bool operator<=(const type_index& rhs) const noexcept;

bool operator>=(const type_index& rhs) const noexcept;

7 Returns: !target->before(*rhs.target).
size_t hash_code() const noexcept;

Returns: target->hash_code().

const char* name() const noexcept;

Returns: target->name().

19.17.4 Hash support

template<> struct hash<type_index>;

For an object index of type type_index, hash<type_index>()(index) shall evaluate to the same result as index.hash_code().

19.18 Execution policies

19.18.1 In general

This subclause describes classes that are execution policy types. An object of an execution policy type indicates the kinds of parallelism allowed in the execution of an algorithm and expresses the consequent requirements on the element access functions. [Example:

```cpp
using namespace std;
vector<int> v = /* ... */;

// standard sequential sort
sort(v.begin(), v.end());

// explicitly sequential sort
sort(execution::seq, v.begin(), v.end());

// permitting parallel execution
sort(execution::par, v.begin(), v.end());

// permitting vectorization as well
sort(execution::par_unseq, v.begin(), v.end());

— end example] [Note: Because different parallel architectures may require idiosyncratic parameters for efficient execution, implementations may provide additional execution policies to those described in this standard as extensions. — end note]

19.18.2 Header <execution> synopsis

namespace std {

// 19.18.3, execution policy type trait
template<class T> struct is_execution_policy;
template<class T> inline constexpr bool is_execution_policy_v = is_execution_policy<T>::value;
}

namespace std::execution {

// 19.18.4, sequenced execution policy
class sequenced_policy;

// 19.18.5, parallel execution policy
class parallel_policy;

// 19.18.6, parallel and unsequenced execution policy
class parallel_unsequenced_policy;

// 19.18.7, execution policy objects
inline constexpr sequenced_policy seq{ unspecified };  
inline constexpr parallel_policy par{ unspecified };  
inline constexpr parallel_unsequenced_policy par_unseq{ unspecified };
}

§ 19.18.2
19.18.3 Execution policy type trait

```cpp
template<class T> struct is_execution_policy { see below; }
```

1. `is_execution_policy` can be used to detect execution policies for the purpose of excluding function
   signatures from otherwise ambiguous overload resolution participation.

2. `is_execution_policy<T>` shall be a `Cpp17UnaryTypeTrait` with a base characteristic of `true_type` if
   `T` is the type of a standard or implementation-defined execution policy, otherwise `false_type`.
   [Note: This provision reserves the privilege of creating non-standard execution policies to the library
    implementation. — end note]

3. The behavior of a program that adds specializations for `is_execution_policy` is undefined.

19.18.4 Sequenced execution policy

```cpp
class execution::sequenced_policy { unspecified; }
```

1. The class `execution::sequenced_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and require that a parallel algorithm’s execution may not be
   parallelized.

2. During the execution of a parallel algorithm with the `execution::sequenced_policy` policy, if the
   invocation of an element access function exits via an uncaught exception, `terminate()` shall be called.

19.18.5 Parallel execution policy

```cpp
class execution::parallel_policy { unspecified; }
```

1. The class `execution::parallel_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm’s execution may be
   parallelized.

2. During the execution of a parallel algorithm with the `execution::parallel_policy` policy, if the
   invocation of an element access function exits via an uncaught exception, `terminate()` shall be called.

19.18.6 Parallel and unsequenced execution policy

```cpp
class execution::parallel_unsequenced_policy { unspecified; }
```

1. The class `execution::parallel_unsequenced_policy` is an execution policy type used as a unique type to disambiguate parallel algorithm overloading and indicate that a parallel algorithm’s execution may be
   parallelized and vectorized.

2. During the execution of a parallel algorithm with the `execution::parallel_unsequenced_policy` policy, if the
   invocation of an element access function exits via an uncaught exception, `terminate()` shall be called.

19.18.7 Execution policy objects

```cpp
inline constexpr execution::sequenced_policy execution::seq{ unspecified; }
inline constexpr execution::parallel_policy execution::par{ unspecified; }
inline constexpr execution::parallel_unsequenced_policy execution::par_unseq{ unspecified; }
```

1. The header `<execution>` declares global objects associated with each type of execution policy.

19.19 Primitive numeric conversions

19.19.1 Header `<charconv>` synopsis

```cpp
namespace std {
   // floating-point format for primitive numerical conversion
   enum class chars_format {
      scientific = unspecified,
      fixed = unspecified,
      hex = unspecified,
      general = fixed | scientific
   };
```
// 19.19.2, primitive numerical output conversion
struct to_chars_result {
    char* ptr;
    errc ec;
};
to_chars_result to_chars(char* first, char* last, see below value, int base = 10);
to_chars_result to_chars(char* first, char* last, float value);
to_chars_result to_chars(char* first, char* last, double value);
to_chars_result to_chars(char* first, char* last, long double value);
to_chars_result to_chars(char* first, char* last, float value, chars_format fmt);
to_chars_result to_chars(char* first, char* last, double value, chars_format fmt);
to_chars_result to_chars(char* first, char* last, long double value, chars_format fmt);
to_chars_result to_chars(char* first, char* last, float value, chars_format fmt, int precision);
to_chars_result to_chars(char* first, char* last, double value, chars_format fmt, int precision);
to_chars_result to_chars(char* first, char* last, long double value, chars_format fmt, int precision);

// 19.19.3, primitive numerical input conversion
struct from_chars_result {
    const char* ptr;
    errc ec;
};
from_chars_result from_chars(const char* first, const char* last, see below value, int base = 10);
from_chars_result from_chars(const char* first, const char* last, float& value,
    chars_format fmt = chars_format::general);
from_chars_result from_chars(const char* first, const char* last, double& value,
    chars_format fmt = chars_format::general);
from_chars_result from_chars(const char* first, const char* last, long double& value,
    chars_format fmt = chars_format::general);

1 The type chars_format is a bitmask type (15.4.2.1.4) with elements scientific, fixed, and hex.

19.19.2 Primitive numeric output conversion

1 All functions named to_chars convert value into a character string by successively filling the range [first, last), where [first, last) is required to be a valid range. If the member ec of the return value is such that the value is equal to the value of a value-initialized errc, the conversion was successful and the member ptr is the one-past-the-end pointer of the characters written. Otherwise, the member ec has the value errc::value_too_large, the member ptr has the value last, and the contents of the range [first, last) are unspecified.

2 The functions that take a floating-point value but not a precision parameter ensure that the string representation consists of the smallest number of characters such that there is at least one digit before the radix point (if present) and parsing the representation using the corresponding from_chars function recovers value exactly. [Note: This guarantee applies only if to_chars and from_chars are executed on the same implementation. — end note] If there are several such representations, the representation with the smallest difference from the floating-point argument value is chosen, resolving any remaining ties using rounding according to round_to_nearest (16.3.3.1).

3 The functions taking a chars_format parameter determine the conversion specifier for printf as follows: The conversion specifier is f if fmt is chars_format::fixed, e if fmt is chars_format::scientific, a (without leading "0x" in the result) if fmt is chars_format::hex, and g if fmt is chars_format::general.
to_chars_result to_chars(char* first, char* last, see below value, int base = 10);

Requires: base has a value between 2 and 36 (inclusive).
Effects: The value of value is converted to a string of digits in the given base (with no redundant leading zeroes). Digits in the range 10..35 (inclusive) are represented as lowercase characters a..z. If value is less than zero, the representation starts with ' - '.
Throws: Nothing.
Remarks: The implementation shall provide overloads for all signed and unsigned integer types and char as the type of the parameter value.

to_chars_result to_chars(char* first, char* last, float value);
to_chars_result to_chars(char* first, char* last, double value);
to_chars_result to_chars(char* first, char* last, long double value);

Effects: value is converted to a string in the style of printf in the "C" locale. The conversion specifier is f or e, chosen according to the requirement for a shortest representation (see above); a tie is resolved in favor of f.
Throws: Nothing.

to_chars_result to_chars(char* first, char* last, float value, chars_format fmt);
to_chars_result to_chars(char* first, char* last, double value, chars_format fmt);
to_chars_result to_chars(char* first, char* last, long double value, chars_format fmt);

Requires: fmt has the value of one of the enumerators of chars_format.
Effects: value is converted to a string in the style of printf in the "C" locale.
Throws: Nothing.

to_chars_result to_chars(char* first, char* last, float value, chars_format fmt, int precision);
to_chars_result to_chars(char* first, char* last, double value, chars_format fmt, int precision);
to_chars_result to_chars(char* first, char* last, long double value, chars_format fmt, int precision);

Requires: fmt has the value of one of the enumerators of chars_format.
Effects: value is converted to a string in the style of printf in the "C" locale with the given precision.
Throws: Nothing.

See also: ISO C 7.21.6.1

19.19.3 Primitive numeric input conversion [charconv.from.chars]
All functions named from_chars analyze the string [first, last) for a pattern, where [first, last) is required to be a valid range. If no characters match the pattern, value is unmodified, the member ptr of the return value is first and the member ec is equal to errc::invalid_argument. [Note: If the pattern allows for an optional sign, but the string has no digit characters following the sign, no characters match the pattern. — end note] Otherwise, the characters matching the pattern are interpreted as a representation of a value of the type of value. The member ptr of the return value points to the first character not matching the pattern, or has the value last if all characters match. If the parsed value is not in the range representable by the type of value, value is unmodified and the member ec of the return value is equal to errc::result_out_of_range. Otherwise, value is set to the parsed value, after rounding according to round_to_nearest (16.3.3.1), and the member ec is value-initialized.

from_chars_result from_chars(const char* first, const char* last, see below value, int base = 10);

Requires: base has a value between 2 and 36 (inclusive).
Effects: The pattern is the expected form of the subject sequence in the "C" locale for the given nonzero base, as described for strtol, except that no "0x" or "0X" prefix shall appear if the value of base is 16, and except that ' - ' is the only sign that may appear, and only if value has a signed type.
Throws: Nothing.
Remarks: The implementation shall provide overloads for all signed and unsigned integer types and
char as the referenced type of the parameter value.

from_chars_result from_chars(const char* first, const char* last, float& value,
chars_format fmt = chars_format::general);
from_chars_result from_chars(const char* first, const char* last, double& value,
chars_format fmt = chars_format::general);
from_chars_result from_chars(const char* first, const char* last, long double& value,
chars_format fmt = chars_format::general);

Requires: fmt has the value of one of the enumerators of chars_format.

Effects: The pattern is the expected form of the subject sequence in the "C" locale, as described for
strtod, except that

(7.1) — the sign ‘+’ may only appear in the exponent part;
(7.2) — if fmt has chars_format::scientific set but not chars_format::fixed, the otherwise optional
exponent part shall appear;
(7.3) — if fmt has chars_format::fixed set but not chars_format::scientific, the optional exponent
part shall not appear; and
(7.4) — if fmt is chars_format::hex, the prefix "0x" or "0X" is assumed. [Example: The string 0x123 is
parsed to have the value 0 with remaining characters x123. — end example]

In any case, the resulting value is one of at most two floating-point values closest to the value of the
string matching the pattern.

Throws: Nothing.

20 Strings library [strings]

20.1 General [strings.general]

1 This Clause describes components for manipulating sequences of any non-array trivial standard-layout (6.7) type. Such types are called char-like types, and objects of char-like types are called char-like objects or simply characters.

2 The following subclauses describe a character traits class, string classes, and null-terminated sequence utilities, as summarized in Table 56.

Table 56 — Strings library summary

20.2 Character traits [char.traits]

1 This subclause defines requirements on classes representing character traits, and defines a class template char_traits<charT>, along with four specializations, char_traits<char>, char_traits<char16_t>, char_traits<char32_t>, and char_traits<wchar_t>, that satisfy those requirements.

2 Most classes specified in 20.3 and Clause 27 need a set of related types and functions to complete the definition of their semantics. These types and functions are provided as a set of member typedef-names and functions in the template parameter traits used by each such template. This subclause defines the semantics of these members.

3 To specialize those templates to generate a string or iostream class to handle a particular character container type CharT, that and its related character traits class Traits are passed as a pair of parameters to the string or iostream template as parameters charT and traits. Traits::char_type shall be the same as CharT.

4 This subclause specifies a class template, char_traits<charT>, and four explicit specializations of it, char_traits<char>, char_traits<char16_t>, char_traits<char32_t>, and char_traits<wchar_t>, all of which appear in the header <string> and satisfy the requirements below.

20.2.1 Character traits requirements [char.traits.require]

1 In Table 57, X denotes a Traits class defining types and functions for the character container type CharT; c and d denote values of type CharT; p and q denote values of type const CharT*; s denotes a value of type CharT*; n, i and j denote values of type size_t; e and f denote values of type X::int_type; pos denotes a value of type X::pos_type; state denotes a value of type X::state_type; and r denotes an lvalue of type CharT. Operations on Traits shall not throw exceptions.

<td>Returns: for all ( c ) and ( d ), ( X::\text{eq}(c,d) ) is equal to ( X::\text{eq_int_type}(X::\text{to_int_type}(c), X::\text{to_int_type}(d)) ); otherwise, yields true if ( e ) and ( f ) are both copies of ( X::\text{eof()} ); otherwise, yields false if one of ( e ) and ( f ) is a copy of ( X::\text{eof()} ) and the other is not; otherwise the value is unspecified.</td>
<td>constant</td>
</tr>
<tr>
<td>( X::\text{eof()} )</td>
<td>( X::\text{int_type} )</td>
<td>Returns: a value ( e ) such that ( X::\text{eq_int_type}(e,X::\text{to_int_type}(c)) ) is false for all values ( c ).</td>
<td>constant</td>
</tr>
</tbody>
</table>

2 The class template

