name with the list of template-arguments in the same way as template-arguments are specified in uses of a class template specialization. [Example:

    template<class T> void sort(Array<T>& v);
    void f(Array<dcomplex>& cv, Array<int>& ci) {
        sort<dcomplex>(cv); // sort(Array<dcomplex>&)
        sort<int>(ci); // sort(Array<int>&)
    }

and
template<class U, class V> U convert(V v);

void g(double d) {
    int i = convert<int,double>(d); // int convert(double)
    char c = convert<char,double>(d); // char convert(double)
}

— end example

2 A template argument list may be specified when referring to a specialization of a function template

— when a function is called,
— when the address of a function is taken, when a function initializes a reference to function, or when a
  pointer to member function is formed,
— in an explicit specialization,
— in an explicit instantiation, or
— in a friend declaration.

3 Trailing template arguments that can be deduced (12.9.2) or obtained from default template-arguments
  may be omitted from the list of explicit template-arguments. A trailing template parameter pack (12.6.3)
  not otherwise deduced will be deduced to an empty sequence of template arguments. If all of the template
  arguments can be deduced, they may all be omitted; in this case, the empty template argument list <>
  itself may also be omitted. In contexts where deduction is done and fails, or in contexts where deduction
  is not done, if a template argument list is specified and it, along with any default template arguments,
  identifies a single function template specialization, then the template-id is an lvalue for the function template
  specialization. [Example:

  template<class X, class Y> X f(Y);
  template<class X, class Y, class ... Z> X g(Y);
  void h() {
    int i = f<int>(5.6);       // Y is deduced to be double
    int j = f(5.6);           // ill-formed: X cannot be deduced
    f<void>(f<int, bool>);   // Y for outer f deduced to be int (*)(bool)
    f<void>(f<int>);         // ill-formed: f<int> does not denote a single function template specialization
    int k = g<int>(5.6);     // Y is deduced to be double, Z is deduced to an empty sequence
    f<void>(g<int, bool>);  // Y for outer f is deduced to be int (*)(bool),
                           // Z is deduced to an empty sequence
  }
  — end example

4 [Note: An empty template argument list can be used to indicate that a given use refers to a specialization
   of a function template even when a non-template function (9.2.3.5) is visible that would otherwise be used. For
   example:

   template <class T> int f(T);  // #1
   int f(int);                   // #2
   int k = f(1);                 // uses #2
   int l = f<>();                // uses #1
  — end note]

5 Template arguments that are present shall be specified in the declaration order of their corresponding
  template-parameters. The template argument list shall not specify more template-arguments than there
  are corresponding template-parameters unless one of the template-parameters is a template parameter pack.
  [Example:

  template<class X, class Y, class Z> X f(Y,Z);
  template<class ... Args> void f2();
  void g() {
    f<int, const char*, double>("aa", 3.0);  // Z is deduced to be double
    f<int, const char*>("aa", 3.0);          // Z is deduced to be double
    f<int>("aa", 3.0);                      // Y is deduced to be const char*, and Z is deduced to be double
    f("aa", 3.0);                           // error: X cannot be deduced
    f2<char, short, int, long>();          // OK
  }

§ 12.9.1 376
Implicit conversions (7.3) will be performed on a function argument to convert it to the type of the corresponding function parameter if the parameter type contains no template-parameters that participate in template argument deduction. [Note: Template parameters do not participate in template argument deduction if they are explicitly specified. For example,

```cpp
template<class T> void f(T);

class Complex {
    Complex(double);
};

void g() {
    f<Complex>(1);  // OK, means f<Complex>(Complex(1))
}
```

—end note]

[Note: Because the explicit template argument list follows the function template name, and because constructor templates (10.3.4) are named without using a function name (6.4.3.1), there is no way to provide an explicit template argument list for these function templates. —end note]

Template argument deduction can extend the sequence of template arguments corresponding to a template parameter pack, even when the sequence contains explicitly specified template arguments. [Example:

```cpp
template<class ... Types> void f(Types ... values);

void g() {
    f<int*, float*>(0, 0, 0);   // Types is deduced to the sequence int*, float*, int
}
```

—end example]

12.9.2 Template argument deduction

[temp.deduct]

When a function template specialization is referenced, all of the template arguments shall have values. The values can be explicitly specified or, in some cases, be deduced from the use or obtained from default template-arguments. [Example:

```cpp
void f(Array<dcomplex>& cv, Array<int>& ci) {
    sort(cv);           // calls sort(Array<dcomplex>&)
    sort(ci);           // calls sort(Array<int>&)
}
```

and

```cpp
void g(double d) {
    int i = convert<int>(d);       // calls convert<int,double>(double)
    int c = convert<char>(d);      // calls convert<char,double>(double)
}
```

—end example]

When an explicit template argument list is specified, if the given template-id is not valid (12.2), type deduction fails. Otherwise, the specified template argument values are substituted for the corresponding template parameters as specified below.

3 After this substitution is performed, the function parameter type adjustments described in 9.2.3.5 are performed. [Example: A parameter type of “void (const int, int[5])” becomes “void(*)[int,int*]”. —end example] [Note: A top-level qualifier in a function parameter declaration does not affect the function type but still affects the type of the function parameter variable within the function. —end note] [Example:

```cpp
template <class T> void f(T t);
template <class X> void g(const X x);
template <class Z> void h(Z, Z*);

int main() {
    // #1: function type is f(int), t is non const
    f<int>(1);
}
```
// #2: function type is f(int), t is const
f<const int>(1);

// #3: function type is g(int), x is const
g<int>(1);

// #4: function type is g(int), x is const
g<const int>(1);

// #5: function type is h(int, const int*)
h<const int>(1,0);

—end example

[Note: f<int>(1) and f<const int>(1) call distinct functions even though both of the functions called have the same function type. —end note]

4 The resulting substituted and adjusted function type is used as the type of the function template for template argument deduction. If a template argument has not been deduced and its corresponding template parameter has a default argument, the template argument is determined by substituting the template arguments determined for preceding template parameters into the default argument. If the substitution results in an invalid type, as described above, type deduction fails. [Example:

```cpp
template <class T, class U = double>
void f(T t = 0, U u = 0);

void g() {
  f(1, 'c');  // f<int,char>(1,'c')
  f(1);     // f<int,double>(1,0)
  f();      // error: T cannot be deduced
  f<int>(); // f<int,double>(0,0)
  f<int,char>(); // f<int,char>(0,0)
}

—end example]
```

5 When all template arguments have been deduced or obtained from default template arguments, all uses of template parameters in the template parameter list of the template and the function type are replaced with the corresponding deduced or default argument values. If the substitution results in an invalid type, as described above, type deduction fails. If the function template has associated constraints (12.4.2), those constraints are checked for satisfaction (12.4.1). If the constraints are not satisfied, type deduction fails.

At certain points in the template argument deduction process it is necessary to take a function type that makes use of template parameters and replace those template parameters with the corresponding template arguments. This is done at the beginning of template argument deduction when any explicitly specified template arguments are substituted into the function type, and again at the end of template argument deduction when any template arguments that were deduced or obtained from default arguments are substituted.

7 The substitution occurs in all types and expressions that are used in the function type and in template parameter declarations. The expressions include not only constant expressions such as those that appear in array bounds or as nontype template arguments but also general expressions (i.e., non-constant expressions) inside sizeof, decltype, and other contexts that allow non-constant expressions. The substitution proceeds in lexical order and stops when a condition that causes deduction to fail is encountered. If substitution into different declarations of the same function template would cause template instantiations to occur in a different order or not at all, the program is ill-formed; no diagnostic required. [Note: The equivalent substitution in exception specifications is done only when the noexcept-specifier is instantiated, at which point a program is ill-formed if the substitution results in an invalid type or expression. —end note] [Example:

```cpp
template <class T> struct A { using X = typename T::X; };
template <class T> typename T::X f(typename A<T>::X);
template <class T> void f(...) { }
template <class T> auto g(typename A<T>::X) -> typename T::X;
template <class T> void g(...) { }
template <class T> typename T::X h(typename A<T>::X);
template <class T> auto h(typename A<T>::X) -> typename T::X;  // redeclaration
```
template <class T> void h(...) { }

void x() {
  f<int>(0);    // OK, substituting return type causes deduction to fail
  g<int>(0);    // error, substituting parameter type instantiates A<int>
  h<int>(0);    // ill-formed, no diagnostic required
}
— end example]

8 If a substitution results in an invalid type or expression, type deduction fails. An invalid type or expression
is one that would be ill-formed, with a diagnostic required, if written using the substituted arguments. [Note:
If no diagnostic is required, the program is still ill-formed. Access checking is done as part of the substitution
process. — end note] Only invalid types and expressions in the immediate context of the function type, its
template parameter types, and its explicit-specifier can result in a deduction failure. [Note: The substitution
into types and expressions can result in effects such as the instantiation of class template specializations
and/or function template specializations, the generation of implicitly-defined functions, etc. Such effects are
not in the “immediate context” and can result in the program being ill-formed. — end note]

9 A lambda-expression appearing in a function type or a template parameter is not considered part of the
immediate context for the purposes of template argument deduction. [Note: The intent is to avoid requiring
implementations to deal with substitution failure involving arbitrary statements. [Example:

template <class T>
  auto f(T) -> decltype([() { T::invalid; } ()]);
void f(...);
  f(0);    // error: invalid expression not part of the immediate context

template <class T, std::size_t = sizeof([() { T::invalid; }()])>
void g(T);
void g(...);
g(0);    // error: invalid expression not part of the immediate context

template <class T>
  auto h(T) -> decltype([x = T::invalid]() { });
void h(...);
h(0);    // error: invalid expression not part of the immediate context

template <class T>
  auto i(T) -> decltype([() -> typename T::invalid { });
void i(...);
i(0);    // error: invalid expression not part of the immediate context

template <class T>
  auto j(T t) -> decltype([auto x] -> decltype(x.invalid) { } (t)); // #1
void j(...);
j(0);    // deduction fails on #1, calls #2
— end example] — end note]

[Example:

| X x1, x2; | X x3 = f(x1, x2); | deduction fails on #1 (cannot add X+X), calls #2 |
|———|———|———|

— end example]

[Note: Type deduction may fail for the following reasons:

(11.1) — Attempting to instantiate a pack expansion containing multiple packs of differing lengths.

§ 12.9.2
Attempting to create an array with an element type that is void, a function type, or a reference type, or attempting to create an array with a size that is zero or negative. [Example:

```cpp
template <class T> int f(T[5]);
int i = f<int>(0);
int j = f<void>(0);  // invalid array
end example]
```

Attempting to use a type that is not a class or enumeration type in a qualified name. [Example:

```cpp
template <class T> int f(typename T::B*);
int i = f<int>(0);
end example]
```

Attempting to use a type in a nested-name-specifier of a qualified-id when that type does not contain the specified member, or

- the specified member is not a type where a type is required, or
- the specified member is not a template where a template is required, or
- the specified member is not a non-type where a non-type is required.

[Example:

```cpp
template <int I> struct X { };
template <template <class T> class> struct Z { };
template <class T> void f(typename T::Y*){}
template <class T> void g(X<T::N>*){}
template <class T> void h(Z<T::template TT>*){}
struct A {};
struct B { int Y; };
struct C {
  typedef int N;
};
struct D {
  typedef int TT;
};

int main() {
  // Deduction fails in each of these cases:
  f<A>(0);  // A does not contain a member Y
  f<B>(0);  // The Y member of B is not a type
  g<C>(0);  // The N member of C is not a non-type
  h<D>(0);  // The TT member of D is not a template
}
end example]
```

Attempting to create a pointer to reference type.

Attempting to create a reference to void.

Attempting to create “pointer to member of T” when T is not a class type. [Example:

```cpp
template <class T> int f(int T::*);
int i = f<int>(0);
end example]
```

Attempting to give an invalid type to a non-type template parameter. [Example:

```cpp
template <class T, T> struct S {};
template <class T> int f(S<T, T>()*);
struct X {};
int i0 = f<X>(0);
end example]
```

Attempting to perform an invalid conversion in either a template argument expression, or an expression used in the function declaration. [Example:

```cpp
template <class T, T*> int f(int);
```
int i2 = f<int,1>(0); // can't conv 1 to int*
— end example]

— Attempting to create a function type in which a parameter has a type of void, or in which the return type is a function type or array type.

— end note]

[Example: In the following example, assuming a signed char cannot represent the value 1000, a narrowing conversion (9.3.4) would be required to convert the template-argument of type int to signed char, therefore substitution fails for the second template (12.3.2).

```
template <int> int f(int);
template <signed char> int f(int);
int i1 = f<1000>(0); // OK
int i2 = f<1>(0); // ambiguous; not narrowing
```
— end example]

12.9.2.1 Deducing template arguments from a function call [temp.deduct.call]

Template argument deduction is done by comparing each function template parameter type (call it \(P\)) that contains template-parameters that participate in template argument deduction with the type of the corresponding argument of the call (call it \(A\)) as described below. If removing references and cv-qualifiers from \(P\) gives \(std::initializer_list<P>\) or \(P[N]\) for some \(P\) and \(N\) and the argument is a non-empty initializer list (9.3.4), then deduction is performed instead for each element of the initializer list, taking \(P\) as a function template parameter type and the initializer element as its argument, and in the \(P[N]\) case, if \(N\) is a non-type template parameter, \(N\) is deduced from the length of the initializer list. Otherwise, an initializer list argument causes the parameter to be considered a non-deducted context (12.9.2.5). [Example:

```
template<class T> void f(std::initializer_list<T>);
f({1,2,3}); // T deduced to int
f({"asdf"}); // error: T deduced to both int and const char*
```

```
template<class T> void g(T);
g({1,2,3}); // error: no argument deduced for T
```

```
template<class T, int N> void h(T const(&)[N]);
h({1,2,3}); // T deduced to int, N deduced to 3
```

```
template<class T> void j(T const(&)[3]);
j({42}); // T deduced to int, array bound not considered
```

```
struct Aggr { int i; int j; };  
template<class N> void k(Aggr const(&)[N]);
k({1,2,3}); // error: deduction fails, no conversion from int to Aggr
k({{1},{2},{3}}); // OK, N deduced to 3
```

```
template<class M, int N> void m(int const(&)[M][N]);
m({{1,2},{3,4}}); // M and N both deduced to 2
```

```
template<class T, int N> void n(T const(&)[N], T);
n({{1},{2},{3}},Aggr()); // OK, T is Aggr, N is 3
```

— end example] For a function parameter pack that occurs at the end of the parameter-declaration-list, deduction is performed for each remaining argument of the call, taking the type \(P\) of the declarator-id of the function parameter pack as the corresponding function template parameter type. Each deduction deduces template arguments for subsequent positions in the template parameter packs expanded by the function parameter pack. When a function parameter pack appears in a non-deducted context (12.9.2.5), the type of that pack is never deduced. [Example:

```
template<class ... Types> void f(Types& ...);
template<class T1, class ... Types> void g(T1, Types ...);
template<class T1, class ... Types> void g1(Types ..., T1);
```

```
void h(int x, float& y) {
    const int z = x;
}
```
f(x, y, z); // Types is deduced to int, float, const int
g(x, y, z); // T1 is deduced to int; Types is deduced to float, int
gl(x, y, z); // error: Types is not deduced
gl<int, int, int>(x, y, z); // OK, no deduction occurs

— end example]  

2 If P is not a reference type:

(2.1) — If A is an array type, the pointer type produced by the array-to-pointer standard conversion (7.3.2) is used in place of A for type deduction; otherwise,

(2.2) — If A is a function type, the pointer type produced by the function-to-pointer standard conversion (7.3.3) is used in place of A for type deduction; otherwise,

(2.3) — If A is a cv-qualified type, the top-level cv-qualifiers of A’s type are ignored for type deduction.

3 If P is a cv-qualified type, the top-level cv-qualifiers of P’s type are ignored for type deduction. If P is a reference type, the type referred to by P is used for type deduction. [Example:

```cpp
template<class T> int f(const T&);
int n1 = f(5); // calls f<int>(const int&)
const int i = 0;
int n2 = f(i); // calls f<int>(const int&)
template <class T> int g(volatile T&);
int n3 = g(i); // calls g<volatile T>(volatile T&)

— end example] A forwarding reference is an rvalue reference to a cv-unqualified template parameter that does not represent a template parameter of a class template (during class template argument deduction (11.3.1.8)). If P is a forwarding reference and the argument is an lvalue, the type “lvalue reference to A” is used in place of A for type deduction. [Example:

```cpp
template <class T> int f(T&& heisenreference);
template <class T> int g(const T&&);
int i;
int n1 = f(i); // calls f<int>(int&&)
int n2 = f(0); // calls f<int>(int&&)
int n3 = g(i); // error: would call g<int>(const int&&), which would bind an rvalue reference to an lvalue

template <class T> struct A {
  template <class U>
  A(T&&, U&&, int*); // #1: T&& is not a forwarding reference.
  // U&& is a forwarding reference.
  A(T&&, int*); // #2
};
template <class T> A(T&&, int*) -> A<T>; // #3: T&& is a forwarding reference.
```

int *ip;
A a{i, 0, ip}; // error: cannot deduce from #1
A a0{0, 0, ip}; // uses #1 to deduce A<int> and #1 to initialize
A a2{i, ip}; // uses #3 to deduce A<int&> and #2 to initialize

— end example]

4 In general, the deduction process attempts to find template argument values that will make the deduced A identical to A (after the type A is transformed as described above). However, there are three cases that allow a difference:

(4.1) — If the original P is a reference type, the deduced A (i.e., the type referred to by the reference) can be more cv-qualified than the transformed A.

(4.2) — The transformed A can be another pointer or pointer-to-member type that can be converted to the deduced A via a function pointer conversion (7.3.13) and/or qualification conversion (7.3.5).

(4.3) — If P is a class and P has the form simple-template-id, then the transformed A can be a derived class of the deduced A. Likewise, if P is a pointer to a class of the form simple-template-id, the transformed A can be a pointer to a derived class pointed to by the deduced A.

§ 12.9.2.1 382
These alternatives are considered only if type deduction would otherwise fail. If they yield more than one possible deduced A, the type deduction fails. [Note: If a template-parameter is not used in any of the function parameters of a function template, or is used only in a non-deduced context, its corresponding template-argument cannot be deduced from a function call and the template-argument must be explicitly specified. — end note]

When P is a function type, function pointer type, or pointer-to-member-function type:

(6.1) — If the argument is an overload set containing one or more function templates, the parameter is treated as a non-deduced context.

(6.2) — If the argument is an overload set (not containing function templates), trial argument deduction is attempted using each of the members of the set. If deduction succeeds for only one of the overload set members, that member is used as the argument value for the deduction. If deduction succeeds for more than one member of the overload set the parameter is treated as a non-deduced context.

[Example:

// Only one function of an overload set matches the call so the function parameter is a deduced context.
template <class T> int f(T (*p)(T));
int g(int);
int g(char);
int i = f(g); // calls f(int (*)(int))
— end example]

[Example:

// Ambiguous deduction causes the second function parameter to be a non-deduced context.
template <class T> int f(T, T (*p)(T));
int g(int);
char g(char);
int i = f(1, g); // calls f(int, int (*)(int))
— end example]

[Example:

// The overload set contains a template, causing the second function parameter to be a non-deduced context.
template <class T> int f(T, T (*p)(T));
char g(char);
template <class T> T g(T);
int i = f(1, g); // calls f(int, int (*)(int))
— end example]

If deduction succeeds for all parameters that contain template-parameters that participate in template argument deduction, and all template arguments are explicitly specified, deduced, or obtained from default template arguments, remaining parameters are then compared with the corresponding arguments. For each remaining parameter P with a type that was non-dependent before substitution of any explicitly-specified template arguments, if the corresponding argument A cannot be implicitly converted to P, deduction fails. [Note: Parameters with dependent types in which no template-parameters participate in template argument deduction, and parameters that became non-dependent due to substitution of explicitly-specified template arguments, will be checked during overload resolution. — end note] [Example:

    template <class T> struct Z {
        typedef typename T::x xx;
    };
    template <class T> typename Z<T>::xx f(void *, T); // #1
    template <class T> void f(int, T); // #2
    struct A {} a;
    int main() {
        f(1, a); // OK, deduction fails for #1 because there is no conversion from int to void*
    }
— end example]
12.9.2.2 Deducing template arguments taking the address of a function template

Template arguments can be deduced from the type specified when taking the address of an overloaded function (11.4). The function template’s function type and the specified type are used as the types of \( P \) and \( A \), and the deduction is done as described in 12.9.2.5.

A placeholder type (9.1.7.4) in the return type of a function template is a non-deduced context. If template argument deduction succeeds for such a function, the return type is determined from instantiations of the function body.

12.9.2.3 Deducing conversion function template arguments

Template argument deduction is done by comparing the return type of the conversion function template (call it \( P \)) with the type that is required as the result of the conversion (call it \( A \); see 9.3, 11.3.1.5, and 11.3.1.6 for the determination of that type) as described in 12.9.2.5.

If \( P \) is a reference type, the type referred to by \( P \) is used in place of \( P \) for type deduction and for any further references to or transformations of \( P \) in the remainder of this subclause.

If \( A \) is not a reference type:

1. If \( P \) is an array type, the pointer type produced by the array-to-pointer standard conversion (7.3.2) is used in place of \( P \) for type deduction; otherwise,
2. If \( P \) is a function type, the pointer type produced by the function-to-pointer standard conversion (7.3.3) is used in place of \( P \) for type deduction; otherwise,
3. If \( P \) is a cv-qualified type, the top-level cv-qualifiers of \( P \)’s type are ignored for type deduction.
4. If \( A \) is a cv-qualified type, the top-level cv-qualifiers of \( A \)’s type are ignored for type deduction. If \( A \) is a reference type, the type referred to by \( A \) is used for type deduction.

In general, the deduction process attempts to find template argument values that will make the deduced \( A \) identical to \( A \). However, there are four cases that allow a difference:

1. If the original \( A \) is a reference type, \( A \) can be more cv-qualified than the deduced \( A \) (i.e., the type referred to by the reference)
2. If the original \( A \) is a function pointer type, \( A \) can be “pointer to function” even if the deduced \( A \) is “pointer to noexcept function”.
3. If the original \( A \) is a pointer-to-member-function type, \( A \) can be “pointer to member of type function” even if the deduced \( A \) is “pointer to member of type noexcept function”.
4. The deduced \( A \) can be another pointer or pointer-to-member type that can be converted to \( A \) via a qualification conversion.

These alternatives are considered only if type deduction would otherwise fail. If they yield more than one possible deduced \( A \), the type deduction fails.

When the deduction process requires a qualification conversion for a pointer or pointer-to-member type as described above, the following process is used to determine the deduced template argument values:

If \( A \) is a type

\[
\text{cv}_1,0 \text{ "pointer to ..." } \text{cv}_1,n-1 \text{ "pointer to" } T_1
\]

and \( P \) is a type

\[
\text{cv}_2,0 \text{ "pointer to ..." } \text{cv}_2,n-1 \text{ "pointer to" } T_2,
\]

then the cv-unqualified \( T_1 \) and \( T_2 \) are used as the types of \( A \) and \( P \) respectively for type deduction. [Example:

```cpp
struct A {
    template <class T> operator T***();
};
A a;
const int * const * const * p1 = a; // T is deduced as int, not const int
```
— end example]
12.9.2.4 Deducing template arguments during partial ordering  

Template argument deduction is done by comparing certain types associated with the two function templates being compared.

Two sets of types are used to determine the partial ordering. For each of the templates involved there is the original function type and the transformed function type. [Note: The creation of the transformed type is described in 12.6.6.2. — end note] The deduction process uses the transformed type as the argument template and the original type of the other template as the parameter template. This process is done twice for each type involved in the partial ordering comparison: once using the transformed template-1 as the argument template and template-2 as the parameter template and again using the transformed template-2 as the argument template and template-1 as the parameter template.

The types used to determine the ordering depend on the context in which the partial ordering is done:

- In the context of a function call, the types used are those function parameter types for which the function call has arguments.  
- In the context of a call to a conversion function, the return types of the conversion function templates are used.
- In other contexts (12.6.6.2) the function template’s function type is used.

Each type nominated above from the parameter template and the corresponding type from the argument template are used as the types of \( P \) and \( A \).

Before the partial ordering is done, certain transformations are performed on the types used for partial ordering:

- If \( P \) is a reference type, \( P \) is replaced by the type referred to.
- If \( A \) is a reference type, \( A \) is replaced by the type referred to.

If both \( P \) and \( A \) were reference types (before being replaced with the type referred to above), determine which of the two types (if any) is more cv-qualified than the other; otherwise the types are considered to be equally cv-qualified for partial ordering purposes. The result of this determination will be used below.

Remove any top-level cv-qualifiers:

- If \( P \) is a cv-qualified type, \( P \) is replaced by the cv-unqualified version of \( P \).
- If \( A \) is a cv-qualified type, \( A \) is replaced by the cv-unqualified version of \( A \).

Using the resulting types \( P \) and \( A \), the deduction is then done as described in 12.9.2.5. If \( P \) is a function parameter pack, the type \( A \) of each remaining parameter type of the argument template is compared with the type \( P \) of the declarator-id of the function parameter pack. Each comparison deduces template arguments for subsequent positions in the template parameter packs expanded by the function parameter pack. Similarly, if \( A \) was transformed from a function parameter pack, it is compared with each remaining parameter type of the parameter template. If deduction succeeds for a given type, the type from the argument template is considered to be at least as specialized as the type from the parameter template. [Example:

```c
template<class... Args> void f(Args... args); // #1
template<class T1, class... Args> void f(T1 a1, Args... args); // #2
template<class T1, class T2> void f(T1 a1, T2 a2); // #3
```

```c
f(); // calls #1
f(1, 2, 3); // calls #2
f(1, 2); // calls #3; non-variadic template #3 is more specialized
// than the variadic templates #1 and #2
```

- end example]

If, for a given type, the types are identical after the transformations above and both \( P \) and \( A \) were reference types (before being replaced with the type referred to above):

- if the type from the argument template was an lvalue reference and the type from the parameter template was not, the parameter type is not considered to be at least as specialized as the argument type; otherwise,

143) Default arguments are not considered to be arguments in this context; they only become arguments after a function has been selected.
— if the type from the argument template is more cv-qualified than the type from the parameter template (as described above), the parameter type is not considered to be at least as specialized as the argument type.

Function template $F$ is at least as specialized as function template $G$ if, for each pair of types used to determine the ordering, the type from $F$ is at least as specialized as the type from $G$. $F$ is more specialized than $G$ if $F$ is at least as specialized as $G$ and $G$ is not at least as specialized as $F$.

If, after considering the above, function template $F$ is at least as specialized as function template $G$ and vice-versa, and if $G$ has a trailing function parameter pack for which $F$ does not have a corresponding parameter, and if $F$ does not have a trailing function parameter pack, then $F$ is more specialized than $G$.

In most cases, deduction fails if not all template parameters have values, but for partial ordering purposes a template parameter may remain without a value provided it is not used in the types being used for partial ordering. [Note: A template parameter used in a non-deducted context is considered used. — end note]

[Example:

```cpp
template <class T> T f(int); // #1
template <class T, class U> T f(U); // #2
void g() {
  f<int>(1); // calls #1
}
end example]

[Note: Partial ordering of function templates containing template parameter packs is independent of the number of deduced arguments for those template parameter packs. — end note] [Example:

```cpp
template<class ...> struct Tuple { }
template<class ... Types> void g(Tuple<Types ...>); // #1
template<class T1, class ... Types> void g(Tuple<T1, Types ...>); // #2
template<class T1, class ... Types> void g(Tuple<T1, Types& ...>); // #3

g(Tuple<>()); // calls #1
g(Tuple<int, float>()); // calls #2
g(Tuple<int, float&>()); // calls #3
g(Tuple<int>()); // calls #3

end example]
```

12.9.2.5 Deducing template arguments from a type

Template arguments can be deduced in several different contexts, but in each case a type that is specified in terms of template parameters (call it $P$) is compared with an actual type (call it $A$), and an attempt is made to find template argument values (a type for a type parameter, a value for a non-type parameter, or a template for a template parameter) that will make $P$, after substitution of the deduced values (call it the deduced $A$), compatible with $A$.

In some cases, the deduction is done using a single set of types $P$ and $A$, in other cases, there will be a set of corresponding types $P$ and $A$. Type deduction is done independently for each $P/A$ pair, and the deduced template argument values are then combined. If type deduction cannot be done for any $P/A$ pair, or if for any pair the deduction leads to more than one possible set of deduced values, or if different pairs yield different deduced values, or if any template argument remains neither deduced nor explicitly specified, template argument deduction fails. The type of a type parameter is only deduced from an array bound if it is not otherwise deduced.

A given type $P$ can be composed from a number of other types, templates, and non-type values:

- A function type includes the types of each of the function parameters and the return type.
- A pointer-to-member type includes the type of the class object pointed to and the type of the member pointed to.
- A type that is a specialization of a class template (e.g., $A<$int$>$) includes the types, templates, and non-type values referenced by the template argument list of the specialization.
- An array type includes the array element type and the value of the array bound.

In most cases, the types, templates, and non-type values that are used to compose $P$ participate in template argument deduction. That is, they may be used to determine the value of a template argument, and template
argument deduction fails if the value so determined is not consistent with the values determined elsewhere.

In certain contexts, however, the value does not participate in type deduction, but instead uses the values of template arguments that were either deduced elsewhere or explicitly specified. If a template parameter is used only in non-deduced contexts and is not explicitly specified, template argument deduction fails. [Note: Under 12.9.2.1, if \( P \) contains no template-parameters that appear in deduced contexts, no deduction is done, so \( P \) and \( A \) need not have the same form. — end note]

The non-deduced contexts are:

1. The nested-name-specifier of a type that was specified using a qualified-id.
2. The expression of a decltype-specifier.
3. A non-type template argument or an array bound in which a subexpression references a template parameter.
4. A template parameter used in the parameter type of a function parameter that has a default argument that is being used in the call for which argument deduction is being done.
5. A function parameter for which argument deduction cannot be done because the associated function argument is a function, or a set of overloaded functions (11.4), and one or more of the following apply:
   - more than one function matches the function parameter type (resulting in an ambiguous deduction), or
   - no function matches the function parameter type, or
   - the set of functions supplied as an argument contains one or more function templates.
6. A function parameter for which the associated argument is an initializer list (9.3.4) but the parameter does not have a type for which deduction from an initializer list is specified (12.9.2.1).

When a type name is specified in a way that includes a non-deduced context, all of the types that comprise that type name are also non-deduced. However, a compound type can include both deduced and non-deduced types. [Example: If a type is specified as \( A<T>::B<T2> \), both \( T \) and \( T2 \) are non-deduced. Likewise, if a type is specified as \( A<\mathbf{I+J}>::X<T> \), \( I \), \( J \), and \( T \) are non-deduced. If a type is specified as \( \text{void } f(\text{typename } A<T>::B, \ A<T>) \), the \( T \) in \( A<T>::B \) is non-deduced but the \( T \) in \( A<T> \) is deduced. — end example]

[Example: Here is an example in which different parameter/argument pairs produce inconsistent template argument deductions:

\[
\begin{align*}
\text{template<class T> void } & f(T x, T y) \{ /* ... */ } \}\n\text{struct A } \{ /* ... */ } \} ;
\text{struct B : A } \{ /* ... */ } \} ;
\text{void g(A a, B b) } \{ \\
\quad f(a,b) ; & \quad \text{ // error: } T \text{ could be } A \text{ or } B \\
\quad f(b,a) ; & \quad \text{ // error: } T \text{ could be } A \text{ or } B \\
\quad f(a,a) ; & \quad \text{ // OK: } T \text{ is } A \\
\quad f(b,b) ; & \quad \text{ // OK: } T \text{ is } B \\
\} \\
\end{align*}
\]

Here is an example where two template arguments are deduced from a single function parameter/argument pair. This can lead to conflicts that cause type deduction to fail:

\[
\begin{align*}
\text{template } & \langle \text{class T, class U} \rangle \text{ void } f( \ T (*) ( \ T, U, U ) ) ;
\text{int g1( int, float, float) ;}
\text{char g2( int, float, float) ;}
\text{int g3( int, char, float) ;}
\text{void r() } \{ \\
\quad f(g1) ; & \quad \text{ // OK: } T \text{ is int and } U \text{ is float} \\
\quad f(g2) ; & \quad \text{ // error: } T \text{ could be char or int} \\
\quad f(g3) ; & \quad \text{ // error: } U \text{ could be char or float} \\
\} \\
\end{align*}
\]
Here is an example where a qualification conversion applies between the argument type on the function call and the deduced template argument type:

```cpp
template<class T> void f(const T*) { }
int* p;
void s() {
    f(p);       // f(const int*)
}
```

Here is an example where the template argument is used to instantiate a derived class type of the corresponding function parameter type:

```cpp
template <class T> struct B { };
template <class T> struct D : public B<T> {};
struct D2 : public B<int> {};
template <class T> void f(B<T>&){}
void t() {
    D<int> d;
    D2  d2;
    f(d);       // calls f(B<int>&)
    f(d2);      // calls f(B<int>&)
}
```

— end example]

8 A template type argument \( T \), a template template argument \( TT \) or a template non-type argument \( i \) can be deduced if \( P \) and \( A \) have one of the following forms:

- \( T \)
- \( cv \ T \)
- \( T* \)
- \( T& \)
- \( T&& \)
- \( T[\text{integer-constant}] \)
- \( \text{template-name}<T> \) (where \( \text{template-name} \) refers to a class template)
- \( \text{type}(T) \)
- \( T() \)
- \( T(T) \)
- \( T\text{ type::*} \)
- \( \text{type } T::* \)
- \( T\text{ type::*}() \)
- \( T\text{ type::*}()() \)
- \( \text{type } (T::*)() \)
- \( T\text{ type::*}(T) \)
- \( T\text{ type::*}(T)() \)
- \( T\text{ type::*}(T)()() \)
- \( T\text{ type::*}(T::*)() \)
- \( T\text{ type::*}(T::*)()() \)
- \( \text{template-name}<i> \) (where \( \text{template-name} \) refers to a class template)
- \( TT<T> \)
- \( TT<i> \)
- \( TT<> \)

where \( T \) represents a parameter-type-list (9.2.3.5) where at least one parameter type contains a \( T \), and \( () \) represents a parameter-type-list where no parameter type contains a \( T \). Similarly, \( <T> \) represents template argument lists where at least one argument contains a \( T \), \( <i> \) represents template argument lists where at least one argument contains an \( i \) and \( <> \) represents template argument lists where no argument contains a \( T \) or an \( i \).

9 If \( P \) has a form that contains \( <T> \) or \( <i> \), then each argument \( P_i \) of the respective template argument list of \( P \) is compared with the corresponding argument \( A_i \) of the corresponding template argument list of \( A \). If the template argument list of \( P \) contains a pack expansion that is not the last template argument, the entire template argument list is a non-deduced context. If \( P_i \) is a pack expansion, then the pattern of \( P_i \) is compared with each remaining argument in the template argument list of \( A \). Each comparison deduces template arguments for subsequent positions in the template parameter packs expanded by \( P_i \). During partial ordering (12.9.2.4), if \( A_i \) was originally a pack expansion:
If \( P \) does not contain a template argument corresponding to \( A \), then \( A \) is ignored;

otherwise, if \( P_i \) is not a pack expansion, template argument deduction fails.

**Example:**

```cpp
template<class T1, class... Z> class S;  // #1
template<class T1, class... Z> class S<T1, const Z&...> { };  // #2
S<int, const int&> s;  // both #2 and #3 match; #3 is more specialized
```

SIMILARLY, IF \( P \) HAS A FORM THAT CONTAINS \((T)\), THEN EACH PARAMETER TYPE \( P_i \) OF THE RESPECTIVE PARAMETER-TYPE-LIST (9.2.3.5) OF \( P \) IS COMPARED WITH THE CORRESPONDING PARAMETER TYPE \( A_i \) OF THE CORRESPONDING PARAMETER-TYPE-LIST OF \( A \). IF \( P \) AND \( A \) ARE FUNCTION TYPES THAT ORIGINATED FROM DEDUCTION WHEN TAKING THE ADDRESS OF A FUNCTION TEMPLATE (12.9.2.2) OR WHEN DEDUCTION TAKES ARGUMENTS FROM A FUNCTION DECLARATION (12.9.2.6) AND \( P_i \) AND \( A_i \) ARE PARAMETERS OF THE TOP-LEVEL PARAMETER-TYPE-LIST OF \( P \) AND \( A \), RESPECTIVELY, \( P_i \) IS ADJUSTED IF IT IS A FORWARDING REFERENCE (12.9.2.1) AND \( A_i \) IS AN LVALUE REFERENCE, IN WHICH CASE THE TYPE OF \( P_i \) IS CHANGED TO BE THE Template Parameter Type (I.E., \( T&& \) IS CHANGED TO SIMPLY \( T \)).

**Example:**

```cpp
template <class T> void f(T&&);
template <> void f(int&) { }  // #1
template <> void f(int&&) { }  // #2
void g(int i) {
    f(i);  // calls f<int&>(int&), i.e., #1
    f(0);  // calls f<int>(int&&), i.e., #2
}
```

If the parameter-declaration corresponding to \( P_i \) is a function parameter pack, then the type of its declarator-id is compared with each remaining parameter type in the parameter-type-list of \( A \). Each comparison deduces template arguments for subsequent positions in the template parameter packs expanded by the function parameter pack. During partial ordering (12.9.2.4), if \( A_i \) was originally a function parameter pack:

1. If \( P \) does not contain a function parameter type corresponding to \( A_i \) then \( A_i \) is ignored;
2. Otherwise, if \( P_i \) is not a function parameter pack, template argument deduction fails.

**Example:**

```cpp
template<class T> class S<T*, T...> { };  // #2
struct A { };  // #1
struct A<T1, T2*, U...> { };  // #2
struct A<T1, T2> { };  // #3
```

These forms can be used in the same way as \( T \) is for further composition of types. **Example:**

```cpp
X<int> (*)(char[6])
```

... is of the form

```cpp
template-name<T> (*)(type[i])
```

which is a variant of

```cpp
type (*)(T)
```

where type is \( X<int> \) and \( T \) is \( char[6] \). **End example**

Template arguments cannot be deduced from function arguments involving constructs other than the ones specified above.

When the value of the argument corresponding to a non-type template parameter \( P \) that is declared with a dependent type is deduced from an expression, the template parameters in the type of \( P \) are deduced from the type of the value. **Example:**
template<long n> struct A { };

template<typename T> struct C;
template<typename T, long n> struct C<A<n>> {
    using Q = T;
};

using R = long;
using R = C<A<2>>::Q; // OK; T was deduced to long from the
                      // template argument value in the type A<2>

— end example] The type of N in the type T[N] is std::size_t. [Example:

template<typename T> struct S;
template<typename T, int n> struct S<int[n]> {  
    using Q = T;
};

using V = decltype(sizeof 0);
using V = S<int[42]>::Q; // OK; T was deduced to std::size_t from the type int[42]

— end example]

[Example:

template<class T, int i> void f(int (&a)[i]);
int v[10];
void g() {
    f(v); // OK: T is std::size_t
}

— end example]

[Note: Except for reference and pointer types, a major array bound is not part of a function parameter type
and cannot be deduced from an argument:

template<int i> void f1(int a[10][i]);
template<int i> void f2(int a[i][20]);
template<int i> void f3(int (&a)[i][20]);

void g() {
    int v[10][20];
    f1(v); // OK: i deduced to be 20
    f1<20>(v); // OK
    f2(v); // error: cannot deduce template-argument i
    f2<10>(v); // OK
    f3(v); // OK: i deduced to be 10
}

— end note]

[Note: If, in the declaration of a function template with a non-type template parameter, the non-type
template parameter is used in a subexpression in the function parameter list, the expression is a non-deduced
context as specified above. [Example:

template <int i> class A { /* ... */ };  
template <int i> void g(A<i+1>);  
template <int i> void f(A<i>, A<i+1>);
void k() {
    A<i1> a1;
    A<i2> a2;
    g(a1); // error: deduction fails for expression i+1
    g<0>(a1); // OK
    f(a1, a2); // OK
}

— end example] — end note]

[Note: Template parameters do not participate in template argument deduction if they are used only in
non-deduced contexts. For example,
template<int i, typename T>
T deduce(typename A<T>::X x, // T is not deduced here
          T t, // but T is deduced here
typename B<i>::Y y); // i is not deduced here

A<int> a;
B<77> b;

int x = deduce<77>(a.xm, 62, b.ym);
// T is deduced to be int, a.xm must be convertible to A<int>::X
// i is explicitly specified to be 77, b.ym must be convertible to B<77>::Y

— end note]

18 If P has a form that contains <i>, and if the type of i differs from the type of the corresponding template parameter of the template named by the enclosing simple-template-id, deduction fails. If P has a form that contains [i], and if the type of i is not an integral type, deduction fails.\footnote{Example:

template<int i> class A { /* ... */ };  
template<short s> void f(A<s>);  
void k1() {
  A<int> a;
  f(a);  // error: deduction fails for conversion from int to short
  f<1>(a);  // OK
}

template<const short cs> class B { };  
template<short s> void g(B<s>);  
void k2() {
  B<1> b;
  g(b);  // OK: cv-qualifiers are ignored on template parameter types
}
— end example]

19 A template-argument can be deduced from a function, pointer to function, or pointer-to-member-function type.  
[Example:

template<class T> void f(void(*)(T,int));  
template<class T> void foo(T,int);  
void g(int,int);  
void g(char,int);  
void h(int,int,int);  
void h(char,int);

int m() {
  f(kg);  // error: ambiguous
  f(kh);  // OK: void h(char,int) is a unique match
  f(&foo);  // error: type deduction fails because foo is a template
}
— end example]

20 A template type-parameter cannot be deduced from the type of a function default argument.  [Example:

template <class T> void f(T = 5, T = 7);
void g() {
  f(1);  // OK: call f<int>(1,7)
  f();  // error: cannot deduce T
  f<int>();  // OK: call f<int>(5,7)
}
— end example]

21 The template-argument corresponding to a template type-parameter is deduced from the type of the template-argument of a class template specialization used in the argument list of a function call.  [Example:

\footnote{Although the template-argument corresponding to a template-parameter of type bool may be deduced from an array bound, the resulting value will always be \texttt{true} because the array bound will be nonzero.}
template <template <class T> class X> struct A { }
template <template <class T> class X> void f(A<X>) { }

template<class T> struct B { }
A<B> ab;
f(ab); // calls f(A<B>)

— end example

[Note: Template argument deduction involving parameter packs (12.6.3) can deduce zero or more arguments for each parameter pack. — end note] [Example:

    template<class> struct X { };
    template<class R, class ... ArgTypes> struct X<R(int, ArgTypes ...)>> { };
    template<class ... Types> struct Y { };
    template<class T, class ... Types> struct Y<T, Types& ...> { };
    template<class ... Types> int f(void (*)(Types ...));
    void g(int, float);

    X<int> x1; // uses primary template
    X<int(int, float, double)> x2; // uses partial specialization; ArgTypes contains float, double
    X<int(float, int)> x3; // uses primary template
    Y<int & , float & , double & > y1; // uses primary template; Types is empty
    Y<int, float, double> y2; // uses partial specialization; T is int, Types contains float, double
    Y<int , float , double> y3; // uses primary template; Types contains int, float, double
    int fv = f(g); // OK; Types contains int, float

— end example]

12.9.2.6 Deducing template arguments from a function declaration [temp.deduct.decl]

In a declaration whose declarator-id refers to a specialization of a function template, template argument deduction is performed to identify the specialization to which the declaration refers. Specifically, this is done for explicit instantiations (12.8.2), explicit specializations (12.8.3), and certain friend declarations (12.6.4). This is also done to determine whether a deallocation function template specialization matches a placement operator new (6.6.4.4.2, 7.6.2.4). In all these cases, P is the type of the function template being considered as a potential match and A is either the function type from the declaration or the type of the deallocation function that would match the placement operator new as described in 7.6.2.4. The deduction is done as described in 12.9.2.5.

2 If, for the set of function templates so considered, there is either no match or more than one match after partial ordering has been considered (12.6.6.2), deduction fails and, in the declaration cases, the program is ill-formed.

12.9.3 Overload resolution [temp.over]

When a call to the name of a function or function template is written (explicitly, or implicitly using the operator notation), template argument deduction (12.9.2) and checking of any explicit template arguments (12.3) are performed for each function template to find the template argument values (if any) that can be used with that function template to instantiate a function template specialization that can be invoked with the call arguments. For each function template, if the argument deduction and checking succeeds, the template-arguments (deduced and/or explicit) are used to synthesize the declaration of a single function template specialization which is added to the candidate functions set to be used in overload resolution. If, for a given function template, argument deduction fails or the synthesized function template specialization would be ill-formed, no such function is added to the set of candidate functions for that template. The complete set of candidate functions includes all the synthesized declarations and all of the non-template overloaded functions of the same name. The synthesized declarations are treated like any other functions in the remainder of overload resolution, except as explicitly noted in 11.3.3.145

2 [Example:

    template<class T> T max(T a, T b) { return a>b?a:b; }

145) The parameters of function template specializations contain no template parameter types. The set of conversions allowed on deduced arguments is limited, because the argument deduction process produces function templates with parameters that either match the call arguments exactly or differ only in ways that can be bridged by the allowed limited conversions. Non-deduced arguments allow the full range of conversions. Note also that 11.3.3 specifies that a non-template function will be given preference over a template specialization if the two functions are otherwise equally good candidates for an overload match.

§ 12.9.3
void f(int a, int b, char c, char d) {
    int m1 = max(a,b); // max(int, int)
    char m2 = max(c,d); // max(char, char)
    int m3 = max(a,c); // error: cannot generate max(int, char)
}

Adding the non-template function

int max(int, int);

to the example above would resolve the third call, by providing a function that could be called for `max(a, c)` after using the standard conversion of `char` to `int` for `c`. — end example

Example: Here is an example involving conversions on a function argument involved in template-argument deduction:

```cpp
template<class T> struct B { /* ... */ };
template<class T> struct D : public B<T> { /* ... */ };
template<class T> void f(B<T>&);

void g(B<int>& bi, D<int>& di) {
    f(bi); // f(bi)
    f(di); // f((B<int>&)di)
}
— end example
```

Example: Here is an example involving conversions on a function argument not involved in template-parameter deduction:

```cpp
template<class T> void f(T*, int); // #1
template<class T> void f(T, char); // #2

void h(int* pi, int i, char c) {
    f(pi,i); // #1: f<int*>(pi,i)
    f(pi,c); // #2: f<int*>(pi,c)
    f(i,c); // #2: f<int>(i,c);
    f(i,i); // #2: f<int>(i, char(i))
}
— end example
```

Only the signature of a function template specialization is needed to enter the specialization in a set of candidate functions. Therefore only the function template declaration is needed to resolve a call for which a template specialization is a candidate. [Example:]

```cpp
template<class T> void f(T); // declaration

void g() {
    f("Annemarie"); // call of f<const char*>  
}
```

The call of `f` is well-formed even if the template `f` is only declared and not defined at the point of the call. The program will be ill-formed unless a specialization for `f<const char*>`, either implicitly or explicitly generated, is present in some translation unit. — end example

12.10 Deduction guides

Deduction guides are used when a `template-name` appears as a type specifier for a deduced class type (9.1.7.5). Deduction guides are not found by name lookup. Instead, when performing class template argument deduction (11.3.1.8), any deduction guides declared for the class template are considered.

`deduction-guide`: explicit_opt template-name ( parameter-declaration-clause ) -> simple-template-id ;

Example:

```cpp
template<class T, class D = int>
struct S {
    T data;
};
```
template<class U>
S(U) -> S<typename U::type>;

struct A {
    using type = short;
    operator type();
};
S x{A();};       // x is of type S<short, int>

— end example]

3 The same restrictions apply to the parameter-declaration-clause of a deduction guide as in a function declaration (9.2.3.5). The simple-template-id shall name a class template specialization. The template-name shall be the same identifier as the template-name of the simple-template-id. A deduction-guide shall be declared in the same scope as the corresponding class template and, for a member class template, with the same access. Two deduction guide declarations in the same translation unit for the same class template shall not have equivalent parameter-declaration-clauses.
13 Exception handling

Exception handling provides a way of transferring control and information from a point in the execution of a thread to an exception handler associated with a point previously passed by the execution. A handler will be invoked only by throwing an exception in code executed in the handler’s try block or in functions called from the handler’s try block.

```
try-block:
  try compound-statement handler-seq
function-try-block:
  try ctor-initializer opt compound-statement handler-seq
handler-seq:
  handler handler-seq opt
handler:
  catch ( exception-declaration ) compound-statement
exception-declaration:
  attribute-specifier-seq opt type-specifier-seq declarator
  attribute-specifier-seq opt type-specifier-seq abstract-declarator opt
```

The optional attribute-specifier-seq in an exception-declaration appertains to the parameter of the catch clause (13.3).

2 A try-block is a statement (Clause 8). [Note: Within this Clause “try block” is taken to mean both try-block and function-try-block. —end note]

3 A goto or switch statement shall not be used to transfer control into a try block or into a handler. [Example:

```c
void f() {
  goto l1;  // ill-formed
  goto l2;  // ill-formed
  try {
    goto l1;  // OK
    goto l2;  // ill-formed
    l1: ;
  } catch (...) {
    l2: ;
    goto l1;  // ill-formed
    goto l2;  // OK
  }
}
```

—end example] A goto, break, return, or continue statement can be used to transfer control out of a try block or handler. When this happens, each variable declared in the try block will be destroyed in the context that directly contains its declaration. [Example:

```c
lab: try {
  T1 t1;
  try {
    T2 t2;
    if (condition)
    goto lab;
  } catch(...) { /* handler 2 */ }
  catch(...) { /* handler 1 */ }
}
```

Here, executing goto lab; will destroy first t2, then t1, assuming the condition does not declare a variable. Any exception thrown while destroying t2 will result in executing handler 2; any exception thrown while destroying t1 will result in executing handler 1. —end example]

4 A function-try-block associates a handler-seq with the ctor-initializer, if present, and the compound-statement. An exception thrown during the execution of the compound-statement or, for constructors and destructors, during the initialization or destruction, respectively, of the class’s subobjects, transfers control to a handler
in a function-try-block in the same way as an exception thrown during the execution of a try-block transfers control to other handlers. [Example:

```cpp
int f(int);
class C {
    int i;
    double d;
public:
    C(int, double);
};

c::C(int ii, double id)
try : i(f(ii)), d(id) {
    // constructor statements
} catch (...) {
    // handles exceptions thrown from the ctor-initializer and from the constructor statements
}
```

—end example]

5 In this Clause, “before” and “after” refer to the “sequenced before” relation (6.8.1).

13.1 Throwing an exception [except.throw]

1 Throwing an exception transfers control to a handler. [Note: An exception can be thrown from one of the following contexts: throw-expressions (7.6.17), allocation functions (6.6.4.4.1), dynamic_cast (7.6.1.7), typeid (7.6.1.8), new-expressions (7.6.2.4), and standard library functions (15.4.1.4).—end note] An object is passed and the type of that object determines which handlers can catch it. [Example:

```cpp
throw "Help!";
```

can be caught by a handler of const char* type:

```cpp
try {
    // ...
} catch(const char* p) {
    // handle character string exceptions here
}
```

and

```cpp
class Overflow {
public:
    Overflow(char,double,double);
};

void f(double x) {
    throw Overflow(‘+’,x,3.45e107);
}
```

can be caught by a handler for exceptions of type Overflow:

```cpp
try {
    f(1.2);
} catch(Overflow& oo) {
    // handle exceptions of type Overflow here
}
```

—end example]

2 When an exception is thrown, control is transferred to the nearest handler with a matching type (13.3); “nearest” means the handler for which the compound-statement or ctor-initializer following the try keyword was most recently entered by the thread of control and not yet exited.

3 Throwing an exception copy-initializes (9.3, 10.3.5) a temporary object, called the exception object. An lvalue denoting the temporary is used to initialize the variable declared in the matching handler (13.3). If the type of the exception object would be an incomplete type, an abstract class type (10.6.3), or a pointer to an incomplete type other than cv void the program is ill-formed.
The memory for the exception object is allocated in an unspecified way, except as noted in 6.6.4.4.1. If a handler exits by rethrowing, control is passed to another handler for the same exception object. The points of potential destruction for the exception object are:

1. When an active handler for the exception exits by any means other than rethrowing, immediately after the destruction of the object (if any) declared in the exception-declaration in the handler;
2. When an object of type std::exception_ptr (16.9.6) that refers to the exception object is destroyed, before the destructor of std::exception_ptr returns.

Among all points of potential destruction for the exception object, there is an unspecified last one where the exception object is destroyed. All other points happen before that last one (6.8.2.1). [Note: No other thread synchronization is implied in exception handling. — end note] The implementation may then deallocate the memory for the exception object; any such deallocation is done in an unspecified way. [Note: A thrown exception does not propagate to other threads unless caught, stored, and rethrown using appropriate library functions; see 16.9.6 and 30.6. — end note]

When the thrown object is a class object, the constructor selected for the copy-initialization as well as the constructor selected for a copy-initialization considering the thrown object as an lvalue shall be non-deleted and accessible, even if the copy/move operation is elided (10.9.5). The destructor is potentially invoked (10.3.7).

An exception is considered caught when a handler for that exception becomes active (13.3). [Note: An exception can have active handlers and still be considered uncaught if it is rethrown. — end note]

If the exception handling mechanism handling an uncaught exception (13.5.2) directly invokes a function that exits via an exception, the function std::terminate is called (13.5.1). [Example:

```cpp
struct C {
    C() { }
    C(const C&) {
        if (std::uncaught_exceptions()) {
            throw 0;  // throw during copy to handler’s exception-declaration object (13.3)
        }
    }
};

int main() {  
    try {
        throw C();  // calls std::terminate if construction of the handler’s
        // exception-declaration object is not elided (10.9.5)
    } catch(C) { }
}
— end example] [Note: Consequently, destructors should generally catch exceptions and not let them propagate. — end note]

13.2 Constructors and destructors [except.ctor]

As control passes from the point where an exception is thrown to a handler, destructors are invoked by a process, specified in this subclause, called stack unwinding.

The destructor is invoked for each automatic object of class type constructed, but not yet destroyed, since the try block was entered. If an exception is thrown during the destruction of temporaries or local variables for a return statement (8.6.3), the destructor for the returned object (if any) is also invoked. The objects are destroyed in the reverse order of the completion of their construction. [Example:

```cpp
struct A { };  

struct Y { 
    -Y() noexcept(false) { throw 0; }
};

A f() {  
    try {
        A a;  
        Y y;  
        A b;  
        return {};
        // #1
```
At #1, the returned object of type A is constructed. Then, the local variable b is destroyed (8.6). Next, the local variable y is destroyed, causing stack unwinding, resulting in the destruction of the returned object, followed by the destruction of the local variable a. Finally, the returned object is constructed again at #2.

Example

3 If the initialization or destruction of an object other than by delegating constructor is terminated by an exception, the destructor is invoked for each of the object’s direct subobjects and, for a complete object, virtual base class subobjects, whose initialization has completed (9.3) and whose destructor has not yet begun execution, except that in the case of destruction, the variant members of a union-like class are not destroyed. The subobjects are destroyed in the reverse order of the completion of their construction. Such destruction is sequenced before entering a handler of the function-try-block of the constructor or destructor, if any.

4 If the compound-statement of the function-body of a delegating constructor for an object exits via an exception, the object’s destructor is invoked. Such destruction is sequenced before entering a handler of the function-try-block of a delegating constructor for that object, if any.

5 [Note: If the object was allocated by a new-expression (7.6.2.4), the matching deallocation function (6.6.4.4.2), if any, is called to free the storage occupied by the object. — end note]

13.3 Handling an exception

1 The exception-declaration in a handler describes the type(s) of exceptions that can cause that handler to be entered. The exception-declaration shall not denote an incomplete type, an abstract class type, or an rvalue reference type. The exception-declaration shall not denote a pointer or reference to an incomplete type, other than void*, const void*, volatile void*, or const volatile void*.

2 A handler of type “array of T” or function type T is adjusted to be of type “pointer to T”.

3 A handler is a match for an exception object of type E if

   (3.1) — The handler is of type cv T or cv T& and E and T are the same type (ignoring the top-level cv-qualifiers), or
   (3.2) — the handler is of type cv T or cv T& and T is an unambiguous public base class of E, or
   (3.3) — the handler is of type cv T or const T& where T is a pointer or pointer-to-member type and E is a pointer or pointer-to-member type that can be converted to T by one or more of
          (3.3.1) — a standard pointer conversion (7.3.11) not involving conversions to pointers to private or protected or ambiguous classes
          (3.3.2) — a function pointer conversion (7.3.13)
          (3.3.3) — a qualification conversion (7.3.5), or
   (3.4) — the handler is of type cv T or const T& where T is a pointer or pointer-to-member type and E is std::nullptr_t.

   [Note: A throw-expression whose operand is an integer literal with value zero does not match a handler of pointer or pointer-to-member type. A handler of reference to array or function type is never a match for any exception object (7.6.17). — end note]

Example:

```cpp
class Matherr { /* ... */ virtual void vf(); }; class Overflow: public Matherr { /* ... */ }; class Underflow: public Matherr { /* ... */ }; class Zerodivide: public Matherr { /* ... */ }; void f() {
  try {
    g();
  } catch (Overflow oo) {
    // ...
  } catch (Matherr mm) {
    // ...
```
Here, the Overflow handler will catch exceptions of type Overflow and the Matherr handler will catch exceptions of type Matherr and of all types publicly derived from Matherr including exceptions of type Underflow and Zerodivide. —end example]

The handlers for a try block are tried in order of appearance. [Note: This makes it possible to write handlers that can never be executed, for example by placing a handler for a final derived class after a handler for a corresponding unambiguous public base class. —end note]

A . . . in a handler’s exception-declaration functions similarly to . . . in a function parameter declaration; it specifies a match for any exception. If present, a . . . handler shall be the last handler for its try block.

If no match is found among the handlers for a try block, the search for a matching handler continues in a dynamically surrounding try block of the same thread.

A handler is considered active when initialization is complete for the parameter (if any) of the catch clause. [Note: The stack will have been unwound at that point. —end note] Also, an implicit handler is considered active when the function std::terminate is entered due to a throw. A handler is no longer considered active when the catch clause exits.

The exception with the most recently activated handler that is still active is called the currently handled exception.

If no matching handler is found, the function std::terminate is called; whether or not the stack is unwound before this call to std::terminate is implementation-defined (13.5.1).

Referring to any non-static member or base class of an object in the handler for a function-try-block of a constructor or destructor for that object results in undefined behavior.

The scope and lifetime of the parameters of a function or constructor extend into the handlers of a function-try-block.

Exceptions thrown in destructors of objects with static storage duration or in constructors of namespace-scope objects with static storage duration are not caught by a function-try-block on the main function (6.8.3.1). Exceptions thrown in destructors of objects with thread storage duration or in constructors of namespace-scope objects with thread storage duration are not caught by a function-try-block on the initial function of the thread.

If a return statement (8.6.3) appears in a handler of the function-try-block of a constructor, the program is ill-formed.

The currently handled exception is rethrown if control reaches the end of a handler of the function-try-block of a constructor or destructor. Otherwise, flowing off the end of the compound-statement of a handler of a function-try-block is equivalent to flowing off the end of the compound-statement of that function (see 8.6.3).

The variable declared by the exception-declaration, of type cv T or cv T&, is initialized from the exception object, of type E, as follows:

(15.1) — if T is a base class of E, the variable is copy-initialized (9.3) from the corresponding base class subobject of the exception object;

(15.2) — otherwise, the variable is copy-initialized (9.3) from the exception object.

The lifetime of the variable ends when the handler exits, after the destruction of any automatic objects initialized within the handler.

When the handler declares an object, any changes to that object will not affect the exception object. When the handler declares a reference to an object, any changes to the referenced object are changes to the exception object and will have effect should that object be rethrown.

13.4 Exception specifications

The predicate indicating whether a function cannot exit via an exception is called the exception specification of the function. If the predicate is false, the function has a potentially-throwing exception specification, otherwise it has a non-throwing exception specification. The exception specification is either defined implicitly, or defined explicitly by using a noexcept-specifier as a suffix of a function declarator (9.2.3.5).
In a `noexcept-specifier`, the `constant-expression`, if supplied, shall be a contextually converted constant expression of type `bool` (7.7); that constant expression is the exception specification of the function type in which the `noexcept-specifier` appears. A `(` token that follows `noexcept` is part of the `noexcept-specifier` and does not commence an initializer (9.3). The `noexcept-specifier` `noexcept` without a `constant-expression` is equivalent to the `noexcept-specifier` `noexcept(true)`.

If a declaration of a function does not have a `noexcept-specifier`, the declaration has a potentially throwing exception specification unless it is a destructor or a deallocation function or is defaulted on its first declaration, in which cases the exception specification is as specified below and no other declaration for that function shall have a `noexcept-specifier`. In an explicit instantiation (12.8.2) a `noexcept-specifier` may be specified, but is not required. If a `noexcept-specifier` is specified in an explicit instantiation directive, the exception specification shall be the same as the exception specification of all other declarations of that function. A diagnostic is required only if the exception specifications are not the same within a single translation unit.

If a virtual function has a non-throwing exception specification, all declarations, including the definition, of any function that overrides that virtual function in any derived class shall have a non-throwing exception specification, unless the overriding function is defined as deleted. [Example:

```c++
struct B {
  virtual void f() noexcept;
  virtual void g();
  virtual void h() noexcept = delete;
};

struct D: B {
  void f(); // ill-formed
  void g() noexcept; // OK
  void h() = delete; // OK
};
```

The declaration of `D::f` is ill-formed because it has a potentially-throwing exception specification, whereas `B::f` has a non-throwing exception specification. — end example]

Whenever an exception is thrown and the search for a handler (13.3) encounters the outermost block of a function with a non-throwing exception specification, the function `std::terminate` is called (13.5.1). [Note: An implementation shall not reject an expression merely because, when executed, it throws or might throw an exception from a function with a non-throwing exception specification. — end note] [Example:

```c++
extern void f(); // potentially-throwing

void g() noexcept {
  f(); // valid, even if f throws
  throw 42; // valid, effectively a call to std::terminate
}
```

The call to `f` is well-formed even though, when called, `f` might throw an exception. — end example]

An expression `e` is potentially-throwing if

(6.1) — `e` is a function call (7.6.1.2) whose `postfix-expression` has a function type, or a pointer-to-function type, with a potentially-throwing exception specification, or

(6.2) — `e` implicitly invokes a function (such as an overloaded operator, an allocation function in a `new-expression`, a constructor for a function argument, or a destructor if `e` is a full-expression (6.8.1)) that is potentially-throwing, or

(6.3) — `e` is a `throw-expression` (7.6.17), or

(6.4) — `e` is a `dynamic_cast` expression that casts to a reference type and requires a runtime check (7.6.1.7), or

(6.5) — `e` is a `typeid` expression applied to a (possibly parenthesized) built-in unary `*` operator applied to a pointer to a polymorphic class type (7.6.1.8), or

(6.6) — any of the immediate subexpressions (6.8.1) of `e` is potentially-throwing.

§ 13.4
An implicitly-declared constructor for a class \( X \), or a constructor without a \texttt{noexcept-specifier} that is defaulted on its first declaration, has a potentially-throwing exception specification if and only if any of the following constructs is potentially-throwing:

- a constructor selected by overload resolution in the implicit definition of the constructor for class \( X \) to initialize a potentially constructed subobject, or
- a subexpression of such an initialization, such as a default argument expression, or,
- for a default constructor, a default member initializer.

[Note: Even though destructors for fully-constructed subobjects are invoked when an exception is thrown during the execution of a constructor (13.2), their exception specifications do not contribute to the exception specification of the constructor, because an exception thrown from such a destructor would call the function \texttt{std::terminate} rather than escape the constructor (13.1, 13.5.1). — end note]

The exception specification for an implicitly-declared destructor, or a destructor without a \texttt{noexcept-specifier}, is potentially-throwing if and only if any of the destructors for any of its potentially constructed subobjects is potentially throwing.

The exception specification for an implicitly-declared assignment operator, or an assignment-operator without a \texttt{noexcept-specifier} that is defaulted on its first declaration, is potentially-throwing if and only if the invocation of any assignment operator in the implicit definition is potentially-throwing.

A deallocation function (6.6.4.4.2) with no explicit \texttt{noexcept-specifier} has a non-throwing exception specification.

The exception specification for a comparison operator (7.6.8, 7.6.9, 7.6.10) without a \texttt{noexcept-specifier} that is defaulted on its first declaration is potentially-throwing if and only if the invocation of any comparison operator in the implicit definition is potentially-throwing.

[Example:

```cpp
struct A {
    A(int = (A(5), 0)) noexcept;
    A(const A&) noexcept;
    A(A&&) noexcept;
    ~A();
};
struct B {
    B() noexcept;
    B(const B&) = default;    // implicit exception specification is noexcept(true)
    B(B&&, int = (throw Y(), 0)) noexcept;
    ~B() noexcept(false);
};
int n = 7;
struct D : public A, public B {
    int * p = new int[n];
    //D::D() potentially-throwing, as the new operator may throw bad_alloc or bad_array_new_length
    //D::D(const D&) non-throwing
    //D::D(D&&) potentially-throwing, as the default argument for B's constructor may throw
    //D::~D() potentially-throwing
};
```

Furthermore, if A::\texttt{~A()} were virtual, the program would be ill-formed since a function that overrides a virtual function from a base class shall not have a potentially-throwing exception specification if the base class function has a non-throwing exception specification. — end example]

An exception specification is considered to be \textit{needed} when:

- in an expression, the function is the unique lookup result or the selected member of a set of overloaded functions (6.4, 11.3, 11.4);
- the function is odr-used (6.2) or, if it appears in an unevaluated operand, would be odr-used if the expression were potentially-evaluated;
- the exception specification is compared to that of another declaration (e.g., an explicit specialization or an overriding virtual function);
- the function is defined; or

§ 13.4 401
The exception specification of a defaulted special member function is evaluated as described above only when needed; similarly, the noexcept-specifier of a specialization of a function template or member function of a class template is instantiated only when needed.

### 13.5 Special functions

The function `std::terminate` (13.5.1) is used by the exception handling mechanism for coping with errors related to the exception handling mechanism itself. The function `std::current_exception()` (16.9.6) and the class `std::nested_exception` (16.9.7) can be used by a program to capture the currently handled exception.

#### 13.5.1 The `std::terminate` function

In some situations exception handling must be abandoned for less subtle error handling techniques. [Note: These situations are:

- when the exception handling mechanism, after completing the initialization of the exception object but before activation of a handler for the exception (13.1), calls a function that exits via an exception, or
- when the exception handling mechanism cannot find a handler for a thrown exception (13.3), or
- when the search for a handler (13.3) encounters the outermost block of a function with a non-throwing exception specification (13.4), or
- when the destruction of an object during stack unwinding (13.2) terminates by throwing an exception, or
- when initialization of a non-local variable with static or thread storage duration (6.8.3.3) exits via an exception, or
- when destruction of an object with static or thread storage duration exits via an exception (6.8.3.4), or
- when execution of a function registered with `std::atexit` or `std::at_quick_exit` exits via an exception (16.5), or
- when evaluation of the predicate of a contract (9.11.4) exits via an exception, or
- when the violation handler invoked for a failed contract condition check (9.11.4) on a noexcept function exits via an exception, or
- when the violation handler has completed after a failed contract check and the continuation mode is `off`, or
- when a `throw-expression` (7.6.17) with no operand attempts to rethrow an exception and no exception is being handled (13.1), or
- when the function `std::nested_exception::rethrow_nested` is called for an object that has captured no exception (16.9.7), or
- when execution of the initial function of a thread exits via an exception (30.3.2.2), or
- for a parallel algorithm whose `ExecutionPolicy` specifies such behavior (19.18.4, 19.18.5, 19.18.6), when execution of an element access function (23.3.1) of the parallel algorithm exits via an exception (23.3.4), or
- when the destructor or the copy assignment operator is invoked on an object of type `std::thread` that refers to a joinable thread (30.3.2.3, 30.3.2.4), or
- when a call to a `wait()`, `wait_until()`, or `wait_for()` function on a condition variable (30.5.3, 30.5.4) fails to meet a postcondition.

—end note]
unwound partially, or not unwound at all before the function `std::terminate` is called. In all other situations, the stack shall not be unwound before the function `std::terminate` is called. An implementation is not permitted to finish stack unwinding prematurely based on a determination that the unwind process will eventually cause a call to the function `std::terminate`.

13.5.2 The `std::uncaught_exceptions()` function

An exception is considered uncaught after completing the initialization of the exception object (13.1) until completing the activation of a handler for the exception (13.3). This includes stack unwinding. If an exception is rethrown (7.6.17, 16.9.6), it is considered uncaught from the point of rethrow until the rethrown exception is caught. The function `std::uncaught_exceptions()` (16.9.5) returns the number of uncaught exceptions in the current thread.
14 Preprocessing directives

1 A **preprocessing directive** consists of a sequence of preprocessing tokens that satisfies the following constraints: The first token in the sequence is a # preprocessing token that (at the start of translation phase 4) is either the first character in the source file (optionally after white space containing no new-line characters) or that follows white space containing at least one new-line character. The last token in the sequence is the first new-line character that follows the first token in the sequence.\textsuperscript{1} A new-line character ends the preprocessing directive even if it occurs within what would otherwise be an invocation of a function-like macro.

```plaintext
preprocessing-file:
  group_opt

group:
  group-part
  group group-part

group-part:
  control-line
  if-section
  text-line
  # conditionally-supported-directive

control-line:
  # include pp-tokens new-line
  # define identifier replacement-list new-line
  # define identifier lparen identifier-list_opt ) replacement-list new-line
  # define identifier lparen ) replacement-list new-line
  # define identifier lparen identifier-list , ... ) replacement-list new-line
  # undef identifier new-line
  # line pp-tokens new-line
  # error pp-tokens_new-line
  # pragma pp-tokens new-line
  # new-line

if-section:
  if-group elif-groups_opt else-group_opt endif-line

if-group:
  # if constant-expression new-line group_opt
  # ifdef identifier new-line group_opt
  # ifndef identifier new-line group_opt

elif-groups:
  elif-group
  elif-groups elif-group

elif-group:
  # elif constant-expression new-line group_opt

else-group:
  # else new-line group_opt

endif-line:
  # endif new-line

text-line:
  pp-tokens_new-line

conditionally-supported-directive:
  pp-tokens new-line

lparen:
  a ( character not immediately preceded by white-space
```

\textsuperscript{1} Thus, preprocessing directives are commonly called “lines”. These “lines” have no other syntactic significance, as all white space is equivalent except in certain situations during preprocessing (see the # character string literal creation operator in 14.3.2, for example).
A text line shall not begin with a `#` preprocessing token. A conditionally-supported-directive shall not begin with any of the directive names appearing in the syntax. A conditionally-supported-directive is conditionally-supported with implementation-defined semantics.

When in a group that is skipped (14.1), the directive syntax is relaxed to allow any sequence of preprocessing tokens to occur between the directive name and the following new-line character.

The only white-space characters that shall appear between preprocessing tokens within a preprocessing directive (from just after the introducing `#` preprocessing token through just before the terminating new-line character) are space and horizontal-tab (including spaces that have replaced comments or possibly other white-space characters in translation phase 3).

The implementation can process and skip sections of source files conditionally, include other source files, and replace macros. These capabilities are called preprocessing, because conceptually they occur before translation of the resulting translation unit.

The preprocessing tokens within a preprocessing directive are not subject to macro expansion unless otherwise stated.

[Example: In:

```
#define EMPTY
EMPTY # include <file.h>
```

the sequence of preprocessing tokens on the second line is not a preprocessing directive, because it does not begin with a `#` at the start of translation phase 4, even though it will do so after the macro `EMPTY` has been replaced. — end example]

## 14.1 Conditional inclusion

The expression that controls conditional inclusion shall be an integral constant expression except that identifiers (including those lexically identical to keywords) are interpreted as described below and it may contain zero or more defined-macro-expressions and/or has-include-expressions and/or has-attribute-expressions as unary operator expressions.

147) Because the controlling constant expression is evaluated during translation phase 4, all identifiers either are or are not macro names — there simply are no keywords, enumeration constants, etc.
A defined-macro-expression evaluates to 1 if the identifier is currently defined as a macro name (that is, if it is predefined or if it has been the subject of a \#define preprocessing directive without an intervening \#undef directive with the same subject identifier), 0 if it is not.

The third and fourth forms of has-include-expression are considered only if neither of the first or second forms matches, in which case the preprocessing tokens are processed just as in normal text.

The header or source file identified by the parentheses preprocessing token sequence in each contained has-include-expression is searched for as if that preprocessing token sequence were the pp-tokens in a \#include directive, except that no further macro expansion is performed. If such a directive would not satisfy the syntactic requirements of a \#include directive, the program is ill-formed. The has-include-expression evaluates to 1 if the search for the source file succeeds, and to 0 if the search fails.

Each has-attribute-expression is replaced by a non-zero pp-number matching the form of an integer-literal if the implementation supports an attribute with the name specified by interpreting the pp-tokens as an attribute-token, and by 0 otherwise. The program is ill-formed if the pp-tokens do not match the form of an attribute-token.

For an attribute specified in this document, the value of the has-attribute-expression is given by Table 15. For other attributes recognized by the implementation, the value is implementation-defined. [Note: It is expected that the availability of an attribute can be detected by any non-zero result. — end note]

</tbody>
</table>

The \#ifdef and \#ifndef directives, and the defined conditional inclusion operator, shall treat __has_-include and __has_cpp_attribute as if they were the names of defined macros. The identifiers __has_-include and __has_cpp_attribute shall not appear in any context not mentioned in this subclause.

Each preprocessing token that remains (in the list of preprocessing tokens that will become the controlling expression) after all macro replacements have occurred shall be in the lexical form of a token (5.6).

Preprocessing directives of the forms

```
# if constant-expression new-line group_opt
# elif constant-expression new-line group_opt
```

check whether the controlling constant expression evaluates to nonzero.

Prior to evaluation, macro invocations in the list of preprocessing tokens that will become the controlling constant expression are replaced (except for those macro names modified by the defined unary operator), just as in normal text. If the token defined is generated as a result of this replacement process or use of the defined unary operator does not match one of the two specified forms prior to macro replacement, the behavior is undefined.

After all replacements due to macro expansion and evaluations of defined-macro-expressions and has-include-expressions have been performed, all remaining identifiers and keywords, except for true and false, are replaced with the pp-number 0, and then each preprocessing token is converted into a token. [Note: An alternative token (5.5) is not an identifier, even when its spelling consists entirely of letters and underscores. Therefore it is not subject to this replacement. — end note]

The resulting tokens comprise the controlling constant expression which is evaluated according to the rules of 7.7 using arithmetic that has at least the ranges specified in 16.3. For the purposes of this token
conversion and evaluation all signed and unsigned integer types act as if they have the same representation as, respectively, `intmax_t` or `uintmax_t` (16.4). [Note: Thus on an implementation where `std::numeric_limits<int>::max()` is `0x7FFF` and `std::numeric_limits<unsigned int>::max()` is `0xFFFF`, the integer literal `0x8000` is signed and positive within a `#if` expression even though it is unsigned in translation phase 7 (5.2). — end note] This includes interpreting character literals, which may involve converting escape sequences into execution character set members. Whether the numeric value for these character literals matches the value obtained when an identical character literal occurs in an expression (other than within a `#if` or `#elif` directive) is implementation-defined. [Note: Thus, the constant expression in the following `#if` directive and `if` statement (8.4.1) is not guaranteed to evaluate to the same value in these two contexts:

```
# if 'z' - 'a' == 25  
if ('z' - 'a' == 25)
```

— end note] Also, whether a single-character character literal may have a negative value is implementation-defined. Each subexpression with type `bool` is subjected to integral promotion before processing continues.

Preprocessing directives of the forms

```
# ifdef identifier new-line group_opt
# ifndef identifier new-line group_opt
```

check whether the identifier is or is not currently defined as a macro name. Their conditions are equivalent to `#if defined identifier` and `#if !defined identifier` respectively.

Each directive’s condition is checked in order. If it evaluates to false (zero), the group that it controls is skipped: directives are processed only through the name that determines the directive in order to keep track of the level of nested conditionals; the rest of the directives’ preprocessing tokens are ignored, as are the other preprocessing tokens in the group. Only the first group whose control condition evaluates to true (nonzero) is processed; any following groups are skipped and their controlling directives are processed as if they were in a group that is skipped. If none of the conditions evaluates to true, and there is a `#else` directive, the group controlled by the `#else` is processed; lacking a `#else` directive, all the groups until the `#endif` are skipped.  

[Example: This demonstrates a way to include a library `optional` facility only if it is available:

```
#include <optional>
#if __cpp_lib_optional >= 201603
#define have_optional 1
#endif
#endif
#ifndef have_optional
#define have_optional 0
#endif
```

— end example]

15

[Example: This demonstrates a way to use the attribute `[[acme::deprecated]]` only if it is available.