```cpp
template<class charT> struct char_traits;
```

shall be provided in the header `<string>` as a basis for explicit specializations.

### 20.2.2 Traits typedefs

[char.traits.typedefs]

```cpp
using char_type = CHAR_T;
```

1 The type `char_type` is used to refer to the character container type in the implementation of the library classes defined in 20.3 and Clause 27.

```cpp
using int_type = INT_T;
```

2 Requires: For a certain character container type `char_type`, a related container type `INT_T` shall be a type or class which can represent all of the valid characters converted from the corresponding `char_type` values, as well as an end-of-file value, `eof()`. The type `int_type` represents a character container type which can hold end-of-file to be used as a return type of the iostream class member functions.\(^\text{226}\)

```cpp
using off_type = implementation-defined;
```

```cpp
using pos_type = implementation-defined;
```

3 Requires: Requirements for `off_type` and `pos_type` are described in 27.2.2 and 27.3.

```cpp
using state_type = STATE_T;
```

4 Requires: `state_type` shall satisfy the `Cpp17CopyAssignable` (Table 28), `Cpp17CopyConstructible` (Table 26), and `Cpp17DefaultValueConstructible` (Table 24) requirements.

### 20.2.3 char_traits specializations

[char.traits.specializations]

```cpp
namespace std {
    template<> struct char_traits<char>;
    template<> struct char_traits<char16_t>;
    template<> struct char_traits<char32_t>;
    template<> struct char_traits<wchar_t>;
}
```

1 The header `<string>` shall define four specializations of the class template `char_traits`: `char_traits<char>`, `char_traits<char16_t>`, `char_traits<char32_t>`, and `char_traits<wchar_t>`.

2 The requirements for the members of these specializations are given in 20.2.1.

\(^{226}\) If `eof()` can be held in `char_type` then some iostreams operations may give surprising results.
20.2.3.1 struct char_traits<char>

namespace std {
    template<> struct char_traits<char> {
        using char_type = char;
        using int_type = int;
        using off_type = streamoff;
        using pos_type = streampos;
        using state_type = mbstate_t;

        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;
        static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
        static constexpr size_t length(const char_type* s);
        static constexpr const char_type* find(const char_type* s, size_t n, const char_type& a);
        static char_type* move(char_type* s1, const char_type* s2, size_t n);
        static char_type* copy(char_type* s1, const char_type* s2, size_t n);
        static char_type* assign(char_type* s, size_t n, char_type a);
        static constexpr int_type not_eof(int_type c) noexcept;
        static constexpr char_type to_char_type(int_type c) noexcept;
        static constexpr int_type to_int_type(char_type c) noexcept;
        static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
        static constexpr int_type eof() noexcept;
    };
}

1 The defined types for int_type, pos_type, off_type, and state_type shall be int, streampos, streamoff, and mbstate_t respectively.

2 The type streampos shall be an implementation-defined type that satisfies the requirements for pos_type in 27.2.2 and 27.3.

3 The type streamoff shall be an implementation-defined type that satisfies the requirements for off_type in 27.2.2 and 27.3.

4 The type mbstate_t is defined in <cwchar> and can represent any of the conversion states that can occur in an implementation-defined set of supported multibyte character encoding rules.

5 The two-argument member assign shall be defined identically to the built-in operator =. The two-argument members eq and lt shall be defined identically to the built-in operators == and < for type unsigned char.

6 The member eof() shall return EOF.

20.2.3.2 struct char_traits<char16_t>

namespace std {
    template<> struct char_traits<char16_t> {
        using char_type = char16_t;
        using int_type = uint_least16_t;
        using off_type = streamoff;
        using pos_type = u16streampos;
        using state_type = mbstate_t;

        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;
        static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
        static constexpr size_t length(const char_type* s);
        static constexpr const char_type* find(const char_type* s, size_t n, const char_type& a);
        static char_type* move(char_type* s1, const char_type* s2, size_t n);
        static char_type* copy(char_type* s1, const char_type* s2, size_t n);
        static char_type* assign(char_type* s, size_t n, char_type a);
    };
}

§ 20.2.3.2 679
static constexpr int_type not_eof(int_type c) noexcept;
static constexpr char_type to_char_type(int_type c) noexcept;
static constexpr int_type to_int_type(char_type c) noexcept;
static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
static constexpr int_type eof() noexcept;
};

1 The type `u16streampos` shall be an implementation-defined type that satisfies the requirements for `pos_type` in 27.2.2 and 27.3.

2 The two-argument members `assign`, `eq`, and `lt` shall be defined identically to the built-in operators `=`, `==`, and `<` respectively.

3 The member `eof()` shall return an implementation-defined constant that cannot appear as a valid UTF-16 code unit.

20.2.3.3 struct char_traits<char32_t> [char.traits.specializations.char32_t]
namespace std {
    template<> struct char_traits<char32_t> {
        using char_type = char32_t;
        using int_type = uint_least32_t;
        using off_type = streamoff;
        using pos_type = u32streampos;
        using state_type = mbstate_t;

        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;
        static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
        static constexpr size_t length(const char_type* s);
        static char_type* find(const char_type* s, size_t n, const char_type& a);
        static char_type* move(char_type* s1, const char_type* s2, size_t n);
        static char_type* copy(char_type* s1, const char_type* s2, size_t n);
        static char_type* assign(char_type* s, size_t n, char_type a);
        static constexpr int_type not_eof(int_type c) noexcept;
        static constexpr char_type to_char_type(int_type c) noexcept;
        static constexpr int_type to_int_type(char_type c) noexcept;
        static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
        static constexpr int_type eof() noexcept;
    };
}

1 The type `u32streampos` shall be an implementation-defined type that satisfies the requirements for `pos_type` in 27.2.2 and 27.3.

2 The two-argument members `assign`, `eq`, and `lt` shall be defined identically to the built-in operators `=`, `==`, and `<` respectively.

3 The member `eof()` shall return an implementation-defined constant that cannot appear as a Unicode code point.

20.2.3.4 struct char_traits<wchar_t> [char.traits.specializations.wchar.t]
namespace std {
    template<> struct char_traits<wchar_t> {
        using char_type = wchar_t;
        using int_type = wint_t;
        using off_type = streamoff;
        using pos_type = wstreampos;
        using state_type = mbstate_t;

        static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
        static constexpr bool eq(char_type c1, char_type c2) noexcept;
        static constexpr bool lt(char_type c1, char_type c2) noexcept;
        static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
        static constexpr size_t length(const char_type* s);
        static char_type* find(const char_type* s, size_t n, const char_type& a);
        static char_type* move(char_type* s1, const char_type* s2, size_t n);
        static char_type* copy(char_type* s1, const char_type* s2, size_t n);
        static char_type* assign(char_type* s, size_t n, char_type a);
        static constexpr int_type not_eof(int_type c) noexcept;
        static constexpr char_type to_char_type(int_type c) noexcept;
        static constexpr int_type to_int_type(char_type c) noexcept;
        static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
        static constexpr int_type eof() noexcept;
    };
}
static constexpr void assign(char_type& c1, const char_type& c2) noexcept;
static constexpr bool eq(char_type c1, char_type c2) noexcept;
static constexpr bool lt(char_type c1, char_type c2) noexcept;
static constexpr int compare(const char_type* s1, const char_type* s2, size_t n);
static constexpr size_t length(const char_type* s);
static constexpr const char_type* find(const char_type* s, size_t n, const char_type& a);

static char_type* assign(char_type* s, size_t n, char_type a);
static constexpr int_type not_eof(int_type c) noexcept;
static constexpr char_type to_char_type(int_type c) noexcept;
static constexpr int_type to_int_type(char_type c) noexcept;
static constexpr bool eq_int_type(int_type c1, int_type c2) noexcept;
static constexpr int_type eof() noexcept;
};

1 The defined types for int_type, pos_type, and state_type shall be wint_t, wstreampos, and mbstate_t respectively.
2 The type wstreampos shall be an implementation-defined type that satisfies the requirements for pos_type in 27.2.2 and 27.3.
3 The type mbstate_t is defined in <cwchar> and can represent any of the conversion states that can occur in an implementation-defined set of supported multibyte character encoding rules.
4 The two-argument members assign, eq, and lt shall be defined identically to the built-in operators =, ==, and < respectively.
5 The member eof() shall return WEOF.

20.3 String classes

1 The header <string> defines the basic_string class template for manipulating varying-length sequences of char-like objects and four typedef-names, string, u16string, u32string, and wstring, that name the specializations basic_string<char>, basic_string<char16_t>, basic_string<char32_t>, and basic_string<wchar_t>, respectively.

20.3.1 Header <string> synopsis

§ 20.3.1
20.3.2 Class template basic_string

The class template `basic_string` describes objects that can store a sequence consisting of a varying number of arbitrary char-like objects with the first element of the sequence at position zero. Such a sequence is also called a “string” if the type of the char-like objects that it holds is clear from context. In the rest of this Clause, the type of the char-like objects held in a `basic_string` object is designated by `charT`.

A `basic_string` is a contiguous container (21.2.1).

In all cases, `[data(), data() + size()]` is a valid range, `data() + size()` points at an object with value `charT()` (a “null terminator”), and `size() <= capacity()` is true.

The functions described in this Clause can report two kinds of errors, each associated with an exception type:

1. a length error is associated with exceptions of type `length_error` (18.2.5);
2. an out-of-range error is associated with exceptions of type `out_of_range` (18.2.6).

```
namespace std {
    template<class charT, class traits = char_traits<charT>,
             class Allocator = allocator<charT>>
    class basic_string {
        public:
            // types
            using traits_type = traits;
            using value_type = charT;
            using allocator_type = Allocator;
            using size_type = typename allocator_traits<Allocator>::size_type;
            using difference_type = typename allocator_traits<Allocator>::difference_type;
            using pointer = typename allocator_traits<Allocator>::pointer;
            using const_pointer = typename allocator_traits<Allocator>::const_pointer;
            using reference = value_type&;
            using const_reference = const value_type&;
            using iterator = implementation-defined; // see 21.2
            using const_iterator = implementation-defined; // see 21.2
            using reverse_iterator = std::reverse_iterator<iterator>;
            using const_reverse_iterator = std::reverse_iterator<const_iterator>;
            static const size_type npos = -1;

            // 20.3.2.2, construct/copy/destroy
            basic_string() noexcept(noexcept(Allocator())) : basic_string(Allocator()) {}
            explicit basic_string(const Allocator& a) noexcept;
            basic_string(const basic_string& str);
            basic_string(basic_string&& str) noexcept;
            basic_string(const basic_string& str, size_type pos, const Allocator& a = Allocator());
```

Notes:

1. `[data(), data() + size()]` is a valid range.
2. `data() + size()` points at an object with value `charT()` (a “null terminator”).
3. `size() <= capacity()` is true.
4. A `basic_string` is a contiguous container (21.2.1).
5. The functions described in this Clause can report two kinds of errors, each associated with an exception type:
   - a length error is associated with exceptions of type `length_error` (18.2.5);
   - an out-of-range error is associated with exceptions of type `out_of_range` (18.2.6).

---

227) `Allocator::value_type` must name the same type as `charT` (20.3.2.1).

6 A size_type parameter type in a basic_string deduction guide refers to the size_type member type of
the type deduced by the deduction guide.

20.3.2.1 General requirements [string.require]

1 If any operation would cause size() to exceed max_size(), that operation shall throw an exception object
of type length_error.

2 If any member function or operator of basic_string throws an exception, that function or operator shall
have no other effect.

§ 20.3.2.1
In every specialization `basic_string<charT, traits, Allocator>`, the type `allocator_traits<Allocator>::value_type` shall name the same type as `charT`. Every object of type `basic_string<charT, traits, Allocator>` shall use an object of type `Allocator` to allocate and free storage for the contained `charT` objects as needed. The `Allocator` object used shall be obtained as described in 21.2.1. In every specialization `basic_string<charT, traits, Allocator>`, the type `traits` shall satisfy the character traits requirements (20.2), and the type `traits::char_type` shall name the same type as `charT`.

References, pointers, and iterators referring to the elements of a `basic_string` sequence may be invalidated by the following uses of that `basic_string` object:

(4.1) — as an argument to any standard library function taking a reference to non-const `basic_string` as an argument.228

(4.2) — Calling non-const member functions, except `operator[]`, `at`, `data`, `front`, `back`, `begin`, `rbegin`, `end`, and `rend`.

### 20.3.2.2 Constructors and assignment operators

```cpp
explicit basic_string(const Allocator& a) noexcept;
```

*Effects:* Constructs an object of class `basic_string`.

*Ensures:* `size()` is 0 and `capacity()` is an unspecified value.

```cpp
basic_string(const basic_string& str);
basic_string(basic_string&& str) noexcept;
```

*Effects:* Constructs an object of class `basic_string`.

*Ensures:* `data()` points at the first element of an allocated copy of the array whose first element is pointed at by the original value `str.data()`, `size()` is equal to the original value of `str.size()`, and `capacity()` is a value at least as large as `size()`. In the second form, `str` is left in a valid state with an unspecified value.

```cpp
basic_string(const basic_string& str, size_type pos, const Allocator& a = Allocator());
basic_string(const basic_string& str, size_type pos, size_type n, const Allocator& a = Allocator());
```

*Throws:* `out_of_range` if `pos > str.size()`.

*Effects:* Constructs an object of class `basic_string` and determines the effective length `rlen` of the initial string value as `str.size() - pos` in the first form and as the smaller of `str.size() - pos` and `n` in the second form.

*Ensures:* `data()` points at the first element of an allocated copy of `rlen` consecutive elements of the string controlled by `str` beginning at position `pos`, `size()` is equal to `rlen`, and `capacity()` is a value at least as large as `size()`.

```cpp
template<class T>
basic_string(const T& t, size_type pos, size_type n, const Allocator& a = Allocator());
```

*Effects:* Creates a variable, `sv`, as if by `basic_string_view<charT, traits> sv = t`; and then behaves the same as:

```cpp
basic_string(sv.substr(pos, n), a);
```

*Remarks:* This constructor shall not participate in overload resolution unless `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true.

```cpp
template<class T>
explicit basic_string(const T& t, const Allocator& a = Allocator());
```

*Effects:* Creates a variable, `sv`, as if by `basic_string_view<charT, traits> sv = t`; and then behaves the same as `basic_string(sv.data(), sv.size(), a)`.

*Remarks:* This constructor shall not participate in overload resolution unless

228) For example, as an argument to non-member functions `swap` (20.3.3.8), `operator>>` (20.3.3.9), and `getline` (20.3.3.9), or as an argument to `basic_string::swap`.
is_convertible_v<const T&, const charT*> is false.

basic_string(const charT* s, size_type n, const Allocator& a = Allocator());

Requires: s points to an array of at least n elements of charT.

Effects: Constructs an object of class basic_string and determines its initial string value from the array of charT of length n whose first element is designated by s.

Ensures: data() points at the first element of an allocated copy of the array whose first element is pointed at by s, size() is equal to n, and capacity() is a value at least as large as size().

basic_string(const charT* s, const Allocator& a = Allocator());

Requires: s points to an array of at least traits::length(s) + 1 elements of charT.

Effects: Constructs an object of class basic_string and determines its initial string value from the array of charT of length traits::length(s) whose first element is designated by s.

Ensures: data() points at the first element of an allocated copy of the array whose first element is pointed at by s, size() is equal to traits::length(s), and capacity() is a value at least as large as size().

Remarks: Shall not participate in overload resolution if Allocator is a type that does not qualify as an allocator (21.2.1). [Note: This affects class template argument deduction. —end note]

basic_string(size_type n, charT c, const Allocator& a = Allocator());

Requires: n < npos.

Effects: Constructs an object of class basic_string and determines its initial string value by repeating the char-like object c for all n elements.

Ensures: data() points at the first element of an allocated array of n elements, each storing the initial value c, size() is equal to n, and capacity() is a value at least as large as size().

Remarks: Shall not participate in overload resolution if Allocator is a type that does not qualify as an allocator (21.2.1). [Note: This affects class template argument deduction. —end note]

template<class InputIterator>
basic_string(InputIterator begin, InputIterator end, const Allocator& a = Allocator());

Effects: If InputIterator is an integral type, equivalent to:

basic_string(static_cast<size_type>(begin), static_cast<value_type>(end), a);

Otherwise constructs a string from the values in the range [begin, end), as indicated in the Sequence Requirements table (see 21.2.3).

basic_string(initializer_list<charT> il, const Allocator& a = Allocator());

Effects: Same as basic_string(il.begin(), il.end(), a).

basic_string(const basic_string& str, const Allocator& alloc);

basic_string(basic_string&& str, const Allocator& alloc);

Effects: Constructs an object of class basic_string. The stored allocator is constructed from alloc. 

Ensures: data() points at the first element of an allocated copy of the array whose first element is pointed at by the original value of str.data(), size() is equal to the original value of str.size(), capacity() is a value at least as large as size(), and get_allocator() is equal to alloc. In the second form, str is left in a valid state with an unspecified value.

Throws: The second form throws nothing if alloc == str.get_allocator().

template<class InputIterator, 
class Allocator = allocator<typename iterator_traits<InputIterator>::value_type>>
basic_string(InputIterator, InputIterator, Allocator = Allocator())

-> basic_string<typename iterator_traits<InputIterator>::value_type, 
char_traits<typename iterator_traits<InputIterator>::value_type>, 
Allocator>;

Remarks: Shall not participate in overload resolution if InputIterator is a type that does not qualify as an input iterator, or if Allocator is a type that does not qualify as an allocator (21.2.1).
template<class charT,  
   class traits,  
   class Allocator = allocator<charT>>  
   explicit basic_string(basic_string_view<charT, traits>, const Allocator& = Allocator())  
   -> basic_string<charT, traits, Allocator>;

template<class charT,  
   class traits,  
   class Allocator = allocator<charT>>  
   basic_string(basic_string_view<charT, traits>,  
               typename see below::size_type, typename see below::size_type,  
               const Allocator& = Allocator())  
   -> basic_string<charT, traits, Allocator>;

   Remarks: Shall not participate in overload resolution if Allocator is a type that does not qualify as  
   an allocator (21.2.1).

   basic_string& operator=(const basic_string& str);

   Returns: *this.

   Ensures: If *this and str are the same object, the member has no effect. Otherwise, data() points  
   at the first element of an allocated copy of the array whose first element is pointed at by str.data(),  
   size() is equal to str.size(), and capacity() is a value at least as large as size().

   basic_string& operator=(basic_string&& str)  
   noexcept(algorithm_traits<Allocator>::propagate_on_container_move_assignment::value  
   || algorithm_traits<Allocator>::is_always_equal::value);

   Effects: Move assigns as a sequence container (21.2), except that iterators, pointers and references may  
   be invalidated.

   Returns: *this.

   template<class T>  
   basic_string& operator=(const T& t);

   Effects: Equivalent to:
   {
      basic_string_view<charT, traits> sv = t;
      return assign(sv);
   }

   Remarks: This function shall not participate in overload resolution unless is_convertible_v<const T&,  
   basic_string_view<charT, traits>> is true and is_convertible_v<const T&, const charT*> is false.

   basic_string& operator=(const charT* s);

   Returns: *this = basic_string(s).

   Remarks: Uses traits::length().

   basic_string& operator=(charT c);

   Returns: *this = basic_string(1, c).

   basic_string& operator=(initializer_list<charT> il);

   Effects: As if by: *this = basic_string(il);

   Returns: *this.

20.3.2.3 Iterator support  
   [string.iterators]

   iterator begin() noexcept;
   const_iterator begin() const noexcept;
   const_iterator cbegin() const noexcept;

   Returns: An iterator referring to the first character in the string.
iterator end() noexcept;
const_iterator end() const noexcept;
const_iterator cend() const noexcept;

2
Returns: An iterator which is the past-the-end value.

reverse_iterator rbegin() noexcept;
const_reverse_iterator rbegin() const noexcept;
const_reverse_iterator crbegin() const noexcept;

3
Returns: An iterator which is semantically equivalent to reverse_iterator(end()).

reverse_iterator rend() noexcept;
const_reverse_iterator rend() const noexcept;
const_reverse_iterator crend() const noexcept;

4
Returns: An iterator which is semantically equivalent to reverse_iterator(begin()).

20.3.2.4 Capacity [string.capacity]

size_type size() const noexcept;

1
Returns: A count of the number of char-like objects currently in the string.

Complexity: Constant time.

size_type length() const noexcept;

3
Returns: size().

size_type max_size() const noexcept;

4
Returns: The largest possible number of char-like objects that can be stored in a basic_string.

Complexity: Constant time.

void resize(size_type n, charT c);

6
Throws: length_error if n > max_size().

Effects: Alters the length of the string designated by *this as follows:

(7.1) If n <= size(), the function replaces the string designated by *this with a string of length n
whose elements are a copy of the initial elements of the original string designated by *this.

(7.2) If n > size(), the function replaces the string designated by *this with a string of length n
whose first size() elements are a copy of the original string designated by *this, and whose
remaining elements are all initialized to c.

void resize(size_type n);

8
Effects: As if by resize(n, charT()).

size_type capacity() const noexcept;

9
Returns: The size of the allocated storage in the string.

Complexity: Constant time.

void reserve(size_type res_arg);

11
Effects: A directive that informs a basic_string of a planned change in size, so that the storage
allocation can be managed accordingly. After reserve(), capacity() is greater or equal to the
argument of reserve if reallocation happens; and equal to the previous value of capacity() otherwise.
Reallocation happens at this point if and only if the current capacity is less than the argument of
reserve().

12
Throws: length_error if res_arg > max_size().229

229) reserve() uses allocator_traits<Allocator>::allocate() which may throw an appropriate exception.
void shrink_to_fit();
13  Effects: shrink_to_fit is a non-binding request to reduce capacity() to size(). [Note: The request is non-binding to allow latitude for implementation-specific optimizations. —end note] It does not increase capacity(), but may reduce capacity() by causing reallocation.
14  Complexity: Linear in the size of the sequence.
15  Remarks: Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence as well as the past-the-end iterator. If no reallocation happens, they remain valid.

void clear() noexcept;
16  Effects: Behaves as if the function calls:
17     erase(begin(), end());
18  Returns: size() == 0.

20.3.2.5 Element access
[string.access]
const_reference operator[](size_type pos) const;
1  reference operator[](size_type pos);
2  Requires: pos <= size().
3  Returns: *(begin() + pos) if pos < size(). Otherwise, returns a reference to an object of type charT with value charT(), where modifying the object to any value other than charT() leads to undefined behavior.
4  Throws: Nothing.
5  Complexity: Constant time.

const_reference at(size_type pos) const;
6  reference at(size_type pos);
7  Throws: out_of_range if pos >= size().
8  Returns: operator[](pos).

const charT& front() const;
9  charT& front();
10  Requires: !empty().
11  Effects: Equivalent to: return operator[](0);

const charT& back() const;
12  charT& back();
13  Requires: !empty().
14  Effects: Equivalent to: return operator[](size() - 1);

20.3.2.6 Modifiers
[string.modifiers]
20.3.2.6.1 basic_string::operator+=
[string.op+=]
basic_string& operator+=(const basic_string& str);
1  Effects: Calls append(str).
2  Returns: *this.

template<class T>
1  basic_string& operator+=(const T& t);
2  Effects: Creates a variable, sv, as if by basic_string_view<charT, traits> sv = t; and then calls append(sv).
3  Returns: *this.
Remarks: This function shall not participate in overload resolution unless is_convertible_v<const T&,
basic_string_view<charT, traits>> is true and is_convertible_v<const T&, const charT*> is false.

basic_string& operator+=(const charT* s);
Effects: Calls append(s).
Returns: *this.

basic_string& operator+=(charT c);
Effects: Calls push_back(c).
Returns: *this.

basic_string& operator+=(initializer_list<charT> il);
Effects: Calls append(il).
Returns: *this.

20.3.2.6.2 basic_string::append
[string.append]

basic_string& append(const basic_string& str);
Effects: Calls append(str.data(), str.size()).
Returns: *this.

basic_string& append(const basic_string& str, size_type pos, size_type n = npos);
Throws: out_of_range if pos > str.size().
Effects: Determines the effective length rlen of the string to append as the smaller of n and str.size() - pos and calls append(str.data() + pos, rlen).
Returns: *this.

template<class T>
basic_string& append(const T& t);
Effects: Equivalent to:
{
    basic_string_view<charT, traits> sv = t;
    return append(sv.data(), sv.size());
}
Remarks: This function shall not participate in overload resolution unless is_convertible_v<const T&,
basic_string_view<charT, traits>> is true and is_convertible_v<const T&, const charT*> is false.

template<class T>
basic_string& append(const T& t, size_type pos, size_type n = npos);
Throws: out_of_range if pos > sv.size().
Effects: Creates a variable, sv, as if by basic_string_view<charT, traits> sv = t. Determines the effective length rlen of the string to append as the smaller of n and sv.size() - pos and calls append(sv.data() + pos, rlen).
Remarks: This function shall not participate in overload resolution unless is_convertible_v<const T&,
basic_string_view<charT, traits>> is true and is_convertible_v<const T&, const charT*> is false.
Returns: *this.

basic_string& append(const charT* s, size_type n);
Requires: s points to an array of at least n elements of charT.
Throws: length_error if size() + n > max_size().
Effects: The function replaces the string controlled by 
*this with a string of length size() + n  
whose first size() elements are a copy of the original string controlled by 
*this and whose remaining  
elements are a copy of the initial n elements of s.

Returns: *this.

basic_string& append(const charT* s);

Requires: s points to an array of at least traits::length(s) + 1 elements of charT.
Effects: Calls append(s, traits::length(s)).
Returns: *this.

basic_string& append(size_type n, charT c);

Effects: Equivalent to: return append(basic_string(n, c));

template<class InputIterator>
basic_string& append(InputIterator first, InputIterator last);

Requires: [first, last) is a valid range.
Effects: Equivalent to: return append(basic_string(first, last, get_allocator()));

basic_string& append(initializer_list<charT> il);

Effects: Calls append(il.begin(), il.size()).
Returns: *this.

void push_back(charT c);

Effects: Equivalent to append(static_cast<size_type>(1), c).

20.3.2.6.3 basic_string::assign

basic_string& assign(const basic_string& str);

Effects: Equivalent to: return *this = str;

basic_string& assign(basic_string&& str)  
noexcept(allocator_traits<Allocator>::propagate_on_container_move_assignment::value ||  
allocator_traits<Allocator>::is_always_equal::value);

Effects: Equivalent to: return *this = std::move(str);

basic_string& assign(const basic_string& str, size_type pos, size_type n = npos);

Throws: out_of_range if pos > str.size().

Effects: Determines the effective length rlen of the string to assign as the smaller of n and str.size()  
- pos and calls assign(str.data() + pos, rlen).

Returns: *this.

template<class T>
basic_string& assign(const T& t);

Effects: Equivalent to:
{
  basic_string_view<charT, traits> sv = t;
  return assign(sv.data(), sv.size());
}

Remarks: This function shall not participate in overload resolution unless is_convertible_v<const T&,  
basic_string_view<charT, traits>> is true and is_convertible_v<const T&, const charT*>  
is false.

template<class T>
basic_string& assign(const T& t, size_type pos, size_type n = npos);

Throws: out_of_range if pos > sv.size().

§ 20.3.2.6.3 696
Effects: Creates a variable, sv, as if by `basic_string_view<charT, traits> sv = t`. Determines the effective length rlen of the string to assign as the smaller of n and sv.size() - pos and calls `assign(sv.data() + pos, rlen)`.

Remarks: This function shall not participate in overload resolution unless `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and `is_convertible_v<const T&, const charT*>` is false.

Returns: `*this`.