```
#include <optional>
#if __cpp_lib_optional >= 201603
#define have_optional 1
#endif
```

— end example]

16

14.2 Source file inclusion

A `#include` directive shall identify a header or source file that can be processed by the implementation.

---

148) As indicated by the syntax, a preprocessing token shall not follow a `#else` or `#endif` directive before the terminating new-line character. However, comments may appear anywhere in a source file, including within a preprocessing directive.
A preprocessing directive of the form

```
#include <h-char-sequence > new-line
```

searches a sequence of implementation-defined places for a header identified uniquely by the specified sequence between the `<` and `>` delimiters, and causes the replacement of that directive by the entire contents of the header. How the places are specified or the header identified is implementation-defined.

A preprocessing directive of the form

```
#include "q-char-sequence " new-line
```

causes the replacement of that directive by the entire contents of the source file identified by the specified sequence between the `"` delimiters. The named source file is searched for in an implementation-defined manner. If this search is not supported, or if the search fails, the directive is reprocessed as if it read

```
#include <h-char-sequence > new-line
```

with the identical contained sequence (including `>` characters, if any) from the original directive.

A preprocessing directive of the form

```
#include pp-tokens new-line
```

(that does not match one of the two previous forms) is permitted. The preprocessing tokens after `include` in the directive are processed just as in normal text (i.e., each identifier currently defined as a macro name is replaced by its replacement list of preprocessing tokens). If the directive resulting after all replacements does not match one of the two previous forms, the behavior is undefined. The method by which a sequence of preprocessing tokens between a `<` and a `>` preprocessing token pair or a pair of `"` characters is combined into a single header name preprocessing token is implementation-defined.

The implementation shall provide unique mappings for sequences consisting of one or more `nondigits` or `digits` (5.10) followed by a period (`.`) and a single `nondigit`. The first character shall not be a `digit`. The implementation may ignore distinctions of alphabetical case.

A `#include` preprocessing directive may appear in a source file that has been read because of a `#include` directive in another file, up to an implementation-defined nesting limit.

[Note: Although an implementation may provide a mechanism for making arbitrary source files available to the `< >` search, in general programmers should use the `< >` form for headers provided with the implementation, and the `" "` form for sources outside the control of the implementation. For instance:

```
#include <stdio.h>
#include <unistd.h>
#include "usefullib.h"
#include "myprog.h"
```

—end note]

[Example: This illustrates macro-replaced `#include` directives:

```
#if VERSION == 1
#define INCFILE "vers1.h"
#elif VERSION == 2
#define INCFILE "vers2.h" // and so on
#else
#define INCFILE "versN.h"
#endif
#include INCFILE
```

—end example]

14.3 Macro replacement

Two replacement lists are identical if and only if the preprocessing tokens in both have the same number, ordering, spelling, and white-space separation, where all white-space separations are considered identical.

An identifier currently defined as an object-like macro (see below) may be redefined by another `#define` preprocessing directive provided that the second definition is an object-like macro definition and the two replacement lists are identical, otherwise the program is ill-formed. Likewise, an identifier currently defined as a function-like macro (see below) may be redefined by another `#define` preprocessing directive provided that

149) Note that adjacent string literals are not concatenated into a single string literal (see the translation phases in 5.2); thus, an expansion that results in two string literals is an invalid directive.
the second definition is a function-like macro definition that has the same number and spelling of parameters, and the two replacement lists are identical, otherwise the program is ill-formed.

3 There shall be white-space between the identifier and the replacement list in the definition of an object-like macro.

4 If the identifier-list in the macro definition does not end with an ellipsis, the number of arguments (including those arguments consisting of no preprocessing tokens) in an invocation of a function-like macro shall equal the number of parameters in the macro definition. Otherwise, there shall be at least as many arguments in the invocation as there are parameters in the macro definition (excluding the . . .). There shall exist a ) preprocessing token that terminates the invocation.

5 The identifiers __VA_ARGS__ and __VA_OPT__ shall occur only in the replacement-list of a function-like macro that uses the ellipsis notation in the parameters.

6 A parameter identifier in a function-like macro shall be uniquely declared within its scope.

7 The identifier immediately following the define is called the macro name. There is one name space for macro names. Any white-space characters preceding or following the replacement list of preprocessing tokens are not considered part of the replacement list for either form of macro.

8 If a # preprocessing token, followed by an identifier, occurs lexically at the point at which a preprocessing directive could begin, the identifier is not subject to macro replacement.

9 A preprocessing directive of the form

   # define identifier replacement-list new-line

defines an object-like macro that causes each subsequent instance of the macro name to be replaced by the replacement list of preprocessing tokens that constitute the remainder of the directive. The replacement list is then rescanned for more macro names as specified below.

A preprocessing directive of the form

   # define identifier lparen identifier-list opt ) replacement-list new-line  
   # define identifier lparen . . . ) replacement-list new-line  
   # define identifier lparen identifier-list , . . . ) replacement-list new-line

defines a function-like macro with parameters, whose use is similar syntactically to a function call. The parameters are specified by the optional list of identifiers, whose scope extends from their declaration in the identifier list until the new-line character that terminates the #define preprocessing directive. Each subsequent instance of the function-like macro name followed by a ( as the next preprocessing token introduces the sequence of preprocessing tokens that is replaced by the replacement list in the definition (an invocation of the macro). The replaced sequence of preprocessing tokens is terminated by the matching ) preprocessing token, skipping intervening matched pairs of left and right parenthesis preprocessing tokens. Within the sequence of preprocessing tokens making up an invocation of a function-like macro, new-line is considered a normal white-space character.

The sequence of preprocessing tokens bounded by the outside-most matching parentheses forms the list of arguments for the function-like macro. The individual arguments within the list are separated by comma preprocessing tokens, but comma preprocessing tokens between matching inner parentheses do not separate arguments. If there are sequences of preprocessing tokens within the list of arguments that would otherwise act as preprocessing directives, the behavior is undefined.

If there is a . . . immediately preceding the ) in the function-like macro definition, then the trailing arguments (if any), including any separating comma preprocessing tokens, are merged to form a single item: the variable arguments. The number of arguments so combined is such that, following merger, the number of arguments is either equal to or one more than the number of parameters in the macro definition (excluding the . . .).

14.3.1 Argument substitution

cpp.subst

After the arguments for the invocation of a function-like macro have been identified, argument substitution takes place. For each parameter in the replacement list that is neither preceded by a # or ## preprocessing
token nor followed by a ## preprocessing token, the preprocessing tokens naming the parameter are replaced by a token sequence determined as follows:

(1.1) — If the parameter is of the form __VA_OPT__(content), the replacement preprocessing tokens are the preprocessing token sequence for the corresponding argument.

(1.2) — Otherwise, the replacement preprocessing tokens are the preprocessing tokens of corresponding argument after all macros contained therein have been expanded. The argument’s preprocessing tokens are completely macro replaced before being substituted as if they formed the rest of the preprocessing file with no other preprocessing tokens being available.

[Example:

```c
#define LPAREN() (  
#define G(Q) 42  
#define F(R, X, ...) __VA_OPT__(G R X)  
int x = F(LPAREN(), 0, <:-);  // replaced by int x = 42;

— end example]

2 An identifier __VA_ARGS__ that occurs in the replacement list shall be treated as if it were a parameter, and the variable arguments shall form the preprocessing tokens used to replace it.

3 The identifier __VA_OPT__ shall always occur as part of the preprocessing token sequence __VA_OPT__(content), where content is an arbitrary sequence of preprocessing-tokens other than __VA_OPT__, which is terminated by the closing ) and skips intervening pairs of matching left and right parentheses. If content would be ill-formed as the replacement list of the current function-like macro, the program is ill-formed. The preprocessing token sequence __VA_OPT__(content) shall be treated as if it were a parameter, and the preprocessing token sequence for the corresponding argument is defined as follows. If the substitution of __VA_ARGS__ as neither an operand of # nor ## consists of no preprocessing tokens, the argument consists of a single placemarker preprocessing token (14.3.3, 14.3.4). Otherwise, the argument consists of the results of the expansion of content as the replacement list of the current function-like macro before removal of placemarkers, rescanning, and further replacement. [Note: The placemaker tokens are removed before stringization (14.3.2), and can be removed by rescanning and further replacement (14.3.4). — end note]

[Example:

```c
#define F(...)
#define G(X, ...) f(0, X __VA_OPT__(,) __VA_ARGS__)  
#define SDEF(sname, ...) S sname __VA_OPT__(= { __VA_ARGS__ })
#define EMP
F(a, b, c)  // replaced by f(0, a, b, c)  
F()  // replaced by f(0)  
F(EMP)  // replaced by f(0)

G(a, b, c)  // replaced by f(0, a, b, c)  
G(a)  // replaced by f(0, a)  
G(a)  // replaced by f(0, a)
SDEF(foo);  // replaced by S foo;  
SDEF(bar, 1, 2);  // replaced by S bar = { 1, 2 };  

#define H1(X, ...) X __VA_OPT__(##) __VA_ARGS__  // ill-formed: ## may not appear at  
// the beginning of a replacement list (14.3.3)

#define H2(X, Y, ...) __VA_OPT__(X ## Y, __VA_ARGS__)  
#define H3(X, ...) __VA_OPT__(X##X X##X)  
#define H4(X, Y, Z) __VA_OPT__ (a X ## X) ## b
#define H5A(..., __VA_OPT__()/**/__VA_OPT__())
#define H5B(X) a ## X ## b
#define H5C(X) H5B(X)
```

§ 14.3.1
### 14.3.2 The `#` operator

1. Each `#` preprocessing token in the replacement list for a function-like macro shall be followed by a parameter as the next preprocessing token in the replacement list.

2. A *character string literal* is a *string-literal* with no prefix. If, in the replacement list, a parameter is immediately preceded by a `#` preprocessing token, both are replaced by a single character string literal preprocessing token that contains the spelling of the preprocessing token sequence for the corresponding argument (excluding placemarker tokens). Let the *stringizing argument* be the preprocessing token sequence for the corresponding argument with placemarker tokens removed. Each occurrence of white space between the stringizing argument’s preprocessing tokens becomes a single space character in the character string literal. White space before the first preprocessing token and after the last preprocessing token comprising the stringizing argument is deleted. Otherwise, the original spelling of each preprocessing token in the stringizing argument is retained in the character string literal, except for special handling for producing the spelling of string literals and character literals: a `\` character is inserted before each " and \ character of a character literal or string literal (including the delimiting " characters). If the replacement that results is not a valid character string literal, the behavior is undefined. The character string literal corresponding to an empty stringizing argument is ". The order of evaluation of `#` and `##` operators is unspecified.

### 14.3.3 The `##` operator

1. A `##` preprocessing token shall not occur at the beginning or at the end of a replacement list for either form of macro definition.

2. If, in the replacement list of a function-like macro, a parameter is immediately preceded or followed by a `##` preprocessing token, the parameter is replaced by the corresponding argument’s preprocessing token sequence; however, if an argument consists of no preprocessing tokens, the parameter is replaced by a placemarker preprocessing token instead.\[153\]

3. For both object-like and function-like macro invocations, before the replacement list is reexamined for more macro names to replace, each instance of a `##` preprocessing token in the replacement list (not from an argument) is deleted and the preceding preprocessing token is concatenated with the following preprocessing token. Placemarker preprocessing tokens are handled specially: concatenation of two placemarkers results in a single placemarker preprocessing token, and concatenation of a placemarker with a non-placemarker preprocessing token results in the non-placemarker preprocessing token. If the result is not a valid preprocessing token, the behavior is undefined. The resulting token is available for further macro replacement. The order of evaluation of `##` operators is unspecified.

[Example: In the following fragment:

```c
#define hash_hash # ## #
#define mkstr(a) # a
#define in_between(a) mkstr(a)
#define join(c, d) in_between(c hash_hash d)
char p[] = join(x, y);  // equivalent to char p[] = "x ## y";
```

The expansion produces, at various stages:

```
join(x, y)
in_between(x hash_hash y)
in_between(x ## y)
mkstr(x ## y)
"x ## y"
```

In other words, expanding `hash_hash` produces a new token, consisting of two adjacent sharp signs, but this new token is not the `##` operator. — end example]

### 14.3.4 Rescanning and further replacement

1. After all parameters in the replacement list have been substituted and `#` and `##` processing has taken place, all placemarker preprocessing tokens are removed. Then the resulting preprocessing token sequence is rescanned, along with all subsequent preprocessing tokens of the source file, for more macro names to replace.

\[153\] Placemarker preprocessing tokens do not appear in the syntax because they are temporary entities that exist only within translation phase 4.
If the name of the macro being replaced is found during this scan of the replacement list (not including the rest of the source file's preprocessing tokens), it is not replaced. Furthermore, if any nested replacements encounter the name of the macro being replaced, it is not replaced. These nonreplaced macro name preprocessing tokens are no longer available for further replacement even if they are later (re)examined in contexts in which that macro name preprocessing token would otherwise have been replaced.

The resulting completely macro-replaced preprocessing token sequence is not processed as a preprocessing directive even if it resembles one, but all pragma unary operator expressions within it are then processed as specified in 14.9 below.

14.3.5 Scope of macro definitions [cpp.scope]

A macro definition lasts (independent of block structure) until a corresponding #undef directive is encountered or (if none is encountered) until the end of the translation unit. Macro definitions have no significance after translation phase 4.

A preprocessing directive of the form

```cpp
#define f(a) f(x * (a))
```

causes the specified identifier no longer to be defined as a macro name. It is ignored if the specified identifier is not currently defined as a macro name.

[Example: The simplest use of this facility is to define a “manifest constant”, as in

```cpp
#define TABSIZE 100
int table[TABSIZE];
```

—end example]

The following defines a function-like macro whose value is the maximum of its arguments. It has the advantages of working for any compatible types of the arguments and of generating in-line code without the overhead of function calling. It has the disadvantages of evaluating one or the other of its arguments a second time (including side effects) and generating more code than a function if invoked several times. It also cannot have its address taken, as it has none.

```cpp
#define max(a, b) ((a) > (b) ? (a) : (b))
```

The parentheses ensure that the arguments and the resulting expression are bound properly. —end example]

[Example: To illustrate the rules for redefinition and reexamination, the sequence

```cpp
#define x 3
#define f(a) f(x * (a))
#undef x
#define x 2
#define g f
#define z[0] g(~
#define m(a) a(w)
#define x 2
#define t(a) a
#define p() int
#define q(x) x
#define r(x,y) x ## y
#define str(x) # x

f(y+1) + f(f(z)) % t(t(g)(0) + t)(1);
g(x+(3,4)-w) | h 5) & m
```

results in

```cpp
f(2 * (y+1)) + f(2 * (f(2 * (z[0])))) % f(2 * (0)) + t(1);
f(2 * (2+(3,4)-0,1)) | f(2 * (~ 5)) & f(2 * (0,1))"m(0,1);
```

int i[] = { 1, 23, 4, 5, t};
char c[2][6] = { "hello", " " };
```

—end example]

§ 14.3.5 412
6 [Example: To illustrate the rules for creating character string literals and concatenating tokens, the sequence

```c
#define str(s) # s
#define xstr(s) str(s)
#define debug(s, t) printf("x" # s "= %d, x" # t "= %s", \
    x ## s, x ## t)
#define INCFILE(n) vers ## n
#define glue(a, b) a ## b
#define xglue(a, b) glue(a, b)
#define HIGHLOW "hello"
#define LOW LOW ", world"

define INCFILE(1) vers ## 1
#define glue(HIGH, LOW)
xglue(HIGH, LOW)
```

results in

```c
#define INCFILE(2) vers ## 2
#include xstr(INCFILE(2).h)
```

```
glue(HIGH, LOW);
xglue(HIGH, LOW)
```

results in

```c
#define INCFILE(2) vers ## 2
#include "vers2.h"  
```

```
#define INCFILE(2) vers ## 2
#include "vers2.h"  
```

Space around the # and ## tokens in the macro definition is optional. —end example]

7 [Example: To illustrate the rules for placemarker preprocessing tokens, the sequence

```c
#define t(x,y,z) x ## y ## z
```

```c
int j[] = { t(1,2,3), t(,4,5), t(6,,7), t(8,9,), t(10,,), t(,11,), t(,,12), t(,,) };
```

results in

```c
int j[] = { 123, 45, 67, 89, 10, 11, 12, };  
```

—end example]

8 [Example: To demonstrate the redefinition rules, the following sequence is valid.

```c
#define OBJ_LIKE (1-1)
#define OBJ_LIKE /* white space */ (1-1) /* other */
#define FUNC_LIKE(a) ( a )
#define FUNC_LIKE(b) ( b )
```

But the following redefinitions are invalid:

```c
#define OBJ_LIKE (0)       // different token sequence
#define OBJ_LIKE (1 - 1)    // different white space
#define FUNC_LIKE(b) ( a )  // different parameter usage
#define FUNC_LIKE(b) ( b )  // different parameter spelling
```

—end example]

9 [Example: Finally, to show the variable argument list macro facilities:

```c
#define debug(...) fprintf(stderr, __VA_ARGS__)
#define showlist(...) puts(#__VA_ARGS__)
#define report(test, ...) ((test) ? puts(#test) : printf(__VA_ARGS__))

define debug("Flag");
```
debug("X = %d\n", x);
showlist(The first, second, and third items.);
report(x>y, "x is %d but y is %d", x, y);

results in

fprintf(stderr, "Flag");
fprintf(stderr, "X = %d\n", x);
puts("The first, second, and third items.");
((x>y) ? puts("x>y") : printf("x is %d but y is %d", x, y));

—end example

14.4 Line control

1 The string literal of a #line directive, if present, shall be a character string literal.

2 The line number of the current source line is one greater than the number of new-line characters read or introduced in translation phase 1 (5.2) while processing the source file to the current token.

3 A preprocessing directive of the form

    # line digit-sequence new-line

causes the implementation to behave as if the following sequence of source lines begins with a source line that has a line number as specified by the digit sequence (interpreted as a decimal integer). If the digit sequence specifies zero or a number greater than 2147483647, the behavior is undefined.

4 A preprocessing directive of the form

    # line digit-sequence "s-char-sequence opt" new-line

sets the presumed line number similarly and changes the presumed name of the source file to be the contents of the character string literal.

5 A preprocessing directive of the form

    # line pp-tokens new-line

(that does not match one of the two previous forms) is permitted. The preprocessing tokens after line on the directive are processed just as in normal text (each identifier currently defined as a macro name is replaced by its replacement list of preprocessing tokens). If the directive resulting after all replacements does not match one of the two previous forms, the behavior is undefined; otherwise, the result is processed as appropriate.

14.5 Error directive

1 A preprocessing directive of the form

    # error pp-tokens opt new-line

causes the implementation to produce a diagnostic message that includes the specified sequence of preprocessing tokens, and renders the program ill-formed.

14.6 Pragma directive

1 A preprocessing directive of the form

    # pragma pp-tokens opt new-line

causes the implementation to behave in an implementation-defined manner. The behavior might cause translation to fail or cause the translator or the resulting program to behave in a non-conforming manner. Any pragma that is not recognized by the implementation is ignored.

14.7 Null directive

1 A preprocessing directive of the form

    # new-line

has no effect.

14.8 Predefined macro names

1 The following macro names shall be defined by the implementation:
The integer literal 201703L. [Note: It is intended that future versions of this International Standard will replace the value of this macro with a greater value. — end note]

The date of translation of the source file: a character string literal of the form "Mmm dd yyyy", where the names of the months are the same as those generated by the asctime function, and the first character of dd is a space character if the value is less than 10. If the date of translation is not available, an implementation-defined valid date shall be supplied.

The presumed name of the current source file (a character string literal).

The presumed line number (within the current source file) of the current source line (an integer literal).

The integer literal 1 if the implementation is a hosted implementation or the integer literal 0 if it is not.

An integer literal of type std::size_t whose value is the alignment guaranteed by a call to operator new (std::size_t) or operator new[] (std::size_t). [Note: Larger alignments will be passed to operator new (std::size_t, std::align_val_t), etc. (7.6.2.4). — end note]

The time of translation of the source file: a character string literal of the form "hh:mm:ss" as in the time generated by the asctime function. If the time of translation is not available, an implementation-defined valid time shall be supplied.

2 The following macro names are conditionally defined by the implementation:

```c
__STDC__
Whether __STDC__ is predefined and if so, what its value is, are implementation-defined.
```

```c
__STDC_MB_MIGHT_NEQ_WC__
The integer literal 1, intended to indicate that, in the encoding for wchar_t, a member of the basic character set need not have a code value equal to its value when used as the lone character in an ordinary character literal.
```

```c
__STDC_VERSION__
Whether __STDC_VERSION__ is predefined and if so, what its value is, are implementation-defined.
```

```c
__STDC_ISO_10646__
An integer literal of the form yyyymmL (for example, 199712L). If this symbol is defined, then every character in the Unicode required set, when stored in an object of type wchar_t, has the same value as the short identifier of that character. The Unicode required set consists of all the characters that are defined by ISO/IEC 10646, along with all amendments and technical corrigenda as of the specified year and month.
```

```c
__STDCPP STRICT POINTER SAFETY__
Defined, and has the value integer literal 1, if and only if the implementation has strict pointer safety (6.6.4.4.3).
```

```c
__STDCPP THREADS__
Defined, and has the value integer literal 1, if and only if a program can have more than one thread of execution (6.8.2).
```
3 The values of the predefined macros (except for \_\_FILE\_ and \_\_LINE\_) remain constant throughout the translation unit.

4 If any of the pre-defined macro names in this subclause, or the identifier defined, is the subject of a \#define or a \#undef preprocessing directive, the behavior is undefined. Any other predefined macro names shall begin with a leading underscore followed by an uppercase letter or a second underscore.

14.9 Pragma operator [cpp.pragma.op]

A unary operator expression of the form:

\_Pragma ( string-literal )

is processed as follows: The string literal is destringized by deleting the L prefix, if present, deleting the leading and trailing double-quotes, replacing each escape sequence \" by a double-quote, and replacing each escape sequence " by a single backslash. The resulting sequence of characters is processed through translation phase 3 to produce preprocessing tokens that are executed as if they were the pp-tokens in a pragma directive. The original four preprocessing tokens in the unary operator expression are removed.

[Example:

\#pragma listing on "..\listing.dir"

can also be expressed as:

\_Pragma ( "listing on "..\listing.dir\"" )

The latter form is processed in the same way whether it appears literally as shown, or results from macro replacement, as in:

\#define LISTING(x) PRAGMA(listing on #x)
\#define PRAGMA(x) \_Pragma(#x)

LISTING( ..\listing.dir )

— end example]
15 Library introduction

15.1 General

This Clause describes the contents of the C++ standard library, how a well-formed C++ program makes use of the library, and how a conforming implementation may provide the entities in the library.

The following subclauses describe the definitions (15.3), method of description (15.4), and organization (15.5.1) of the library. 15.5, Clause 16 through Clause 30, and Annex D specify the contents of the library, as well as library requirements and constraints on both well-formed C++ programs and conforming implementations.

Detailed specifications for each of the components in the library are in Clause 16–Clause 30, as shown in Table 17.

4 The language support library (Clause 16) provides components that are required by certain parts of the C++ language, such as memory allocation (7.6.2.4, 7.6.2.5) and exception processing (Clause 13).

5 The concepts library (Clause 17) describes library components that C++ programs may use to perform compile-time validation of template arguments and perform function dispatch based on properties of types.

6 The diagnostics library (Clause 18) provides a consistent framework for reporting errors in a C++ program, including predefined exception classes.

7 The general utilities library (Clause 19) includes components used by other library elements, such as a predefined storage allocator for dynamic storage management (6.6.4.4), and components used as infrastructure in C++ programs, such as tuples, function wrappers, and time facilities.

8 The strings library (Clause 20) provides support for manipulating text represented as sequences of type char, sequences of type char16_t, sequences of type char32_t, sequences of type wchar_t, and sequences of any other character-like type.

9 The localization library (Clause 26) provides extended internationalization support for text processing.

10 The containers (Clause 21), iterators (Clause 22), and algorithms (Clause 23) libraries provide a C++ program with access to a subset of the most widely used algorithms and data structures.

11 The numerics library (Clause 24) provides numeric algorithms and complex number components that extend support for numeric processing. The valarray component provides support for n-at-a-time processing, potentially implemented as parallel operations on platforms that support such processing. The random number component provides facilities for generating pseudo-random numbers.

12 The input/output library (Clause 27) provides the iostream components that are the primary mechanism for C++ program input and output. They can be used with other elements of the library, particularly strings, locales, and iterators.
The regular expressions library (Clause 28) provides regular expression matching and searching.

The atomic operations library (Clause 29) allows more fine-grained concurrent access to shared data than is possible with locks.

The thread support library (Clause 30) provides components to create and manage threads, including mutual exclusion and interthread communication.

15.2 The C standard library

The C++ standard library also makes available the facilities of the C standard library, suitably adjusted to ensure static type safety.

The descriptions of many library functions rely on the C standard library for the semantics of those functions. In some cases, the signatures specified in this document may be different from the signatures in the C standard library, and additional overloads may be declared in this document, but the behavior and the preconditions (including any preconditions implied by the use of an ISO C restrict qualifier) are the same unless otherwise stated.

15.3 Definitions

[Note: Clause 3 defines additional terms used elsewhere in this document. — end note]

15.3.1 arbitrary-positional stream

stream (described in Clause 27) that can seek to any integral position within the length of the stream

[Note 1 to entry: Every arbitrary-positional stream is also a repositional stream. — end note]

15.3.2 character

(Clause 20, Clause 26, Clause 27, and Clause 28) object which, when treated sequentially, can represent text

[Note 1 to entry: The term does not mean only char, char16_t, char32_t, and wchar_t objects, but any value that can be represented by a type that provides the definitions specified in these Clauses. — end note]

15.3.3 character container type

class or a type used to represent a character

[Note 1 to entry: It is used for one of the template parameters of the string, iostream, and regular expression class templates. — end note]

15.3.4 comparison function

operator function (11.5) for any of the equality (7.6.10) or relational (7.6.9) operators

15.3.5 component

group of library entities directly related as members, parameters, or return types

[Note 1 to entry: For example, the class template basic_string and the non-member function templates that operate on strings are referred to as the string component. — end note]

15.3.6 constant subexpression

expression whose evaluation as subexpression of a conditional-expression CE (7.6.16) would not prevent CE from being a core constant expression (7.7)

15.3.7 deadlock

situation wherein one or more threads are unable to continue execution because each is blocked waiting for one or more of the others to satisfy some condition

15.3.8 default behavior

(implementation) specific behavior provided by the implementation, within the scope of the required behavior
15.3.9 default behavior
(specification) description of replacement function and handler function semantics

15.3.10 direct-non-list-initialization
direct-initialization (9.3) that is not list-initialization (9.3.4)

15.3.11 expression-equivalent
expressions that all have the same effects, either are all potentially-throwing (13.4) or are all not potentially-throwing, and either are all constant subexpressions or are all not constant subexpressions

[Example: For a value \( x \) of type \( \text{int} \) and a function \( f \) that accepts integer arguments, the expressions \( f(x + 2) \), \( f(2 + x) \), and \( f(1 + x + 1) \) are expression-equivalent. — end example]

15.3.12 handler function
non-reserved function whose definition may be provided by a C++ program

[Note 1 to entry: A C++ program may designate a handler function at various points in its execution by supplying a pointer to the function when calling any of the library functions that install handler functions (Clause 16). — end note]

15.3.13 iostream class templates
templates, defined in Clause 27, that take two template arguments

[Note 1 to entry: The arguments are named \( \text{charT} \) and \( \text{traits} \). The argument \( \text{charT} \) is a character container class, and the argument \( \text{traits} \) is a class which defines additional characteristics and functions of the character type represented by \( \text{charT} \) necessary to implement the iostream class templates. — end note]

15.3.14 modifier function
class member function (10.3.1) other than a constructor, assignment operator, or destructor that alters the state of an object of the class

15.3.15 move assignment
assignment of an rvalue of some object type to a modifiable lvalue of the same type

15.3.16 move construction
direct-initialization of an object of some type with an rvalue of the same type

15.3.17 NTCTS
sequence of values that have character type that precede the terminating null character type value \( \text{charT}() \)

15.3.18 observer function
class member function (10.3.1) that accesses the state of an object of the class but does not alter that state

[Note 1 to entry: Observer functions are specified as \( \text{const} \) member functions (10.3.2.1). — end note]

15.3.19 program-defined specialization
explicit template specialization or partial specialization that is not part of the C++ standard library and not defined by the implementation
15.3.20  
program-defined type  
class type or enumeration type that is not part of the C++ standard library and not defined by the implementation, or an instantiation of a program-defined specialization  
[Note 1 to entry: Types defined by the implementation include extensions (4.1) and internal types used by the library. — end note]

15.3.21  
referenceable type  
type that is either an object type, a function type that does not have cv-qualifiers or a ref-qualifier, or a reference type  
[Note 1 to entry: The term describes a type to which a reference can be created, including reference types. — end note]

15.3.22  
replacement function  
non-reserved function whose definition is provided by a C++ program  
[Note 1 to entry: Only one definition for such a function is in effect for the duration of the program’s execution, as the result of creating the program (5.2) and resolving the definitions of all translation units (6.5). — end note]

15.3.23  
repositional stream  
stream (described in Clause 27) that can seek to a position that was previously encountered

15.3.24  
required behavior  
description of replacement function and handler function semantics applicable to both the behavior provided by the implementation and the behavior of any such function definition in the program  
[Note 1 to entry: If such a function defined in a C++ program fails to meet the required behavior when it executes, the behavior is undefined. — end note]

15.3.25  
reserved function  
fuction, specified as part of the C++ standard library, that is defined by the implementation  
[Note 1 to entry: If a C++ program provides a definition for any reserved function, the results are undefined. — end note]

15.3.26  
stable algorithm  
algorithm that preserves, as appropriate to the particular algorithm, the order of elements  
[Note 1 to entry: Requirements for stable algorithms are given in 15.5.5.7. — end note]

15.3.27  
traits class  
class that encapsulates a set of types and functions necessary for class templates and function templates to manipulate objects of types for which they are instantiated

15.3.28  
valid but unspecified state  
value of an object that is not specified except that the object’s invariants are met and operations on the object behave as specified for its type  
[Example: If an object \( x \) of type `std::vector<int>` is in a valid but unspecified state, \( x.empty() \) can be called unconditionally, and \( x.front() \) can be called only if \( x.empty() \) returns `false`. — end example]
15.4 Method of description (Informative) [description]

This subclause describes the conventions used to specify the C++ standard library. 15.4.1 describes the structure of the normative Clause 16 through Clause 30 and Annex D. 15.4.2 describes other editorial conventions.

15.4.1 Structure of each clause [structure]

15.4.1.1 Elements [structure.elements]

1 Each library clause contains the following elements, as applicable:156

(1.1) — Summary
(1.2) — Requirements
(1.3) — Detailed specifications
(1.4) — References to the C standard library

15.4.1.2 Summary [structure.summary]

1 The Summary provides a synopsis of the category, and introduces the first-level subclauses. Each subclause also provides a summary, listing the headers specified in the subclause and the library entities provided in each header.

2 The contents of the summary and the detailed specifications include:

(2.1) — macros
(2.2) — values
(2.3) — types
(2.4) — classes and class templates
(2.5) — functions and function templates
(2.6) — objects
(2.7) — concepts

15.4.1.3 Requirements [structure.requirements]

1 Requirements describe constraints that shall be met by a C++ program that extends the standard library. Such extensions are generally one of the following:

(1.1) — Template arguments
(1.2) — Derived classes
(1.3) — Containers, iterators, and algorithms that meet an interface convention or satisfy a concept

2 The string and iostream components use an explicit representation of operations required of template arguments. They use a class template char_traits to define these constraints.

3 Interface convention requirements are stated as generally as possible. Instead of stating “class X has to define a member function operator++( )”, the interface requires “for any object x of class X, ++x is defined”. That is, whether the operator is a member is unspecified.

4 Requirements are stated in terms of well-defined expressions that define valid terms of the types that satisfy the requirements. For every set of well-defined expression requirements there is either a named concept or a table that specifies an initial set of the valid expressions and their semantics. Any generic algorithm (Clause 23) that uses the well-defined expression requirements is described in terms of the valid expressions for its template type parameters.

5 The library specification uses a typographical convention for naming requirements. Names in italic type that begin with the prefix Cpp17 refer to sets of well-defined expression requirements typically presented in tabular form, possibly with additional prose semantic requirements. For example, Cpp17Destructible (Table 29) is such a named requirement. Names in constant width type refer to library concepts which are presented as a concept definition (Clause 12), possibly with additional prose semantic requirements. For example, Destructible (17.4.10) is such a named requirement.

156) To save space, items that do not apply to a Clause are omitted. For example, if a Clause does not specify any requirements, there will be no “Requirements” subclause.
Template argument requirements are sometimes referenced by name. See 15.4.2.1.

In some cases the semantic requirements are presented as C++ code. Such code is intended as a specification of equivalence of a construct to another construct, not necessarily as the way the construct must be implemented.\textsuperscript{157}

Required operations of any concept defined in this document need not be total functions; that is, some arguments to a required operation may result in the required semantics failing to be satisfied. \textit{Example:} The required $<$ operator of the \texttt{StrictTotallyOrdered} concept (17.5.4) does not meet the semantic requirements of that concept when operating on NaNs. \textit{—end example} This does not affect whether a type satisfies the concept.

A declaration may explicitly impose requirements through its associated constraints (12.4.2). When the associated constraints refer to a concept (12.6.8), the semantic constraints specified for that concept are additionally imposed on the use of the declaration.

### 15.4.1.4 Detailed specifications

The detailed specifications each contain the following elements:

- name and brief description
- synopsis (class definition or function declaration, as appropriate)
- restrictions on template arguments, if any
- description of class invariants
- description of function semantics

Descriptions of class member functions follow the order (as appropriate):\textsuperscript{158}

- constructor(s) and destructor
- copying, moving & assignment functions
- comparison functions
- modifier functions
- observer functions
- operators and other non-member functions

Descriptions of function semantics contain the following elements (as appropriate):\textsuperscript{159}

- \textit{Requires}: the preconditions for calling the function.
- \textit{Constraints}: the conditions for the function’s participation in overload resolution (11.3). \textit{[Note:} Failure to meet such a condition results in the function’s silent non-viability. \textit{—end note]} \textit{[Example:} An implementation might express such a condition via a \texttt{constraint-expression} (12.4.2). \textit{—end example]}
- \textit{Mandates}: the conditions that, if not met, render the program ill-formed. \textit{[Example:} An implementation might express such a condition via the \texttt{constant-expression} in a \texttt{static assert-declaration} (Clause 9). If the diagnostic is to be emitted only after the function has been selected by overload resolution, an implementation might express such a condition via a \texttt{constraint-expression} (12.4.2) and also define the function as deleted. \textit{—end example]}
- \textit{Expects}: the conditions (sometimes termed preconditions) that the function assumes to hold whenever it is called. \textit{[Example:} An implementation might express such conditions via an attribute such as \texttt{[[expects]]} (9.11.4). However, some such conditions might not lend themselves to expression via code. \textit{—end example]}
- \textit{Effects}: the actions performed by the function.
- \textit{Synchronization}: the synchronization operations (6.8.2) applicable to the function.
- \textit{Ensures}: the conditions (sometimes termed observable results or postconditions) established by the function.

\textsuperscript{157} Although in some cases the code given is unambiguously the optimum implementation.

\textsuperscript{158} To save space, items that do not apply to a class are omitted. For example, if a class does not specify any comparison functions, there will be no “Comparison functions” subclause.

\textsuperscript{159} To save space, elements that do not apply to a function are omitted. For example, if a function specifies no preconditions, there will be no \textit{Expects:} element.
Whenever the Effects element specifies that the semantics of some function F are Equivalent to some code sequence, then the various elements are interpreted as follows. If F’s semantics specifies any Constraints or Mandates elements, then those requirements are logically imposed prior to the equivalent-to semantics. Next, the semantics of the code sequence are determined by the Constraints, Mandates, Expects, Effects, Synchronization, Ensures, Returns, Throws, Complexity, Remarks, and Error conditions specified for the function invocations contained in the code sequence. The value returned from F is specified by F’s Returns element, or if F has no Returns element, a non-void return from F is specified by the return statements (8.6.3) in the code sequence. If F’s semantics contains a Throws, Ensures, or Complexity element, then that supersedes any occurrences of that element in the code sequence.

For non-reserved replacement and handler functions, Clause 16 specifies two behaviors for the functions in question: their required and default behavior. The default behavior describes a function definition provided by the implementation. The required behavior describes the semantics of a function definition provided by either the implementation or a C++ program. Where no distinction is explicitly made in the description, the behavior described is the required behavior.

If the formulation of a complexity requirement calls for a negative number of operations, the actual requirement is zero operations.\(^{160}\)

Complexity requirements specified in the library clauses are upper bounds, and implementations that provide better complexity guarantees satisfy the requirements.

Error conditions specify conditions where a function may fail. The conditions are listed, together with a suitable explanation, as the enum class errc constants (18.5).

15.4.1.5 C library

Paragraphs labeled “See also” contain cross-references to the relevant portions of other standards (Clause 2).

15.4.2 Other conventions

This subclause describes several editorial conventions used to describe the contents of the C++ standard library. These conventions are for describing implementation-defined types (15.4.2.1), and member functions (15.4.2.2).

15.4.2.1 Type descriptions

15.4.2.1.1 General

The Requirements subclauses may describe names that are used to specify constraints on template arguments.\(^{161}\) These names are used in library Clauses to describe the types that may be supplied as arguments by a C++ program when instantiating template components from the library.

Certain types defined in Clause 27 are used to describe implementation-defined types. They are based on other types, but with added constraints.

15.4.2.1.2 Exposition-only types

Several types defined in Clause 16 through Clause 30 and Annex D that are used as function parameter or return types are defined for the purpose of exposition only in order to capture their language linkage. The declarations of such types are followed by a comment ending in exposition only. [Example:

```cpp
namespace std {
    extern "C" using some-handler = int(int, void*, double);  // exposition only
}
```

The type placeholder some-handler can now be used to specify a function that takes a callback parameter with C language linkage. — end example]
15.4.2.1.3 Enumerated types

Several types defined in Clause 27 are enumerated types. Each enumerated type may be implemented as an enumeration or as a synonym for an enumeration.\(^{162}\)

The enumerated type `enumerated` can be written:

```c
enum enumerated { V0, V1, V2, V3, ... };
inline const enumerated C0(V0);
inline const enumerated C1(V1);
inline const enumerated C2(V2);
inline const enumerated C3(V3);
...;
```

Here, the names `C_0`, `C_1`, etc. represent enumerated elements for this particular enumerated type. All such elements have distinct values.

15.4.2.1.4 Bitmask types

Several types defined in Clause 16 through Clause 30 and Annex D are bitmask types. Each bitmask type can be implemented as an enumerated type that overloads certain operators, as an integer type, or as a `bitset` (19.9.2).

The bitmask type `bitmask` can be written:

```c
// For exposition only.
// int_type is an integral type capable of representing all values of the bitmask type.
enum bitmask : int_type {
    V0 = 1 << 0,
    V1 = 1 << 1,
    V2 = 1 << 2,
    V3 = 1 << 3,
    ...;
}
inline constexpr bitmask C0(V0);
inline constexpr bitmask C1(V1);
inline constexpr bitmask C2(V2);
inline constexpr bitmask C3(V3);
...;
```

```c
constexpr bitmask operator&(bitmask X, bitmask Y) {
    return static_cast<bitmask>(static_cast<int_type>(X) & static_cast<int_type>(Y));
}
constexpr bitmask operator|(bitmask X, bitmask Y) {
    return static_cast<bitmask>(static_cast<int_type>(X) | static_cast<int_type>(Y));
}
constexpr bitmask operator^ (bitmask X, bitmask Y) {
    return static_cast<bitmask>(static_cast<int_type>(X) ^ static_cast<int_type>(Y));
}
constexpr bitmask operator~ (bitmask X) {
    return static_cast<bitmask>(~static_cast<int_type>(X));
}
```

```c
bitmask& operator&=(bitmask& X, bitmask Y) {
    X = X & Y; return X;
}
bitmask& operator|=(bitmask& X, bitmask Y) {
    X = X | Y; return X;
}
bitmask& operator^=(bitmask& X, bitmask Y) {
    X = X ^ Y; return X;
}
```

\(^{162}\) Such as an integer type, with constant integer values (6.7.1).
Here, the names \( C_0, C_1, \ldots \) represent bitmask elements for this particular bitmask type. All such elements have distinct, nonzero values such that, for any pair \( C_i \) and \( C_j \) where \( i \neq j \), \( C_i \) is nonzero and \( C_i \land C_j \) is zero. Additionally, the value 0 is used to represent an empty bitmask, in which no bitmask elements are set.

The following terms apply to objects and values of bitmask types:

- To set a value \( Y \) in an object \( X \) is to evaluate the expression \( X \text{ |= } Y \).
- To clear a value \( Y \) in an object \( X \) is to evaluate the expression \( X \text{ &= } \sim Y \).
- The value \( Y \) is set in the object \( X \) if the expression \( X \text{ & } Y \) is nonzero.

### 15.4.2.1.5 Character sequences

The C standard library makes widespread use of characters and character sequences that follow a few uniform conventions:

- A letter is any of the 26 lowercase or 26 uppercase letters in the basic execution character set.
- The decimal-point character is the (single-byte) character used by functions that convert between a (single-byte) character sequence and a value of one of the floating-point types. It is used in the character sequence to denote the beginning of a fractional part. It is represented in Clause 16 through Clause 30 and Annex D by a period, \( '.' \), which is also its value in the "C" locale, but may change during program execution by a call to \text{setlocale}(int, const char*),\(^\text{163}\) or by a change to a \text{locale} object, as described in Clause 26.3 and Clause 27.
- A character sequence is an array object (9.2.3.4) \( A \) that can be declared as \( T A[N] \), where \( T \) is any of the types \text{char}, \\text{unsigned char}, \text{or signed char} (6.7.1), optionally qualified by any combination of \text{const} or \text{volatile}. The initial elements of the array have defined contents up to and including an element determined by some predicate. A character sequence can be designated by a pointer value \( S \) that points to its first element.

### 15.4.2.1.5.1 Byte strings

A null-terminated byte string, or NTBS, is a character sequence whose highest-addressed element with defined content has the value zero (the terminating null character); no other element in the sequence has the value zero.\(^\text{164}\)

The length of an NTBS is the number of elements that precede the terminating null character. An empty NTBS has a length of zero.

The value of an NTBS is the sequence of values of the elements up to and including the terminating null character.

A static NTBS is an NTBS with static storage duration.\(^\text{165}\)

### 15.4.2.1.5.2 Multibyte strings

A null-terminated multibyte string, or NTMBS, is an NTBS that constitutes a sequence of valid multibyte characters, beginning and ending in the initial shift state.\(^\text{166}\)

A static NTMBS is an NTMBS with static storage duration.

### 15.4.2.1.6 Customization Point Object types

A customization point object is a function object (19.14) with a literal class type that interacts with program-defined types while enforcing semantic requirements on that interaction.

The type of a customization point object shall satisfy \text{Semiregular} (17.6).

All instances of a specific customization point object type shall be equal (17.2).

The type \( T \) of a customization point object shall satisfy \text{Invocable<const Tk, Args...>} (17.7.2) when the types in \text{Args}... meet the requirements specified in that customization point object's definition. When the types of \text{Args}... do not meet the customization point object's requirements, \( T \) shall not have a function call operator that participates in overload resolution.

---

163) declared in \texttt{<locale>} (26.5).
164) Many of the objects manipulated by function signatures declared in \texttt{<cstring>} (20.5) are character sequences or NTBSs. The size of some of these character sequences is limited by a length value, maintained separately from the character sequence.
165) A string literal, such as "abc", is a static NTBS.
166) An NTBS that contains characters only from the basic execution character set is also an NTMBS. Each multibyte character then consists of a single byte.
Each customization point object type constrains its return type to satisfy a particular concept.

[Note: Many of the customization point objects in the library evaluate function call expressions with an unqualified name which results in a call to a program-defined function found by argument dependent name lookup (6.4.2). To preclude such an expression resulting in a call to unconstrained functions with the same name in namespace std, customization point objects specify that lookup for these expressions is performed in a context that includes deleted overloads matching the signatures of overloads defined in namespace std. When the deleted overloads are viable, program-defined overloads need be more specialized (12.6.6.2) or more constrained (12.4.4) to be used by a customization point object. — end note]

15.4.2.2 Functions within classes

For the sake of exposition, Clause 16 through Clause 30 and Annex D do not describe copy/move constructors, assignment operators, or (non-virtual) destructors with the same apparent semantics as those that can be generated by default (10.3.5, 10.3.6, 10.3.7). It is unspecified whether the implementation provides explicit definitions for such member function signatures, or for virtual destructors that can be generated by default.

15.4.2.3 Operators

In this library, whenever a declaration is provided for an operator!=, operator>, operator<=, or operator>= for a type T, its requirements and semantics are as follows, unless explicitly specified otherwise.

```cpp
bool operator!=(const T& x, const T& y);

Requires: Type T is Cpp17EqualityComparable (Table 22).
Returns: !(x == y).

bool operator>=(const T& x, const T& y);

Requires: Type T is Cpp17LessThanComparable (Table 23).
Returns: !(y < x).
```

15.4.2.4 Private members

Clause 16 through Clause 30 and Annex D do not specify the representation of classes, and intentionally omit specification of class members (10.3). An implementation may define static or non-static class members, or both, as needed to implement the semantics of the member functions specified in Clause 16 through Clause 30 and Annex D.

For the sake of exposition, some subclauses provide representative declarations, and semantic requirements, for private members of classes that meet the external specifications of the classes. The declarations for such members are followed by a comment that ends with exposition only, as in:

```cpp
streambuf* sb; // exposition only
```

An implementation may use any technique that provides equivalent observable behavior.

15.5 Library-wide requirements

This subclause specifies requirements that apply to the entire C++ standard library. Clause 16 through Clause 30 and Annex D specify the requirements of individual entities within the library.

Requirements specified in terms of interactions between threads do not apply to programs having only a single thread of execution.

Within this subclause, 15.5.1 describes the library’s contents and organization, 15.5.2 describes how well-formed C++ programs gain access to library entities, 15.5.3 describes constraints on types and functions used with the C++ standard library, 15.5.4 describes constraints on well-formed C++ programs, and 15.5.5 describes constraints on conforming implementations.
15.5.1 Library contents and organization

15.5.1.1 Library contents

The C++ standard library provides definitions for the entities and macros described in the synopses of the C++ standard library headers (15.5.1.2).

2 All library entities except operator new and operator delete are defined within the namespace std or namespaces nested within namespace std. It is unspecified whether names declared in a specific namespace are declared directly in that namespace or in an inline namespace inside that namespace.

3 Whenever a name x defined in the standard library is mentioned, the name x is assumed to be fully qualified as ::std::x, unless explicitly described otherwise. For example, if the Effects: element for library function F is described as calling library function G, the function ::std::G is meant.

15.5.1.2 Headers

Each element of the C++ standard library is declared or defined (as appropriate) in a header.

The C++ standard library provides the C++ library headers, shown in Table 18.

<table>
<thead>

4 Except as noted in Clause 15 through Clause 30 and Annex D, the contents of each header cname is the same as that of the corresponding header name.h as specified in the C standard library (Clause 2). In the C++ standard library, however, the declarations (except for names which are defined as macros in C) are D.6 also define names within the global namespace, while the C++ headers for C library facilities (15.5.1.2) may also define names within the global namespace. This gives implementers freedom to use inline namespaces to support multiple configurations of the library. A header is not necessarily a source file, nor are the sequences delimited by < and > in header names necessarily valid source file names (14.2). It is intentional that there is no C++ header for any of these C headers: <stdatomic.h>, <stdnoreturn.h>, <threads.h>
within namespace scope (6.3.6) of the namespace std. It is unspecified whether these names (including any overloads added in Clause 16 through Clause 30 and Annex D) are first declared within the global namespace scope and are then injected into namespace std by explicit using-declarations (9.8).

Names which are defined as macros in C shall be defined as macros in the C++ standard library, even if C grants license for implementation as functions. \[\text{Note: The names defined as macros in C include the following: assert, offsetof, setjmp, va_arg, va_end, and va_start. — end note}\]

Names that are defined as functions in C shall be defined as functions in the C++ standard library.\[171\]

Identifiers that are keywords or operators in C++ shall not be defined as macros in C++ standard library headers.\[172\]

D.6, C standard library headers, describes the effects of using the name .h (C header) form in a C++ program.\[173\]

Annex K of the C standard describes a large number of functions, with associated types and macros, which “promote safer, more secure programming” than many of the traditional C library functions. The names of the functions have a suffix of _s; most of them provide the same service as the C library function with the unsuffixed name, but generally take an additional argument whose value is the size of the result array. If any C++ header is included, it is implementation-defined whether any of these names is declared in the global namespace. (None of them is declared in namespace std.)

Table 20 lists the Annex K names that may be declared in some header. These names are also subject to the restrictions of 15.5.4.3.2.

15.5.1.3 Freestanding implementations

Two kinds of implementations are defined: hosted and freestanding (4.1). For a hosted implementation, this document describes the set of available headers.

A freestanding implementation has an implementation-defined set of headers. This set shall include at least the headers shown in Table 21.

The supplied version of the header <cstdlib> shall declare at least the functions abort, atexit, at_quick_exit, exit, and quick_exit (16.5). The other headers listed in this table shall meet the same requirements as for a hosted implementation.

171) This disallows the practice, allowed in C, of providing a masking macro in addition to the function prototype. The only way to achieve equivalent inline behavior in C++ is to provide a definition as an extern inline function.

172) In particular, including the standard header <iso646.h> has no effect.

173) The .h* headers dump all their names into the global namespace, whereas the newer forms keep their names in namespace std. Therefore, the newer forms are the preferred forms for all uses except for C++ programs which are intended to be strictly compatible with C.

15.5.2 Using the library

15.5.2.1 Overview

Subclause 15.5.2 describes how a C++ program gains access to the facilities of the C++ standard library. 15.5.2.2 describes effects during translation phase 4, while 15.5.2.3 describes effects during phase 8 (5.2).

15.5.2.2 Headers

The entities in the C++ standard library are defined in headers, whose contents are made available to a translation unit when it contains the appropriate `#include` preprocessing directive (14.2).

A translation unit may include library headers in any order (Clause 5). Each may be included more than once, with no effect different from being included exactly once, except that the effect of including either `<cassert>` or `<assert.h>` depends each time on the lexically current definition of `NDEBUG`.

A translation unit shall include a header only outside of any declaration or definition, and shall include the header lexically before the first reference in that translation unit to any of the entities declared in that header. No diagnostic is required.

15.5.2.3 Linkage

Entities in the C++ standard library have external linkage (6.5). Unless otherwise specified, objects and functions have the default `extern "C++"` linkage (9.10).

Whether a name from the C standard library declared with external linkage has `extern "C"` or `extern "C++"` linkage is implementation-defined. It is recommended that an implementation use `extern "C++"` linkage for this purpose.

Objects and functions defined in the library and required by a C++ program are included in the program prior to program startup.

See also replacement functions (15.5.4.6), runtime changes (15.5.4.7).

15.5.3 Requirements on types and expressions

15.5.3.1 describes requirements on types and expressions used to instantiate templates defined in the C++ standard library. 15.5.3.2 describes the requirements on swappable types and swappable expressions. 15.5.3.3 describes the requirements on pointer-like types that support null values. 15.5.3.4 describes the requirements on hash function objects. 15.5.3.5 describes the requirements on storage allocators.

15.5.3.1 Template argument requirements

The template definitions in the C++ standard library refer to various named requirements whose details are set out in Tables 22–29. In these tables, `T` is an object or reference type to be supplied by a C++ program instantiating a template; `a`, `b`, and `c` are values of type (possibly `const`) `T`; `s` and `t` are modifiable lvalues of

---

174) This is the same as the C standard library.

175) The only reliable way to declare an object or function signature from the C standard library is by including the header that declares it, notwithstanding the latitude granted in 7.1.4 of the C Standard.
type `T`; `u` denotes an identifier; `rv` is an rvalue of type `T`; and `v` is an lvalue of type (possibly `const`) `T` or an rvalue of type `const T`.

2 In general, a default constructor is not required. Certain container class member function signatures specify `T()` as a default argument. `T()` shall be a well-defined expression (9.3) if one of those signatures is called using the default argument (9.2.3.6).

<td>All resources owned by u are reclaimed, no exception is propagated.</td>
</tr>
</tbody>
</table>

15.5.3.2 Swappable requirements

1 This subclause provides definitions for swappable types and expressions. In these definitions, let t denote an expression of type T, and let u denote an expression of type U.

2 An object t is swappable with an object u if and only if:

(2.1) — the expressions swap(t, u) and swap(u, t) are valid when evaluated in the context described below, and

(2.2) — these expressions have the following effects:

(2.2.1) — the object referred to by t has the value originally held by u and

(2.2.2) — the object referred to by u has the value originally held by t.

3 The context in which swap(t, u) and swap(u, t) are evaluated shall ensure that a binary non-member function named “swap” is selected via overload resolution (11.3) on a candidate set that includes:

(3.1) — the two swap function templates defined in <utility> (19.2) and

(3.2) — the lookup set produced by argument-dependent lookup (6.4.2).

[Note: If T and U are both fundamental types or arrays of fundamental types and the declarations from the header <utility> are in scope, the overall lookup set described above is equivalent to that of the qualified name lookup applied to the expression std::swap(t, u) or std::swap(u, t) as appropriate. — end note]

[Note: It is unspecified whether a library component that has a swappable requirement includes the header <utility> to ensure an appropriate evaluation context. — end note]

4 An rvalue or lvalue t is swappable if and only if t is swappable with any rvalue or lvalue, respectively, of type T.

5 A type X satisfying any of the iterator requirements (22.2) satisfies the Cpp17ValueSwappable requirements if, for any dereferenceable object x of type X, *x is swappable.

[Example: User code can ensure that the evaluation of swap calls is performed in an appropriate context under the various conditions as follows:

#include <utility>
// Requires: std::forward<T>(t) shall be swappable with std::forward<U>(u).
template<class T, class U>
void value_swap(T&& t, U&& u) {
    using std::swap;
    swap(std::forward<T>(t), std::forward<U>(u)); // OK: uses “swappable with” conditions
    // for rvalues and lvalues
}

// Requires: lvalues of T shall be swappable.
template<class T>
void lv_swap(T& t1, T& t2) {
    using std::swap;
    swap(t1, t2); // OK: uses swappable conditions for lvalues of type T
}

namespace N {
    struct A { int m; }
    struct Proxy { A* a; }
    Proxy proxy(A& a) { return Proxy{ &a }; }

    void swap(A& x, Proxy p) {
        std::swap(x.m, p.a->m); // OK: uses context equivalent to swappable
        // conditions for fundamental types
    }
    void swap(Proxy p, A& x) { swap(x, p); } // satisfy symmetry constraint
}

int main() {
    int i = 1, j = 2;
    lv_swap(i, j);
    assert(i == 2 && j == 1);

    N::A a1 = { 5 }, a2 = { -5 };
    value_swap(a1, proxy(a2));
    assert(a1.m == -5 && a2.m == 5);
}

—end example]

15.5.3.3 Cpp17NullablePointer requirements [nullablepointer.requirements]
1 A Cpp17NullablePointer type is a pointer-like type that supports null values. A type P satisfies the Cpp17NullablePointer requirements if:
   (1.1) — P satisfies the Cpp17EqualityComparable, Cpp17DefaultConstructible, Cpp17CopyConstructible, Cpp17CopyAssignable, and Cpp17Destructible requirements,
   (1.2) — lvalues of type P are swappable (15.5.3.2),
   (1.3) — the expressions shown in Table 30 are valid and have the indicated semantics, and
   (1.4) — P satisfies all the other requirements of this subclause.
2 A value-initialized object of type P produces the null value of the type. The null value shall be equivalent only to itself. A default-initialized object of type P may have an indeterminate value. [Note: Operations involving indeterminate values may cause undefined behavior. — end note]
3 An object p of type P can be contextually converted to bool (7.3). The effect shall be as if p != nullptr had been evaluated in place of p.
4 No operation which is part of the Cpp17NullablePointer requirements shall exit via an exception.
5 In Table 30, u denotes an identifier, t denotes a non-const lvalue of type P, a and b denote values of type (possibly const) P, and np denotes a value of type (possibly const) std::nullptr_t.

15.5.3.4 Cpp17Hash requirements [hash.requirements]
1 A type H meets the Cpp17Hash requirements if:
   (1.1) — it is a function object type (19.14),
Table 30 — Cpp17NullablePointer requirements

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
</tr>
</thead>
<tbody>
<tr>
<td>P u(np); P u = np;</td>

(1.2) — it satisfies the Cpp17CopyConstructible (Table 26) and Cpp17Destructible (Table 29) requirements, and
(1.3) — the expressions shown in Table 31 are valid and have the indicated semantics.

2 Given Key is an argument type for function objects of type H, in Table 31 h is a value of type (possibly const) H, u is an lvalue of type Key, and k is a value of a type convertible to (possibly const) Key.

Table 31 — Cpp17Hash requirements

[Note: Thus all evaluations of the expression h(k) with the same value for k yield the same result for a given execution of the program. — end note] [Note: For two different values t1 and t2, the probability that h(t1) and h(t2) compare equal should be very small, approaching 1.0 / numeric_limits&lt;size_t&gt;::max(). — end note]</td>
</tr>
<tr>
<td>h(u)</td>
<td>size_t</td>
<td>Shall not modify u.</td>
</tr>
</tbody>
</table>

15.5.3.5 Cpp17Allocator requirements [allocator.requirements]

1 The library describes a standard set of requirements for allocators, which are class-type objects that encapsulate the information about an allocation model. This information includes the knowledge of pointer types, the type of their difference, the type of the size of objects in this allocation model, as well as the memory allocation and deallocation primitives for it. All of the string types (Clause 20), containers (Clause 21) (except array), string buffers and string streams (Clause 27), and match_results (Clause 28) are parameterized in terms of allocators.

2 The class template allocator_traits (19.10.9) supplies a uniform interface to all allocator types. Table 32 describes the types manipulated through allocators. Table 33 describes the requirements on allocator types and thus on types used to instantiate allocator_traits. A requirement is optional if the last column of Table 33 specifies a default for a given expression. Within the standard library allocator_traits template, an optional requirement that is not supplied by an allocator is replaced by the specified default expression. A user specialization of allocator_traits may provide different defaults and may provide defaults for different requirements than the primary template. Within Tables 32 and 33, the use of move and forward always refers to std::move and std::forward, respectively.

<td>is_empty&lt;X&gt;::type</td>
</tr>
</tbody>
</table>

3 Note A: The member class template *rebind* in the table above is effectively a typedef template. [Note: In general, if the name *Allocator* is bound to *SomeAllocator<T>* , then *Allocator::rebind<U>::other* is the same type as *SomeAllocator<U>*, where SomeAllocator<T>::value_type is T and SomeAllocator<U>::value_type is U. — end note] If *Allocator* is a class template instantiation of the form SomeAllocator<T>, ...
where Args is zero or more type arguments, and Allocator does not supply a rebind member template, the standard allocator_traits template uses SomeAllocator<U, Args> in place of Allocator::rebind<U>::other by default. For allocator types that are not template instantiations of the above form, no default is provided.

Note B: If X::propagate_on_container_copy_assignment::value is true, X shall satisfy the Cpp17CopyAssignable requirements (Table 28) and the copy operation shall not throw exceptions. If X::propagate_on_container_move_assignment::value is true, X shall satisfy the Cpp17MoveAssignable requirements (Table 27) and the move operation shall not throw exceptions. If X::propagate_on_container_swap::value is true, lvalues of type X shall be swappable (15.5.3.2) and the swap operation shall not throw exceptions.

An allocator type X shall satisfy the Cpp17CopyConstructible requirements (Table 26). The X::pointer, X::const_pointer, X::void_pointer, and X::const_void_pointer types shall satisfy the Cpp17NullablePointer requirements (Table 30). No constructor, comparison function, copy operation, move operation, or swap operation on these pointer types shall exit via an exception. X::pointer and X::const_pointer shall also satisfy the requirements for a random access iterator (22.2.7) and of a contiguous iterator (22.2.1).

Let x1 and x2 denote objects of (possibly different) types X::void_pointer, X::const_void_pointer, X::pointer, or X::const_pointer. Then, x1 and x2 are equivalently-valued pointer values, if and only if both x1 and x2 can be explicitly converted to the two corresponding objects px1 and px2 of type X::const_pointer, using a sequence of static_casts using only these four types, and the expression px1 == px2 evaluates to true.

Let w1 and w2 denote objects of type X::void_pointer. Then for the expressions

w1 == w2
w1 != w2

either or both objects may be replaced by an equivalently-valued object of type X::const_void_pointer with no change in semantics.

Let p1 and p2 denote objects of type X::pointer. Then for the expressions

p1 == p2
p1 != p2
p1 < p2
p1 <= p2
p1 > p2
p1 >= p2
p1 - p2

either or both objects may be replaced by an equivalently-valued object of type X::const_pointer with no change in semantics.

An allocator may constrain the types on which it can be instantiated and the arguments for which its construct or destroy members may be called. If a type cannot be used with a particular allocator, the allocator class or the call to construct or destroy may fail to instantiate.

[Example: The following is an allocator class template supporting the minimal interface that satisfies the requirements of Table 33:

```cpp
template<class Tp>
struct SimpleAllocator {
    typedef Tp value_type;
    SimpleAllocator(ctor args);

    template<class T> SimpleAllocator(T& other);

    [[nodiscard]] T* allocate(std::size_t n);
    void deallocate(T* p, std::size_t n);
};

template<class T, class U>
bool operator=(const SimpleAllocator<T>&, const SimpleAllocator<U>&);

template<class T, class U>
bool operator=(const SimpleAllocator<T>&, const SimpleAllocator<U>&);

— end example]

§ 15.5.3.5
If the alignment associated with a specific over-aligned type is not supported by an allocator, instantiation of the allocator for that type may fail. The allocator also may silently ignore the requested alignment. [Note: Additionally, the member function allocate for that type may fail by throwing an object of type bad_alloc. — end note]

15.5.3.5.1 Allocator completeness requirements [allocator.requirements.completeness]

If \( X \) is an allocator class for type \( T \), \( X \) additionally satisfies the allocator completeness requirements if, whether or not \( T \) is a complete type:

1. \( X \) is a complete type, and
2. all the member types of \( \text{allocator_traits}<X> \) (19.10.9) other than \( \text{value_type} \) are complete types.

15.5.4 Constraints on programs [constraints]

15.5.4.1 Overview [constraints.overview]

Subclause 15.5.4 describes restrictions on C++ programs that use the facilities of the C++ standard library. The following subclauses specify constraints on the program’s use of namespaces (15.5.4.2.1), its use of various reserved names (15.5.4.3), its use of standard library classes as base classes (15.5.4.5), its definitions of replacement functions (15.5.4.6), and its installation of handler functions during execution (15.5.4.7).

15.5.4.2 Namespace use [namespace.constraints]

15.5.4.2.1 Namespace std [namespace.std]

1. Unless otherwise specified, the behavior of a C++ program is undefined if it adds declarations or definitions to namespace std or to a namespace within namespace std.

2. Unless explicitly prohibited, a program may add a template specialization for any standard library class template to namespace std provided that (a) the added declaration depends on at least one program-defined type and (b) the specialization meets the standard library requirements for the original template.\(^{177}\)

3. The behavior of a C++ program is undefined if it declares an explicit or partial specialization of any standard library variable template, except where explicitly permitted by the specification of that variable template.

4. The behavior of a C++ program is undefined if it declares
   1. an explicit specialization of any member function of a standard library class template, or
   2. an explicit specialization of any member function template of a standard library class or class template, or
   3. an explicit or partial specialization of any member class template of a standard library class or class template, or
   4. a deduction guide for any standard library class template.

5. A program may explicitly instantiate a class template defined in the standard library only if the declaration (a) depends on the name of at least one program-defined type and (b) the instantiation meets the standard library requirements for the original template.

6. Let \( F \) denote a standard library function (15.5.5.4), a standard library static member function, or an instantiation of a standard library function template. Unless \( F \) is designated an addressable function, the behavior of a C++ program is unspecified (possibly ill-formed) if it explicitly or implicitly attempts to form a pointer to \( F \). [Note: Possible means of forming such pointers include application of the unary & operator (7.6.2.1), addressof (19.10.11.1), or a function-to-pointer standard conversion (7.3.3). — end note] Moreover, the behavior of a C++ program is unspecified (possibly ill-formed) if it attempts to form a reference to \( F \) or if it attempts to form a pointer-to-member designating either a standard library non-static member function (15.5.5.5) or an instantiation of a standard library member function template.

7. Other than in namespace std or in a namespace within namespace std, a program may provide an overload for any library function template designated as a customization point, provided that (a) the overload’s declaration depends on at least one user-defined type and (b) the overload meets the standard library requirements for

\(^{177}\) Any library code that instantiates other library templates must be prepared to work adequately with any user-supplied specialization that meets the minimum requirements of this document.
the customization point.\textsuperscript{178} [Note: This permits a (qualified or unqualified) call to the customization point to invoke the most appropriate overload for the given arguments. – end note]

8 A translation unit shall not declare namespace \texttt{std} to be an inline namespace (9.7.1).

### 15.5.4.2.2 Namespace posix

1 The behavior of a C++ program is undefined if it adds declarations or definitions to namespace \texttt{posix} or to a namespace within namespace \texttt{posix} unless otherwise specified. The namespace \texttt{posix} is reserved for use by ISO/IEC 9945 and other POSIX standards.

### 15.5.4.2.3 Namespaces for future standardization

1 Top level namespaces with a name starting with \texttt{std} and followed by a non-empty sequence of digits are reserved for future standardization. The behavior of a C++ program is undefined if it adds declarations or definitions to such a namespace. [Example: The top level namespace \texttt{std2} is reserved for use by future revisions of this International Standard. – end example]

### 15.5.4.3 Reserved names

1 The C++ standard library reserves the following kinds of names:

\begin{enumerate}
\item macros
\item global names
\item names with external linkage
\end{enumerate}

2 If a program declares or defines a name in a context where it is reserved, other than as explicitly allowed by this Clause, its behavior is undefined.

### 15.5.4.3.1 Zombie names

In namespace \texttt{std}, the following names are reserved for previous standardization:

\begin{enumerate}
\item auto\_ptr,
\item auto\_ptr\_ref,
\item binary\_function,
\item binary\_negate,
\item bind\_1st,
\item bind\_2nd,
\item binder\_1st,
\item binder\_2nd,
\item const\_mem\_funi\_ref\_t,
\item const\_mem\_funi\_t,
\item const\_mem\_fun\_ref\_t,
\item const\_mem\_fun\_t,
\item get\_temporary\_buffer,
\item get\_unexpected,
\item gets,
\item is\_literal\_type,
\item is\_literal\_type\_v,
\item mem\_funi\_ref\_t,
\item mem\_funi\_t,
\item mem\_fun\_ref\_t,
\item mem\_fun\_t,
\item mem\_ref\_t,
\item std\_begin,
\item std\_end,
\item std\_value\_t,
\item std\_value\_t\_ref,
\item std\_value\_t\_ref\_t,
\item std\_value\_t\_t,
\item std\_value\_t\_v,
\item std\_value\_t\_v\_v,
\item std\_value\_t\_v\_v\_v,
\item std\_w\_is\_literal\_type,
\item std\_w\_is\_literal\_type\_v,
\item std\_w\_mem\_funi\_ref\_t,
\item std\_w\_mem\_funi\_t,
\item std\_w\_mem\_fun\_ref\_t,
\item std\_w\_mem\_fun\_t,
\item std\_w\_mem\_ref\_t,
\item std\_w\_mem\_t,
\item std\_w\_ref\_t,
\item std\_w\_t,
\item std\_w\_value\_t,
\item std\_w\_value\_t\_ref,
\item std\_w\_value\_t\_ref\_t,
\item std\_w\_value\_t\_t,
\item std\_w\_value\_t\_v,
\item std\_w\_value\_t\_v\_v,
\item std\_w\_value\_t\_v\_v\_v,
\item std\_w\_w\_is\_literal\_type,
\item std\_w\_w\_is\_literal\_type\_v,
\item std\_w\_w\_mem\_funi\_ref\_t,
\item std\_w\_w\_mem\_funi\_t,
\item std\_w\_w\_mem\_fun\_ref\_t,
\item std\_w\_w\_mem\_fun\_t,
\item std\_w\_w\_mem\_ref\_t,
\item std\_w\_w\_mem\_t,
\item std\_w\_w\_ref\_t,
\item std\_w\_w\_t,
\item std\_w\_w\_value\_t,
\item std\_w\_w\_value\_t\_ref,
\item std\_w\_w\_value\_t\_ref\_t,
\item std\_w\_w\_value\_t\_t,
\item std\_w\_w\_value\_t\_v,
\item std\_w\_w\_value\_t\_v\_v,
\item std\_w\_w\_value\_t\_v\_v\_v,
\item std\_w\_w\_w\_is\_literal\_type,
\item std\_w\_w\_w\_is\_literal\_type\_v,
\item std\_w\_w\_w\_mem\_funi\_ref\_t,
\item std\_w\_w\_w\_mem\_funi\_t,
\item std\_w\_w\_w\_mem\_fun\_ref\_t,
\item std\_w\_w\_w\_mem\_fun\_t,
\item std\_w\_w\_w\_mem\_ref\_t,
\item std\_w\_w\_w\_mem\_t,
\item std\_w\_w\_w\_ref\_t,
\item std\_w\_w\_w\_t,
\item std\_w\_w\_w\_value\_t,
\item std\_w\_w\_w\_value\_t\_ref,
\item std\_w\_w\_w\_value\_t\_ref\_t,
\item std\_w\_w\_w\_value\_t\_t,
\item std\_w\_w\_w\_value\_t\_v,
\item std\_w\_w\_w\_value\_t\_v\_v,
\item std\_w\_w\_w\_value\_t\_v\_v\_v,
\end{enumerate}

\textsuperscript{178} Any library customization point must be prepared to work adequately with any user-defined overload that meets the minimum requirements of this document. Therefore an implementation may elect, under the as-if rule (6.8.1), to provide any customization point in the form of an instantiated function object (19.14) even though the customization point’s specification is in the form of a function template. The template parameters of each such function object and the function parameters and return type of the object’s \texttt{operator()} must match those of the corresponding customization point’s specification.

§ 15.5.4.3.1 440
The following names are reserved as member types for previous standardization, and may not be used as a name for object-like macros in portable code:

1. argument_type,
2. first_argument_type,
3. io_state,
4. open_mode,
5. second_argument_type, and
6. seek_dir.

The name stossc is reserved as a member function for previous standardization, and may not be used as a name for function-like macros in portable code.

The header names `<ccomplex>`, `<ciso646>`, `<cstdalign>`, `<cstdbool>`, and `<ctgmath>` are reserved for previous standardization.

15.5.4.3.2 Macro names

A translation unit that includes a standard library header shall not `#define` or `#undef` names declared in any standard library header.

A translation unit shall not `#define` or `#undef` names lexically identical to keywords, to the identifiers listed in Table 4, or to the attribute-tokens described in 9.11.

15.5.4.3.3 External linkage

Each name declared as an object with external linkage in a header is reserved to the implementation to designate that library object with external linkage, both in namespace `std` and in the global namespace.

Each global function signature declared with external linkage in a header is reserved to the implementation to designate that function signature with external linkage.

Each name from the C standard library declared with external linkage is reserved to the implementation for use as a name with `extern "C"` linkage, both in namespace `std` and in the global namespace.

179) The list of such reserved names includes `errno`, declared or defined in `<cerrno>`.

180) The list of such reserved function signatures with external linkage includes `setjmp(jmp_buf)`, declared or defined in `<csetjmp>`, and `va_end(va_list)`, declared or defined in `<cstdarg>`.
Each function signature from the C standard library declared with external linkage is reserved to the implementation for use as a function signature with both extern "C" and extern "C++" linkage,\(^{181}\) or as a name of namespace scope in the global namespace.

15.5.4.3.4 Types \([\text{extern.types}]\)

For each type \(T\) from the C standard library,\(^{182}\) the types ::\(T\) and std::\(T\) are reserved to the implementation and, when defined, ::\(T\) shall be identical to std::\(T\).

15.5.4.3.5 User-defined literal suffixes \([\text{usrlit.suffix}]\)

Literal suffix identifiers (11.5.8) that do not start with an underscore are reserved for future standardization.

15.5.4.4 Headers \([\text{alt.headers}]\)

If a file with a name equivalent to the derived file name for one of the C++ standard library headers is not provided as part of the implementation, and a file with that name is placed in any of the standard places for a source file to be included (14.2), the behavior is undefined.

15.5.4.5 Derived classes \([\text{derived.classes}]\)

Virtual member function signatures defined for a base class in the C++ standard library may be overridden in a derived class defined in the program (10.6.2).

15.5.4.6 Replacement functions \([\text{replacement.functions}]\)

Clause 16 through Clause 30 and Annex D describe the behavior of numerous functions defined by the C++ standard library. Under some circumstances, however, certain of these function descriptions also apply to replacement functions defined in the program (15.3).

A C++ program may provide the definition for any of the following dynamic memory allocation function signatures declared in header <new> (6.6.4.4, 16.6):

\[
\begin{align*}
\text{operator new} & (\text{std::size\_t}) \\
\text{operator new} & (\text{std::size\_t, std::align\_val\_t}) \\
\text{operator new} & (\text{std::size\_t, const std::nothrow\_t&}) \\
\text{operator new} & (\text{std::size\_t, std::align\_val\_t, const std::nothrow\_t&})
\end{align*}
\]

\[
\begin{align*}
\text{operator delete} & (\text{void*}) \\
\text{operator delete} & (\text{void*, std::size\_t}) \\
\text{operator delete} & (\text{void*, std::align\_val\_t}) \\
\text{operator delete} & (\text{void*, std::size\_t, std::align\_val\_t}) \\
\text{operator delete} & (\text{void*, const std::nothrow\_t&}) \\
\text{operator delete} & (\text{void*, std::align\_val\_t, const std::nothrow\_t&})
\end{align*}
\]

\[
\begin{align*}
\text{operator new[]} & (\text{std::size\_t}) \\
\text{operator new[]} & (\text{std::size\_t, std::align\_val\_t}) \\
\text{operator new[]} & (\text{std::size\_t, const std::nothrow\_t&}) \\
\text{operator new[]} & (\text{std::size\_t, std::align\_val\_t, const std::nothrow\_t&}) \\
\text{operator delete[]} & (\text{void*}) \\
\text{operator delete[]} & (\text{void*, std::size\_t}) \\
\text{operator delete[]} & (\text{void*, std::align\_val\_t}) \\
\text{operator delete[]} & (\text{void*, std::size\_t, std::align\_val\_t}) \\
\text{operator delete[]} & (\text{void*, const std::nothrow\_t&}) \\
\text{operator delete[]} & (\text{void*, std::align\_val\_t, const std::nothrow\_t&})
\end{align*}
\]

The program’s definitions are used instead of the default versions supplied by the implementation (16.6). Such replacement occurs prior to program startup (6.2, 6.8.3). The program’s declarations shall not be specified as inline. No diagnostic is required.

15.5.4.7 Handler functions \([\text{handler.functions}]\)

The C++ standard library provides a default version of the following handler function (Clause 16):

\[
(1.1) \quad \text{terminate\_handler}
\]

\(^{181}\) The function signatures declared in <cuchar>, <cwchar>, and <cwctype> are always reserved, notwithstanding the restrictions imposed in subclause 4.5.1 of Amendment 1 to the C Standard for these headers.

\(^{182}\) These types are clock_t, div_t, FILE, fpos_t, lconv, ldiv_t, mbstate_t, ptdiff_t, sig_atomic_t, size_t, time_t, tm, va_list, wctrans_t, wctype_t, and wint_t.
A C++ program may install different handler functions during execution, by supplying a pointer to a function defined in the program or the library as an argument to (respectively):

(2.1) \text{set\_new\_handler}

(2.2) \text{set\_terminate}

See also subclauses 16.6.3, Storage allocation errors, and 16.9, Exception handling.

A C++ program can get a pointer to the current handler function by calling the following functions:

(3.1) \text{get\_new\_handler}

(3.2) \text{get\_terminate}

Calling the set\_* and get\_* functions shall not incur a data race. A call to any of the set\_* functions shall synchronize with subsequent calls to the same set\_* function and to the corresponding get\_* function.

15.5.4.8 Other functions

In certain cases (replacement functions, handler functions, operations on types used to instantiate standard library template components), the C++ standard library depends on components supplied by a C++ program. If these components do not meet their requirements, this document places no requirements on the implementation.

In particular, the effects are undefined in the following cases:

(2.1) for replacement functions (16.6.2), if the installed replacement function does not implement the semantics of the applicable Required behavior: paragraph.

(2.2) for handler functions (16.6.3.3, 16.9.4.1), if the installed handler function does not implement the semantics of the applicable Required behavior: paragraph

(2.3) for types used as template arguments when instantiating a template component, if the operations on the type do not implement the semantics of the applicable Requirements subclause (15.5.3.5, 21.2, 22.2, 23.2, 24.3). Operations on such types can report a failure by throwing an exception unless otherwise specified.

(2.4) if any replacement function or handler function or destructor operation exits via an exception, unless specifically allowed in the applicable Required behavior: paragraph.

(2.5) if an incomplete type (6.7) is used as a template argument when instantiating a template component or evaluating a concept, unless specifically allowed for that component.

15.5.4.9 Function arguments

Each of the following applies to all arguments to functions defined in the C++ standard library, unless explicitly stated otherwise.

(1.1) If an argument to a function has an invalid value (such as a value outside the domain of the function or a pointer invalid for its intended use), the behavior is undefined.

(1.2) If a function argument is described as being an array, the pointer actually passed to the function shall have a value such that all address computations and accesses to objects (that would be valid if the pointer did point to the first element of such an array) are in fact valid.

(1.3) If a function argument binds to an rvalue reference parameter, the implementation may assume that this parameter is a unique reference to this argument. [Note: If the parameter is a generic parameter of the form T&& and an lvalue of type A is bound, the argument binds to an lvalue reference (12.9.2.1) and thus is not covered by the previous sentence. — end note] [Note: If a program casts an lvalue to an xvalue while passing that lvalue to a library function (e.g., by calling the function with the argument \text{std::move(x)}), the program is effectively asking that function to treat that lvalue as a temporary object. The implementation is free to optimize away aliasing checks which might be needed if the argument was an lvalue. — end note]

15.5.4.10 Library object access

The behavior of a program is undefined if calls to standard library functions from different threads may introduce a data race. The conditions under which this may occur are specified in 15.5.5.9. [Note: Modifying an object of a standard library type that is shared between threads risks undefined behavior unless objects of that type are explicitly specified as being shareable without data races or the user supplies a locking mechanism. — end note]
If an object of a standard library type is accessed, and the beginning of the object’s lifetime (6.6.3) does not happen before the access, or the access does not happen before the end of the object’s lifetime, the behavior is undefined unless otherwise specified. [Note: This applies even to objects such as mutexes intended for thread synchronization. — end note]

15.5.4.11 Requires paragraph

Violation of any preconditions specified in a function’s Requires: element results in undefined behavior unless the function’s Throws: element specifies throwing an exception when the precondition is violated.

Violation of any preconditions specified in a function’s Expects: element results in undefined behavior.

15.5.4.12 Semantic requirements

If the semantic requirements of a declaration’s constraints (15.4.1.3) are not satisfied at the point of use, the program is ill-formed, no diagnostic required.

15.5.5 Conforming implementations

15.5.5.1 Overview

Subclause 15.5.5 describes the constraints upon, and latitude of, implementations of the C++ standard library. An implementation’s use of headers is discussed in 15.5.5.2, its use of macros in 15.5.5.3, non-member functions in 15.5.5.4, member functions in 15.5.5.5, data race avoidance in 15.5.5.9, access specifiers in 15.5.5.10, class derivation in 15.5.5.11, and exceptions in 15.5.5.12.

15.5.5.2 Headers

A C++ header may include other C++ headers. A C++ header shall provide the declarations and definitions that appear in its synopsis. A C++ header shown in its synopsis as including other C++ headers shall provide the declarations and definitions that appear in the synopses of those other headers. Certain types and macros are defined in more than one header. Every such entity shall be defined such that any header that defines it may be included after any other header that also defines it (6.2).

The C standard library headers (D.6) shall include only their corresponding C++ standard library header, as described in 15.5.1.2.