```cpp
basic_string& assign(const charT* s, size_type n);
```

Requires: s points to an array of at least n elements of charT.

Throws: `length_error` if n > max_size().

Effects: Replaces the string controlled by `*this` with a string of length n whose elements are a copy of those pointed to by s.

Returns: `*this`.

```cpp
basic_string& assign(const charT* s);
```

Effects: Calls `assign(s, traits::length(s))`.

Returns: `*this`.

```cpp
basic_string& assign(initializer_list<charT> il);
```

Effects: Calls `assign(il.begin(), il.size())`.

Returns: `*this`.

```cpp
basic_string& assign(size_type n, charT c);
```

Effects: Equivalent to: `return assign(basic_string(n, c));`

```cpp
template<class InputIterator>
basic_string& assign(InputIterator first, InputIterator last);
```

Effects: Equivalent to: `return assign(basic_string(first, last, get_allocator()));`

### 20.3.2.6.4 basic_string::insert [string.insert]

```cpp
basic_string& insert(size_type pos, const basic_string& str);
```

Effects: Equivalent to: `return insert(pos, str.data(), str.size());`

```cpp
basic_string& insert(size_type pos1, const basic_string& str, size_type pos2, size_type n = npos);
```

Throws: `out_of_range` if pos1 > size() or pos2 > str.size().

Effects: Determines the effective length rlen of the string to insert as the smaller of n and str.size() - pos2 and calls `insert(pos1, str.data() + pos2, rlen)`.

Returns: `*this`.

```cpp
template<class T>
basic_string& insert(size_type pos, const T& t);
```

Effects: Equivalent to:

```cpp
{
    basic_string_view<charT, traits> sv = t;
    return insert(pos, sv.data(), sv.size());
}
```

Remarks: This function shall not participate in overload resolution unless `is_convertible_v<const T&, basic_string_view<charT, traits>>` is true and `is_convertible_v<const T&, const charT*>` is false.
template<class T>
    basic_string& insert(size_type pos1, const T& t, size_type pos2, size_type n = npos);

Throws: out_of_range if pos1 > size() or pos2 > sv.size().
Effects: Creates a variable, sv, as if by basic_string_view<charT, traits> sv = t. Determines
the effective length rlen of the string to assign as the smaller of n and sv.size() - pos2 and calls
insert(pos1, sv.data() + pos2, rlen).
Remarks: This function shall not participate in overload resolution unless is_convertible_v<const T&,
basic_string_view<charT, traits>> is true and is_convertible_v<const T&, const charT*> is false.
Returns: *this.

basic_string& insert(size_type pos, const charT* s, size_type n);
Requires: s points to an array of at least n elements of charT.
Throws: out_of_range if pos > size() or length_error if size() + n > max_size().
Effects: Replaces the string controlled by *this with a string of length size() + n whose first pos
elements are a copy of the initial elements of the original string controlled by *this and whose next n
elements are a copy of the elements in s and whose remaining elements are a copy of the remaining
elements of the original string controlled by *this.
Returns: *this.

basic_string& insert(size_type pos, const charT* s);
Requires: s points to an array of at least traits::length(s) + 1 elements of charT.
Effects: Equivalent to: return insert(pos, s, traits::length(s));

basic_string& insert(size_type pos, size_type n, charT c);
Effects: Equivalent to: return insert(pos, basic_string(n, c));

iterator insert(const_iterator p, charT c);
Requires: p is a valid iterator on *this.
Effects: Inserts a copy of c before the character referred to by p.
Returns: An iterator which refers to the copy of the inserted character.

iterator insert(const_iterator p, size_type n, charT c);
Requires: p is a valid iterator on *this.
Effects: Inserts n copies of c before the character referred to by p.
Returns: An iterator which refers to the copy of the first inserted character, or p if n == 0.

template<class InputIterator>
    iterator insert(const_iterator p, InputIterator first, InputIterator last);
Requires: p is a valid iterator on *this. [first, last) is a valid range.
Effects: Equivalent to insert(p - begin(), basic_string(first, last, get_allocator()))).
Returns: An iterator which refers to the copy of the first inserted character, or p if first == last.

iterator insert(const_iterator p, initializer_list<charT> il);
Effects: As if by insert(p, il.begin(), il.end()).
Returns: An iterator which refers to the copy of the first inserted character, or p if il is empty.

20.3.2.6.5 basic_string::erase
[不喜欢 erase]

basic_string& erase(size_type pos = 0, size_type n = npos);

Throws: out_of_range if pos > size().
Effects: Determines the effective length xlen of the string to be removed as the smaller of n and size() - pos.

§ 20.3.2.6.5 698
The function then replaces the string controlled by *this with a string of length size() - xlen whose first pos elements are a copy of the initial elements of the original string controlled by *this, and whose remaining elements are a copy of the elements of the original string controlled by *this beginning at position pos + xlen.

Returns: *this.

iterator erase(const_iterator p);

Throws: Nothing.

Effects: Removes the character referred to by p.

Returns: An iterator which points to the element immediately following p prior to the element being erased. If no such element exists, end() is returned.

iterator erase(const_iterator first, const_iterator last);

Requires: first and last are valid iterators on *this, defining a range [first, last).

Throws: Nothing.

Effects: Removes the characters in the range [first, last).

Returns: An iterator which points to the element pointed to by last prior to the other elements being erased. If no such element exists, end() is returned.

void pop_back();

Requires: !empty().

Throws: Nothing.

Effects: Equivalent to erase(size() - 1, 1).

20.3.2.6.6 basic_string::replace

basic_string& replace(size_type pos1, size_type n1, const basic_string& str);

Effects: Equivalent to: return replace(pos1, n1, str.data(), str.size());

basic_string& replace(size_type pos1, size_type n1, const basic_string& str,
            size_type pos2, size_type n2 = npos);

Throws: out_of_range if pos1 > size() or pos2 > str.size().

Effects: Determines the effective length rlen of the string to be inserted as the smaller of n2 and str.size() - pos2 and calls replace(pos1, n1, str.data() + pos2, rlen).

Returns: *this.

template<class T>
basic_string& replace(size_type pos1, size_type n1, const T& t);

Effects: Equivalent to:

{  
    basic_string_view<charT, traits> sv = t;  
    return replace(pos1, n1, sv.data(), sv.size());  
}

Remarks: This function shall not participate in overload resolution unless is_convertible_v<const T&, basic_string_view<charT, traits>> is true and is_convertible_v<const T&, const charT*> is false.

template<class T>
basic_string& replace(size_type pos1, size_type n1, const T& t,
            size_type pos2, size_type n2 = npos);

Throws: out_of_range if pos1 > size() or pos2 > sv.size().

Effects: Creates a variable, sv, as if by basic_string_view<charT, traits> sv = t. Determines the effective length rlen of the string to be inserted as the smaller of n2 and sv.size() - pos2 and calls replace(pos1, n1, sv.data() + pos2, rlen).
Remarks: This function shall not participate in overload resolution unless \( \text{is\_convertible\_v<\text{const T&}, basic\_string\_view<charT, traits>>} \) is true and \( \text{is\_convertible\_v<\text{const T&}, const charT*>>} \) is false.

Returns: \*this.

basic_string& replace(size_type pos1, size_type n1, const charT* s, size_type n2);

Requires: \( s \) points to an array of at least \( n2 \) elements of charT.

Throws: out\_of\_range if \( pos1 > \text{size()} \) or length\_error if the length of the resulting string would exceed max\_size() (see below).

Effects: Determines the effective length \( xlen \) of the string to be removed as the smaller of \( n1 \) and \( \text{size()} - \text{pos1} \). If \( \text{size()} - xlen >= \text{max\_size()} - n2 \) throws length\_error. Otherwise, the function replaces the string controlled by \*this with a string of length \( \text{size()} - xlen + n2 \) whose first \( pos1 \) elements are a copy of the initial elements of the original string controlled by \*this, whose next \( n2 \) elements are a copy of the initial \( n2 \) elements of \( s \), and whose remaining elements are a copy of the elements of the original string controlled by \*this beginning at position \( pos + xlen \).

Returns: \*this.

basic_string& replace(size_type pos, size_type n, const charT* s);

Requires: \( s \) points to an array of at least traits::length(\( s \)) + 1 elements of charT.

Effects: Equivalent to: return replace(pos, n, \( s \), traits::length(\( s \))).

basic_string& replace(size_type pos1, size_type n1, size_type n2, charT c);

Effects: Equivalent to: return replace(pos1, n1, basic_string(n2, c)).

basic_string& replace(const_iterator i1, const_iterator i2, const basic_string& str);

Requires: [begin(), i1) and [i1, i2) are valid ranges.

Effects: Calls replace(i1 - begin(), i2 - i1, \( str \)).

Returns: \*this.

template<class T>

basic_string& replace(const_iterator i1, const_iterator i2, const T& t);

Requires: [begin(), i1) and [i1, i2) are valid ranges.

Effects: Creates a variable, \( sv \), as if by basic\_string\_view<charT, traits> \( sv = t \); and then calls replace(i1 - begin(), i2 - i1, \( sv \)).

Returns: \*this.

Remarks: This function shall not participate in overload resolution unless \( \text{is\_convertible\_v<\text{const T&}, basic\_string\_view<charT, traits>>} \) is true and \( \text{is\_convertible\_v<\text{const T&}, const charT*>>} \) is false.

basic_string& replace(const_iterator i1, const_iterator i2, const charT* s, size_type n);

Requires: [begin(), i1) and [i1, i2) are valid ranges and \( s \) points to an array of at least \( n \) elements of charT.

Effects: Calls replace(i1 - begin(), i2 - i1, \( s, n \)).

Returns: \*this.

basic_string& replace(const_iterator i1, const_iterator i2, const charT* s);

Requires: [begin(), i1) and [i1, i2) are valid ranges and \( s \) points to an array of at least traits::length(\( s \)) + 1 elements of charT.

Effects: Calls replace(i1 - begin(), i2 - i1, \( s, \text{traits::length}(s) \)).

Returns: \*this.

basic_string& replace(const_iterator i1, const_iterator i2, size_type n, charT c);

Requires: [begin(), i1) and [i1, i2) are valid ranges.

Returns: \*this.
Effects: Calls replace(i1 - begin(), i2 - i1, basic_string(n, c)).

Returns: *this.

template<class InputIterator>
basic_string& replace(const_iterator i1, const_iterator i2, InputIterator j1, InputIterator j2);

Requires: [begin(), i1), [i1, i2) and [j1, j2) are valid ranges.

Effects: Calls replace(i1 - begin(), i2 - i1, basic_string(j1, j2, get_allocator())).

Returns: *this.

basic_string& replace(const_iterator i1, const_iterator i2, initializer_list<charT> il);

Requires: [begin(), i1) and [i1, i2) are valid ranges.

Effects: Calls replace(i1 - begin(), i2 - i1, il.begin(), il.size()).

Returns: *this.

20.3.2.6.7 basic_string::copy [string.copy]

size_type copy(charT* s, size_type n, size_type pos = 0) const;

1 Let rlen be the smaller of n and size() - pos.
2 Throws: out_of_range if pos > size().
3 Requires: [s, s + rlen) is a valid range.
4 Effects: Equivalent to traits::copy(s, data() + pos, rlen). [Note: This does not terminate s with a null object. — end note]
5 Returns: rlen.

20.3.2.6.8 basic_string::swap [string.swap]

void swap(basic_string& s)

nothrow(allocator_traits<Allocator>::propagate_on_container_swap::value ||
allocator_traits<Allocator>::is_always_equal::value);

1 Ensures: *this contains the same sequence of characters that was in s, s contains the same sequence of characters that was in *this.
2 Throws: Nothing.
3 Complexity: Constant time.

20.3.2.7 String operations [string.ops]

20.3.2.7.1 Accessors [string.accessors]

const charT* c_str() const noexcept;
const charT* data() const noexcept;

1 Returns: A pointer p such that p + i == &operator[]() for each i in [0, size()).
2 Complexity: Constant time.
3 Requires: The program shall not alter any of the values stored in the character array.

charT* data() noexcept;

4 Returns: A pointer p such that p + i == &operator[]() for each i in [0, size()).
5 Complexity: Constant time.
6 Requires: The program shall not alter the value stored at p + size().

operator basic_string_view<charT, traits>() const noexcept;

7 Effects: Equivalent to: return basic_string_view<charT, traits>(data(), size());

allocator_type get_allocator() const noexcept;

8 Returns: A copy of the Allocator object used to construct the string or, if that allocator has been replaced, a copy of the most recent replacement.
20.3.2.7.2 basic_string::find

template<class T>
size_type find(const T& t, size_type pos = 0) const;

Effects: Creates a variable, sv, as if by basic_string_view<charT, traits> sv = t; and then determines the lowest position xpos, if possible, such that both of the following conditions hold:

(1.1) pos <= xpos and xpos + sv.size() <= size();
(1.2) traits::eq(at(xpos + I), sv.at(I)) for all elements I of the data referenced by sv.

Returns: xpos if the function can determine such a value for xpos. Otherwise, returns npos.

Remarks: This function shall not participate in overload resolution unless is_convertible_v<const T&, basic_string_view<charT, traits>> is true and is_convertible_v<const T&, const charT*> is false.

Throws: Nothing unless the initialization of sv throws an exception.

size_type find(const basic_string& str, size_type pos = 0) const noexcept;

Effects: Equivalent to: return find(basic_string_view<charT, traits>(str), pos);

size_type find(const charT* s, size_type pos, size_type n) const;

Returns: find(basic_string_view<charT, traits>(s, n), pos).

Requires: s points to an array of at least traits::length(s) + 1 elements of charT.

size_type find(charT c, size_type pos = 0) const;

Returns: find(basic_string(1, c), pos).

20.3.2.7.3 basic_string::rfind

template<class T>
size_type rfind(const T& t, size_type pos = npos) const;

Effects: Creates a variable, sv, as if by basic_string_view<charT, traits> sv = t; and then determines the highest position xpos, if possible, such that both of the following conditions hold:

(1.1) xpos <= pos and xpos + sv.size() <= size();
(1.2) traits::eq(at(xpos + I), sv.at(I)) for all elements I of the data referenced by sv.

Returns: xpos if the function can determine such a value for xpos. Otherwise, returns npos.

Remarks: This function shall not participate in overload resolution unless is_convertible_v<const T&, basic_string_view<charT, traits>> is true and is_convertible_v<const T&, const charT*> is false.

Throws: Nothing unless the initialization of sv throws an exception.

size_type rfind(const basic_string& str, size_type pos = npos) const noexcept;

Effects: Equivalent to: return rfind(basic_string_view<charT, traits>(str), pos);

size_type rfind(const charT* s, size_type pos, size_type n) const;

Returns: rfind(basic_string_view<charT, traits>(s, n), pos).

size_type rfind(const charT* s, size_type pos = npos) const;

Requires: s points to an array of at least traits::length(s) + 1 elements of charT.

size_type rfind(charT c, size_type pos = npos) const;

Returns: rfind(basic_string(1, c), pos).
20.3.2.7.4 basic_string::find_first_of

template<class T>
size_type find_first_of(const T& t, size_type pos = 0) const;

Effects: Creates a variable, sv, as if by basic_string_view<charT, traits> sv = t; and then determines the lowest position xpos, if possible, such that both of the following conditions hold:

(1.1) pos <= xpos and xpos < size();
(1.2) traits::eq(at(xpos), sv.at(I)) for some element I of the data referenced by sv.

Returns: xpos if the function can determine such a value for xpos. Otherwise, returns npos.

Remarks: This function shall not participate in overload resolution unless is_convertible_v<const T&, basic_string_view<charT, traits>> is true and is_convertible_v<const T&, const charT*> is false.

Throws: Nothing unless the initialization of sv throws an exception.

size_type find_first_of(const basic_string& str, size_type pos = 0) const noexcept;
Effects: Equivalent to: return find_first_of(basic_string_view<charT, traits>(str), pos);

size_type find_first_of(const charT* s, size_type pos, size_type n) const;
Returns: find_first_of(basic_string_view<charT, traits>(s, n), pos).

size_type find_first_of(charT c, size_type pos = npos) const;
Returns: find_first_of(basic_string(1, c), pos).

20.3.2.7.5 basic_string::find_last_of

template<class T>
size_type find_last_of(const T& t, size_type pos = npos) const;

Effects: Creates a variable, sv, as if by basic_string_view<charT, traits> sv = t; and then determines the highest position xpos, if possible, such that both of the following conditions hold:

(1.1) xpos <= pos and xpos < size();
(1.2) traits::eq(at(xpos), sv.at(I)) for some element I of the data referenced by sv.

Returns: xpos if the function can determine such a value for xpos. Otherwise, returns npos.

Remarks: This function shall not participate in overload resolution unless is_convertible_v<const T&, basic_string_view<charT, traits>> is true and is_convertible_v<const T&, const charT*> is false.

Throws: Nothing unless the initialization of sv throws an exception.

size_type find_last_of(const basic_string& str, size_type pos = npos) const noexcept;
Effects: Equivalent to: return find_last_of(basic_string_view<charT, traits>(str), pos);

size_type find_last_of(const charT* s, size_type pos, size_type n) const;
Returns: find_last_of(basic_string_view<charT, traits>(s, n), pos).

size_type find_last_of(const charT* s, size_type pos = npos) const;
Requires: s points to an array of at least traits::length(s) + 1 elements of charT.
Returns: find_last_of(basic_string_view<charT, traits>(s), pos).

size_type find_last_of(charT c, size_type pos = npos) const;
Returns: find_last_of(basic_string(1, c), pos).
20.3.2.7.6 basic_string::find_first_not_of

\[\text{template<class T>}\]
\[
\text{size_type find_first_not_of(const T& t, size_type pos = 0) const;}
\]
1
\hspace{1em} \text{Effects: Creates a variable, } sv, \text{ as if by basic_string_view<charT, traits> sv = t; and then determines the lowest position xpos, if possible, such that both of the following conditions hold:}

1.1. \hspace{1em} \text{pos} \leq \text{xpos} \text{ and } \text{xpos} < \text{size();}

1.2. \hspace{1em} \text{traits::eq(at(xpos), sv.at(I)) for no element I of the data referenced by sv.}

2
\hspace{1em} \text{Remarks: This function shall not participate in overload resolution unless is_convertible_v<const T&, basic_string_view<charT, traits>> is true and is_convertible_v<const T&, const charT*> is false.}

3
\hspace{1em} \text{Throws: Nothing unless the initialization of } sv \text{ throws an exception.}

4
\hspace{1em} \text{Returns: xpos if the function can determine such a value for } xpos. \text{ Otherwise, returns npos.}

size_type find_first_not_of(const basic_string& str, size_type pos = 0) const noexcept;

5
\hspace{1em} \text{Effects: Equivalent to:}
\[
\text{return find_first_not_of(basic_string_view<charT, traits>(str), pos);}
\]

size_type find_first_not_of(const charT* s, size_type pos, size_type n) const;

6
\hspace{1em} \text{Returns: find_first_not_of(basic_string_view<charT, traits>(s, n), pos).}

size_type find_first_not_of(const charT* s, size_type pos = 0) const;

7
\hspace{1em} \text{Requires: } s \text{ points to an array of at least traits::length(s) + 1 elements of charT.}

8
\hspace{1em} \text{Returns: find_first_not_of(basic_string_view<charT, traits>(s), pos).}

size_type find_first_not_of(charT c, size_type pos = 0) const;

9
\hspace{1em} \text{Returns: find_first_not_of(basic_string(1, c), pos).}

20.3.2.7.7 basic_string::find_last_not_of

\[\text{template<class T>}\]
\[
\text{size_type find_last_not_of(const T& t, size_type pos = npos) const;}
\]
1
\hspace{1em} \text{Effects: Creates a variable, } sv, \text{ as if by basic_string_view<charT, traits> sv = t; and then determines the highest position xpos, if possible, such that both of the following conditions hold:}

1.1. \hspace{1em} \text{xpos} \leq \text{pos} \text{ and } \text{xpos} < \text{size();}

1.2. \hspace{1em} \text{traits::eq(at(xpos), sv.at(I)) for no element I of the data referenced by sv.}

2
\hspace{1em} \text{Remarks: This function shall not participate in overload resolution unless is_convertible_v<const T&, basic_string_view<charT, traits>> is true and is_convertible_v<const T&, const charT*> is false.}

3
\hspace{1em} \text{Throws: Nothing unless the initialization of } sv \text{ throws an exception.}

4
\hspace{1em} \text{Returns: xpos if the function can determine such a value for } xpos. \text{ Otherwise, returns npos.}

size_type find_last_not_of(const basic_string& str, size_type pos = npos) const noexcept;

5
\hspace{1em} \text{Effects: Equivalent to:}
\[
\text{return find_last_not_of(basic_string_view<charT, traits>(str), pos);}
\]

size_type find_last_not_of(const charT* s, size_type pos, size_type n) const;

6
\hspace{1em} \text{Returns: find_last_not_of(basic_string_view<charT, traits>(s, n), pos).}

size_type find_last_not_of(const charT* s, size_type pos = npos) const;

7
\hspace{1em} \text{Requires: } s \text{ points to an array of at least traits::length(s) + 1 elements of charT.}

8
\hspace{1em} \text{Returns: find_last_not_of(basic_string_view<charT, traits>(s), pos).}

§ 20.3.2.7.7
size_type find_last_not_of(charT c, size_type pos = npos) const;
  Returns: find_last_not_of(basic_string(1, c), pos).

20.3.2.7.8 basic_string::substr

basic_string substr(size_type pos = 0, size_type n = npos) const;
  Throws: out_of_range if pos > size().
  Effects: Determines the effective length rlen of the string to copy as the smaller of n and size() - pos.
  Returns: basic_string(data()+pos, rlen).

20.3.2.7.9 basic_string::compare

template<class T>
int compare(const T& t) const;
  Effects: Creates a variable, sv, as if by basic_string_view<charT, traits> sv = t; and then determines the effective length rlen of the strings to compare as the smaller of size() and sv.size(). The function then compares the two strings by calling traits::compare(data(), sv.data(), rlen).
  Returns: The nonzero result if the result of the comparison is nonzero. Otherwise, returns a value as indicated in Table 58.

Table 58 — compare() results

<table>
<thead>
<tr>
<th>Condition</th>
<th>Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>size() &lt; sv.size()</td>
<td>&lt; 0</td>
</tr>
<tr>
<td>size() == sv.size()</td>
<td>0</td>
</tr>
<tr>
<td>size() &gt; sv.size()</td>
<td>&gt; 0</td>
</tr>
</tbody>
</table>

Remarks: This function shall not participate in overload resolution unless is_convertible_v<const T&, basic_string_view<charT, traits>> is true and is_convertible_v<const T&, const charT*> is false.

Throws: Nothing unless the initialization of sv throws an exception.

template<class T>
int compare(size_type pos1, size_type n1, const T& t) const;
  Effects: Equivalent to:
  {
    basic_string_view<charT, traits> sv = t;
    return basic_string_view<charT, traits>(data(), size()).substr(pos1, n1).compare(sv);
  }

Remarks: This function shall not participate in overload resolution unless is_convertible_v<const T&, basic_string_view<charT, traits>> is true and is_convertible_v<const T&, const charT*> is false.

template<class T>
int compare(size_type pos1, size_type n1, const T& t, size_type pos2, size_type n2 = npos) const;
  Effects: Equivalent to:
  basic_string_view<charT, traits> sv = t;
  return basic_string_view<charT, traits>(
    data(), size()).substr(pos1, n1).compare(sv.substr(pos2, n2));

Remarks: This function shall not participate in overload resolution unless is_convertible_v<const T&, basic_string_view<charT, traits>> is true and is_convertible_v<const T&, const charT*> is false.

int compare(const basic_string& str) const noexcept;
  Effects: Equivalent to: return compare(basic_string_view<charT, traits>(str));
int compare(size_type pos1, size_type n1, const basic_string& str) const;

Effects: Equivalent to: return compare(pos1, n1, basic_string_view<charT, traits>(str));

int compare(size_type pos1, size_type n1, const basic_string& str, size_type pos2, size_type n2 = npos) const;

Effects: Equivalent to:
return compare(pos1, n1, basic_string_view<charT, traits>(str), pos2, n2);

int compare(const charT* s) const;

Returns: compare(basic_string(s)).

int compare(size_type pos, size_type n1, const charT* s) const;

Returns: basic_string(*this, pos, n1).compare(basic_string(s));

int compare(size_type pos, size_type n1, const charT* s, size_type n2) const;

Returns: basic_string(*this, pos, n1).compare(basic_string(s, n2));

20.3.2.7.10 basic_string::starts_with

bool starts_with(basic_string_view<charT, traits> x) const noexcept;
bool starts_with(charT x) const noexcept;
bool starts_with(const charT* x) const;

Effects: Equivalent to:
return basic_string_view<charT, traits>(data(), size()).starts_with(x);

20.3.2.7.11 basic_string::ends_with

bool ends_with(basic_string_view<charT, traits> x) const noexcept;
bool ends_with(charT x) const noexcept;
bool ends_with(const charT* x) const;

Effects: Equivalent to:
return basic_string_view<charT, traits>(data(), size()).ends_with(x);

20.3.3 Non-member functions

20.3.3.1 operator+

template<class charT, class traits, class Allocator>
basic_string<charT, traits, Allocator>
operator+(const basic_string<charT, traits, Allocator>& lhs,
const basic_string<charT, traits, Allocator>& rhs);

Returns: basic_string<charT, traits, Allocator>(lhs).append(rhs).

template<class charT, class traits, class Allocator>
operator+(basic_string<charT, traits, Allocator>&& lhs,
const basic_string<charT, traits, Allocator>& rhs);

Returns: std::move(lhs.append(rhs)).

template<class charT, class traits, class Allocator>
operator+(basic_string<charT, traits, Allocator>&& lhs,
basic_string<charT, traits, Allocator>&& rhs);

Returns: std::move(rhs.insert(0, lhs)).

—end note}
template<class charT, class traits, class Allocator>
  basic_string<charT, traits, Allocator>
  operator+(const charT* lhs, const basic_string<charT, traits, Allocator>& rhs);

  Returns: basic_string<charT, traits, Allocator>(lhs) + rhs.

  Remarks: Uses traits::length().

template<class charT, class traits, class Allocator>
  basic_string<charT, traits, Allocator>
  operator+(const charT* lhs, basic_string<charT, traits, Allocator>&& rhs);

  Returns: std::move(rhs.insert(0, lhs)).

  Remarks: Uses traits::length().

template<class charT, class traits, class Allocator>
  basic_string<charT, traits, Allocator>
  operator+(charT lhs, const basic_string<charT, traits, Allocator>& rhs);

  Returns: basic_string<charT, traits, Allocator>(1, lhs) + rhs.

  Remarks: Uses traits::length().

template<class charT, class traits, class Allocator>
  basic_string<charT, traits, Allocator>
  operator+(charT lhs, basic_string<charT, traits, Allocator>&& rhs);

  Returns: std::move(rhs.insert(0, 1, lhs)).

  Remarks: Uses traits::length().

template<class charT, class traits, class Allocator>
  basic_string<charT, traits, Allocator>
  operator+(const basic_string<charT, traits, Allocator>& lhs, const charT* rhs);

  Returns: lhs + basic_string<charT, traits, Allocator>(rhs).

  Remarks: Uses traits::length().

20.3.3.2  operator==

    [string.operator==]

template<class charT, class traits, class Allocator>
  bool operator==(const basic_string<charT, traits, Allocator>& lhs, const basic_string<charT, traits, Allocator>& rhs) noexcept;

  Returns: lhs.compare(rhs) == 0.

template<class charT, class traits, class Allocator>
  bool operator==(const charT* lhs, const basic_string<charT, traits, Allocator>& rhs);

  Returns: rhs == lhs.

template<class charT, class traits, class Allocator>
  bool operator==(const charT* lhs, const basic_string<charT, traits, Allocator>&& rhs);

  Requires: rhs points to an array of at least traits::length(rhs) + 1 elements of charT.

  Returns: lhs.compare(rhs) == 0.
20.3.3.3 operator!=