15.5.5.3 Restrictions on macro definitions

The names and global function signatures described in 15.5.1.1 are reserved to the implementation. All object-like macros defined by the C standard library and described in this Clause as expanding to integral constant expressions are also suitable for use in #if preprocessing directives, unless explicitly stated otherwise.

15.5.5.4 Non-member functions

It is unspecified whether any non-member functions in the C++ standard library are defined as inline (9.1.6). A call to a non-member function signature described in Clause 16 through Clause 30 and Annex D shall behave as if the implementation declared no additional non-member function signatures. An implementation shall not declare a non-member function signature with additional default arguments.

Unless otherwise specified, calls made by functions in the standard library to non-operator, non-member functions do not use functions from another namespace which are found through argument-dependent name lookup (6.4.2). [Note: The phrase “unless otherwise specified” applies to cases such as the swappable with requirements (15.5.3.2). The exception for overloaded operators allows argument-dependent lookup in cases like that of ostream_iterator::operator= (22.6.2.2):

Effects:

* out_stream << value;
  if (delim != 0)
    * out_stream << delim;
  return *this;
— end note]

15.5.5.4 Conforming implementations

444
15.5.5.5 Member functions

It is unspecified whether any member functions in the C++ standard library are defined as inline (9.1.6).

For a non-virtual member function described in the C++ standard library, an implementation may declare a different set of member function signatures, provided that any call to the member function that would select an overload from the set of declarations described in this document behaves as if that overload were selected. [Note: For instance, an implementation may add parameters with default values, or replace a member function with default arguments with two or more member functions with equivalent behavior, or add additional signatures for a member function name. — end note]

15.5.5.6 Constexpr functions and constructors

This document explicitly requires that certain standard library functions are constexpr (9.1.5). An implementation shall not declare any standard library function signature as constexpr except for those where it is explicitly required. Within any header that provides any non-defining declarations of constexpr functions or constructors an implementation shall provide corresponding definitions.

15.5.5.7 Requirements for stable algorithms

When the requirements for an algorithm state that it is “stable” without further elaboration, it means:

- (1.1) For the sort algorithms the relative order of equivalent elements is preserved.
- (1.2) For the remove and copy algorithms the relative order of the elements that are not removed is preserved.
- (1.3) For the merge algorithms, for equivalent elements in the original two ranges, the elements from the first range (preserving their original order) precede the elements from the second range (preserving their original order).

15.5.5.8 Reentrancy

Except where explicitly specified in this document, it is implementation-defined which functions in the C++ standard library may be recursively reentered.

15.5.5.9 Data race avoidance

This subclause specifies requirements that implementations shall meet to prevent data races (6.8.2). Every standard library function shall meet each requirement unless otherwise specified. Implementations may prevent data races in cases other than those specified below.

A C++ standard library function shall not directly or indirectly access objects (6.8.2) accessible by threads other than the current thread unless the objects are accessed directly or indirectly via the function’s arguments, including this.

A C++ standard library function shall not directly or indirectly modify objects (6.8.2) accessible by threads other than the current thread unless the objects are accessed directly or indirectly via the function’s non-const arguments, including this.

[Note: This means, for example, that implementations can’t use a static object for internal purposes without synchronization because it could cause a data race even in programs that do not explicitly share objects between threads. — end note]

A C++ standard library function shall not access objects indirectly accessible via its arguments or via elements of its container arguments except by invoking functions required by its specification on those container elements.

Operations on iterators obtained by calling a standard library container or string member function may access the underlying container, but shall not modify it. [Note: In particular, container operations that invalidate iterators conflict with operations on iterators associated with that container. — end note]

Implementations may share their own internal objects between threads if the objects are not visible to users and are protected against data races.

Unless otherwise specified, C++ standard library functions shall perform all operations solely within the current thread if those operations have effects that are visible (6.8.2) to users.

[Note: This allows implementations to parallelize operations if there are no visible side effects. — end note]
15.5.5.10 Protection within classes

It is unspecified whether any function signature or class described in Clause 16 through Clause 30 and Annex D is a friend of another class in the C++ standard library.

15.5.5.11 Derived classes

An implementation may derive any class in the C++ standard library from a class with a name reserved to the implementation.

1 Certain classes defined in the C++ standard library are required to be derived from other classes in the C++ standard library. An implementation may derive such a class directly from the required base or indirectly through a hierarchy of base classes with names reserved to the implementation.

3 In any case:

— Every base class described as virtual shall be virtual;
— Every base class not specified as virtual shall not be virtual;
— Unless explicitly stated otherwise, types with distinct names shall be distinct types.

4 All types specified in the C++ standard library shall be non-final types unless otherwise specified.

15.5.5.12 Restrictions on exception handling

Any of the functions defined in the C++ standard library can report a failure by throwing an exception of a type described in its Throws: paragraph, or of a type derived from a type named in the Throws: paragraph that would be caught by an exception handler for the base type.

2 Functions from the C standard library shall not throw exceptions except when such a function calls a program-supplied function that throws an exception.

3 Destructor operations defined in the C++ standard library shall not throw exceptions. Every destructor in the C++ standard library shall behave as if it had a non-throwing exception specification.

4 Functions defined in the C++ standard library that do not have a Throws: paragraph but do have a potentially-throwing exception specification may throw implementation-defined exceptions. Implementations should report errors by throwing exceptions of or derived from the standard exception classes (16.6.3.1, 16.9, 18.2).

5 An implementation may strengthen the exception specification for a non-virtual function by adding a non-throwing exception specification.

15.5.5.13 Restrictions on storage of pointers

Objects constructed by the standard library that may hold a user-supplied pointer value or an integer of type std::intptr_t shall store such values in a traceable pointer location (6.6.4.4.3). [Note: Other libraries are strongly encouraged to do the same, since not doing so may result in accidental use of pointers that are not safely derived. Libraries that store pointers outside the user’s address space should make it appear that they are stored and retrieved from a traceable pointer location. — end note]

15.5.5.14 Value of error codes

Certain functions in the C++ standard library report errors via a std::error_code (18.5.3.1) object. That object’s category() member shall return std::system_category() for errors originating from the operating system, or a reference to an implementation-defined error_category object for errors originating elsewhere. The implementation shall define the possible values of value() for each of these error categories. [Example: For operating systems that are based on POSIX, implementations should define the std::system_category() values as identical to the POSIX errno values, with additional values as defined by the operating system’s documentation. Implementations for operating systems that are not based on POSIX should define values identical to the operating system’s values. For errors that do not originate from the operating system, the implementation may provide enums for the associated values. — end example]

---

184) There is an implicit exception to this rule for types that are described as synonyms for basic integral types, such as size_t (16.2) and streamoff (27.5.2).
185) That is, the C library functions can all be treated as if they are marked noexcept. This allows implementations to make performance optimizations based on the absence of exceptions at runtime.
186) The functions qsort() and bsearch() (23.10) meet this condition.
187) In particular, they can report a failure to allocate storage by throwing an exception of type bad_alloc, or a class derived from bad_alloc (16.6.3.1).
15.5.5.15  Moved-from state of library types

[lib.types.movedfrom]

1 Objects of types defined in the C++ standard library may be moved from (10.3.5). Move operations may be explicitly specified or implicitly generated. Unless otherwise specified, such moved-from objects shall be placed in a valid but unspecified state.
16 Language support library

[language.support]

16.1 General

This Clause describes the function signatures that are called implicitly, and the types of objects generated implicitly, during the execution of some C++ programs. It also describes the headers that declare these function signatures and define any related types.

The following subclauses describe common type definitions used throughout the library, characteristics of the predefined types, functions supporting start and termination of a C++ program, support for dynamic memory management, support for dynamic type identification, support for contract violation handling, support for exception processing, support for initializer lists, and other runtime support, as summarized in Table 34.

int mbtowc(const wchar_t* pwc, const char* s, size_t n);
int wcstombs(char* s, const wchar_t* pwcs, size_t n);

// 16.2.3 Null pointers

1 The contents and meaning of the header <cstdlib> are the same as the C standard library header <stdlib.h>, except that it does not declare the type wchar_t, and except as noted in 16.2.3, 16.2.4, 16.5, 19.10.12, 20.5.6, 23.10, 24.7.9, and 24.9.2. [Note: Several functions have additional overloads in this document, but they have the same behavior as in the C standard library (15.2). — end note]

See also: ISO C 7.22

16.2.3 Null pointers

The type nullptr_t is a synonym for the type of a nullptr expression, and it has the characteristics described in 6.7.1 and 7.3.11. [Note: Although nullptr’s address cannot be taken, the address of another nullptr_t object that is an lvalue can be taken. — end note]

The macro NULL is an implementation-defined null pointer constant. 188

See also: ISO C 7.19

188) Possible definitions include 0 and 0L, but not (void*)0.
16.2.4 Sizes, alignments, and offsets

The macro \texttt{offsetof(type, member-designator)} has the same semantics as the corresponding macro in the C standard library header \texttt{<stddef.h>}, but accepts a restricted set of \texttt{type} arguments in this document. Use of the \texttt{offsetof} macro with a \texttt{type} other than a standard-layout class (Clause 10) is conditionally-supported.\(^1\)\(^2\) The expression \texttt{offsetof(type, member-designator)} is never type-dependent (12.7.2.2) and it is value-dependent (12.7.2.3) if and only if \texttt{type} is dependent. The result of applying the \texttt{offsetof} macro to a static data member or a function member is undefined. No operation invoked by the \texttt{offsetof} macro shall throw an exception and \texttt{noexcept(offsetof(type, member-designator))} shall be \texttt{true}.

The type \texttt{ptrdiff_t} is an implementation-defined signed integer type that can hold the difference of two subscripts in an array object, as described in 7.6.6.

The type \texttt{size_t} is an implementation-defined unsigned integer type that is large enough to contain the size in bytes of any object (7.6.2.3).

[\textit{Note}: It is recommended that implementations choose types for \texttt{ptrdiff_t} and \texttt{size_t} whose integer conversion ranks (6.7.4) are no greater than that of \texttt{signed long int} unless a larger size is necessary to contain all the possible values. —end note]

The type \texttt{max_align_t} is a trivial standard-layout type whose alignment requirement is at least as great as that of every scalar type, and whose alignment requirement is supported in every context (6.6.5).

See also: ISO C 7.19

16.2.5 byte type operations

template<class IntType>
constexpr byte& operator<<=(byte& b, IntType shift) noexcept;

\begin{enumerate}
\item \textit{Effects}: Equivalent to: \texttt{return b = b << shift;}
\item \textit{Remarks}: This function shall not participate in overload resolution unless \texttt{is_integral_v<IntType>} is \texttt{true}.
\end{enumerate}

template<class IntType>
constexpr byte operator<<(byte b, IntType shift) noexcept;

\begin{enumerate}
\item \textit{Effects}: Equivalent to:
\begin{verbatim}
    return static_cast<byte>(static_cast<unsigned char>(
        static_cast<unsigned int>(b) << shift));
\end{verbatim}
\item \textit{Remarks}: This function shall not participate in overload resolution unless \texttt{is_integral_v<IntType>} is \texttt{true}.
\end{enumerate}

template<class IntType>
constexpr byte& operator>>=(byte& b, IntType shift) noexcept;

\begin{enumerate}
\item \textit{Effects}: Equivalent to: \texttt{return b >> shift;}
\item \textit{Remarks}: This function shall not participate in overload resolution unless \texttt{is_integral_v<IntType>} is \texttt{true}.
\end{enumerate}

template<class IntType>
constexpr byte operator>>(byte b, IntType shift) noexcept;

\begin{enumerate}
\item \textit{Effects}: Equivalent to:
\begin{verbatim}
    return static_cast<byte>(static_cast<unsigned char>(
        static_cast<unsigned int>(b) >> shift));
\end{verbatim}
\item \textit{Remarks}: This function shall not participate in overload resolution unless \texttt{is_integral_v<IntType>} is \texttt{true}.
\end{enumerate}

constexpr byte& operator|=(byte& l, byte r) noexcept;

\begin{enumerate}
\item \textit{Effects}: Equivalent to: \texttt{return l = l | r;}
\end{enumerate}

\footnote{Note that \texttt{offsetof} is required to work as specified even if unary \texttt{operator\&} is overloaded for any of the types involved.}

\section*{§ 16.2.5}

451
constexpr byte operator|(byte l, byte r) noexcept;
10  Effects: Equivalent to:
    return static_cast<byte>(static_cast<unsigned char>(static_cast<unsigned int>(l) |
                               static_cast<unsigned int>(r)));

constexpr byte& operator&=(byte& l, byte r) noexcept;
11  Effects: Equivalent to: return l = l & r;

constexpr byte operator&(byte l, byte r) noexcept;
12  Effects: Equivalent to:
    return static_cast<byte>(static_cast<unsigned char>(static_cast<unsigned int>(l) &
                               static_cast<unsigned int>(r)));

constexpr byte& operator^=(byte& l, byte r) noexcept;
13  Effects: Equivalent to: return l = l ^ r;

constexpr byte operator^(byte l, byte r) noexcept;
14  Effects: Equivalent to:
    return static_cast<byte>(static_cast<unsigned char>(static_cast<unsigned int>(l) ^
                               static_cast<unsigned int>(r)));

constexpr byte operator~(byte b) noexcept;
15  Effects: Equivalent to:
    return static_cast<byte>(static_cast<unsigned char>(
                               ~static_cast<unsigned int>(b)));

template<class IntType>
constexpr IntType to_integer(byte b) noexcept;
16  Effects: Equivalent to: return static_cast<IntType>(b);

Remarks: This function shall not participate in overload resolution unless is_integral_v<IntType> is true.

16.3 Implementation properties

16.3.1 General

1 The headers <limits> (16.3.2), <climits> (16.3.5), and <cfloat> (16.3.6) supply characteristics of implementation-dependent arithmetic types (6.7.1).

2 The header <version> supplies implementation-dependent information about the C++ standard library (e.g., version number and release date).

3 The macros in Table 35 are defined after inclusion of the header <version> or one of the corresponding headers specified in the table. [Note: Future versions of this International Standard might replace the values of these macros with greater values. — end note]

16.3.2 Header <limits> synopsis

namespace std {

    // 16.3.3, floating-point type properties
    enum float_round_style;
    enum float_denorm_style;

    // 16.3.4, class template numeric_limits
    template<class T> class numeric_limits;

    template<> class numeric_limits<bool>;
    template<> class numeric_limits<char>;
    template<> class numeric_limits<signed char>;
    template<> class numeric_limits<unsigned char>;
    template<> class numeric_limits<short_t>;
    template<> class numeric_limits<int>;
    template<> class numeric_limits<long>;
    template<> class numeric_limits<long long>;
    template<> class numeric_limits<unsigned short_t>;
    template<> class numeric_limits<unsigned int>;
    template<> class numeric_limits<unsigned long>;
    template<> class numeric_limits<unsigned long long>;
    template<> class numeric_limits<float>;
    template<> class numeric_limits<double>;
    template<> class numeric_limits<long double>;
}

16.3.3 Floating-point type properties

16.3.3.1 Type float_round_style

namespace std {

    enum float_round_style {
        round_indeterminate = -1,
        round_toward_zero = 0,
    }

§ 16.3.3.1
The rounding mode for floating-point arithmetic is characterized by the values:

- \( \text{round_indeterminate} \) if the rounding style is indeterminable
- \( \text{round_toward_zero} \) if the rounding style is toward zero
- \( \text{round_to_nearest} \) if the rounding style is to the nearest representable value
- \( \text{round_toward_infinity} \) if the rounding style is toward infinity
- \( \text{round_toward_neg_infinity} \) if the rounding style is toward negative infinity

### 16.3.3.2 Type `float_denorm_style`

```cpp
class float_denorm_style {
    enum {
        denorm_indeterminate = -1,
        denorm_absent = 0,
        denorm_present = 1
    };
};
```

The presence or absence of subnormal numbers (variable number of exponent bits) is characterized by the values:

- \( \text{denorm_indeterminate} \) if it cannot be determined whether or not the type allows subnormal values
- \( \text{denorm_absent} \) if the type does not allow subnormal values
- \( \text{denorm_present} \) if the type does allow subnormal values

### 16.3.4 Class template `numeric_limits`

The `numeric_limits` class template provides a C++ program with information about various properties of the implementation’s representation of the arithmetic types.

```cpp
namespace std {
    template<class T> class numeric_limits {
    public:
        static constexpr bool is_specialized = false;
        static constexpr T min() noexcept { return T(); }
        static constexpr T max() noexcept { return T(); }
        static constexpr T lowest() noexcept { return T(); }
        static constexpr int digits = 0;
        static constexpr int digits10 = 0;
        static constexpr int max_digits10 = 0;
        static constexpr bool is_signed = false;
        static constexpr bool is_integer = false;
        static constexpr bool is_exact = false;
        static constexpr int radix = 0;
        static constexpr T epsilon() noexcept { return T(); }
        static constexpr T round_error() noexcept { return T(); }
        static constexpr int min_exponent = 0;
        static constexpr int min_exponent10 = 0;
        static constexpr int max_exponent = 0;
        static constexpr int max_exponent10 = 0;
        static constexpr bool has_infinity = false;
        static constexpr bool has_quiet_NaN = false;
        static constexpr bool has_signaling_NaN = false;
        static constexpr float_denorm_style has_denorm = denorm_absent;
        static constexpr bool has_denorm_loss = false;
        static constexpr T infinity() noexcept { return T(); }
    };
};
```
static constexpr T quiet_NaN() noexcept { return T(); }
static constexpr T signaling_NaN() noexcept { return T(); }
static constexpr T denorm_min() noexcept { return T(); }
static constexpr bool is_iec559 = false;
static constexpr bool is_bounded = false;
static constexpr bool is_modulo = false;
static constexpr bool traps = false;
static constexpr float_round_style round_style = round_toward_zero;
};

template<class T> class numeric_limits<const T>;
template<class T> class numeric_limits<volatile T>;
template<class T> class numeric_limits<const volatile T>;

For all members declared static constexpr in the numeric_limits template, specializations shall define these values in such a way that they are usable as constant expressions.

The default numeric_limits<T> template shall have all members, but with 0 or false values.

Specializations shall be provided for each arithmetic type, both floating-point and integer, including bool. The member is_specialized shall be true for all such specializations of numeric_limits.

The value of each member of a specialization of numeric_limits on a cv-qualified type cv T shall be equal to the value of the corresponding member of the specialization on the unqualified type T.

Non-arithmetic standard types, such as complex<T> (24.5.2), shall not have specializations.

16.3.4.1 numeric_limits members

Each member function defined in this subclause is signal-safe (16.12.4).

static constexpr T min() noexcept;
Minimum finite value.

For floating-point types with subnormal numbers, returns the minimum positive normalized value.

Meaningful for all specializations in which is_bounded != false, or is_bounded == false && is_signed == false.

static constexpr T max() noexcept;
Maximum finite value.

Meaningful for all specializations in which is_bounded != false.

static constexpr T lowest() noexcept;
A finite value x such that there is no other finite value y where y < x.

Meaningful for all specializations in which is_bounded != false.

static constexpr int digits;
Number of radix digits that can be represented without change.

For integer types, the number of non-sign bits in the representation.

For floating-point types, the number of radix digits in the mantissa.

static constexpr int digits10;

Number of base 10 digits that can be represented without change.

---

190) Equivalent to CHAR_MIN, SHRT_MIN, FLT_MIN, DBL_MIN, etc.
191) Equivalent to CHAR_MAX, SHRT_MAX, FLT_MAX, DBL_MAX, etc.
192) lowest() is necessary because not all floating-point representations have a smallest (most negative) value that is the negative of the largest (most positive) finite value.
193) Equivalent to FLT_MANT_DIG, DBL_MANT_DIG, LDBL_MANT_DIG.
194) Equivalent to FLT_DIG, DBL_DIG, LDBL_DIG.
Meaningful for all specializations in which \texttt{is\_bounded} != \texttt{false}.

\begin{verbatim}
static constexpr int max_digits10;
Number of base 10 digits required to ensure that values which differ are always differentiated.
Meaningful for all floating-point types.

static constexpr bool is_signed;
true if the type is signed.
Meaningful for all specializations.

static constexpr bool is_integer;
true if the type is integer.
Meaningful for all specializations.

static constexpr bool is_exact;
true if the type uses an exact representation. All integer types are exact, but not all exact types are
integer. For example, rational and fixed-exponent representations are exact but not integer.
Meaningful for all specializations.

static constexpr int radix;
For floating-point types, specifies the base or radix of the exponent representation (often 2).\footnote{Equivalent to FLT\_RADIX.}
For integer types, specifies the base of the representation.\footnote{Distinguishes types with bases other than 2 (e.g. BCD).}
Meaningful for all specializations.

static constexpr T epsilon() noexcept;
Machine epsilon: the difference between 1 and the least value greater than 1 that is representable.\footnote{Equivalent to FLT\_EPSILON, DBL\_EPSILON, LDBL\_EPSILON.}
Meaningful for all floating-point types.

static constexpr T round_error() noexcept;
Measure of the maximum rounding error.\footnote{Rounding error is described in LIA-1 Section 5.2.4 and Annex C Rationale Section C.5.2.4 — Rounding and rounding
constants.}

static constexpr int min_exponent;
Minimum negative integer such that \texttt{radix} raised to the power of one less than that integer is a
normalized floating-point number.\footnote{Equivalent to FLT\_MIN\_EXP, DBL\_MIN\_EXP, LDBL\_MIN\_EXP.}
Meaningful for all floating-point types.

static constexpr int min_exponent10;
Minimum negative integer such that 10 raised to that power is in the range of normalized floating-point
numbers.\footnote{Equivalent to FLT\_MIN\_10\_EXP, DBL\_MIN\_10\_EXP, LDBL\_MIN\_10\_EXP.}
Meaningful for all floating-point types.

static constexpr int max_exponent;
Maximum positive integer such that \texttt{radix} raised to the power one less than that integer is a representable
finite floating-point number.\footnote{Equivalent to FLT\_MAX\_EXP, DBL\_MAX\_EXP, LDBL\_MAX\_EXP.}
Meaningful for all floating-point types.
\end{verbatim}

\footnotesize
\begin{enumerate}
\item \footnote{Equivalent to FLT\_RADIX.}
\item \footnote{Distinguishes types with bases other than 2 (e.g. BCD).}
\item \footnote{Equivalent to FLT\_EPSILON, DBL\_EPSILON, LDBL\_EPSILON.}
\item \footnote{Rounding error is described in LIA-1 Section 5.2.4 and Annex C Rationale Section C.5.2.4 — Rounding and rounding
constants.}
\item \footnote{Equivalent to FLT\_MIN\_EXP, DBL\_MIN\_EXP, LDBL\_MIN\_EXP.}
\item \footnote{Equivalent to FLT\_MIN\_10\_EXP, DBL\_MIN\_10\_EXP, LDBL\_MIN\_10\_EXP.}
\item \footnote{Equivalent to FLT\_MAX\_EXP, DBL\_MAX\_EXP, LDBL\_MAX\_EXP.}
\end{enumerate}
static constexpr int max_exponent10;
    Maximum positive integer such that 10 raised to that power is in the range of representable finite
    floating-point numbers.\(^{202}\)
    Meaningful for all floating-point types.

static constexpr bool has_infinity;
    \textbf{true} if the type has a representation for positive infinity.
    Meaningful for all floating-point types.
    Shall be \textbf{true} for all specializations in which \texttt{is_iec559 \neq false}.

static constexpr bool has_quiet_NaN;
    \textbf{true} if the type has a representation for a quiet (non-signaling) “Not a Number”.\(^{203}\)
    Meaningful for all floating-point types.
    Shall be \textbf{true} for all specializations in which \texttt{is_iec559 \neq false}.

static constexpr bool has_signaling_NaN;
    \textbf{true} if the type has a representation for a signaling “Not a Number”.\(^{204}\)
    Meaningful for all floating-point types.
    Shall be \textbf{true} for all specializations in which \texttt{is_iec559 \neq false}.

static constexpr float_denorm_style has_denorm;
    \texttt{denorm_present} if the type allows subnormal values (variable number of exponent bits)\(^ {205}\), \texttt{denorm_-absent} if the type does not allow subnormal values, and \texttt{denorm_indeterminate} if it is indeterminate
    at compile time whether the type allows subnormal values.
    Meaningful for all floating-point types.

static constexpr bool has_denorm_loss;
    \textbf{true} if loss of accuracy is detected as a denormalization loss, rather than as an inexact result.\(^ {206}\)

static constexpr T infinity() noexcept;
    Representation of positive infinity, if available.\(^ {207}\)
    Meaningful for all specializations for which \texttt{has_infinity \neq false}. Required in specializations for
    which \texttt{is_iec559 \neq false}.

static constexpr T quiet_NaN() noexcept;
    Representation of a quiet “Not a Number”, if available.\(^ {208}\)
    Meaningful for all specializations for which \texttt{has_quiet_NaN \neq false}. Required in specializations for
    which \texttt{is_iec559 \neq false}.

static constexpr T signaling_NaN() noexcept;
    Representation of a signaling “Not a Number”, if available.\(^ {209}\)
    Meaningful for all specializations for which \texttt{has_signaling_NaN \neq false}. Required in specializations for
    which \texttt{is_iec559 \neq false}.

static constexpr T denorm_min() noexcept;
    Minimum positive subnormal value.\(^ {210}\)

\(^{202}\) Equivalent to \texttt{FLT_MAX_10_EXP}, \texttt{DBL_MAX_10_EXP}, \texttt{LDBL_MAX_10_EXP}.
\(^{203}\) Required by LIA-1.
\(^{204}\) Required by LIA-1.
\(^{205}\) Required by LIA-1.
\(^{206}\) See ISO/IEC/IEEE 60559.
\(^{207}\) Required by LIA-1.
\(^{208}\) Required by LIA-1.
\(^{209}\) Required by LIA-1.
\(^{210}\) Required by LIA-1.
Meaningful for all floating-point types. In specializations for which `has_denorm == false`, returns the minimum positive normalized value.

```cpp
static constexpr bool is_iec559;
true if and only if the type adheres to ISO/IEC/IEEE 60559.\(^{211}\)
```

Meaningful for all floating-point types.

```cpp
static constexpr bool is_bounded;
true if the set of values representable by the type is finite.\(^{212}\) [Note: All fundamental types (6.7.1) are bounded. This member would be `false` for arbitrary precision types. — end note]
```

Meaningful for all specializations.

```cpp
static constexpr bool is_modulo;
true if the type is modulo.\(^{213}\) A type is modulo if, for any operation involving `+`, `-`, or `*` on values of that type whose result would fall outside the range `[min(), max()]`, the value returned differs from the true value by an integer multiple of `max() - min() + 1`.
```

```cpp
[Example: `is_modulo` is `false` for signed integer types (6.7.1) unless an implementation, as an extension to this document, defines signed integer overflow to wrap. — end example]
```

Meaningful for all specializations.

```cpp
static constexpr bool traps;
true if, at program startup, there exists a value of the type that would cause an arithmetic operation using that value to trap.\(^{214}\)
```

Meaningful for all specializations.

```cpp
static constexpr bool tinyness_before;
true if tinyness is detected before rounding.\(^{215}\)
```

Meaningful for all floating-point types.

```cpp
static constexpr float_round_style round_style;
The rounding style for the type.\(^{216}\)
```

Meaningful for all floating-point types. Specializations for integer types shall return `round_toward_-zero`. 

### 16.3.4.2 numeric_limits specializations

```
[numeric.special]

All members shall be provided for all specializations. However, many values are only required to be meaningful under certain conditions (for example, `epsilon()` is only meaningful if `is_integer` is `false`). Any value that is not “meaningful” shall be set to 0 or `false`.

```

```
[Example:

```cpp
namespace std {
    template<> class numeric_limits<float> {
    public:
        static constexpr bool is_specialized = true;

        static constexpr float min() noexcept { return 1.17549435E-38F; }  
        static constexpr float max() noexcept { return 3.40282347E+38F; }  
        static constexpr float lowest() noexcept { return -3.40282347E+38F; }  

        static constexpr int digits = 24;
        static constexpr int digits10 = 6;
        static constexpr int max_digits10 = 9;

212) Required by LIA-1.
213) Required by LIA-1.
214) Required by LIA-1.
216) Equivalent to FLT_ROUNDS. Required by LIA-1.

§ 16.3.4.2 459
```
static constexpr bool is_signed = true;
static constexpr bool is_integer = false;
static constexpr bool is_exact = false;
static constexpr int radix = 2;
static constexpr float epsilon() noexcept { return 1.19209290E-07F; }
static constexpr float round_error() noexcept { return 0.5F; }
static constexpr int min_exponent = -125;
static constexpr int min_exponent10 = -37;
static constexpr int max_exponent = +128;
static constexpr int max_exponent10 = +38;
static constexpr bool has_infinity = true;
static constexpr bool has_quiet_NaN = true;
static constexpr bool has_signaling_NaN = true;
static constexpr float_denorm_style has_denorm = denorm_absent;
static constexpr bool has_denorm_loss = false;
static constexpr float infinity() noexcept { return value; }
static constexpr float quiet_NaN() noexcept { return value; }
static constexpr float signaling_NaN() noexcept { return value; }
static constexpr float denorm_min() noexcept { return min(); }
static constexpr bool is_iec559 = true;
static constexpr bool is_bounded = true;
static constexpr bool is_modulo = false;
static constexpr bool traps = true;
static constexpr bool tinyness_before = true;
static constexpr float_round_style round_style = round_to_nearest;
};

—end example

§ 16.3.4.2 460

The specialization for bool shall be provided as follows:

namespace std {
    template<> class numeric_limits<bool> {
        public:
            static constexpr bool is_specialized = true;
            static constexpr bool min() noexcept { return false; }
            static constexpr bool max() noexcept { return true; }
            static constexpr bool lowest() noexcept { return false; }
            static constexpr int digits = 1;
            static constexpr int digits10 = 0;
            static constexpr int max_digits10 = 0;
            static constexpr bool is_signed = false;
            static constexpr bool is_integer = true;
            static constexpr bool is_exact = true;
            static constexpr int radix = 2;
            static constexpr bool epsilon() noexcept { return 0; }
            static constexpr bool round_error() noexcept { return 0; }
            static constexpr int min_exponent = 0;
            static constexpr int min_exponent10 = 0;
            static constexpr int max_exponent = 0;
            static constexpr int max_exponent10 = 0;
            static constexpr bool has_infinity = false;
            static constexpr bool has_quiet_NaN = false;
            static constexpr bool has_signaling_NaN = false;
        };

§ 16.3.6 461
The header `<cfloat>` defines all macros the same as the C standard library header `<float.h>`.

**See also:** ISO C 5.2.4.2.2

### 16.4 Integer types

#### 16.4.1 Header `<cstdint>` synopsis

```cpp
namespace std {
    using int8_t = signed integer type; // optional
    using int16_t = signed integer type; // optional
    using int32_t = signed integer type; // optional
    using int64_t = signed integer type; // optional

    using int_fast8_t = signed integer type;
    using int_fast16_t = signed integer type;
    using int_fast32_t = signed integer type;
    using int_fast64_t = signed integer type;

    using int_least8_t = signed integer type;
    using int_least16_t = signed integer type;
    using int_least32_t = signed integer type;
    using int_least64_t = signed integer type;

    using intmax_t = signed integer type;
    using intptr_t = signed integer type; // optional

    using uint8_t = unsigned integer type; // optional
    using uint16_t = unsigned integer type; // optional
    using uint32_t = unsigned integer type; // optional
    using uint64_t = unsigned integer type; // optional

    using uint_fast8_t = unsigned integer type;
    using uint_fast16_t = unsigned integer type;
    using uint_fast32_t = unsigned integer type;
    using uint_fast64_t = unsigned integer type;

    using uint_least8_t = unsigned integer type;
    using uint_least16_t = unsigned integer type;
    using uint_least32_t = unsigned integer type;
    using uint_least64_t = unsigned integer type;

    using uintmax_t = unsigned integer type;
}
```
using uintptr_t = unsigned integer type; // optional

The header also defines numerous macros of the form:

- \texttt{INT\{FAST LEAST\}{8 16 32 64}\_MIN}
- \texttt{[U]INT\{FAST LEAST\}{8 16 32 64}\_MAX}
- \texttt{INT\{MAX PTR\}\_MIN}
- \texttt{[U]INT\{MAX PTR\}\_MAX}
- \texttt{\{PTRDIFF SIG_ATOMIC WCHAR WINT\}\{\_MAX \_MIN\} SIZE\_MAX}

plus function macros of the form:

- \texttt{[U]INT\{8 16 32 64 MAX\}\_C}

The header defines all types and macros the same as the C standard library header \texttt{<stdint.h>}. See also: ISO C 7.20

### 16.5 Start and termination [support.start.term]

[Note: The header \texttt{<cstdlib>} (16.2.2) declares the functions described in this subclause. — end note]

- **[[noretturn]] void \_Exit(int status) noexcept;**
  - **Effects:** This function has the semantics specified in the C standard library.
  - **Remarks:** The program is terminated without executing destructors for objects of automatic, thread, or static storage duration and without calling functions passed to \texttt{atexit()} (6.8.3.4). The function \_Exit is signal-safe (16.12.4).

- **[[noretturn]] void abort() noexcept;**
  - **Effects:** This function has the semantics specified in the C standard library.
  - **Remarks:** The program is terminated without executing destructors for objects of automatic, thread, or static storage duration and without calling functions passed to \texttt{atexit()} (6.8.3.4). The function abort is signal-safe (16.12.4).

- **int atexit(c-\texttt{atexit-handler}\* f) noexcept;**
  - **Effects:** The \texttt{atexit()} functions register the function pointed to by \texttt{f} to be called without arguments at normal program termination. It is unspecified whether a call to \texttt{atexit()} that does not happen before (6.8.2) a call to \texttt{exit()} will succeed. [Note: The \texttt{atexit()} functions do not introduce a data race (15.5.5.9). — end note]

- **Implementation limits:** The implementation shall support the registration of at least 32 functions.

- **Returns:** The \texttt{atexit()} function returns zero if the registration succeeds, nonzero if it fails.

- **[[noretturn]] void exit(int status);**
  - **Effects:**
    - First, objects with thread storage duration and associated with the current thread are destroyed. Next, objects with static storage duration are destroyed and functions registered by calling \texttt{atexit} are called. See 6.8.3.4 for the order of destructions and calls. (Automatic objects are not destroyed as a result of calling exit().)\(^\text{218}\)
      
      If control leaves a registered function called by \texttt{exit} because the function does not provide a handler for a thrown exception, the function \texttt{std::terminate} shall be called (13.5.1).

    - Next, all open C streams (as mediated by the function signatures declared in \texttt{<cstdio>}) with unwritten buffered data are flushed, all open C streams are closed, and all files created by calling \texttt{tmpfile()} are removed.

\(^{217}\) A function is called for every time it is registered.

\(^{218}\) Objects with automatic storage duration are all destroyed in a program whose \texttt{main} function (6.8.3.1) contains no automatic objects and executes the call to \texttt{exit()}. Control can be transferred directly to such a \texttt{main} function by throwing an exception that is caught in \texttt{main}.  

\section*{§ 16.5}
Finally, control is returned to the host environment. If \texttt{status} is zero or \texttt{EXIT\_SUCCESS}, an implementation-defined form of the status \textit{successful termination} is returned. If \texttt{status} is \texttt{EXIT\_FAILURE}, an implementation-defined form of the status \textit{unsuccessful termination} is returned. Otherwise the status returned is implementation-defined.

\begin{verbatim}
int at_quick_exit(c-atexit-handler* f) noexcept;
int at_quick_exit(atexit-handler* f) noexcept;
\end{verbatim}

\begin{itemize}
\item \textbf{Effects:} The \texttt{at_quick_exit()} functions register the function pointed to by \texttt{f} to be called without arguments when \texttt{quick_exit} is called. It is unspecified whether a call to \texttt{at_quick_exit()} that does not happen before (6.8.2) all calls to \texttt{quick_exit} will succeed. [Note: The \texttt{at_quick_exit()} functions do not introduce a data race (15.5.5.9). — end note] [Note: The order of registration may be indeterminate if \texttt{at_quick_exit} was called from more than one thread. — end note] [Note: The \texttt{at_quick_exit} registrations are distinct from the \texttt{atexit} registrations, and applications may need to call both registration functions with the same argument. — end note]
\item \textbf{Implementation limits:} The implementation shall support the registration of at least 32 functions.
\item \textbf{Returns:} Zero if the registration succeeds, nonzero if it fails.
\end{itemize}

\begin{verbatim}
[[noretturn]] void quick_exit(int status) noexcept;
\end{verbatim}

\begin{itemize}
\item \textbf{Effects:} Functions registered by calls to \texttt{at_quick_exit} are called in the reverse order of their registration, except that a function shall be called after any previously registered functions that had already been called at the time it was registered. Objects shall not be destroyed as a result of calling \texttt{quick_exit}. If control leaves a registered function called by \texttt{quick_exit} because the function does not provide a handler for a thrown exception, the function \texttt{std::terminate} shall be called. [Note: A function registered via \texttt{at_quick_exit} is invoked by the thread that calls \texttt{quick_exit}, which can be a different thread than the one that registered it, so registered functions should not rely on the identity of objects with thread storage duration. — end note] After calling registered functions, \texttt{quick_exit} shall call \texttt{_Exit(status)}.
\item \textbf{Remarks:} The function \texttt{quick_exit} is signal-safe (16.12.4) when the functions registered with \texttt{at_quick_exit} are.
\end{itemize}

\textbf{See also:} ISO C 7.22.4

\section{Dynamic memory management}

The header \texttt{<new>} defines several functions that manage the allocation of dynamic storage in a program. It also defines components for reporting storage management errors.

\subsection{Header \texttt{<new>} synopsis}

\begin{verbatim}
namespace std {
    class bad_alloc;
    class bad_array_new_length;

    struct destroying_delete_t {
        explicit destroying_delete_t() = default;
    };
    inline constexpr destroying_delete_t destroying_delete{};

    struct nothrow_t {
        explicit nothrow_t() = default;
    };
    extern const nothrow_t nothrow;

    using new_handler = void (*)();
    new_handler get_new_handler() noexcept;
    new_handler set_new_handler(new_handler new_p) noexcept;

    // 16.6.4, pointer optimization barrier
    template<class T> [[nodiscard]] constexpr T* launder(T* p) noexcept;
}\end{verbatim}

\footnote{The macros \texttt{EXIT\_FAILURE} and \texttt{EXIT\_SUCCESS} are defined in \texttt{<cstdlib>}.}

\section*{§ 16.6.1}
// 16.6.5, hardware interference size
inline constexpr size_t hardware_destructive_interference_size = implementation-defined;
inline constexpr size_t hardware_constructive_interference_size = implementation-defined;

[[nodiscard]] void* operator new(std::size_t size);
[[nodiscard]] void* operator new(std::size_t size, std::align_val_t alignment);
[[nodiscard]] void* operator new(std::size_t size, const std::nothrow_t&) noexcept;
[[nodiscard]] void* operator new(std::size_t size, std::align_val_t alignment, const std::nothrow_t&) noexcept;
void operator delete(void* ptr) noexcept;
void operator delete(void* ptr, std::size_t size) noexcept;
void operator delete(void* ptr, std::align_val_t alignment) noexcept;
void operator delete(void* ptr, std::size_t size, std::align_val_t alignment) noexcept;
void operator delete(void* ptr, const std::nothrow_t&) noexcept;
void operator delete(void* ptr, std::align_val_t alignment, const std::nothrow_t&) noexcept;

16.6.2 Storage allocation and deallocation [new.delete]

Except where otherwise specified, the provisions of 6.6.4.4 apply to the library versions of operator new and operator delete. If the value of an alignment argument passed to any of these functions is not a valid alignment value, the behavior is undefined.

16.6.2.1 Single-object forms [new.delete.single]

[[nodiscard]] void* operator new(std::size_t size);
[[nodiscard]] void* operator new(std::size_t size, std::align_val_t alignment);

Effects: The allocation functions (6.6.4.4.1) called by a new-expression (7.6.2.4) to allocate size bytes of storage. The second form is called for a type with new-extended alignment, and allocates storage with the specified alignment. The first form is called otherwise, and allocates storage suitably aligned to represent any object of that size provided the object’s type does not have new-extended alignment.

Replaceable: A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.

Required behavior: Return a non-null pointer to suitably aligned storage (6.6.4.4), or else throw a bad_alloc exception. This requirement is binding on any replacement versions of these functions.

Default behavior:

(4.1) Executes a loop: Within the loop, the function first attempts to allocate the requested storage. Whether the attempt involves a call to the C standard library functions malloc or aligned_alloc is unspecified.

(4.2) Returns a pointer to the allocated storage if the attempt is successful. Otherwise, if the current new_handler (16.6.3.5) is a null pointer value, throws bad_alloc.
— Otherwise, the function calls the current `new_handler` function (16.6.3.3). If the called function returns, the loop repeats.

— The loop terminates when an attempt to allocate the requested storage is successful or when a called `new_handler` function does not return.

```cpp
[[nodiscard]] void* operator new(std::size_t size, const std::nothrow_t&) noexcept;
[[nodiscard]] void* operator new(std::size_t size, std::align_val_t alignment, const std::nothrow_t&) noexcept;
```

**Effects:** Same as above, except that these are called by a placement version of a `new-expression` when a C++ program prefers a null pointer result as an error indication, instead of a `bad_alloc` exception.

**Replaceable:** A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.

**Required behavior:** Return a non-null pointer to suitably aligned storage (6.6.4.4), or else return a null pointer. Each of these nothrow versions of `operator new` returns a pointer obtained as if acquired from the (possibly replaced) corresponding non-placement function. This requirement is binding on any replacement versions of these functions.

**Default behavior:** Calls `operator new(size)`, or `operator new(size, alignment)`, respectively. If the call returns normally, returns the result of that call. Otherwise, returns a null pointer.

```cpp
T* p1 = new T;  // throws bad_alloc if it fails
T* p2 = new(nothrow) T;  // returns nullptr if it fails
```

**Example:**

```cpp
void operator delete(void* ptr) noexcept;
void operator delete(void* ptr, std::size_t size) noexcept;
void operator delete(void* ptr, std::align_val_t alignment) noexcept;
void operator delete(void* ptr, std::size_t size, std::align_val_t alignment) noexcept;
```

**Effects:** The deallocation functions (6.6.4.4.2) called by a `delete-expression` (7.6.2.5) to render the value of `ptr` invalid.

**Replaceable:** A C++ program may define functions with any of these function signatures, and thereby displace the default versions defined by the C++ standard library. If a function without a `size` parameter is defined, the program should also define the corresponding function with a `size` parameter. If a function with a `size` parameter is defined, the program shall also define the corresponding version without the `size` parameter. [Note: The default behavior below may change in the future, which will require replacing both deallocation functions when replacing the allocation function. — end note]

**Requires:** `ptr` shall be a null pointer or its value shall represent the address of a block of memory allocated by an earlier call to a (possibly replaced) `operator new(std::size_t)` or `operator new(std::size_t, std::align_val_t)` which has not been invalidated by an intervening call to `operator delete`.

**Requires:** If an implementation has strict pointer safety (6.6.4.4.3) then `ptr` shall be a safely-derived pointer.

**Requires:** If the `alignment` parameter is not present, `ptr` shall have been returned by an allocation function without an `alignment` parameter. If present, the `alignment` argument shall equal the `alignment` argument passed to the allocation function that returned `ptr`. If present, the `size` argument shall equal the `size` argument passed to the allocation function that returned `ptr`.

**Required behavior:** A call to an `operator delete` with a `size` parameter may be changed to a call to the corresponding `operator delete` without a `size` parameter, without affecting memory allocation. [Note: A conforming implementation is for `operator delete(void* ptr, std::size_t size)` to simply call `operator delete(ptr)`. — end note]

**Default behavior:** The functions that have a `size` parameter forward their other parameters to the corresponding function without a `size` parameter. [Note: See the note in the above Replaceable: paragraph. — end note]

**Default behavior:** If `ptr` is null, does nothing. Otherwise, reclaims the storage allocated by the earlier call to `operator new`.

§ 16.6.2.1
Remarks: It is unspecified under what conditions part or all of such reclaimed storage will be allocated by subsequent calls to `operator new` or any of `aligned_alloc`, `calloc`, `malloc`, or `realloc`, declared in `<cstdlib>`.

```cpp
void operator delete(void* ptr, const std::nothrow_t&) noexcept;
void operator delete(void* ptr, std::align_val_t alignment, const std::nothrow_t&) noexcept;
```

Effects: The deallocation functions (6.6.4.4.2) called by the implementation to render the value of `ptr` invalid when the constructor invoked from a noexcept placement version of the new-expression throws an exception.

Replaceable: A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.

Requires: `ptr` shall be a null pointer or its value shall represent the address of a block of memory allocated by an earlier call to a (possibly replaced) `operator new(std::size_t)` or `operator new(std::size_t, std::align_val_t)` which has not been invalidated by an intervening call to `operator delete`.

Requires: If an implementation has strict pointer safety (6.6.4.4.3) then `ptr` shall be a safely-derived pointer.

Requires: If the `alignment` parameter is not present, `ptr` shall have been returned by an allocation function without an `alignment` parameter. If present, the `alignment` argument shall equal the `alignment` argument passed to the allocation function that returned `ptr`.

Default behavior: Calls `operator delete(ptr)`, or `operator delete(ptr, alignment)`, respectively.

### 16.6.2.2 Array forms

```cpp
[[nodiscard]] void* operator new[](std::size_t size);
[[nodiscard]] void* operator new[](std::size_t size, std::align_val_t alignment);
```

Effects: The allocation functions (6.6.4.4.1) called by the array form of a new-expression (7.6.2.4) to allocate `size` bytes of storage. The second form is called for a type with new-extended alignment, and allocates storage with the specified alignment. The first form is called otherwise, and allocates storage suitably aligned to represent any array object of that size or smaller, provided the object’s type does not have new-extended alignment.  

Replaceable: A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.

Required behavior: Same as for the corresponding single-object forms. This requirement is binding on any replacement versions of these functions.

Default behavior: Returns `operator new(size)`, or `operator new(size, alignment)`, respectively.

```cpp
[[nodiscard]] void* operator new[](std::size_t size, const std::nothrow_t&) noexcept;
[[nodiscard]] void* operator new[](std::size_t size, std::align_val_t alignment, const std::nothrow_t&) noexcept;
```

Effects: Same as above, except that these are called by a placement version of a new-expression when a C++ program prefers a null pointer result as an error indication, instead of a bad_alloc exception.

Replaceable: A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.

Required behavior: Return a non-null pointer to suitably aligned storage (6.6.4.4), or else return a null pointer. Each of these nothrow versions of `operator new[]` returns a pointer obtained as if acquired from the (possibly replaced) corresponding non-placement function. This requirement is binding on any replacement versions of these functions.

Default behavior: Calls `operator new[](size)`, or `operator new[](size, alignment)`, respectively. If the call returns normally, returns the result of that call. Otherwise, returns a null pointer.

```cpp
void operator delete[](void* ptr) noexcept;
void operator delete[](void* ptr, std::size_t size) noexcept;
void operator delete[](void* ptr, std::align_val_t alignment) noexcept;
```

220) It is not the direct responsibility of `operator new[]` or `operator delete[]` to note the repetition count or element size of the array. Those operations are performed elsewhere in the array new and delete expressions. The array new expression, may, however, increase the `size` argument to `operator new[]` to obtain space to store supplemental information.
void operator delete[](void* ptr, std::size_t size, std::align_val_t alignment) noexcept;

Effects: The deallocation functions (6.6.4.4.2) called by the array form of a delete-expression to render the value of ptr invalid.

Replaceable: A C++ program may define functions with any of these function signatures, and thereby displace the default versions defined by the C++ standard library. If a function without a size parameter is defined, the program should also define the corresponding function with a size parameter. If a function with a size parameter is defined, the program shall also define the corresponding version without the size parameter. [Note: The default behavior below may change in the future, which will require replacing both deallocation functions when replacing the allocation function. — end note]

Requires: ptr shall be a null pointer or its value shall represent the address of a block of memory allocated by an earlier call to a (possibly replaced) operator new[](std::size_t) or operator new[](std::size_t, std::align_val_t) which has not been invalidated by an intervening call to operator delete[].

Requires: If an implementation has strict pointer safety (6.6.4.4.3) then ptr shall be a safely-derived pointer.

Requires: If the alignment parameter is not present, ptr shall have been returned by an allocation function without an alignment parameter. If present, the alignment argument shall equal the alignment argument passed to the allocation function that returned ptr. If present, the size argument shall equal the size argument passed to the allocation function that returned ptr.

Required behavior: A call to an operator delete[] with a size parameter may be changed to a call to the corresponding operator delete[] without a size parameter, without affecting memory allocation. [Note: A conforming implementation is for operator delete[](void* ptr, std::size_t size) to simply call operator delete[](ptr). — end note]

Default behavior: The functions that have a size parameter forward their other parameters to the corresponding function without a size parameter. The functions that do not have a size parameter forward their parameters to the corresponding operator delete (single-object) function.

void operator delete[](void* ptr, const std::nothrow_t&) noexcept;
void operator delete[](void* ptr, std::align_val_t alignment, const std::nothrow_t&) noexcept;

Effects: The deallocation functions (6.6.4.4.2) called by the implementation to render the value of ptr invalid when the constructor invoked from a nothrow placement version of the array new-expression throws an exception.

Replaceable: A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.

Requires: ptr shall be a null pointer or its value shall represent the address of a block of memory allocated by an earlier call to a (possibly replaced) operator new[](std::size_t) or operator new[](std::size_t, std::align_val_t) which has not been invalidated by an intervening call to operator delete[].

Requires: If an implementation has strict pointer safety (6.6.4.4.3) then ptr shall be a safely-derived pointer.

Requires: If the alignment parameter is not present, ptr shall have been returned by an allocation function without an alignment parameter. If present, the alignment argument shall equal the alignment argument passed to the allocation function that returned ptr.

Default behavior: Calls operator delete[](ptr), or operator delete[](ptr, alignment), respectively.

16.6.2.3 Non-allocating forms [new.delete.placement]

These functions are reserved; a C++ program may not define functions that displace the versions in the C++ standard library (15.5.4). The provisions of 6.6.4.4 do not apply to these reserved placement forms of operator new and operator delete.

[[nodiscard]] void* operator new(std::size_t size, void* ptr) noexcept;

Returns: ptr.

Remarks: Intentionally performs no other action.
Example: This can be useful for constructing an object at a known address:

```cpp
void* place = operator new(sizeof(Something));
Something* p = new (place) Something();
```
—end example

```cpp
[[nodiscard]] void* operator new[](std::size_t size, void* ptr) noexcept;
```

Returns: `ptr`.

Remarks: Intentionally performs no other action.

```cpp
void operator delete(void* ptr, void*) noexcept;
```

Effects: Intentionally performs no action.

Remarks: If an implementation has strict pointer safety (6.6.4.4.3) then `ptr` shall be a safely-derived pointer.

```cpp
void operator delete[](void* ptr, void*) noexcept;
```

Effects: Intentionally performs no action.

Remarks: If an implementation has strict pointer safety (6.6.4.4.3) then `ptr` shall be a safely-derived pointer.

16.6.2.4 Data races

For purposes of determining the existence of data races, the library versions of `operator new`, user replacement versions of global `operator new`, the C standard library functions `aligned_alloc`, `calloc`, and `malloc`, the library versions of `operator delete`, user replacement versions of `operator delete`, the C standard library function `free`, and the C standard library function `realloc` shall not introduce a data race (15.5.5.9). Calls to these functions that allocate or deallocate a particular unit of storage shall occur in a single total order, and each such deallocation call shall happen before (6.8.2) the next allocation (if any) in this order.

16.6.3 Storage allocation errors

16.6.3.1 Class `bad_alloc`

```cpp
namespace std {
    class bad_alloc : public exception {
    public:
        bad_alloc() noexcept;
        bad_alloc(const bad_alloc&) noexcept;
        bad_alloc& operator=(const bad_alloc&) noexcept;
        const char* what() const noexcept override;
    }; 
}
```

The class `bad_alloc` defines the type of objects thrown as exceptions by the implementation to report a failure to allocate storage.

```cpp
bad_alloc() noexcept;
```

Effects: Constructs an object of class `bad_alloc`.

```cpp
bad_alloc(const bad_alloc&) noexcept;
bad_alloc& operator=(const bad_alloc&) noexcept;
```

Effects: Copies an object of class `bad_alloc`.

```cpp
const char* what() const noexcept override;
```

Returns: An implementation-defined NTBS.

Remarks: The message may be a null-terminated multibyte string (15.4.2.1.5.2), suitable for conversion and display as a `wstring` (20.3, 26.4.1.4).
16.6.3.2 Class bad_array_new_length

```cpp
namespace std {
    class bad_array_new_length : public bad_alloc {
    public:
        bad_array_new_length() noexcept;
        const char* what() const noexcept override;
    };  
}
```

The class `bad_array_new_length` defines the type of objects thrown as exceptions by the implementation to report an attempt to allocate an array of size less than zero or greater than an implementation-defined limit (7.6.2.4).

1. `bad_array_new_length() noexcept;`
   - **Effects:** Constructs an object of class `bad_array_new_length`.

2. `const char* what() const noexcept override;`
   - **Returns:** An implementation-defined `ntbs`.
   - **Remarks:** The message may be a null-terminated multibyte string (15.4.2.1.5.2), suitable for conversion and display as a `wstring` (20.3, 26.4.1.4).

16.6.3.3 Type new_handler

```cpp
using new_handler = void (*)();
```

The type of a `handler function` to be called by `operator new()` or `operator new[]()` (16.6.2) when they cannot satisfy a request for additional storage.

1. **Required behavior:** A `new_handler` shall perform one of the following:
   - (2.1) make more storage available for allocation and then return;
   - (2.2) throw an exception of type `bad_alloc` or a class derived from `bad_alloc`;
   - (2.3) terminate execution of the program without returning to the caller.

16.6.3.4 set_new_handler

```cpp
new_handler set_new_handler(new_handler new_p) noexcept;
```

1. **Effects:** Establishes the function designated by `new_p` as the current `new_handler`.

2. **Returns:** The previous `new_handler`.

3. **Remarks:** The initial `new_handler` is a null pointer.

16.6.3.5 get_new_handler

```cpp
new_handler get_new_handler() noexcept;
```

1. **Returns:** The current `new_handler`. [Note: This may be a null pointer value. — end note]

16.6.4 Pointer optimization barrier

```cpp
template<class T> [[nodiscard]] constexpr T* launder(T* p) noexcept;
```

1. **Requires:** `p` represents the address `A` of a byte in memory. An object `X` that is within its lifetime (6.6.3) and whose type is similar (7.3.5) to `T` is located at the address `A`. All bytes of storage that would be reachable through the result are reachable through `p` (see below).

2. **Returns:** A value of type `T *` that points to `X`.

3. **Remarks:** An invocation of this function may be used in a core constant expression whenever the value of its argument may be used in a core constant expression. A byte of storage is reachable through a pointer value that points to an object `Y` if it is within the storage occupied by `Y`, an object that is pointer-interconvertible with `Y`, or the immediately-enclosing array object if `Y` is an array element. The program is ill-formed if `T` is a function type or `cv void`.

4. [Note: If a new object is created in storage occupied by an existing object of the same type, a pointer to the original object can be used to refer to the new object unless the type contains `const` or reference types. — end note]
members; in the latter cases, this function can be used to obtain a usable pointer to the new object.
See 6.6.3. — end note]

5

[Example:

    struct X { const int n; };  
    X *p = new X(3);  
    const int a = p->n;  
    new (p) X(5);  // p does not point to new object (6.6.3) because X::n is const  
    const int b = p->n;  // undefined behavior  
    const int c = std::launder(p)->n;  // OK

—— end example]

16.6.5 Hardware interference size [hardware.interference]

inline constexpr size_t hardware_destructive_interference_size = implementation-defined;

This number is the minimum recommended offset between two concurrently-accessed objects to avoid
additional performance degradation due to contention introduced by the implementation. It shall be at least
alignof(max_align_t).

[Example:

    struct keep_apart {
        alignas(hardware_destructive_interference_size) atomic<int> cat;
        alignas(hardware_destructive_interference_size) atomic<int> dog;
    };

—— end example]

inline constexpr size_t hardware_constructive_interference_size = implementation-defined;

This number is the maximum recommended size of contiguous memory occupied by two objects accessed
with temporal locality by concurrent threads. It shall be at least alignof(max_align_t).

[Example:

    struct together {
        atomic<int> dog;
        int puppy;
    };
    struct kennel {
        // Other data members...
        alignas(sizeof(together)) together pack;
        // Other data members...
    };
    static_assert(sizeof(together) <= hardware_constructive_interference_size);

—— end example]

16.7 Type identification [support.rtti]

1 The header <typeinfo> defines a type associated with type information generated by the implementation. It
also defines two types for reporting dynamic type identification errors.

16.7.1 Header <typeinfo> synopsis [typeinfo.syn]

namespace std {
    class type_info;
    class bad_cast;
    class bad_typeid;
}

16.7.2 Class type_info [type.info]

namespace std {
    class type_info {
        public:
            virtual ~type_info();
            bool operator==(const type_info& rhs) const noexcept;
            bool operator!=(const type_info& rhs) const noexcept;
    }
The class `type_info` describes type information generated by the implementation (7.6.1.8). Objects of this class effectively store a pointer to a name for the type, and an encoded value suitable for comparing two types for equality or collating order. The names, encoding rule, and collating sequence for types are all unspecified and may differ between programs.

```cpp
bool before(const type_info& rhs) const noexcept;
size_t hash_code() const noexcept;
const char* name() const noexcept;
type_info(const type_info& rhs) = delete;  // cannot be copied
type_info& operator=(const type_info& rhs) = delete;  // cannot be copied
```

1. The class `type_info` defines type information generated by the implementation (7.6.1.8). Objects of this class effectively store a pointer to a name for the type, and an encoded value suitable for comparing two types for equality or collating order. The names, encoding rule, and collating sequence for types are all unspecified and may differ between programs.

```cpp
bool operator==(const type_info& rhs) const noexcept;
Effects: Compares the current object with `rhs`.
Returns: true if the two values describe the same type.

bool operator!=(const type_info& rhs) const noexcept;
Returns: !(this == rhs).

bool before(const type_info& rhs) const noexcept;
Effects: Compares the current object with `rhs`.
Returns: true if *this precedes rhs in the implementation’s collation order.

size_t hash_code() const noexcept;
Returns: An unspecified value, except that within a single execution of the program, it shall return the same value for any two `type_info` objects which compare equal.
Remarks: An implementation should return different values for two `type_info` objects which do not compare equal.

const char* name() const noexcept;
Returns: An implementation-defined ntbs.
Remarks: The message may be a null-terminated multibyte string (15.4.2.1.5.2), suitable for conversion and display as a wstring (20.3, 26.4.1.4)
```

### 16.7.3 Class `bad_cast`

```cpp
namespace std {
    class bad_cast : public exception {
    public:
        bad_cast() noexcept;
        bad_cast(const bad_cast&) noexcept;
        bad_cast& operator=(const bad_cast&) noexcept;
        const char* what() const noexcept override;
    };
}
```

1. The class `bad_cast` defines the type of objects thrown as exceptions by the implementation to report the execution of an invalid `dynamic_cast` expression (7.6.1.7).

```cpp
bad_cast() noexcept;
Effects: Constructs an object of class `bad_cast`.

bad_cast(const bad_cast&) noexcept;
bad_cast& operator=(const bad_cast&) noexcept;
Effects: Copies an object of class `bad_cast`.

const char* what() const noexcept override;
Returns: An implementation-defined ntbs.
```
Remarks: The message may be a null-terminated multibyte string (15.4.2.1.5.2), suitable for conversion and display as a wstring (20.3, 26.4.1.4)

16.7.4 Class bad_typeid

namespace std {
    class bad_typeid : public exception {
    public:
        bad_typeid() noexcept;
        bad_typeid(const bad_typeid&) noexcept;
        bad_typeid& operator=(const bad_typeid&) noexcept;
        const char* what() const noexcept override;
    }
}

The class bad_typeid defines the type of objects thrown as exceptions by the implementation to report a null pointer in a typeid expression (7.6.1.8).

bad_typeid() noexcept;

Effects: Constructs an object of class bad_typeid.

bad_typeid(const bad_typeid&) noexcept;
bad_typeid& operator=(const bad_typeid&) noexcept;

Effects: Copies an object of class bad_typeid.

const char* what() const noexcept override;

Returns: An implementation-defined ntbs.

Remarks: The message may be a null-terminated multibyte string (15.4.2.1.5.2), suitable for conversion and display as a wstring (20.3, 26.4.1.4)

16.8 Contract violation handling

16.8.1 Header <contract> synopsis

The header <contract> defines a type for reporting information about contract violations generated by the implementation.

namespace std {
    class contract_violation;
}

16.8.2 Class contract_violation

namespace std {
    class contract_violation {
    public:
        uint_least32_t line_number() const noexcept;
        string_view file_name() const noexcept;
        string_view function_name() const noexcept;
        string_view comment() const noexcept;
        string_view assertion_level() const noexcept;
    }
}

The class contract_violation describes information about a contract violation generated by the implementation.

uint_least32_t line_number() const noexcept;

Returns: The source code location where the contract violation happened (9.11.4). If the location is unknown, an implementation may return 0.

string_view file_name() const noexcept;

Returns: The source file name where the contract violation happened (9.11.4). If the file name is unknown, an implementation may return string_view{).
string_view function_name() const noexcept;

Returns: The name of the function where the contract violation happened (9.11.4). If the function name is unknown, an implementation may return string_view().

string_view comment() const noexcept;

Returns: Implementation-defined text describing the predicate of the violated contract.

string_view assertion_level() const noexcept;

Returns: Text describing the assertion-level of the violated contract.

16.9 Exception handling

The header <exception> defines several types and functions related to the handling of exceptions in a C++ program.

16.9.1 Header <exception> synopsis

namespace std {
    class exception;
    class bad_exception;
    class nested_exception;

    using terminate_handler = void (*)();
    terminate_handler get_terminate() noexcept;
    terminate_handler set_terminate(terminate_handler f) noexcept;

    [[noreturn]] void terminate() noexcept;

    int uncaught_exceptions() noexcept;

    using exception_ptr = unspecified;

    exception_ptr current_exception() noexcept;

    [[noreturn]] void rethrow_exception(exception_ptr p);

    template<class E> exception_ptr make_exception_ptr(E e) noexcept;

    template<class T> [[noreturn]] void throw_with_nested(T&& t);

    template<class E> void rethrow_if_nested(const E& e);
}

16.9.2 Class exception

namespace std {
    class exception {
        public:
            exception() noexcept;
            exception(const exception&) noexcept;
            exception& operator=(const exception&) noexcept;
            virtual ~exception();
            virtual const char* what() const noexcept;
    };
}

The class exception defines the base class for the types of objects thrown as exceptions by C++ standard library components, and certain expressions, to report errors detected during program execution.

Each standard library class T that derives from class exception shall have a publicly accessible copy constructor and a publicly accessible copy assignment operator that do not exit with an exception. These member functions shall meet the following postcondition: If two objects lhs and rhs both have dynamic type T and lhs is a copy of rhs, then strcmp(lhs.what(), rhs.what()) shall equal 0.

exception() noexcept;

Effects: Constructs an object of class exception.
exception(const exception& rhs) noexcept;
exception& operator=(const exception& rhs) noexcept;

4 Effects: Copies an exception object.
5 Ensures: If *this and rhs both have dynamic type exception then the value of the expression
   strcmp(what(), rhs.what()) shall equal 0.

virtual ~exception();
6 Effects: Destroys an object of class exception.

virtual const char* what() const noexcept override;
7 Returns: An implementation-defined NTBS.
8 Remarks: The message may be a null-terminated multibyte string (15.4.2.1.5.2), suitable for conversion
   and display as a wstring (20.3, 26.4.1.4). The return value remains valid until the exception object
   from which it is obtained is destroyed or a non-const member function of the exception object is called.

16.9.3 Class bad_exception

namespace std {
   class bad_exception : public exception {
   public:
      bad_exception() noexcept;
      bad_exception(const bad_exception&) noexcept;
      bad_exception& operator=(const bad_exception&) noexcept;
      const char* what() const noexcept override;
   }
};

1 The class bad_exception defines the type of the object referenced by the exception_ptr returned from a
   call to current_exception (16.9.6) when the currently active exception object fails to copy.

bad_exception() noexcept;
2 Effects: Constructs an object of class bad_exception.

bad_exception(const bad_exception&) noexcept;
bad_exception& operator=(const bad_exception&) noexcept;
3 Effects: Copies an object of class bad_exception.

const char* what() const noexcept override;
4 Returns: An implementation-defined NTBS.
5 Remarks: The message may be a null-terminated multibyte string (15.4.2.1.5.2), suitable for conversion
   and display as a wstring (20.3, 26.4.1.4).

16.9.4 Abnormal termination

16.9.4.1 Type terminate_handler

using terminate_handler = void (*)();

1 The type of a handler function to be called by std::terminate() when terminating exception processing.
2 Required behavior: A terminate_handler shall terminate execution of the program without returning to the caller.
3 Default behavior: The implementation’s default terminate_handler calls abort().

16.9.4.2 set_terminate

terminate_handler set_terminate(terminate_handler f) noexcept;
1 Effects: Establishes the function designated by f as the current handler function for terminating
   exception processing.
2 Remarks: It is unspecified whether a null pointer value designates the default terminate_handler.
3 Returns: The previous terminate_handler.
16.9.4.3  get_terminate

terminate_handler get_terminate() noexcept;

1   Returns: The current terminate_handler. [Note: This may be a null pointer value. — end note]

16.9.4.4  terminate

[noreturn] void terminate() noexcept;

1   Remarks: Called by the implementation when exception handling must be abandoned for any of several reasons (13.5.1). May also be called directly by the program.
2   Effects: Calls a terminate_handler function. It is unspecified which terminate_handler function will be called if an exception is active during a call to set_terminate. Otherwise calls the current terminate_handler function. [Note: A default terminate_handler is always considered a callable handler in this context. — end note]

16.9.5  uncaught_exceptions

int uncaught_exceptions() noexcept;

1   Returns: The number of uncaught exceptions (13.5.2).
2   Remarks: When uncaught_exceptions() > 0, throwing an exception can result in a call of the function std::terminate (13.5.1).

16.9.6  Exception propagation

using exception_ptr = unspecified;

1   The type exception_ptr can be used to refer to an exception object.
2   exception_ptr shall satisfy the requirements of Cpp17NullablePointer (Table 30).
3   Two non-null values of type exception_ptr are equivalent and compare equal if and only if they refer to the same exception.
4   The default constructor of exception_ptr produces the null value of the type.
5   exception_ptr shall not be implicitly convertible to any arithmetic, enumeration, or pointer type.
6   [Note: An implementation might use a reference-counted smart pointer as exception_ptr. — end note]
7   For purposes of determining the presence of a data race, operations on exception_ptr objects shall access and modify only the exception_ptr objects themselves and not the exceptions they refer to. Use of rethrow_exception on exception_ptr objects that refer to the same exception object shall not introduce a data race. [Note: If rethrow_exception rethrows the same exception object (rather than a copy), concurrent access to that rethrown exception object may introduce a data race. Changes in the number of exception_ptr objects that refer to a particular exception do not introduce a data race. — end note]

exception_ptr current_exception() noexcept;

8   Returns: An exception_ptr object that refers to the currently handled exception (13.3) or a copy of the currently handled exception, or a null exception_ptr object if no exception is being handled. The referenced object shall remain valid at least as long as there is an exception_ptr object that refers to it. If the function needs to allocate memory and the attempt fails, it returns an exception_ptr object that refers to an instance of bad_alloc. It is unspecified whether the return values of two successive calls to current_exception refer to the same exception object. [Note: That is, it is unspecified whether current_exception creates a new copy each time it is called. — end note] If the attempt to copy the current exception object throws an exception, the function returns an exception_ptr object that refers to the thrown exception or, if this is not possible, to an instance of bad_exception. [Note: The copy constructor of the thrown exception may also fail, so the implementation is allowed to substitute a bad_exception object to avoid infinite recursion. — end note]

[noreturn] void rethrow_exception(exception_ptr p);

9   Requires: p shall not be a null pointer.
Declares the exception object to which `p` refers.

```cpp
template<class E> exception_ptr make_exception_ptr(E e) noexcept;
```

**Effects:** Creates an `exception_ptr` object that refers to a copy of `e`, as if:
```
try {
    throw e;
} catch(...) {
    return current_exception();
}
```

*[Note: This function is provided for convenience and efficiency reasons. — end note]*

### 16.9.7 nested_exception

```cpp
namespace std {
    class nested_exception {
        public:
            nested_exception() noexcept;
            nested_exception(const nested_exception&) noexcept = default;
            nested_exception& operator=(const nested_exception&) noexcept = default;
            virtual ~nested_exception() = default;

            // access functions
            [[noreturn]] void rethrow_nested() const;
            exception_ptr nested_ptr() const noexcept;
        }

        template<class T> [[noreturn]] void throw_with_nested(T&& t);
        template<class E> void rethrow_if_nested(const E& e);
    }
```

The class `nested_exception` is designed for use as a mixin through multiple inheritance. It captures the currently handled exception and stores it for later use.

*[Note: `nested_exception` has a virtual destructor to make it a polymorphic class. Its presence can be tested for with `dynamic_cast`. — end note]*

```cpp
nested_exception() noexcept;
```

**Effects:** The constructor calls `current_exception()` and stores the returned value.

```cpp
[[noreturn]] void rethrow_nested() const;
```

**Effects:** If `nested_ptr()` returns a null pointer, the function calls the function `std::terminate`. Otherwise, it throws the stored exception captured by `*this`.

```cpp
exception_ptr nested_ptr() const noexcept;
```

**Returns:** The stored exception captured by this `nested_exception` object.

```cpp
template<class T> [[noreturn]] void throw_with_nested(T& t);
```

**Let** `U` be `decay_t<T>`.

**Requires:** `U` shall be `Cpp17CopyConstructible`.

**Throws:** If `is_class_v<U> && !is_final_v<U> && !is_base_of_v<nested_exception, U>` is true, an exception of unspecified type that is publicly derived from both `U` and `nested_exception` and constructed from `std::forward<T>(t)`, otherwise `std::forward<T>(t)`.

```cpp
template<class E> void rethrow_if_nested(const E& e);
```

**Effects:** If `E` is not a polymorphic class type, or if `nested_exception` is an inaccessible or ambiguous base class of `E`, there is no effect. Otherwise, performs:
```
if (auto p = dynamic_cast<const nested_exception*>(addressof(e)))
    p->rethrow_nested();
```
16.10 Initializer lists

The header `<initializer_list>` defines a class template and several support functions related to list-initialization (see 9.3.4). All functions specified in this subclause are signal-safe (16.12.4).

16.10.1 Header `<initializer_list>` synopsis

```cpp
namespace std {
  template<class E> class initializer_list {
    public:
      using value_type = E;
      using reference = const E&;
      using const_reference = const E&;
      using size_type = size_t;

      using iterator = const E*;
      using const_iterator = const E*;

      constexpr initializer_list() noexcept;
      constexpr size_t size() const noexcept; // number of elements
      constexpr const E* begin() const noexcept; // first element
      constexpr const E* end() const noexcept; // one past the last element
  };
}
```

An object of type `initializer_list<E>` provides access to an array of objects of type `const E`.

1 Note: A pair of pointers or a pointer plus a length would be obvious representations for `initializer_list`. `initializer_list` is used to implement initializer lists as specified in 9.3.4. Copying an initializer list does not copy the underlying elements. — end note

2 If an explicit specialization or partial specialization of `initializer_list` is declared, the program is ill-formed.

16.10.2 Initializer list constructors

```cpp
constexpr initializer_list() noexcept;
```

1 Effects: Constructs an empty `initializer_list` object.

2 Ensures: `size()` == 0.

16.10.3 Initializer list access

```cpp
constexpr const E* begin() const noexcept;
constexpr const E* end() const noexcept;
```

1 Returns: A pointer to the beginning of the array. If `size()` == 0 the values of `begin()` and `end()` are unspecified but they shall be identical.

2 Returns: `begin()` + `size()`.

16.10.4 Initializer list range access

```cpp
template<class E> constexpr const E* begin(initializer_list<E> il) noexcept;
```

1 Returns: `il.begin()`.

§ 16.10.4 478
template<class E> constexpr const E* end(initializer_list<E> il) noexcept;

Returns: il.end().

16.11 Comparisons

16.11.1 Header <compare> synopsis

The header <compare> specifies types, objects, and functions for use primarily in connection with the three-way comparison operator (7.6.8).

namespace std {
  // 16.11.2, comparison category types
  class weak_equality;
  class strong_equality;
  class partial_ordering;
  class weak_ordering;
  class strong_ordering;

  // named comparison functions
  constexpr bool is_eq (weak_equality cmp) noexcept { return cmp == 0; }
  constexpr bool is_neq (weak_equality cmp) noexcept { return cmp != 0; }
  constexpr bool is_lt (partial_ordering cmp) noexcept { return cmp < 0; }
  constexpr bool is_lteq(partial_ordering cmp) noexcept { return cmp <= 0; }
  constexpr bool is_gt (partial_ordering cmp) noexcept { return cmp > 0; }
  constexpr bool is_gteq(partial_ordering cmp) noexcept { return cmp >= 0; }

  // 16.11.3, common comparison category type
  template<class... Ts>
  struct common_comparison_category {
    using type = see below;
  };
  template<class... Ts>
  using common_comparison_category_t = typename common_comparison_category<Ts...>::type;

  // 16.11.4, comparison algorithms
  template<class T> constexpr strong_ordering strong_order(const T& a, const T& b);
  template<class T> constexpr weak_ordering weak_order(const T& a, const T& b);
  template<class T> constexpr partial_ordering partial_order(const T& a, const T& b);
  template<class T> constexpr strong_equality strong_equal(const T& a, const T& b);
  template<class T> constexpr weak_equality weak_equal(const T& a, const T& b);
}

16.11.2 Comparison category types

16.11.2.1 Preamble

The types weak_equality, strong_equality, partial_ordering, weak_ordering, and strong_ordering are collectively termed the comparison category types. Each is specified in terms of an exposition-only data member named value whose value typically corresponds to that of an enumerator from one of the following exposition-only enumerations:

enum class eq { equal = 0, equivalent = equal,
               nonequal = 1, nonequivalent = nonequal }; // exposition only
enum class ord { less = -1, greater = 1 }; // exposition only
enum class ncmp { unordered = -127 }; // exposition only

[Note: The types strong_ordering and weak_equality correspond, respectively, to the terms total ordering and equivalence in mathematics. — end note]

The relational and equality operators for the comparison category types are specified with an anonymous parameter of unspecified type. This type shall be selected by the implementation such that these parameters can accept literal 0 as a corresponding argument. [Example: nullptr_t satisfies this requirement. — end example] In this context, the behavior of a program that supplies an argument other than a literal 0 is undefined.

For the purposes of this subclause, substitutability is the property that f(a) == f(b) is true whenever a == b is true, where f denotes a function that reads only comparison-salient state that is accessible via the argument’s public const members.

§ 16.11.2.1
16.11.2.2 Class weak_equality

The `weak_equality` type is typically used as the result type of a three-way comparison operator (7.6.8) that (a) admits only equality and inequality comparisons, and (b) does not imply substitutability.

```cpp
namespace std {
    class weak_equality {
        int value; // exposition only

        // exposition-only constructor
        explicit constexpr weak_equality(eq v) noexcept : value(int(v)) {} // exposition only

    public:
        // valid values
        static const weak_equality equivalent;
        static const weak_equality nonequivalent;

        // comparisons
        friend constexpr bool operator==(weak_equality v, unspecified) noexcept;
        friend constexpr bool operator!=(weak_equality v, unspecified) noexcept;
        friend constexpr bool operator==(unspecified, weak_equality v) noexcept;
        friend constexpr bool operator!=(unspecified, weak_equality v) noexcept;
        friend constexpr weak_equality operator<=>(weak_equality v, unspecified) noexcept;
        friend constexpr weak_equality operator<=>(unspecified, weak_equality v) noexcept;
    }

    // valid values' definitions
    inline constexpr weak_equality weak_equality::equivalent(eq::equivalent);
    inline constexpr weak_equality weak_equality::nonequivalent(eq::nonequivalent);
}
```

2

```cpp
constexpr bool operator==(weak_equality v, unspecified) noexcept;
constexpr bool operator==(unspecified, weak_equality v) noexcept;
```

3

```cpp
Returns: v.value == 0.
```

4

```cpp
constexpr bool operator!=(weak_equality v, unspecified) noexcept;
constexpr bool operator!=(unspecified, weak_equality v) noexcept;
```

5

```cpp
Returns: v.value != 0.
```

16.11.2.3 Class strong_equality

The `strong_equality` type is typically used as the result type of a three-way comparison operator (7.6.8) that (a) admits only equality and inequality comparisons, and (b) does imply substitutability.