```
template<class charT, class traits, class Allocator>
bool operator!=(const basic_string<charT, traits, Allocator>& lhs,
               const basic_string<charT, traits, Allocator>& rhs) noexcept;
```

1 Returns: !(lhs == rhs).

```
template<class charT, class traits, class Allocator>
bool operator!=(const charT* lhs, const basic_string<charT, traits, Allocator>& rhs);
```

2 Returns: rhs != lhs.

```
template<class charT, class traits, class Allocator>
bool operator!=(const basic_string<charT, traits, Allocator>& lhs, const charT* rhs);
```

3 Returns: !(rhs.compare(lhs) != 0).

### 20.3.3.4 operator<

```
template<class charT, class traits, class Allocator>
bool operator<(const basic_string<charT, traits, Allocator>& lhs,
               const basic_string<charT, traits, Allocator>& rhs) noexcept;
```

1 Returns: lhs.compare(rhs) < 0.

```
template<class charT, class traits, class Allocator>
bool operator<(const charT* lhs, const basic_string<charT, traits, Allocator>& rhs);
```

2 Returns: rhs.compare(lhs) > 0.

```
template<class charT, class traits, class Allocator>
bool operator<(const basic_string<charT, traits, Allocator>& lhs, const charT* rhs);
```

3 Returns: lhs.compare(rhs) < 0.

### 20.3.3.5 operator>

```
template<class charT, class traits, class Allocator>
bool operator>(const basic_string<charT, traits, Allocator>& lhs,
               const basic_string<charT, traits, Allocator>& rhs) noexcept;
```

1 Returns: lhs.compare(rhs) > 0.

```
template<class charT, class traits, class Allocator>
bool operator>(const charT* lhs, const basic_string<charT, traits, Allocator>& rhs);
```

2 Returns: rhs.compare(lhs) < 0.

```
template<class charT, class traits, class Allocator>
bool operator>(const basic_string<charT, traits, Allocator>& lhs, const charT* rhs);
```

3 Returns: lhs.compare(rhs) > 0.

### 20.3.3.6 operator<=

```
template<class charT, class traits, class Allocator>
bool operator<=(const basic_string<charT, traits, Allocator>& lhs,
                const basic_string<charT, traits, Allocator>& rhs) noexcept;
```

1 Returns: lhs.compare(rhs) <= 0.

```
template<class charT, class traits, class Allocator>
bool operator<=(const charT* lhs, const basic_string<charT, traits, Allocator>& rhs);
```

2 Returns: rhs.compare(lhs) >= 0.

```
template<class charT, class traits, class Allocator>
bool operator<=(const basic_string<charT, traits, Allocator>& lhs, const charT* rhs);
```

3 Returns: lhs.compare(rhs) <= 0.
20.3.3.7 operator>=

```
template<class charT, class traits, class Allocator>
bool operator>=(const basic_string<charT, traits, Allocator>& lhs,
               const basic_string<charT, traits, Allocator>& rhs) noexcept;
```

1 Returns: \( \text{lhs}\text{.compare}(\text{rhs}) \geq 0 \).

```
template<class charT, class traits, class Allocator>
bool operator>=(const charT* lhs, const basic_string<charT, traits, Allocator>& rhs);
```

2 Returns: \( \text{rhs}\text{.compare}(\text{lhs}) \leq 0 \).

```
template<class charT, class traits, class Allocator>
bool operator>=(const basic_string<charT, traits, Allocator>& lhs, const charT* rhs);
```

3 Returns: \( \text{lhs}\text{.compare}(\text{rhs}) \geq 0 \).

20.3.3.8 swap

```
template<class charT, class traits, class Allocator>
void swap(basic_string<charT, traits, Allocator>& lhs,
          basic_string<charT, traits, Allocator>& rhs);
```

1 Effects: Equivalent to \( \text{lhs}\text{.swap}(\text{rhs}) \).

20.3.3.9 Inserters and extractors

```
template<class charT, class traits, class Allocator>
basic_istream<charT, traits>& operator>>(
basic_istream<charT, traits>&& is, basic_string<charT, traits, Allocator>& str);
```

1 Effects: Behaves as a formatted input function (27.7.4.2.1). After constructing a \text{sentry} object, if the sentry converts to true, calls \text{str.erase()} and then extracts characters from is and appends them to str as if by calling \text{str.append(1, c)}. If \text{is.width()} is greater than zero, the maximum number \( n \) of characters appended is \( \text{is.width()} \); otherwise \( n \) is \text{str.max_size()}. Characters are extracted and appended until any of the following occurs:

\begin{enumerate}[label=(\arabic*)]
\item \( n \) characters are stored;
\item end-of-file occurs on the input sequence;
\item \text{isspace(c, is.getloc())} is true for the next available input character \( c \).
\end{enumerate}

2 After the last character (if any) is extracted, \text{is.width(0)} is called and the \text{sentry} object is destroyed.

3 If the function extracts no characters, it calls \text{is.setstate(ios::failbit)}, which may throw \text{ios-base::failure (27.5.5.4)}.

4 Returns: is.

```
template<class charT, class traits, class Allocator>
basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& os,
                                           const basic_string<charT, traits, Allocator>& str);
```

5 Effects: Equivalent to: return \( \text{os << basic_string_view<charT, traits>}(\text{str}) \);

```
template<class charT, class traits, class Allocator>
basic_istream<charT, traits>& getline(basic_istream<charT, traits>&& is,
                                       basic_string<charT, traits, Allocator>& str,
                                       charT delim);
```

6 Effects: Behaves as an unformatted input function (27.7.4.3), except that it does not affect the value returned by subsequent calls to \text{basic_istream::<gcount()}. After constructing a \text{sentry} object,
if the sentry converts to **true**, calls `str.erase()` and then extracts characters from `is` and appends them to `str` as if by calling `str.append(1, c)` until any of the following occurs:

1. end-of-file occurs on the input sequence (in which case, the `getline` function calls `is.setstate(ios_base::eofbit)`).
2. `traits::eq(c, delim)` for the next available input character `c` (in which case, `c` is extracted but not appended) (27.5.5.4)
3. `str.max_size()` characters are stored (in which case, the function calls `is.setstate(ios_base::failbit)`) (27.5.5.4)

The conditions are tested in the order shown. In any case, after the last character is extracted, the sentry object is destroyed.

If the function extracts no characters, it calls `is.setstate(ios_base::failbit)` which may throw `ios_base::failure` (27.5.5.4).

**Returns:** `is`.

```cpp
template<class charT, class traits, class Allocator>
basic_istream<charT, traits>&
ggetline(basic_istream<charT, traits>& is, basic_string<charT, traits, Allocator>& str);
```

**Returns:** `getline(is, str, is.widen('\n'))`.

### 20.3.4  Numeric conversions

**Effects:** The first two functions call `strtol(str.c_str(), ptr, base)`, and the last three functions call
`strtoul(str.c_str(), ptr, base)`, `strtoll(str.c_str(), ptr, base)`, and `strtoull(str.c_str(), ptr, base)`, respectively. Each function returns the converted result, if any. The argument `ptr` designates a pointer to an object internal to the function that is used to determine what to store at `*idx`. If the function does not throw an exception and `idx != 0`, the function stores in `*idx` the index of the first unconverted element of `str`.

**Returns:** The converted result.

**Throws:** `invalid_argument` if `strtol`, `strtoul`, `strtoll`, or `strtoull` reports that no conversion could be performed. Throws `out_of_range` if `strtol`, `strtoul`, `strtoll` or `strtoull` sets `errno` to `ERANGE`, or if the converted value is outside the range of representable values for the return type.

```cpp
float stof(const string& str, size_t* idx = nullptr);
double stod(const string& str, size_t* idx = nullptr);
long double stold(const string& str, size_t* idx = nullptr);
```

**Effects:** These functions call `strtof(str.c_str(), ptr)`, `strtod(str.c_str(), ptr)`, and `strtold(str.c_str(), ptr)`, respectively. Each function returns the converted result, if any. The argument `ptr` designates a pointer to an object internal to the function that is used to determine what to store at `*idx`. If the function does not throw an exception and `idx != 0`, the function stores in `*idx` the index of the first unconverted element of `str`.

**Returns:** The converted result.

**Throws:** `invalid_argument` if `strtof`, `strtod`, or `strtold` reports that no conversion could be performed. Throws `out_of_range` if `strtof`, `strtod`, or `strtold` sets `errno` to `ERANGE` or if the converted value is outside the range of representable values for the return type.
7 Returns: Each function returns a string object holding the character representation of the value of its argument that would be generated by calling `sprintf(buf, fmt, val)` with a format specifier of "%d", "%u", "%ld", "%lu", "%lld", "%llu", "%f", "%F", or "%Lf", respectively, where `buf` designates an internal character buffer of sufficient size.

8 Effects: The first two functions call `wcstol(str.c_str(), ptr, base)`, and the last three functions call `wcstoul(str.c_str(), ptr, base)`, `wcstoll(str.c_str(), ptr, base)`, and `wcstoull(str.c_str(), ptr, base)`, respectively. Each function returns the converted result, if any. The argument `ptr` designates a pointer to an object internal to the function that is used to determine what to store at `*idx`. If the function does not throw an exception and `idx` != 0, the function stores in `*idx` the index of the first unconverted element of `str`.

9 Returns: The converted result.

10 Throws: invalid_argument if `wcstol`, `wcstoul`, `wcstoll`, or `wcstoull` reports that no conversion could be performed. Throws out_of_range if the converted value is outside the range of representable values for the return type.

11 Effects: These functions call `wcstof(str.c_str(), ptr)`, `wcstod(str.c_str(), ptr)`, and `wcstold(str.c_str(), ptr)`, respectively. Each function returns the converted result, if any. The argument `ptr` designates a pointer to an object internal to the function that is used to determine what to store at `*idx`. If the function does not throw an exception and `idx` != 0, the function stores in `*idx` the index of the first unconverted element of `str`.

12 Returns: The converted result.

13 Throws: invalid_argument if `wcstof`, `wcstod`, or `wcstold` reports that no conversion could be performed. Throws out_of_range if `wcstof`, `wcstod`, or `wcstold` sets errno to ERANGE.

14 Returns: Each function returns a wstring object holding the character representation of the value of its argument that would be generated by calling `swprintf(buf, buffsz, fmt, val)` with a format specifier of L"%d", L"%u", L"%ld", L"%lu", L"%lld", L"%llu", L"%f", L"%F", or L"%Lf", respectively, where `buf` designates an internal character buffer of sufficient size `buffsz`.

20.3.5 Hash support

[basic.string.hash]
If $S$ is one of these string types, $SV$ is the corresponding string view type, and $s$ is an object of type $S$, then $\text{hash}<S>()(s) == \text{hash}<SV>()(SV(s))$.

### 20.3.6 Suffix for `basic_string` literals

[string.literal]

```cpp
class operator"s(const char* str, size_t len);

Returns: `string{str, len}`.
```

```cpp
class operator"s(const char16_t* str, size_t len);

Returns: `u16string{str, len}`.
```

```cpp
class operator"s(const char32_t* str, size_t len);

Returns: `u32string{str, len}`.
```

```cpp
class operator"s(const wchar_t* str, size_t len);

Returns: `wstring{str, len}`.
```

[Note: The same suffix $s$ is used for `chrono::duration` literals denoting seconds but there is no conflict, since duration suffixes apply to numbers and string literal suffixes apply to character array literals. — end note]

### 20.4 String view classes

[string.view]

1 The class template `basic_string_view` describes an object that can refer to a constant contiguous sequence of char-like (20.1) objects with the first element of the sequence at position zero. In the rest of this subclause, the type of the char-like objects held in a `basic_string_view` object is designated by `charT`.

[Note: The library provides implicit conversions from `const charT*` and `std::basic_string<charT, ...>` to `std::basic_string_view<charT, ...>` so that user code can accept just `std::basic_string_view` in order to interoperate with these functions. — end note]

3 The complexity of `basic_string_view` member functions is $O(1)$ unless otherwise specified.

### 20.4.1 Header `<string_view>` synopsis

[string.view.synop]

```cpp
namespace std {
    // 20.4.2, class template `basic_string_view`
    template<class charT, class traits = char_traits<charT>>
    class basic_string_view;