```cpp
namespace std {
    class strong_equality {
        int value; // exposition only

        // exposition-only constructor
        explicit constexpr strong_equality(eq v) noexcept : value(int(v)) {} // exposition only

    public:
        // valid values
        static const strong_equality equal;
        static const strong_equality nonequal;
        static const strong_equality equivalent;
        static const strong_equality nonequivalent;

        // conversion
        constexpr operator weak_equality() const noexcept;
    }

    // valid values' definitions
    inline constexpr strong_equality strong_equality::equal(eq::equal);
    inline constexpr strong_equality strong_equality::nonequal(eq::nonequal);
    inline constexpr strong_equality strong_equality::equivalent(eq::equivalent);
    inline constexpr strong_equality strong_equality::nonequivalent(eq::nonequivalent);

    // conversion
    constexpr operator weak_equality() const noexcept;
```
// comparisons
friend constexpr bool operator==(strong_equality v, unspecified) noexcept;
friend constexpr bool operator!=(strong_equality v, unspecified) noexcept;
friend constexpr bool operator==(unspecified, strong_equality v) noexcept;
friend constexpr bool operator!=(unspecified, strong_equality v) noexcept;
friend constexpr strong_equality operator<=>(strong_equality v, unspecified) noexcept;
friend constexpr strong_equality operator<=>(unspecified, strong_equality v) noexcept;
};

// valid values' definitions
inline constexpr strong_equality strong_equality::equal(eq::equal);
inline constexpr strong_equality strong_equality::nonequal(eq::nonequal);
inline constexpr strong_equality strong_equality::equivalent(eq::equivalent);
inline constexpr strong_equality strong_equality::nonequivalent(eq::nonequivalent);

constexpr operator weak_equality() const noexcept;

Returns: value == 0 ? weak_equality::equivalent : weak_equality::nonequivalent.

constexpr bool operator==(strong_equality v, unspecified) noexcept;
constexpr bool operator==(unspecified, strong_equality v) noexcept;

Returns: v.value == 0.

constexpr bool operator!=(strong_equality v, unspecified) noexcept;
constexpr bool operator!=(unspecified, strong_equality v) noexcept;

Returns: v.value != 0.

constexpr strong_equality operator<=>(strong_equality v, unspecified) noexcept;
constexpr strong_equality operator<=>(unspecified, strong_equality v) noexcept;

Returns: v.

16.11.2.4 Class partial_ordering

The partial_ordering type is typically used as the result type of a three-way comparison operator (7.6.8) that (a) admits all of the six two-way comparison operators (7.6.9, 7.6.10), (b) does not imply substitutability, and (c) permits two values to be incomparable.221

namespace std {
    class partial_ordering {
        int value; // exposition only
        bool is_ordered; // exposition only

        // exposition-only constructors
        explicit constexpr partial_ordering(eq v) noexcept : value(int(v)), is_ordered(true) {} // exposition only
        explicit constexpr partial_ordering(ord v) noexcept : value(int(v)), is_ordered(true) {} // exposition only
        explicit constexpr partial_ordering(ncmp v) noexcept : value(int(v)), is_ordered(false) {} // exposition only

    public:
        // valid values
        static const partial_ordering less;
        static const partial_ordering equivalent;
        static const partial_ordering greater;
        static const partial_ordering unordered;

        // conversion
        constexpr operator weak_equality() const noexcept;
    }

221) That is, a < b, a == b, and a > b might all be false.
// comparisons
friend constexpr bool operator==(partial_ordering v, unspecified) noexcept;
friend constexpr bool operator!=(partial_ordering v, unspecified) noexcept;
friend constexpr bool operator<(partial_ordering v, unspecified) noexcept;
friend constexpr bool operator>(partial_ordering v, unspecified) noexcept;
friend constexpr bool operator<=(partial_ordering v, unspecified) noexcept;
friend constexpr bool operator>=(partial_ordering v, unspecified) noexcept;
friend constexpr bool operator== (unspecified, partial_ordering v) noexcept;
friend constexpr bool operator!= (unspecified, partial_ordering v) noexcept;
friend constexpr bool operator< (unspecified, partial_ordering v) noexcept;
friend constexpr bool operator> (unspecified, partial_ordering v) noexcept;
friend constexpr bool operator<= (unspecified, partial_ordering v) noexcept;
friend constexpr bool operator>= (unspecified, partial_ordering v) noexcept;
friend constexpr partial_ordering operator<=>(partial_ordering v, unspecified) noexcept;
friend constexpr partial_ordering operator<=>(unspecified, partial_ordering v) noexcept;
};

// valid values' definitions
inline constexpr partial_ordering partial_ordering::less(ord::less);
inline constexpr partial_ordering partial_ordering::equivalent(eq::equivalent);
inline constexpr partial_ordering partial_ordering::greater(ord::greater);
inline constexpr partial_ordering partial_ordering::unordered(ncmp::unordered);

constexpr operator weak_equality() const noexcept;

Returns: value == 0 ? weak_equality::equivalent : weak_equality::nonequivalent. [Note: The result is independent of the is_ordered member. —end note]

constexpr bool operator==(partial_ordering v, unspecified) noexcept;
constexpr bool operator< (partial_ordering v, unspecified) noexcept;
constexpr bool operator> (partial_ordering v, unspecified) noexcept;
constexpr bool operator<=(partial_ordering v, unspecified) noexcept;
constexpr bool operator>=(partial_ordering v, unspecified) noexcept;
Returns: For operator@, v.is_ordered && v.value @ 0.

constexpr bool operator==(unspecified, partial_ordering v) noexcept;
constexpr bool operator< (unspecified, partial_ordering v) noexcept;
constexpr bool operator> (unspecified, partial_ordering v) noexcept;
constexpr bool operator<=(unspecified, partial_ordering v) noexcept;
constexpr bool operator>=(unspecified, partial_ordering v) noexcept;
Returns: For operator@, v.is_ordered && 0 @ v.value.

constexpr bool operator!=(partial_ordering v, unspecified) noexcept;
constexpr bool operator!= (unspecified, partial_ordering v) noexcept;
Returns: For operator@, !v.is_ordered || v.value != 0.

constexpr partial_ordering operator<=>(partial_ordering v, unspecified) noexcept;
constexpr partial_ordering operator<=>(unspecified, partial_ordering v) noexcept;
Returns: v < 0 ? partial_ordering::greater : v > 0 ? partial_ordering::less : v.

16.11.2.5 Class weak_ordering

The weak_ordering type is typically used as the result type of a three-way comparison operator (7.6.8) that (a) admits all of the six two-way comparison operators (7.6.9, 7.6.10), and (b) does not imply substitutability.

namespace std {
    class weak_ordering {
        int value; // exposition only
    // exposition-only constructors
    explicit constexpr weak_ordering(eq v) noexcept : value(int(v)) {} // exposition only
}
explicit constexpr weak_ordering(ord v) noexcept : value(int(v)) {} // exposition only

public:
    // valid values
    static const weak_ordering less;
    static const weak_ordering equivalent;
    static const weak_ordering greater;

    // conversions
    constexpr operator weak_equality() const noexcept;
    constexpr operator partial_ordering() const noexcept;

    // comparisons
    friend constexpr bool operator==(weak_ordering v, unspecified) noexcept;
    friend constexpr bool operator!=(weak_ordering v, unspecified) noexcept;
    friend constexpr bool operator<(weak_ordering v, unspecified) noexcept;
    friend constexpr bool operator>(weak_ordering v, unspecified) noexcept;
    friend constexpr bool operator<=(weak_ordering v, unspecified) noexcept;
    friend constexpr bool operator>=(weak_ordering v, unspecified) noexcept;
    friend constexpr weak_ordering operator<=>(weak_ordering v, unspecified) noexcept;
    friend constexpr weak_ordering operator<=>(unspecified, weak_ordering v) noexcept;

    // valid values' definitions
    inline constexpr weak_ordering weak_ordering::less(ord::less);
    inline constexpr weak_ordering weak_ordering::equivalent(eq::equivalent);
    inline constexpr weak_ordering weak_ordering::greater(ord::greater);

constexpr operator weak_equality() const noexcept;
2 Returns: value == 0 ? weak_equality::equivalent : weak_equality::nonequivalent.

constexpr operator partial_ordering() const noexcept;
3 Returns:
    value == 0 ? partial_ordering::equivalent :
    value < 0 ? partial_ordering::less :
        partial_ordering::greater

constexpr bool operator==(weak_ordering v, unspecified) noexcept;
constexpr bool operator!=(weak_ordering v, unspecified) noexcept;
constexpr bool operator<(weak_ordering v, unspecified) noexcept;
constexpr bool operator>(weak_ordering v, unspecified) noexcept;
constexpr bool operator<=(weak_ordering v, unspecified) noexcept;
constexpr bool operator>=(weak_ordering v, unspecified) noexcept;
constexpr weak_ordering operator<=>(weak_ordering v, unspecified) noexcept;
constexpr weak_ordering operator<=>(unspecified, weak_ordering v) noexcept;

Returns: v.value @ 0 for operator@.

Returns: v.value @ 0 for operator@.

constexpr weak_ordering operator<=>(weak_ordering v, unspecified) noexcept;
6 Returns: v.
constexpr weak_ordering operator<=>(unspecified, weak_ordering v) noexcept;

Returns: \( v < 0 \) ? weak_ordering::greater : \( v > 0 \) ? weak_ordering::less : v.

### 16.11.2.6 Class strong_ordering

The strong_ordering type is typically used as the result type of a three-way comparison operator (7.6.8) that (a) admits all of the six two-way comparison operators (7.6.9, 7.6.10), and (b) does imply substitutability.

```cpp
namespace std {
    class strong_ordering {

    public:
        // valid values
        static const strong_ordering less;
        static const strong_ordering equal;
        static const strong_ordering equivalent;
        static const strong_ordering greater;

    // conversions
        constexpr operator weak_equality() const noexcept;
        constexpr operator strong_equality() const noexcept;
        constexpr operator partial_ordering() const noexcept;
        constexpr operator weak_ordering() const noexcept;

    // comparisons
        friend constexpr bool operator==(strong_ordering v, unspecified) noexcept;
        friend constexpr bool operator!=(strong_ordering v, unspecified) noexcept;
        friend constexpr bool operator<(strong_ordering v, unspecified) noexcept;
        friend constexpr bool operator<=(strong_ordering v, unspecified) noexcept;
        friend constexpr bool operator>(strong_ordering v, unspecified) noexcept;
        friend constexpr bool operator>=(strong_ordering v, unspecified) noexcept;
        friend constexpr strong_ordering operator<=>(strong_ordering v, unspecified) noexcept;
        friend constexpr strong_ordering operator<=>(unspecified, strong_ordering v) noexcept;

    // valid values' definitions
        inline constexpr strong_ordering strong_ordering::less(ord::less);
        inline constexpr strong_ordering strong_ordering::equal(eq::equal);
        inline constexpr strong_ordering strong_ordering::greater(ord::greater);
    }
}
```

constexpr operator weak_equality() const noexcept;

Returns: value == 0 ? weak_equality::equivalent : weak_equality::nonequivalent.

constexpr operator strong_equality() const noexcept;

Returns: value == 0 ? strong_equality::equal : strong_equality::nonequal.

constexpr operator partial_ordering() const noexcept;

Returns:
value == 0 ? partial_ordering::equivalent :
value < 0 ? partial_ordering::less :
    partial_ordering::greater

constexpr operator weak_ordering() const noexcept;

Returns:
value == 0 ? weak_ordering::equivalent :
value < 0 ? weak_ordering::less :
    weak_ordering::greater

constexpr bool operator==(strong_ordering v, unspecified) noexcept;
constexpr bool operator!=(strong_ordering v, unspecified) noexcept;
constexpr bool operator<(strong_ordering v, unspecified) noexcept;
constexpr bool operator>(strong_ordering v, unspecified) noexcept;
constexpr bool operator<=(strong_ordering v, unspecified) noexcept;
constexpr bool operator>=(strong_ordering v, unspecified) noexcept;

Returns: v.value @ 0 for operator@.

constexpr strong_ordering operator<=>(strong_ordering v, unspecified) noexcept;

Returns: 0 @ v.value for operator@.

constexpr strong_ordering operator<=>(unspecified, strong_ordering v) noexcept;

Returns: v.

constexpr strong_ordering operator<=>(unspecified, strong_ordering v) noexcept;

Returns: v < 0 ? strong_ordering::greater : v > 0 ? strong_ordering::less : v.

16.11.3 Class template common_comparison_category

The type common_comparison_category provides an alias for the strongest comparison category to which all of the template arguments can be converted. [Note: A comparison category type is stronger than another if they are distinct types and an instance of the former can be converted to an instance of the latter. — end note]

template<class... Ts>
struct common_comparison_category {
    using type = see below;
};

Remarks: The member typedef-name type denotes the common comparison type (10.10.2) of Ts..., the expanded parameter pack. [Note: This is well-defined even if the expansion is empty or includes a type that is not a comparison category type. — end note]

16.11.4 Comparison algorithms

template<class T> constexpr strong_ordering strong_order(const T& a, const T& b);

Effects: Compares two values and produces a result of type strong_ordering:

(1.1) If numeric_limits<T>::is_iec559 is true, returns a result of type strong_ordering that is consistent with the totalOrder operation as specified in ISO/IEC/IEEE 60559.
(1.2) Otherwise, returns a <=> b if that expression is well-formed and convertible to strong_ordering.
(1.3) Otherwise, if the expression a <=> b is well-formed, then the function is defined as deleted.
(1.4) Otherwise, if the expressions a == b and a < b are each well-formed and convertible to bool, then
    (1.4.1) if a == b is true, returns strong_ordering::equal;
    (1.4.2) otherwise, if a < b is true, returns strong_ordering::less;
(1.4.3) — otherwise, returns strong_ordering::greater.

(1.5) — Otherwise, the function is defined as deleted.

template<class T> constexpr weak_ordering weak_order(const T& a, const T& b);

Effects: Compares two values and produces a result of type weak_ordering:

(2.1) — Returns a <=> b if that expression is well-formed and convertible to weak_ordering.

(2.2) — Otherwise, if the expression a <=> b is well-formed, then the function is defined as deleted.

(2.3) — Otherwise, if the expressions a == b and a < b are each well-formed and convertible to bool, then

(2.3.1) — if a == b is true, returns weak_ordering::equivalent;

(2.3.2) — otherwise, if a < b is true, returns weak_ordering::less;

(2.3.3) — otherwise, returns weak_ordering::greater.

(2.4) — Otherwise, the function is defined as deleted.

template<class T> constexpr partial_ordering partial_order(const T& a, const T& b);

Effects: Compares two values and produces a result of type partial_ordering:

(3.1) — Returns a <=> b if that expression is well-formed and convertible to partial_ordering.

(3.2) — Otherwise, if the expression a <=> b is well-formed, then the function is defined as deleted.

(3.3) — Otherwise, if the expressions a == b and a < b are each well-formed and convertible to bool, then

(3.3.1) — if a == b is true, returns partial_ordering::equivalent;

(3.3.2) — otherwise, if a < b is true, returns partial_ordering::less;

(3.3.3) — otherwise, returns partial_ordering::greater.

(3.4) — Otherwise, the function is defined as deleted.

template<class T> constexpr strong_equality strong_equal(const T& a, const T& b);

Effects: Compares two values and produces a result of type strong_equality:

(4.1) — Returns a <=> b if that expression is well-formed and convertible to strong_equality.

(4.2) — Otherwise, if the expression a <=> b is well-formed, then the function is defined as deleted.

(4.3) — Otherwise, if the expression a == b is well-formed and convertible to bool, then

(4.3.1) — if a == b is true, returns strong_equality::equal;

(4.3.2) — otherwise, returns strong_equality::nonequal.

(4.4) — Otherwise, the function is defined as deleted.

template<class T> constexpr weak_equality weak_equal(const T& a, const T& b);

Effects: Compares two values and produces a result of type weak_equality:

(5.1) — Returns a <=> b if that expression is well-formed and convertible to weak_equality.

(5.2) — Otherwise, if the expression a <=> b is well-formed, then the function is defined as deleted.

(5.3) — Otherwise, if the expression a == b is well-formed and convertible to bool, then

(5.3.1) — if a == b is true, returns weak_equality::equivalent;

(5.3.2) — otherwise, returns weak_equality::nonequivalent.

(5.4) — Otherwise, the function is defined as deleted.

16.12 Other runtime support

[support.runtime]

1 Headers <setjmp> (nonlocal jumps), <csignal> (signal handling), <cstdarg> (variable arguments), and <cstdlib> (runtime environment getenv, system), provide further compatibility with C code.
2 Calls to the function getenv (16.2.2) shall not introduce a data race (15.5.5.9) provided that nothing modifies the environment. [Note: Calls to the POSIX functions setenv and putenv modify the environment. — end note]

3 A call to the setlocale function (26.5) may introduce a data race with other calls to the setlocale function or with calls to functions that are affected by the current C locale. The implementation shall behave as if no library function other than locale::global calls the setlocale function.

16.12.1 Header <cstdarg> synopsis

namespace std {
    using va_list = see below;
}

#define va_arg(V, P) see below
#define va_copy(VDST, VSRC) see below
#define va_end(V) see below
#define va_start(V, P) see below

1 The contents of the header <cstdarg> are the same as the C standard library header <stdarg.h>, with the following changes: The restrictions that ISO C places on the second parameter to the va_start macro in header <stdarg.h> are different in this document. The parameter parmN is the rightmost parameter in the variable parameter list of the function definition (the one just before the ...). If the parameter parmN is a pack expansion (12.6.3) or an entity resulting from a lambda capture (7.5.5), the program is ill-formed, no diagnostic required. If the parameter parmN is of a reference type, or of a type that is not compatible with the type that results when passing an argument for which there is no parameter, the behavior is undefined.

See also: ISO C 7.16.1.1

16.12.2 Header <csetjmp> synopsis

namespace std {
    using jmp_buf = see below;
    [[noreturn]] void longjmp(jmp_buf env, int val);
}

#define setjmp(env) see below

1 The contents of the header <csetjmp> are the same as the C standard library header <setjmp.h>.

2 The function signature longjmp(jmp_buf jbuf, int val) has more restricted behavior in this document. A setjmp/longjmp call pair has undefined behavior if replacing the setjmp and longjmp by catch and throw would invoke any non-trivial destructors for any automatic objects.

See also: ISO C 7.13

16.12.3 Header <csignal> synopsis

namespace std {
    using sig_atomic_t = see below;

    // 16.12.4, signal handlers
    extern "C" using signal-handler = void(int); // exposition only
    signal-handler* signal(int sig, signal-handler* func);
    int raise(int sig);
}

#define SIG_DFL see below
#define SIG_ERR see below
#define SIG_IGN see below
#define SIGABRT see below
#define SIGFPE see below
#define SIGILL see below
#define SIGINT see below
#define SIGSEGV see below

222) Note that va_start is required to work as specified even if unary operator& is overloaded for the type of parmN.
#define SIGTERM see below

1 The contents of the header `<signal>` are the same as the C standard library header `<signal.h>.

16.12.4 Signal handlers [support.signal]

1 A call to the function `signal` synchronizes with any resulting invocation of the signal handler so installed.

2 A plain lock-free atomic operation is an invocation of a function `f` from Clause 29, such that:

(2.1) — `f` is the function `atomic_is_lock_free()`, or

(2.2) — `f` is the member function `is_lock_free()`, or

(2.3) — `f` is a non-static member function invoked on an object `A`, such that `A.is_lock_free()` yields `true`, or

(2.4) — `f` is a non-member function, and for every pointer-to-atomic argument `A` passed to `f`, `atomic_is_lock_free(A)` yields `true`.

3 An evaluation is signal-safe unless it includes one of the following:

(3.1) — a call to any standard library function, except for plain lock-free atomic operations and functions explicitly identified as signal-safe. [Note: This implicitly excludes the use of `new` and `delete` expressions that rely on a library-provided memory allocator. — end note]

(3.2) — an access to an object with thread storage duration;

(3.3) — a `dynamic_cast` expression;

(3.4) — throwing of an exception;

(3.5) — control entering a try-block or function-try-block;

(3.6) — initialization of a variable with static storage duration requiring dynamic initialization (6.8.3.3, 8.7)\textsuperscript{223};

or

(3.7) — waiting for the completion of the initialization of a variable with static storage duration (8.7).

A signal handler invocation has undefined behavior if it includes an evaluation that is not signal-safe.

4 The function `signal` is signal-safe if it is invoked with the first argument equal to the signal number corresponding to the signal that caused the invocation of the handler.

See also: ISO C 7.14

\textsuperscript{223} Such initialization might occur because it is the first odr-use (6.2) of that variable.
17 Concepts library

17.1 General

This Clause describes library components that C++ programs may use to perform compile-time validation of template arguments and perform function dispatch based on properties of types. The purpose of these concepts is to establish a foundation for equational reasoning in programs.

The following subclauses describe language-related concepts, comparison concepts, object concepts, and callable concepts as summarized in Table 36.

Table 36 — Fundamental concepts library summary

<table>
<thead>
<tr>
<th>Subclause</th>
<th>Header(s)</th>

</tr>
<tr>
<td>17.7</td>
<td>Callable concepts</td>
</tr>
</tbody>
</table>

17.2 Equality preservation

An expression is equality-preserving if, given equal inputs, the expression results in equal outputs. The inputs to an expression are the set of the expression’s operands. The output of an expression is the expression’s result and all operands modified by the expression.

Not all input values need be valid for a given expression; e.g., for integers a and b, the expression a / b is not well-defined when b is 0. This does not preclude the expression a / b being equality-preserving. The domain of an expression is the set of input values for which the expression is required to be well-defined.

Expressions required by this document to be equality-preserving are further required to be stable: two evaluations of such an expression with the same input objects are required to have equal outputs absent any explicit intervening modification of those input objects. [Note: This requirement allows generic code to reason about the current values of objects based on knowledge of the prior values as observed via equality-preserving expressions. It effectively forbids spontaneous changes to an object, changes to an object from another thread of execution, changes to an object as side effects of non-modifying expressions, and changes to an object as side effects of modifying a distinct object if those changes could be observable to a library function via an equality-preserving expression that is required to be valid for that object. —end note]

Expressions declared in a requires-expression in this document are required to be equality-preserving, except for those annotated with the comment “not required to be equality-preserving.” An expression so annotated may be equality-preserving, but is not required to be so.

An expression that may alter the value of one or more of its inputs in a manner observable to equality-preserving expressions is said to modify those inputs. This document uses a notational convention to specify which expressions declared in a requires-expression modify which inputs: except where otherwise specified, an expression operand that is a non-constant lvalue or rvalue may be modified. Operands that are constant lvalues or rvalues are required to not be modified.

Where a requires-expression declares an expression that is non-modifying for some constant lvalue operand, additional variations of that expression that accept a non-constant lvalue or (possibly constant) rvalue for the given operand are also required except where such an expression variation is explicitly required with differing semantics. These implicit expression variations are required to meet the semantic requirements of the declared expression. The extent to which an implementation validates the syntax of the variations is unspecified.

[Example:

```cpp
template<class T>
concept C = requires(T a, T b, const T c, const T d) {
    c == d;  // #1
    a = std::move(b); // #2
```]

§ 17.2
a = c;    // #3
);

For the above example:

(7.1) — Expression #1 does not modify either of its operands, #2 modifies both of its operands, and #3 modifies only its first operand a.

(7.2) — Expression #1 implicitly requires additional expression variations that meet the requirements for c == d (including non-modification), as if the expressions

\[
\begin{align*}
    c &= \text{std::move}(d); & c &= \text{std::move}(b); \\
    \text{std::move}(c) &= d; & \text{std::move}(c) &= b; \\
    \text{std::move}(c) &= \text{std::move}(d); & \text{std::move}(c) &= \text{std::move}(b); \\
    a &= d; & a &= b; \\
    \text{std::move}(a) &= d; & \text{std::move}(a) &= b; \\
    \text{std::move}(a) &= \text{std::move}(d); & \text{std::move}(a) &= \text{std::move}(b);
\end{align*}
\]

had been declared as well.

(7.3) — Expression #3 implicitly requires additional expression variations that meet the requirements for a = c (including non-modification of the second operand), as if the expressions a = b and a = \text{std::move}(c) had been declared. Expression #3 does not implicitly require an expression variation with a non-constant rvalue second operand, since expression #2 already specifies exactly such an expression explicitly.

—end example

[Example: The following type T meets the explicitly stated syntactic requirements of concept C above but does not meet the additional implicit requirements:

```cpp
struct T {
    bool operator==(const T&) const { return true; }
    bool operator==(T&) = delete;
};
```

T fails to meet the implicit requirements of C, so \text{C}\langle{T}\rangle is not satisfied. Since implementations are not required to validate the syntax of implicit requirements, it is unspecified whether an implementation diagnoses as ill-formed a program that requires \text{C}\langle{T}\rangle. —end example]

17.3 Header <concepts> synopsis

```cpp
namespace std {
    // 17.4, language-related concepts
    // 17.4.2, concept Same
    template<class T, class U>

17.4 Language-related concepts

17.4.1 General

This subclause contains the definition of concepts corresponding to language features. These concepts express relationships between types, type classifications, and fundamental type properties.

17.4.2 Concept Same

```cpp
template<class T, class U>
concept Same = is_same_v<T, U>;
```

Same<T, U> subsumes Same<U, T> and vice versa.

17.4.3 Concept DerivedFrom

```cpp
template<class Derived, class Base>
concept DerivedFrom =
is_base_of_v<Base, Derived> &&
is_convertible_v<const volatile Derived*, const volatile Base*>;
```

[Note: DerivedFrom<Derived, Base> is satisfied if and only if Derived is publicly and unambiguously derived from Base, or Derived and Base are the same class type ignoring cv-qualifiers. — end note]

17.4.4 ConceptConvertibleTo

```cpp
template<class From, class To>
concept ConvertibleTo =
is_convertible_v<From, To> &&
requires(From (&f)()) {
    static_cast<To>(f());
};
```

Let `test` be the invented function:

```cpp
to test(From (kf)()) {
    return f();
}
```

and let `f` be a function with no arguments and return type `From` such that `f()` is equality-preserving. `ConvertibleTo<From, To>` is satisfied only if:

- To is not an object or reference-to-object type, or `static_cast<To>(f())` is equal to `test(f)`. 

(2.1)
— From is not a reference-to-object type, or

— If From is an rvalue reference to a non const-qualified type, the resulting state of the object referenced by f() after either above expression is valid but unspecified (15.5.5.15).

— Otherwise, the object referred to by f() is not modified by either above expression.

### 17.4.5 Concept CommonReference

For two types T and U, if common_reference_t<T, U> is well-formed and denotes a type C such that both
ConvertibleTo<T, C> and ConvertibleTo<U, C> are satisfied, then T and U share a common reference type,
C. [Note: C could be the same as T, or U, or it could be a different type. C may be a reference type. — end note]

```cpp
template<class T, class U>
concept CommonReference =
    Same<common_reference_t<T, U>, common_reference_t<U, T>> &&
    ConvertibleTo<T, common_reference_t<T, U>> &&
    ConvertibleTo<U, common_reference_t<T, U>>;
```

Let C be common_reference_t<T, U>. Let t be a function whose return type is T, and let u be a
function whose return type is U. CommonReference<T, U> is satisfied only if:

— C(t()) equals C(t()) if and only if t() is an equality-preserving expression (17.2).
— C(u()) equals C(u()) if and only if u() is an equality-preserving expression.

[Note: Users can customize the behavior of CommonReference by specializing the basic_common_reference class template (19.15.7.6). — end note]

### 17.4.6 Concept Common

If T and U can both be explicitly converted to some third type, C, then T and U share a common type,
C. [Note: C could be the same as T, or U, or it could be a different type. C might not be unique. — end note]

```cpp
template<class T, class U>
concept Common =
    Same<common_type_t<T, U>, common_type_t<U, T>> &&
    ConvertibleTo<T, common_type_t<T, U>> &&
    ConvertibleTo<U, common_type_t<T, U>> &&
    CommonReference<
        add_lvalue_reference_t<const T>,
        add_lvalue_reference_t<const U>> &&
    CommonReference<
        add_lvalue_reference_t<common_type_t<T, U>>,
        common_type_t<T>,
        common_reference_t<
            add_lvalue_reference_t<const T>,
            add_lvalue_reference_t<const U>>;`
```

Let C be common_type_t<T, U>. Let t be a function whose return type is T, and let u be a function
whose return type is U. Common<T, U> is satisfied only if:

— C(t()) equals C(t()) if and only if t() is an equality-preserving expression (17.2).
— C(u()) equals C(u()) if and only if u() is an equality-preserving expression (17.2).

[Note: Users can customize the behavior of Common by specializing the common_type class template (19.15.7.6). — end note]

### 17.4.7 Integral concepts

```cpp
template<class T>
concept Integral = is_integral_v<T>;
```

```cpp
template<class T>
concept SignedIntegral = Integral<T> && is_signed_v<T>;
```

```cpp
template<class T>
concept UnsignedIntegral = Integral<T> && !SignedIntegral<T>;
```

[Note: SignedIntegral<T> can be satisfied even by types that are not signed integral types (6.7.1); for example, char. — end note]
2  [Note: UnsignedIntegral<T> can be satisfied even by types that are not unsigned integral types (6.7.1); for example, bool. — end note]

17.4.8 Concept Assignable

```cpp
template<class LHS, class RHS>
concept Assignable =
is_lvalue_reference_v<LHS> &&
CommonReference<const remove_reference_t<LHS>&, const remove_reference_t<RHS>&> &&
requires(LHS lhs, RHS&& rhs) {
    lhs = std::forward<RHS>(rhs);
    requires Same<decltype(lhs = std::forward<RHS>(rhs)), LHS>;
};
```

1  Let:

1.1  — lhs be an lvalue that refers to an object lcopy such that decltype((lhs)) is LHS,

1.2  — rhs be an expression such that decltype((rhs)) is RHS, and

1.3  — rcopy be a distinct object that is equal to rhs.

Assignable<LHS, RHS> is satisfied only if

1.4  — addressof(lhs = rhs) == addressof(lcopy).

1.5  — After evaluating lhs = rhs:

1.5.1  — lhs is equal to rcopy, unless rhs is a non-const xvalue that refers to lcopy.

1.5.2  — If rhs is a non-const xvalue, the resulting state of the object to which it refers is valid but unspecified (15.5.5.15).

1.5.3  — Otherwise, if rhs is a glvalue, the object to which it refers is not modified.

2  [Note: Assignment need not be a total function (15.4.1.3); in particular, if assignment to an object x can result in a modification of some other object y, then x = y is likely not in the domain of =. — end note]

17.4.9 Concept Swappable

```cpp
template<class T>
concept Swappable = is_swappable_v<T>;
```

1  Let a1 and a2 denote distinct equal objects of type T, and let b1 and b2 similarly denote distinct equal objects of type T. Swappable<T> is satisfied only if after evaluating either swap(a1, b1) or swap(b1, a1) in the context described below, a1 is equal to b2 and b1 is equal to a2.

2  The context in which swap(a1, b1) or swap(b1, a1) is evaluated shall ensure that a binary non-member function named swap is selected via overload resolution (11.3) on a candidate set that includes:

2.1  — the two swap function templates defined in <utility> (19.2) and

2.2  — the lookup set produced by argument-dependent lookup (6.4.2).

```cpp
template<class T, class U>
concept SwappableWith =
is_swappable_with_v<T, T> && is_swappable_with_v<U, U> &&
CommonReference<const remove_reference_t<T>&, const remove_reference_t<U>&> &&
is_swappable_with_v<T, U> && is_swappable_with_v<vU, T>;
```

3  Let:

3.1  — t1 and t2 denote distinct equal objects of type remove_cvref_t<T>,

3.2  — E_t be an expression that denotes t1 such that decltype((E_t)) is T,

3.3  — u1 and u2 similarly denote distinct equal objects of type remove_cvref_t<U>,

3.4  — E_u be an expression that denotes u1 such that decltype((E_u)) is U, and

3.5  — C be

```cpp
common_reference_t<const remove_reference_t<T>&, const remove_reference_t<U>&>
```
SwappableWith<T, U> is satisfied only if after evaluating either \texttt{swap(E_t, E_u)} or \texttt{swap(E_u, E_t)} in the context described above, \texttt{C(t1)} is equal to \texttt{C(u2)} and \texttt{C(u1)} is equal to \texttt{C(t2)}.

The context in which \texttt{swap(E_t, E_u)} or \texttt{swap(E_u, E_t)} is evaluated shall ensure that a binary non-member function named \texttt{swap} is selected via overload resolution (11.3) on a candidate set that includes:

1. the two \texttt{swap} function templates defined in \texttt{<utility>} (19.2) and
2. the lookup set produced by argument-dependent lookup (6.4.2).

[Example: User code can ensure that the evaluation of \texttt{swap} calls is performed in an appropriate context under the various conditions as follows:

```cpp
#include <cassert>
#include <concepts>
#include <utility>

template<class T, std::SwappableWith<T> U>
void value_swap(T&& t, U&& u) {
    using std::swap;
    swap(std::forward<T>(t), std::forward<U>(u)); // OK: uses "swappable with" conditions
    // for rvalues and lvalues
}

template<std::Swappable T>
void lv_swap(T& t1, T& t2) {
    using std::swap;
    swap(t1, t2); // OK: uses swappable conditions for
    // lvalues of type T
}

namespace N {
    struct A { int m; }
    struct Proxy { A* a; }
    Proxy proxy(A& a) { return Proxy{ &a }; }

    void swap(A& x, Proxy p) {
        std::swap(x.m, p.a->m); // OK: uses context equivalent to swappable
        // conditions for fundamental types
    }

    void swap(Proxy p, A& x) { swap(x, p); } // satisfy symmetry constraint
}

int main() {
    int i = 1, j = 2;
    lv_swap(i, j);
    assert(i == 2 && j == 1);
    N::A a1 = { 5 }, a2 = { -5 };
    value_swap(a1, proxy(a2));
    assert(a1.m == -5 && a2.m == 5);
}

---end example]

17.4.10 Concept Destructible [concept.destructible]

The \texttt{Destructible} concept specifies properties of all types, instances of which can be destroyed at the end of their lifetime, or reference types.

```cpp
template<class T>
concept Destructible = is_nothrow_destructible_v<T>;
```

[Note: Unlike the Cpp17Destructible requirements (Table 29), this concept forbids destructors that are potentially throwing, even if a particular invocation of the destructor does not actually throw. — end note]
17.4.11 Concept Constructible

The Constructible concept constrains the initialization of a variable of a given type with a particular set of argument types.

```
template<class T, class... Args>
    concept Constructible = Destructible<T> && is_constructible_v<T, Args...>;
```

17.4.12 Concept DefaultConstructible

```
template<class T>
    concept DefaultConstructible = Constructible<T>;
```

17.4.13 Concept MoveConstructible

```
template<class T>
    concept MoveConstructible = Constructible<T, T> && ConvertibleTo<T, T>;
```

If T is an object type, then let rv be an rvalue of type T and u2 a distinct object of type T equal to rv. MoveConstructible<T> is satisfied only if:

1. After the definition T u = rv; , u is equal to u2.
2. T(rv) is equal to u2.
3. If T is not const, rv’s resulting state is valid but unspecified (15.5.5.15); otherwise, it is unchanged.

17.4.14 Concept CopyConstructible

```
template<class T>
    concept CopyConstructible =
        MoveConstructible<T> &&
        Constructible<T, T&> && ConvertibleTo<T&, T> &&
        Constructible<T, const T&> && ConvertibleTo<const T&, T> &&
        Constructible<T, const T> && ConvertibleTo<const T, T>;
```

If T is an object type, then let v be an lvalue of type (possibly const) T or an rvalue of type const T. CopyConstructible<T> is satisfied only if:

1. After the definition T u = v; , u is equal to v.
2. T(v) is equal to v.

17.5 Comparison concepts

17.5.1 General

This subclause describes concepts that establish relationships and orderings on values of possibly differing object types.

17.5.2 Concept Boolean

```
template<class B>
    concept Boolean =
        Movable<remove_cvref_t<B>> && // (see 17.6)
        requires(const remove_reference_t<B>& b1, const remove_reference_t<B>& b2, const bool a) {
            requires ConvertibleTo<const remove_reference_t<B>&, bool>;
            !b1; requires ConvertibleTo<dec_type(!b1), bool>;
            b1 && a; requires Same<dec_type(b1 && a), bool>;
            b1 || a; requires Same<dec_type(b1 || a), bool>;
            b1 && b2; requires Same<dec_type(b1 && b2), bool>;
            a && b2; requires Same<dec_type(a && b2), bool>;
            b1 || b2; requires Same<dec_type(b1 || b2), bool>;
            a || b2; requires Same<dec_type(a || b2), bool>;
            b1 == b2; requires ConvertibleTo<dec_type(b1 == b2), bool>;
            b1 == a; requires ConvertibleTo<dec_type(b1 == a), bool>;
            a == b2; requires ConvertibleTo<dec_type(a == b2), bool>;
            b1 != b2; requires ConvertibleTo<dec_type(b1 != b2), bool>;
        }
```

§ 17.5.2
Let b1 and b2 be lvalues of type `const remove_reference_t<B>`. Boolean<B> is satisfied only if

1. \( b1 != a; \) requires `ConvertibleTo< decltype(b1 != a), bool>;`  
2. \( a != b2; \) requires `ConvertibleTo< decltype(a != b2), bool>;`  

2. Let b1 and b2 be lvalues of type `const remove_reference_t<B>`. Boolean<B> is satisfied only if

   1. \( \text{bool}(b1) == \text{!bool}(\text{!b1}); \)  
   2. \( (b1 && b2), (b1 && \text{bool}(b2)), \) and \( (\text{bool}(b1) && b2) \) are all equal to \( (\text{bool}(b1) && \text{bool}(b2)) \), and have the same short-circuit evaluation.  
   3. \( (b1 || b2), (b1 || \text{bool}(b2)), \) and \( (\text{bool}(b1) || b2) \) are all equal to \( (\text{bool}(b1) == \text{bool}(b2)) \), and have the same short-circuit evaluation.  
   4. \( \text{bool}(b1 == b2), \text{bool}(b1 == \text{bool}(b2)), \) and \( \text{bool}(\text{bool}(b1) == b2) \) are all equal to \( (\text{bool}(b1) == \text{bool}(b2)) \).  
   5. \( \text{bool}(b1 != b2), \text{bool}(b1 != \text{bool}(b2)), \) and \( \text{bool}(\text{bool}(b1) != b2) \) are all equal to \( (\text{bool}(b1) != \text{bool}(b2)) \).

3. [Example: The types `bool`, `true_type` (19.15.2), and `bitset<N>::reference` (19.9.2) are Boolean types. Pointers, smart pointers, and types with only explicit conversions to `bool` are not Boolean types. — end example]

### 17.5.3 Concept `EqualityComparable` [concept.equalitycomparable]

#### template<class T, class U>  
concept `weakly-equality-comparable-with` // exposition only  
requires(const remove_reference_t<T>& t,  
const remove_reference_t<U>& u) {  
t == u; requires Boolean<decltype(t == u)>;  
t != u; requires Boolean<decltype(t != u)>;  
u == t; requires Boolean<decltype(u == t)>;  
u != t; requires Boolean<decltype(u != t)>;  
};

1. Let t and u be lvalues of types `const remove_reference_t<T>` and `const remove_reference_t<U>` respectively. `weakly-equality-comparable-with<T, U>` is satisfied only if:

   1. \( t == u, u == t, t != u, \) and \( u != t \) have the same domain.  
   2. \( \text{bool}(u == t) == \text{bool}(t == u); \)  
   3. \( \text{bool}(t != u) == \text{!bool}(t == u); \)  
   4. \( \text{bool}(u != t) == \text{bool}(t != u); \)

#### template<class T>  
concept `EqualityComparable` = `weakly-equality-comparable-with<T, T>``;

2. Let a and b be objects of type T. `EqualityComparable<T>` is satisfied only if `bool(a == b)` is true when a is equal to b (17.2), and false otherwise.

3. [Note: The requirement that the expression \( a == b \) is equality-preserving implies that `==` is transitive and symmetric. — end note]

#### template<class T, class U>  
concept `EqualityComparableWith` =  
`EqualityComparable<T> && EqualityComparable<U> &&  
CommonReference<const remove_reference_t<T>&, const remove_reference_t<U>&> &&  
EqualityComparable<  
    common_reference_t<  
    const remove_reference_t<T>&,  
    const remove_reference_t<U>&>  
    &&  
    weakly-equality-comparable-with<T, U>;`

4. Let t be an lvalue of type `const remove_reference_t<T>`, u be an lvalue of type `const remove_reference_t<U>`, and C be:  

   \( \text{common_reference_t<const remove_reference_t<T>&, const remove_reference_t<U>&> EqualityComparableWith<T, U> \) is satisfied only if `bool(t == u) == bool(C(t) == C(u));`
17.5.4 Concept StrictTotallyOrdered

```cpp
template<class T>
concept StrictTotallyOrdered =
    EqualityComparable<T> &&
    requires(const remove_reference_t<T>& a,
             const remove_reference_t<T>& b) {
        a < b; requires Boolean<decltype(a < b)>;
        a > b; requires Boolean<decltype(a > b)>;
        a <= b; requires Boolean<decltype(a <= b)>;
        a >= b; requires Boolean<decltype(a >= b)>;
    };
```

Let a, b, and c be lvalues of type `const remove_reference_t<T>`. StrictTotallyOrdered<T> is satisfied only if

1. Exactly one of `bool(a < b)`, `bool(a > b)`, or `bool(a == b)` is true.
2. If `bool(a < b)` and `bool(b < c)`, then `bool(a < c)`.
3. `bool(a > b) == bool(b < a)`.
4. `bool(a <= b) == !bool(b < a)`.
5. `bool(a >= b) == !bool(a < b)`.

```cpp
template<class T, class U>
concept StrictTotallyOrderedWith =
    StrictTotallyOrdered<T> && StrictTotallyOrdered<U> &&
    CommonReference<const remove_reference_t<T>&, const remove_reference_t<U>&> &&
    StrictTotallyOrdered<
        common_reference_t<const remove_reference_t<T>&, const remove_reference_t<U>&>,
        const remove_reference_t<T>&, const remove_reference_t<U>&> &&
    EqualityComparableWith<T, U> &&
    requires(const remove_reference_t<T>& t,
             const remove_reference_t<T>& u) {
        t < u; requires Boolean<decltype(t < u)>;
        t > u; requires Boolean<decltype(t > u)>;
        t <= u; requires Boolean<decltype(t <= u)>;
        t >= u; requires Boolean<decltype(t >= u)>;
        u < t; requires Boolean<decltype(u < t)>;
        u > t; requires Boolean<decltype(u > t)>;
        u <= t; requires Boolean<decltype(u <= t)>;
        u >= t; requires Boolean<decltype(u >= t)>;
    };
```

Let t be an lvalue of type `const remove_reference_t<T>`, u be an lvalue of type `const remove_reference_t<U>`, and C be:

```cpp
    common_reference_t<const remove_reference_t<T>&, const remove_reference_t<T>&>
```

StrictTotallyOrderedWith<T, U> is satisfied only if

1. `bool(t < u) == bool(C(t) < C(u))`.
2. `bool(t > u) == bool(C(t) > C(u))`.
3. `bool(t <= u) == bool(C(t) <= C(u))`.
4. `bool(t >= u) == bool(C(t) >= C(u))`.
5. `bool(u < t) == bool(C(u) < C(t))`.
6. `bool(u > t) == bool(C(u) > C(t))`.
7. `bool(u <= t) == bool(C(u) <= C(t))`.
8. `bool(u >= t) == bool(C(u) >= C(t))`.

17.6 Object concepts

This subclause describes concepts that specify the basis of the value-oriented programming style on which the library is based.
template<class T>
concept Movable = is_object_v<T> && MoveConstructible<T> && Assignable<T&, T> && Swappable<T>;

template<class T>
concept Copyable = CopyConstructible<T> && Movable<T> && Assignable<T&, const T&>;

template<class T>
concept Semiregular = Copyable<T> && DefaultConstructible<T>;

template<class T>
concept Regular = Semiregular<T> && EqualityComparable<T>;

[Note: The Semiregular concept is satisfied by types that behave similarly to built-in types like int, except that they might not be comparable with ==. — end note]

[Note: The Regular concept is satisfied by types that behave similarly to built-in types like int and that are comparable with ==. — end note]

17.7 Callable concepts

17.7.1 General

The concepts in this subclause describe the requirements on function objects (19.14) and their arguments.

17.7.2 Concept Invocable

The Invocable concept specifies a relationship between a callable type (19.14.2) F and a set of argument types Args... which can be evaluated by the library function invoke (19.14.4).

template<class F, class... Args>
concept Invocable = requires(F&& f, Args&&... args) {
    invoke(std::forward<F>(f), std::forward<Args>(args)...); // not required to be equality-preserving
};

[Example: A function that generates random numbers can satisfy Invocable, since the invoke function call expression is not required to be equality-preserving (17.2). — end example]

17.7.3 Concept RegularInvocable

template<class F, class... Args>
concept RegularInvocable = Invocable<F, Args...>;

The invoke function call expression shall be equality-preserving and shall not modify the function object or the arguments (17.2). [Note: This requirement supersedes the annotation in the definition of Invocable. — end note]

[Example: A random number generator does not satisfy RegularInvocable. — end example]

[Note: The distinction between Invocable and RegularInvocable is purely semantic. — end note]

17.7.4 Concept Predicate

template<class F, class... Args>
concept Predicate = RegularInvocable<F, Args...> && Boolean<invoke_result_t<F, Args...>>;

17.7.5 Concept Relation

template<class R, class T, class U>
concept Relation =
    Predicate<R, T, T> && Predicate<R, U, U> &&
    CommonReference<Const remove_reference_t<T<r>>, Const remove_reference_t<U<r>>, R>
    &&
    Predicate<R, Const remove_reference_t<T<r>>, Const remove_reference_t<U<r>>, Const remove_reference_t<T<r>>, Const remove_reference_t<U<r>>, R>
    &&
    Predicate<R, T, U> && Predicate<R, U, T>;

Let

— r be an expression such that decltype((r)) is R,
— t be an expression such that decltype((t)) is T,
— u be an expression such that decltype((u)) is U, and

§ 17.7.5
C be

\[
\text{Relation<R, T, U> is satisfied only if}
\]

\[\text{bool(r(t, u)) == bool(r(C(t), C(u))}.\]

\[\text{bool(r(u, t)) == bool(r(C(u), C(t))}.\]

\textbf{17.7.6 Concept StrictWeakOrder} [concept.strictweakorder]

\texttt{template<class R, class T, class U>}

\texttt{concept StrictWeakOrder = Relation<R, T, U>;} 

A Relation satisfies StrictWeakOrder only if it imposes a \textit{strict weak ordering} on its arguments.

The term \textit{strict} refers to the requirement of an irreflexive relation (\texttt{!comp(x, x)} for all \texttt{x}), and the term \textit{weak} to requirements that are not as strong as those for a total ordering, but stronger than those for a partial ordering. If we define \texttt{equiv(a, b)} as \texttt{!comp(a, b) && !comp(b, a)}, then the requirements are that \texttt{comp} and \texttt{equiv} both be transitive relations:

\[\text{comp(a, b) && comp(b, c) implies comp(a, c)}\]

\[\text{equiv(a, b) && equiv(b, c) implies equiv(a, c)}\]

[Note: Under these conditions, it can be shown that

\[\text{equiv is an equivalence relation,}\]

\[\text{comp induces a well-defined relation on the equivalence classes determined by equiv, and}\]

\[\text{the induced relation is a strict total ordering.}\]

\textbf{- end note]}

\texttt{§ 17.7.6 500}
18 Diagnostics library

18.1 General

This Clause describes components that C++ programs may use to detect and report error conditions.

The following subclauses describe components for reporting several kinds of exceptional conditions, documenting program assertions, and a global variable for error number codes, as summarized in Table 37.

Table 37 — Diagnostics library summary

18.2 Exception classes

The C++ standard library provides classes to be used to report certain errors (15.5.5.12) in C++ programs. In the error model reflected in these classes, errors are divided into two broad categories: logic errors and runtime errors.

The distinguishing characteristic of logic errors is that they are due to errors in the internal logic of the program. In theory, they are preventable.

By contrast, runtime errors are due to events beyond the scope of the program. They cannot be easily predicted in advance. The header <stdexcept> defines several types of predefined exceptions for reporting errors in a C++ program. These exceptions are related by inheritance.

18.2.1 Header <stdexcept> synopsis

```c++
namespace std {
    class logic_error;
    class domain_error;
    class invalid_argument;
    class length_error;
    class out_of_range;
    class runtime_error;
    class range_error;
    class overflow_error;
    class underflow_error;
}
```

18.2.2 Class logic_error

```c++
namespace std {
    class logic_error : public exception {
        public:
        explicit logic_error(const string& what_arg);
        explicit logic_error(const char* what_arg);
    }
}
```

The class logic_error defines the type of objects thrown as exceptions to report errors presumably detectable before the program executes, such as violations of logical preconditions or class invariants.

```c++
logic_error(const string& what_arg);
```

1. Effects: Constructs an object of class logic_error.
2. Ensures: strcmp(what(), what_arg.c_str()) == 0.
logic_error(const char* what_arg);

Effects: Constructs an object of class logic_error.

Ensures: strcmp(what(), what_arg) == 0.

18.2.3 Class domain_error

namespace std {
    class domain_error : public logic_error {
    public:
        explicit domain_error(const string& what_arg);
        explicit domain_error(const char* what_arg);
    };
}

The class domain_error defines the type of objects thrown as exceptions by the implementation to report domain errors.

domain_error(const string& what_arg);

Effects: Constructs an object of class domain_error.

Ensures: strcmp(what(), what_arg.c_str()) == 0.

domain_error(const char* what_arg);

Effects: Constructs an object of class domain_error.

Ensures: strcmp(what(), what_arg) == 0.

18.2.4 Class invalid_argument

namespace std {
    class invalid_argument : public logic_error {
    public:
        explicit invalid_argument(const string& what_arg);
        explicit invalid_argument(const char* what_arg);
    };
}

The class invalid_argument defines the type of objects thrown as exceptions to report an invalid argument.

invalid_argument(const string& what_arg);

Effects: Constructs an object of class invalid_argument.

Ensures: strcmp(what(), what_arg.c_str()) == 0.

invalid_argument(const char* what_arg);

Effects: Constructs an object of class invalid_argument.

Ensures: strcmp(what(), what_arg) == 0.

18.2.5 Class length_error

namespace std {
    class length_error : public logic_error {
    public:
        explicit length_error(const string& what_arg);
        explicit length_error(const char* what_arg);
    };
}

The class length_error defines the type of objects thrown as exceptions to report an attempt to produce an object whose length exceeds its maximum allowable size.

length_error(const string& what_arg);

Effects: Constructs an object of class length_error.

Ensures: strcmp(what(), what_arg.c_str()) == 0.
length_error(const char* what_arg);

Effects: Constructs an object of class length_error.
Ensures: strcmp(what(), what_arg) == 0.

18.2.6 Class out_of_range

namespace std {
  class out_of_range : public logic_error {
    public:
      explicit out_of_range(const string& what_arg);
      explicit out_of_range(const char* what_arg);
    }
}

The class out_of_range defines the type of objects thrown as exceptions to report an argument value not in its expected range.

out_of_range(const string& what_arg);

Effects: Constructs an object of class out_of_range.
Ensures: strcmp(what(), what_arg.c_str()) == 0.

out_of_range(const char* what_arg);

Effects: Constructs an object of class out_of_range.
Ensures: strcmp(what(), what_arg) == 0.

18.2.7 Class runtime_error

namespace std {
  class runtime_error : public exception {
    public:
      explicit runtime_error(const string& what_arg);
      explicit runtime_error(const char* what_arg);
    }
}

The class runtime_error defines the type of objects thrown as exceptions to report errors presumably detectable only when the program executes.

runtime_error(const string& what_arg);

Effects: Constructs an object of class runtime_error.
Ensures: strcmp(what(), what_arg.c_str()) == 0.

runtime_error(const char* what_arg);

Effects: Constructs an object of class runtime_error.
Ensures: strcmp(what(), what_arg) == 0.

18.2.8 Class range_error

namespace std {
  class range_error : public runtime_error {
    public:
      explicit range_error(const string& what_arg);
      explicit range_error(const char* what_arg);
    }
}

The class range_error defines the type of objects thrown as exceptions to report range errors in internal computations.

range_error(const string& what_arg);

Effects: Constructs an object of class range_error.
Ensures: strcmp(what(), what_arg.c_str()) == 0.
range_error(const char* what_arg);

   *Effects:* Constructs an object of class `range_error`.

   *Ensures:* `strcmp(what(), what_arg) == 0`.

18.2.9 Class `overflow_error`  
[overflow.error]

namespace std {
    class overflow_error : public runtime_error {
    public:
        explicit overflow_error(const string& what_arg);
        explicit overflow_error(const char* what_arg);
    };
}

The class `overflow_error` defines the type of objects thrown as exceptions to report an arithmetic overflow error.

overflow_error(const string& what_arg);

   *Effects:* Constructs an object of class `overflow_error`.

   *Ensures:* `strcmp(what(), what_arg.c_str()) == 0`.

overflow_error(const char* what_arg);

   *Effects:* Constructs an object of class `overflow_error`.

   *Ensures:* `strcmp(what(), what_arg) == 0`.

18.2.10 Class `underflow_error`  
[underflow.error]

namespace std {
    class underflow_error : public runtime_error {
    public:
        explicit underflow_error(const string& what_arg);
        explicit underflow_error(const char* what_arg);
    };
}

The class `underflow_error` defines the type of objects thrown as exceptions to report an arithmetic underflow error.

underflow_error(const string& what_arg);

   *Effects:* Constructs an object of class `underflow_error`.

   *Ensures:* `strcmp(what(), what_arg.c_str()) == 0`.

underflow_error(const char* what_arg);

   *Effects:* Constructs an object of class `underflow_error`.

   *Ensures:* `strcmp(what(), what_arg) == 0`.

18.3 Assertions  
[assertions]

The header `<cassert>` provides a macro for documenting C++ program assertions and a mechanism for disabling the assertion checks.

18.3.1 Header `<cassert>` synopsis  
[cassert.syn]

#define assert(E) see below

The contents are the same as the C standard library header `<assert.h>`, except that a macro named `static_assert` is not defined.

See also:  ISO C 7.2

18.3.2 The assert macro  
[assertions.assert]

An expression `assert(E)` is a constant subexpression (15.3.6), if

(1.1) — `NDEBUG` is defined at the point where `assert` is last defined or redefined, or

§ 18.3.2
E contextually converted to bool (7.3) is a constant subexpression that evaluates to the value true.

18.4 Error numbers

The contents of the header <cerrno> are the same as the POSIX header <errno.h>, except that errno shall be defined as a macro. [Note: The intent is to remain in close alignment with the POSIX standard. — end note] A separate errno value shall be provided for each thread.

18.4.1 Header <cerrno> synopsis

```c
#define errno see below
#define E2BIG see below
#define EACCES see below
#define EADDRINUSE see below
#define EADDRNOTAVAIL see below

#define ENOPROTOOPT see below
#define ENOSPC see below
#define ENOSR see below
#define ENOSTR see below
#define ENOSYS see below

§ 18.4.1 505
The meaning of the macros in this header is defined by the POSIX standard.

See also: ISO C 7.5

18.5 System error support

This subclause describes components that the standard library and C++ programs may use to report error conditions originating from the operating system or other low-level application program interfaces.

Components described in this subclause shall not change the value of `errno` (18.4). Implementations should leave the error states provided by other libraries unchanged.

18.5.1 Header `<system_error>` synopsis

```cpp
namespace std {
    class error_category;
    const error_category& generic_category() noexcept;
    const error_category& system_category() noexcept;

    class error_code;
    class error_condition;
    class system_error;

    template<class T>
    struct is_error_code_enum : public false_type {};

    template<class T>
    struct is_error_condition_enum : public false_type {};

    enum class errc {
        address_family_not_supported,  // EAFNOSUPPORT
        address_in_use,               // EADDRINUSE
        address_not_available,        // EADDRNOTAVAIL
        already_connected,            // EISCONN
        argument_list_too_long,       // E2BIG
        argument_out_of_domain,       // EDOM
        bad_address,                  // EFAULT
        bad_file_descriptor,          // EBADF
        bad_message,                  // EBADF
        broken_pipe,                  // EPIPE
        ...  // other error codes
    }
}

// 18.5.5, comparison functions
bool operator==(const error_code& lhs, const error_code& rhs) noexcept;
bool operator==(const error_code& lhs, const error_condition& rhs) noexcept;
bool operator==(const error_condition& lhs, const error_code& rhs) noexcept;
bool operator==(const error_condition& lhs, const error_condition& rhs) noexcept;
bool operator!=(const error_code& lhs, const error_code& rhs) noexcept;
bool operator!=(const error_code& lhs, const error_condition& rhs) noexcept;
bool operator!=(const error_condition& lhs, const error_code& rhs) noexcept;
bool operator!=(const error_condition& lhs, const error_condition& rhs) noexcept;

// 18.5.6, hash support
template<class T> struct hash;
template<> struct hash<error_code>;
template<> struct hash<error_condition>;

1 The value of each enum errc constant shall be the same as the value of the <cerrno> macro shown in the above synopsis. Whether or not the <system_error> implementation exposes the <cerrno> macros is unspecified.

2 The is_error_code_enum and is_error_condition_enum may be specialized for program-defined types to indicate that such types are eligible for class error_code and class error_condition automatic conversions, respectively.

18.5.2 Class error_category [syserr.errcat]
18.5.2.1 Overview [syserr.errcat.overview]

The class error_category serves as a base class for types used to identify the source and encoding of a particular category of error code. Classes may be derived from error_category to support categories of errors in addition to those defined in this document. Such classes shall behave as specified in this subclause 18.5.2.

[Note: error_category objects are passed by reference, and two such objects are equal if they have the same address. This means that applications using custom error_category types should create a single object of each such type. — end note]

namespace std {
    class error_category {
    public:
        constexpr error_category() noexcept;
        virtual ~error_category();
    }
error_category(const error_category&) = delete;
error_category& operator=(const error_category&) = delete;
virtual const char* name() const noexcept = 0;
virtual error_condition default_error_condition(int ev) const noexcept;
virtual bool equivalent(int code, const error_condition& condition) const noexcept;
virtual bool equivalent(const error_code& code, int condition) const noexcept;
virtual string message(int ev) const = 0;

bool operator==(const error_category& rhs) const noexcept;
bool operator!=(const error_category& rhs) const noexcept;
bool operator< (const error_category& rhs) const noexcept;
};

const error_category& generic_category() noexcept;
const error_category& system_category() noexcept;

18.5.2.2 Virtual members

virtual ~error_category();
1 Effects: Destroys an object of class error_category.

virtual const char* name() const noexcept = 0;
2 Returns: A string naming the error category.

virtual error_condition default_error_condition(int ev) const noexcept;
3 Returns: error_condition(ev, *this).

virtual bool equivalent(int code, const error_condition& condition) const noexcept;
4 Returns: default_error_condition(code) == condition.

virtual bool equivalent(const error_code& code, int condition) const noexcept;
5 Returns: *this == code.category() && code.value() == condition.

virtual string message(int ev) const = 0;
6 Returns: A string that describes the error condition denoted by ev.

18.5.2.3 Non-virtual members

constexpr error_category() noexcept;
1 Effects: Constructs an object of class error_category.

bool operator==(const error_category& rhs) const noexcept;
2 Returns: this == &rhs.

bool operator!=(const error_category& rhs) const noexcept;
3 Returns: !(this == rhs).

bool operator< (const error_category& rhs) const noexcept;
4 Returns: less<const error_category*>(this, &rhs).

[Note: less (19.14.7) provides a total ordering for pointers. — end note]

18.5.2.4 Program-defined classes derived from error_category

virtual const char* name() const noexcept = 0;
1 Returns: A string naming the error category.

virtual error_condition default_error_condition(int ev) const noexcept;
2 Returns: An object of type error_condition that corresponds to ev.
virtual bool equivalent(int code, const error_condition& condition) const noexcept;

Returns: true if, for the category of error represented by *this, code is considered equivalent to condition; otherwise, false.

virtual bool equivalent(const error_code& code, int condition) const noexcept;

Returns: true if, for the category of error represented by *this, code is considered equivalent to condition; otherwise, false.

18.5.2.5 Error category objects

const error_category& generic_category() noexcept;

Returns: A reference to an object of a type derived from class error_category. All calls to this function shall return references to the same object.

Remarks: The object’s default_error_condition and equivalent virtual functions shall behave as specified for the class error_category. The object’s name virtual function shall return a pointer to the string "generic".

const error_category& system_category() noexcept;

Returns: A reference to an object of a type derived from class error_category. All calls to this function shall return references to the same object.

Remarks: The object’s equivalent virtual functions shall behave as specified for class error_category. The object’s name virtual function shall return a pointer to the string "system". The object’s default_error_condition virtual function shall behave as follows:

If the argument ev corresponds to a POSIX errno value posv, the function shall return error_condition(posv, generic_category()). Otherwise, the function shall return error_condition(ev, system_category()). What constitutes correspondence for any given operating system is unspecified.

[Note: The number of potential system error codes is large and unbounded, and some may not correspond to any POSIX errno value. Thus implementations are given latitude in determining correspondence. —end note]

18.5.3 Class error_code

18.5.3.1 Overview

The class error_code describes an object used to hold error code values, such as those originating from the operating system or other low-level application program interfaces. [Note: Class error_code is an adjunct to error reporting by exception. —end note]
private:
    int val_; // exposition only
    const error_category* cat_; // exposition only
};

// 18.5.3.5, non-member functions
error_code make_error_code(errc e) noexcept;

template<class charT, class traits>
basic_ostream<charT, traits>&
    operator<<(basic_ostream<charT, traits>& os, const error_code& ec);

18.5.3.2 Constructors
[syserr.errcode.constructors]
error_code() noexcept;
1 Effects: Constructs an object of type error_code.
2 Ensures: val_ == 0 and cat_ == &system_category().

error_code(int val, const error_category& cat) noexcept;
3 Effects: Constructs an object of type error_code.
4 Ensures: val_ == val and cat_ == &cat.

template<class ErrorCodeEnum>
error_code(ErrorCodeEnum e) noexcept;
5 Effects: Constructs an object of type error_code.
6 Ensures: *this == make_error_code(e).
7 Remarks: This constructor shall not participate in overload resolution unless
            is_error_code_enum_v<ErrorCodeEnum> is true.

18.5.3.3 Modifiers
[syserr.errcode.modifiers]
void assign(int val, const error_category& cat) noexcept;
1 Ensures: val_ == val and cat_ == &cat.

template<class ErrorCodeEnum>
error_code& operator=(ErrorCodeEnum e) noexcept;
2 Ensures: *this == make_error_code(e).
3 Returns: *this.
4 Remarks: This operator shall not participate in overload resolution unless
            is_error_code_enum_v<ErrorCodeEnum> is true.

void clear() noexcept;
5 Ensures: value() == 0 and category() == system_category().

18.5.3.4 Observers
[syserr.errcode.observers]
int value() const noexcept;
1 Returns: val_.

const error_category& category() const noexcept;
2 Returns: *cat_.

error_condition default_error_condition() const noexcept;
3 Returns: category().default_error_condition(value()).

string message() const;
4 Returns: category().message(value()).
explicit operator bool() const noexcept;

>Returns: value() != 0.

18.5.3.5 Non-member functions

error_code make_error_code(errc e) noexcept;

>Returns: error_code(static_cast<int>(e), generic_category()).

template<class charT, class traits>
basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& os, const error_code& ec);

>Effects: As if by: os << ec.category().name() << ':' << ec.value();

18.5.4 Class error_condition

18.5.4.1 Overview

The class error_condition describes an object used to hold values identifying error conditions. [Note: error_condition values are portable abstractions, while error_code values (18.5.3) are implementation specific. —end note]

namespace std {
    class error_condition {
        public:
            // 18.5.4.2, constructors
            error_condition() noexcept;
            error_condition(int val, const error_category& cat) noexcept;
            template<class ErrorConditionEnum>
                error_condition(ErrorConditionEnum e) noexcept;

            // 18.5.4.3, modifiers
            void assign(int val, const error_category& cat) noexcept;
            template<class ErrorConditionEnum>
                error_condition& operator=(ErrorConditionEnum e) noexcept;
            void clear() noexcept;

            // 18.5.4.4, observers
            int value() const noexcept;
            const error_category& category() const noexcept;
            string message() const;
            explicit operator bool() const noexcept;

        private:
            int val_; // exposition only
            const error_category* cat_; // exposition only
    };
}

18.5.4.2 Constructors

error_condition() noexcept;

>Effects: Constructs an object of type error_condition.

>Ensures: val_ == 0 and cat_ == &generic_category().

error_condition(int val, const error_category& cat) noexcept;

>Effects: Constructs an object of type error_condition.

>Ensures: val_ == val and cat_ == &cat.

template<class ErrorConditionEnum>
    error_condition(ErrorConditionEnum e) noexcept;

>Effects: Constructs an object of type error_condition.

>Ensures: *this == make_error_condition(e).
Remarks: This constructor shall not participate in overload resolution unless
is_error_condition_enum_v<ErrorConditionEnum> is true.

18.5.4.3 Modifiers

void assign(int val, const error_category& cat) noexcept;

Ensures: val_ == val and cat_ == &cat.

template<class ErrorConditionEnum>
error_condition& operator=(ErrorConditionEnum e) noexcept;

Ensures: *this == make_error_condition(e).

Returns: *this.

Remarks: This operator shall not participate in overload resolution unless
is_error_condition_enum_v<ErrorConditionEnum> is true.

void clear() noexcept;

Ensures: value() == 0 and category() == generic_category().

18.5.4.4 Observers

int value() const noexcept;

Returns: val_.

const error_category& category() const noexcept;

Returns: *cat_.

string message() const;

Returns: category().message(value()).

explicit operator bool() const noexcept;

Returns: value() != 0.

18.5.4.5 Non-member functions

error_condition make_error_condition(errc e) noexcept;

Returns: error_condition(static_cast<int>(e), generic_category()).

18.5.5 Comparison functions

bool operator==(const error_code& lhs, const error_code& rhs) noexcept;

Returns: 
lhs.category() == rhs.category() && lhs.value() == rhs.value()

bool operator==(const error_code& lhs, const error_condition& rhs) noexcept;

Returns: 
lhs.category().equivalent(lhs.value(), rhs) || rhs.category().equivalent(lhs, rhs.value())

bool operator==(const error_condition& lhs, const error_code& rhs) noexcept;

Returns: 
rhs.category().equivalent(rhs.value(), lhs) || lhs.category().equivalent(rhs, lhs.value())

bool operator==(const error_condition& lhs, const error_condition& rhs) noexcept;

Returns: 
lhs.category() == rhs.category() && lhs.value() == rhs.value()

bool operator!=(const error_code& lhs, const error_code& rhs) noexcept;

bool operator!=(const error_code& lhs, const error_condition& rhs) noexcept;

bool operator!=(const error_condition& lhs, const error_code& rhs) noexcept;

bool operator!=(const error_condition& lhs, const error_condition& rhs) noexcept;

§ 18.5.5
bool operator!=(const error_condition& lhs, const error_condition& rhs) noexcept;

Returns: !(lhs == rhs).

bool operator<(const error_code& lhs, const error_code& rhs) noexcept;

Returns:
lhs.category() < rhs.category() ||
(lhs.category() == rhs.category() && lhs.value() < rhs.value())

bool operator<(const error_condition& lhs, const error_condition& rhs) noexcept;

Returns:
lhs.category() < rhs.category() ||
(lhs.category() == rhs.category() && lhs.value() < rhs.value())

18.5.6 System error hash support

template<> struct hash<error_code>;
template<> struct hash<error_condition>;

The specializations are enabled (19.14.16).

18.5.7 Class system_error

18.5.7.1 Overview

The class system_error describes an exception object used to report error conditions that have an associated error code. Such error conditions typically originate from the operating system or other low-level application program interfaces.

[Note: If an error represents an out-of-memory condition, implementations are encouraged to throw an exception object of type bad_alloc (16.6.3.1) rather than system_error. — end note]

namespace std {
    class system_error : public runtime_error {
public:
    system_error(error_code ec, const string& what_arg);
    system_error(error_code ec, const char* what_arg);
    system_error(error_code ec);
    system_error(int ev, const error_category& ecat, const string& what_arg);
    system_error(int ev, const error_category& ecat, const char* what_arg);
    system_error(int ev, const error_category& ecat);
    const error_code& code() const noexcept;
    const char* what() const noexcept override;
    
};
}

18.5.7.2 Members

system_error(error_code ec, const string& what_arg);

Effects: Constructs an object of class system_error.

Ensures: code() == ec and string(what()).find(what_arg) != string::npos.

1

system_error(error_code ec, const char* what_arg);

Effects: Constructs an object of class system_error.

Ensures: code() == ec and string(what()).find(what_arg) != string::npos.

2

system_error(error_code ec);

Effects: Constructs an object of class system_error.

Ensures: code() == ec.

3

system_error(int ev, const error_category& ecat, const string& what_arg);

Effects: Constructs an object of class system_error.

4

system_error(int ev, const error_category& ecat, const char* what_arg);

Effects: Constructs an object of class system_error.

5

system_error(int ev, const error_category& ecat);

Effects: Constructs an object of class system_error.

6

system_error(error_code ec);

Effects: Constructs an object of class system_error.

7
Ensures: code() == error_code(ev, ecat) and
string(what()).find(what_arg) != string::npos.

system_error(int ev, const error_category& ecat, const char* what_arg);

Effects: Constructs an object of class system_error.
Ensures: code() == error_code(ev, ecat) and
string(what()).find(what_arg) != string::npos.

system_error(int ev, const error_category& ecat);

Effects: Constructs an object of class system_error.
Ensures: code() == error_code(ev, ecat).

const error_code& code() const noexcept;

Returns: ec or error_code(ev, ecat), from the constructor, as appropriate.

const char* what() const noexcept override;

Returns: An ntsbs incorporating the arguments supplied in the constructor.

[Note: The returned ntsbs might be the contents of what_arg + ": " + code.message(). — end note]
19   General utilities library  [utilities]

19.1   General  [utilities.general]
1 This Clause describes utilities that are generally useful in C++ programs; some of these utilities are used by other elements of the C++ standard library. These utilities are summarized in Table 38.

Table 38 — General utilities library summary

19.2   Utility components  [utility]

19.2.1   Header <utility> synopsis  [utility.syn]

1 The header <utility> contains some basic function and class templates that are used throughout the rest of the library.

```cpp
#include <initializer_list>  // see 16.10.1

namespace std {
    // 19.2.2, swap
    template<class T>
    constexpr void swap(T& a, T& b) noexcept(see below);  
    template<class T, size_t N>
    constexpr void swap(T (&a)[N], T (&b)[N]) noexcept(is_nothrow_swappable_v<T>);

    // 19.2.3, exchange
    template<class T, class U = T>
    constexpr T exchange(T& obj, U& new_val);

    // 19.2.4, forward/move
    template<class T>
    constexpr T& forward(remove_reference_t<T>& t) noexcept;
    template<class T>
    constexpr T& forward(remove_reference_t<T>&& t) noexcept;
    template<class T>
    constexpr remove_reference_t<T>&& move(T&&) noexcept;
```
template<class T>
constexpr conditional_t<
  !is_nothrow_move_constructible_v<T> && is_copy_constructible_v<T>,
  const T&, T&&>
move_if_noexcept(T& x) noexcept;

// 19.2.5, as_const
template<class T>
constexpr add_const_t<T>& as_const(T& t) noexcept;

// 19.2.6, declval
template<class T>
add_rvalue_reference_t<T> declval() noexcept; // as unevaluated operand

// 19.3, Compile-time integer sequences
template<class T, T...>
struct integer_sequence;
template<size_t... I>
using index_sequence = integer_sequence<
  size_t, I...>

constexpr bool operator< (const pair<T1, T2>&, const pair<T1, T2>&);
template<class T1, class T2>
constexpr bool operator> (const pair<T1, T2>&, const pair<T1, T2>&);
template<class T1, class T2>
constexpr bool operator<=(const pair<T1, T2>&, const pair<T1, T2>&);
template<class T1, class T2>
constexpr bool operator>=(const pair<T1, T2>&, const pair<T1, T2>&);
template<class T1, class T2>
void swap(pair<T1, T2>& x, pair<T1, T2>& y) noexcept(noexcept(x.swap(y)));
template<class T1, class T2>
constexpr see below make_pair(T1&&, T2&&);

// 19.4.4, tuple-like access to pair
template<class T> class tuple_size;
template<size_t I, class T> class tuple_element;
template<class T1, class T2> struct tuple_size<pair<T1, T2>>;
template<size_t I, class T1, class T2> struct tuple_element<pair<T1, T2>>;

§ 19.2.1
template<
    size_t I,
    class T1,
    class T2>
constexpr const tuple_element_t<I, pair<T1, T2>>& get(const pair<T1, T2>&) noexcept;

template<
    size_t I,
    class T1,
    class T2>
constexpr const tuple_element_t<I, pair<T1, T2>>& get(const pair<T1, T2>&&) noexcept;

template<class T1, class T2>
constexpr T1& get(pair<T1, T2>& p) noexcept;

template<class T1, class T2>
constexpr const T1& get(const pair<T1, T2>& p) noexcept;

template<class T1, class T2>
constexpr T1&& get(pair<T1, T2>&& p) noexcept;

template<class T1, class T2>
constexpr const T1&& get(const pair<T1, T2>&& p) noexcept;

template<class T2, class T1>
constexpr T2& get(pair<T1, T2>& p) noexcept;

template<class T2, class T1>
constexpr const T2& get(const pair<T1, T2>& p) noexcept;

template<class T2, class T1>
constexpr T2&& get(pair<T1, T2>&& p) noexcept;

template<class T2, class T1>
constexpr const T2&& get(const pair<T1, T2>&& p) noexcept;

// 19.4.5, pair piecewise construction
struct piecewise_construct_t {
    explicit piecewise_construct_t() = default;
};

inline constexpr piecewise_construct_t piecewise_construct{};

template<class... Types> class tuple;  // defined in <tuple> (19.5.2)

// in-place construction
struct in_place_t {
    explicit in_place_t() = default;
};

inline constexpr in_place_t in_place{};

template<class T>
struct in_place_type_t {
    explicit in_place_type_t() = default;
};

template<class T> inline constexpr in_place_type_t<T> in_place_type{};

template<size_t I>
struct in_place_index_t {
    explicit in_place_index_t() = default;
};

template<size_t I> inline constexpr in_place_index_t<I> in_place_index{};

19.2.2 swap [utility.swap]

template<class T>
constexpr void swap(T& a, T& b) noexcept(see below);

Remarks: This function is a designated customization point (15.5.4.2.1) and shall not participate in
overload resolution unless is_move_constructible_v<T> is true and is_moveAssignable_v<T> is
ture. The expression inside noexcept is equivalent to:

is_nothrow_move_constructible_v<T> && is_nothrow_moveAssignable_v<T>

Requires: Type T shall be Cpp17MoveConstructible (Table 25) and Cpp17MoveAssignable (Table 27).

Effects: Exchanges values stored in two locations.

template<class T, size_t N>
constexpr void swap(T (&a)[N], T (&b)[N]) noexcept(is_nothrow_swappable_v<T>);

Remarks: This function shall not participate in overload resolution unless is_swappable_v<T> is true.

Requires: a[i] shall be swappable with (15.5.3.2) b[i] for all i in the range [0, N).

Effects: As if by swap_ranges(a, a + N, b).
19.2.3 exchange

```cpp
template<class T, class U = T>
constexpr T exchange(T& obj, U&& new_val);
```

**Effects:** Equivalent to:

```cpp
T old_val = std::move(obj);
obj = std::forward<U>(new_val);
return old_val;
```

19.2.4 Forward/move helpers

The library provides templated helper functions to simplify applying move semantics to an lvalue and to simplify the implementation of forwarding functions. All functions specified in this subclause are signal-safe (16.12.4).

```cpp
template<class T> constexpr T&& forward(remove_reference_t<T>& t) noexcept;
template<class T> constexpr T&& forward(remove_reference_t<T>&& t) noexcept;
```

**Returns:**

```cpp
static_cast<T&&>(t).
```

**Remarks:** If the second form is instantiated with an lvalue reference type, the program is ill-formed.

**Example:**

```cpp
template<class T, class A1, class A2>
shared_ptr<T> factory(A1&& a1, A2&& a2) {
  return shared_ptr<T>(new T(std::forward<A1>(a1), std::forward<A2>(a2)));
}

struct A {
  A(int&, const double&);
};

void g() {
  shared_ptr<A> sp1 = factory<A>(2, 1.414); // error: 2 will not bind to int&
  int i = 2;
  shared_ptr<A> sp2 = factory<A>(i, 1.414); // OK
}
```

In the first call to `factory`, `A1` is deduced as `int`, so `2` is forwarded to `A`'s constructor as an rvalue. In the second call to `factory`, `A1` is deduced as `int&`, so `i` is forwarded to `A`'s constructor as an lvalue. In both cases, `A2` is deduced as `double`, so `1.414` is forwarded to `A`'s constructor as an rvalue. —end example

```cpp
template<class T> constexpr remove_reference_t<T>&& move(T&& t) noexcept;
```

**Returns:**

```cpp
static_cast<remove_reference_t<T>&&>(t).
```

**Example:**

```cpp
template<class T, class A1>
shared_ptr<T> factory(A1&& a1) {
  return shared_ptr<T>(new T(std::forward<A1>(a1)));
}

struct A {
  A(); // copies from lvalues
  A(A&&); // moves from rvalues
};

void g() {
  A a;
  shared_ptr<A> sp1 = factory<A>(a); // "a" binds to A(const A&)
  shared_ptr<A> sp1 = factory<A>(std::move(a)); // "a" binds to A(A&&)
}
```

In the first call to `factory`, `A1` is deduced as `A&`, so `a` is forwarded as a non-const lvalue. This binds to the constructor `A(const A&)`, which copies the value from `a`. In the second call to `factory`, because of
the call `std::move(a)`, `A1` is deduced as `A`, so `a` is forwarded as an rvalue. This binds to the constructor `A(A&&)`, which moves the value from `a`. — end example

```cpp
template<class T> constexpr conditional_t<
    !is_nothrow_move_constructible_v<T> && is_copy_constructible_v<T>, const T&, T&&>
move_if_noexcept(T& x) noexcept;
```

7 Returns: `std::move(x)`.

19.2.5 Function template `as_const` [utility.as_const]

```cpp
template<class T> constexpr add_const_t<T>& as_const(T& t) noexcept;
```

1 Returns: `t`.

19.2.6 Function template `declval` [declval]

The library provides the function template `declval` to simplify the definition of expressions which occur as unevaluated operands (7.2).

```cpp
template<class T> add_rvalue_reference_t<T> declval() noexcept;
```

2 Remarks: If this function is odr-used (6.2), the program is ill-formed.
3 Remarks: The template parameter `T` of `declval` may be an incomplete type.
4
```
[Example:
  template<class To, class From> decltype(static_cast<To>(declval<From>())()) convert(From&&);
```
declares a function template `convert` which only participates in overloading if the type `From` can be explicitly converted to type `To`. For another example see class template `common_type` (19.15.7.6). — end example]

19.3 Compile-time integer sequences [intseq]

19.3.1 In general [intseq.general]

The library provides a class template that can represent an integer sequence. When used as an argument to a function template the template parameter pack defining the sequence can be deduced and used in a pack expansion. [Note: The `index_sequence` alias template is provided for the common case of an integer sequence of type `size_t`; see also 19.5.3.5. — end note]

19.3.2 Class template `integer_sequence` [intseq.intseq]

```cpp
namespace std {
    template<class T, T... I> struct integer_sequence {
        using value_type = T;
        static constexpr size_t size() noexcept { return sizeof...(I); }
    };
}
```

1 `T` shall be an integer type.

19.3.3 Alias template `make_integer_sequence` [intseq.make]

```cpp
template<class T, T N>
using make_integer_sequence = integer_sequence<T, see below>;
```

1 If `N` is negative the program is ill-formed. The alias template `make_integer_sequence` denotes a specialization of `integer_sequence` with `N` template non-type arguments. The type `make_integer_sequence<T, N>` denotes the type `integer_sequence<T, 0, 1, ..., N-1>`. [Note: `make_integer_sequence<int, 0>` denotes the type `integer_sequence<int>` — end note]

19.4 Pairs [pairs]

19.4.1 In general [pairs.general]

The library provides a template for heterogeneous pairs of values. The library also provides a matching function template to simplify their construction and several templates that provide access to `pair` objects as if they were `tuple` objects (see 19.5.3.6 and 19.5.3.7).
19.4.2 Class template pair

namespace std {
    template<class T1, class T2>
    struct pair {
        using first_type = T1;
        using second_type = T2;
        T1 first;
        T2 second;

        pair(const pair&) = default;
        pair(pair&&) = default;
        explicit(see below) constexpr pair();
        explicit(see below) constexpr pair(const T1& x, const T2& y);
        template<class U1, class U2>
            explicit(see below) constexpr pair(U1&& x, U2&& y);
        template<class U1, class U2>
            explicit(see below) constexpr pair(const pair<U1, U2>& p);
        template<class U1, class U2>
            explicit(see below) constexpr pair(pair<U1, U2>&& p);
        template<class... Args1, class... Args2>
            pair(piecewise_construct_t, tuple<Args1...> first_args, tuple<Args2...> second_args);

        pair& operator=(const pair& p);
        template<class U1, class U2>
            pair& operator=(const pair<U1, U2>& p);
        pair& operator=(pair&& p) noexcept(see below);
        template<class U1, class U2>
            pair& operator=(pair<U1, U2>&& p);

        void swap(pair& p) noexcept(see below);
    };

    template<class T1, class T2>
    pair(T1, T2) -> pair<T1, T2>;
}

Constructors and member functions of pair shall not throw exceptions unless one of the element-wise operations specified to be called for that operation throws an exception.

The defaulted move and copy constructor, respectively, of pair shall be a constexpr function if and only if all required element-wise initializations for copy and move, respectively, would satisfy the requirements for a constexpr function.

If (is_trivially_destructible_v<T1> && is_trivially_destructible_v<T2>) is true, then the destructor of pair is trivial.

explicit(see below) constexpr pair();

Effects: Value-initializes first and second.

Remarks: This constructor shall not participate in overload resolution unless is_default_constructible_v<first_type> is true and is_default_constructible_v<second_type> is true. [Note: This behavior can be implemented by a constructor template with default template arguments. — end note] The expression inside explicit evaluates to true if and only if either first_type or second_type is not implicitly default-constructible. [Note: This behavior can be implemented with a trait that checks whether a const first_type& or a const second_type& can be initialized with {}. — end note]

explicit(see below) constexpr pair(const T1& x, const T2& y);

Effects: Initializes first with x and second with y.

Remarks: This constructor shall not participate in overload resolution unless is_copy_constructible_v<first_type> is true and is_copy_constructible_v<second_type> is true. The expression inside explicit is equivalent to:

§ 19.4.2
!is_convertible_v<const first_type&, first_type> ||
!is_convertible_v<const second_type&, second_type>

template<class U1, class U2> explicit(see below) constexpr pair(U1&& x, U2&& y);

Effects: Initializes first with std::forward<U1>(x) and second with std::forward<U2>(y).
Remarks: This constructor shall not participate in overload resolution unless is_constructible_v<first_type, U1&&> is true and is_constructible_v<second_type, U2&&> is true. The expression inside explicit is equivalent to:

!is_convertible_v<U1, first_type> || !is_convertible_v<U2, second_type>

template<class U1, class U2> explicit(see below) constexpr pair(const pair<U1, U2>& p);

Effects: Initializes members from the corresponding members of the argument.
Remarks: This constructor shall not participate in overload resolution unless is_constructible_v<first_type, const U1&> is true and is_constructible_v<second_type, const U2&> is true. The expression inside explicit is equivalent to:

!is_convertible_v<const U1&, first_type> || !is_convertible_v<const U2&, second_type>

template<class U1, class U2> explicit(see below) constexpr pair(pair<U1, U2>&& p);

Effects: Initializes first with std::forward<U1>(p.first) and second with std::forward<U2>(p.second).
Remarks: This constructor shall not participate in overload resolution unless is_constructible_v<first_type, U1&&> is true and is_constructible_v<second_type, U2&&> is true. The expression inside explicit is equivalent to:

!is_convertible_v<const U1&, first_type> || !is_convertible_v<const U2&, second_type>

template<class... Args1, class... Args2>
pair(piecewise_construct_t, tuple<Args1...> first_args, tuple<Args2...> second_args);

Requires: is_constructible_v<first_type, Args11&...> is true and is_constructible_v<second_type, Args22&...> is true.
Effects: Initializes first with arguments of types Args1... obtained by forwarding the elements of first_args and initializes second with arguments of types Args2... obtained by forwarding the elements of second_args. (Here, forwarding an element x of type U within a tuple object means calling std::forward<U>(x).) This form of construction, whereby constructor arguments for first and second are each provided in a separate tuple object, is called piecewise construction.

pair& operator=(const pair& p);

Effects: Assigns p.first to first and p.second to second.
Remarks: This operator shall be defined as deleted unless is_copy_assignable_v<first_type> is true and is_copy_assignable_v<second_type> is true.
Returns: *this.

template<class U1, class U2> pair& operator=(const pair<U1, U2>& p);

Effects: Assigns p.first to first and p.second to second.
Remarks: This operator shall not participate in overload resolution unless is_assignable_v<first_type, const U1&> is true and is_assignable_v<second_type, const U2&> is true.
Returns: *this.

pair& operator=(pair&& p) noexcept(see below);

Effects: Assigns to first with std::forward<first_type>(p.first) and to second with std::forward<second_type>(p.second).
Remarks: This operator shall not participate in overload resolution unless is_move_assignable_v<first_type> is true and is_move_assignable_v<second_type> is true.
Remarks: The expression inside noexcept is equivalent to:
is_nothrow_move_assignable_v<T1> && is_nothrow_move_assignable_v<T2>

§ 19.4.2
template<class U1, class U2> pair& operator=(pair<U1, U2>&& p);

Effects: Assigns to first with std::forward<U1>(p.first) and to second with std::forward<U2>(p.second).

Remarks: This operator shall not participate in overload resolution unless is_assignable_v<first_type&, U1&&> is true and is_assignable_v<second_type&, U2&&> is true.

Returns: *this.

void swap(pair& p) noexcept(see below);

Requires: first shall be swappable with (15.5.3.2) p.first and second shall be swappable with p.second.

Effects: Swaps first with p.first and second with p.second.

Remarks: The expression inside noexcept is equivalent to:

is_nothrow_swappable_v<first_type> && is_nothrow_swappable_v<second_type>

19.4.3 Specialized algorithms

template<class T1, class T2>
constexpr bool operator==(const pair<T1, T2>& x, const pair<T1, T2>& y);

Returns: x.first == y.first && x.second == y.second.

template<class T1, class T2>
constexpr bool operator!=(const pair<T1, T2>& x, const pair<T1, T2>& y);

Returns: !x == y.

template<class T1, class T2>
constexpr bool operator<(const pair<T1, T2>& x, const pair<T1, T2>& y);

Returns: x.first < y.first || ((!y.first < x.first) && x.second < y.second).

template<class T1, class T2>
constexpr bool operator>(const pair<T1, T2>& x, const pair<T1, T2>& y);

Returns: y < x.

template<class T1, class T2>
constexpr bool operator<=(const pair<T1, T2>& x, const pair<T1, T2>& y);

Returns: !y < x.

template<class T1, class T2>
constexpr bool operator>=(const pair<T1, T2>& x, const pair<T1, T2>& y);

Returns: !x < y.

template<class T1, class T2>
void swap(pair<T1, T2>& x, pair<T1, T2>& y) noexcept(noexcept(x.swap(y)));

Effects: As if by x.swap(y).

Remarks: This function shall not participate in overload resolution unless is_swappable_v<T1> is true and is_swappable_v<T2> is true.

template<class T1, class T2>
constexpr pair<V1, V2> make_pair(T1&& x, T2&& y);

Returns: pair<V1, V2>(std::forward<T1>(x), std::forward<T2>(y)), where V1 and V2 are determined as follows: Let Ui be decay_t<Ti> for each Ti. If Ui is a specialization of reference_wrapper, then Vi is Ui::type&, otherwise Vi is Ui.

[Example: In place of:

return pair<int, double>(5, 3.1415926); // explicit types

a C++ program may contain:
return make_pair(5, 3.1415926);  // types are deduced
— end example]

19.4.4 Tuple-like access to pair [pair.astuple]

template<class T1, class T2>
struct tuple_size<pair<T1, T2>> : integral_constant<size_t, 2> { }

tuple_element<I, pair<T1, T2>>::type

1 Requires: I < 2. The program is ill-formed if I is out of bounds.

2 Value: The type T1 if I == 0, otherwise the type T2.

template<size_t I, class T1, class T2>
constexpr tuple_element_t<I, pair<T1, T2>>& get(pair<T1, T2>& p) noexcept;
template<size_t I, class T1, class T2>
constexpr const tuple_element_t<I, pair<T1, T2>>& get(const pair<T1, T2>& p) noexcept;

3 Returns: If I == 0 returns a reference to p.first; if I == 1 returns a reference to p.second; otherwise the program is ill-formed.

template<class T1, class T2>
constexpr T1& get(pair<T1, T2>& p) noexcept;
template<class T1, class T2>
constexpr const T1& get(const pair<T1, T2>& p) noexcept;

4 Requires: T1 and T2 are distinct types. Otherwise, the program is ill-formed.

5 Returns: A reference to p.first.

template<class T2, class T1>
constexpr T2& get(pair<T1, T2>& p) noexcept;
template<class T2, class T1>
constexpr const T2& get(const pair<T1, T2>& p) noexcept;

6 Requires: T1 and T2 are distinct types. Otherwise, the program is ill-formed.

7 Returns: A reference to p.second.

19.4.5 Piecewise construction [pair.piecewise]

struct piecewise_construct_t {
    explicit piecewise_construct_t() = default;
};
inline constexpr piecewise_construct_t piecewise_construct{};

1 The struct piecewise_construct_t is an empty structure type used as a unique type to disambiguate constructor and function overloading. Specifically, pair has a constructor with piecewise_construct_t as the first argument, immediately followed by two tuple arguments used for piecewise construction of the elements of the pair object.

19.5 Tuples [tuple]

19.5.1 In general [tuple.general]

This subclause describes the tuple library that provides a tuple type as the class template tuple that can be instantiated with any number of arguments. Each template argument specifies the type of an element in the...
tuple. Consequently, tuples are heterogeneous, fixed-size collections of values. An instantiation of tuple with two arguments is similar to an instantiation of pair with the same two arguments. See 19.4.

19.5.2 Header <tuple> synopsis

```cpp
namespace std {
    // 19.5.3, class template tuple
    template<class... Types>
    class tuple;

    // 19.5.3.4, tuple creation functions
    inline constexpr unspecified ignore;

    template<class... TTypes>
    constexpr tuple<TTypes&&...> make_tuple(TTypes&&...);

    template<class... TTypes>
    constexpr tuple<TTypes&&...> forward_as_tuple(TTypes&&...) noexcept;

    template<class... TTypes>
    constexpr tuple<TTypes&...> tie(TTypes&...) noexcept;

    template<class... TTypes>
    constexpr tuple<TTypes...> tuple_cat(TTypes&&...);

    // 19.5.3.5, calling a function with a tuple of arguments
    template<class F, class Tuple>
    constexpr decltype(auto) apply(F&& f, Tuple&& t);

    template<class T, class Tuple>
    constexpr T make_from_tuple(Tuple&& t);

    // 19.5.3.6, tuple helper classes
    template<class T> class tuple_size; // not defined
    template<class T> class tuple_size<const T>;
    template<class T> class tuple_size<volatile T>;
    template<class T> class tuple_size<const volatile T>;
    template<class... Types> class tuple_size<tuple<Types...>>;
    template<size_t I, class T> class tuple_element; // not defined
    template<size_t I, class T> class tuple_element<I, const T>;
    template<size_t I, class T> class tuple_element<I, volatile T>;
    template<size_t I, class T> class tuple_element<I, const volatile T>;
    template<size_t I, class... Types>
    class tuple_element<I, tuple<Types...>>;
    template<size_t I, class T>
    using tuple_element_t = typename tuple_element<I, T>::type;

    // 19.5.3.7, element access
    template<size_t I, class... Types>
    constexpr tuple_element_t<I, tuple<Types...>> get(tuple<Types...>&) noexcept;
    template<size_t I, class... Types>
    constexpr tuple_element_t<I, tuple<Types...>> get(tuple<Types...>&&) noexcept;
    template<size_t I, class... Types>
    constexpr const tuple_element_t<I, tuple<Types...>>& get(const tuple<Types...>&) noexcept;
    template<size_t I, class... Types>
    constexpr const tuple_element_t<I, tuple<Types...>>& get(const tuple<Types...>&&) noexcept;
    template<class T, class... Types>
    constexpr T& get(tuple<Types...>& t) noexcept;
    template<class T, class... Types>
    constexpr T&& get(tuple<Types...>&& t) noexcept;
}
```

§ 19.5.2 525
template<

template<class U1, class U2>
tuple& operator=(pair<U1, U2>&&);

// 19.5.3.3, tuple swap
void swap(tuple&) noexcept;

§ 19.5.3.1 Construction [tuple.cnstr]

1 In the descriptions that follow, let \( i \) be in the range \([0, \text{sizeof}(\text{Types}))\) in order, \( T_i \) be the \( i^{\text{th}} \) type in \text{Types}, and \( U_i \) be the \( i^{\text{th}} \) type in a template parameter pack named \text{UTypes}, where indexing is zero-based.

2 For each \text{tuple} constructor, an exception is thrown only if the construction of one of the types in \text{Types} throws an exception.

3 The defaulted move and copy constructor, respectively, of \text{tuple} shall be a constexpr function if and only if all required element-wise initializations for copy and move, respectively, would satisfy the requirements for a constexpr function. The defaulted move and copy constructor of \text{tuple<>()} shall be constexpr functions.

4 If \text{is_trivially_destructible_v<T}_i\text{>} is \text{true} for all \( T_i \), then the destructor of \text{tuple} is trivial.

\text{explicit(see below) constexpr tuple();}

5 \text{Effects:} Value-initializes each element.

6 \text{Remarks:} This constructor shall not participate in overload resolution unless \text{is_default_constructible_v<T}_i\text{>} is \text{true} for all \( i \). [\text{Note:} This behavior can be implemented by a constructor template with default template arguments. — end note] The expression inside \text{explicit} evaluates to \text{true} if and only if \( T_i \) is not implicitly default-constructible for at least one \( i \). [\text{Note:} This behavior can be implemented with a trait that checks whether a \text{const} \( T_i \& \) can be initialized with \{\}. — end note]
explicit(see below) constexpr tuple(const Types&...);

7 Effects: Initializes each element with the value of the corresponding parameter.
8 Remarks: This constructor shall not participate in overload resolution unless sizeof...(Types) >= 1
d and is_copy_constructible_v<T_i> is true for all i. The expression inside explicit is equivalent to:

!conjunction_v<is_convertible<const Types&, Types>...>

template<class... UTypes> explicit(see below) constexpr tuple(UTypes&&... u);

9 Effects: Initializes the elements in the tuple with the corresponding value in std::forward<UTypes>(u).
10 Remarks: This constructor shall not participate in overload resolution unless sizeof...(Types) ==
sizeof...(UTypes) and sizeof...(Types) >= 1 and is_constructible_v<T_i, U_i&&> is true for all i. The expression inside explicit is equivalent to:

!conjunction_v<is_convertible<UTypes, Types>...>

tuple(const tuple& u) = default;

11 Requires: is_copy_constructible_v<T_i> is true for all i.
12 Effects: Initializes each element of *this with the corresponding element of u.

tuple(tuple&& u) = default;

13 Requires: is_move_constructible_v<T_i> is true for all i.
14 Effects: For all i, initializes the i-th element of *this with std::forward<T_i>(get<i>(u)).

template<class... UTypes> explicit(see below) constexpr tuple(const tuple<UTypes...>& u);

15 Effects: Initializes each element of *this with the corresponding element of u.
16 Remarks: This constructor shall not participate in overload resolution unless

(16.1) sizeof...(Types) == sizeof...(UTypes) and
(16.2) is_constructible_v<T_i, const U_i&> is true for all i, and
(16.3) either sizeof...(Types) != 1, or (when Types... expands to T and UTypes... expands
to U) is_convertible_v<const tuple<U>&, T>, is_constructible_v<T_i, const tuple<U>&>,
and is_same_v<T_i, U> are all false.

The expression inside explicit is equivalent to:

!conjunction_v<is_convertible<const UTypes&, Types>...>

template<class... UTypes> explicit(see below) constexpr tuple(tuple<UTypes...>&& u);

17 Effects: For all i, initializes the i-th element of *this with std::forward<T_i>(get<i>(u)).
18 Remarks: This constructor shall not participate in overload resolution unless

(18.1) sizeof...(Types) == sizeof...(UTypes), and
(18.2) is_constructible_v<T_i, U_i&> is true for all i, and
(18.3) either sizeof...(Types) != 1, or (when Types... expands to T and UTypes... expands
to U) is_convertible_v<tuple<U>, T>, is_constructible_v<T_i, tuple<U>>, and is_same_v<T_i, U>
are all false.

The expression inside explicit is equivalent to:

!conjunction_v<is_convertible<UTypes, Types>...>

template<class U1, class U2> explicit(see below) constexpr tuple(const pair<U1, U2>& u);

19 Effects: Initializes the first element with u.first and the second element with u.second.
20 Remarks: This constructor shall not participate in overload resolution unless sizeof...(Types) == 2,
is_constructible_v<T_0, const U1&> is true and is_constructible_v<T_i, const U2&> is true.
21 The expression inside explicit is equivalent to:

!is_convertible_v<const U1&, T_0> | | !is_convertible_v<const U2&, T_i>
template<class U1, class U2> explicit(see below) constexpr tuple(pair<U1, U2>&& u);

Effects: Initializes the first element with std::forward<U1>(u.first) and the second element with std::forward<U2>(u.second).

Remarks: This constructor shall not participate in overload resolution unless sizeof...(Types) == 2, is_constructible_v<T0, U1&&> is true and is_constructible_v<T1, U2&&> is true.

The expression inside explicit is equivalent to:

!is_convertible_v<U1, T0> || !is_convertible_v<U2, T1>

template<class Alloc>
    tuple(allocator_arg_t, const Alloc& a);

template<class Alloc>
    explicit(see below) tuple(allocator_arg_t, const Alloc& a, const Types&...);

template<class Alloc, class... UTypes>
    explicit(see below) tuple(allocator_arg_t, const Alloc& a, UTypes&&...);

template<class Alloc>
    tuple(allocator_arg_t, const Alloc& a, const tuple&);

template<class Alloc>
    tuple(allocator_arg_t, const Alloc& a, tuple&&);

template<class Alloc, class... UTypes>
    explicit(see below) tuple(allocator_arg_t, const Alloc& a, const tuple<UTypes...>&);

template<class Alloc, class... UTypes>
    explicit(see below) tuple(allocator_arg_t, const Alloc& a, tuple<UTypes...>&&);

template<class Alloc, class U1, class U2>
    explicit(see below) tuple(allocator_arg_t, const Alloc& a, const pair<U1, U2>&);

template<class Alloc, class U1, class U2>
    explicit(see below) tuple(allocator_arg_t, const Alloc& a, pair<U1, U2>&&);

Requires: Alloc shall satisfy the Cpp17Allocator requirements (Table 33).

Effects: Equivalent to the preceding constructors except that each element is constructed with uses-allocator construction (19.10.8.2).

19.5.3.2 Assignment

tuple& operator=(const tuple& u);

Effects: Assigns each element of u to the corresponding element of *this.

Remarks: This operator shall be defined as deleted unless is_copy_assignable_v<Ti> is true for all i.

Returns: *this.

tuple& operator=(tuple&& u) noexcept(see below);

Effects: For all i, assigns std::forward<Ti>(get<i>(u)) to get<i>(*this).

Remarks: This operator shall not participate in overload resolution unless is_move_assignable_v<Ti> is true for all i.

Remarks: The expression inside noexcept is equivalent to the logical AND of the following expressions:

is_nothrow_move_assignable_v<Ti>

where Ti is the i-th type in Types.

Returns: *this.

template<class... UTypes> tuple& operator=(const tuple<UTypes...>&& u);

Effects: Assigns each element of u to the corresponding element of *this.

Remarks: This operator shall not participate in overload resolution unless sizeof...(Types) == sizeof...(UTypes) and is_assignable_v<Ti&, const Uj&> is true for all i.

Returns: *this.
template<class... UTypes> tuple& operator=(tuple<UTypes...>&& u);

Effects: For all i, assigns std::forward<Ui>(get<i>(u)) to get<i>(*this).

Remarks: This operator shall not participate in overload resolution unless is_assignable_v<Ti&, Ui&&> == true for all i and sizeof...(Types) == sizeof...(UTypes).

Returns: *this.

template<class U1, class U2> tuple& operator=(const pair<U1, U2>& u);

Effects: Assigns u.first to the first element of *this and u.second to the second element of *this.

Remarks: This operator shall not participate in overload resolution unless sizeof...(Types) == 2 and is_assignable_v<T0&, const U1&> is true for the first type T0 in Types and is_assignable_v<T1&, const U2&> is true for the second type T1 in Types.

Returns: *this.

template<class U1, class U2> tuple& operator=(pair<U1, U2>&& u);

Effects: Assigns std::forward<U1>(u.first) to the first element of *this and std::forward<U2>(u.second) to the second element of *this.

Remarks: This operator shall not participate in overload resolution unless sizeof...(Types) == 2 and is_assignable_v<T0&, U1&&> is true for the first type T0 in Types and is_assignable_v<T1&, U2&&> is true for the second type T1 in Types.

Returns: *this.

19.5.3.3 swap [tuple.swap]

void swap(tuple& rhs) noexcept(see below);

Requires: Each element in *this shall be swappable with (15.5.3.2) the corresponding element in rhs.

Effects: Calls swap for each element in *this and its corresponding element in rhs.

Remarks: The expression inside noexcept is equivalent to the logical AND of the following expressions:

is_nothrow_swappable_v<Ti>

where Ti is the i-th type in Types.

Throws: Nothing unless one of the element-wise swap calls throws an exception.

19.5.3.4 Tuple creation functions [tuple.creation]

In the function descriptions that follow, the members of a template parameter pack XTypes are denoted by Xi for i in [0, sizeof...(XTypes)) in order, where indexing is zero-based.

template<class... TTypes>
constexpr tuple<VTypes...> make_tuple(TTypes&&... t);

The pack VTypes is defined as follows. Let Ui be decay_t<Ti> for each Ti in TTypes. If Ui is a specialization of reference_wrapper, then Vi in VTypes is Ui::type&, otherwise Vi is Ui.

Returns: tuple<VTypes...>(std::forward<TTypes>(t)...).

[Example:
int i; float j;
make_tuple(1, ref(i), cref(j))
creates a tuple of type tuple<int, int&, const float&>. — end example]

template<class... TTypes>
constexpr tuple<TTypes&&...> forward_as_tuple(TTypes&&... t) noexcept;

Effects: Constructs a tuple of references to the arguments in t suitable for forwarding as arguments to a function. Because the result may contain references to temporary variables, a program shall ensure that the return value of this function does not outlive any of its arguments (e.g., the program should typically not store the result in a named variable).

Returns: tuple<TTypes&&...>(std::forward<TTypes>(t)...).
template<class... TTypes>
constexpr tuple<TTypes&...> tie(TTypes&... t) noexcept;

Returns: tuple<TTypes&...>(t...). When an argument in t is ignore, assigning any value to the corresponding tuple element has no effect.

Example: tie functions allow one to create tuples that unpack tuples into variables. ignore can be used for elements that are not needed:

```cpp
int i; std::string s;
tie(i, ignore, s) = make_tuple(42, 3.14, "C++");
// i == 42, s == "C++"
```

--- end example

template<class... Tuples>
constexpr tuple<CTypes...> tuple_cat(Tuples&&... tpls);

In the following paragraphs, let Ti be the i-th type in Tuples, Ui be remove_reference_t<Ti>, and tp_i be the i-th parameter in the function parameter pack tpls, where all indexing is zero-based.

Requires: For all i, Ui shall be the type cv_i tuple<Args_i,...>, where cv_i is the (possibly empty) i-th cv-qualifier-seq and Args_i is the template parameter pack representing the element types in Ui. Let A_{ik} be the k-th type in Args_i. For all A_{ik} the following requirements shall be satisfied:

1. If Ti is deduced as an lvalue reference type, then is_constructible_v<A_{ik}, cv_i A_{ik}&> == true, otherwise
2. is_constructible_v<A_{ik}, cv_i A_{ik}&&> == true.

Remarks: The types in CTuples shall be equal to the ordered sequence of the extended types Args_0,..., Args_{n-1}..., Args_{n-1}..., where n is equal to sizeof...(Tuples). Let e_{i}... be the i-th ordered sequence of tuple elements of the resulting tuple object corresponding to the type sequence Args_i.

Returns: A tuple object constructed by initializing the k_i-th type element e_{ik} in e_{i}... with get<k_i>(std::forward<Ti>(tp_i)) for each valid k_i and each group e_{i} in order.

[Note: An implementation may support additional types in the template parameter pack Tuples that support the tuple-like protocol, such as pair and array. —end note]

19.5.3.5 Calling a function with a tuple of arguments [tuple.apply]

template<class F, class Tuple>
constexpr decltype(auto) apply(F&& f, Tuple&& t);

Effects: Given the exposition-only function:

```cpp
template<class F, class Tuple, size_t... I>
constexpr decltype(auto) apply_impl(F&& f, Tuple&& t, index_sequence<I...>) {
    return INVOKE(std::forward<F>(f), std::get<I>(std::forward<Tuple>(t))...); // see 19.14.3
}
```

Equivalent to:

```cpp
return apply_impl(std::forward<F>(f), std::forward<Tuple>(t), make_index_sequence<tuple_size_v<remove_reference_t<Tuple>>>{});
```

template<class T, class Tuple>
constexpr T make_from_tuple(Tuple&& t);

Effects: Given the exposition-only function:

```cpp
template<class T, class Tuple, size_t... I>
constexpr T make_from_tuple_impl(Tuple&& t, index_sequence<I...>) {
    return T(get<I>(std::forward<Tuple>(t))...);
}
```

Equivalent to:
return make_from_tuple_impl<T>(
    forward<Tuple>(t),
    make_index_sequence<tuple_size_v<remove_reference_t<Tuple>>>{});

[Note: The type of T must be supplied as an explicit template parameter, as it cannot be deduced from
the argument list. — end note]

19.5.3.6 Tuple helper classes [tuple.helper]

template<class T> struct tuple_size;

1 Remarks: All specializations of tuple_size shall satisfy the Cpp17UnaryTypeTrait requirements
(19.15.1) with a base characteristic of integral_constant<size_t, N> for some N.

template<class... Types>
    class tuple_size<tuple<Types...>> : public integral_constant<size_t, sizeof...(Types)> { };

    template<size_t I, class... Types>
    class tuple_element<I, tuple<Types...>> {
    public:
        using type = TI;
    };

2 Requires: I < sizeof...(Types). The program is ill-formed if I is out of bounds.

    Type: TI is the type of the I\textsuperscript{th} element of Types, where indexing is zero-based.

    template<class T> class tuple_size<const T>;
    template<class T> class tuple_size<volatile T>;
    template<class T> class tuple_size<const volatile T>;

4 Let TS denote tuple_size<T> of the cv-unqualified type T. If the expression TS::value is well-
formed when treated as an unevaluated operand, then each of the three templates shall satisfy the Cpp17UnaryTypeTrait requirements (19.15.1) with a base characteristic of
    integral_constant<size_t, TS::value>
Otherwise, they shall have no member value.

5 Access checking is performed as if in a context unrelated to TS and T. Only the validity of the immediate
context of the expression is considered. [Note: The compilation of the expression can result in side
effects such as the instantiation of class template specializations and function template specializations,
the generation of implicitly-defined functions, and so on. Such side effects are not in the “immediate
context” and can result in the program being ill-formed. — end note]

6 In addition to being available via inclusion of the <tuple> header, the three templates are available
when either of the headers <array> or <utility> are included.

    template<size_t I, class T> class tuple_element<I, const T>;
    template<size_t I, class T> class tuple_element<I, volatile T>;
    template<size_t I, class T> class tuple_element<I, const volatile T>;

7 Let TE denote tuple_element_t<I, T> of the cv-unqualified type T. Then each of the three templates
shall satisfy the Cpp17TransformationTrait requirements (19.15.1) with a member typedef type that
names the following type:

(7.1) — for the first specialization, add_const_t<TE>,
(7.2) — for the second specialization, add_volatile_t<TE>, and
(7.3) — for the third specialization, add_cv_t<TE>.

8 In addition to being available via inclusion of the <tuple> header, the three templates are available
when either of the headers <array> or <utility> are included.

19.5.3.7 Element access [tuple.elem]

template<size_t I, class... Types>
    constexpr tuple_element_t<I, tuple<Types...>>&
    get(tuple<Types...>& t) noexcept;

§ 19.5.3.7
template<
    size_t I,
    class... Types>
constexpr

tuple_element_t<I, tuple<Types...>>
&&
get(t) noexcept;  // Note A

template<
    size_t I,
    class... Types>
const

tuple_element_t<I, tuple<Types...>>&
get(t) noexcept;  // Note B

template<
    size_t I,
    class... Types>
const

tuple_element_t<I, tuple<Types...>>
&&
get(t) noexcept;

1
Requires: I < sizeof...(Types). The program is ill-formed if I is out of bounds.

2
Returns: A reference to the Ith element of t, where indexing is zero-based.

3
[Note A: If a T in Types is some reference type X&, the return type is X&, not X&&. However, if the
element type is a non-reference type T, the return type is T&&. — end note]

4
[Note B: Constness is shallow. If a T in Types is some reference type X&, the return type is X&,
not const X&. However, if the element type is a non-reference type T, the return type is const T&. This is
consistent with how constness is defined to work for member variables of reference type. — end note]

template<class T, class... Types>
constexpr

T&
get(t) noexcept;

template<class T, class... Types>
constexpr

T&&
get(t) noexcept;

template<class T, class... Types>
constexpr

const T&
get(t) noexcept;

template<class T, class... Types>
constexpr

const T&&
get(t) noexcept;

5
Requires: The type T occurs exactly once in Types.... Otherwise, the program is ill-formed.

6
Returns: A reference to the element of t corresponding to the type T in Types....

7
[Example:
const tuple<int, const int, double, double> t(1, 2, 3.4, 5.6);
const int& i1 = get<int>(t);  // OK. Not ambiguous. i1 == 1
const int& i2 = get<const int>(t);  // OK. Not ambiguous. i2 == 2
const double& d = get<double>(t);  // ERROR. ill-formed
— end example]

8
[Note: The reason get is a non-member function is that if this functionality had been provided as a member
function, code where the type depended on a template parameter would have required using the template
keyword. — end note]

19.5.3.8  Relational operators

1
template<class... TTypes, class... UTypes>
constexpr

bool
operator==(const tuple<TTypes...>& t, const tuple<UTypes...>& u);

1
Requires: For all i, where 0 <= i and i < sizeof...(TTypes), get<i>(t) == get<i>(u) is a valid
expression returning a type that is convertible to bool. sizeof...(TTypes) == sizeof...(UTypes).

2
Returns: true if get<i>(t) == get<i>(u) for all i, otherwise false. For any two zero-length tuples
e and f, e == f returns true.

3
Effects: The elementary comparisons are performed in order from the zeroth index upwards. No
comparisons or element accesses are performed after the first equality comparison that evaluates to
false.

4
template<class... TTypes, class... UTypes>
constexpr

bool
operator!=(const tuple<TTypes...>& t, const tuple<UTypes...>& u);

4
Returns: !(t == u).

5
template<class... TTypes, class... UTypes>
constexpr

bool
operator<(const tuple<TTypes...>& t, const tuple<UTypes...>& u);

5
Requires: For all i, where 0 <= i and i < sizeof...(TTypes), both get<i>(t) < get<i>(u) and
get<i>(u) < get<i>(t) are valid expressions returning types that are convertible to bool.
sizeof...(TTypes) == sizeof...(UTypes).
Returns: The result of a lexicographical comparison between \( t \) and \( u \). The result is defined as:
\[
(\text{bool})(\text{get}<0>(t) < \text{get}<0>(u)) || (!\text{(bool)}(\text{get}<0>(u) < \text{get}<0>(t)) && \text{t\_tail} < \text{u\_tail}),
\]
where \( r_{\text{tail}} \) for some tuple \( r \) is a tuple containing all but the first element of \( r \). For any two zero-length tuples \( e \) and \( f \), \( e < f \) returns false.

```cpp
template<class... TTypes, class... UTypes>
constexpr bool operator>(const tuple<TTypes...>& t, const tuple<UTypes...>& u);
```

Returns: \( u < t \).

```cpp
template<class... TTypes, class... UTypes>
constexpr bool operator<=(const tuple<TTypes...>& t, const tuple<UTypes...>& u);
```

Returns: \( ! (u < t) \).

```cpp
template<class... TTypes, class... UTypes>
constexpr bool operator>=(const tuple<TTypes...>& t, const tuple<UTypes...>& u);
```

Returns: \( ! (t < u) \).

[Note: The above definitions for comparison functions do not require \( t_{\text{tail}} \) (or \( u_{\text{tail}} \)) to be constructed. It may not even be possible, as \( t \) and \( u \) are not required to be copy constructible. Also, all comparison functions are short circuited; they do not perform element accesses beyond what is required to determine the result of the comparison. —end note]

19.5.3.9 Tuple traits

```cpp
template<class... Types, class Alloc>
struct uses_allocator<tuple<Types...>, Alloc> : true_type { };
```

Requires: Alloc shall satisfy the Cpp17Allocator requirements (Table 33).

[Note: Specialization of this trait informs other library components that tuple can be constructed with an allocator, even though it does not have a nested allocator_type. —end note]

19.5.3.10 Tuple specialized algorithms

```cpp
template<class... Types>
void swap(tuple<Types...>& x, tuple<Types...>& y) noexcept(see below);
```

Remarks: This function shall not participate in overload resolution unless \( \text{is\_swappable\_v<T_i>} \) is true for all \( i \), where \( 0 \leq i < \text{sizeof...}(\text{Types}) \). The expression inside noexcept is equivalent to:
\[
\text{noexcept}(x.\text{swap}(y))
\]

Effects: As if by \( x.\text{swap}(y) \).

19.6 Optional objects

19.6.1 In general

This subclause describes class template \( \text{optional} \) that represents optional objects. An \( \text{optional} \) object is an object that contains the storage for another object and manages the lifetime of this contained object, if any. The contained object may be initialized after the optional object has been initialized, and may be destroyed before the optional object has been destroyed. The initialization state of the contained object is tracked by the optional object.

19.6.2 Header \( \text{optional} \) synopsis

```cpp
namespace std {
    // 19.6.3, class template optional
    template<class T>
    class optional;

    // 19.6.4, no-value state indicator
    struct nullopt_t(see below);
    inline constexpr nullopt_t nullopt(unspecified);

    // 19.6.5, class bad_optional_access
    class bad_optional_access;
}
```
// 19.6.6, relational operators
template<class T, class U>
constexpr bool operator==(const optional<T>&, const optional<U>&);

template<class T, class U>
constexpr bool operator!=(const optional<T>&, const optional<U>&);

template<class T, class U>
constexpr bool operator<(const optional<T>&, const optional<U>&);

template<class T, class U>
constexpr bool operator>(const optional<T>&, const optional<U>&);

template<class T, class U>
constexpr bool operator<=(const optional<T>&, const optional<U>&);

template<class T, class U>
constexpr bool operator>=(const optional<T>&, const optional<U>&);

// 19.6.7, comparison with nullopt
template<class T> constexpr bool operator==(const optional<T>&, nullopt_t) noexcept;

template<class T> constexpr bool operator==(nullopt_t, const optional<T>&) noexcept;

template<class T> constexpr bool operator!=(const optional<T>&, nullopt_t) noexcept;

template<class T> constexpr bool operator!=(nullopt_t, const optional<T>&) noexcept;

template<class T> constexpr bool operator<(const optional<T>&, nullopt_t) noexcept;

template<class T> constexpr bool operator<(nullopt_t, const optional<T>&) noexcept;

template<class T> constexpr bool operator>(const optional<T>&, nullopt_t) noexcept;

template<class T> constexpr bool operator>(nullopt_t, const optional<T>&) noexcept;

template<class T> constexpr bool operator<=(const optional<T>&, nullopt_t) noexcept;

  template<class T>
    struct hash {

      template<class T>
        using value_type = T;

  finished
// 19.6.3.1, constructors
constexpr optional() noexcept;
constexpr optional(nullopt_t) noexcept;
constexpr optional(const optional&);
constexpr optional(optional&&) noexcept(see below);
template<class... Args>
    constexpr optional(in_place_t, Args&&...);
template<class U, class... Args>
    constexpr explicit optional(in_place_t, initializer_list<U>, Args&&...);
template<class U = T>
    explicit(see below) constexpr optional(U&&);
template<class U>
    explicit(see below) optional(const optional<U>&);
template<class U>
    explicit(see below) optional(optional<U>&&);

// 19.6.3.2, destructor
~optional();

// 19.6.3.3, assignment
optional& operator=(nullopt_t) noexcept;
optional& operator=(const optional&);
optional& operator=(optional&&) noexcept(see below);
template<class U = T> optional& operator=(U&&);
template<class U> optional& operator=(const optional<U>&);
template<class U> optional& operator=(optional<U>&&);

// 19.6.3.4, swap
void swap(optional&) noexcept(see below);

// 19.6.3.5, observers
constexpr const T* operator->() const;
constexpr T* operator->();
constexpr const T& operator*() const&;
constexpr T& operator*() &;
constexpr T&& operator*() &&;
constexpr const T&& operator*() const&&;
constexpr explicit operator bool() const noexcept;
constexpr const T value() const&;
constexpr T& value() &;
constexpr T&& value() &&;
constexpr const T&& value() const&&;
template<class U> constexpr T value_or(U&&) const&;
template<class U> constexpr T value_or(U&&) &&;

// 19.6.3.6, modifiers
void reset() noexcept;

private:
    T *val;  // exposition only

};

template<class T>
    optional<T> -> optional<T>;

1 Any instance of optional<T> at any given time either contains a value or does not contain a value. When
an instance of optional<T> contains a value, it means that an object of type T, referred to as the optional
object’s contained value, is allocated within the storage of the optional object. Implementations are not
permitted to use additional storage, such as dynamic memory, to allocate its contained value. The contained
value shall be allocated in a region of the optional<T> storage suitably aligned for the type T. When an

§ 19.6.3
object of type `optional<T>` is contextually converted to `bool`, the conversion returns `true` if the object contains a value; otherwise the conversion returns `false`.

2. Member `val` is provided for exposition only. When an `optional<T>` object contains a value, `val` points to the contained value.

3. `T` shall be an object type other than `cv in_place_t` or `cv nullopt_t` and shall satisfy the `Cpp17Destructible` requirements (Table 29).

### 19.6.3.1 Constructors

```cpp
constexpr optional() noexcept;
constexpr optional(nullopt_t) noexcept;
```

1. **Ensures**: `*this` does not contain a value.

2. **Remarks**: No contained value is initialized. For every object type `T` these constructors shall be constexpr constructors (9.1.5).

```cpp
constexpr optional(const optional& rhs);
```

3. **Effects**: If `rhs` contains a value, initializes the contained value as if direct-non-list-initializing an object of type `T` with the expression `*rhs`.

4. **Ensures**: `bool(rhs) == bool(*this)`.

5. **Throws**: Any exception thrown by the selected constructor of `T`.

6. **Remarks**: This constructor shall be defined as deleted unless `is_copy_constructible_v<T>` is true. If `is_trivially_copy_constructible_v<T>` is true, this constructor shall be a `constexpr` constructor.

```cpp
constexpr optional(optional&& rhs) noexcept;
```

7. **Effects**: If `rhs` contains a value, initializes the contained value as if direct-non-list-initializing an object of type `T` with the expression `std::move(*rhs)`. `bool(rhs)` is unchanged.

8. **Ensures**: `bool(rhs) == bool(*this)`.

9. **Throws**: Any exception thrown by the selected constructor of `T`.

10. **Remarks**: The expression inside `noexcept` is equivalent to `is_nothrow_move_constructible_v<T>`.

```cpp
template<class... Args> constexpr explicit optional(in_place_t, Args&&... args);
```

11. **Effects**: Initializes the contained value as if direct-non-list-initializing an object of type `T` with the arguments `std::forward<Args>(args)`.

12. **Ensures**: `*this` contains a value.

13. **Throws**: Any exception thrown by the selected constructor of `T`.

14. **Remarks**: If `T`'s constructor selected for the initialization is a `constexpr` constructor, this constructor shall be a `constexpr` constructor. This constructor shall not participate in overload resolution unless `is_constructible_v<T, Args...>` is true.

```cpp
template<class U, class... Args>
constexpr explicit optional(in_place_t, initializer_list<U> il, Args&&... args);
```

15. **Effects**: Initializes the contained value as if direct-non-list-initializing an object of type `T` with the arguments `il, std::forward<Args>(args)`.

16. **Ensures**: `*this` contains a value.

17. **Throws**: Any exception thrown by the selected constructor of `T`.

18. **Remarks**: This constructor shall not participate in overload resolution unless `is_constructible_v<T, initializer_list<U>&, Args&&...>` is true. If `T`'s constructor selected for the initialization is a `constexpr` constructor, this constructor shall be a `constexpr` constructor.
template<class U = T> explicit(see below) constexpr optional(U&& v);
19
19 Effects: Initializes the contained value as if direct-non-list-initializing an object of type T with the expression std::forward<U>(v).
20
20 Ensures: *this contains a value.
21
21 Throws: Any exception thrown by the selected constructor of T.
22
22 Remarks: If T's selected constructor is a constexpr constructor, this constructor shall be a constexpr constructor. This constructor shall not participate in overload resolution unless is_constructible_v<T, U&&> is true, is_same_v<remove_cvref_t<U>, in_place_t> is false, and is_same_v<remove_cvref_t<U>, optional> is false. The expression inside explicit is equivalent to:
23
23 !is_convertible_v<U, T>

template<class U> explicit(see below) optional(optional<U>&& rhs);
23
23 Effects: If rhs contains a value, initializes the contained value as if direct-non-list-initializing an object of type T with the expression *rhs.
24
24 Ensures: bool(rhs) == bool(*this).
25
25 Throws: Any exception thrown by the selected constructor of T.
26
26 Remarks: This constructor shall not participate in overload resolution unless
26.1 is_constructible_v<T, const U&> is true,
26.2 is_constructible_v<T, optional<U>&> is false,
26.3 is_constructible_v<T, optional<U>&&> is false,
26.4 is_constructible_v<T, const optional<U>&> is false,
26.5 is_constructible_v<T, const optional<U>&&> is false,
26.6 is_convertible_v<optional<U>&, T> is false,
26.7 is_convertible_v<optional<U>&&, T> is false,
26.8 is_convertible_v<optional<U>&, T> is false, and
26.9 is_convertible_v<optional<U>&&, T> is false.

The expression inside explicit is equivalent to:
27 !is_convertible_v<const U&, T>

template<class U> explicit(see below) optional(optional<optional<U>&& rhs);
27
27 Effects: If rhs contains a value, initializes the contained value as if direct-non-list-initializing an object of type T with the expression std::move(*rhs). bool(rhs) is unchanged.
28
28 Ensures: bool(rhs) == bool(*this).
29
29 Throws: Any exception thrown by the selected constructor of T.
30
30 Remarks: This constructor shall not participate in overload resolution unless
30.1 is_constructible_v<T, U&&> is true,
30.2 is_constructible_v<T, optional<U>&> is false,
30.3 is_constructible_v<T, optional<U>&&> is false,
30.4 is_constructible_v<T, const optional<U>&> is false,
30.5 is_constructible_v<T, const optional<U>&&> is false,
30.6 is_convertible_v<optional<U>&, T> is false,
30.7 is_convertible_v<optional<U>&&, T> is false,
30.8 is_convertible_v<optional<U>&, T> is false, and
30.9 is_convertible_v<optional<U>&&, T> is false.

The expression inside explicit is equivalent to:
31 !is_convertible_v<optional<U>, T>

§ 19.6.3.1
19.6.3.2 Destructor

~optional();

1  Effects: If \texttt{is\_trivially\_destructible\_v<T>} \(!= \texttt{true} \) and \texttt{*this} contains a value, calls \texttt{val->T::~T()}

2  Remarks: If \texttt{is\_trivially\_destructible\_v<T>} is \texttt{true}, then this destructor is trivial.

19.6.3.3 Assignment

optional\langle T\rangle & \operatorname{operator=} (\texttt{nullopt\_t}) \texttt{noexcept};

1  Effects: If \texttt{*this} contains a value, calls \texttt{val->T::~T()} to destroy the contained value; otherwise no effect.

2  Returns: \texttt{*this}.

3  Ensures: \texttt{*this} does not contain a value.

optional\langle T\rangle & \operatorname{operator=} (\texttt{const optional\& rhs});

4  Effects: See Table 39.

\begin{tabular}{|c|c|c|}
\hline
\texttt{rhs} contains a value & \texttt{*this} contains a value & \texttt{*this} does not contain a value \\
\hline
\texttt{rhs} contains a value & assigns \texttt{*rhs} to the contained value & initializes the contained value as if direct-non-list-initializing an object of type \texttt{T} with \texttt{*rhs} \\
\texttt{rhs} does not contain a value & destroys the contained value by calling \texttt{val->T::~T()} & \texttt{no effect} \\
\hline
\end{tabular}

5  Returns: \texttt{*this}.

6  Ensures: \texttt{bool(rhs) == bool(*this)}.

7  Remarks: If any exception is thrown, the result of the expression \texttt{bool(*this)} remains unchanged. If an exception is thrown during the call to \texttt{T}'s copy constructor, no effect. If an exception is thrown during the call to \texttt{T}'s copy assignment, the state of its contained value is as defined by the exception safety guarantee of \texttt{T}'s copy assignment. This operator shall be defined as deleted unless \texttt{is\_copy\_constructible\_v<T>} is \texttt{true} and \texttt{is\_copy\_assignable\_v<T> is true}.

optional\langle T\rangle & \operatorname{operator=} (\texttt{optional\&\& rhs}) \texttt{noexcept(see below)};

8  Effects: See Table 40. The result of the expression \texttt{bool(rhs)} remains unchanged.

\begin{tabular}{|c|c|c|}
\hline
\texttt{rhs} contains a value & \texttt{*this} contains a value & \texttt{*this} does not contain a value \\
\hline
\texttt{rhs} contains a value & assigns \texttt{std::move(*rhs)} to the contained value & initializes the contained value as if direct-non-list-initializing an object of type \texttt{T} with \texttt{std::move(*rhs)} \\
\texttt{rhs} does not contain a value & destroys the contained value by calling \texttt{val->T::~T()} & \texttt{no effect} \\
\hline
\end{tabular}

9  Returns: \texttt{*this}.

10  Ensures: \texttt{bool(rhs) == bool(*this)}.

11  Remarks: The expression inside \texttt{noexcept} is equivalent to:

\texttt{is\_nothrow\_move\_assignable\_v<T> \&\& is\_nothrow\_move\_constructible\_v<T>}

§ 19.6.3.3 539
If any exception is thrown, the result of the expression \( \text{bool}(*\text{this}) \) remains unchanged. If an exception is thrown during the call to \( T \)'s move constructor, the state of \( \star \text{rhs}.\text{val} \) is determined by the exception safety guarantee of \( T \)'s move constructor. If an exception is thrown during the call to \( T \)'s move assignment, the state of \( \star \text{val} \) and \( \star \text{rhs}.\text{val} \) is determined by the exception safety guarantee of \( T \)'s move assignment. This operator shall not participate in overload resolution unless \( \text{is\_move\_constructible\_v}<T> \) is true and \( \text{is\_move\_assignable\_v}<T> \) is true.

\[
\text{template<class U = T> optional<T>& operator=(U&& v);}\
\]

**Effects:** If \( \star \text{this} \) contains a value, assigns \( \text{std::forward}<U>(v) \) to the contained value; otherwise initializes the contained value as if direct-non-list-initializing object of type \( T \) with \( \text{std::forward}<U>(v) \).

**Returns:** \( \star \text{this} \).

**Ensures:** \( \star \text{this} \) contains a value.

**Remarks:** If any exception is thrown, the result of the expression \( \text{bool}(*\text{this}) \) remains unchanged. If an exception is thrown during the call to \( T \)'s constructor, the state of \( v \) is determined by the exception safety guarantee of \( T \)'s constructor. If an exception is thrown during the call to \( T \)'s assignment, the state of \( \star \text{val} \) and \( v \) is determined by the exception safety guarantee of \( T \)'s assignment. This function shall not participate in overload resolution unless \( \text{is\_same\_v}<\text{remove\_cvref\_t}<U>, \text{optional}> \) is false, \( \text{conjunction\_vcis\_scalar}<T>, \text{is\_same}<T>, \text{decay\_t}<U>>> \) is false, \( \text{is\_constructible\_v}<T, U> \) is true, and \( \text{is\_assignable\_v}<T&, U> \) is true.

\[
\text{template<class U> optional<T>& operator=(const optional<U>& rhs);}\
\]

**Effects:** See Table 41.

**Table 41 — optional::operator=(const optional<U>&) effects**

<table>
<thead>
<tr>
<th>( \text{rhs contains a value} )</th>
<th>( \star \text{this contains a value} )</th>
<th>( \star \text{this does not contain a value} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>assigns ( \star \text{rhs} ) to the contained value</td>
<td>initializes the contained value as if direct-non-list-initializing an object of type ( T ) with ( \star \text{rhs} )</td>
<td>destroys the contained value by calling ( \text{val} \rightarrow T::\neg T() )</td>
</tr>
</tbody>
</table>

**Returns:** \( \star \text{this} \).

**Ensures:** \( \text{bool}(\text{rhs}) == \text{bool}(*\text{this}) \).

**Remarks:** If any exception is thrown, the result of the expression \( \text{bool}(*\text{this}) \) remains unchanged. If an exception is thrown during the call to \( T \)'s constructor, the state of \( \star \text{rhs}.\text{val} \) is determined by the exception safety guarantee of \( T \)'s constructor. If an exception is thrown during the call to \( T \)'s assignment, the state of \( \star \text{val} \) and \( \star \text{rhs}.\text{val} \) is determined by the exception safety guarantee of \( T \)'s assignment. This function shall not participate in overload resolution unless

\[
\begin{align*}
\text{(20.1)} & \quad \text{is\_constructible\_v}<T, \text{const } U&> \text{ is true}, \\
\text{(20.2)} & \quad \text{is\_assignable\_v}<T&, \text{const } U&> \text{ is true}, \\
\text{(20.3)} & \quad \text{is\_constructible\_v}<T, \text{optional}<U&>&> \text{ is false}, \\
\text{(20.4)} & \quad \text{is\_constructible\_v}<T, \text{optional}<U>&>&> \text{ is false}, \\
\text{(20.5)} & \quad \text{is\_constructible\_v}<T, \text{const optional}<U>&>& \text{ is false}, \\
\text{(20.6)} & \quad \text{is\_constructible\_v}<T, \text{const optional}<U>&>& \text{ is false}, \\
\text{(20.7)} & \quad \text{is\_convertible\_v}<\text{optional}<U>& &, T> \text{ is false}, \\
\text{(20.8)} & \quad \text{is\_convertible\_v}<\text{optional}<U>&&, T> \text{ is false}, \\
\text{(20.9)} & \quad \text{is\_convertible\_v}<\text{const optional}<U>&&, T> \text{ is false}, \\
\text{(20.10)} & \quad \text{is\_convertible\_v}<\text{const optional}<U>&&, T> \text{ is false}, \\
\text{(20.11)} & \quad \text{is\_assignable\_v}<T&, \text{optional}<U>&> \text{ is false}, \\
\text{(20.12)} & \quad \text{is\_assignable\_v}<T&, \text{optional}<U>&>& \text{ is false},
\end{align*}
\]
is_assignable_v<T&, const optional<U>&> is false, and
is_assignable_v<T&, const optional<U>&&> is false.

```cpp
template<class U> optional<T>& operator=(optional<U>&& rhs);
```

**Effects:** See Table 42. The result of the expression bool(rhs) remains unchanged.

<table>
<thead>
<tr>
<th>*this contains a value</th>
<th>*this does not contain a value</th>
</tr>
</thead>
<tbody>
<tr>
<td>rhs contains a value</td>
<td>assigns std::move(*rhs) to the contained value initializes the contained value as if direct-non-list-initializing an object of type T with std::move(*rhs)</td>
</tr>
<tr>
<td>rhs does not contain a value</td>
<td>destroys the contained value by calling val-&gt;T::~T()</td>
</tr>
</tbody>
</table>

**Returns:** *this.

**Ensures:** bool(rhs) == bool(*this).

**Remarks:** If any exception is thrown, the result of the expression bool(*this) remains unchanged. If an exception is thrown during the call to T’s constructor, the state of *rhs.val is determined by the exception safety guarantee of T’s constructor. If an exception is thrown during the call to T’s assignment, the state of *val and *rhs.val is determined by the exception safety guarantee of T’s assignment. This function shall not participate in overload resolution unless

- is_constructible_v<T, U> is true,
- is_assignable_v<T&, U> is true,
- is_constructible_v<T, optional<U>&&> is false,
- is_constructible_v<T, optional<U>&&> is false,
- is_constructible_v<T, const optional<U>&> is false,
- is_constructible_v<T, const optional<U>&&> is false,
- is_convertible_v<optional<U>&, T> is false,
- is_convertible_v<optional<U>&&, T> is false,
- is_convertible_v<optional<U>&, T> is false,
- is_convertible_v<optional<U>&&., T> is false,
- is_assignable_v<T&, optional<U>&> is false,
- is_assignable_v<T&, optional<U>&&> is false,
- is_assignable_v<T&, const optional<U>&> is false, and
- is_assignable_v<T&, const optional<U>&&> is false.

```cpp
template<class... Args> T& emplace(Args&&... args);
```

**Requires:** is_constructible_v<T, Args&&...> is true.

**Effects:** Calls *this = nullopt. Then initializes the contained value as if direct-non-list-initializing an object of type T with the arguments std::forward<Args>(args)....

**Ensures:** *this contains a value.

**Returns:** A reference to the new contained value.

**Throws:** Any exception thrown by the selected constructor of T.

**Remarks:** If an exception is thrown during the call to T’s constructor, *this does not contain a value, and the previous *val (if any) has been destroyed.
template<class U, class... Args> T& emplace(initializer_list<U> il, Args&&... args);

31 **Effects:** Calls *this = nullopt. Then initializes the contained value as if direct-non-list-initializing an object of type T with the arguments il, std::forward<Args>(args)....

32 **Ensures:** *this contains a value.

33 **Returns:** A reference to the new contained value.

34 **Throws:** Any exception thrown by the selected constructor of T.

35 **Remarks:** If an exception is thrown during the call to T's constructor, *this does not contain a value, and the previous *val (if any) has been destroyed. This function shall not participate in overload resolution unless is_constructible_v<T, initializer_list<U>&, Args&&...> is true.

19.6.3.4 Swap [optional.swap]

void swap(optional& rhs) noexcept(see below);

1 **Requires:** Lvalues of type T shall be swappable and is_move_constructible_v<T> is true.

2 **Effects:** See Table 43.

Table 43 — optional::swap(optional&) effects

<table>
<thead>
<tr>
<th>*this contains a value</th>
<th>*this does not contain a value</th>
</tr>
</thead>
<tbody>
<tr>
<td>rhs contains a value</td>
<td>calls swap(*(*this), *rhs)</td>
</tr>
<tr>
<td>rhs does not contain a value</td>
<td>initializes the contained value of *this as if direct-non-list-initializing an object of type T with the expression std::move(*rhs), followed by rhs.val-&gt;T::~T(); postcondition is that *this contains a value and rhs does not contain a value</td>
</tr>
<tr>
<td>rhs does not contain a value</td>
<td>no effect</td>
</tr>
</tbody>
</table>

3 **Throws:** Any exceptions thrown by the operations in the relevant part of Table 43.

4 **Remarks:** The expression inside noexcept is equivalent to:

\[
\text{is\_nothrow\_move\_constructible\_v<T> \&\& is\_nothrow\_swappable\_v<T>}
\]

If any exception is thrown, the results of the expressions bool(*this) and bool(rhs) remain unchanged. If an exception is thrown during the call to function swap, the state of *val and *rhs.val is determined by the exception safety guarantee of swap for lvalues of T. If an exception is thrown during the call to T's move constructor, the state of *val and *rhs.val is determined by the exception safety guarantee of T's move constructor.

19.6.3.5 Observers [optional.observe]

constexpr const T* operator->() const;

constexpr T* operator->();

1 **Requires:** *this contains a value.

2 **Returns:** val.

3 **Throws:** Nothing.
Remarks: These functions shall be constexpr functions.

```cpp
constexpr const T& operator*() const&;
constexpr T& operator*() &;
```

Requires: *this contains a value.

Returns: *val.

Throws: Nothing.

Remarks: These functions shall be constexpr functions.

```cpp
constexpr T&& operator*() &&;
constexpr const T&& operator*() const&&;
```

Requires: *this contains a value.

Effects: Equivalent to: return std::move(*val);

Remarks: This function shall be a constexpr function.

```cpp
constexpr explicit operator bool() const noexcept;
```

Returns: true if and only if *this contains a value.

Remarks: This function shall be a constexpr function.

```cpp
constexpr const T& value() const&;
constexpr T& value() &;
```

Effects: Equivalent to:

```cpp
return bool(*this) ? *val : throw bad_optional_access();
```

Remarks: If is_copy_constructible_v<T> && is_convertible_v<U&&, T> is false, the program is ill-formed.

```cpp
template<class U> constexpr T value_or(U&& v) const&;
```

Effects: Equivalent to:

```cpp
return bool(*this) ? **this : static_cast<T>(std::forward<U>(v));
```

Remarks: If is_move_constructible_v<T> && is_convertible_v<U&&, T> is false, the program is ill-formed.

```cpp
template<class U> constexpr T value_or(U&& v) &&;
```

Effects: Equivalent to:

```cpp
return bool(*this) ? std::move(**this) : static_cast<T>(std::forward<U>(v));
```

Remarks: If is_move_constructible_v<T> && is_convertible_v<U&&, T> is false, the program is ill-formed.

### 19.6.3.6 Modifiers

```cpp
void reset() noexcept;
```

Effects: If *this contains a value, calls val->T::~T() to destroy the contained value; otherwise no effect.

Ensures: *this does not contain a value.

### 19.6.4 No-value state indicator

```cpp
struct nullopt_t{see below};
inline constexpr nullopt_t nullopt(unspecified);
```
The struct `nullopt_t` is an empty structure type used as a unique type to indicate the state of not containing a value for optional objects. In particular, `optional<T>` has a constructor with `nullopt_t` as a single argument; this indicates that an optional object not containing a value shall be constructed.

Type `nullopt_t` shall not have a default constructor or an initializer-list constructor, and shall not be an aggregate.

### 19.6.5 Class `bad_optional_access` [optional.bad.access]

```cpp
class bad_optional_access : public exception {
  public:
    bad_optional_access();
};
```

The class `bad_optional_access` defines the type of objects thrown as exceptions to report the situation where an attempt is made to access the value of an optional object that does not contain a value.

```cpp
bad_optional_access();
```

**Effects:** Constructs an object of class `bad_optional_access`.

**Ensures:** `what()` returns an implementation-defined `ntbs`.

### 19.6.6 Relational operators [optional.relops]

- **Template:** `template<class T, class U> constexpr bool operator==(const optional<T>& x, const optional<U>& y);`
  - **Requires:** The expression `*x == *y` shall be well-formed and its result shall be convertible to `bool`.
  - **Note:** `T` need not be `Cpp17EqualityComparable`. — end note
  - **Returns:** If `bool(x) != bool(y)`, `false`; otherwise if `bool(x) == false, true`; otherwise `*x == *y`.
  - **Remarks:** Specializations of this function template for which `*x == *y` is a core constant expression shall be constexpr functions.

- **Template:** `template<class T, class U> constexpr bool operator!=(const optional<T>& x, const optional<U>& y);`
  - **Requires:** The expression `*x != *y` shall be well-formed and its result shall be convertible to `bool`.
  - **Returns:** If `bool(x) != bool(y)`, `true`; otherwise, if `bool(x) == false, false`; otherwise `*x != *y`.
  - **Remarks:** Specializations of this function template for which `*x != *y` is a core constant expression shall be constexpr functions.

- **Template:** `template<class T, class U> constexpr bool operator<(const optional<T>& x, const optional<U>& y);`
  - **Requires:** `*x < *y` shall be well-formed and its result shall be convertible to `bool`.
  - **Returns:** If `!y`, `false`; otherwise, if `!x, true`; otherwise `*x < *y`.
  - **Remarks:** Specializations of this function template for which `*x < *y` is a core constant expression shall be constexpr functions.

- **Template:** `template<class T, class U> constexpr bool operator>(const optional<T>& x, const optional<U>& y);`
  - **Requires:** The expression `*x > *y` shall be well-formed and its result shall be convertible to `bool`.
  - **Returns:** If `!x`, `false`; otherwise, if `!y, true`; otherwise `*x > *y`.
  - **Remarks:** Specializations of this function template for which `*x > *y` is a core constant expression shall be constexpr functions.

- **Template:** `template<class T, class U> constexpr bool operator<=(const optional<T>& x, const optional<U>& y);`
  - **Requires:** The expression `*x <= *y` shall be well-formed and its result shall be convertible to `bool`.
  - **Returns:** If `!x`, `true`; otherwise, if `!y`, `false`; otherwise `*x <= *y`.
  - **Remarks:** Specializations of this function template for which `*x <= *y` is a core constant expression shall be constexpr functions.

- **Template:** `template<class T, class U> constexpr bool operator>=(const optional<T>& x, const optional<U>& y);`
  - **Requires:** The expression `*x >= *y` shall be well-formed and its result shall be convertible to `bool`.
  - **Returns:** If `!y`, `true`; otherwise, if `!x, false`; otherwise `*x >= *y`.
  - **Remarks:** Specializations of this function template for which `*x >= *y` is a core constant expression shall be constexpr functions.
Remarks: Specializations of this function template for which \( *x \geq *y \) is a core constant expression shall be constexpr functions.

### 19.6.7 Comparison with nullopt

```
template<class T> constexpr bool operator==(const optional<T>& x, nullopt_t) noexcept;
```
1  
Returns: \( !x \).

```
template<class T> constexpr bool operator!=(const optional<T>& x, nullopt_t) noexcept;
```
2  
Returns: \( bool(x) \).

```
template<class T> constexpr bool operator<=(const optional<T>& x, nullopt_t) noexcept;
```
3  
Returns: \( !x \).

```
template<class T> constexpr bool operator>=(const optional<T>& x, nullopt_t) noexcept;
```
4  
Returns: \( bool(x) \).

```
template<class T> constexpr bool operator<(nullopt_t, const optional<T>& x) noexcept;
```
5  
Returns: \( false \).

```
template<class T> constexpr bool operator>(nullopt_t, const optional<T>& x) noexcept;
```
6  
Returns: \( false \).

```
template<class T> constexpr bool operator==(nullopt_t, const optional<T>& x) noexcept;
```
7  
Returns: \( true \).

```
template<class T> constexpr bool operator!=(nullopt_t, const optional<T>& x) noexcept;
```
8  
Returns: \( true \).

```
template<class T> constexpr bool operator<=(nullopt_t, const optional<T>& x) noexcept;
```
9  
Returns: \( !x \).

```
template<class T> constexpr bool operator>=(nullopt_t, const optional<T>& x) noexcept;
```
10  Returns: \( !x \).

### 19.6.8 Comparison with T

```
template<class T, class U> constexpr bool operator==(const optional<T>& x, const U& v);
```
1  
Requires: The expression \( *x == v \) shall be well-formed and its result shall be convertible to bool.  
\[ \text{Note}: \text{T need not be Cpp17EqualityComparable. — end note} \]
Effects: Equivalent to: \( \text{return } bool(x) ? *x == v : false; \)

```
template<class T, class U> constexpr bool operator==(const T& v, const optional<U>& x);
```
2  
Requires: The expression \( v == *x \) shall be well-formed and its result shall be convertible to bool.  
Effects: Equivalent to: \( \text{return } bool(x) ? v == *x : false; \)

```
template<class T, class U> constexpr bool operator!=(const optional<T>& x, const U& v);
```
3  
Requires: The expression \( *x != v \) shall be well-formed and its result shall be convertible to bool.  
Effects: Equivalent to: \( \text{return } bool(x) ? *x != v : true; \)

```
template<class T, class U> constexpr bool operator!=(const T& v, const optional<U>& x);
```
4  
Requires: The expression \( v != *x \) shall be well-formed and its result shall be convertible to bool.  
Effects: Equivalent to: \( \text{return } bool(x) ? v != *x : true; \)
template<class T, class U> constexpr bool operator<(const optional<T> & x, const U & v);

Requires: The expression \( *x < v \) shall be well-formed and its result shall be convertible to bool.

Effects: Equivalent to: return bool(x) ? *x < v : true;

template<class T, class U> constexpr bool operator<(const T & v, const optional<U> & x);

Requires: The expression \( v < *x \) shall be well-formed and its result shall be convertible to bool.

Effects: Equivalent to: return bool(x) ? v < *x : false;

template<class T, class U> constexpr bool operator>(const optional<T> & x, const U & v);

Requires: The expression \( *x > v \) shall be well-formed and its result shall be convertible to bool.

Effects: Equivalent to: return bool(x) ? *x > v : false;

template<class T, class U> constexpr bool operator>(const T & v, const optional<U> & x);

Requires: The expression \( v > *x \) shall be well-formed and its result shall be convertible to bool.

Effects: Equivalent to: return bool(x) ? v > *x : true;

template<class T, class U> constexpr bool operator<=(const optional<T> & x, const U & v);

Requires: The expression \( *x <= v \) shall be well-formed and its result shall be convertible to bool.

Effects: Equivalent to: return bool(x) ? *x <= v : true;

template<class T, class U> constexpr bool operator<=(const T & v, const optional<U> & x);

Requires: The expression \( v <= *x \) shall be well-formed and its result shall be convertible to bool.

Effects: Equivalent to: return bool(x) ? v <= *x : false;

template<class T, class U> constexpr bool operator>=(const optional<T> & x, const U & v);

Requires: The expression \( *x >= v \) shall be well-formed and its result shall be convertible to bool.

Effects: Equivalent to: return bool(x) ? *x >= v : false;

template<class T, class U> constexpr bool operator>=(const T & v, const optional<U> & x);

Requires: The expression \( v >= *x \) shall be well-formed and its result shall be convertible to bool.

Effects: Equivalent to: return bool(x) ? v >= *x : true;

19.6.9 Specialized algorithms

[optional.specalg]

template<class T> void swap(optional<T>& x, optional<T>& y) noexcept(noexcept(x.swap(y)));

Effects: Calls x.swap(y).

Remarks: This function shall not participate in overload resolution unless is_move_constructible_v<T> is true and is_swappable_v<T> is true.

template<class T> constexpr optional<decay_t<T>> make_optional(T&& v);

Returns: optional<decay_t<T>>(std::forward<T>(v)).

template<class T, class... Args>
constexpr optional<T> make_optional(Args&&... args);

Effects: Equivalent to: return optional<T>(in_place, std::forward<Args>(args)...);

template<class T, class U, class... Args>
constexpr optional<T> make_optional(initializer_list<U> il, Args&&... args);

Effects: Equivalent to: return optional<T>(in_place, il, std::forward<Args>(args)...);

19.6.10 Hash support

[optional.hash]

template<class T> struct hash<optional<T>>;

The specialization hash<optional<T>> is enabled (19.14.16) if and only if hash<remove_const_t<T>> is enabled. When enabled, for an object o of type optional<T>, if bool(o) == true, then
hash<optional<T>>(o) shall evaluate to the same value as hash<remove_const_t<T>>(*o); otherwise it evaluates to an unspecified value. The member functions are not guaranteed to be noexcept.

19.7 Variants

19.7.1 In general

A variant object holds and manages the lifetime of a value. If the variant holds a value, that value’s type has to be one of the template argument types given to variant. These template arguments are called alternatives.

19.7.2 Header <variant> synopsis

namespace std {

    // 19.7.3, class template variant
    template<class... Types>
    class variant;

    // 19.7.4, variant helper classes
    template<class T> struct variant_size; // not defined
    template<class T> struct variant_size<const T>;
    template<class T> struct variant_size<volatile T>;
    template<class T> struct variant_size<const volatile T>;
    template<class T> inline constexpr size_t variant_size_v = variant_size<T>::value;
    template<class... Types>
    struct variant_size<variant<Types...>>;
    template<size_t I, class... Types>
    struct variant_alternative;
    // not defined
    template<size_t I, class T> struct variant_alternative<I, const T>;
    template<size_t I, class T> struct variant_alternative<I, volatile T>;
    template<size_t I, class T> struct variant_alternative<I, const volatile T>;
    template<size_t I, class T>
    using variant_alternative_t = typename variant_alternative<I, T>::type;
    template<size_t I, class... Types>
    struct variant_alternative<I, variant<Types...>>;
    inline constexpr size_t variant_npos = -1;

    // 19.7.5, value access
    template<class T, class... Types>
    constexpr bool holds_alternative(const variant<Types...>&) noexcept;
    template<size_t I, class... Types>
    constexpr variant_alternative_t<I, variant<Types...>>& get(variant<Types...>&);
    template<size_t I, class... Types>
    constexpr variant_alternative_t<I, variant<Types...>>&& get(variant<Types...>&&);
    template<size_t I, class... Types>
    constexpr const variant_alternative_t<I, variant<Types...>>& get(const variant<Types...>&);
    template<size_t I, class... Types>
    constexpr const variant_alternative_t<I, variant<Types...>>&& get(const variant<Types...>&&);
    template<class T, class... Types>
    constexpr T& get(variant<Types...>&);
    template<class T, class... Types>
    constexpr T&& get(variant<Types...>&&);
    template<class T, class... Types>
    constexpr const T& get(const variant<Types...>&);
    template<class T, class... Types>
    constexpr const T&& get(const variant<Types...>&&);

    template<size_t I, class... Types>
    constexpr add_pointer_t<variant_alternative_t<I, variant<Types...>>
    get_if(variant<Types...>*&) noexcept;

§ 19.7.2
template<
    size_t I, class... Types>
constexpr add_pointer_t<const variant_alternative_t<I, variant<Types...>>>
    get_if(const variant<Types...>*) noexcept;

template<class T, class... Types>
constexpr add_pointer_t<T>
    get_if(variant<Types...>*) noexcept;

template<class T, class... Types>
constexpr add_pointer_t<const T>
    get_if(const variant<Types...>*) noexcept;

// 19.7.6, relational operators

// 19.7.8, class monostate

// 19.7.9, monostate relational operators

// 19.7.10, specialized algorithms

// 19.7.11, class bad_variant_access

// 19.7.12, hash support

19.7.3 Class template variant

namespace std {
    template<class... Types>
    class variant {
    public:
        // 19.7.3.1, constructors
        constexpr variant() noexcept(see below);
        variant(const variant&);
        variant(variant&&) noexcept(see below);
    }
template<class T> constexpr variant(T&&) noexcept(see below);

template<class T, class... Args> constexpr explicit variant(in_place_type_t<T>, Args&&...);
template<class T, class U, class... Args> constexpr explicit variant(in_place_type_t<T>, initializer_list<U>, Args&&...);
template<size_t I, class... Args> constexpr explicit variant(in_place_index_t<I>, Args&&...);
template<size_t I, class U, class... Args> constexpr explicit variant(in_place_index_t<I>, initializer_list<U>, Args&&...);

// 19.7.3.2, destructor
~variant();

// 19.7.3.3, assignment
variant& operator=(const variant&);
variant& operator=(variant&&) noexcept(see below);
template<class T> variant& operator=(T&&) noexcept(see below);

// 19.7.3.4, modifiers
template<class T, class... Args>
  T& emplace(Args&&...);
template<class T, class U, class... Args>
  T& emplace(initializer_list<U>, Args&&...);
template<size_t I, class... Args>
  variant_alternative_t<I, variant<Types...>>& emplace(Args&&...);
template<size_t I, class U, class... Args>
  variant_alternative_t<I, variant<Types...>>& emplace(initializer_list<U>, Args&&...);

// 19.7.3.5, value status
constexpr bool valueless_by_exception() const noexcept;
constexpr size_t index() const noexcept;

// 19.7.3.6, swap
void swap(variant&) noexcept(see below);
overload resolution unless \texttt{is\_default\_constructible\_v\langle T_0 \rangle} is \texttt{true}. \textit{[Note: See also class monostate. —end note]}

\texttt{variant(const variant\& w);}  

\textit{Effects:} If \texttt{w} holds a value, initializes the \texttt{variant} to hold the same alternative as \texttt{w} and direct-initializes the contained value with \texttt{get\langle j\rangle(w)}, where \texttt{j} is \texttt{w.index()}. Otherwise, initializes the \texttt{variant} to not hold a value.

\textit{Throws:} Any exception thrown by direct-initializing any \texttt{T_i} for all \texttt{i}.

\textit{Remarks:} This constructor shall be defined as deleted unless \texttt{is\_copy\_constructible\_v\langle T_i \rangle} is \texttt{true} for all \texttt{i}.

\texttt{variant(variant\&\& w) noexcept(see below);}  

\textit{Effects:} If \texttt{w} holds a value, initializes the \texttt{variant} to hold the same alternative as \texttt{w} and direct-initializes the contained value with \texttt{get\langle j\rangle(std::move(w))}, where \texttt{j} is \texttt{w.index()}. Otherwise, initializes the \texttt{variant} to not hold a value.

\textit{Throws:} Any exception thrown by move-constructing any \texttt{T_i} for all \texttt{i}.

\textit{Remarks:} The expression inside \texttt{noexcept} is equivalent to the logical AND of \texttt{is\_nothrow\_move\_constructible\_v\langle T_i \rangle} for all \texttt{i}. This function shall not participate in overload resolution unless \texttt{is\_move\_constructible\_v\langle T_i \rangle} is \texttt{true} for all \texttt{i}.

\texttt{template<class T> constexpr variant(T\&\& t) noexcept(see below);}  

\textit{Let} \texttt{T_j} be a type that is determined as follows: build an imaginary function \texttt{FUN(T_i)} for each alternative type \texttt{T_i}. The overload \texttt{FUN(T_j)} selected by overload resolution for the expression \texttt{FUN(std::forward<T\langle T\rangle(t))} defines the alternative \texttt{T_j} which is the type of the contained value after construction.

\textit{Effects:} Initializes \*\texttt{this} to hold the alternative type \texttt{T_j} and direct-initializes the contained value as if direct-non-list-initializing it with \texttt{std::forward\langle T\rangle(t)}.

\textit{Ensures:} \texttt{holds\_alternative\langle T_j \rangle\langle \*this \rangle} is \texttt{true}.

\textit{Throws:} Any exception thrown by the initialization of the selected alternative \texttt{T_j}.

\textit{Remarks:} This function shall not participate in overload resolution unless

\begin{itemize}
  \item \texttt{sizeof...(Types)} is nonzero,
  \item \texttt{is\_same\_v\langle remove\_cvref\_t\langle T\rangle, variant\rangle} is \texttt{false},
  \item \texttt{remove\_cvref\_t\langle T\rangle} is neither a specialization of \texttt{in\_place\_type\_t} nor a specialization of \texttt{in\_place\_index\_t},
  \item \texttt{is\_constructible\_v\langle T_j, T \rangle} is \texttt{true}, and
  \item the expression \texttt{FUN(std::forward\langle T\rangle\langle t\rangle)} (with \texttt{FUN} being the above-mentioned set of imaginary functions) is well-formed.
\end{itemize}

\textit{[Note: variant<string, string> v("abc"); is ill-formed, as both alternative types have an equally viable constructor for the argument. —end note]}

The expression inside \texttt{noexcept} is equivalent to \texttt{is\_nothrow\_constructible\_v\langle T_j, T \rangle}. \texttt{T_j}'s selected constructor is a constexpr constructor, this constructor shall be a constexpr constructor.

\texttt{template<class T, class... Args> constexpr explicit variant(in\_place\_type\_t\langle T\rangle, Args\&\&... args);}  

\textit{Effects:} Initializes the contained value as if direct-non-list-initializing an object of type \texttt{T} with the arguments \texttt{std::forward\langle Args\rangle(args)\ldots}. \texttt{std::forward\langle Args\rangle(args)\ldots}.

\textit{Ensures:} \texttt{holds\_alternative\langle T\rangle\langle \*this \rangle} is \texttt{true}.

\textit{Throws:} Any exception thrown by calling the selected constructor of \texttt{T}.

\textit{Remarks:} This function shall not participate in overload resolution unless there is exactly one occurrence of \texttt{T} in \texttt{Types\ldots} and \texttt{is\_constructible\_v\langle T, Args\ldots \rangle} is \texttt{true}. If \texttt{T_j}'s selected constructor is a constexpr constructor, this constructor shall be a constexpr constructor.
template<class T, class U, class... Args>
constexpr explicit variant(in_place_type_t<T>, initializer_list<U> il, Args&&... args);

Effects: Initializes the contained value as if direct-non-list-initializing an object of type T with the
arguments il, std::forward<Args>(args)....

Ensures: holds_alternative<T>(*this) is true.

Throws: Any exception thrown by calling the selected constructor of T.

Remarks: This function shall not participate in overload resolution unless there is exactly one occurrence
of T in Types... and is_constructible_v<T, initializer_list<U>&, Args...> is true. If T's
selected constructor is a constexpr constructor, this constructor shall be a constexpr constructor.

template<size_t I, class... Args> constexpr explicit variant(in_place_index_t<I>, Args&&... args);

Effects: Initializes the contained value as if direct-non-list-initializing an object of type T_I with the
arguments std::forward<Args>(args)....

Ensures: index() is I.

Throws: Any exception thrown by calling the selected constructor of T_I.

Remarks: This function shall not participate in overload resolution unless
(30.1) I is less than sizeof...(Types) and
(30.2) is_constructible_v<T_I, Args...> is true.

If T_I's selected constructor is a constexpr constructor, this constructor shall be a constexpr constructor.

template<size_t I, class U, class... Args>
constexpr explicit variant(in_place_index_t<I>, initializer_list<U> il, Args&&... args);

Effects: Initializes the contained value as if direct-non-list-initializing an object of type T_I with the
arguments il, std::forward<Args>(args)....

Ensures: index() is I.

Remarks: This function shall not participate in overload resolution unless
(33.1) I is less than sizeof...(Types) and
(33.2) is_constructible_v<T_I, initializer_list<U>&, Args...> is true.

If T_I's selected constructor is a constexpr constructor, this constructor shall be a constexpr constructor.

19.7.3.2 Destructor [variant.dtor]

~variant();

Effects: If valueless_by_exception() is false, destroys the currently contained value.

Remarks: If is_trivially_destructible_v<T_I> is true for all T_i, then this destructor is trivial.

19.7.3.3 Assignment [variant.assign]

variant& operator=(const variant& rhs);

Let j be rhs.index().

Effects:
(2.1) If neither *this nor rhs holds a value, there is no effect.
(2.2) Otherwise, if *this holds a value but rhs does not, destroys the value contained in *this and
sets *this to not hold a value.
(2.3) Otherwise, if index() == j, assigns the value contained in rhs to the value contained in *this.
(2.4) Otherwise, if either is_nothrow_copy_constructible_v<T_I> is true or is_nothrow_move_con-
structible_v<T_I> is false, equivalent to emplace<j>(get<j>(rhs)).
(2.5) Otherwise, equivalent to operator=(variant(rhs)).

Returns: *this.

Ensures: index() == rhs.index().
Remarks: This operator shall be defined as deleted unless \texttt{is\_copy\_constructible\_v}\langle\text{T}\_i\rangle \&\& \texttt{is\_copy\_assignable\_v}\langle\text{T}\_i\rangle \text{ is true for all } i.

\texttt{variant\& operator=}(\texttt{variant\&& rhs}) noexcept(see below);

Let \( j \) be \( \text{rhs.index()} \).

Effects:

\begin{enumerate}[\item]
\item If neither \texttt{*this} nor \texttt{rhs} holds a value, there is no effect.
\item Otherwise, if \texttt{*this} holds a value but \texttt{rhs} does not, destroys the value contained in \texttt{*this} and sets \texttt{*this} to not hold a value.
\item Otherwise, if \texttt{index()} \( = j \), assigns \texttt{get\_\langle j \rangle(\texttt{std\_move(rhs)})} to the value contained in \texttt{*this}.
\item Otherwise, equivalent to \texttt{emplace\_\langle j \rangle(get\_\langle j \rangle(\texttt{std\_move(rhs)}))}.
\end{enumerate}

Returns: \texttt{*this}.

Remarks: This function shall not participate in overload resolution unless \texttt{is\_move\_constructible\_v}\langle\text{T}\_i\rangle \&\& \texttt{is\_move\_assignable\_v}\langle\text{T}\_i\rangle \text{ is true for all } i. The expression inside noexcept is equivalent to: \texttt{is\_nothrow\_move\_constructible\_v}\langle\text{T}\_i\rangle \&\& \texttt{is\_nothrow\_move\_assignable\_v}\langle\text{T}\_i\rangle \text{ for all } i.

\begin{enumerate}[\item]
\item If an exception is thrown during the call to \( \text{T}\_j \)'s move construction (with \( j \) being \texttt{rhs.index()}), the \texttt{variant} will hold no value.
\item If an exception is thrown during the call to \( \text{T}\_j \)'s move assignment, the state of the contained value is as defined by the exception safety guarantee of \( \text{T}\_j \)'s move assignment; \texttt{index()} will be \( j \).
\end{enumerate}

\texttt{template<class T> variant\& operator=(T\&\& t)} noexcept(see below);

Let \( T\_j \) be a type that is determined as follows: build an imaginary function \texttt{FUN}(\text{T}\_i) for each alternative type \text{T}\_i. The overload \texttt{FUN}(\text{T}\_i) selected by overload resolution for the expression \texttt{FUN(\texttt{std\_\forward<T>(t)})} defines the alternative \( \text{T}\_j \) which is the type of the contained value after assignment.

Effects:

\begin{enumerate}[\item]
\item If \texttt{*this} holds a \( \text{T}\_j \), assigns \texttt{\\forward<T>(t)} to the value contained in \texttt{*this}.
\item Otherwise, if \texttt{is\_nothrow\_constructible\_v}\langle\text{T}\_j\rangle \&\& \texttt{is\_nothrow\_move\_constructible\_v}\langle\text{T}\_j\rangle \text{ is true, equivalent to \texttt{emplace\_\langle j \rangle(\texttt{\\forward<T>(t))}}.}
\item Otherwise, equivalent to \texttt{operator=(\texttt{variant(\texttt{\forward<T>(t))}})}.
\end{enumerate}

Ensures: \texttt{holds\_alternative}\langle\text{T}\_j\rangle(*\texttt{this}) \text{ is true, with } \text{T}\_j \text{ selected by the imaginary function overload resolution described above.}

Returns: \texttt{*this}.

Remarks: This function shall not participate in overload resolution unless

\begin{enumerate}[\item]
\item \texttt{is\_same\_v<remove\_cvref\_t<\text{T}\_>, \text{variant>> is false,}
\item \texttt{is\_assignable\_v<\text{T}\_\&, \text{T}\_> \&\& \texttt{is\_constructible\_v}\langle\text{T}\_j\rangle \rightarrow \text{T} \text{ is true, and}
\texttt{is\_nothrow\_assignable\_v}\langle\text{T}\_\&, \text{T}\_> \&\& \texttt{is\_nothrow\_constructible\_v}\langle\text{T}\_\&, \text{T}\_> \text{ is true for all } i.
\item The \text{expression} \texttt{\\forward<T>(t)} (with \texttt{FUN} being the above-mentioned set of imaginary functions) is well-formed.
\end{enumerate}

[Note:

\texttt{variant<string, string> v;}
\texttt{v = "abc";} is ill-formed, as both alternative types have an equally viable constructor for the argument. — end note]

The expression inside noexcept is equivalent to:

\texttt{is\_nothrow\_assignable\_v}\langle\text{T}\_\&, \text{T}\_> \&\& \texttt{is\_nothrow\_constructible\_v}\langle\text{T}\_\&, \text{T}\_>

\begin{enumerate}[\item]
\item If an exception is thrown during the assignment of \texttt{\\forward<T>(t)} to the value contained in \texttt{*this}, the state of the contained value and \texttt{t} are as defined by the exception safety guarantee of the assignment expression; \texttt{valueless\_by\_exception()} will be \texttt{false}.
\item If an exception is thrown during the initialization of the contained value, the \texttt{variant} object might not hold a value.
\end{enumerate}
19.7.3.4 Modifiers

```cpp
template<class T, class... Args> T& emplace(Args&&... args);
```

Let \( I \) be the zero-based index of \( T \) in Types.

**Effects:** Equivalent to: return emplace\(<I\>(std::forward<Args>(args)...);

**Remarks:** This function shall not participate in overload resolution unless `is_constructible_v<T, Args...>` is true, and \( T \) occurs exactly once in Types.

```cpp
template<class T, class U, class... Args> T& emplace(initializer_list<U> il, Args&&... args);
```

Let \( I \) be the zero-based index of \( T \) in Types.

**Effects:** Equivalent to: return emplace\(<I\>(il, std::forward<Args>(args)...);

**Remarks:** This function shall not participate in overload resolution unless `is_constructible_v<T, initializer_list<U>&, Args...>` is true, and \( T \) occurs exactly once in Types.

```cpp
template<size_t I, class... Args> variant_alternative_t<I, variant<Types...>>& emplace(Args&&... args);
```

**Requires:** \( I < \text{sizeof...}(\text{Types}) \).

**Effects:** Destroys the currently contained value if `valueless_by_exception()` is false. Then initializes the contained value as if direct-non-list-initializing a value of type \( T_I \) with the arguments `std::forward<Args>(args)...`

**Ensures:** `index()` is \( I \).

**Returns:** A reference to the new contained value.

**Throws:** Any exception thrown during the initialization of the contained value.

**Remarks:** This function shall not participate in overload resolution unless `is_constructible_v<T_I, Args...>` is true. If an exception is thrown during the initialization of the contained value, the `variant` might not hold a value.

```cpp
template<size_t I, class U, class... Args> variant_alternative_t<I, variant<Types...>>& emplace(initializer_list<U> il, Args&&... args);
```

**Requires:** \( I < \text{sizeof...}(\text{Types}) \).

**Effects:** Destroys the currently contained value if `valueless_by_exception()` is false. Then initializes the contained value as if direct-non-list-initializing a value of type \( T_I \) with the arguments `il, std::forward<Args>(args)...`

**Ensures:** `index()` is \( I \).

**Returns:** A reference to the new contained value.

**Throws:** Any exception thrown during the initialization of the contained value.

**Remarks:** This function shall not participate in overload resolution unless `is_constructible_v<T_I, initializer_list<U>&, Args...>` is true. If an exception is thrown during the initialization of the contained value, the `variant` might not hold a value.

19.7.3.5 Value status

```cpp
constexpr bool valueless_by_exception() const noexcept;
```

**Effects:** Returns \( \text{false} \) if and only if the `variant` holds a value.

**Note:** A `variant` might not hold a value if an exception is thrown during a type-changing assignment or emplacement. The latter means that even a `variant<float, int>` can become `valueless_by_exception()`, for instance by

```cpp
struct S { operator int() { throw 42; };

variant<float, int> v(12.f);

v.emplace<1>(S());
```

— end note]
constexpr size_t index() const noexcept;

Effects: If `valueless_by_exception()` is true, returns `variant_npos`. Otherwise, returns the zero-based index of the alternative of the contained value.

19.7.3.6 Swap

void swap(variant& rhs) noexcept(see below);

Requires: Lvalues of type T₁ shall be swappable (15.5.3.2) and `is_move_constructible_v<T₁>` shall be true for all i.

Effects:

(2.1) — If `valueless_by_exception() && rhs.valueless_by_exception()` no effect.

(2.2) — Otherwise, if `index() == rhs.index()`, calls `swap(get<i>(*this), get<i>(rhs))` where i is `index()`.

(2.3) — Otherwise, exchanges values of rhs and *this.

Throws: If `index() == rhs.index()`, any exception thrown by `swap(get<i>(*this), get<i>(rhs))` with i being `index()`. Otherwise, any exception thrown by the move constructor of Tᵢ or Tⱼ with i being `index()` and j being `rhs.index()`.

Remarks: If an exception is thrown during the call to function `swap(get<i>(*this), get<i>(rhs))`, the states of the contained values of *this and of rhs are determined by the exception safety guarantee of swap for lvalues of Tᵢ with i being `index()`. If an exception is thrown during the exchange of the values of *this and rhs, the states of the values of *this and of rhs are determined by the exception safety guarantee of variant’s move constructor. The expression inside noexcept is equivalent to the logical AND of `is_nothrow_move_constructible_v<Tᵢ>` && `is_nothrow_swappable_v<Tᵢ>` for all i.

19.7.4 variant helper classes

template<class T> struct variant_size;

Remarks: All specializations of variant_size shall satisfy the Cpp17UnaryTypeTrait requirements (19.15.1) with a base characteristic of `integral_constant<size_t, N>` for some N.

template<class T> class variant_size<const T> ;
template<class T> class variant_size<volatile T> ;
template<class T> class variant_size<const volatile T> ;

Let VS denote `variant_size<T>` of the cv-unqualified type T. Then each of the three templates shall satisfy the Cpp17UnaryTypeTrait requirements (19.15.1) with a base characteristic of `integral_constant<size_t, VS::value>`.

template<class... Types>
struct variant_size<variant<Types...>> : integral_constant<size_t, sizeof...(Types)> { }; 

template<size_t I, class T> class variant_alternative< const I, T> ;
template<size_t I, class T> class variant_alternative< volatile I, T> ;
template<size_t I, class T> class variant_alternative< const volatile I, T> ;

Let VA denote `variant_alternative<I, T>` of the cv-unqualified type T. Then each of the three templates shall meet the Cpp17TransformationTrait requirements (19.15.1) with a member typedef type that names the following type:

(3.1) — for the first specialization, `add_const_t<VA::type>`,

(3.2) — for the second specialization, `add_volatile_t<VA::type>`, and

(3.3) — for the third specialization, `add_cv_t<VA::type>`.

variant_alternative<I, variant<Types...>>::type

Requires: I < sizeof...(Types). The program is ill-formed if I is out of bounds.

Value: The type Tᵢ.
19.7.5 Value access

```cpp
template<class T, class... Types>
constexpr bool holds_alternative(const variant<Types...>& v) noexcept;
```

1. Requires: The type T occurs exactly once in Types.... Otherwise, the program is ill-formed.
2. Returns: true if index() is equal to the zero-based index of T in Types....

```cpp
template<size_t I, class... Types>
constexpr variant_alternative_t<I, variant<Types...>>& get(variant<Types...>& v);
template<size_t I, class... Types>
constexpr variant_alternative_t<I, variant<Types...>>&& get(variant<Types...>&& v);
template<size_t I, class... Types>
constexpr const variant_alternative_t<I, variant<Types...>>& get(const variant<Types...>& v);
```

3. Requires: I < sizeof...(Types). Otherwise, the program is ill-formed.
4. Effects: If v.index() is I, returns a reference to the object stored in the variant. Otherwise, throws an exception of type bad_variant_access.

```cpp
template<class T, class... Types> constexpr T& get(variant<Types...>& v);
```

5. Requires: The type T occurs exactly once in Types.... Otherwise, the program is ill-formed.
6. Effects: If v holds a value of type T, returns a reference to that value. Otherwise, throws an exception of type bad_variant_access.

```cpp
template<class... Types> constexpr bool operator==(const variant<Types...>& v, const variant<Types...>& w);
```  

1. Requires: get<i>(v) == get<i>(w) is a valid expression returning a type that is convertible to bool, for all i.
2. Returns: If v.index() != w.index(), false; otherwise if v.valueless_by_exception(), true; otherwise get<i>(v) == get<i>(w) with i being v.index().

```cpp
template<class... Types> constexpr bool operator!=(const variant<Types...>& v, const variant<Types...>& w);
```  

3. Requires: get<i>(v) != get<i>(w) is a valid expression returning a type that is convertible to bool, for all i.

§ 19.7.6 Relational operators
Returns: If \( \text{v.index()} \neq \text{w.index()} \), \text{true}; otherwise if \( \text{v.valueless_by_exception()} \), \text{false}; otherwise \( \text{get}<i>(v) \neq \text{get}<i>(w) \) with \( i \) being \( \text{v.index()} \).

```cpp
template<class... Types>
constexpr bool operator<(const variant<Types...>& v, const variant<Types...>& w);
```

Requires: \( \text{get}<i>(v) < \text{get}<i>(w) \) is a valid expression returning a type that is convertible to \( \text{bool} \), for all \( i \).

Returns: If \( \text{v.valueless_by_exception()} \), \text{false}; otherwise if \( \text{v.valueless_by_exception()} \), \text{true}; otherwise if \( \text{v.index()} < \text{w.index()} \), \text{true}; otherwise if \( \text{v.index()} > \text{w.index()} \), \text{false}; otherwise \( \text{get}<i>(v) < \text{get}<i>(w) \) with \( i \) being \( \text{v.index()} \).

```cpp
template<class... Types>
constexpr bool operator>= (const variant<Types...>& v, const variant<Types...>& w);
```

Requires: \( \text{get}<i>(v) >= \text{get}<i>(w) \) is a valid expression returning a type that is convertible to \( \text{bool} \), for all \( i \).

Returns: If \( \text{v.valueless_by_exception()} \), \text{true}; otherwise if \( \text{v.valueless_by_exception()} \), \text{false}; otherwise if \( \text{v.index()} < \text{w.index()} \), \text{true}; otherwise if \( \text{v.index()} > \text{w.index()} \), \text{false}; otherwise \( \text{get}<i>(v) >= \text{get}<i>(w) \) with \( i \) being \( \text{v.index()} \).

```cpp
template<class... Types>
constexpr bool operator>(const variant<Types...>& v, const variant<Types...>& w);
```

Requires: \( \text{get}<i>(v) > \text{get}<i>(w) \) is a valid expression returning a type that is convertible to \( \text{bool} \), for all \( i \).

Returns: If \( \text{v.valueless_by_exception()} \), \text{true}; otherwise if \( \text{v.valueless_by_exception()} \), \text{false}; otherwise if \( \text{v.index()} > \text{w.index()} \), \text{true}; otherwise if \( \text{v.index()} < \text{w.index()} \), \text{false}; otherwise \( \text{get}<i>(v) > \text{get}<i>(w) \) with \( i \) being \( \text{v.index()} \).

```cpp
template<class... Types>
constexpr bool operator<= (const variant<Types...>& v, const variant<Types...>& w);
```

Requires: \( \text{get}<i>(v) <= \text{get}<i>(w) \) is a valid expression returning a type that is convertible to \( \text{bool} \), for all \( i \).

Returns: If \( \text{v.valueless_by_exception()} \), \text{true}; otherwise if \( \text{v.valueless_by_exception()} \), \text{false}; otherwise if \( \text{v.index()} > \text{w.index()} \), \text{true}; otherwise if \( \text{v.index()} < \text{w.index()} \), \text{false}; otherwise \( \text{get}<i>(v) <= \text{get}<i>(w) \) with \( i \) being \( \text{v.index()} \).

### 19.7.7 Visitation

#### [variant.visit]

```cpp
template<class Visitor, class... Variants>
constexpr see below visit(Visitor&& vis, Variants&&... vars);
```

Let \( n \) be \( \text{sizeof}(...(\text{Variants})) \). Let \( m \) be a pack of \( n \) values of type \( \text{size_t} \). Such a pack is called valid if \( 0 \leq m_i < \text{variant.size<remove_reference_t<\text{Variants>}} \) for all \( 0 \leq i < n \). For each valid pack \( m \), let \( e(m) \) denote the expression:

```
INVoke(std::forward<Visitor>(vis), get<m>(std::forward<variant<Types...>>(vars))...)
```

Returns: For each valid pack \( m \), \( e(m) \) shall be a valid expression. All such expressions shall be of the same type and value category; otherwise, the program is ill-formed.

Returns: \( e(m) \), where \( m \) is the pack for which \( m_i \) is \( \text{vars}_{i}.\text{index()} \) for all \( 0 \leq i < n \). The return type is \( \text{decltype}(e(m)) \).

Throws: \( \text{bad_variant_access} \) if any \( \text{variant} \) in \( \text{vars} \) is \( \text{valueless_by_exception}() \).

Complexity: For \( n \leq 1 \), the invocation of the callable object is implemented in constant time, i.e., for \( n = 1 \), it does not depend on the number of alternative types of \( \text{Variants}_0 \). For \( n > 1 \), the invocation of the callable object has no complexity requirements.
19.7.8 Class monostate

struct monostate{}

The class monostate can serve as a first alternative type for a variant to make the variant type default constructible.

19.7.9 monostate relational operators

constexpr bool operator==(monostate, monostate) noexcept { return true; }
customexpr bool operator!=(monostate, monostate) noexcept { return false; }
customexpr bool operator<(monostate, monostate) noexcept { return false; }
customexpr bool operator>(monostate, monostate) noexcept { return false; }
customexpr bool operator<=(monostate, monostate) noexcept { return true; }
customexpr bool operator>=(monostate, monostate) noexcept { return true; }

[Note: monostate objects have only a single state; they thus always compare equal. — end note]

19.7.10 Specialized algorithms

template<class... Types>
void swap(variant<Types...>& v, variant<Types...>& w) noexcept(see below);

Effects: Equivalent to v.swap(w).

Remarks: This function shall not participate in overload resolution unless is_move_constructible_v<T_i> && is_swappable_v<T_i> is true for all i. The expression inside noexcept is equivalent to noexcept(v.swap(w)).

19.7.11 Class bad_variant_access

class bad_variant_access : public exception {
public:
    bad_variant_access() noexcept;
    const char* what() const noexcept override;
};

Objects of type bad_variant_access are thrown to report invalid accesses to the value of a variant object.

bad_variant_access() noexcept;

Constructs a bad_variant_access object.

const char* what() const noexcept override;

Returns: An implementation-defined ntbs.

19.7.12 Hash support

template<class... Types> struct hash<variant<Types...>>;

The specialization hash<variant<Types...>> is enabled (19.14.16) if and only if every specialization in hash<remove_const<Types>>... is enabled. The member functions are not guaranteed to be noexcept.

template<> struct hash<monostate>

The specialization is enabled (19.14.16).

19.8 Storage for any type

This subclause describes components that C++ programs may use to perform operations on objects of a discriminated type.

[Note: The discriminated type may contain values of different types but does not attempt conversion between them, i.e., 5 is held strictly as an int and is not implicitly convertible either to "5" or to 5.0. This indifference to interpretation but awareness of type effectively allows safe, generic containers of single values, with no scope for surprises from ambiguous conversions. — end note]
19.8.1 Header <any> synopsis

namespace std {
  // 19.8.2, class bad_any_cast
  class bad_any_cast;
  
  // 19.8.3, class any
  class any;
  
  // 19.8.4, non-member functions
  void swap(any& x, any& y) noexcept;
  
  template<class T, class... Args>
  any make_any(Args&& ...args);
  template<class T, class U, class... Args>
  any make_any(initializer_list<U> il, Args&& ...args);
  template<class T>
  T any_cast(const any& operand);
  template<class T>
  T any_cast(any&& operand);
  template<class T>
  const T* any_cast(const any* operand) noexcept;
  template<class T>
  T* any_cast(any* operand) noexcept;
}

19.8.2 Class bad_any_cast

class bad_any_cast : public bad_cast {
public:
  const char* what() const noexcept override;
};

1 Objects of type bad_any_cast are thrown by a failed any_cast (19.8.4).

const char* what() const noexcept override;

2 Returns: An implementation-defined ntbs.

3 Remarks: The message may be a null-terminated multibyte string (15.4.2.1.5.2), suitable for conversion and display as a wstring (20.3, 26.4.1.4).

19.8.3 Class any

namespace std {
  class any {
public:
  // 19.8.3.1, construction and destruction
  constexpr any() noexcept;
  any(const any& other);
  any(any&& other) noexcept;
  
  template<class T>
  any(T& value);
  template<class T, class... Args>
  explicit any(in_place_type_t<T>, Args&&...);
  template<class T, class U, class... Args>
  explicit any(in_place_type_t<T>, initializer_list<U>, Args&&...);
  ~any();
};
1 An object of class `any` stores an instance of any type that satisfies the constructor requirements or it has no value, and this is referred to as the state of the class `any` object. The stored instance is called the contained value. Two states are equivalent if either they both have no value, or both have a value and the contained values are equivalent.

2 The non-member `any_cast` functions provide type-safe access to the contained value.

3 Implementations should avoid the use of dynamically allocated memory for a small contained value. However, any such small-object optimization shall only be applied to types `T` for which `is_nothrow_move_constructible_v<T>` is true. [Example: A contained value of type `int` could be stored in an internal buffer, not in separately-allocated memory. — end example]

### 19.8.3.1 Construction and destruction

```cpp
class any {
    // 19.8.3.1, construction
    constexpr any() noexcept;
    any(const any& other);
    any(any&& other) noexcept;
    template<class T> any(T&& value);
};
```  

1 `Ensures: has_value()` is false.

2 `Effects: If other.has_value() is false, constructs an object that has no value. Otherwise, equivalent to any(in_place_type<T>, any_cast<const T&>(other))` where `T` is the type of the contained value.

3 `Throws: Any exceptions arising from calling the selected constructor for the contained value.`

4 `Effects: If other.has_value() is false, constructs an object that has no value. Otherwise, constructs an object of type `any` that contains either the contained value of `other`, or contains an object of the same type constructed from the contained value of `other` considering that contained value as an rvalue.

5 `Ensures: other is left in a valid but otherwise unspecified state.`

6 `Let VT be decay_t<T>.

7 `Requires: VT shall satisfy the Cpp17CopyConstructible requirements.

8 `Effects: Constructs an object of type `any` that contains an object of type `VT` direct-initialized with std::forward<T>(value).

9 `Remarks: This constructor shall not participate in overload resolution unless VT is not the same type as any, VT is not a specialization of in_place_type_t, and is_copy_constructible_v<VT> is true.`

10 `Throws: Any exception thrown by the selected constructor of VT.`
template<class T, class... Args>
explicit any(in_place_type_t<T>, Args&&... args);

Let VT be decay_t<T>.

Requires: VT shall satisfy the Cpp17CopyConstructible requirements.

Effects: Initializes the contained value as if direct-non-list-initializing an object of type VT with the
arguments std::forward<Args>(args)....

Ensures: *this contains a value of type VT.

Remarks: This constructor shall not participate in overload resolution unless is_copy_constructible_v<VT> is true and is_constructible_v<VT, Args...> is true.

template<class T, class U, class... Args>
explicit any(in_place_type_t<T>, initializer_list<U> il, Args&&... args);

Let VT be decay_t<T>.

Requires: VT shall satisfy the Cpp17CopyConstructible requirements.

Effects: Initializes the contained value as if direct-non-list-initializing an object of type VT with the
arguments il, std::forward<Args>(args)....

Ensures: *this contains a value.

Remarks: This constructor shall not participate in overload resolution unless is_copy_constructible_v<VT> is true and is_constructible_v<VT, initializer_list<U>&, Args...> is true.

~any();

Effects: As if by reset().

19.8.3.2 Assignment

any& operator=(const any& rhs);

Effects: As if by any(rhs).swap(*this). No effects if an exception is thrown.

Returns: *this.

Throws: Any exceptions arising from the copy constructor for the contained value.

any& operator=(any&& rhs) noexcept;

Effects: As if by any(std::move(rhs)).swap(*this).

Returns: *this.

Ensures: The state of *this is equivalent to the original state of rhs and rhs is left in a valid but
otherwise unspecified state.

template<class T>
any& operator=(T&& rhs);

Let VT be decay_t<T>.

Requires: VT shall satisfy the Cpp17CopyConstructible requirements.

Effects: Constructs an object tmp of type any that contains an object of type VT direct-initialized with
std::forward<T>(rhs), and tmp.swap(*this). No effects if an exception is thrown.

Returns: *this.

Remarks: This operator shall not participate in overload resolution unless VT is not the same type as
any and is_copy_constructible_v<VT> is true.

Throws: Any exception thrown by the selected constructor of VT.

19.8.3.3 Modifiers
`decay_t<T>& emplace(Args&&... args);`

Let VT be `decay_t<T>`.  

Requires: VT shall satisfy the `Cpp17CopyConstructible` requirements.  

Effects: Calls `reset()`. Then initializes the contained value as if direct-non-list-initializing an object of type VT with the arguments `std::forward<Args>(args)`....  

Ensures: `*this` contains a value.  

Returns: A reference to the new contained value.  

Throws: Any exception thrown by the selected constructor of VT.  

Remarks: If an exception is thrown during the call to VT’s constructor, `*this` does not contain a value, and any previously contained value has been destroyed. This function shall not participate in overload resolution unless `is_copy_constructible_v<VT>` is true and `is_constructible_v<VT, Args...>` is true.

```cpp
template<class T, class U, class... Args>
decay_t<T>& emplace(initializer_list<U> il, Args&&... args);
```

Let VT be `decay_t<T>`.  

Requires: VT shall satisfy the `Cpp17CopyConstructible` requirements.  

Effects: Calls `reset()`. Then initializes the contained value as if direct-non-list-initializing an object of type VT with the arguments `il, std::forward<Args>(args)`....  

Ensures: `*this` contains a value.  

Returns: A reference to the new contained value.  

Throws: Any exception thrown by the selected constructor of VT.  

Remarks: If an exception is thrown during the call to VT’s constructor, `*this` does not contain a value, and any previously contained value has been destroyed. The function shall not participate in overload resolution unless `is_copy_constructible_v<VT>` is true and `is_constructible_v<VT, initializer_list<U>&, Args...>` is true.

```cpp
void reset() noexcept;
```

Effects: If `has_value()` is true, destroys the contained value.  

Ensures: `has_value()` is false.

```cpp
void swap(any& rhs) noexcept;
```

Effects: Exchanges the states of `*this` and rhs.

### 19.8.3.4 Observers

`bool has_value() const noexcept;`

Returns: true if `*this` contains an object, otherwise false.

```cpp
const type_info& type() const noexcept;
```

Returns: `typeid(T)` if `*this` has a contained value of type T, otherwise `typeid(void)`.

[Note: Useful for querying against types known either at compile time or only at runtime. — end note]

### 19.8.4 Non-member functions

`void swap(any& x, any& y) noexcept;`

Effects: As if by `x.swap(y)`.

```cpp
template<class T, class... Args>
any make_any(Args&& ...args);
```

Effects: Equivalent to: `return any(in_place_type<T>, std::forward<Args>(args)...);`
template<class T, class U, class... Args>
any make_any(initializer_list<U> il, Args&& ...args);

Effects: Equivalent to: return any(in_place_type<T>, il, std::forward<Args>(args)...);

template<class T>
T any_cast(const any& operand);

template<class T>
T any_cast(any& operand);

template<class T>
T any_cast(any&& operand);

Let U be the type remove_cvref_v<T>.

Requires: For the first overload, is_constructible_v<T, const U&> is true. For the second overload, is_constructible_v<T, U&> is true. For the third overload, is_constructible_v<T, U> is true. Otherwise the program is ill-formed.

Returns: For the first and second overload, static_cast<T>(*any_cast<U>(&operand)). For the third overload, static_cast<T>(std::move(*any_cast<U>(&operand))).

Throws: bad_any_cast if operand.type() != typeid(remove_reference_t<T>).

[Example:

```cpp
template<class T>
const T* any_cast(const any* operand) noexcept;

T* any_cast(any* operand) noexcept;

Returns: If operand != nullptr & operand->type() == typeid(T), a pointer to the object contained by operand; otherwise, nullptr.

[Example:

```cpp
bool is_string(const any& operand) {
  return any_cast<std::string>(operand) != nullptr;
}

— end example]

19.9 Bitsets

19.9.1 Header <bitset> synopsis

#include <string>

§ 19.9.1 562
The header `<bitset>` defines a class template and several related functions for representing and manipulating fixed-size sequences of bits.

### 19.9.2 Class template `bitset`

```cpp
namespace std {
    template<size_t N> class bitset {
        public:
            // bit reference
            class reference {
                friend class bitset;
                reference() noexcept;
                reference(const reference&) = default;
                ~reference();
                reference& operator=(bool x) noexcept; // for b[i] = x;
                reference& operator=(const reference&) noexcept; // for b[i] = b[j];
                bool operator~() const noexcept; // flips the bit
                operator bool() const noexcept; // for x = b[i];
                reference& flip() noexcept; // for b[i].flip();
            };

        // 19.9.2.1, constructors
        constexpr bitset() noexcept;
        constexpr bitset(unsigned long long val) noexcept;
        template<class charT, class traits, class Allocator>
        explicit bitset(
            const basic_string<charT, traits, Allocator>& str,
            typename basic_string<charT, traits, Allocator>::size_type pos = 0,
            typename basic_string<charT, traits, Allocator>::size_type n = basic_string<charT, traits, Allocator>::npos,
            charT zero = charT('0'),
            charT one = charT('1'));
        template<class charT>
        explicit bitset(
            const charT* str,
            typename basic_string<charT>::size_type n = basic_string<charT>::npos,
            charT zero = charT('0'),
            charT one = charT('1'));

        // 19.9.2.2, bitset operations
        bitset<N>& operator&=(const bitset<N>& rhs) noexcept;
        bitset<N>& operator|=(const bitset<N>& rhs) noexcept;
        bitset<N>& operator^=(const bitset<N>& rhs) noexcept;
    }
}
```
The class template `bitset<N>` describes an object that can store a sequence consisting of a fixed number of bits, N.

Each bit represents either the value zero (reset) or one (set). To **toggle** a bit is to change the value zero to one, or the value one to zero. Each bit has a non-negative position `pos`. When converting between an object of class `bitset<N>` and a value of some integral type, bit position `pos` corresponds to the bit value `1 << pos`. The integral value corresponding to two or more bits is the sum of their bit values.

The functions described in this subclause can report three kinds of errors, each associated with a distinct exception:

1. **Invalid argument** error is associated with exceptions of type `invalid_argument` (18.2.4);
2. **Out of range** error is associated with exceptions of type `out_of_range` (18.2.6);
3. **Overflow** error is associated with exceptions of type `overflow_error` (18.2.9).

### 19.9.2.1 `bitset` Constructors

**Constexpr** `bitset()` noexcept;

**Effects**: Constructs an object of class `bitset<N>`, initializing all bits to zero.

**Constexpr** `bitset(unsigned long long val)` noexcept;

**Effects**: Constructs an object of class `bitset<N>`, initializing the first M bit positions to the corresponding bit values in val. M is the smaller of N and the number of bits in the value representation (6.7) of `unsigned long long`. If M < N, the remaining bit positions are initialized to zero.
template<class charT, class traits, class Allocator>
explicit bitset(
    const basic_string<charT, traits, Allocator>& str,
    typename basic_string<charT, traits, Allocator>::size_type pos = 0,
    typename basic_string<charT, traits, Allocator>::size_type n = basic_string<charT, traits, Allocator>::npos,
    charT zero = charT('0'),
    charT one = charT('1'));

3 
**Throws:** out_of_range if pos > str.size() or invalid_argument if an invalid character is found (see below).

4 
**Effects:** Determines the effective length rlen of the initializing string as the smaller of n and str.size() - pos.

The function then throws invalid_argument if any of the rlen characters in str beginning at position pos is other than zero or one. The function uses traits::eq() to compare the character values.

Otherwise, the function constructs an object of class bitset<N>, initializing the first M bit positions to values determined from the corresponding characters in the string str. M is the smaller of N and rlen.

An element of the constructed object has value zero if the corresponding character in str, beginning at position pos, is zero. Otherwise, the element has the value one. Character position pos + M - 1 corresponds to bit position zero. Subsequent decreasing character positions correspond to increasing bit positions.

5 
If M < N, remaining bit positions are initialized to zero.

template<class charT>
explicit bitset(
    const charT* str,
    typename basic_string<charT>::size_type n = basic_string<charT>::npos,
    charT zero = charT('0'),
    charT one = charT('1'));

7 
**Effects:** Constructs an object of class bitset<N> as if by:

\[
\text{bitset}(n == \text{basic_string<charT>::npos} \Rightarrow \text{basic_string<charT>(str)} \text{, n, zero, one})
\]

19.9.2.2 bitset members

[bitset.members]

bitset<N>& operator&=(const bitset<N>& rhs) noexcept;

1 
**Effects:** Clears each bit in *this for which the corresponding bit in rhs is clear, and leaves all other bits unchanged.

2 
**Returns:** *this.

bitset<N>& operator|=(const bitset<N>& rhs) noexcept;

3 
**Effects:** Sets each bit in *this for which the corresponding bit in rhs is set, and leaves all other bits unchanged.

4 
**Returns:** *this.

bitset<N>& operator^=(const bitset<N>& rhs) noexcept;

5 
**Effects:** Toggles each bit in *this for which the corresponding bit in rhs is set, and leaves all other bits unchanged.

6 
**Returns:** *this.

bitset<N>& operator<<(size_t pos) noexcept;

7 
**Effects:** Replaces each bit at position I in *this with a value determined as follows:

(7.1) If I < pos, the new value is zero;

(7.2) If I >= pos, the new value is the previous value of the bit at position I - pos.

8 
**Returns:** *this.
```cpp
bitset<N>& operator>>=(size_t pos) noexcept;

Effects: Replaces each bit at position \( I \) in \*this with a value determined as follows:

- If \( pos \geq N - I \), the new value is zero;
- If \( pos < N - I \), the new value is the previous value of the bit at position \( I + pos \).

Returns: \*this.

bitset<N>& set() noexcept;

Effects: Sets all bits in \*this.

Returns: \*this.

bitset<N>& set(size_t pos, bool val = true);

Throws: out_of_range if \( pos \) does not correspond to a valid bit position.

Effects: Stores a new value in the bit at position \( pos \) in \*this. If \( val \) is true, the stored value is one, otherwise it is zero.

Returns: \*this.

bitset<N>& reset() noexcept;

Effects: Resets all bits in \*this.

Returns: \*this.

bitset<N>& reset(size_t pos);

Throws: out_of_range if \( pos \) does not correspond to a valid bit position.

Effects: Resets the bit at position \( pos \) in \*this.

Returns: \*this.

bitset<N> operator~() const noexcept;

Effects: Constructs an object \( x \) of class bitset<N> and initializes it with \*this.

Returns: \( x.flip() \).

bitset<N>& flip() noexcept;

Effects: Toggles all bits in \*this.

Returns: \*this.

bitset<N>& flip(size_t pos);

Throws: out_of_range if \( pos \) does not correspond to a valid bit position.

Effects: Toggles the bit at position \( pos \) in \*this.

Returns: \*this.

unsigned long to_ulong() const;

Throws: overflow_error if the integral value \( x \) corresponding to the bits in \*this cannot be represented as type unsigned long.

Returns: \( x \).

unsigned long long to_ullong() const;

Throws: overflow_error if the integral value \( x \) corresponding to the bits in \*this cannot be represented as type unsigned long long.

Returns: \( x \).

template<class charT = char,
     class traits = char_traits<charT>,
     class Allocator = allocator<charT>>
basic_string<charT, traits, Allocator>
```
to_string(charT zero = charT('0'), charT one = charT('1')) const;

Effects: Constructs a string object of the appropriate type and initializes it to a string of length
N characters. Each character is determined by the value of its corresponding bit position in *this.
Character position N - 1 corresponds to bit position zero. Subsequent decreasing character positions
 correspond to increasing bit positions. Bit value zero becomes the character zero, bit value one becomes
the character one.

Returns: The created object.

size_t count() const noexcept;

Returns: A count of the number of bits set in *this.

constexpr size_t size() const noexcept;

Returns: N.

bool operator==(const bitset<N>& rhs) const noexcept;

Returns: true if the value of each bit in *this equals the value of the corresponding bit in rhs.

bool operator!=(const bitset<N>& rhs) const noexcept;

Returns: true if !(this == rhs).

bool test(size_t pos) const;

Throws: out_of_range if pos does not correspond to a valid bit position.

Returns: true if the bit at position pos in *this has the value one.

bool all() const noexcept;

Returns: count() == size().

bool any() const noexcept;

Returns: count() != 0.

bool none() const noexcept;

Returns: count() == 0.

bitset<N> operator<<(size_t pos) const noexcept;

Returns: bitset<N>(*this) <<= pos.

bitset<N> operator>>(size_t pos) const noexcept;

Returns: bitset<N>(*this) >>= pos.

constexpr bool operator[](size_t pos) const;

Requires: pos shall be valid.

Returns: true if the bit at position pos in *this has the value one, otherwise false.

Throws: Nothing.

bitset<N>::reference operator[](size_t pos);

Requires: pos shall be valid.

Returns: An object of type bitset<N>::reference such that (*this)[pos] == this->test(pos),
and such that (*this)[pos] = val is equivalent to this->set(pos, val).

Throws: Nothing.

Remarks: For the purpose of determining the presence of a data race (6.8.2), any access or update
through the resulting reference potentially accesses or modifies, respectively, the entire underlying
bitset.
19.9.3 bitset hash support

\[ \text{template} \langle \text{size}_t \ N \rangle \ \text{struct} \ \text{hash} \langle \text{bitset} \langle N \rangle \rangle; \]

1 The specialization is enabled (19.14.16).

19.9.4 bitset operators

\[ \text{bitset} \langle N \rangle \ \text{operator} \&\text{(const bitset} \langle N \rangle \& \ \text{lhs}, \ \text{const bitset} \langle N \rangle \& \ \text{rhs}) \ \text{noexcept}; \]

1 \text{Returns: bitset} \langle N \rangle \langle \text{lhs} \rangle \ &= \ \text{rhs}. \]

\[ \text{bitset} \langle N \rangle \ \text{operator} \text{\mid}(\text{const bitset} \langle N \rangle \& \ \text{lhs}, \ \text{const bitset} \langle N \rangle \& \ \text{rhs}) \ \text{noexcept}; \]

2 \text{Returns: bitset} \langle N \rangle \langle \text{lhs} \rangle \text{\mid} \text{rhs}. \]

\[ \text{bitset} \langle N \rangle \ \text{operator}\text{\^{}(const bitset} \langle N \rangle \& \ \text{lhs}, \ \text{const bitset} \langle N \rangle \& \ \text{rhs}) \ \text{noexcept}; \]

3 \text{Returns: bitset} \langle N \rangle \langle \text{lhs} \rangle \text{\^{}rhs}. \]

\[ \text{template<class charT, class traits, size_t} \ N \rangle \]

1 \text{basic\_istream} \langle \text{charT, traits} \rangle \&

1 \text{operator} \text{\rangle\rangle}(\text{basic\_istream} \langle \text{charT, traits} \rangle \& \ \text{is}, \ \text{bitset} \langle N \rangle \& \ \text{x}); \]

4 A formatted input function (27.7.4.2).

5 \text{Effects: Extracts up to} \ N \ \text{characters from} \ \text{is}. \ \text{Stores these characters in a temporary object} \ \text{str} \ \text{of type}

5 \text{basic\_string} \langle \text{charT, traits} \rangle, \ \text{then evaluates the expression} \ \text{x} = \ \text{bitset} \langle N \rangle \langle \text{str} \rangle. \ \text{Characters are}

5 \ \text{extracted and stored until any of the following occurs:}

5 \text{(5.1)} \quad \text{—} \ N \ \text{characters have been extracted and stored;}

5 \text{(5.2)} \quad \text{—} \ \text{end\_of\_file occurs on the input sequence;}

5 \text{(5.3)} \quad \text{—} \ \text{the next input character is neither} \ \text{is\_widen}(\text{\^{}0\^{'}}) \ \text{nor} \ \text{is\_widen}(\text{\^{}1\^{'}}) \ \text{(in which case the input}

5 \text{character is not extracted).}

6 \text{If no characters are stored in} \ \text{str}, \ \text{calls} \ \text{is\_setstate(isos\_base::failbit)} \ \text{(which may throw} \ \text{ios\_base::failure} \ \text{(27.5.5.4))}.

7 \text{Returns: is}. \]

\[ \text{template<class charT, class traits, size_t} \ N \rangle \]

1 \text{basic\_ostream} \langle \text{charT, traits} \rangle \&

1 \text{operator} \text{\rangle\rangle}(\text{basic\_ostream} \langle \text{charT, traits} \rangle \& \ \text{os}, \ \text{const bitset} \langle N \rangle \& \ \text{x}); \]

8 \text{Returns:}

8 \text{os} \text{\langle\langle} \ \text{x.template to\_string} \langle \text{charT, traits, allocator} \langle \text{charT} \rangle \rangle(\text{use\_facet\_\text{\langle\text{ctype} \langle \text{charT} \rangle\rangle(is.getloc());\text{widen}(\text{\^{}0\^{'}}),}

8 \text{use\_facet\_\text{\langle\text{ctype} \langle \text{charT} \rangle\rangle(is.getloc());\text{widen}(\text{\^{}1\^{'}}})

8 \text{(see} \ \text{27.7.5.2)}. \]

19.10 Memory

19.10.1 In general

1 This subclause describes the contents of the header \langle memory \rangle (19.10.2) and some of the contents of the header \langle cstdlib \rangle (16.2.2).

19.10.2 Header \langle memory \rangle synopsis

1 The header \langle memory \rangle defines several types and function templates that describe properties of pointers and pointer-like types, manage memory for containers and other template types, destroy objects, and construct multiple objects in uninitialized memory buffers (19.10.3–19.10.11). The header also defines the templates unique\_ptr, shared\_ptr, weak\_ptr, and various function templates that operate on objects of these types (19.11).

\[ \text{namespace} \ \text{std} \{ \]

1 // 19.10.3, pointer traits

template<class T, class U>
    shared_ptr<T> reinterpret_pointer_cast(const shared_ptr<U>& r) noexcept;
19.10.3 Pointer traits

The class template `pointer_traits` supplies a uniform interface to certain attributes of pointer-like types.

```cpp
namespace std {
    template<class Ptr> struct pointer_traits {
        using pointer = Ptr;
        using element_type = see below;
        using difference_type = see below;
        template<class U> using rebind = see below;

        static pointer pointer_to(see below r);
    };

    template<class T> struct pointer_traits<T*> {
        using pointer = T*;
        using element_type = T;
        using difference_type = ptdiff_t;
        template<class U> using rebind = U*;

        static pointer pointer_to(see below r) noexcept;
    };
}
```

19.10.3.1 Pointer traits member types

```cpp
using element_type = see below;
```

Type: `Ptr::element_type` if the qualified-id `Ptr::element_type` is valid and denotes a type (12.9.2); otherwise, `T` if `Ptr` is a class template instantiation of the form `SomePointer<T, Args>`, where `Args` is
zero or more type arguments; otherwise, the specialization is ill-formed.

using difference_type = see below;

Type: 

template<class U> using rebind = see below;

Alias template: 

Remarks:

Specializations of pointer_traits may define the member declared in this subclause to customize the behavior of the standard library.

Returns: A pointer of type element_type* that references the same location as the argument p.

[Note: This function should be the inverse of pointer_to. If defined, it customizes the behavior of the non-member function to_address (19.10.4). — end note]

Returns: pointer_traits<Ptr>::to_address(p) if that expression is well-formed (see 19.10.3.3), otherwise to_address(p.operator->()).

Requires: T is not a function type. Otherwise the program is ill-formed.

Returns: p.

A complete object is declared reachable while the number of calls to declare_reachable with an argument referencing the object exceeds the number of calls to undeclare_reachable with an argument referencing the object.

void declare_reachable(void* p);

Requires: p shall be a safely-derived pointer (6.6.4.4.3) or a null pointer value.

Effects: If p is not null, the complete object referenced by p is subsequently declared reachable (6.6.4.4.3).

Throws: May throw bad_alloc if the system cannot allocate additional memory that may be required to track objects declared reachable.

template<class T> T* undeclare_reachable(T* p);

Requires: If p is not null, the complete object referenced by p shall have been previously declared reachable, and shall be live (6.6.3) from the time of the call until the last undeclare_reachable(p) call on the object.

Returns: A safely derived copy of p which shall compare equal to p.

Throws: Nothing.
void declare_no_pointers(char* p, size_t n);

Requires: No bytes in the specified range are currently registered with `declare_no_pointers()`. If the specified range is in an allocated object, then it shall be entirely within a single allocated object. The object shall be live until the corresponding `undeclare_no_pointers()` call. [Note: In a garbage-collecting implementation, the fact that a region in an object is registered with `declare_no_pointers()` should not prevent the object from being collected. — end note]

Effects: The n bytes starting at p no longer contain traceable pointer locations, independent of their type. Hence indirection through a pointer located there is undefined if the object it points to was created by global `operator new` and not previously declared reachable. [Note: This may be used to inform a garbage collector or leak detector that this region of memory need not be traced. — end note]

Throws: Nothing.

void undeclare_no_pointers(char* p, size_t n);

Requires: The same range shall previously have been passed to `declare_no_pointers()`.

Effects: Unregisters a range registered with `declare_no_pointers()` for destruction. It shall be called before the lifetime of the object ends.

Throws: Nothing.

pointer_safety get_pointer_safety() noexcept;

Returns: `pointer_safety::strict` if the implementation has strict pointer safety (6.6.4.4.3). It is implementation-defined whether `get_pointer_safety` returns `pointer_safety::relaxed` or `pointer_safety::preferred` if the implementation has relaxed pointer safety.

19.10.6 Align

void* align(size_t alignment, size_t size, void*& ptr, size_t& space);

Effects: If it is possible to fit size bytes of storage aligned by alignment into the buffer pointed to by ptr with length space, the function updates ptr to represent the first possible address of such storage and decreases space by the number of bytes used for alignment. Otherwise, the function does nothing.

Requires:
(2.1) alignment shall be a power of two
(2.2) ptr shall represent the address of contiguous storage of at least space bytes

Returns: A null pointer if the requested aligned buffer would not fit into the available space, otherwise the adjusted value of ptr.

[Note: The function updates its ptr and space arguments so that it can be called repeatedly with possibly different alignment and size arguments for the same buffer. — end note]

19.10.7 Allocator argument tag

namespace std {
    struct allocator_arg_t { explicit allocator_arg_t() = default; 
    };
    inline constexpr allocator_arg_t allocator_arg{};
}

The allocator_arg_t struct is an empty structure type used as a unique type to disambiguate constructor and function overloading. Specifically, several types (see tuple 19.5) have constructors with allocator_arg_t as the first argument, immediately followed by an argument of a type that satisfies the Cpp17Allocator requirements (Table 33).

---

224) `pointer_safety::preferred` might be returned to indicate that a leak detector is running so that the program can avoid spurious leak reports.
19.10.8 uses_allocator

19.10.8.1 uses_allocator trait

template<class T, class Alloc> struct uses_allocator;

Remarks: Automatically detects whether T has a nested allocator_type that is convertible from Alloc. Meets the Cpp17BinaryTypeTrait requirements (19.15.1). The implementation shall provide a definition that is derived from true_type if the qualified-id T::allocator_type is valid and denotes a type (12.9.2) and is_convertible_v<Alloc, T::allocator_type> != false, otherwise it shall be derived from false_type. A program may specialize this template to derive from true_type for a program-defined type T that does not have a nested allocator_type but nonetheless can be constructed with an allocator where either:

19.10.8.2 Uses-allocator construction

Uses-allocator construction with allocator Alloc refers to the construction of an object obj of type T, using constructor arguments v1, v2, ..., vN of types V1, V2, ..., VN, respectively, and an allocator alloc of type Alloc, according to the following rules:

— the first argument of a constructor has type allocator_arg_t and the second argument has type Alloc or

— the last argument of a constructor has type Alloc.

19.10.9 Allocator traits

The class template allocator_traits supplies a uniform interface to all allocator types. An allocator cannot be a non-class type, however, even if allocator_traits supplies the entire required interface. [Note: Thus, it is always possible to create a derived class from an allocator. — end note]

namespace std {
    template<class Alloc> struct allocator_traits {
        using allocator_type = Alloc;

        using value_type = typename Alloc::value_type;

        using pointer = see below;
        using const_pointer = see below;
        using void_pointer = see below;
        using const_void_pointer = see below;

        using difference_type = see below;
        using size_type = see below;

        using propagate_on_container_copy_assignment = see below;
        using propagate_on_container_move_assignment = see below;
        using propagate_on_container_swap = see below;
        using is_always_equal = see below;

        template<class T> using rebind_alloc = see below;
        template<class T> using rebind_traits = allocator_traits<rebind_alloc<T>>;

        [[nodiscard]] static pointer allocate(Alloc a, size_type n);
        [[nodiscard]] static pointer allocate(Alloc a, size_type n, const_void_pointer hint);
    };
}

§ 19.10.9 576
static void deallocate(Alloc& a, pointer p, size_type n);

template<class T, class... Args>
static void construct(Alloc& a, T* p, Args&&... args);

template<class T>
static void destroy(Alloc& a, T* p);

static size_type max_size(const Alloc& a) noexcept;

static Alloc select_on_container_copy_construction(const Alloc& rhs);
};

19.10.9.1 Allocator traits member types

using pointer = see below;

Type: Alloc::pointer if the qualified-id Alloc::pointer is valid and denotes a type (12.9.2); otherwise, value_type*.

using const_pointer = see below;

Type: Alloc::const_pointer if the qualified-id Alloc::const_pointer is valid and denotes a type (12.9.2); otherwise, pointer_traits<pointer>::rebind<const value_type>.

using void_pointer = see below;

Type: Alloc::void_pointer if the qualified-id Alloc::void_pointer is valid and denotes a type (12.9.2); otherwise, pointer_traits<pointer>::rebind<void>.

using const_void_pointer = see below;

Type: Alloc::const_void_pointer if the qualified-id Alloc::const_void_pointer is valid and denotes a type (12.9.2); otherwise, pointer_traits<pointer>::rebind<const void>.

using difference_type = see below;

Type: Alloc::difference_type if the qualified-id Alloc::difference_type is valid and denotes a type (12.9.2); otherwise, pointer_traits<pointer>::difference_type.

using size_type = see below;

Type: Alloc::size_type if the qualified-id Alloc::size_type is valid and denotes a type (12.9.2); otherwise, make_unsigned_t<difference_type>.

using propagate_on_container_copy_assignment = see below;

Type: Alloc::propagate_on_container_copy_assignment if the qualified-id Alloc::propagate_on_container_copy_assignment is valid and denotes a type (12.9.2); otherwise false_type.

using propagate_on_container_move_assignment = see below;

Type: Alloc::propagate_on_container_move_assignment if the qualified-id Alloc::propagate_on_container_move_assignment is valid and denotes a type (12.9.2); otherwise false_type.

using propagate_on_container_swap = see below;

Type: Alloc::propagate_on_container_swap if the qualified-id Alloc::propagate_on_container_swap is valid and denotes a type (12.9.2); otherwise false_type.

using is_always_equal = see below;

Type: Alloc::is_always_equal if the qualified-id Alloc::is_always_equal is valid and denotes a type (12.9.2); otherwise is_empty<Alloc>::type.

template<class T> using rebind_alloc = see below;

Alias template: Alloc::rebind<T>::other if the qualified-id Alloc::rebind<T>::other is valid and denotes a type (12.9.2); otherwise, Alloc<T, Args> if Alloc is a class template instantiation of the
form Alloc<U, Args>, where Args is zero or more type arguments; otherwise, the instantiation of `rebind_alloc` is ill-formed.

### 19.10.9.2 Allocator traits static member functions

```cpp
[[nodiscard]] static pointer allocate(Alloc& a, size_type n);

Returns: a.allocate(n).
```

```cpp
[[nodiscard]] static pointer allocate(Alloc& a, size_type n, const_void_pointer hint);

Returns: a.allocate(n, hint) if that expression is well-formed; otherwise, a.allocate(n).
```

```cpp
static void deallocate(Alloc& a, pointer p, size_type n);

Effects: Calls a.deallocate(p, n).
Throws: Nothing.
```

```cpp
template<class T, class... Args>
static void construct(Alloc& a, T* p, Args&&... args);

Effects: Calls a.construct(p, std::forward<Args>(args)...) if that call is well-formed; otherwise, invokes ::new (static_cast<void*>(p)) T(std::forward<Args>(args)...).
```

```cpp
template<class T>
static void destroy(Alloc& a, T* p);

Effects: Calls a.destroy(p) if that call is well-formed; otherwise, invokes p->T().
```

```cpp
static size_type max_size(const Alloc& a) noexcept;

Returns: a.max_size() if that expression is well-formed; otherwise, numeric_limits<size_type>::max()/sizeof(value_type).
```

```cpp
static Alloc select_on_container_copy_construction(const Alloc& rhs);

Returns: rhs.select_on_container_copy_construction() if that expression is well-formed; otherwise, rhs.
```

### 19.10.10 The default allocator

All specializations of the default allocator satisfy the allocator completeness requirements (15.5.3.5.1).

```cpp
namespace std {
    template<class T> class allocator {
        public:
            using value_type = T;
            using size_type = size_t;
            using difference_type = ptrdiff_t;
            using propagate_on_container_move_assignment = true_type;
            using is_always_equal = true_type;

            constexpr allocator() noexcept;
            constexpr allocator(const allocator&) noexcept;
            template<class U> constexpr allocator(const allocator<U>&) noexcept;
            ~allocator();
            allocator& operator=(const allocator&) = default;

            [[nodiscard]] T* allocate(size_t n);
            void deallocate(T* p, size_t n);
        }
    }
}
```

### 19.10.10.1 allocator members

Except for the destructor, member functions of the default allocator shall not introduce data races (6.8.2) as a result of concurrent calls to those member functions from different threads. Calls to these functions that allocate or deallocate a particular unit of storage shall occur in a single total order, and each such deallocation call shall happen before the next allocation (if any) in this order.
`[[nodiscard]]` T* allocate(size_t n);

Returns: A pointer to the initial element of an array of storage of size `n * sizeof(T)`, aligned appropriately for objects of type T.

Remarks: the storage is obtained by calling `::operator new (16.6.2)`, but it is unspecified when or how often this function is called.

Throws: `bad_alloc` if the storage cannot be obtained.

void deallocate(T* p, size_t n);

Requires: p shall be a pointer value obtained from `allocate()`. n shall equal the value passed as the first argument to the invocation of allocate which returned p.

Effects: Deallocates the storage referenced by p.

Remarks: Uses `::operator delete (16.6.2)`, but it is unspecified when this function is called.

19.10.10.2 allocator globals

```plaintext
template<class T, class U>
bool operator==(const allocator<T>&, const allocator<U>&) noexcept;

Returns: true.
```

```plaintext
template<class T, class U>
bool operator!=(const allocator<T>&, const allocator<U>&) noexcept;

Returns: false.
```

19.10.11 Specialized algorithms

Throughout this subclause, the names of template parameters are used to express type requirements.

— If an algorithm’s template parameter is named `InputIterator`, the template argument shall satisfy the `Cpp17InputIterator` requirements (22.2.3).

— If an algorithm’s template parameter is named `ForwardIterator`, the template argument shall satisfy the `Cpp17ForwardIterator` requirements (22.2.5), and is required to have the property that no exceptions are thrown from increment, assignment, comparison, or indirection through valid iterators.

Unless otherwise specified, if an exception is thrown in the following algorithms there are no effects.

19.10.11.1 addressof

```plaintext
template<class T> constexpr T* addressof(T& r) noexcept;

Returns: The actual address of the object or function referenced by r, even in the presence of an overloaded `operator&`.
```

Remarks: An expression `addressof(E)` is a constant subexpression (15.3.6) if E is an lvalue constant subexpression.

19.10.11.2 uninitialized_default_construct

```plaintext
template<class ForwardIterator>
void uninitialized_default_construct(ForwardIterator first, ForwardIterator last);

Effects: Equivalent to:
```
19.10.11.3 uninitialized_value_construct

```cpp
template<class ForwardIterator>
void uninitialized_value_construct(ForwardIterator first, ForwardIterator last);
```

**Effects:** Equivalent to:

```cpp```
for (; first != last; ++first)
    ::new (static_cast<void*>(addressof(*first)))
    typename iterator_traits<ForwardIterator>::value_type();
```

```cpp
template<class ForwardIterator, class Size>
ForwardIterator uninitialized_value_construct_n(ForwardIterator first, Size n);
```

**Effects:** Equivalent to:

```cpp```
for (; n > 0; (void)++first, --n)
    ::new (static_cast<void*>(addressof(*first)))
    typename iterator_traits<ForwardIterator>::value_type();
return first;
```

19.10.11.4 uninitialized_copy

```cpp
template<class InputIterator, class ForwardIterator>
ForwardIterator uninitialized_copy(InputIterator first, InputIterator last,
                                    ForwardIterator result);
```

**Effects:** As if by:

```cpp```
for (; first != last; ++result, (void) ++first)
    ::new (static_cast<void*>(addressof(*result)))
    typename iterator_traits<ForwardIterator>::value_type(*first);
```

**Returns:** result.

```cpp
template<class InputIterator, class Size, class ForwardIterator>
pair<InputIterator, ForwardIterator>
uninitialized_copy_n(InputIterator first, Size n, ForwardIterator result);
```

**Effects:** As if by:

```cpp```
for ( ; n > 0; ++result, (void) ++first, --n) {
    ::new (static_cast<void*>(addressof(*result)))
    typename iterator_traits<ForwardIterator>::value_type(*first);
}
```

**Returns:** result.

19.10.11.5 uninitialized_move

```cpp
template<class InputIterator, class ForwardIterator>
ForwardIterator uninitialized_move(InputIterator first, InputIterator last,
                                    ForwardIterator result);
```

**Effects:** Equivalent to:

```cpp```
for (; first != last; (void)++result, ++first)
    ::new (static_cast<void*>(addressof(*result)))
    typename iterator_traits<ForwardIterator>::value_type(std::move(*first));
return result;
```

**Remarks:** If an exception is thrown, some objects in the range [first, last) are left in a valid but unspecified state.

```cpp
template<class InputIterator, class Size, class ForwardIterator>
pair<InputIterator, ForwardIterator>
uninitialized_move_n(InputIterator first, Size n, ForwardIterator result);
```

**Effects:** Equivalent to:

```cpp```
for (; n > 0; ++result, (void) ++first, --n)
    ::new (static_cast<void*>(addressof(*result)))
    typename iterator_traits<ForwardIterator>::value_type(std::move(*first));
return {first,result};
```
Remarks: If an exception is thrown, some objects in the range \([\text{first}, \text{std::next(first,n)})\) are left in a valid but unspecified state.

19.10.11.6 uninitialized_fill

```cpp
template<class ForwardIterator, class T>
void uninitialized_fill(ForwardIterator first, ForwardIterator last, const T& x);
```

Effects: As if by:

```cpp
for (; first != last; ++first)
  ::new (static_cast<void*>(addressof(*first))) typename iterator_traits<ForwardIterator>::value_type(x);
```

```cpp
template<class ForwardIterator, class Size, class T>
ForwardIterator uninitialized_fill_n(ForwardIterator first, Size n, const T& x);
```

Effects: As if by:

```cpp
for (; n--; ++first)
  ::new (static_cast<void*>(addressof(*first)))
  typename iterator_traits<ForwardIterator>::value_type(x);
return first;
```

19.10.11.7 destroy

```cpp
template<class T>
void destroy_at(T* location);
```

Effects: Equivalent to:

```cpp
location->~T();
```

```cpp
template<class ForwardIterator>
void destroy(ForwardIterator first, ForwardIterator last);
```

Effects: Equivalent to:

```cpp
for (; first!=last; ++first)
  destroy_at(addressof(*first));
```

```cpp
template<class ForwardIterator, class Size>
ForwardIterator destroy_n(ForwardIterator first, Size n);
```

Effects: Equivalent to:

```cpp
for (; n > 0; (void)++first, --n)
  destroy_at(addressof(*first));
return first;
```

19.10.12 C library memory allocation

```cpp
void* aligned_alloc(size_t alignment, size_t size);
void* calloc(size_t nmemb, size_t size);
void* malloc(size_t size);
void* realloc(void* ptr, size_t size);
```

Effects: These functions have the semantics specified in the C standard library.

Remarks: These functions do not attempt to allocate storage by calling ::operator new() (16.6).

Storage allocated directly with these functions is implicitly declared reachable (see 6.6.4.4.3) on allocation, ceases to be declared reachable on deallocation, and need not cease to be declared reachable as the result of an undeclare_reachable() call. [Note: This allows existing C libraries to remain unaffected by restrictions on pointers that are not safely derived, at the expense of providing far fewer garbage collection and leak detection options for malloc()-allocated objects. It also allows realloc() to be implemented with a separate allocation arena, bypassing the normal declare_reachable() implementation. The above functions should never intentionally be used as a replacement for declare_reachable(), and newly written code is strongly encouraged to treat memory allocated with these functions as though it were allocated with operator new. — end note]
void free(void* ptr);

Effects: This function has the semantics specified in the C standard library.

Remarks: This function does not attempt to deallocate storage by calling ::operator delete().

See also: ISO C 7.22.3

19.11 Smart pointers

19.11.1 Class template unique_ptr

A unique pointer is an object that owns another object and manages that other object through a pointer. More precisely, a unique pointer is an object \( u \) that stores a pointer to a second object \( p \) and will dispose of \( p \) when \( u \) is itself destroyed (e.g., when leaving block scope (8.7)). In this context, \( u \) is said to own \( p \).

The mechanism by which \( u \) disposes of \( p \) is known as \( p \)'s associated deleter, a function object whose correct invocation results in \( p \)'s appropriate disposition (typically its deletion).

Let the notation \( u.p \) denote the pointer stored by \( u \), and let \( u.d \) denote the associated deleter. Upon request, \( u \) can reset (replace) \( u.p \) and \( u.d \) with another pointer and deleter, but properly disposes of its owned object via the associated deleter before such replacement is considered completed.

Each object of a type \( U \) instantiated from the unique_ptr template specified in this subclause has the strict ownership semantics, specified above, of a unique pointer. In partial satisfaction of these semantics, each such \( U \) is Cpp17MoveConstructible and Cpp17MoveAssignable, but is not Cpp17CopyConstructible nor Cpp17CopyAssignable. The template parameter \( T \) of unique_ptr may be an incomplete type.

[Note: The uses of unique_ptr include providing exception safety for dynamically allocated memory, passing ownership of dynamically allocated memory to a function, and returning dynamically allocated memory from a function. —end note]

19.11.1.1 Default deleters

19.11.1.1.1 In general

The class template default_delete serves as the default deleter (destruction policy) for the class template unique_ptr.

The template parameter \( T \) of default_delete may be an incomplete type.

19.11.1.1.2 default_delete

```cpp
namespace std {
  template<class T> struct default_delete {
    constexpr default_delete() noexcept = default;
    template<class U> default_delete(const default_delete<U>&) noexcept;
    void operator()(T*) const;
  };
}
```

```cpp
template<class U> default_delete(const default_delete<U>& other) noexcept;
```

Effects: Constructs a default_delete object from another default_delete<U> object.

Remarks: This constructor shall not participate in overload resolution unless \( U* \) is implicitly convertible to \( T* \).

```cpp
void operator()(T* ptr) const;
```

Effects: Calls delete on ptr.

Remarks: If \( T \) is an incomplete type, the program is ill-formed.

19.11.1.1.3 default_delete<T[]>

```cpp
namespace std {
  template<class T> struct default_delete<T[]>{
    constexpr default_delete() noexcept = default;
    template<class U> default_delete(const default_delete<U[]>&) noexcept;
    template<class U> void operator()(U* ptr) const;
  };
}
```

§ 19.11.1.3
template<class U> default_delete(const default_delete<U>& other) noexcept;

1. Effects: Constructs a default_delete object from another default_delete<U> object.
2. Remarks: This constructor shall not participate in overload resolution unless U(*)[] is convertible to T(*)[].

template<class U> void operator()(U* ptr) const;

3. Effects: Calls delete[] on ptr.
4. Remarks: If U is an incomplete type, the program is ill-formed. This function shall not participate in overload resolution unless U(*)[] is convertible to T(*)[].

19.11.1.2 unique_ptr for single objects

namespace std {
    template<class T, class D = default_delete<T>> class unique_ptr {
    public:
        using pointer = see below;
        using element_type = T;
        using deleter_type = D;

        // 19.11.1.2.1, constructors
        constexpr unique_ptr() noexcept;
        explicit unique_ptr(pointer p) noexcept;
        unique_ptr(pointer p, see below d1) noexcept;
        unique_ptr(pointer p, see below d2) noexcept;
        unique_ptr(unique_ptr&& u) noexcept;
        constexpr unique_ptr(unique_ptr(nullptr_t) noexcept;
        template<class U, class E>
            unique_ptr(unique_ptr<U, E>&& u) noexcept;

        // 19.11.1.2.2, destructor
        ~unique_ptr();

        // 19.11.1.2.3, assignment
        unique_ptr& operator=(unique_ptr&& u) noexcept;
        template<class U, class E>
            unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;
        unique_ptr& operator=(nullptr_t) noexcept;

        // 19.11.1.2.4, observers
        add_lvalue_reference_t<T> operator*() const;
        pointer operator->() const noexcept;
        pointer get() const noexcept;
        deleter_type& get_deleter() noexcept;
        const deleter_type& get_deleter() const noexcept;
        explicit operator bool() const noexcept;

        // 19.11.1.2.5, modifiers
        pointer release() noexcept;
        void reset(pointer p = pointer()) noexcept;
        void swap(unique_ptr& u) noexcept;

        // disable copy from lvalue
        unique_ptr(const unique_ptr&) = delete;
        unique_ptr& operator=(const unique_ptr&) = delete;
    };
}

1. The default type for the template parameter D is default_delete. A client-supplied template argument D shall be a function object type (19.14), lvalue reference to function, or lvalue reference to function object type for which, given a value d of type D and a value ptr of type unique_ptr<T, D>::pointer, the expression d(ptr) is valid and has the effect of disposing of the pointer as appropriate for that deleter.
2. If the deleter’s type D is not a reference type, D shall satisfy the Cpp17Destructible requirements (Table 29).
If the qualified-id `remove_reference_t<D>::pointer` is valid and denotes a type (12.9.2), then `unique_ptr<T, D>::pointer` shall be a synonym for `remove_reference_t<D>::pointer`. Otherwise `unique_ptr<T, D>::pointer` shall be a synonym for `element_type*`. The type `unique_ptr<T, D>::pointer` shall satisfy the `Cpp17NullablePointer` requirements (Table 30).

[Example: Given an allocator type `X` (Table 33) and letting `A` be a synonym for `allocator_traits<X>`, the types `A::pointer`, `A::const_pointer`, `A::void_pointer`, and `A::const_void_pointer` may be used as `unique_ptr<T, D>::pointer`. — end example]

### 19.11.1.2.1 Constructors [unique.ptr.single.ctor]

```cpp
conestexpr unique_ptr() noexcept;
conestexpr unique_ptr(nullptr_t) noexcept;
```

1. **Requires:** `D` shall satisfy the `Cpp17DefaultConstructible` requirements (Table 24), and that construction shall not throw an exception.
2. **Effects:** Constructs a `unique_ptr` object that owns nothing, value-initializing the stored pointer and the stored deleter.
3. **Ensures:** `get() == nullptr.get_deleter()` returns a reference to the stored deleter.
4. **Remarks:** If `is_pointer_v<deleter_type>` is `true` or `is_default_constructible_v<deleter_type>` is `false`, this constructor shall not participate in overload resolution.

```cpp
explicit unique_ptr(pointer p) noexcept;
unique_ptr(pointer p, const A& d) noexcept;
unique_ptr(pointer p, A& d) noexcept;
unique_ptr(pointer p, A&& d) noexcept;
```

5. **Requires:** `D` shall satisfy the `Cpp17DefaultConstructible` requirements (Table 24), and that construction shall not throw an exception.
6. **Effects:** Constructs a `unique_ptr` which owns `p`, initializing the stored pointer with `p` and value-initializing the stored deleter.
7. **Ensures:** `get() == p.get_deleter()` returns a reference to the stored deleter.
8. **Remarks:** If `is_pointer_v<deleter_type>` is `true` or `is_default_constructible_v<deleter_type>` is `false`, this constructor shall not participate in overload resolution. If class template argument deduction (11.3.1.8) would select the function template corresponding to this constructor, then the program is ill-formed.

```cpp
unique_ptr(pointer p, see below d1) noexcept;
unique_ptr(pointer p, see below d2) noexcept;
```

9. The signature of these constructors depends upon whether `D` is a reference type. If `D` is a non-reference type `A`, then the signatures are:
   ```cpp
   unique_ptr(pointer p, const A& d) noexcept;
   unique_ptr(pointer p, A& d) noexcept;
   ```
10. If `D` is an lvalue reference type `A&`, then the signatures are:
    ```cpp
    unique_ptr(pointer p, A& d) noexcept;
    unique_ptr(pointer p, A&& d) = delete;
    ```
11. If `D` is an lvalue reference type `const A&`, then the signatures are:
    ```cpp
    unique_ptr(pointer p, const A& d) noexcept;
    unique_ptr(pointer p, const A&& d) = delete;
    ```
12. **Requires:** For the first constructor, if `D` is not a reference type, `D` shall satisfy the `Cpp17CopyConstructible` requirements and such construction shall not exit via an exception. For the second constructor, if `D` is not a reference type, `D` shall satisfy the `Cpp17MoveConstructible` requirements and such construction shall not exit via an exception.
13. **Effects:** Constructs a `unique_ptr` object which owns `p`, initializing the stored pointer with `p` and initializing the deleter from `std::forward<deleter_type(d)>`(d).
14. **Remarks:** These constructors shall not participate in overload resolution unless `is_constructible_v<D, deleter_type(d)>)` is `true`.
15. **Ensures:** `get() == p.get_deleter()` returns a reference to the stored deleter. If `D` is a reference type then `get_deleter()` returns a reference to the lvalue `d`.

§ 19.11.1.2.1
Remarks: If class template argument deduction (11.3.1.8) would select a function template corresponding to either of these constructors, then the program is ill-formed.

[Example:

```cpp
D d;
unique_ptr<int, D> p1(new int, D()); // D must be Cpp17MoveConstructible
unique_ptr<int, D> p2(new int, d); // D must be Cpp17CopyConstructible
unique_ptr<int, &D> p3(new int, d); // p3 holds a reference to d
unique_ptr<int, const D&> p4(new int, D()); // error: rvalue deleter object combined with reference deleter type
```
—end example]

unique_ptr(unique_ptr&& u) noexcept;

Requires: If D is not a reference type, D shall satisfy the Cpp17MoveConstructible requirements (Table 25). Construction of the deleter from an rvalue of type D shall not throw an exception.

Effects: Constructs a unique_ptr from u. If D is a reference type, this deleter is copy constructed from u’s deleter; otherwise, this deleter is move constructed from u’s deleter. [Note: The construction of the deleter can be implemented with std::forward<D>. — end note]

Ensures: get() yields the value u.get() yielded before the construction. u.get() == nullptr.

get_deleter() returns a reference to the stored deleter that was constructed from u.get_deleter(). If D is a reference type then get_deleter() and u.get_deleter() both reference the same lvalue deleter.

template<class U, class E> unique_ptr(unique_ptr<U, E>&& u) noexcept;

Requires: If E is not a reference type, construction of the deleter from an rvalue of type E shall be well-formed and shall not throw an exception. Otherwise, E is a reference type and construction of the deleter from an lvalue of type E shall be well-formed and shall not throw an exception.

Remarks: This constructor shall not participate in overload resolution unless:

(22.1) unique_ptr<U, E>::pointer is implicitly convertible to pointer.

(22.2) U is not an array type, and

(22.3) either D is a reference type and E is the same type as D, or D is not a reference type and E is implicitly convertible to D.

Effects: Constructs a unique_ptr from u. If E is a reference type, this deleter is copy constructed from u’s deleter; otherwise, this deleter is move constructed from u’s deleter. [Note: The deleter constructor can be implemented with std::forward<E>. — end note]

Ensures: get() yields the value u.get() yielded before the construction. u.get() == nullptr.

get_deleter() returns a reference to the stored deleter that was constructed from u.get_deleter().

19.11.1.2.2 Destructor [unique.ptr.single.dtor]

~unique_ptr();

Requires: The expression get_deleter()(get()) shall be well-formed, shall have well-defined behavior, and shall not throw exceptions. [Note: The use of default_delete requires T to be a complete type. — end note]

Effects: If get() == nullptr there are no effects. Otherwise get_deleter()(get()).

19.11.1.2.3 Assignment [unique.ptr.single.asgn]

unique_ptr& operator=(unique_ptr&& u) noexcept;

Requires: If D is not a reference type, D shall satisfy the Cpp17MoveAssignable requirements (Table 27) and assignment of the deleter from an rvalue of type D shall not throw an exception. Otherwise, D is a reference type; remove_reference_t<D> shall satisfy the Cpp17CopyAssignable requirements and assignment of the deleter from an lvalue of type D shall not throw an exception.

Effects: Calls reset(u.release()) followed by get_deleter() = std::forward<D>(u.get_deleter()).

Returns: *this.

Ensures: u.get() == nullptr.
template<class U, class E> unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;

Requires: If E is not a reference type, assignment of the deleter from an rvalue of type E shall be well-formed and shall not throw an exception. Otherwise, E is a reference type and assignment of the deleter from an lvalue of type E shall be well-formed and shall not throw an exception.

Remarks: This operator shall not participate in overload resolution unless:

(6.1) unique_ptr<U, E>::pointer is implicitly convertible to pointer, and
(6.2) U is not an array type, and
(6.3) is_assignable_v<D&, E&&> is true.

Effects: Calls reset(u.release()) followed by get_deleter() = std::forward<E>(u.get_deleter()).

Returns: *this.

Ensures: u.get() == nullptr.

unique_ptr& operator=(nullptr_t) noexcept;

Effects: As if by reset().

Ensures: get() == nullptr.

Returns: *this.

19.11.1.2.4 Observers

add_lvalue_reference_t<T> operator*() const;

Requires: get() != nullptr.

Returns: *get().

pointer operator->() const noexcept;

Requires: get() != nullptr.

Returns: get().

[Note: The use of this function typically requires that T be a complete type. — end note]

pointer get() const noexcept;

Returns: The stored pointer.

deleter_type& get_deleter() noexcept;

const deleter_type& get_deleter() const noexcept;

Returns: A reference to the stored deleter.

explicit operator bool() const noexcept;

Returns: get() != nullptr.

19.11.1.2.5 Modifiers

pointer release() noexcept;

Requires: The expression get_deleter()(get()) shall be well-formed, shall have well-defined behavior, and shall not throw exceptions.

Effects: Assigns p to the stored pointer, and then if and only if the old value of the stored pointer, old_p, was not equal to nullptr, calls get_deleter()(old_p). [Note: The order of these operations is significant because the call to get_deleter() may destroy *this. — end note]

Ensures: get() == p. [Note: The postcondition does not hold if the call to get_deleter() destroys *this since this->get() is no longer a valid expression. — end note]
void swap(unique_ptr& u) noexcept;

Requires: get_deleter() shall be swappable (15.5.3.2) and shall not throw an exception under swap.

Effects: Invokes swap on the stored pointers and on the stored deleters of *this and u.

19.11.1.3 unique_ptr for array objects with a runtime length

namespace std {
    template<class T, class D> class unique_ptr<T[], D> {
        public:
            using pointer = see below;
            using element_type = T;
            using deleter_type = D;

            // 19.11.1.3.1, constructors
            constexpr unique_ptr() noexcept;
            template<class U> explicit unique_ptr(U p) noexcept;
            template<class U> unique_ptr(U p, see below d) noexcept;
            unique_ptr(unique_ptr&& u) noexcept;
            template<class U, class E>
                unique_ptr(unique_ptr<U, E>&& u) noexcept;
            constexpr unique_ptr(nullptr_t) noexcept;

            // destructor
            ~unique_ptr();

            // assignment
            unique_ptr& operator=(unique_ptr&& u) noexcept;
            template<class U, class E>
                unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;
            unique_ptr& operator=(nullptr_t) noexcept;

            // 19.11.1.3.3, observers
            T& operator[](size_t i) const;
            pointer get() const noexcept;
            deleter_type& get_deleter() noexcept;
            const deleter_type& get_deleter() const noexcept;
            explicit operator bool() const noexcept;

            // 19.11.1.3.4, modifiers
            pointer release() noexcept;
            template<class U> void reset(U p) noexcept;
            void reset(nullptr_t = nullptr) noexcept;
            void swap(unique_ptr& u) noexcept;

            // disable copy from lvalue
            unique_ptr(const unique_ptr&) = delete;
            unique_ptr& operator=(const unique_ptr&) = delete;
    };
}

1 A specialization for array types is provided with a slightly altered interface.

(1.1) — Conversions between different types of unique_ptr<T[], D> that would be disallowed for the cor-
responding pointer-to-array types, and conversions to or from the non-array forms of unique_ptr,
produce an ill-formed program.

(1.2) — Pointers to types derived from T are rejected by the constructors, and by reset.

(1.3) — The observers operator* and operator-> are not provided.

(1.4) — The indexing observer operator[] is provided.

(1.5) — The default deleter will call delete[].

2 Descriptions are provided below only for members that differ from the primary template.

3 The template argument T shall be a complete type.
19.11.1.3.1 Constructors

\[\text{template<class } T \text{> explicit } \text{unique_ptr}(T \ p) \ \text{noexcept};\]

1 This constructor behaves the same as the constructor in the primary template that takes a single parameter of type \text{pointer} except that it additionally shall not participate in overload resolution unless:

\((1.1)\) \quad T \text{ is the same type as } \text{pointer}, or
\((1.2)\) \quad \text{pointer} \text{ is the same type as } \text{element_type*}, \text{ } T \text{ is a pointer type } V*, \text{ and } V(*)[] \text{ is convertible to } \text{element_type(*)[]}.\]

\[\text{template<class } T \text{> unique_ptr}(T \ p, \text{ see below } d) \ \text{noexcept;}\]

2 These constructors behave the same as the constructors in the primary template that take a parameter of type \text{pointer} and a second parameter except that they shall not participate in overload resolution unless either:

\((2.1)\) \quad T \text{ is the same type as } \text{pointer},
\((2.2)\) \quad T \text{ is } \text{nullptr_t}, \text{ or}
\((2.3)\) \quad \text{pointer} \text{ is the same type as } \text{element_type*}, \text{ } T \text{ is a pointer type } V*, \text{ and } V(*)[] \text{ is convertible to } \text{element_type(*)[]}.\]

\[\text{template<class } T, \text{ class } E \text{> unique_ptr(unique_ptr< } T, \ E&& \text{> } u) \ \text{noexcept;}\]

3 This constructor behaves the same as in the primary template, except that it shall not participate in overload resolution unless all of the following conditions hold, where \text{UP} \text{ is } \text{unique_ptr< } T, \ E>:\]

\((3.1)\) \quad T \text{ is an array type, and}
\((3.2)\) \quad \text{pointer} \text{ is the same type as } \text{element_type*}, \text{ and}
\((3.3)\) \quad \text{UP::pointer} \text{ is the same type as UP::element_type*, and}
\((3.4)\) \quad \text{UP::element_type(*)[]} \text{ is convertible to } \text{element_type(*)[]}, \text{ and}
\((3.5)\) \quad \text{either } D \text{ is a reference type and } E \text{ is the same type as } D, \text{ or } D \text{ is not a reference type and } E \text{ is implicitly convertible to } D.\]

[Note: This replaces the overload-resolution specification of the primary template — end note]

19.11.1.3.2 Assignment

\[\text{template<class } T, \text{ class } E \text{> unique_ptr& operator=(unique_ptr< } T, \ E&& \text{> } u) \ \text{noexcept;}\]

1 This operator behaves the same as in the primary template, except that it shall not participate in overload resolution unless all of the following conditions hold, where \text{UP} \text{ is } \text{unique_ptr< } T, \ E>:\]

\((1.1)\) \quad T \text{ is an array type, and}
\((1.2)\) \quad \text{pointer} \text{ is the same type as } \text{element_type*}, \text{ and}
\((1.3)\) \quad \text{UP::pointer} \text{ is the same type as UP::element_type*, and}
\((1.4)\) \quad \text{UP::element_type(*)[]} \text{ is convertible to } \text{element_type(*)[]}, \text{ and}
\((1.5)\) \quad \text{is_assignable_v< } D&, \ E&& \text{> is true.}\]

[Note: This replaces the overload-resolution specification of the primary template — end note]

19.11.1.3.3 Observers

\[T& \ \text{operator[](size_t } i \text{) const;}\]

1 Requires: \text{i < the number of elements in the array to which the stored pointer points.}
2 Returns: \text{get()[i].}\]

19.11.1.3.4 Modifiers

\[\text{void reset(nullptr_t } p = \text{nullptr) noexcept;}\]

1 Effects: Equivalent to \text{reset(pointer())}.\]
template<class U> void reset(U p) noexcept;

This function behaves the same as the `reset` member of the primary template, except that it shall not participate in overload resolution unless either

1. `U` is the same type as `pointer`, or
2. `pointer` is the same type as `element_type*`, `U` is a pointer type `V*`, and `V(*)[]` is convertible to `element_type(*)[]`.

### 19.11.1.4 Creation

```cpp
template<class T, class... Args> unique_ptr<T> make_unique(Args&&... args);
```

**Remarks:** This function shall not participate in overload resolution unless `T` is not an array.

**Returns:** `std::unique_ptr<T>{std::forward<Args>(args)...}`.

```cpp
template<class T> unique_ptr<T> make_unique(size_t n);
```

**Remarks:** This function shall not participate in overload resolution unless `T` is an array of unknown bound.

**Returns:** `std::unique_ptr<T>(new remove_extent_t<T>[n]()`.

```cpp
template<class T, class... Args> unspecified make_unique(Args&&...); = delete;
```

**Remarks:** This function shall not participate in overload resolution unless `T` is an array of known bound.

### 19.11.1.5 Specialized algorithms

```cpp
template<class T1, class D1, class T2, class D2> bool operator==(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
```

**Returns:** `x.get() == y.get()`.

```cpp
template<class T1, class D1, class T2, class D2> bool operator!=(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
```

**Returns:** `x.get() != y.get()`.

```cpp
template<class T1, class D1, class T2, class D2> bool operator<(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
```

**Requires:** Let `CT` denote

```
common_type_t<typename unique_ptr<T1, D1>::pointer,
              typename unique_ptr<T2, D2>::pointer>
```

Then the specialization `less<CT>` shall be a function object type (19.14) that induces a strict weak ordering (23.7) on the pointer values.

**Returns:** `less<CT>()(x.get(), y.get())`.

**Remarks:** If `unique_ptr<T1, D1>::pointer` is not implicitly convertible to `CT` or `unique_ptr<T2, D2>::pointer` is not implicitly convertible to `CT`, the program is ill-formed.

```cpp
template<class T1, class D1, class T2, class D2> bool operator>(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
```

**Returns:** `y < x`.

```cpp
template<class T1, class D1, class T2, class D2> bool operator<=(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
```

**Returns:** `!(y < x)`.

```cpp
template<class T1, class D1, class T2, class D2> bool operator>=(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
```

**Returns:** `!(x < y)`.
template<class T, class D>
bool operator==(const unique_ptr<T, D>& x, nullptr_t) noexcept;

Returns: !x.

template<class T, class D>
bool operator!=(const unique_ptr<T, D>& x, nullptr_t) noexcept;

Returns: (bool)x.

template<class T, class D>
bool operator==(nullptr_t, const unique_ptr<T, D>& x) noexcept;

Returns: (bool)x.

template<class T, class D>
bool operator!=(nullptr_t, const unique_ptr<T, D>& x) noexcept;

Returns: (bool)x.

11

template<class T, class D>

Returns: !x.

template<class T, class D>
bool operator!=(const unique_ptr<T, D>& x, nullptr_t) noexcept;

Returns: (bool)x.

template<class T, class D>

Returns: (bool)x.

template<class T, class D>

Returns: (bool)x.

12

template<class T, class D>

Returns: !x.

template<class T, class D>
bool operator==(nullptr_t, const unique_ptr<T, D>& x) noexcept;

Returns: (bool)x.

template<class T, class D>

Returns: (bool)x.

13

Returns: The first function template returns nullptr < x. The second function template returns x < nullptr.

template<class T, class D>

Returns: The first function template returns !nullptr < x. The second function template returns !(x < nullptr).

14

 Returns: The specialization less<unique_ptr<T, D>::pointer> shall be a function object type (19.14) that induces a strict weak ordering (23.7) on the pointer values.

15

Returns: The first function template returns !nullptr < x. The second function template returns !(x < nullptr).

16

Returns: The first function template returns !(nullptr < x). The second function template returns !(x < nullptr).

17

19.11.1.6 I/O [unique.ptr.io]

template<class E, class T, class Y, class D>
basic_ostream<E, T>& operator<<(basic_ostream<E, T>& os, const unique_ptr<Y, D>& p);

1 Effects: Equivalent to: os << p.get();

2 Returns: os.

3 Remarks: This function shall not participate in overload resolution unless os << p.get() is a valid expression.

19.11.2 Class bad_weak_ptr [util.smartptr.weak.bad]

namespace std {
    class bad_weak_ptr : public exception {
    public:
        bad_weak_ptr() noexcept;
    }
An exception of type `bad_weak_ptr` is thrown by the `shared_ptr` constructor taking a `weak_ptr`.

```cpp
bad_weak_ptr() noexcept;
```

    Ensures: what() returns an implementation-defined NTBS.

### 19.11.3 Class template `shared_ptr` [util.smartptr.shared]

The `shared_ptr` class template stores a pointer, usually obtained via `new`. `shared_ptr` implements semantics of shared ownership: the last remaining owner of the pointer is responsible for destroying the object, or otherwise releasing the resources associated with the stored pointer. A `shared_ptr` is said to be empty if it does not own a pointer.

```cpp
namespace std {
  template<class T> class shared_ptr {
    public:
      using element_type = remove_extent_t<T>;
      using weak_type = weak_ptr<T>;

      // 19.11.3.1, constructors
      constexpr shared_ptr() noexcept;
      constexpr shared_ptr(nullptr_t) noexcept : shared_ptr() { }
      template<class Y>
        explicit shared_ptr(Y* p);
      template<class Y, class D>
        shared_ptr(Y* p, D d);
      template<class Y, class D, class A>
        shared_ptr(Y* p, D d, A a);
      template<class D>
        shared_ptr(nullptr_t p, D d);
      template<class D, class A>
        shared_ptr(nullptr_t p, D d, A a);
      template<class Y>
        shared_ptr(const shared_ptr<Y>& r, element_type* p) noexcept;
      shared_ptr(const shared_ptr& r) noexcept;
      template<class Y>
        shared_ptr(const shared_ptr<Y>& r) noexcept;
      shared_ptr(shared_ptr&& r) noexcept;
      template<class Y>
        shared_ptr(shared_ptr<Y>&& r);
      template<class Y, class D>
        shared_ptr(unique_ptr<Y, D>&& r);

      // 19.11.3.2, destructor
      ~shared_ptr();

      // 19.11.3.3, assignment
      shared_ptr& operator=(const shared_ptr& r) noexcept;
      template<class Y>
        shared_ptr& operator=(const shared_ptr<Y>& r) noexcept;
      shared_ptr& operator=(shared_ptr& r) noexcept;
      template<class Y>
        shared_ptr& operator=(shared_ptr<Y>& r) noexcept;
      template<class Y, class D>
        shared_ptr& operator=(unique_ptr<Y, D>&& r);

      // 19.11.3.4, modifiers
      void swap(shared_ptr& r) noexcept;
      void reset() noexcept;
      template<class Y>
        void reset(Y* p);
  }
}
```
template<class Y, class D>
void reset(Y* p, D d);
template<class Y, class D, class A>
void reset(Y* p, D d, A a);

// 19.11.3.5, observers

element_type* get() const noexcept;
T& operator*() const noexcept;
T* operator->() const noexcept;
element_type& operator[](ptrdiff_t i) const;
long use_count() const noexcept;
explicit operator bool() const noexcept;
template<class U>
bool owner_before(const shared_ptr<U>& b) const noexcept;
template<class U>
bool owner_before(const weak_ptr<U>& b) const noexcept;
};

template<class T>
shared_ptr(weak_ptr<T>) -> shared_ptr<T>;
template<class T, class D>
shared_ptr(unique_ptr<T, D>) -> shared_ptr<T>;

2 Specializations of shared_ptr shall be Cpp17CopyConstructible, Cpp17CopyAssignible, and Cpp17LessThanComparible, allowing their use in standard containers. Specializations of shared_ptr shall be contextually convertible to bool, allowing their use in boolean expressions and declarations in conditions. The template parameter T of shared_ptr may be an incomplete type.

3 [Example:
    if (shared_ptr<X> px = dynamic_pointer_cast<X>(py)) {
      // do something with px
    }
   —end example]

4 For purposes of determining the presence of a data race, member functions shall access and modify only the shared_ptr and weak_ptr objects themselves and not objects they refer to. Changes in use_count() do not reflect modifications that can introduce data races.

5 For the purposes of subclause 19.11, a pointer type Y* is said to be compatible with a pointer type T* when either Y* is convertible to T* or Y is U[N] and T is cv U[].

19.11.3.1 Constructors [util.smartptr.shared.const]

In the constructor definitions below, enables shared_from_this with p, for a pointer p of type Y*, means that if Y has an unambiguous and accessible base class that is a specialization of enable_shared_from_this (19.11.6), then remove_cv_t<T>* shall be implicitly convertible to T* and the constructor evaluates the statement:

    if (p != nullptr && p->weak_this.expired())
      p->weak_this = shared_ptr<remove_cv_t<T>>(*this, const_cast<remove_cv_t<T>*>(p));

The assignment to the weak_this member is not atomic and conflicts with any potentially concurrent access to the same object (6.8.2).

constexpr shared_ptr() noexcept;

Effects: Constructs an empty shared_ptr object.

Ensures: use_count() == 0 & get() == nullptr.

template<class Y> explicit shared_ptr(Y* p);

Requires: Y shall be a complete type. The expression delete[] p, when T is an array type, or delete p, when T is not an array type, shall have well-defined behavior, and shall not throw exceptions.

Effects: When T is not an array type, constructs a shared_ptr object that owns the pointer p. Otherwise, constructs a shared_ptr that owns p and a deleter of an unspecified type that calls delete[] p. When...
T is not an array type, enables `shared_from_this` with p. If an exception is thrown, delete p is called when T is not an array type, delete[] p otherwise.

**Ensures:** use_count() == 1 & get() == p.

**Throws:** `bad_alloc`, or an implementation-defined exception when a resource other than memory could not be obtained.

**Remarks:** When T is an array type, this constructor shall not participate in overload resolution unless the expression delete[] p is well-formed and either T is U[N] and Y(*)[N] is convertible to T*, or T is U[] and Y(*)[] is convertible to T*. When T is not an array type, this constructor shall not participate in overload resolution unless the expression delete p is well-formed and Y* is convertible to T*.

```cpp
template<class Y, class D> shared_ptr(Y* p, D d);
template<class Y, class D, class A> shared_ptr(Y* p, D d, A a);
```

**Requires:** Construction of d and a deleter of type D initialized with std::move(d) shall not throw exceptions. The expression d(p) shall have well-defined behavior and shall not throw exceptions. A shall satisfy the Cpp17Allocator requirements (Table 33).

**Effects:** Constructs a `shared_ptr` object that owns the object p and the deleter d. When T is not an array type, the first and second constructors enable `shared_from_this` with p. The second and fourth constructors shall use a copy of a to allocate memory for internal use. If an exception is thrown, d(p) is called.

**Ensures:** use_count() == 1 & get() == p.

**Throws:** `bad_alloc`, or an implementation-defined exception when a resource other than memory could not be obtained.

**Remarks:** When T is an array type, this constructor shall not participate in overload resolution unless is_move_constructible_v<D> is true, the expression d(p) is well-formed, and either T is U[N] and Y(*)[N] is convertible to T*, or T is U[] and Y(*)[] is convertible to T*. When T is not an array type, this constructor shall not participate in overload resolution unless is_move_constructible_v<D> is true, the expression d(p) is well-formed, and Y* is convertible to T*.

```cpp
template<class Y> shared_ptr(const shared_ptr<Y>& r, element_type* p) noexcept;
```

**Effects:** Constructs a `shared_ptr` instance that stores p and shares ownership with r.

**Ensures:** get() == p & use_count() == r.use_count().

[Note: To avoid the possibility of a dangling pointer, the user of this constructor should ensure that p remains valid at least until the ownership group of r is destroyed. — end note]

[Note: This constructor allows creation of an empty `shared_ptr` instance with a non-null stored pointer. — end note]

```cpp
shared_ptr(const shared_ptr& r) noexcept;
```

**Remarks:** The second constructor shall not participate in overload resolution unless Y* is compatible with T*.

**Effects:** If r is empty, constructs an empty `shared_ptr` object; otherwise, constructs a `shared_ptr` object that shares ownership with r.

**Ensures:** get() == r.get() & use_count() == r.use_count().

```cpp
shared_ptr(shared_ptr&& r) noexcept;
```

**Remarks:** The second constructor shall not participate in overload resolution unless Y* is compatible with T*.

**Effects:** Move constructs a `shared_ptr` instance from r.

**Ensures:** *this shall contain the old value of r. r shall be empty. r.get() == nullptr.
template<class Y> explicit shared_ptr(const weak_ptr<Y>& r);
24 Effects: Constructs a shared_ptr object that shares ownership with r and stores a copy of the pointer stored in r. If an exception is thrown, the constructor has no effect.
25 Ensures: use_count() == r.use_count().
26 Throws: bad_weak_ptr when r.expired().
27 Remarks: This constructor shall not participate in overload resolution unless Y* is compatible with T*.

template<class Y, class D> shared_ptr(unique_ptr<Y, D>&& r);
28 Remarks: This constructor shall not participate in overload resolution unless Y* is compatible with T* and unique_ptr<Y, D>::pointer is convertible to element_type*.
29 Effects: If r.get() == nullptr, equivalent to shared_ptr(). Otherwise, if D is not a reference type, equivalent to shared_ptr(r.release(), r.get_deleter()). Otherwise, equivalent to shared_ptr(r.release(), ref(r.get_deleter())). If an exception is thrown, the constructor has no effect.

19.11.3.2 Destructor
~shared_ptr();
1 Effects:
(1.1) — If *this is empty or shares ownership with another shared_ptr instance (use_count() > 1), there are no side effects.
(1.2) — Otherwise, if *this owns an object p and a deleter d, d(p) is called.
(1.3) — Otherwise, *this owns a pointer p, and delete p is called.
2 [Note: Since the destruction of *this decreases the number of instances that share ownership with *this by one, after *this has been destroyed all shared_ptr instances that shared ownership with *this will report a use_count() that is one less than its previous value. — end note]

19.11.3.3 Assignment
shared_ptr& operator=(const shared_ptr& r) noexcept;
template<class Y> shared_ptr& operator=(const shared_ptr<Y>& r) noexcept;
1 Effects: Equivalent to shared_ptr(r).swap(*this).
2 Returns: *this.
3 [Note: The use count updates caused by the temporary object construction and destruction are not observable side effects, so the implementation may meet the effects (and the implied guarantees) via different means, without creating a temporary. In particular, in the example:

shared_ptr<int> p(new int);
shared_ptr<void> q(p);
p = p;
q = p;
both assignments may be no-ops. — end note]

shared_ptr& operator=(shared_ptr&& r) noexcept;
template<class Y> shared_ptr& operator=(shared_ptr<Y>&& r) noexcept;
4 Effects: Equivalent to shared_ptr(std::move(r)).swap(*this).
5 Returns: *this.

template<class Y, class D> shared_ptr& operator=(unique_ptr<Y, D>&& r);
6 Effects: Equivalent to shared_ptr(std::move(r)).swap(*this).
7 Returns: *this.

19.11.3.4 Modifiers
void swap(shared_ptr& r) noexcept;
1 Effects: Exchanges the contents of *this and r.
void reset() noexcept;

Effects: Equivalent to shared_ptr().swap(*this).

template<class Y> void reset(Y* p);

Effects: Equivalent to shared_ptr(p).swap(*this).

template<class Y, class D> void reset(Y* p, D d);

Effects: Equivalent to shared_ptr(p, d).swap(*this).

template<class Y, class D, class A> void reset(Y* p, D d, A a);

Effects: Equivalent to shared_ptr(p, d, a).swap(*this).

19.11.3.5 Observers

[util.smartptr.shared.obs]

element_type* get() const noexcept;

Returns: The stored pointer.

T& operator*() const noexcept;

Requires: get() != 0.

Returns: *get().

Remarks: When T is an array type or cv void, it is unspecified whether this member function is
declared. If it is declared, it is unspecified what its return type is, except that the declaration (although
not necessarily the definition) of the function shall be well-formed.

T* operator->() const noexcept;

Requires: get() != 0.

Returns: get().

Remarks: When T is an array type, it is unspecified whether this member function is declared. If it is
declared, it is unspecified what its return type is, except that the declaration (although not necessarily
the definition) of the function shall be well-formed.

element_type& operator[](ptrdiff_t i) const;

Requires: get() != 0 && i >= 0. If T is U[N], i < N.

Returns: get()[i].

Remarks: When T is not an array type, it is unspecified whether this member function is declared.
If it is declared, it is unspecified what its return type is, except that the declaration (although not
necessarily the definition) of the function shall be well-formed.

Throws: Nothing.

long use_count() const noexcept;

Returns: The number of shared_ptr objects, *this included, that share ownership with *this, or 0
when *this is empty.

Synchronization: None.

[Note: get() == nullptr does not imply a specific return value of use_count(). — end note]

[Note: weak_ptr<T>::lock() can affect the return value of use_count(). — end note]

[Note: When multiple threads can affect the return value of use_count(), the result should be treated
as approximate. In particular, use_count() == 1 does not imply that accesses through a previously
destroyed shared_ptr have in any sense completed. — end note]

explicit operator bool() const noexcept;

Returns: get() != 0.

template<class U> bool owner_before(const shared_ptr<U>& b) const noexcept;
template<class U> bool owner_before(const weak_ptr<U>& b) const noexcept;

Returns: An unspecified value such that
— \( x.\text{owner\_before}(y) \) defines a strict weak ordering as defined in 23.7;

— under the equivalence relation defined by \( \text{owner\_before} \), \( a.\text{owner\_before}(b) \&\& !b.\text{owner\_before}(a) \), two \textit{shared\_ptr} or \textit{weak\_ptr} instances are equivalent if and only if they share ownership or are both empty.

### 19.11.3.6 Creation

[util.smartptr.shared.create]

The common requirements that apply to all \texttt{make\_shared} and \texttt{allocate\_shared} overloads, unless specified otherwise, are described below.

```cpp
template<class T, ...>
shared_ptr<T> make_shared(args);

template<class T, class A, ...>
shared_ptr<T> allocate_shared(const A& a, args);
```

**Requires:** \( A \) shall satisfy the \texttt{Cpp17\_Allocator} requirements (Table 33).

**Effects:** Allocates memory for an object of type \( T \) (or \( U[N] \) when \( T \) is \( U[] \), where \( N \) is determined from \( \text{args} \) as specified by the concrete overload). The object is initialized from \( \text{args} \) as specified by the concrete overload. The \texttt{allocate\_shared} templates use a copy of \( a \) (rebound for an unspecified \texttt{value\_type}) to allocate memory. If an exception is thrown, the functions have no effect.

**Returns:** A \texttt{shared\_ptr} instance that stores and owns the address of the newly constructed object.

**Ensures:** \( r.\text{get()} != 0 \&\& r.\text{use\_count()} == 1 \), where \( r \) is the return value.

**Throws:** \texttt{bad\_alloc}, or an exception thrown from \texttt{allocate} or from the initialization of the object.

**Remarks:**

— (7.1) Implementations should perform no more than one memory allocation. \[\text{Note: This provides efficiency equivalent to an intrusive smart pointer. \quad \text{- end note}}\]

— (7.2) When an object of an array type \( U \) is specified to have an initial value of \( u \) (of the same type), this shall be interpreted to mean that each array element of the object has as its initial value the corresponding element from \( u \).

— (7.3) When an object of an array type is specified to have a default initial value, this shall be interpreted to mean that each array element of the object has a default initial value.

— (7.4) When a (sub)object of a non-array type \( U \) is specified to have an initial value of \( v \), or \( U(\ldots) \), where \( \ldots \) is a list of constructor arguments, \texttt{make\_shared} shall initialize this (sub)object via the expression \( \texttt{::new}(p) \ U(v) \) or \( \texttt{::new}(p) \ U(\ldots) \) respectively, where \( p \) has type \texttt{void*} and points to storage suitable to hold an object of type \( U \).

— (7.5) When a (sub)object of a non-array type \( U \) is specified to have an initial value of \( v \), or \( U(\ldots) \), where \( \ldots \) is a list of constructor arguments, \texttt{allocate\_shared} shall initialize this (sub)object via the expression

---

**§ 19.11.3.6 596**
[Note: These functions will typically allocate more memory than sizeof(T) to allow for internal bookkeeping structures such as reference counts. — end note]

```cpp
template<class T, class... Args>
shared_ptr<T> make_shared(Args&&... args); // T is not array

template<class T, class A, class... Args>
shared_ptr<T> allocate_shared(const A& a, Args&&... args); // T is not array
```

Returns: A shared_ptr to an object of type T with an initial value T(forward<Args>(args)...)..

Remarks: These overloads shall only participate in overload resolution when T is not an array type. The shared_ptr constructors called by these functions enable shared_from_this with the address of the newly constructed object of type T.

[Example:]
```
shared_ptr<int> p = make_shared<int>(); // shared_ptr to int()
shared_ptr<vector<int>> q = make_shared<vector<int>>(16, 1);
    // shared_ptr to vector of 16 elements with value 1
```

```cpp
template<class T> shared_ptr<T> make_shared(); // T is U[N]

template<class T, class A>
shared_ptr<T> allocate_shared(const A& a); // T is U[N]
```

Returns: A shared_ptr to an object of type U[N] with a default initial value, where U is remove_extent_t<T>.

Remarks: These overloads shall only participate in overload resolution when T is of the form U[].

[Example:]
```
shared_ptr<double[]> p = make_shared<double[]>(1024);
    // shared_ptr to a value-initialized double[1024]
shared_ptr<double[][]> q = make_shared<double[][]>(6);
    // shared_ptr to a value-initialized double[6][2][2]
```

```cpp
template<class T>
shared_ptr<T> make_shared(size_t N);

template<class T, class A, class... Args>
shared_ptr<T> allocate_shared(const A& a, size_t N, Args&&... args); // T is not array
```

Returns: A shared_ptr to an object of type U[N] with an initial value of u.

Remarks: These overloads shall only participate in overload resolution when T is of the form U[].

[Example:]
```
shared_ptr<double> p = make_shared<double[](1024, 1.0);
```
// shared_ptr to a double[1024], where each element is 1.0
shared_ptr<double[1024]> q = make_shared<double[1024]>({1.0, 0.0});
// shared_ptr to a double[6][2], where each double[2] element is {1.0, 0.0}
// shared_ptr to a vector<int>[4], where each vector has contents {1, 2}
— end example

template<class T>
shared_ptr<T> make_shared(const remove_extent_t<T>& u); // T is U[N]
template<class T, class A>
shared_ptr<T> allocate_shared(const A& a,
const remove_extent_t<T>& u); // T is U[N]
20
Returns: A shared_ptr to an object of type T, where each array element of type remove_extent_t<T>
has an initial value of u.
21
Remarks: These overloads shall only participate in overload resolution when T is of the form U[N].
22
[Example:
shared_ptr<double[1024]> p = make_shared<double[1024]>({1.0});
// shared_ptr to a double[1024], where each element is 1.0
shared_ptr<double[6][2]> q = make_shared<double[6][2]>({1.0, 0.0});
// shared_ptr to a double[6][2], where each double[2] element is {1.0, 0.0}
// shared_ptr to a vector<int>[4], where each vector has contents {1, 2}
— end example]

19.11.3.7 Comparison [util.smartptr.shared.cmp]
template<class T, class U>
bool operator==(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;
1
Returns: a.get() == b.get().
template<class T, class U>
bool operator<(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;
2
Returns: less<>()(a.get(), b.get()).
3
[Note: Defining a comparison function allows shared_ptr objects to be used as keys in associative
containers. — end note]
template<class T>
bool operator==(const shared_ptr<T>& a, nullptr_t) noexcept;
template<class T>
bool operator==(nullptr_t, const shared_ptr<T>& a) noexcept;
4
Returns: !a.
template<class T>
bool operator!=(const shared_ptr<T>& a, nullptr_t) noexcept;
template<class T>
bool operator!=(nullptr_t, const shared_ptr<T>& a) noexcept;
5
Returns: (bool)a.
template<class T>
bool operator<(const shared_ptr<T>& a, nullptr_t) noexcept;
template<class T>
bool operator<(nullptr_t, const shared_ptr<T>& a) noexcept;
6
Returns: The first function template returns
less<typename shared_ptr<T>::element_type*>(a.get(), nullptr)
The second function template returns
less<typename shared_ptr<T>::element_type*>(nullptr, a.get())
template<class T>
bool operator>(const shared_ptr<T>& a, nullptr_t) noexcept;

template<class T>
bool operator>(nullptr_t, const shared_ptr<T>& a) noexcept;

Returns: The first function template returns nullptr < a. The second function template returns a < nullptr.

template<class T>
bool operator<=(const shared_ptr<T>& a, nullptr_t) noexcept;

template<class T>
bool operator<=(nullptr_t, const shared_ptr<T>& a) noexcept;

Returns: The first function template returns !(nullptr < a). The second function template returns !(a < nullptr).

template<class T>
bool operator>=(const shared_ptr<T>& a, nullptr_t) noexcept;

template<class T>
bool operator>=(nullptr_t, const shared_ptr<T>& a) noexcept;

Returns: The first function template returns !(a < nullptr). The second function template returns !(nullptr < a).

19.11.3.8 Specialized algorithms

template<class T>
void swap(shared_ptr<T>& a, shared_ptr<T>& b) noexcept;

Effects: Equivalent to a.swap(b).

19.11.3.9 Casts

template<class T, class U>
shared_ptr<T> static_pointer_cast(const shared_ptr<U>& r) noexcept;

Requires: The expression static_cast<T*>((U*)nullptr) shall be well-formed.

Returns:
shared_ptr<T>(r, static_cast<typename shared_ptr<T>::element_type*>(r.get()))

[Note: The seemingly equivalent expression shared_ptr<T>(static_cast<T*>(r.get())) will eventually result in undefined behavior, attempting to delete the same object twice. —end note]

template<class T, class U>
shared_ptr<T> dynamic_pointer_cast(const shared_ptr<U>& r) noexcept;

Requires: The expression dynamic_cast<T*>((U*)nullptr) shall be well-formed. The expression dynamic_cast<typename shared_ptr<T>::element_type*>(r.get()) shall be well-formed and shall have well-defined behavior.

Returns:
(5.1) When dynamic_cast<typename shared_ptr<T>::element_type*>(r.get()) returns a non-null value p, shared_ptr<T>(r, p).
(5.2) Otherwise, shared_ptr<T>().

[Note: The seemingly equivalent expression shared_ptr<T>(dynamic_cast<T*>(r.get())) will eventually result in undefined behavior, attempting to delete the same object twice. —end note]

template<class T, class U>
shared_ptr<T> const_pointer_cast(const shared_ptr<U>& r) noexcept;

Requires: The expression const_cast<T*>((U*)nullptr) shall be well-formed.

Returns:
shared_ptr<T>(r, const_cast<typename shared_ptr<T>::element_type*>(r.get()))

[Note: The seemingly equivalent expression shared_ptr<T>(const_cast<T*>(r.get())) will eventually result in undefined behavior, attempting to delete the same object twice. —end note]
template<class T, class U>
    shared_ptr<T> reinterpret_pointer_cast(const shared_ptr<U>& r) noexcept;

10  Requires: The expression reinterpret_cast<T*>(U*)(nullptr) shall be well-formed.

11  Returns:
    shared_ptr<T>(r, reinterpret_cast<typename shared_ptr<T>::element_type*>(r.get()))

12  [Note: The seemingly equivalent expression shared_ptr<T>(reinterpret_cast<T*>(r.get())) will
eventually result in undefined behavior, attempting to delete the same object twice. — end note]

19.11.3.10 get_deleter

template<class D, class T>
D* get_deleter(const shared_ptr<T>& p) noexcept;

1  Returns: If p owns a deleter d of type cv-unqualified D, returns addressof(d); otherwise returns
nullptr. The returned pointer remains valid as long as there exists a shared_ptr instance that owns
D. [Note: It is unspecified whether the pointer remains valid longer than that. This can happen if the
implementation doesn’t destroy the deleter until all weak_ptr instances that share ownership with p
have been destroyed. — end note]

19.11.3.11 I/O

template<class E, class T, class Y>
basic_ostream<E, T>& operator<<(basic_ostream<E, T>& os, const shared_ptr<Y>& p);

1  Effects: As if by: os << p.get();

2  Returns: os.

19.11.4 Class template weak_ptr

The weak_ptr class template stores a weak reference to an object that is already managed by a shared_ptr.
To access the object, a weak_ptr can be converted to a shared_ptr using the member function lock.

namespace std {
    template<class T> class weak_ptr {
    public:
        using element_type = remove_extent_t<T>;

        // 19.11.4.1, constructors
        constexpr weak_ptr() noexcept;
        template<class Y>
            weak_ptr(const shared_ptr<Y>& r) noexcept;
        template<class Y>
            weak_ptr(const weak_ptr<Y>& r) noexcept;
        template<class Y>
            weak_ptr(weak_ptr<Y>&& r) noexcept;

        // 19.11.4.2, destructor
        ~weak_ptr();

        // 19.11.4.3, assignment
        weak_ptr& operator=(const weak_ptr& r) noexcept;
        template<class Y>
            weak_ptr& operator=(const weak_ptr<Y>& r) noexcept;
        template<class Y>
            weak_ptr& operator=(const shared_ptr<Y>& r) noexcept;
        template<class Y>
            weak_ptr& operator=(weak_ptr<Y>&& r) noexcept;

        // 19.11.4.4, modifiers
        void swap(weak_ptr& r) noexcept;
        void reset() noexcept;
    } }
// 19.11.4.5, observers
long use_count() const noexcept;
bool expired() const noexcept;
shared_ptr<T> lock() const noexcept;

template<class U>
  bool owner_before(const shared_ptr<U>& a, const shared_ptr<U>& b) const noexcept;

// 19.11.4.6, specialized algorithms
void swap(weak_ptr<T>& a, weak_ptr<T>& b) noexcept;

Specializations of weak_ptr shall be Cpp17CopyConstructible and Cpp17CopyAssignable, allowing their use in standard containers. The template parameter T of weak_ptr may be an incomplete type.

19.11.4.1 Constructors

constexpr weak_ptr() noexcept;

Effects: Constructs an empty weak_ptr object.

Ensures: use_count() == 0.

weak_ptr(const weak_ptr& r) noexcept;
template<class Y> weak_ptr(const weak_ptr<Y>& r) noexcept;
template<class Y> weak_ptr(const shared_ptr<Y>& r) noexcept;

Remarks: The second and third constructors shall not participate in overload resolution unless Y* is compatible with T*.

Effects: If r is empty, constructs an empty weak_ptr object; otherwise, constructs a weak_ptr object that shares ownership with r and stores a copy of the pointer stored in r.

Ensures: use_count() == r.use_count().

weak_ptr(weak_ptr&& r) noexcept;
template<class Y> weak_ptr(weak_ptr<Y>&& r) noexcept;

Remarks: The second constructor shall not participate in overload resolution unless Y* is compatible with T*.

Effects: Move constructs a weak_ptr instance from r.

Ensures: *this shall contain the old value of r. r shall be empty. r.use_count() == 0.

19.11.4.2 Destructor

~weak_ptr();

Effects: Destroys this weak_ptr object but has no effect on the object its stored pointer points to.

19.11.4.3 Assignment

weak_ptr& operator=(const weak_ptr& r) noexcept;
template<class Y> weak_ptr& operator=(const weak_ptr<Y>& r) noexcept;
template<class Y> weak_ptr& operator=(const shared_ptr<Y>& r) noexcept;

Effects: Equivalent to weak_ptr(r).swap(*this).

Remarks: The implementation may meet the effects (and the implied guarantees) via different means, without creating a temporary object.

Returns: *this.
weak_ptr& operator=(weak_ptr&& r) noexcept;
template<class Y> weak_ptr& operator=(weak_ptr<Y>&& r) noexcept;

Effects: Equivalent to weak_ptr(std::move(r)).swap(*this).
Returns: *this.

19.11.4.4 Modifiers

void swap(weak_ptr& r) noexcept;
Effects: Exchanges the contents of *this and r.
void reset() noexcept;
Effects: Equivalent to weak_ptr().swap(*this).

19.11.4.5 Observers

long use_count() const noexcept;
Returns: 0 if *this is empty; otherwise, the number of shared_ptr instances that share ownership with *this.

bool expired() const noexcept;
Returns: use_count() == 0.

shared_ptr<T> lock() const noexcept;
Returns: expired() ? shared_ptr<T>(). : shared_ptr<T>(*this), executed atomically.

template<class U> bool owner_before(const shared_ptr<U>& b) const noexcept;
template<class U> bool owner_before(const weak_ptr<U>& b) const noexcept;

Returns: An unspecified value such that
— x.owner_before(y) defines a strict weak ordering as defined in 23.7;
— under the equivalence relation defined by owner_before, !a.owner_before(b) && !b.owner_before(a), two shared_ptr or weak_ptr instances are equivalent if and only if they share ownership or are both empty.

19.11.4.6 Specialized algorithms

template<class T>
void swap(weak_ptr<T>& a, weak_ptr<T>& b) noexcept;
Effects: Equivalent to a.swap(b).

19.11.5 Class template owner_less

The class template owner_less allows ownership-based mixed comparisons of shared and weak pointers.

namespace std {
  template<class T = void> struct owner_less;

  template<class T> struct owner_less<shared_ptr<T>> {
    bool operator()(const shared_ptr<T>&, const shared_ptr<T>&) const noexcept;
    bool operator()(const shared_ptr<T>&, const weak_ptr<T>&) const noexcept;
    bool operator()(const weak_ptr<T>&, const shared_ptr<T>&) const noexcept;
  };

  template<class T> struct owner_less<weak_ptr<T>> {
    bool operator()(const weak_ptr<T>&, const weak_ptr<T>&) const noexcept;
    bool operator()(const shared_ptr<T>&, const weak_ptr<T>&) const noexcept;
    bool operator()(const weak_ptr<T>&, const shared_ptr<T>&) const noexcept;
  };

  template<class T, class U>
  bool operator()(const shared_ptr<T>&, const shared_ptr<U>&) const noexcept;

§ 19.11.5 602
template<class T, class U>
  bool operator()(const shared_ptr<T>&, const weak_ptr<U>&) const noexcept;

operator()(x, y) shall return x.owner_before(y). [Note: Note that
(2.1) — operator() defines a strict weak ordering as defined in 23.7;
(2.2) — under the equivalence relation defined by operator(), !operator()(a, b) && !operator()(b, a),
two shared_ptr or weak_ptr instances are equivalent if and only if they share ownership or are both empty.
—end note]
shared_ptr<T> shared_from_this();
shared_ptr<T const> shared_from_this() const;

Returns: shared_ptr<T>{weak_this}.

weak_ptr<T> weak_from_this() noexcept;
weak_ptr<T const> weak_from_this() const noexcept;

Returns: weak_this.

19.11.7 Smart pointer hash support
[util.smartptr.hash]

template<class T, class D> struct hash<unique_ptr<T, D>>;

Letting UP be unique_ptr<T,D>, the specialization hash<UP> is enabled (19.14.16) if and only if hash<typename UP::pointer> is enabled. When enabled, for an object p of type UP, hash<UP>()(p) shall evaluate to the same value as hash<typename UP::pointer>()(p.get()). The member functions are not guaranteed to be noexcept.

template<class T> struct hash<shared_ptr<T>>;

For an object p of type shared_ptr<T>, hash<shared_ptr<T>>()(p) shall evaluate to the same value as hash<typename shared_ptr<T>::element_type*>(p.get()).

19.11.8 Atomic specializations for smart pointers
[util.smartptr.atomic]
The library provides partial specializations of the atomic template for shared-ownership smart pointers. The behavior of all operations is as specified in 29.7, unless specified otherwise. The template parameter T of these partial specializations may be an incomplete type.

All changes to an atomic smart pointer in this subclause, and all associated use_count increments, are guaranteed to be performed atomically. Associated use_count decrements are sequenced after the atomic operation, but are not required to be part of it. Any associated deletion and deallocation are sequenced after the atomic update step and are not part of the atomic operation. [Note: If the atomic operation uses locks, locks acquired by the implementation will be held when any use_count adjustments are performed, and will not be held when any destruction or deallocation resulting from this is performed. —end note]

19.11.8.1 Atomic specialization for shared_ptr
[util.smartptr.atomic.shared]

namespace std {

    template<class T> struct atomic<shared_ptr<T>> { 
    using value_type = shared_ptr<T>;
    static constexpr bool is_always_lock_free = implementation-defined;

    bool is_lock_free() const noexcept;
    void store(shared_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;
    shared_ptr<T> load(memory_order order = memory_order::seq_cst) const noexcept;
    operator shared_ptr<T>() const noexcept;

    shared_ptr<T> exchange(shared_ptr<T> desired,
                           memory_order order = memory_order::seq_cst) noexcept;

    bool compare_exchange_weak(shared_ptr<T>&& expected, shared_ptr<T> desired,
                                memory_order success, memory_order failure) noexcept;
    bool compare_exchange_strong(shared_ptr<T>&& expected, shared_ptr<T> desired,
                                 memory_order success, memory_order failure) noexcept;

    bool compare_exchange_weak(shared_ptr<T>& expected, shared_ptr<T> desired,
                                memory_order order = memory_order::seq_cst) noexcept;
    bool compare_exchange_strong(shared_ptr<T>& expected, shared_ptr<T> desired,
                                   memory_order order = memory_order::seq_cst) noexcept;

    constexpr atomic() noexcept = default;
    atomic(shared_ptr<T> desired) noexcept;
    atomic(const atomic&) = delete;
    void operator=(const atomic&) = delete;
    void operator=(shared_ptr<T> desired) noexcept;

};

§ 19.11.8.1 604
private:
    shared_ptr<T> p; // exposition only
};

constexpr atomic() noexcept = default;

Effects: Initializes p{}.

atomic(shared_ptr<T> desired) noexcept;

Effects: Initializes the object with the value desired. Initialization is not an atomic operation (6.8.2). [Note: It is possible to have an access to an atomic object A race with its construction, for example, by communicating the address of the just-constructed object A to another thread via memory-order::relaxed operations on a suitable atomic pointer variable, and then immediately accessing A in the receiving thread. This results in undefined behavior. — end note]

void store(shared_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;

Requires: The order argument shall not be memory_order::consume, memory_order::acquire, nor memory_order::acq_rel.

Effects: Atomically replaces the value pointed to by this with the value of desired as if by p.swap(desired). Memory is affected according to the value of order.

void operator=(shared_ptr<T> desired) noexcept;

Effects: Equivalent to store(desired).

shared_ptr<T> load(memory_order order = memory_order::seq_cst) const noexcept;

Requires: order shall not be memory_order::release nor memory_order::acq_rel.

Effects: Memory is affected according to the value of order.

Returns: Atomically returns p.

operator shared_ptr<T>() const noexcept;

Effects: Equivalent to: return load();

shared_ptr<T> exchange(shared_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;

Effects: Atomically replaces p with desired as if by p.swap(desired). Memory is affected according to the value of order. This is an atomic read-modify-write operation (6.8.2.1).

Returns: Atomically returns the value of p immediately before the effects.

bool compare_exchange_weak(shared_ptr<T>& expected, shared_ptr<T> desired, memory_order success, memory_order failure) noexcept;

bool compare_exchange_strong(shared_ptr<T>& expected, shared_ptr<T> desired, memory_order success, memory_order failure) noexcept;

Requires: failure shall not be memory_order::release nor memory_order::acq_rel.

Effects: If p is equivalent to expected, assigns desired to p and has synchronization semantics corresponding to the value of success, otherwise assigns p to expected and has synchronization semantics corresponding to the value of failure.

Returns: true if p was equivalent to expected, false otherwise.

Remarks: Two shared_ptr objects are equivalent if they store the same pointer value and either share ownership, or both are empty. The weak form may fail spuriously. See 29.7.1.

If the operation returns true, expected is not accessed after the atomic update and the operation is an atomic read-modify-write operation (6.8.2) on the memory pointed to by this. Otherwise, the operation is an atomic load operation on that memory, and expected is updated with the existing value read from the atomic object in the attempted atomic update. The use_count update corresponding to the write to expected is part of the atomic operation. The write to expected itself is not required to be part of the atomic operation.
`bool compare_exchange_weak(shared_ptr<T>& expected, shared_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;`  

**Effects:** Equivalent to:

```
return compare_exchange_weak(expected, desired, order, fail_order);
```

where `fail_order` is the same as `order` except that a value of `memory_order::acq_rel` shall be replaced by the value `memory_order::acquire` and a value of `memory_order::release` shall be replaced by the value `memory_order::relaxed`.

`bool compare_exchange_strong(shared_ptr<T>& expected, shared_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;`  

**Effects:** Equivalent to:

```
return compare_exchange_strong(expected, desired, order, fail_order);
```

where `fail_order` is the same as `order` except that a value of `memory_order::acq_rel` shall be replaced by the value `memory_order::acquire` and a value of `memory_order::release` shall be replaced by the value `memory_order::relaxed`.

### 19.11.8.2 Atomic specialization for `weak_ptr`

```cpp
namespace std {
    template<class T> struct atomic<weak_ptr<T>> {
        using value_type = weak_ptr<T>;
        static constexpr bool is_always_lock_free = implementation-defined;

        bool is_lock_free() const noexcept;
        void store(weak_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;
        weak_ptr<T> load(memory_order order = memory_order::seq_cst) const noexcept;
        operator weak_ptr<T>() const noexcept;
        weak_ptr<T> exchange(weak_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;
        bool compare_exchange_weak(weak_ptr<T>& expected, weak_ptr<T> desired, memory_order success, memory_order failure) noexcept;
        bool compare_exchange_strong(weak_ptr<T>& expected, weak_ptr<T> desired, memory_order success, memory_order failure) noexcept;
    };

    constexpr atomic() noexcept = default;
    atomic(weak_ptr<T> desired) noexcept;
    atomic(const atomic&) = delete;
    void operator=(const atomic&) = delete;
    void operator=(weak_ptr<T> desired) noexcept;

private:
    weak_ptr<T> p;        // exposition only
};
```

**Constexpr atomic() noexcept = default;**  

**Effects:** Initializes `p`.

`atomic(weak_ptr<T> desired) noexcept;`  

**Effects:** Initializes the object with the value `desired`. Initialization is not an atomic operation (6.8.2). [Note: It is possible to have an access to an atomic object `A` race with its construction, for example, by communicating the address of the just-constructed object `A` to another thread via `memory_order::relaxed` operations on a suitable atomic pointer variable, and then immediately accessing `A` in the receiving thread. This results in undefined behavior. — end note]
void store(weak_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;

Requires: The order argument shall not be memory_order::consume, memory_order::acquire, nor memory_order::acq_rel.

Effects: Atomically replaces the value pointed to by this with the value of desired as if by p.swap(desired). Memory is affected according to the value of order.

void operator=(weak_ptr<T> desired) noexcept;

Effects: Equivalent to store(desired).

weak_ptr<T> load(memory_order order = memory_order::seq_cst) const noexcept;

Requires: order shall not be memory_order::release nor memory_order::acq_rel.

Effects: Memory is affected according to the value of order.

Returns: Atomically returns p.

operator weak_ptr<T>() const noexcept;

Effects: Equivalent to: return load();

weak_ptr<T> exchange(weak_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;

Effects: Atomically replaces p with desired as if by p.swap(desired). Memory is affected according to the value of order. This is an atomic read-modify-write operation (6.8.2.1).

Returns: Atomically returns the value of p immediately before the effects.

bool compare_exchange_weak(weak_ptr<T>& expected, weak_ptr<T> desired,
memory_order success, memory_order failure) noexcept;

Comparison_strong(weak_ptr<T>& expected, weak_ptr<T> desired,
memory_order success, memory_order failure) noexcept;

Requires: failure shall not be memory_order::release nor memory_order::acq_rel.

Effects: If p is equivalent to expected, assigns desired to p and has synchronization semantics corresponding to the value of success, otherwise assigns p to expected and has synchronization semantics corresponding to the value of failure.

Returns: true if p was equivalent to expected, false otherwise.

Remarks: Two weak_ptr objects are equivalent if they store the same pointer value and either share ownership, or both are empty. The weak form may fail spuriously. See 29.7.1.

If the operation returns true, expected is not accessed after the atomic update and the operation is an atomic read-modify-write operation (6.8.2) on the memory pointed to by this. Otherwise, the operation is an atomic load operation on that memory, and expected is updated with the existing value read from the atomic object in the attempted atomic update. The use_count update corresponding to the write to expected is part of the atomic operation. The write to expected itself is not required to be part of the atomic operation.

bool compare_exchange_weak(weak_ptr<T>& expected, weak_ptr<T> desired,
memory_order order = memory_order::seq_cst) noexcept;

Effects: Equivalent to:
return compare_exchange_weak(expected, desired, order, fail_order);
where fail_order is the same as order except that a value of memory_order::acq_rel shall be replaced by the value memory_order::acquire and a value of memory_order::release shall be replaced by the value memory_order::relaxed.

bool compare_exchange_strong(weak_ptr<T>& expected, weak_ptr<T> desired,
memory_order order = memory_order::seq_cst) noexcept;

Effects: Equivalent to:
return compare_exchange_strong(expected, desired, order, fail_order);
where \texttt{fail\_order} is the same as \texttt{order} except that a value of \texttt{memory\_order::acq\_rel} shall be replaced by the value \texttt{memory\_order::acquire} and a value of \texttt{memory\_order::release} shall be replaced by the value \texttt{memory\_order::relaxed}.

19.12 Memory resources

19.12.1 Header \texttt{<memory\_resource> synopsis}

namespace std::pmr {
    // 19.12.2, class memory\_resource
    class memory\_resource;

    bool operator==(const memory\_resource& a, const memory\_resource& b) noexcept;
    bool operator!=(const memory\_resource& a, const memory\_resource& b) noexcept;

    // 19.12.3, class template polymorphic\_allocator
    template<class Tp> class polymorphic\_allocator;

    template<class T1, class T2>
    bool operator==(const polymorphic\_allocator<T1>& a, const polymorphic\_allocator<T2>& b) noexcept;
    template<class T1, class T2>
    bool operator!=(const polymorphic\_allocator<T1>& a, const polymorphic\_allocator<T2>& b) noexcept;

    // 19.12.4, global memory\_resources
    memory\_resource* new\_delete\_resource() noexcept;
    memory\_resource* null\_memory\_resource() noexcept;
    memory\_resource* set\_default\_resource(memory\_resource* r) noexcept;
    memory\_resource* get\_default\_resource() noexcept;

    // 19.12.5, pool\_resource classes
    struct pool\_options;
    class synchronized\_pool\_resource;
    class unsynchronized\_pool\_resource;
    class monotonic\_buffer\_resource;
}

19.12.2 Class memory\_resource

The \texttt{memory\_resource} class is an abstract interface to an unbounded set of classes encapsulating memory resources.

namespace std::pmr {
    class memory\_resource {
        static constexpr size\_t max\_align = alignof(max\_align\_t);  // exposition only

        public:
            memory\_resource(const memory\_resource&) = default;
            virtual ~memory\_resource();

            memory\_resource& operator=(const memory\_resource&) = default;

            [[noderedcard]] void* allocate(size\_t bytes, size\_t alignment = max\_align);
            void deallocate(void* p, size\_t bytes, size\_t alignment = max\_align);

            bool is\_equal(const memory\_resource& other) const noexcept;

        private:
            virtual void* do\_allocate(size\_t bytes, size\_t alignment) = 0;
            virtual void do\_deallocate(void* p, size\_t bytes, size\_t alignment) = 0;

            virtual bool do\_is\_equal(const memory\_resource& other) const noexcept = 0;
    }
}
19.12.2.1 memory_resource public member functions

~memory_resource();

Effects: Destroys this memory_resource.
[[nodiscard]] void* allocate(size_t bytes, size_t alignment = max_align);

Effects: Equivalent to: return do_allocate(bytes, alignment);
void deallocate(void* p, size_t bytes, size_t alignment = max_align);

Effects: Equivalent to: do_deallocate(p, bytes, alignment).
bool is_equal(const memory_resource& other) const noexcept;

Effects: Equivalent to: return do_is_equal(other);

19.12.2.2 memory_resource private virtual member functions

virtual void* do_allocate(size_t bytes, size_t alignment) = 0;

Requires: alignment shall be a power of two.
Returns: A derived class shall implement this function to return a pointer to allocated storage (6.6.4.4.1) with a size of at least bytes, aligned to the specified alignment.
Throws: A derived class implementation shall throw an appropriate exception if it is unable to allocate memory with the requested size and alignment.

virtual void do_deallocate(void* p, size_t bytes, size_t alignment) = 0;

Requires: p shall have been returned from a prior call to allocate(bytes, alignment) on a memory resource equal to *this, and the storage at p shall not yet have been deallocated.
Effects: A derived class shall implement this function to dispose of allocated storage.
Throws: Nothing.

virtual bool do_is_equal(const memory_resource& other) const noexcept = 0;

Returns: A derived class shall implement this function to return true if memory allocated from this can be deallocated from other and vice-versa, otherwise false. [Note: The most-derived type of other might not match the type of this. For a derived class D, an implementation of this function could immediately return false if dynamic_cast<const D*>(other) == nullptr. —end note]

19.12.2.3 memory_resource equality

bool operator==(const memory_resource& a, const memory_resource& b) noexcept;

Returns: &a == &b || a.is_equal(b).

bool operator!=(const memory_resource& a, const memory_resource& b) noexcept;

Returns: !(a == b).

19.12.3 Class template polymorphic_allocator

A specialization of class template pmr::polymorphic_allocator satisfies the Cpp17Allocator requirements (Table 33). Constructed with different memory resources, different instances of the same specialization of pmr::polymorphic_allocator can exhibit entirely different allocation behavior. This runtime polymorphism allows objects that use polymorphic_allocator to behave as if they used different allocator types at run time even though they use the same static allocator type.

namespace std::pmr {
    template<class Tp> class polymorphic_allocator {
        memory_resource* memory_rsrc; // exposition only

        public:
            using value_type = Tp;

            using value_type = Tp;

            // 19.12.3.1, constructors
            polymorphic_allocator() noexcept;
            polymorphic_allocator(memory_resource* r);

§ 19.12.3 609
polymorphic_allocator(const polymorphic_allocator& other) = default;

template<class U>
polymorphic_allocator(const polymorphic_allocator<U>& other) noexcept;

polymorphic_allocator& operator=(const polymorphic_allocator& rhs) = delete;

// 19.12.3.2, member functions
[[nodiscard]] Tp* allocate(size_t n);
void deallocate(Tp* p, size_t n);

template<class T, class... Args>
void construct(T* p, Args&&... args);

template<class T1, class T2, class... Args1, class... Args2>
void construct(pair<T1, T2>* p, piecewise_construct_t,
    tuple<Args1...> x, tuple<Args2...> y);

template<class T1, class T2, class U, class V>
void construct(pair<T1, T2>* p, const pair<U, V>& pr);

template<class T1, class T2, class U, class V>
void construct(pair<T1, T2>* p, pair<U, V>&& pr);

template<class T>
void destroy(T* p);

polymorphic_allocator select_on_container_copy_construction() const;

memory_resource* resource() const;
}
template<class T, class... Args>
void construct(T* p, Args&&... args);

Requires: Uses-allocator construction of T with allocator *this (see 19.10.8.2) and constructor arguments std::forward<Args>(args)... is well-formed. [Note: Uses-allocator construction is always well-formed for types that do not use allocators. — end note]

Effects: Construct a T object in the storage whose address is represented by p by uses-allocator construction with allocator *this and constructor arguments std::forward<Args>(args)....

Throws: Nothing unless the constructor for T throws.

Remarks: This function shall not participate in overload resolution if T is a specialization of pair.

template<class T1, class T2, class... Args1, class... Args2>
void construct(pair<T1, T2>* p, piecewise_construct_t, tuple<Args1...> x, tuple<Args2...> y);

[Note: This member function and the construct member functions that follow are overloads for piecewise construction of pairs (19.4.2). — end note]

Effects: Let xprime be a tuple constructed from x according to the appropriate rule from the following list. [Note: The following description can be summarized as constructing a pair<T1, T2> object in the storage whose address is represented by p, as if by separate uses-allocator construction with allocator *this (19.10.8.2) of p->first using the elements of x and p->second using the elements of y. — end note]

— (10.1) If uses_allocator_v<T1,polymorphic_allocator> is false and is_constructible_v<T1,Args1...> is true, then xprime is x.

— (10.2) Otherwise, if uses_allocator_v<T1,polymorphic_allocator> is true and is_constructible_v<T1,allocator_arg_t,polymorphic_allocator,Args1...> is true, then xprime is tuple_cat(make_tuple(allocator_arg, *this), std::move(x)).

— (10.3) Otherwise, if uses_allocator_v<T1,polymorphic_allocator> is true and is_constructible_v<T1,Args1...,polymorphic_allocator> is true, then xprime is tuple_cat(std::move(x), make_tuple(*this)).

— (10.4) Otherwise the program is ill formed.

Let yprime be a tuple constructed from y according to the appropriate rule from the following list:

— (10.5) If uses_allocator_v<T2,polymorphic_allocator> is false and is_constructible_v<T2,Args2...> is true, then yprime is y.

— (10.6) Otherwise, if uses_allocator_v<T2,polymorphic_allocator> is true and is_constructible_v<T2,allocator_arg_t,polymorphic_allocator,Args2...> is true, then yprime is tuple_cat(make_tuple(allocator_arg, *this), std::move(y)).

— (10.7) Otherwise, if uses_allocator_v<T2,polymorphic_allocator> is true and is_constructible_v<T2,Args2...,polymorphic_allocator> is true, then yprime is tuple_cat(std::move(y), make_tuple(*this)).

— (10.8) Otherwise the program is ill formed.

Then, using piecewise_construct, xprime, and yprime as the constructor arguments, this function constructs a pair<T1, T2> object in the storage whose address is represented by p.

template<class T1, class T2>
void construct(pair<T1, T2>* p);

Effects: Equivalent to:

construct(p, piecewise_construct, tuple<>(), tuple<>());

template<class T1, class T2, class U, class V>
void construct(pair<T1, T2>* p, U& x, V& y);

Effects: Equivalent to:
construct(p, piecewise_construct,
  forward_as_tuple(std::forward<U>(x)),
  forward_as_tuple(std::forward<V>(y)));

template<class T1, class T2, class U, class V>
void construct(pair<T1, T2>* p, const pair<U, V>& pr);

Effects: Equivalent to:
  construct(p, piecewise_construct,
    forward_as_tuple(pr.first),
    forward_as_tuple(pr.second));

template<class T1, class T2, class U, class V>
void construct(pair<T1, T2>* p, pair<U, V>&& pr);

Effects: Equivalent to:
  construct(p, piecewise_construct,
    forward_as_tuple(std::forward<U>(pr.first)),
    forward_as_tuple(std::forward<V>(pr.second)));

template<class T>
void destroy(T* p);

Effects: As if by p->~T().

polymorphic_allocator select_on_container_copy_construction() const;

Returns: polymorphic_allocator().

[Note: The memory resource is not propagated. —end note]

memory_resource* resource() const;

Returns: memory_rsrc.

19.12.3.3 polymorphic_allocator equality [mem.poly.allocator.eq]

template<class T1, class T2>
bool operator==(const polymorphic_allocator<T1>& a,
  const polymorphic_allocator<T2>& b) noexcept;

Returns: *a.resource() == *b.resource().

template<class T1, class T2>
bool operator!=(const polymorphic_allocator<T1>& a,
  const polymorphic_allocator<T2>& b) noexcept;

Returns: !(a == b).

19.12.4 Access to program-wide memory_resource objects [mem.res.global]

memory_resource* new_delete_resource() noexcept;

Returns: A pointer to a static-duration object of a type derived from memory_resource that can
serve as a resource for allocating memory using ::operator new and ::operator delete. The same
value is returned every time this function is called. For a return value p and a memory resource r,
p->is_equal(r) returns &r == p.

memory_resource* null_memory_resource() noexcept;

Returns: A pointer to a static-duration object of a type derived from memory_resource for which
allocate() always throws bad_alloc and for which deallocate() has no effect. The same value is
returned every time this function is called. For a return value p and a memory resource r, p->is_-equal(r) returns &r == p.

The default memory resource pointer is a pointer to a memory resource that is used by certain facilities when
an explicit memory resource is not supplied through the interface. Its initial value is the return value of
new_delete_resource().

§ 19.12.4
memory_resource* set_default_resource(memory_resource* r) noexcept;

Effects: If \( r \) is non-null, sets the value of the default memory resource pointer to \( r \), otherwise sets the default memory resource pointer to \texttt{new\_delete\_resource}().

Returns: The previous value of the default memory resource pointer.

Remarks: Calling the \texttt{set_default_resource} and \texttt{get_default_resource} functions shall not incur a data race. A call to the \texttt{set_default_resource} function shall synchronize with subsequent calls to the \texttt{set_default_resource} and \texttt{get_default_resource} functions.

memory_resource* get_default_resource() noexcept;

Returns: The current value of the default memory resource pointer.

19.12.5 Pool resource classes

19.12.5.1 Classes \texttt{synchronized\_pool\_resource} and \texttt{unsynchronized\_pool\_resource}

The \texttt{synchronized\_pool\_resource} and \texttt{unsynchronized\_pool\_resource} classes (collectively called \textit{pool resource classes}) are general-purpose memory resources having the following qualities:

1. Each resource frees its allocated memory on destruction, even if \texttt{deallocate} has not been called for some of the allocated blocks.

2. A pool resource consists of a collection of pools, serving requests for different block sizes. Each individual pool manages a collection of chunks that are in turn divided into blocks of uniform size, returned via calls to \texttt{do\_allocate}. Each call to \texttt{do\_allocate(size, alignment)} is dispatched to the pool serving the smallest blocks accommodating at least \texttt{size} bytes.

3. When a particular pool is exhausted, allocating a block from that pool results in the allocation of an additional chunk of memory from the upstream allocator (supplied at construction), thus replenishing the pool. With each successive replenishment, the chunk size obtained increases geometrically. \textit{[Note: By allocating memory in chunks, the pooling strategy increases the chance that consecutive allocations will be close together in memory. \textit{— end note}]}

4. Allocation requests that exceed the largest block size of any pool are fulfilled directly from the upstream allocator.

5. A \texttt{pool\_options} struct may be passed to the pool resource constructors to tune the largest block size and the maximum chunk size.

A \texttt{synchronized\_pool\_resource} may be accessed from multiple threads without external synchronization and may have thread-specific pools to reduce synchronization costs. An \texttt{unsynchronized\_pool\_resource} class may not be accessed from multiple threads simultaneously and thus avoids the cost of synchronization entirely in single-threaded applications.

```cpp
namespace std::pmr {
    struct pool_options {
        size_t max_blocks_per_chunk = 0;
        size_t largest_required_pool_block = 0;
    };

    class synchronized_pool_resource : public memory_resource {
    public:
        synchronized_pool_resource(const pool_options& opts, memory_resource* upstream);

        synchronized_pool_resource()
            : synchronized_pool_resource(pool_options(), get_default_resource()) {}

        explicit synchronized_pool_resource(memory_resource* upstream)
            : synchronized_pool_resource(pool_options(), upstream) {}

        explicit synchronized_pool_resource(const pool_options& opts)
            : synchronized_pool_resource(opts, get_default_resource()) {}

        synchronized_pool_resource(const synchronized_pool_resource&) = delete;
        virtual ~synchronized_pool_resource();

        synchronized_pool_resource& operator=(const synchronized_pool_resource&) = delete;
    }
}
```
void release();
memory_resource* upstream_resource() const;
pool_options options() const;

protected:
void* do_allocate(size_t bytes, size_t alignment) override;
void do_deallocate(void* p, size_t bytes, size_t alignment) override;

bool do_is_equal(const memory_resource& other) const noexcept override;
};

class unsynchronized_pool_resource : public memory_resource {
public:
unsynchronized_pool_resource(const pool_options& opts, memory_resource* upstream);

unsynchronized_pool_resource()
    : unsynchronized_pool_resource(pool_options(), get_default_resource()) {}
explicit unsynchronized_pool_resource(memory_resource* upstream)
    : unsynchronized_pool_resource(pool_options(), upstream) {}
explicit unsynchronized_pool_resource(const pool_options& opts)
    : unsynchronized_pool_resource(opts, get_default_resource()) {}

unsynchronized_pool_resource(const unsynchronized_pool_resource&) = delete;
virtual ~unsynchronized_pool_resource();

unsynchronized_pool_resource& operator=(const unsynchronized_pool_resource&) = delete;

void release();
memory_resource* upstream_resource() const;
pool_options options() const;

protected:
void* do_allocate(size_t bytes, size_t alignment) override;
void do_deallocate(void* p, size_t bytes, size_t alignment) override;

bool do_is_equal(const memory_resource& other) const noexcept override;
};

19.12.5.2 pool_options data members

The members of pool_options comprise a set of constructor options for pool resources. The effect of each
option on the pool resource behavior is described below:

size_t max_blocks_per_chunk;

The maximum number of blocks that will be allocated at once from the upstream memory resource
(19.12.6) to replenish a pool. If the value of max_blocks_per_chunk is zero or is greater than an
implementation-defined limit, that limit is used instead. The implementation may choose to use a
smaller value than is specified in this field and may use different values for different pools.

size_t largest_required_pool_block;

The largest allocation size that is required to be fulfilled using the pooling mechanism. Attempts to
allocate a single block larger than this threshold will be allocated directly from the upstream memory
resource. If largest_required_pool_block is zero or is greater than an implementation-defined limit,
that limit is used instead. The implementation may choose a pass-through threshold larger than
specified in this field.

19.12.5.3 Pool resource constructors and destructors

synchronized_pool_resource(const pool_options& opts, memory_resource* upstream);
unsynchronized_pool_resource(const pool_options& opts, memory_resource* upstream);

Requires: upstream is the address of a valid memory resource.
Effects: Constructs a pool resource object that will obtain memory from `upstream` whenever the pool resource is unable to satisfy a memory request from its own internal data structures. The resulting object will hold a copy of `upstream`, but will not own the resource to which `upstream` points. [Note: The intention is that calls to `upstream->allocate()` will be substantially fewer than calls to `this->allocate()` in most cases. — end note] The behavior of the pooling mechanism is tuned according to the value of the `opts` argument.

Throws: Nothing unless `upstream->allocate()` throws. It is unspecified if, or under what conditions, this constructor calls `upstream->allocate()`.

```cpp
virtual ~synchronized_pool_resource();
virtual ~unsynchronized_pool_resource();
```

Effects: Calls `release()`.

### 19.12.5.4 Pool resource members

#### void release();

Effects: Calls `upstream_resource()->deallocate()` as necessary to release all allocated memory. [Note: The memory is released back to `upstream_resource()` even if `deallocate` has not been called for some of the allocated blocks. — end note]

```cpp
memory_resource* upstream_resource() const;
```

Returns: The value of the `upstream` argument provided to the constructor of this object.

```cpp
pool_options options() const;
```

Returns: The options that control the pooling behavior of this resource. The values in the returned struct may differ from those supplied to the pool resource constructor in that values of zero will be replaced with implementation-defined defaults, and sizes may be rounded to unspecified granularity.

```cpp
void* do_allocate(size_t bytes, size_t alignment) override;
```

Returns: A pointer to allocated storage (6.6.4.4.1) with a size of at least `bytes`. The size and alignment of the allocated memory shall meet the requirements for a class derived from `memory_resource` (19.12.2).

Effects: If the pool selected for a block of size `bytes` is unable to satisfy the memory request from its own internal data structures, it will call `upstream_resource()->allocate()` to obtain more memory. If `bytes` is larger than that which the largest pool can handle, then memory will be allocated using `upstream_resource()->allocate()`.

Throws: Nothing unless `upstream_resource()->allocate()` throws.

```cpp
void do_deallocate(void* p, size_t bytes, size_t alignment) override;
```

Effects: Returns the memory at `p` to the pool. It is unspecified if, or under what circumstances, this operation will result in a call to `upstream_resource()->deallocate()`.

Throws: Nothing.

```cpp
bool do_is_equal(const memory_resource& other) const noexcept override;
```

Returns: `this == &other`.

### 19.12.6 Class monotonic_buffer_resource

A `monotonic_buffer_resource` is a special-purpose memory resource intended for very fast memory allocations in situations where memory is used to build up a few objects and then is released all at once when the memory resource object is destroyed. It has the following qualities:

1. A call to `deallocate` has no effect, thus the amount of memory consumed increases monotonically until the resource is destroyed.
2. The program can supply an initial buffer, which the allocator uses to satisfy memory requests.
3. When the initial buffer (if any) is exhausted, it obtains additional buffers from an `upstream` memory resource supplied at construction. Each additional buffer is larger than the previous one, following a geometric progression.
It is intended for access from one thread of control at a time. Specifically, calls to `allocate` and `deallocate` do not synchronize with one another.

It frees the allocated memory on destruction, even if `deallocate` has not been called for some of the allocated blocks.

```cpp
namespace std::pmr {
    class monotonic_buffer_resource : public memory_resource {
        memory_resource* upstream_rsrc; // exposition only
        void* current_buffer; // exposition only
        size_t next_buffer_size; // exposition only

        public:
            explicit monotonic_buffer_resource(memory_resource* upstream);
            monotonic_buffer_resource(size_t initial_size, memory_resource* upstream);
            monotonic_buffer_resource(void* buffer, size_t buffer_size, memory_resource* upstream);

            monotonic_buffer_resource() // exposition only
                : monotonic_buffer_resource(get_default_resource()) {}
            explicit monotonic_buffer_resource(size_t initial_size)
                : monotonic_buffer_resource(initial_size, get_default_resource()) {}
            monotonic_buffer_resource(void* buffer, size_t buffer_size)
                : monotonic_buffer_resource(buffer, buffer_size, get_default_resource()) {}

            monotonic_buffer_resource(const monotonic_buffer_resource&) = delete;
            virtual ~monotonic_buffer_resource();

            monotonic_buffer_resource& operator=(const monotonic_buffer_resource&) = delete;

            void release();
            memory_resource* upstream_resource() const;

        protected:
            void* do_allocate(size_t bytes, size_t alignment) override;
            void do_deallocate(void* p, size_t bytes, size_t alignment) override;

            bool do_is_equal(const memory_resource& other) const noexcept override;
    };
}
```

### 19.12.6.1 monotonic_buffer_resource constructor and destructor

**[mem.res.monotonic.buffer.ctor]**

```cpp
explicit monotonic_buffer_resource(memory_resource* upstream);
monotonic_buffer_resource(size_t initial_size, memory_resource* upstream);
```

1. *Requires:* `upstream` shall be the address of a valid memory resource. `initial_size`, if specified, shall be greater than zero.

2. *Effects:* Sets `upstream_rsrc` to `upstream` and `current_buffer` to `nullptr`. If `initial_size` is specified, sets `next_buffer_size` to at least `initial_size`; otherwise sets `next_buffer_size` to an implementation-defined size.

```cpp
monotonic_buffer_resource(void* buffer, size_t buffer_size, memory_resource* upstream);
```

3. *Requires:* `upstream` shall be the address of a valid memory resource. `buffer_size` shall be no larger than the number of bytes in `buffer`.

4. *Effects:* Sets `upstream_rsrc` to `upstream`, `current_buffer` to `buffer`, and `next_buffer_size` to `buffer_size` (but not less than 1), then increases `next_buffer_size` by an implementation-defined growth factor (which need not be integral).

`~monotonic_buffer_resource();
```

§ 19.12.6.1 616
19.12.6.2 monotonic_buffer_resource members

void release();

Effects: Calls upstream_rsrc->deallocation() as necessary to release all allocated memory.

[Note: The memory is released back to upstream_rsrc even if some blocks that were allocated from this have not been deallocated from this. — end note]

memory_resource* upstream_resource() const;

Returns: The value of upstream_rsrc.

void* do_allocate(size_t bytes, size_t alignment) override;

Returns: A pointer to allocated storage (6.6.4.4.1) with a size of at least bytes. The size and alignment of the allocated memory shall meet the requirements for a class derived from memory_resource (19.12.2).

Effects: If the unused space in current_buffer can fit a block with the specified bytes and alignment, then allocate the return block from current_buffer; otherwise set current_buffer to upstream_rsrc->allocate(n, m), where n is not less than max(bytes, next_buffer_size) and m is not less than alignment, and increase next_buffer_size by an implementation-defined growth factor (which need not be integral), then allocate the return block from the newly-allocated current_buffer.

Throws: Nothing unless upstream_rsrc->allocate() throws.

void do_deallocate(void* p, size_t bytes, size_t alignment) override;

Effects: None.

Throws: Nothing.

Remarks: Memory used by this resource increases monotonically until its destruction.

bool do_is_equal(const memory_resource& other) const noexcept override;

Returns: this == &other.

19.13 Class template scoped_allocator_adaptor

19.13.1 Header <scoped_allocator> synopsis

namespace std {

// class template scoped allocator adaptor

template<class OuterAlloc, class... InnerAllocs>

class scoped_allocator_adaptor;

// 19.13.5, scoped allocator operators

template<class OuterA1, class OuterA2, class... InnerAllocs>

template<class OuterAlloc, class... InnerAllocs>
  scoped_allocator_adaptor(OuterAlloc, InnerAllocs...) -> scoped_allocator_adaptor<OuterAlloc, InnerAllocs...>;
}

19.13.2 Scoped allocator adaptor member types

using inner_allocator_type = see below;
   Type: scoped_allocator_adaptor<OuterAlloc> if sizeof...(InnerAllocs) is zero; otherwise, scoped_allocator_adaptor<InnerAllocs>.

using propagate_on_container_copy_assignment = see below;
   Type: true_type if allocator_traits<A>::propagate_on_container_copy_assignment::value is true for any A in the set of OuterAlloc and InnerAllocs...; otherwise, false_type.

using propagate_on_container_move_assignment = see below;
   Type: true_type if allocator_traits<A>::propagate_on_container_move_assignment::value is true for any A in the set of OuterAlloc and InnerAllocs...; otherwise, false_type.

using propagate_on_container_swap = see below;
   Type: true_type if allocator_traits<A>::propagate_on_container_swap::value is true for any A in the set of OuterAlloc and InnerAllocs...; otherwise, false_type.

using is_always_equal = see below;
   Type: true_type if allocator_traits<A>::is_always_equal::value is true for every A in the set of OuterAlloc and InnerAllocs...; otherwise, false_type.

19.13.3 Scoped allocator adaptor constructors

scoped_allocator_adaptor();
   Effects: Value-initializes the OuterAlloc base class and the inner allocator object.

template<class OuterA2>
  scoped_allocator_adaptor(OuterA2& outerAlloc, const InnerAllocs&... innerAllocs) noexcept;
   Effects: Initializes the OuterAlloc base class with std::forward<OuterA2>(outerAlloc) and inner with innerAllocs... (hence recursively initializing each allocator within the adaptor with the corresponding allocator from the argument list).

Remarks: This constructor shall not participate in overload resolution unless is_constructible_v<OuterAlloc, OuterA2> is true.

scoped_allocator_adaptor(const scoped_allocator_adaptor& other) noexcept;
   Effects: Initializes each allocator within the adaptor with the corresponding allocator from other.
scoped_allocator_adaptor(scoped_allocator_adaptor&& other) noexcept;

Effects: Move constructs each allocator within the adaptor with the corresponding allocator from other.

template<class OuterA2>
scoped_allocator_adaptor(
    const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& other) noexcept;

Effects: Initializes each allocator within the adaptor with the corresponding allocator from other.

Remarks: This constructor shall not participate in overload resolution unless is_constructible_v<OuterAlloc, const OuterA2&> is true.

template<class OuterA2>
scoped_allocator_adaptor(scoped_allocator_adaptor<OuterA2, InnerAllocs...>&& other) noexcept;

Effects: Initializes each allocator within the adaptor with the corresponding allocator rvalue from other.

Remarks: This constructor shall not participate in overload resolution unless is_constructible_v<OuterAlloc, OuterA2> is true.

19.13.4 Scoped allocator adaptor members [allocator.adaptor.members]

In the const member functions, OUTERMOST(x) is x if x does not have an outer_allocator() member function and OUTERMOST(x.outer_allocator()) otherwise; OUTERMOST_ALLOC_TRAITS(x) is allocator_traits<decltype(OUTERMOST(x))>. [Note: OUTERMOST(x) and OUTERMOST_ALLOC_TRAITS(x) are recursive operations. It is incumbent upon the definition of outer_allocator() to ensure that the recursion terminates. It will terminate for all instantiations of scoped_allocator_adaptor. — end note]

inner_allocator_type& inner_allocator() noexcept;
const inner_allocator_type& inner_allocator() const noexcept;

Returns: *this if sizeof...(InnerAllocs) is zero; otherwise, inner.

outer_allocator_type& outer_allocator() noexcept;
const outer_allocator_type& outer_allocator() const noexcept;

Returns: static_cast<OuterAlloc&>(*this).

[[nodiscard]] pointer allocate(size_type n);

Returns: allocator_traits<OuterAlloc>::allocate(outer_allocator(), n).

[[nodiscard]] pointer allocate(size_type n, const_void_pointer hint);

Returns: allocator_traits<OuterAlloc>::allocate(outer_allocator(), n, hint).

void deallocate(pointer p, size_type n) noexcept;

Effects: As if by: allocator_traits<OuterAlloc>::deallocate(outer_allocator(), p, n);

size_type max_size() const;

Returns: allocator_traits<OuterAlloc>::max_size(outer_allocator()).

template<class T, class... Args>
void construct(T* p, Args&&... args);

Effects:

(9.1) — If uses_allocator_v<T, inner_allocator_type> is false and is_constructible_v<T, Args...> is true, calls:

OUTERMOST_ALLOC_TRAITS(*this)::construct(OUTERMOST(*this), p, std::forward<Args>(args)...) (9.2) — Otherwise, if uses_allocator_v<T, inner_allocator_type> is true and is_constructible_v<T, allocator_arg_t, inner_allocator_type&, Args...> is true, calls:

§ 19.13.4 620
OUTERMOST_ALLOC_TRAITS(*this)::construct(
    OUTERMOST(*this), p, allocator_arg, inner_allocator(), std::forward<Args>(args)...)  
(9.3)
— Otherwise, if uses_allocator_v<T, inner_allocator_type> is true and is_constructible_v<T, Args..., inner_allocator_type&> is true, calls:
OUTERMOST_ALLOC_TRAITS(*this)::construct(
    OUTERMOST(*this), p, std::forward<Args>(args)..., inner_allocator())  
(9.4)
— Otherwise, the program is ill-formed. [Note: An error will result if uses_allocator evaluates to true but the specific constructor does not take an allocator. This definition prevents a silent failure to pass an inner allocator to a contained element. — end note]

Remarks: This function shall not participate in overload resolution if T is a specialization of pair.

template<class T1, class T2, class... Args1, class... Args2>
void construct(pair<T1, T2>* p, piecewise_construct_t, tuple<Args1...> x, tuple<Args2...> y);

Effects: Constructs a tuple object xprime from x by the following rules:
(11.1) If uses_allocator_v<T1, inner_allocator_type> is false and is_constructible_v<T1, Args1...> is true, then xprime is tuple<Args1&&...>(std::move(x)).
(11.2) Otherwise, if uses_allocator_v<T1, inner_allocator_type> is true and is_constructible_v<T1, allocator_arg_t, inner_allocator_type&, Args1...> is true, then xprime is:
    tuple_cat(
        tuple<allocator_arg_t, inner_allocator_type&>(allocator_arg, inner_allocator()),
        tuple<Args1&&...>(std::move(x)))
(11.3) Otherwise, if uses_allocator_v<T1, inner_allocator_type> is true and is_constructible_v<T1, Args1..., inner_allocator_type&> is true, then xprime is:
    tuple_cat(tuple<Args1&&...>(std::move(x)),
              tuple<inner_allocator_type*>(inner_allocator()))
(11.4) Otherwise, the program is ill-formed.

and constructs a tuple object yprime from y by the following rules:
(11.5) If uses_allocator_v<T2, inner_allocator_type> is false and is_constructible_v<T2, Args2...> is true, then yprime is tuple<Args2&&...>(std::move(y)).
(11.6) Otherwise, if uses_allocator_v<T2, inner_allocator_type> is true and is_constructible_v<T2, allocator_arg_t, inner_allocator_type&, Args2...> is true, then yprime is:
    tuple_cat(
        tuple<allocator_arg_t, inner_allocator_type&>(allocator_arg, inner_allocator()),
        tuple<Args2&&...>(std::move(y)))
(11.7) Otherwise, if uses_allocator_v<T2, inner_allocator_type> is true and is_constructible_v<T2, Args2..., inner_allocator_type&> is true, then yprime is:
    tuple_cat(tuple<Args2&&...>(std::move(y)),
              tuple<inner_allocator_type*>(inner_allocator()))
(11.8) Otherwise, the program is ill-formed.

then calls:
OUTERMOST_ALLOC_TRAITS(*this)::construct(
    OUTERMOST(*this), p, piecewise_construct, std::move(xprime), std::move(yprime))

template<class T1, class T2>
void construct(pair<T1, T2>* p);

Effects: Equivalent to:
    construct(p, piecewise_construct, tuple<>(), tuple<>());

template<class T1, class T2, class U, class V>
void construct(pair<T1, T2>* p, U&& x, V&& y);

Effects: Equivalent to:

§ 19.13.4
```
construct(p, piecewise_construct,
    forward_as_tuple(std::forward<U>(x)),
    forward_as_tuple(std::forward<V>(y)));

template<class T1, class T2, class U, class V>
void construct(pair<T1, T2>* p, const pair<U, V>& x);

Effects: Equivalent to:
construct(p, piecewise_construct,
    forward_as_tuple(x.first),
    forward_as_tuple(x.second));

template<class T1, class T2, class U, class V>
void construct(pair<T1, T2>* p, pair<U, V>&& x);

Effects: Equivalent to:
construct(p, piecewise_construct,
    forward_as_tuple(std::forward<U>(x.first)),
    forward_as_tuple(std::forward<V>(x.second)));

template<class T>
void destroy(T* p);

Effects: Calls OUTERMOST_ALLOC_TRAITS(*this)::destroy(OUTERMOST(*this), p).

scoped_allocator_adaptor select_on_container_copy_construction() const;

Returns: A new scoped_allocator_adaptor object where each allocator A in the adaptor is initialized from the result of calling allocator_traits<A>::select_on_container_copy_construction() on the corresponding allocator in *this.

19.13.5 Scoped allocator operators

```

```
```

19.14 Function objects

A function object type is an object type (6.7) that can be the type of the postfix-expression in a function call (7.6.1.2, 11.3.1.1). A function object is an object of a function object type. In the places where one would expect to pass a pointer to a function to an algorithmic template (Clause 23), the interface is specified to accept a function object. This not only makes algorithmic templates work with pointers to functions, but also enables them to work with arbitrary function objects.

19.14.1 Header <functional> synopsis

```
template<class T> class reference_wrapper;

template<class T> reference_wrapper<T> ref(T&) noexcept;
template<class T> reference_wrapper<const T> cref(const T&) noexcept;

[Example: If a C++ program wants to have a by-element addition of two vectors a and b containing double and put the result into a, it can do:
transform(a.begin(), a.end(), b.begin(), a.begin(), plus<double>());
—end example]

[Example: To negate every element of a:
transform(a.begin(), a.end(), a.begin(), negate<double>());
—end example]

19.14.2 Definitions [func.def]
The following definitions apply to this Clause:

1 A call signature is the name of a return type followed by a parenthesized comma-separated list of zero or more argument types.

2 A callable type is a function object type (19.14) or a pointer to member.

3 A callable object is an object of a callable type.

4 A call wrapper type is a type that holds a callable object and supports a call operation that forwards to that object.

5 A call wrapper is an object of a call wrapper type.

6 A target object is the callable object held by a call wrapper.

19.14.3 Requirements [func.require]

1 Define \texttt{INVOKE}(f, t_1, t_2, \ldots, t_N) as follows:

\begin{enumerate}
\item \texttt{(t_1.*f)(t_2, \ldots, t_N)} when \texttt{f} is a pointer to a member function of a class \texttt{T} and \texttt{is\_base\_of\_v}\langle\texttt{T}, remove\_reference\_t<\texttt{decltype(t_1)}\rangle\rangle is true;
\item \texttt{(t_1.get().*f)(t_2, \ldots, t_N)} when \texttt{f} is a pointer to a member function of a class \texttt{T} and \texttt{remove\_-cvref\_t<\texttt{decltype(t_1)}\rangle\rangle} is a specialization of \texttt{reference\_wrapper};
\item \texttt{(*(t_1).*f)(t_2, \ldots, t_N)} when \texttt{f} is a pointer to a member function of a class \texttt{T} and \texttt{t_1} does not satisfy the previous two items;
\item \texttt{t_1.*f} when \texttt{N == 1} and \texttt{f} is a pointer to data member of a class \texttt{T} and \texttt{is\_base\_of\_v}\langle\texttt{T}, remove\_reference\_t<\texttt{decltype(t_1)}\rangle\rangle\rangle is true;
\item \texttt{t_1.get().*f} when \texttt{N == 1} and \texttt{f} is a pointer to data member of a class \texttt{T} and \texttt{remove\_cvref\_t<\texttt{decltype(t_1)}\rangle\rangle} is a specialization of \texttt{reference\_wrapper};
\item \texttt{(*(t_1).*f)} when \texttt{N == 1} and \texttt{f} is a pointer to data member of a class \texttt{T} and \texttt{t_1} does not satisfy the previous two items;
\item \texttt{f(t_1, t_2, \ldots, t_N)} in all other cases.
\end{enumerate}

2 Define \texttt{INVOKE\!<R>(f, t_1, t_2, \ldots, t_N)} as \texttt{static\_cast<void>(INVOKE(f, t_1, t_2, \ldots, t_N))} if \texttt{R} is \texttt{cv\ void}, otherwise \texttt{INVOKE(f, t_1, t_2, \ldots, t_N)} implicitly converted to \texttt{R}.

3 Every call wrapper (19.14.2) shall be \texttt{Cpp17MoveConstructible}. A forwarding call wrapper is a call wrapper that can be called with an arbitrary argument list and delivers the arguments to the wrapped callable object as references. This forwarding step shall ensure that rvalue arguments are delivered as rvalue references and lvalue arguments are delivered as lvalue references. A simple call wrapper is a forwarding call wrapper that is \texttt{Cpp17CopyConstructible} and \texttt{Cpp17CopyAssignable} and whose copy constructor, move constructor, copy assignment operator, and move assignment operator do not throw exceptions. [Note: In a typical implementation forwarding call wrappers have an overloaded function call operator of the form

\begin{verbatim}
template<class... UnBoundArgs>
  R operator()(UnBoundArgs&&... unbound_args) cv-qual;
\end{verbatim}

—end note]
19.14.4 Function template invoke

```
template<class F, class... Args>
invoke_result_t<F, Args...> invoke(F&& f, Args&&... args)
    noexcept(is_nothrow_invocable_v<F, Args...>);
```

Returns: `INVOKE(std::forward<F>(f), std::forward<Args>(args)...)` (19.14.3).

19.14.5 Class template reference_wrapper

```
namespace std {
    template<class T> class reference_wrapper {
        public:
            // types
            using type = T;

            // construct/copy/destroy
            template<class U>
            reference_wrapper(U&&) noexcept(see below);
            reference_wrapper(const reference_wrapper& x) noexcept;

            // assignment
            reference_wrapper& operator=(const reference_wrapper& x) noexcept;

            // access
            operator T& () const noexcept;
            T& get() const noexcept;

            // invocation
            template<class... ArgTypes>
            invoke_result_t<T&, ArgTypes...> operator()(ArgTypes&&...) const;
    }
}
```

`reference_wrapper<T>` is a `Cpp17CopyConstructible` and `Cpp17CopyAssignable` wrapper around a reference to an object or function of type `T`.

`reference_wrapper<T>` is a trivially copyable type (6.7).

19.14.5.1 reference_wrapper construct/copy/destroy

```
template<class U>
reference_wrapper(U&& u) noexcept(see below);
```

Remarks: Let `FUN` denote the exposition-only functions
```
void FUN(T&) noexcept;
void FUN(T&&) = delete;
```

This constructor shall not participate in overload resolution unless the expression `FUN(declval<U>())` is well-formed and `is_same_v<remove_cvref_t<T>, reference_wrapper>` is `false`. The expression inside `noexcept` is equivalent to `noexcept(FUN(declval<U>())`.

Effects: Creates a variable `r` as if by `T r = std::forward<U>(u)`, then constructs a `reference_wrapper` object that stores a reference to `r`.

```
reference_wrapper(const reference_wrapper& x) noexcept;
```

Effects: Constructs a `reference_wrapper` object that stores a reference to `x.get()`.

19.14.5.2 reference_wrapper assignment

```
reference_wrapper& operator=(const reference_wrapper& x) noexcept;
```

Ensures: `*this` stores a reference to `x.get()`.
19.14.5.3 reference_wrapper access
operator T& () const noexcept;
1
Returns: The stored reference.

T& get() const noexcept;
2
Returns: The stored reference.

19.14.5.4 reference_wrapper invocation
template<class... ArgTypes>
invoke_result_t<T&, ArgTypes...>
operator()(ArgTypes&&... args) const;
1
Returns: INVOKE(get(), std::forward<ArgTypes>(args)...). (19.14.3)

19.14.5.5 reference_wrapper helper functions
template<class T> reference_wrapper<T> ref(T& t) noexcept;
1
Returns: reference_wrapper<T>(t).

template<class T> reference_wrapper<T> ref(reference_wrapper<T> t) noexcept;
2
Returns: ref(t.get()).

template<class T> reference_wrapper<const T> cref(const T& t) noexcept;
3
Returns: reference_wrapper<const T>(t).

template<class T> reference_wrapper<const T> cref(reference_wrapper<T> t) noexcept;
4
Returns: cref(t.get()).

19.14.6 Arithmetic operations
The library provides basic function object classes for all of the arithmetic operators in the language (7.6.5, 7.6.6).

19.14.6.1 Class template plus

template<class T = void> struct plus {
    constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;
1
Returns: x + y.

template<> struct plus<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) + std::forward<U>(u));
    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) + std::forward<U>(u));
2
Returns: std::forward<T>(t) + std::forward<U>(u).

19.14.6.2 Class template minus

template<class T = void> struct minus {
    constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;
1
Returns: x - y.
template<> struct minus<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) - std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) - std::forward<U>(u));

Returns: std::forward<T>(t) - std::forward<U>(u).

19.14.6.3 Class template multiplies [arithmetic.operations.multiplies]

template<class T = void> struct multiplies {
    constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

1 Returns: x * y.

template<> struct multiplies<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) * std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) * std::forward<U>(u));

2 Returns: std::forward<T>(t) * std::forward<U>(u).

19.14.6.4 Class template divides [arithmetic.operations.divides]

template<class T = void> struct divides {
    constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

1 Returns: x / y.

template<> struct divides<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) / std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) / std::forward<U>(u));

2 Returns: std::forward<T>(t) / std::forward<U>(u).

19.14.6.5 Class template modulus [arithmetic.operations.modulus]

template<class T = void> struct modulus {
    constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

1 Returns: x % y.

template<> struct modulus<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) % std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
-> decltype(std::forward<T>(t) % std::forward<U>(u));
using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) % std::forward<U>(u));
2

Returns: std::forward<T>(t) % std::forward<U>(u).

19.14.6.6 Class template negate

[arithmetic.operations.negate]
template<class T = void> struct negate {
    constexpr T operator()(const T& x) const;
};

constexpr T operator()(const T& x) const;
1
Returns: -x.

template<> struct negate<void> {
    template<class T> constexpr auto operator()(T&& t) const
        -> decltype(-std::forward<T>(t));
    using is_transparent = unspecified;
};

template<class T> constexpr auto operator()(T&& t) const
    -> decltype(-std::forward<T>(t));
2
Returns: -std::forward<T>(t).

19.14.7 Comparisons

[comparisons]
The library provides basic function object classes for all of the comparison
operators in the language (7.6.9, 7.6.10).
2 For templates less, greater, less_equal, and greater_equal, the specializations
for any pointer type yield a strict total order that is consistent among those
specializations and is also consistent with the partial order imposed by the
built-in operators <, >, <=, >=. [Note: When a < b is well-defined for pointers a
and b of type P, this implies (a < b) == less<P>()(a, b), (a > b) == greater<P>()(a, b),
and so forth. — end note] For template specializations less<void>, greater<void>,
less_equal<void>, and greater_equal<void>, if the call operator calls a built-in operator
comparing pointers, the call operator yields a strict total order that is consistent
among those specializations and is also consistent with the partial order
imposed by those built-in operators.

19.14.7.1 Class template equal_to

[comparisons.equal_to]
template<class T = void> struct equal_to {
    constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;
1
Returns: x == y.

template<> struct equal_to<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) == std::forward<U>(u));
    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) == std::forward<U>(u));
2
Returns: std::forward<T>(t) == std::forward<U>(u).
19.14.7.2 Class template not_equal_to

```cpp
template<class T = void> struct not_equal_to {
    constexpr bool operator()(const T& x, const T& y) const;
};
```

1 Returns: \( x \neq y \).

```cpp
template<> struct not_equal_to<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) \(!=\) std::forward<U>(u));
    using is_transparent = unspecified;
};
```

2 Returns: \( \text{std::forward}<T>(t) \neq \text{std::forward}<U>(u) \).

19.14.7.3 Class template greater

```cpp
template<class T = void> struct greater {
    constexpr bool operator()(const T& x, const T& y) const;
};
```

1 Returns: \( x > y \).

```cpp
template<> struct greater<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) > std::forward<U>(u));
    using is_transparent = unspecified;
};
```

2 Returns: \( \text{std::forward}<T>(t) > \text{std::forward}<U>(u) \).

19.14.7.4 Class template less

```cpp
template<class T = void> struct less {
    constexpr bool operator()(const T& x, const T& y) const;
};
```

1 Returns: \( x < y \).

```cpp
template<> struct less<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) < std::forward<U>(u));
    using is_transparent = unspecified;
};
```

2 Returns: \( \text{std::forward}<T>(t) < \text{std::forward}<U>(u) \).

19.14.7.5 Class template greater_equal

```cpp
template<class T = void> struct greater_equal {
    constexpr bool operator()(const T& x, const T& y) const;
};
```

19.14.7.5 630
constexpr bool operator()(const T& x, const T& y) const;

Returns: x >= y.

template<> struct greater_equal<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) >= std::forward<U>(u));

  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) >= std::forward<U>(u));

Returns: std::forward<T>(t) >= std::forward<U>(u).

19.14.7.6 Class template less_equal

template<class T = void> struct less_equal {
  constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;

Returns: x <= y.

template<> struct less_equal<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) <= std::forward<U>(u));

  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) <= std::forward<U>(u));

Returns: std::forward<T>(t) <= std::forward<U>(u).

19.14.8 Logical operations

The library provides basic function object classes for all of the logical operators in the language (7.6.14, 7.6.15, 7.6.2.1).

19.14.8.1 Class template logical_and

template<class T = void> struct logical_and {
  constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;

Returns: x && y.

template<> struct logical_and<void> {
  template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) && std::forward<U>(u));

  using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
  -> decltype(std::forward<T>(t) && std::forward<U>(u));

Returns: std::forward<T>(t) && std::forward<U>(u).
19.14.8.2 Class template logical_or

```cpp
template<class T = void> struct logical_or {
    constexpr bool operator()(const T& x, const T& y) const;
};
```

```cpp
constexpr bool operator()(const T& x, const T& y) const;
```

1 Returns: `x || y`.

```cpp
template<> struct logical_or<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) || std::forward<U>(u));
};
```

19.14.8.3 Class template logical_not

```cpp
template<class T = void> struct logical_not {
    constexpr bool operator()(const T& x) const;
};
```

```cpp
constexpr bool operator()(const T& x) const;
```

1 Returns: `!x`.

```cpp
template<> struct logical_not<void> {
    template<class T> constexpr auto operator()(T&& t) const
        -> decltype(!std::forward<T>(t));
};
```

19.14.9 Bitwise operations

The library provides basic function object classes for all of the bitwise operators in the language (7.6.11, 7.6.13, 7.6.12, 7.6.2.1).

19.14.9.1 Class template bit_and

```cpp
template<class T = void> struct bit_and {
    constexpr T operator()(const T& x, const T& y) const;
};
```

```cpp
constexpr T operator()(const T& x, const T& y) const;
```

1 Returns: `x & y`.

```cpp
template<> struct bit_and<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) & std::forward<U>(u));
};
```

19.14.9.2 Class template logical_or [logical.operations.or]

19.14.8.3 Class template logical_not [logical.operations.not]

19.14.9 Bitwise operations [bitwise.operations]

19.14.9.1 Class template bit_and [bitwise.operations.and]
19.14.9.2 Class template `bit_or` [bitwise.operations.or]

```cpp
template<class T = void> struct bit_or {
    constexpr T operator()(const T& x, const T& y) const;
};
```

1 Returns: `x | y`.

```cpp
template<> struct bit_or<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) | std::forward<U>(u));
    using is_transparent = unspecified;
};
```

2 Returns: `std::forward<T>(t) | std::forward<U>(u)`.

19.14.9.3 Class template `bit_xor` [bitwise.operations.xor]

```cpp
template<class T = void> struct bit_xor {
    constexpr T operator()(const T& x, const T& y) const;
};
```

1 Returns: `x ^ y`.

```cpp
template<> struct bit_xor<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) ^ std::forward<U>(u));
    using is_transparent = unspecified;
};
```

2 Returns: `std::forward<T>(t) ^ std::forward<U>(u)`.

19.14.9.4 Class template `bit_not` [bitwise.operations.not]

```cpp
template<class T = void> struct bit_not {
    constexpr T operator()(const T& x) const;
};
```

1 Returns: `~x`.

```cpp
template<> struct bit_not<void> {
    template<class T> constexpr auto operator()(T&& t) const
        -> decltype(~std::forward<T>(t));
    using is_transparent = unspecified;
};
```

2 Returns: `~std::forward<T>(t)`.

19.14.10 Class `identity` [func.identity]

```cpp
struct identity {
    template<class T>
        constexpr T&& operator()(T&& t) const noexcept;
};
```

§ 19.14.10
using is_transparent = unspecified;
};

template<class T>
constexpr T&& operator()(T&& t) const noexcept;

19.14.11 Function template not_fn

template<class F> unspecified not_fn(F&& f);

Effects: Equivalent to: return std::forward<F>(f);

19.14.11 Function template not_fn

template<class F> unspecified not_fn(F&& f);

Effects: Equivalent to: return call_wrapper(std::forward<F>(f)); where call_wrapper is an exposition only class defined as follows:

class call_wrapper {
    using FD = decay_t<F>;
    FD fd;
    explicit call_wrapper(F&& f);

public:
    call_wrapper(call_wrapper&&) = default;
    call_wrapper(const call_wrapper&) = default;

    template<class... Args>
    auto operator()(Args&&...) &
    -> decltype(!declval<invoke_result_t<FD&, Args...>>());

    template<class... Args>
    auto operator()(Args&&...) const &
    -> decltype(!declval<invoke_result_t<const FD&, Args...>>());

    template<class... Args>
    auto operator()(Args&&...) &&
    -> decltype(!declval<invoke_result_t<FD, Args...>>());

    template<class... Args>
    auto operator()(Args&&...) const&&
    -> decltype(!declval<invoke_result_t<const FD, Args...>>());
};

explicit call_wrapper(F&& f);

Requires: FD shall satisfy the Cpp17MoveConstructible requirements. is_constructible_v<FD, F> shall be true. fd shall be a callable object (19.14.2).

Effects: Initializes fd from std::forward<F>(f).

Throws: Any exception thrown by construction of fd.

template<class... Args>
auto operator()(Args&&... args) &
-> decltype(!declval<invoke_result_t<FD&, Args...>>());

template<class... Args>
auto operator()(Args&&... args) const &
-> decltype(!declval<invoke_result_t<const FD&, Args...>>());

Effects: Equivalent to:

return !INVOKE(fd, std::forward<Args>(args)...); // see 19.14.3

template<class... Args>
auto operator()(Args&&... args) &&
-> decltype(!declval<invoke_result_t<FD, Args...>>());

template<class... Args>
auto operator()(Args&&... args) const&&
Effects: Equivalent to:

\[
\text{return } !\text{INVOKE}(\text{std::move}(fd), \text{std::forward}<\text{Args}>(\text{args})\ldots); \quad \text{// see 19.14.3}
\]

19.14.12 Function object binders

This subclause describes a uniform mechanism for binding arguments of callable objects.

19.14.12.1 Class template is_bind_expression

```
namespace std {
    template<class T> struct is_bind_expression; \quad \text{// see below}
}
```

1 The class template is_bind_expression can be used to detect function objects generated by bind. The function template bind uses is_bind_expression to detect subexpressions.

2 Instantiations of the is_bind_expression template shall satisfy the Cpp17UnaryTypeTrait requirements (19.15.1). The implementation shall provide a definition that has a base characteristic of true_type if T is a type returned from bind, otherwise it shall have a base characteristic of false_type. A program may specialize this template for a program-defined type T to have a base characteristic of true_type to indicate that T should be treated as a subexpression in a bind call.

19.14.12.2 Class template is_placeholder

```
namespace std {
    template<class T> struct is_placeholder; \quad \text{// see below}
}
```

1 The class template is_placeholder can be used to detect the standard placeholders _1, _2, and so on. The function template bind uses is_placeholder to detect placeholders.

2 Instantiations of the is_placeholder template shall satisfy the Cpp17UnaryTypeTrait requirements (19.15.1). The implementation shall provide a definition that has the base characteristic of integral_constant<int, J> if T is the type of std::placeholders::_, otherwise it shall have a base characteristic of integral_constant<int, 0>. A program may specialize this template for a program-defined type T to have a base characteristic of integral_constant<int, N> with N > 0 to indicate that T should be treated as a placeholder type.

19.14.12.3 Function template bind

```
template<class F, class... BoundArgs>
unspeficied bind(F&& f, BoundArgs&&... bound_args);
```

1 In the text that follows:

- (1.1) FD is the type decay_t<F>.
- (1.2) fd is an lvalue of type FD constructed from std::forward<F>(f),
- (1.3) Ti is the ith type in the template parameter pack BoundArgs,
- (1.4) TDi is the type decay_t<Ti>,
- (1.5) t is the ith argument in the function parameter pack bound_args,
- (1.6) td is an lvalue of type TDi constructed from std::forward<TDi>(ti),
- (1.7) Uj is the jth deduced type of the UnBoundArgs&&... parameter of the forwarding call wrapper, and
- (1.8) uj is the jth argument associated with Uj.

2 Requires: is_constructible_v<FD, F> shall be true. For each Ti in BoundArgs, is_constructible_v<TDi, Ti> shall be true. INVOKE(fd, w1, w2, ..., wN) (19.14.3) shall be a valid expression for some values w1, w2, ..., wN, where N has the value sizeof...(bound_args). The cv-qualifiers cv of the call wrapper g, as specified below, shall be neither volatile nor const volatile.

3 Returns: A forwarding call wrapper g (19.14.3). The effect of g(u1, u2, ..., uM) shall be

\[
\text{INVOKE}(fd, \text{std::forward}<V1>(v1), \text{std::forward}<V2>(v2), \ldots, \text{std::forward}<VN>(vN))
\]
where the values and types of the bound arguments \(v_1, v_2, \ldots, v_N\) are determined as specified below.

The copy constructor and move constructor of the forwarding call wrapper shall throw an exception if and only if the corresponding constructor of \(FD\) or of any of the types \(TD_i\) throws an exception.

*Throws:* Nothing unless the construction of \(fd\) or of one of the values \(td_i\) throws an exception.

*Remarks:* The return type shall satisfy the Cpp17MoveConstructible requirements. If all of \(FD\) and \(TD_i\) satisfy the Cpp17CopyConstructible requirements, then the return type shall satisfy the Cpp17CopyConstructible requirements. [Note: This implies that all of \(FD\) and \(TD_i\) are Cpp17MoveConstructible. —end note]

```cpp
template<class R, class F, class... BoundArgs>
unspecified bind(F&& f, BoundArgs&&... bound_args);
```

*Requires:* is_constructible_v<FD, F> shall be true. For each \(T_i\) in BoundArgs, is_constructible_v<\(v<TD_i, T_i>\), \(T_i\)> shall be true. INVOKE\(fd, w_1, w_2, \ldots, w_N\) shall be a valid expression for some values \(w_1, w_2, \ldots, w_N\), where \(N\) has the value sizeof...(bound_args). The cv-qualifiers \(cv\) of the call wrapper \(g\), as specified below, shall be neither volatile nor const volatile.

*Returns:* A forwarding call wrapper \(g\) (19.14.3). The effect of \(g(u_1, u_2, \ldots, u_M)\) shall be

\[
\text{INVOKE}\_R>(fd, \text{std::forward}<V_1>(v_1), \text{std::forward}<V_2>(v_2), \ldots, \text{std::forward}<V_N>(v_N))
\]

where the values and types of the bound arguments \(v_1, v_2, \ldots, v_N\) are determined as specified below. The copy constructor and move constructor of the forwarding call wrapper shall throw an exception if and only if the corresponding constructor of \(FD\) or of any of the types \(TD_i\) throws an exception.

*Throws:* Nothing unless the construction of \(fd\) or of one of the values \(td_i\) throws an exception.

*Remarks:* The return type shall satisfy the Cpp17MoveConstructible requirements. If all of \(FD\) and \(TD_i\) satisfy the Cpp17CopyConstructible requirements, then the return type shall satisfy the Cpp17CopyConstructible requirements. [Note: This implies that all of \(FD\) and \(TD_i\) are Cpp17MoveConstructible. —end note]

The values of the bound arguments \(v_1, v_2, \ldots, v_N\) and their corresponding types \(V_1, V_2, \ldots, V_N\) depend on the types \(TD_i\), derived from the call to \(\text{bind}\) and the cv-qualifiers \(cv\) of the call wrapper \(g\) as follows:

1. if \(TD_i\) is reference_wrapper<T>, the argument is \(td_i\).get() and its type \(V_i\) is T;
2. if the value of is_bind_expression_v<\(TD_i\)> is true, the argument is \(td_i\)(std::forward<U_j>(u_j)...) and its type \(V_i\) is invoke_result_t<\(TD_i\), cv k, U_j...>&&;
3. if the value \(j\) of is_placeholder_v<\(TD_i\)> is not zero, the argument is std::forward<U_j>(u_j) and its type \(V_i\) is U_j&&;
4. otherwise, the value is \(td_i\) and its type \(V_i\) is TD_i cv k.

### 19.14.12.4 Placeholders

```cpp
namespace std::placeholders {
  // M is the implementation-defined number of placeholders
  see below _1;
  see below _2;
  .
  .
  .
  see below _M;
}
```

All placeholder types shall be Cpp17DefaultConstructible and Cpp17CopyConstructible, and their default constructors and copy/move constructors shall not throw exceptions. It is implementation-defined whether placeholder types are Cpp17CopyAssignable. Cpp17CopyAssignable placeholders’ copy assignment operators shall not throw exceptions.

Placeholders should be defined as:

```cpp
inline constexpr unspecified _1{};
```

If they are not, they shall be declared as:

```cpp
extern unspecified _1;
```
19.14.13 Function template mem_fn

template<class R, class T> unspecified mem_fn(R T::* pm) noexcept;

Returns: A simple call wrapper (19.14.2) fn such that the expression fn(t, a2, ..., aN) is equivalent to INVOKE(pm, t, a2, ..., aN) (19.14.3).

19.14.14 Polymorphic function wrappers

This subclause describes a polymorphic wrapper class that encapsulates arbitrary callable objects.

An exception of type bad_function_call is thrown by function::operator() (19.14.14.2.4) when the function wrapper object has no target.

namespace std {
    class bad_function_call : public exception {
        public:
            bad_function_call() noexcept;
    };
}

bad_function_call() noexcept;

Effects: Constructs a bad_function_call object.

Ensures: what() returns an implementation-defined NTRUE.

19.14.14.2 Class template function

namespace std {
    template<class> class function; // not defined

    template<class R, class... ArgTypes>
    class function<R(ArgTypes...)> {
        public:
            using result_type = R;
            function() noexcept;
            function(nullptr_t) noexcept;
            function(const function&);
            function(function&&);
            template<class F> function(F);
            function& operator=(const function&);
            function& operator=(function&);
            function& operator=(nullptr_t) noexcept;
            template<class F> function& operator=(F&&);
            template<class F> function& operator=(reference_wrapper<F>) noexcept;
            ~function();
            void swap(function&) noexcept;
            explicit operator bool() const noexcept;
            // 19.14.14.2.4, function invocation
            R operator()(ArgTypes...) const;
        };
}
The function class template provides polymorphic wrappers that generalize the notion of a function pointer. Wrappers can store, copy, and call arbitrary callable objects (19.14.2), given a call signature (19.14.2), allowing functions to be first-class objects.

A callable type (19.14.2) \( F \) is **Lvalue-Callable** for argument types \( \text{ArgTypes} \) and return type \( R \) if the expression

\[
\text{INVOKE}\langle R \rangle (\text{declval}<F&>(), \text{declval}<\text{ArgTypes}>()...),
\]

considered as an unevaluated operand (7.2), is well-formed (19.14.3).

The function class template is a call wrapper (19.14.2) whose call signature (19.14.2) is \( R(\text{ArgTypes}...) \).

[Note: The types deduced by the deduction guides for function may change in future versions of this International Standard. — end note]

### 19.14.14.2.1 function construct/copy/destroy

#### function() noexcept;

*Ensures:* \(!*\text{this}.\)

#### function(nullptr_t) noexcept;

*Ensures:* \(!*\text{this}.\)

#### function(const function& f);

*Ensures:* \(!*\text{this} \text{ if } f; \text{ otherwise, } *\text{this} \text{ targets a copy of } f.\text{target}().\)

*Throws:* Shall not throw exceptions if \( f \)’s target is a specialization of reference_wrapper or a function pointer. Otherwise, may throw bad_alloc or any exception thrown by the copy constructor of the stored callable object. [Note: Implementations should avoid the use of dynamically allocated memory for small callable objects, for example, where \( f \)’s target is an object holding only a pointer or reference to an object and a member function pointer. — end note]

#### function(function&& f);

*Ensures:* \(!*\text{this} \text{ has no target; otherwise, the target of } *\text{this} \text{ is equivalent to the target of } f \\text{ before the construction, and } f \text{ is in a valid state with an unspecified value.}\)

*Throws:* Shall not throw exceptions if \( f \)’s target is a specialization of reference_wrapper or a function pointer. Otherwise, may throw bad_alloc or any exception thrown by the copy or move constructor
of the stored callable object. [Note: Implementations should avoid the use of dynamically allocated memory for small callable objects, for example, where f's target is an object holding only a pointer or reference to an object and a member function pointer. — end note]

```
template<class F> function(F f);
```

7

`Requires:` F shall be Cpp17CopyConstructible.

8

`Remarks:` This constructor template shall not participate in overload resolution unless F is Lvalue-Callable (19.14.14.2) for argument types ArgTypes... and return type R.

9

`Ensures:` !*this if any of the following hold:

9.1
— f is a null function pointer value.

9.2
— f is a null member pointer value.

9.3
— F is an instance of the function class template, and !f.

Otherwise, *this targets a copy of f initialized with std::move(f). [Note: Implementations should avoid the use of dynamically allocated memory for small callable objects, for example, where f is an object holding only a pointer or reference to an object and a member function pointer. — end note]

10

`Throws:` Shall not throw exceptions when f is a function pointer or a reference_wrapper<T> for some T. Otherwise, may throw bad_alloc or any exception thrown by F's copy or move constructor.

```
template<class F> function(F) -> function<see below>;
```

12

`Remarks:` This deduction guide participates in overload resolution only if &F::operator() is well-formed when treated as an unevaluated operand. In that case, if decltype(&F::operator()) is of the form R(G::*)(A...) cv `opt noexcept_opt for a class type G, then the deduced type is function<R(A...)>. 

[Example:

```
void f() {
  int i{5};
  function g = [&](double) { return i; }; // deduces function<int(double)>
}
```
— end example]

13

```
function& operator=(const function& f);
```

14

`Effects:` As if by function(f).swap(*this);

15

`Returns:` *this.

```
function& operator=(function&& f);
```

16

`Effects:` Replaces the target of *this with the target of f.

17

`Returns:` *this.

```
function& operator=(nullptr_t) noexcept;
```

18

`Effects:` If *this != nullptr, destroys the target of this.

19

`Ensures:` !(this).

20

`Returns:` *this.

```
template<class F> function& operator=(F&& f);
```

21

`Effects:` As if by: function(std::forward<F>(f)).swap(*this);

22

`Returns:` *this.

```
template<class F> function& operator=(reference_wrapper<F> f) noexcept;
```

23

`Effects:` As if by: function(f).swap(*this);

24

`Returns:` *this.
Effects: If this != nullptr, destroys the target of this.

19.14.14.2.2 function modifiers

void swap(function& other) noexcept;

Effects: Interchanges the targets of *this and other.

19.14.14.2.3 function capacity

define explicit operator bool() const noexcept;

Returns: true if *this has a target, otherwise false.

19.14.14.2.4 function invocation

R operator()(ArgTypes... args) const;

Returns: INVOKE<R>(f, std::forward<ArgTypes>(args)...)(19.14.3), where f is the target object (19.14.2) of *this.

2. Throws: bad_function_call if !*this; otherwise, any exception thrown by the wrapped callable object.

19.14.14.2.5 function target access

cast type_info& target_type() const noexcept;

define template<class T> T* target() noexcept;

define template<class T> const T* target() const noexcept;

Returns: If *this has a target of type T, typeid(T); otherwise, typeid(void).

2. Returns: If target_type() == typeid(T) a pointer to the stored function target; otherwise a null pointer.

19.14.14.2.6 null pointer comparison functions

template<class R, class... ArgTypes>

bool operator==((const function<R(ArgTypes...)>& f, nullptr_t) noexcept;

define template<class R, class... ArgTypes>

bool operator==(nullptr_t, const function<R(ArgTypes...)>& f) noexcept;

Returns: !f.

2. Returns: (bool)f.

19.14.14.2.7 specialized algorithms

template<class R, class... ArgTypes>

define void swap(function<R(ArgTypes...)>& f1, function<R(ArgTypes...)>& f2) noexcept;

Effects: As if by: f1.swap(f2);

19.14.15 Searchers

This subclause provides function object types (19.14) for operations that search for a sequence [pat_first, pat_last) in another sequence [first, last) that is provided to the object’s function call operator. The first sequence (the pattern to be searched for) is provided to the object’s constructor, and the second (the sequence to be searched) is provided to the function call operator.

2. Each specialization of a class template specified in this subclause 19.14.15 shall satisfy the Cpp17CopyConstructible and Cpp17CopyAssignable requirements. Template parameters named
The Boyer-Moore searcher implements the Boyer-Moore search algorithm. The Boyer-Moore-Horspool searcher implements the Boyer-Moore-Horspool search algorithm. In general, the Boyer-Moore searcher will use more memory and give better runtime performance than Boyer-Moore-Horspool.

19.14.15.1 Class template default_searcher

```cpp
template<class ForwardIterator1, class BinaryPredicate = equal_to<>>
class default_searcher {
public:
    default_searcher(ForwardIterator1 pat_first, ForwardIterator1 pat_last,
                     BinaryPredicate pred = BinaryPredicate());
    template<class ForwardIterator2>
    pair<ForwardIterator2, ForwardIterator2>
    operator()(ForwardIterator2 first, ForwardIterator2 last) const;
private:
    ForwardIterator1 pat_first_; // exposition only
    ForwardIterator1 pat_last_; // exposition only
    BinaryPredicate pred_; // exposition only
};
```

1. Effects: Constructs a default_searcher object, initializing pat_first_ with pat_first, pat_last_ with pat_last, and pred_ with pred.
2. Throws: Any exception thrown by the copy constructor of BinaryPredicate or ForwardIterator1.

19.14.15.2 Class template boyer_moore_searcher

```cpp
template<class RandomAccessIterator1,
         class Hash = hash<typename iterator_traits<RandomAccessIterator1>::value_type>,
         class BinaryPredicate = equal_to<>>
class boyer_moore_searcher {
public:
    boyer_moore_searcher(RandomAccessIterator1 pat_first,
                         RandomAccessIterator1 pat_last,
                         Hash hf = Hash(),
                         BinaryPredicate pred = BinaryPredicate());
    template<class RandomAccessIterator2>
    pair<RandomAccessIterator2, RandomAccessIterator2>
    operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;
private:
    RandomAccessIterator1 pat_first_; // exposition only
};
```
RandomAccessIterator1 pat_last_;  // exposition only
Hash hash_;               // exposition only
BinaryPredicate pred_;    // exposition only

boyer_moore_searcher(RandomAccessIterator1 pat_first,
                     RandomAccessIterator1 pat_last,
                     Hash hf = Hash(),
                     BinaryPredicate pred = BinaryPredicate());

1 Requires: The value type of RandomAccessIterator1 shall satisfy the Cpp17DefaultConstructible requirements, the Cpp17CopyConstructible requirements, and the Cpp17CopyAssignable requirements.

2 Requires: For any two values A and B of the type iterator_traits<RandomAccessIterator1>::value_type, if pred(A, B) == true, then hf(A) == hf(B) shall be true.

3 Effects: Constructs a boyer_moore_searcher object, initializing pat_first_ with pat_first, pat_last_ with pat_last, hash_ with hf, and pred_ with pred.

4 Throws: Any exception thrown by the copy constructor of RandomAccessIterator1, or by the default constructor, copy constructor, or the copy assignment operator of the value type of RandomAccessIterator1, or the copy constructor or operator() of BinaryPredicate or Hash. May throw bad_alloc if additional memory needed for internal data structures cannot be allocated.

template<class RandomAccessIterator2> pair<RandomAccessIterator2, RandomAccessIterator2> operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;

5 Requires: RandomAccessIterator1 and RandomAccessIterator2 shall have the same value type.

6 Effects: Finds a subsequence of equal values in a sequence.

7 Returns: A pair of iterators i and j such that

   — i is the first iterator in the range [first, last - (pat_last_ - pat_first_)) such that for every non-negative integer n less than pat_last_ - pat_first_ the following condition holds: pred(*(i + n), *(pat_first_ + n)) != false, and

   — j == next(i, distance(pat_first_, pat_last_)).

Returns make_pair(first, first) if [pat_first_, pat_last_] is empty, otherwise returns make_pair(last, last) if no such iterator is found.

8 Complexity: At most (last - first) * (pat_last_ - pat_first_) applications of the predicate.

19.14.15.3 Class template boyer_moore_horspool_searcher [func.search.bmh]

template<class RandomAccessIterator1,  
       class Hash = hash<typename iterator_traits<RandomAccessIterator1>::value_type>,  
       class BinaryPredicate = equal_to<>>
class boyer_moore_horspool_searcher {
public:

boyer_moore_horspool_searcher(RandomAccessIterator1 pat_first,  
                              RandomAccessIterator1 pat_last,  
                              Hash hf = Hash(),  
                              BinaryPredicate pred = BinaryPredicate());

private:

RandomAccessIterator1 pat_first_;  // exposition only
RandomAccessIterator1 pat_last_;   // exposition only
Hash hash_;                        // exposition only
BinaryPredicate pred_;             // exposition only
};
boyer_moore_horspool_searcher(RandomAccessIterator1 pat_first,
RandomAccessIterator1 pat_last,
Hash hf = Hash(),
BinaryPredicate pred = BinaryPredicate());

Requires: The value type of RandomAccessIterator1 shall satisfy the Cpp17DefaultConstructible,
Cpp17CopyConstructible, and Cpp17CopyAssignable requirements.

Requires: For any two values A and B of the type iterator_traits<RandomAccessIterator1>::value_type,
if pred(A, B) == true, then hf(A) == hf(B) shall be true.

Effects: Constructs a boyer_moore_horspool_searcher object, initializing pat_first_ with pat_first,
pat_last_ with pat_last, hash_ with hf, and pred_ with pred.

Throws: Any exception thrown by the copy constructor of RandomAccessIterator1, or by the default
constructor, copy constructor, or the copy assignment operator of the value type of RandomAccessIterator1 or
the copy constructor or operator() of BinaryPredicate or Hash. May throw bad_alloc
if additional memory needed for internal data structures cannot be allocated.

template<class RandomAccessIterator2>
pair<RandomAccessIterator2, RandomAccessIterator2>
operator()(RandomAccessIterator2 first, RandomAccessIterator2 last) const;

Requires: RandomAccessIterator1 and RandomAccessIterator2 shall have the same value type.

Effects: Finds a subsequence of equal values in a sequence.

Returns: A pair of iterators i and j such that

(7.1) i is the first iterator in the range [first, last - (pat_last_ - pat_first_)) such that for
every non-negative integer n less than pat_last_ - pat_first_ the following condition holds:
pred(*(i + n), *(pat_first_ + n)) != false, and

(7.2) j == next(i, distance(pat_first_, pat_last_)).

Returns make_pair(first, first) if [pat_first_, pat_last_) is empty, otherwise returns make_pair(last, last)
if no such iterator is found.

Complexity: At most (last - first) * (pat_last_ - pat_first_) applications of the predicate.

19.14.16 Class template hash

The unordered associative containers defined in 21.5 use specializations of the class template hash (19.14.1)
as the default hash function.

Each specialization of hash is either enabled or disabled, as described below. [Note: Enabled specializations
meet the Cpp17Hash requirements, and disabled specializations do not. —end note] Each header that
declares the template hash provides enabled specializations of hash for nullptr_t and all cv-unqualified
arithmetic, enumeration, and pointer types. For any type Key for which neither the library nor the user
provides an explicit or partial specialization of the class template hash, hash<Key> is disabled.

If the library provides an explicit or partial specialization of hash<Key>, that specialization is enabled except
as noted otherwise, and its member functions are noexcept except as noted otherwise.

If H is a disabled specialization of hash, these values are false: is_default_constructible_v<H>,
is_copy_constructible_v<H>, is_move_constructible_v<H>, is_copy_assignable_v<H>, and
is_move_assignable_v<H>. Disabled specializations of hash are not function object types (19.14). [Note: This
means that the specialization of hash exists, but any attempts to use it as a Cpp17Hash will be ill-formed.
—end note]

An enabled specialization hash<Key> will:

(5.1) satisfy the Cpp17Hash requirements (Table 31), with Key as the function call argument type, the
Cpp17DefaultConstructible requirements (Table 24), the Cpp17CopyAssignable requirements (Table 28),
(5.2) be swappable (15.5.3.2) for lvalues,
(5.3) satisfy the requirement that if k1 == k2 is true, h(k1) == h(k2) is also true, where h is an object of
type hash<Key> and k1 and k2 are objects of type Key;
— satisfy the requirement that the expression \( h(k) \), where \( h \) is an object of type `hash<Key>` and \( k \) is an object of type `Key`, shall not throw an exception unless `hash<Key>` is a program-defined specialization that depends on at least one program-defined type.

### 19.15 Metaprogramming and type traits

This subclause describes components used by C++ programs, particularly in templates, to support the widest possible range of types, optimise template code usage, detect type related user errors, and perform type inference and transformation at compile time. It includes type classification traits, type property inspection traits, and type transformations. The type classification traits describe a complete taxonomy of all possible C++ types, and state where in that taxonomy a given type belongs. The type property inspection traits allow important characteristics of types or of combinations of types to be inspected. The type transformations allow certain properties of types to be manipulated.

#### 19.15.1 Requirements

1 A `Cpp17UnaryTypeTrait` describes a property of a type. It shall be a class template that takes one template type argument and, optionally, additional arguments that help define the property being described. It shall be `Cpp17DefaultConstructible`, `Cpp17CopyConstructible`, and publicly and unambiguously derived, directly or indirectly, from its `base characteristic`, which is a specialization of the template `integral_constant` (19.15.3), with the arguments to the template `integral_constant` determined by the requirements for the particular property being described. The member names of the base characteristic shall not be hidden and shall be unambiguously available in the `Cpp17UnaryTypeTrait`.

2 A `Cpp17BinaryTypeTrait` describes a relationship between two types. It shall be a class template that takes two template type arguments and, optionally, additional arguments that help define the relationship being described. It shall be `Cpp17DefaultConstructible`, `Cpp17CopyConstructible`, and publicly and unambiguously derived, directly or indirectly, from its `base characteristic`, which is a specialization of the template `integral_constant` (19.15.3), with the arguments to the template `integral_constant` determined by the requirements for the particular relationship being described. The member names of the base characteristic shall not be hidden and shall be unambiguously available in the `Cpp17BinaryTypeTrait`.

3 A `Cpp17TransformationTrait` modifies a property of a type. It shall be a class template that takes one template type argument and, optionally, additional arguments that help define the modification. It shall define a publicly accessible nested type named `type`, which shall be a synonym for the modified type.

#### 19.15.2 Header `<type_traits>` synopsis

```cpp
namespace std {
    // 19.15.3, helper class
    template<class T, T v> struct integral_constant;

1 The behavior of a program that adds specializations for any of the templates defined in this subclause is undefined unless otherwise specified.

2 Unless otherwise specified, an incomplete type may be used to instantiate a template in this subclause.

19.15.3 Helper classes

namespace std {
  template<class T, T v> struct integral_constant {
    static constexpr T value = v;
  }

§ 19.15.3
using value_type = T;
using type = integral_constant<T, v>;

constexpr operator value_type() const noexcept { return value; }
constexpr value_type operator()() const noexcept { return value; }

1 The class template integral_constant, alias template bool_constant, and its associated typedef-names true_type and false_type are used as base classes to define the interface for various type traits.

19.15.4 Unary type traits

This subclause contains templates that may be used to query the properties of a type at compile time.

Each of these templates shall be a Cpp17UnaryTypeTrait (19.15.1) with a base characteristic of true_type if the corresponding condition is true, otherwise false_type.

19.15.4.1 Primary type categories

The primary type categories correspond to the descriptions given in subclause 6.7 of the C++ standard.

For any given type T, the result of applying one of these templates to T and to cv T shall yield the same result.

[Note: For any given type T, exactly one of the primary type categories has a value member that evaluates to true. — end note]

struct is_function;
| T is a function type (6.7.2) | |
19.15.4.2 Composite type traits

These templates provide convenient compositions of the primary type categories, corresponding to the descriptions given in subclause 6.7.

For any given type \( T \), the result of applying one of these templates to \( T \) and to \( cv \ T \) shall yield the same result.

Table 45 — Composite type category predicates

<table>
<thead>
<tr>
<th>Template</th>
<th>Condition</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>

<td>template&lt;class T&gt; struct is_member_pointer;</td>
<td>( T ) is a pointer-to-member type (6.7.2)</td>
<td></td>
</tr>
</tbody>
</table>

19.15.4.3 Type properties

These templates provide access to some of the more important properties of types.

It is unspecified whether the library defines any full or partial specializations of any of these templates.

For all of the class templates \( X \) declared in this subclause, instantiating that template with a template-argument that is a class template specialization may result in the implicit instantiation of the template argument if and only if the semantics of \( X \) require that the argument is a complete type.

For the purpose of defining the templates in this subclause, a function call expression \( \text{declval}<T>() \) for any type \( T \) is considered to be a trivial (6.7, 10.3.3) function call that is not an odr-use (6.2) of \( \text{declval} \) in the context of the corresponding definition notwithstanding the restrictions of 19.2.6.

<td></td>
</tr>
<tr>
<td>template&lt;class T&gt; struct has_unique_object_representations;</td>
<td>For an array type T, the same result as has_unique_object_representations_v&lt;remove_all_extents_t&lt;T&gt;&gt;, otherwise see below</td>
<td>T shall be a complete type, cv void, or an array of unknown bound.</td>
</tr>
</tbody>
</table>

5 [Example:] is_const_v<const volatile int> // true is_const_v<const int*> // false is_const_v<const int[]> // false is_const_v<int[3]> // false is_const_v<const int[3]> // true

6 [Example:]
remove_const_t<const volatile int> // volatile int
remove_const_t<const int* const> // const int*
remove_const_t<const int&> // const int&

— end example]

Example:

// Given:
struct P final { };
union U1 { };
union U2 final { };

// the following assertions hold:
static_assert(!is_final_v<int>);
static_assert(is_final_v<P>);
static_assert(!is_final_v<U1>);
static_assert(is_final_v<U2>);

— end example]

The predicate condition for a template specialization is_constructible<T, Args...> shall be satisfied if and only if the following variable definition would be well-formed for some invented variable t:

T t(declval<Args>()...);

[Note: These tokens are never interpreted as a function declaration. — end note] Access checking is performed as if in a context unrelated to T and any of the Args. Only the validity of the immediate context of the variable initialization is considered. [Note: The evaluation of the initialization can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the “immediate context” and can result in the program being ill-formed. — end note]

The predicate condition for a template specialization has_unique_object_representations<T> shall be satisfied if and only if:

— T is trivially copyable, and
— any two objects of type T with the same value have the same object representation, where two objects of array or non-union class type are considered to have the same value if their respective sequences of direct subobjects have the same values, and two objects of union type are considered to have the same value if they have the same active member and the corresponding members have the same value.

The set of scalar types for which this condition holds is implementation-defined. [Note: If a type has padding bits, the condition does not hold; otherwise, the condition holds true for unsigned integral types. — end note]

19.15.5 Type property queries

This subclause contains templates that may be used to query properties of types at compile time.

Table 47 — Type property queries

<table>
<thead>
<tr>
<th>Template</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>template&lt;class T&gt;</td>
<td>alignof(T).</td>
</tr>
<tr>
<td>struct alignment_of;</td>
<td>Requires: alignof(T) shall be a valid expression (7.6.2.6)</td>
</tr>
<tr>
<td>template&lt;class T&gt;</td>
<td>If T names an array type, an integer value representing the number of dimensions of T; otherwise, 0.</td>
</tr>
<tr>
<td>struct rank;</td>
<td></td>
</tr>
<tr>
<td>template&lt;class T,</td>
<td></td>
</tr>
<tr>
<td>unsigned I = 0&gt;</td>
<td>If T is not an array type, or if it has rank less than or equal to I, or if I is 0 and T has type “array of unknown bound of U”, then 0; otherwise, the bound (9.2.3.4) of the I\textsuperscript{th} dimension of T, where indexing of I is zero-based</td>
</tr>
<tr>
<td>struct extent;</td>
<td></td>
</tr>
</tbody>
</table>

2 Each of these templates shall be a Cpp17UnaryTypeTrait (19.15.1) with a base characteristic of integral_constant<size_t, Value>.

3 [Example:
// the following assertions hold:
assert(rank_v<int> == 0);
assert(rank_v<int[2]> == 1);
assert(rank_v<int[][4]> == 2);
— end example]

[Example:
// the following assertions hold:
assert(extent_v<int> == 0);
assert(extent_v<int[2]> == 2);
assert(extent_v<int[2][4]> == 2);
assert(extent_v<int[][4]> == 0);
assert((extent_v<int, 1>) == 0);
assert((extent_v<int[2], 1>) == 0);
assert((extent_v<int[2][4], 1>) == 4);
assert((extent_v<int[][4], 1>) == 4);
— end example]

19.15.6 Relationships between types
[meta.rel]

This subclause contains templates that may be used to query relationships between types at compile time.

Each of these templates shall be a Cpp17BinaryTypeTrait (19.15.1) with a base characteristic of true_type if the corresponding condition is true, otherwise false_type.

Table 48 — Type relationship predicates

<table>
<thead>
<tr>
<th>Template</th>
<th>Condition</th>
<th>Comments</th>
</tr>
</thead>
</table>
| template<class T, class U>
struct is_same;
| T and U name the same type
with the same
cv-qualifications |
| template<class Base, class Derived>
struct is_base_of;
| Base is a base class of
Derived (10.6) without
regard to cv-qualifiers or Base
and Derived are not unions
and name the same class type
without regard to cv-qualifiers
| If Base and Derived are
non-union class types and are
not possibly cv-qualified
versions of the same type,
Derived shall be a complete
type. [Note: Base classes that
are private, protected, or
ambiguous are, nonetheless,
base classes. — end note] |
| template<class From, class To>
struct is_convertible;
| see below |
| From and To shall be complete
types, arrays of unknown
bound, or cv void types. |
| template<class From, class To>
struct is_nothrow_convertible;
| is_convertible_v<From,
To> is true and the
conversion, as defined by
is_convertible, is known
not to throw any
exceptions (7.6.2.7) |
| From and To shall be complete
types, arrays of unknown
bound, or cv void types. |
| template<class Fn, class... ArgTypes>
struct is_invocable;
| The expression
INVOKE<declval<Fn>,
dclval<ArgTypes>>()
is well-formed when treated as
an unevaluated operand |
| Fn and all types in the
template parameter pack
ArgTypes shall be complete
types, cv void, or arrays of
unknown bound. |
| template<class R, class Fn, class... ArgTypes>
struct is_invocable_r;
| The expression
INVOKE<R>(declval<Fn>,
dclval<ArgTypes>) is well-formed when treated as
an unevaluated operand |
| Fn, R, and all types in the
template parameter pack
ArgTypes shall be complete
types, cv void, or arrays of
unknown bound. |
Table 48 — Type relationship predicates (continued)

<tr>
<td>template&lt;class R, class Fn, class... ArgTypes&gt; struct is_nothrow_invocable_r;</td>
<td>is_invocable_r_v&lt;R, Fn, ArgTypes...&gt; is true and the expression INVOKE&lt;R&gt;(declval&lt;Fn&gt;(), declval&lt;ArgTypes&gt;()...) is known not to throw any exceptions</td>
<td>Fn, R, and all types in the template parameter pack ArgTypes shall be complete types, cv void, or arrays of unknown bound.</td>
</tr>
</tbody>
</table>

3 For the purpose of defining the templates in this subclause, a function call expression declval<T>() for any type T is considered to be a trivial (6.7, 10.3.3) function call that is not an odr-use (6.2) of declval in the context of the corresponding definition notwithstanding the restrictions of 19.2.6.

4 [Example:

```cpp
struct B {}; 
struct B1 : B {}; 
struct B2 : B {}; 
struct D : private B1, private B2 {}; 

is_base_of_v<B, D>    // true 
is_base_of_v<const B, D>    // true 
is_base_of_v<volatile B, D>    // true 
is_base_of_v<volatile const B, D>    // true 
is_base_of_v<const volatile B, B>    // true 
is_base_of_v<volatile const D, B>    // false 
is_base_of_v<volatile B&, B&>    // false 
is_base_of_v<volatile B[3], D[3]>    // false 
is_base_of_v<volatile int, int>    // false 

— end example]
```

5 The predicate condition for a template specialization is_convertible<From, To> shall be satisfied if and only if the return expression in the following code would be well-formed, including any implicit conversions to the return type of the function:

```cpp
To test() {
    return declval<From>();
}
```

[Note: This requirement gives well-defined results for reference types, void types, array types, and function types. — end note] Access checking is performed in a context unrelated to To and From. Only the validity of the immediate context of the expression of the return statement (8.6.3) (including initialization of the returned object or reference) is considered. [Note: The initialization can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the “immediate context” and can result in the program being ill-formed. — end note]

19.15.7 Transformations between types [meta.trans]

1 This subclause contains templates that may be used to transform one type to another following some predefined rule.

2 Each of the templates in this subclause shall be a Cpp17TransformationTrait (19.15.1).

19.15.7.1 Const-volatile modifications [meta.trans.cv]
Table 49 — Const-volatile modifications

<table>
<thead>
<tr>

§ 19.15.7.6
Table 54 — Other transformations (continued)

<table>
<thead>
<tr>
<th>Template</th>
<th>Comments</th>
</tr>
</thead>
</table>
| template<class Fn, class... ArgTypes> struct invoke_result; | If the expression \(\text{INVOLVE}(\text{declval}<\text{Fn}>(), \text{declval}<\text{ArgTypes}>()\ldots)\) is well-formed when treated as an unevaluated operand (7.2), the member typedef type names the type \(\text{decltype}(\text{INVOLVE}(\text{declval}<\text{Fn}>(), \text{declval}<\text{ArgTypes}>()\ldots))\); otherwise, there shall be no member type. Access checking is performed as if in a context unrelated to \(\text{Fn}\) and \(\text{ArgTypes}\). Only the validity of the immediate context of the expression is considered. [Note: The compilation of the expression can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the “immediate context” and can result in the program being ill-formed. — end note] 

Requires: \(\text{Fn}\) and all types in the template parameter pack \(\text{ArgTypes}\) shall be complete types, \(\text{cv void}\), or arrays of unknown bound.

---

1 [Note: A typical implementation would define \texttt{aligned_storage} as:

```cpp
template<size_t Len, size_t Alignment>
struct aligned_storage {
  typedef struct {
    alignas(Alignment) unsigned char __data[Len];
  } type;
};
```

— end note]  

2 It is implementation-defined whether any extended alignment is supported (6.6.5).

3 Let:

\[\ (3.1) \quad \text{CREF}(A) \text{ be } \text{add_lvalue_reference_t<const remove_reference_t<A>>}, \]

\[\ (3.2) \quad \text{XREF}(A) \text{ denote a unary class template } T \text{ such that } T<U> \text{ denotes the same type as } U \text{ with the addition of } A\text{’s cv and reference qualifiers, for a non-reference cv-unqualified type } U, \]

\[\ (3.3) \quad \text{COPYCV}(\text{FROM}, \text{TO}) \text{ be an alias for type } T0 \text{ with the addition of } \text{FROM}\text{’s top-level cv-qualifiers. [Example: } \text{COPYCV}(\text{const int, volatile short}) \text{ is an alias for const volatile short. — end example]} \]

\[\ (3.4) \quad \text{COND_RES}(X, Y) \text{ be decltype(false ? declval<X(&)()>()() : declval<Y(&)()>()()}). \]

Given types \(A\) and \(B\), let \(X\) be \text{remove_reference_t}<A>, let \(Y\) be \text{remove_reference_t}<B>, and let \text{COMMON_REPO}(A, B) be:

\[\ (3.5) \quad \text{If } A \text{ and } B \text{ are both lvalue reference types, } \text{COMMON_REPO}(A, B) \text{ is } \text{COND_RES}(\text{COPYCV}(X, Y) & & \text{COPYCV}(Y, X) & & ) \text{ if that type exists and is a reference type.} \]

\[\ (3.6) \quad \text{Otherwise, let } C \text{ be } \text{remove_reference_t}<\text{COMMON_REPO}(X&, Y&)>&&. \text{ If } A \text{ and } B \text{ are both rvalue reference types, } C \text{ is well-formed, and } \text{is_convertible_v}<A, C> && \text{is_convertible_v}<B, C> \text{ is true, then } \text{COMMON_REPO}(A, B) \text{ is } C. \]

\[\ (3.7) \quad \text{Otherwise, let } D \text{ be } \text{COMMON_REPO}(\text{const X&, Y&}). \text{ If } A \text{ is an rvalue reference and } B \text{ is an lvalue reference and } D \text{ is well-formed and } \text{is_convertible_v}<A, D> \text{ is true, then } \text{COMMON_REPO}(A, B) \text{ is } D. \]

\[\ (3.8) \quad \text{Otherwise, if } A \text{ is an lvalue reference and } B \text{ is an rvalue reference, then } \text{COMMON_REPO}(A, B) \text{ is } \text{COMMON_REPO}(B, A). \]

\[\ (3.9) \quad \text{Otherwise, } \text{COMMON_REPO}(A, B) \text{ is ill-formed.} \]

If any of the types computed above is ill-formed, then \text{COMMON_REPO}(A, B) is ill-formed.

4 Note A: For the \texttt{common_type} trait applied to a template parameter pack \(T\) of types, the member type shall be either defined or not present as follows:

\[\ (4.1) \quad \text{If sizeof...}(T) \text{ is zero, there shall be no member type.} \]

§ 19.15.7.6
If sizeof...(T) is one, let T0 denote the sole type constituting the pack T. The member typedef-name type shall denote the same type, if any, as common_type_t<T0, T0>; otherwise there shall be no member type.

If sizeof...(T) is two, let the first and second types constituting T be denoted by T1 and T2, respectively, and let D1 and D2 denote the same types as decay_t<T1> and decay_t<T2>, respectively.

- If is_same_v<T1, D1> is false or is_same_v<T2, D2> is false, let C denote the same type, if any, as common_type_t<D1, D2>.

- [Note: None of the following will apply if there is a specialization common_type<D1, D2>. — end note]

- Otherwise, if decay_t<decltype(false ? declval<D1>() : declval<D2>())> denotes a valid type, let C denote that type.

- Otherwise, if (COND_RES(CREF(D1), CREF(D2))) denotes a type, let C denote the type decay_t<COND_RES(CREF(D1), CREF(D2))>.

In either case, the member typedef-name type shall denote the same type, if any, as C. Otherwise, there shall be no member type.

If sizeof...(T) is greater than two, let T1, T2, and R, respectively, denote the first, second, and (pack of) remaining types constituting T. Let C denote the same type, if any, as common_type_t<T1, T2>. If there is such a type C, the member typedef-name type shall denote the same type, if any, as common_type_t<C, R...>. Otherwise, there shall be no member type.

Note B: Notwithstanding the provisions of 19.15.2, and pursuant to 15.5.4.2.1, a program may specialize common_type<T1, T2> for types T1 and T2 such that is_same_v<T1, decay_t<T1>> and is_same_v<T2, decay_t<T2>> are each true. [Note: Such specializations are needed when only explicit conversions are desired between the template arguments. — end note] Such a specialization need not have a member named type, but if it does, that member shall be a typedef-name for an accessible and unambiguous cv-unqualified non-reference type C to which each of the types T1 and T2 is explicitly convertible. Moreover, common_type_t<T1, T2> shall denote the same type, if any, as does common_type_t<T2, T1>. No diagnostic is required for a violation of this Note’s rules.

Note C: For the common_reference trait applied to a parameter pack T of types, the member type shall be either defined or not present as follows:

- If sizeof...(T) is zero, there shall be no member type.

- Otherwise, if sizeof...(T) is one, let T0 denote the sole type in the pack T. The member typedef type shall denote the same type as T0.

- Otherwise, if sizeof...(T) is two, let T1 and T2 denote the two types in the pack T. Then

  - If T1 and T2 are reference types and COMMON_REF(T1, T2) is well-formed, then the member typedef type denotes that type.

  - Otherwise, if basic_common_reference<remove_cvref_t<T1>, remove_cvref_t<T2>, XREF(T1), XREF(T2)>::type is well-formed, then the member typedef type denotes that type.

  - Otherwise, if COMMON_RES(T1, T2) is well-formed, then the member typedef type denotes that type.

  - Otherwise, if common_type_t<T1, T2> is well-formed, then the member typedef type denotes that type.

  - Otherwise, there shall be no member type.

- Otherwise, if sizeof...(T) is greater than two, let T1, T2, and Rest, respectively, denote the first, second, and (pack of) remaining types comprising T. Let C be the type common_reference_t<T1, T2>. Then:

  - If there is such a type C, the member typedef type shall denote the same type, if any, as common_reference_t<C, Rest...>.

  - Otherwise, there shall be no member type.

Note D: Notwithstanding the provisions of 19.15.2, and pursuant to 15.5.4.2.1, a program may partially specialize basic_common_reference<T, U, TQual, UQual> for types T and U such that is_same_v<T, decay_—
t<T>> and is_same_v<U, decay_t<U>> are each true. [Note: Such specializations can be used to influence the result of `common_reference`, and are needed when only explicit conversions are desired between the template arguments. — end note] Such a specialization need not have a member named `type`, but if it does, that member shall be a `typedef-name` for an accessible and unambiguous type `C` to which each of the types TQual<T> and UQual<U> is convertible. Moreover, `basic_common_reference<T, U, TQual, UQual>::type` shall denote the same type, if any, as does `basic_common_reference<U, T, UQual, TQual>::type`. No diagnostic is required for a violation of these rules.

8 [Example: Given these definitions:]

```cpp
using PF1 = bool (*)(());
using PF2 = short (*)(long);
struct S {
    operator PF2() const;
    double operator() (char, int&);
    void fn(long) const;
    char data;
};
using PMF = void (S::*)(long) const;
using PMD = char S::*;
```

the following assertions will hold:

```cpp
static_assert(is_same_v<invoke_result_t<S, int>, short>);
static_assert(is_same_v<invoke_result_t<S&, unsigned char, int&>, double>);
static_assert(is_same_v<invoke_result_t<PF1>, bool>);
static_assert(is_same_v<invoke_result_t<PMF, unique_ptr<S>, int>, void>);
static_assert(is_same_v<invoke_result_t<PMF, S>, char&&>);
static_assert(is_same_v<invoke_result_t<PMF, const S*, char&>>,);
```

— end example

19.15.8 Logical operator traits [meta.logical]

This subclause describes type traits for applying logical operators to other type traits.

```cpp
template<class... B> struct conjunction : see below {  };
```

2 The class template `conjunction` forms the logical conjunction of its template type arguments.  

3 For a specialization `conjunction<B1, ..., BN>`, if there is a template type argument `Bi` for which `bool(Bi::value)` is `false`, then instantiating `conjunction<B1, ..., BN>::value` does not require the instantiation of `Bj::value` for `j > i`. [Note: This is analogous to the short-circuiting behavior of the built-in operator &&. — end note] Every template type argument for which `Bi::value` is instantiated shall be usable as a base class and shall have a member `value` which is convertible to `bool`, is not hidden, and is unambiguously available in the type.

5 The specialization `conjunction<B1, ..., BN>` has a public and unambiguous base that is either

5.1 — the first type `Bi` in the list `true_type`, `B1, ..., BN` for which `bool(Bi::value)` is `false`, or

5.2 — if there is no such `Bi`, the last type in the list.

[Note: This means a specialization of `conjunction` does not necessarily inherit from either `true_type` or `false_type`. — end note] The member names of the base class, other than `conjunction` and `operator=`, shall not be hidden and shall be unambiguously available in `conjunction`.

```cpp
template<class... B> struct disjunction : see below {  };
```

7 The class template `disjunction` forms the logical disjunction of its template type arguments.

8 For a specialization `disjunction<B1, ..., BN>`, if there is a template type argument `Bi` for which `bool(Bi::value)` is `true`, then instantiating `disjunction<B1, ..., BN>::value` does not require the instantiation of `Bj::value` for `j > i`. [Note: This is analogous to the short-circuiting behavior of the built-in operator ||. — end note]
Every template type argument for which \(B_i::\text{value}\) is instantiated shall be usable as a base class and shall have a member \texttt{value} which is convertible to \texttt{bool}, is not hidden, and is unambiguously available in the type.

The specialization \texttt{disjunction<\texttt{B}_1, \ldots, \texttt{B}_N>} has a public and unambiguous base that is either

- the first type \(\texttt{B}_i\) in the list \texttt{false_type}, \(\texttt{B}_1, \ldots, \texttt{B}_N\) for which \texttt{bool(\texttt{B}_i::\text{value})} is \texttt{true}, or

- if there is no such \(\texttt{B}_i\), the last type in the list.

[\textit{Note: This means a specialization of \texttt{disjunction} does not necessarily inherit from either \texttt{true_type} or \texttt{false_type}. —end note}]

The member names of the base class, other than \texttt{disjunction} and \texttt{operator=}, shall not be hidden and shall be unambiguously available in \texttt{disjunction}.

\texttt{template<class \texttt{B}> struct negation : see below \{ \};}

The class template \texttt{negation} forms the logical negation of its template type argument. The type \texttt{negation<\texttt{B}>} is a \texttt{Cpp17UnaryTypeTrait} with a base characteristic of \texttt{bool_constant<!bool(\texttt{B}::\text{value})>)}.

### 19.15.9 Endian

Two common methods of byte ordering in multibyte scalar types are big-endian and little-endian in the execution environment. Big-endian is a format for storage of binary data in which the most significant byte is placed first, with the rest in descending order. Little-endian is a format for storage of binary data in which the least significant byte is placed first, with the rest in ascending order. This subclause describes the endianness of the scalar types of the execution environment.

```cpp
enum class endian {
    little = see below,
    big = see below,
    native = see below
};
```

If all scalar types have size 1 byte, then all of \texttt{endian::little}, \texttt{endian::big}, and \texttt{endian::native} have the same value. Otherwise, \texttt{endian::little} is not equal to \texttt{endian::big}. If all scalar types are big-endian, \texttt{endian::native} is equal to \texttt{endian::big}. If all scalar types are little-endian, \texttt{endian::native} is equal to \texttt{endian::little}. Otherwise, \texttt{endian::native} is not equal to either \texttt{endian::big} or \texttt{endian::little}.

### 19.16 Compile-time rational arithmetic

#### 19.16.1 In general

This subclause describes the ratio library. It provides a class template \texttt{ratio} which exactly represents any finite rational number with a numerator and denominator representable by compile-time constants of type \texttt{intmax_t}.

Throughout this subclause, the names of template parameters are used to express type requirements. If a template parameter is named \texttt{R1} or \texttt{R2}, and the template argument is not a specialization of the \texttt{ratio} template, the program is ill-formed.

#### 19.16.2 Header \texttt{<ratio>} synopsis

```cpp
namespace std {
    // 19.16.3, class template ratio
    template<intmax_t \texttt{N}, intmax_t \texttt{D} = 1> class ratio;

    // 19.16.4, ratio arithmetic
    template<class \texttt{R1}, class \texttt{R2}> using ratio_add = see below;
    template<class \texttt{R1}, class \texttt{R2}> using ratio_subtract = see below;
    template<class \texttt{R1}, class \texttt{R2}> using ratio_multiply = see below;
    template<class \texttt{R1}, class \texttt{R2}> using ratio_divide = see below;

    // 19.16.5, ratio comparison
    template<class \texttt{R1}, class \texttt{R2}> struct ratio_equal;
    template<class \texttt{R1}, class \texttt{R2}> struct ratio_not_equal;
}
```
template<class R1, class R2> struct ratio_less;
template<class R1, class R2> struct ratio_less_equal;
template<class R1, class R2> struct ratio_greater;
template<class R1, class R2> struct ratio_greater_equal;

template<class R1, class R2>
inline constexpr bool ratio_equal_v = ratio_equal<R1, R2>::value;
template<class R1, class R2>
inline constexpr bool ratio_not_equal_v = ratio_not_equal<R1, R2>::value;
template<class R1, class R2>
inline constexpr bool ratio_less_v = ratio_less<R1, R2>::value;
template<class R1, class R2>
inline constexpr bool ratio_less_equal_v = ratio_less_equal<R1, R2>::value;
template<class R1, class R2>
inline constexpr bool ratio_greater_v = ratio_greater<R1, R2>::value;
template<class R1, class R2>
inline constexpr bool ratio_greater_equal_v = ratio_greater_equal<R1, R2>::value;

// 19.16.6, convenience SI typedefs
using yocto = ratio<1, 1'000'000'000'000'000'000'000'000'000'; // see below
using zepto = ratio<1, 1'000'000'000'000'000'000'000'000'000'; // see below
using atto = ratio<1, 1'000'000'000'000'000'000'000'000'000';
using femto = ratio<1, 1'000'000'000'000'000'000'000'000'000';
using pico = ratio<1, 1'000'000'000'000'000'000'000'000'000';
using nano = ratio<1, 1'000'000'000'000'000'000'000'000'000';
using micro = ratio<1, 1'000'000'000'000'000'000'000'000'000';
using milli = ratio<1, 1'000';
using centi = ratio<1, 100';
using deci = ratio<1, 10';
using deca = ratio<1, 10';
using hecto = ratio<1, 100';
using kilo = ratio<1, 1'000';
using mega = ratio<1, 1'000';
using giga = ratio<1, 1'000';
using tera = ratio<1, 1'000';
using peta = ratio<1, 1'000';
using exa = ratio<1, 1'000';
using zetta = ratio<1, 1'000';
using yotta = ratio<1, 1'000'; // see below

§ 19.16.3  Class template ratio

namespace std {
    template<intmax_t N, intmax_t D = 1> class ratio {
        public:
            static constexpr intmax_t num;
            static constexpr intmax_t den;
            using type = ratio<num, den>;
        };
    }

1 If the template argument D is zero or the absolute values of either of the template arguments N and D is not representable by type intmax_t, the program is ill-formed. [Note: These rules ensure that infinite ratios are avoided and that for any negative input, there exists a representable value of its absolute value which is positive. In a two's complement representation, this excludes the most negative value. —end note]

2 The static data members num and den shall have the following values, where gcd represents the greatest common divisor of the absolute values of N and D:

(2.1) num shall have the value sign(N) * sign(D) * abs(N) / gcd.
(2.2) den shall have the value abs(D) / gcd.
19.16.4 Arithmetic on ratios

Each of the alias templates `ratio_add`, `ratio_subtract`, `ratio_multiply`, and `ratio_divide` denotes the result of an arithmetic computation on two ratios `R1` and `R2`. With `X` and `Y` computed (in the absence of arithmetic overflow) as specified by Table 55, each alias denotes a `ratio<X, Y>` such that `U` is the same as `ratio<X, Y>::num` and `V` is the same as `ratio<X, Y>::den`.

2 If it is not possible to represent `U` or `V` with `intmax_t`, the program is ill-formed. Otherwise, an implementation should yield correct values of `U` and `V`. If it is not possible to represent `X` or `Y` with `intmax_t`, the program is ill-formed unless the implementation yields correct values of `U` and `V`.

### Table 55 — Expressions used to perform ratio arithmetic

<table>
<thead>
<tr>
<th>Type</th>
<th>Value of <code>X</code></th>
<th>Value of <code>Y</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>ratio_add&lt;R1, R2&gt;</td>
<td><code>R1::num * R2::den + R1::den * R2::den</code></td>
<td><code>R2::num * R1::den</code></td>
</tr>
<tr>
<td>ratio_subtract&lt;R1, R2&gt;</td>
<td><code>R1::num * R2::den - R1::den * R2::den</code></td>
<td><code>R2::num * R1::den</code></td>
</tr>
<tr>
<td>ratio_multiply&lt;R1, R2&gt;</td>
<td><code>R1::num * R2::num</code></td>
<td><code>R1::den * R2::den</code></td>
</tr>
<tr>
<td>ratio_divide&lt;R1, R2&gt;</td>
<td><code>R1::num * R2::num</code></td>
<td><code>R1::den * R2::num</code></td>
</tr>
</tbody>
</table>

3 **Example:**

```
static_assert(ratio_add<ratio<1, 3>, ratio<1, 6>>::num == 1, "1/3+1/6 == 1/2");
static_assert(ratio_add<ratio<1, 3>, ratio<1, 6>>::den == 2, "1/3+1/6 == 1/2");
static_assert(ratio_multiply<ratio<1, 3>, ratio<3, 2>>::num == 1, "1/3*3/2 == 1/2");
static_assert(ratio_multiply<ratio<1, 3>, ratio<3, 2>>::den == 2, "1/3*3/2 == 1/2");
```

// The following cases may cause the program to be ill-formed under some implementations
static_assert(ratio_add<ratio<1, INT_MAX>, ratio<1, INT_MAX>>::num == 2, "1/MAX+1/MAX == 2/MAX");
static_assert(ratio_add<ratio<1, INT_MAX>, ratio<1, INT_MAX>>::den == INT_MAX, "1/MAX+1/MAX == 2/MAX");
static_assert(ratio_multiply<ratio<1, INT_MAX>, ratio<INT_MAX, 2>>::num == 1, "1/MAX * MAX/2 == 1/2");
static_assert(ratio_multiply<ratio<1, INT_MAX>, ratio<INT_MAX, 2>>::den == 2, "1/MAX * MAX/2 == 1/2");

— end example

19.16.5 Comparison of ratios

```
template<class R1, class R2>
    struct ratio_equal : bool_constant<R1::num == R2::num && R1::den == R2::den> { };
template<class R1, class R2>
    struct ratio_not_equal : bool_constant<!ratio_equal_v<R1, R2>> { };
template<class R1, class R2>
    struct ratio_less : bool_constant<see below> { };
```

1 If `R1::num * R2::den` is less than `R2::num * R1::den`, `ratio_less<R1, R2>` shall be derived from `bool_constant<true>`, otherwise it shall be derived from `bool_constant<false>`. Implementations may use other algorithms to compute this relationship to avoid overflow. If overflow occurs, the program is ill-formed.

```
template<class R1, class R2>
    struct ratio_less_equal : bool_constant<!ratio_less_v<R2, R1>> { };
template<class R1, class R2>
    struct ratio_greater : bool_constant<ratio_less_v<R2, R1>> { };
template<class R1, class R2>
    struct ratio_greater_equal : bool_constant<!ratio_less_v<R1, R2>> { };
```
19.16.6 SI types for ratio

For each of the typedef-names yocto, zepto, zetta, and yotta, if both of the constants used in its specification are representable by intmax_t, the typedef shall be defined; if either of the constants is not representable by intmax_t, the typedef shall not be defined.

19.17 Class type_index

19.17.1 Header <typeindex> synopsis

namespace std {
    class type_index;
    template<class T> struct hash;
    template<> struct hash<type_index>;
}

19.17.2 type_index overview

namespace std {
    class type_index {
        public:
            type_index(const type_info& rhs) noexcept;
            bool operator==(const type_index& rhs) const noexcept;
            bool operator!=(const type_index& rhs) const noexcept;
            bool operator<(const type_index& rhs) const noexcept;
            bool operator>(const type_index& rhs) const noexcept;
            bool operator<=(const type_index& rhs) const noexcept;
            bool operator>=(const type_index& rhs) const noexcept;
            size_t hash_code() const noexcept;
            const char* name() const noexcept;
        private:
            const type_info* target;       // exposition only
            // Note that the use of a pointer here, rather than a reference,
            // means that the default copy/move constructor and assignment
            // operators will be provided and work as expected.
    };
}

The class type_index provides a simple wrapper for type_info which can be used as an index type in associative containers (21.4) and in unordered associative containers (21.5).

19.17.3 type_index members

type_index(const type_info& rhs) noexcept;

1 Effects: Constructs a type_index object, the equivalent of target = &rhs.

bool operator==(const type_index& rhs) const noexcept;

2 Returns: *target == *rhs.target.

bool operator!=(const type_index& rhs) const noexcept;

3 Returns: *target != *rhs.target.

bool operator<(const type_index& rhs) const noexcept;

4 Returns: target->before(*rhs.target).

bool operator>(const type_index& rhs) const noexcept;

5 Returns: rhs.target->before(*target).