    // 20.4.3, non-member comparison functions
    template<class charT, class traits>
    constexpr bool operator==(basic_string_view<charT, traits> x, basic_string_view<charT, traits> y) noexcept;
    template<class charT, class traits>
    constexpr bool operator!=(basic_string_view<charT, traits> x, basic_string_view<charT, traits> y) noexcept;
    template<class charT, class traits>
    constexpr bool operator< (basic_string_view<charT, traits> x, basic_string_view<charT, traits> y) noexcept;
    template<class charT, class traits>
    constexpr bool operator> (basic_string_view<charT, traits> x, basic_string_view<charT, traits> y) noexcept;
    template<class charT, class traits>
    constexpr bool operator<=(basic_string_view<charT, traits> x, basic_string_view<charT, traits> y) noexcept;
    template<class charT, class traits>
    constexpr bool operator>=(basic_string_view<charT, traits> x, basic_string_view<charT, traits> y) noexcept;
}
```
template<class charT, class traits>
    constexpr bool operator>=(basic_string_view<charT, traits> x, 
                        basic_string_view<charT, traits> y) noexcept;
// see 20.4.3, sufficient additional overloads of comparison functions

// 20.4.4, inserters and extractors
template<class charT, class traits>
    basic_ostream<charT, traits>& 
    operator<<(basic_ostream<charT, traits>& os, 
                     basic_string_view<charT, traits> str);

// basic_string_view typedef names
using string_view = basic_string_view<char>;
using u16string_view = basic_string_view<char16_t>;
using u32string_view = basic_string_view<char32_t>;
using wstring_view = basic_string_view<wchar_t>;

// 20.4.5, hash support
template<class T> struct hash;
template<> struct hash<string_view>;
template<> struct hash<u16string_view>;
template<> struct hash<u32string_view>;
template<> struct hash<wstring_view>;

inline namespace literals {
    inline namespace string_view_literals {
        // 20.4.6, suffix for basic_string_view literals
        constexpr string_view operator"sv(const char* str, size_t len) noexcept;
        constexpr u16string_view operator"sv(const char16_t* str, size_t len) noexcept;
        constexpr u32string_view operator"sv(const char32_t* str, size_t len) noexcept;
        constexpr wstring_view operator"sv(const wchar_t* str, size_t len) noexcept;
    }
}

1 The function templates defined in 19.2.2 and 22.7 are available when <string_view> is included.

20.4.2 Class template basic_string_view

template<class charT, class traits = char_traits<charT>>
    class basic_string_view {
    public:
        // types
        using traits_type  = traits;
        using value_type   = charT;
        using pointer      = value_type*;
        using const_pointer = const value_type*;
        using reference    = value_type&;
        using const_reference = const value_type&;
        using const_iterator = implementation-defined; // see 20.4.2.2
        using iterator = const_iterator; //230
        using const_reverse_iterator = reverse_iterator<const_iterator>;
        using reverse_iterator = const_reverse_iterator;
        using size_type   = size_t;
        using difference_type = ptrdiff_t;
        static constexpr size_type npos = size_type(-1);

        // 20.4.2.1, construction and assignment
        constexpr basic_string_view() noexcept;
        constexpr basic_string_view(const basic_string_view&) noexcept = default;
        constexpr basic_string_view& operator=(const basic_string_view&) noexcept = default;
        constexpr basic_string_view(const charT* str);
        constexpr basic_string_view(const charT* str, size_type len);

    } // basic_string_view

230) Because basic_string_view refers to a constant sequence, iterator and const_iterator are the same type.
// 20.4.2.2, iterator support
constexpr const_iterator begin() const noexcept;

    size_type size_;     // exposition only
};

1 In every specialization basic_string_view<charT, traits>, the type traits shall satisfy the character traits requirements (20.2), and the type traits::char_type shall name the same type as charT.

2 The type iterator satisfies the constexpr iterator requirements (22.2.1).

20.4.2.1 Construction and assignment

constexpr basic_string_view() noexcept;
    Effects: Constructs an empty basic_string_view.
    Ensures: size_ == 0 and data_ == nullptr.
constexpr basic_string_view(const charT* str);
    Requires: [str, str + traits::length(str)) is a valid range.
    Effects: Constructs a basic_string_view, with the postconditions in Table 59.

Table 59 — basic_string_view(const charT*) effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_</td>
<td>str</td>
</tr>
<tr>
<td>size_</td>
<td>traits::length(str)</td>
</tr>
</tbody>
</table>

Complexity: \(O(\text{traits::length(str)})\).

constexpr basic_string_view(const charT* str, size_type len);
    Requires: [str, str + len) is a valid range.
    Effects: Constructs a basic_string_view, with the postconditions in Table 60.

Table 60 — basic_string_view(const charT*, size_type) effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>

20.4.2.2 Iterator support

using const_iterator = implementation-defined;

1 A type that meets the requirements of a constant random access iterator (22.2.7) and of a contiguous iterator (22.2.1) whose value_type is the template parameter charT.
For a basic_string_view str, any operation that invalidates a pointer in the range \([str.data(), str.data() + str.size())\) invalidates pointers, iterators, and references returned from str’s member functions.

All requirements on container iterators (21.2) apply to basic_string_view::const_iterator as well.

\[
\text{constexpr const_iterator begin() const noexcept;}
\]

\[
\text{constexpr const_iterator cbegin() const noexcept;}
\]

\[
\begin{align*}
\text{— if !empty(), } & \ast \text{begin}() = \text{data}, \\
\text{— otherwise, an unspecified value such that } & \text{[begin(), end()) is a valid range.}
\end{align*}
\]

\[
\text{constexpr const_iterator end() const noexcept;}
\]

\[
\text{constexpr const_iterator cend() const noexcept;}
\]

\[
\begin{align*}
\text{Returns: } & \text{begin()} + \text{size()}.
\end{align*}
\]

\[
\text{constexpr const_reverse_iterator rbegin() const noexcept;}
\]

\[
\text{constexpr const_reverse_iterator crbegin() const noexcept;}
\]

\[
\begin{align*}
\text{Returns: } & \text{const_reverse_iterator(end())}.
\end{align*}
\]

\[
\text{constexpr const_reverse_iterator rend() const noexcept;}
\]

\[
\text{constexpr const_reverse_iterator crend() const noexcept;}
\]

\[
\begin{align*}
\text{Returns: } & \text{const_reverse_iterator(begin())}.
\end{align*}
\]

\section*{20.4.2.3 Capacity \([\text{string.view.capacity}]\)}

\[
\text{constexpr size_type size() const noexcept;}
\]

\[
\text{Returns: size_.}
\]

\[
\text{constexpr size_type length() const noexcept;}
\]

\[
\text{Returns: size_.}
\]

\[
\text{constexpr size_type max_size() const noexcept;}
\]

\[
\text{Returns: The largest possible number of char-like objects that can be referred to by a basic_string_view.}
\]

[[nodiscard]] constexpr bool empty() const noexcept;

\[
\text{Returns: size_ == 0.}
\]

\section*{20.4.2.4 Element access \([\text{string.view.access}]\)}

\[
\text{constexpr const_reference operator[](size_type pos) const;}
\]

\[
\begin{align*}
\text{Requires: } & \text{pos < size().} \\
\text{Returns: } & \text{data_[pos].} \\
\text{Throws: Nothing.} \\
\text{[Note: Unlike basic_string::operator[], basic_string_view::operator[](size()) has undefined behavior instead of returning charT(). — end note]}
\end{align*}
\]

\[
\text{constexpr const_reference at(size_type pos) const;}
\]

\[
\begin{align*}
\text{Throws: out_of_range if } & \text{pos >= size().} \\
\text{Returns: data_[pos].}
\end{align*}
\]

\[
\text{constexpr const_reference front() const;}
\]

\[
\begin{align*}
\text{Requires: } & \text{!empty().} \\
\text{Returns: data_[0].} \\
\text{Throws: Nothing.}
\end{align*}
\]
constexpr const_reference back() const;

Requires: !empty().
Returns: data_[size() - 1].
Throws: Nothing.

constexpr const_pointer data() const noexcept;

Returns: data_.

[Note: Unlike basic_string::data() and string literals, data() may return a pointer to a buffer that is not null-terminated. Therefore it is typically a mistake to pass data() to a function that takes just a const charT* and expects a null-terminated string. — end note]

20.4.2.5 Modifiers

constexpr void remove_prefix(size_type n);

Requires: n <= size().
Effects: Equivalent to: data_ += n; size_ -= n;

constexpr void remove_suffix(size_type n);

Requires: n <= size().
Effects: Equivalent to: size_ -= n;

constexpr void swap(basic_string_view& s) noexcept;
Effects: Exchanges the values of *this and s.

20.4.2.6 String operations

size_type copy(charT* s, size_type n, size_type pos = 0) const;

Let rlen be the smaller of n and size() - pos.
Throws: out_of_range if pos > size().
Requires: [s, s + rlen) is a valid range.
Effects: Equivalent to traits::copy(s, data() + pos, rlen).
Returns: rlen.
Complexity: $\Theta(rlen)$.

constexpr basic_string_view substr(size_type pos = 0, size_type n = npos) const;

Let rlen be the smaller of n and size() - pos.
Throws: out_of_range if pos > size().
Effects: Determines rlen, the effective length of the string to reference.
Returns: basic_string_view(data() + pos, rlen).

constexpr int compare(basic_string_view str) const noexcept;

Let rlen be the smaller of size() and str.size().
Effects: Determines rlen, the effective length of the strings to compare. The function then compares the two strings by calling traits::compare(data(), str.data(), rlen).
Complexity: $\Theta(rlen)$.
Returns: The nonzero result if the result of the comparison is nonzero. Otherwise, returns a value as indicated in Table 61.

constexpr int compare(size_type pos1, size_type n1, basic_string_view str) const;

Effects: Equivalent to: return substr(pos1, n1).compare(str);
Table 61 — compare() results

<table>
<thead>
<tr>
<th>Condition</th>
<th>Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>size() &lt; str.size()</td>
<td>&lt; 0</td>
</tr>
<tr>
<td>size() == str.size()</td>
<td>0</td>
</tr>
<tr>
<td>size() &gt; str.size()</td>
<td>&gt; 0</td>
</tr>
</tbody>
</table>

```cpp
constexpr int compare(size_type pos1, size_type n1, basic_string_view str, 
size_type pos2, size_type n2) const;
Effects: Equivalent to: return substr(pos1, n1).compare(str.substr(pos2, n2));
```

```cpp
constexpr int compare(const charT* s) const;
Effects: Equivalent to: return compare(basic_string_view(s));
```

```cpp
constexpr int compare(size_type pos1, size_type n1, const charT* s) const;
Effects: Equivalent to: return substr(pos1, n1).compare(basic_string_view(s));
```

```cpp
constexpr int compare(size_type pos1, size_type n1, const charT* s, size_type n2) const;
Effects: Equivalent to: return substr(pos1, n1).compare(basic_string_view(s, n2));
```

```cpp
constexpr bool starts_with(basic_string_view x) const noexcept;
Effects: Equivalent to: return compare(0, npos, x) == 0;
```

```cpp
constexpr bool starts_with(charT x) const noexcept;
Effects: Equivalent to: return starts_with(basic_string_view(&x, 1));
```

```cpp
constexpr bool starts_with(const charT* x) const;
Effects: Equivalent to: return starts_with(basic_string_view(x));
```

```cpp
constexpr bool ends_with(basic_string_view x) const noexcept;
Effects: Equivalent to: return size() >= x.size() && compare(size() - x.size(), npos, x) == 0;
```

```cpp
constexpr bool ends_with(charT x) const noexcept;
Effects: Equivalent to: return ends_with(basic_string_view(&x, 1));
```

```cpp
constexpr bool ends_with(const charT* x) const;
Effects: Equivalent to: return ends_with(basic_string_view(x));
```

20.4.2.7 Searching [string.view.find]

1 This subclause specifies the basic_string_view member functions named find, rfind, find_first_of, find_last_of, find_first_not_of, and find_last_not_of.

2 Member functions in this subclause have complexity $O(size() \times str.size())$ at worst, although implementations should do better.

3 Each member function of the form

```cpp
constexpr return-type F(const charT* s, size_type pos);
```

is equivalent to

```cpp
return F(basic_string_view(s), pos);
```

4 Each member function of the form

```cpp
constexpr return-type F(const charT* s, size_type pos, size_type n);
```

is equivalent to

```cpp
return F(basic_string_view(s, n), pos);
```

5 Each member function of the form

```cpp
constexpr return-type F(charT c, size_type pos);
```

is equivalent to

```cpp
return F(basic_string_view(&c, 1), pos);
```
Let \( \text{xpos} \) be the lowest position, if possible, such that the following conditions hold:

- \( \text{pos} \leq \text{xpos} \)
- \( \text{xpos} + \text{str}.\text{size()} \leq \text{size()} \)
- \( \text{traits}::\text{eq}((\text{at})(\text{xpos} + \text{I}), \text{str}.\text{at}(\text{I})) \) for all elements \( \text{I} \) of the string referenced by \( \text{str} \).

**Effects:** Determines \( \text{xpos} \).

**Returns:** \( \text{xpos} \) if the function can determine such a value for \( \text{xpos} \). Otherwise, returns \( \text{npos} \).

---

Let \( \text{xpos} \) be the highest position, if possible, such that the following conditions hold:

- \( \text{xpos} \leq \text{pos} \)
- \( \text{xpos} + \text{str}.\text{size()} \leq \text{size()} \)
- \( \text{traits}::\text{eq}((\text{at})(\text{xpos} + \text{I}), \text{str}.\text{at}(\text{I})) \) for all elements \( \text{I} \) of the string referenced by \( \text{str} \).

**Effects:** Determines \( \text{xpos} \).

**Returns:** \( \text{xpos} \) if the function can determine such a value for \( \text{xpos} \). Otherwise, returns \( \text{npos} \).

---

Let \( \text{xpos} \) be the lowest position, if possible, such that the following conditions hold:

- \( \text{pos} \leq \text{xpos} \)
- \( \text{xpos} < \text{size()} \)
- \( \text{traits}::\text{eq}((\text{at})(\text{xpos}), \text{str}.\text{at}(\text{I})) \) for some element \( \text{I} \) of the string referenced by \( \text{str} \).

**Effects:** Determines \( \text{xpos} \).

**Returns:** \( \text{xpos} \) if the function can determine such a value for \( \text{xpos} \). Otherwise, returns \( \text{npos} \).

---

Let \( \text{xpos} \) be the highest position, if possible, such that the following conditions hold:

- \( \text{xpos} \leq \text{pos} \)
- \( \text{xpos} < \text{size()} \)
- \( \text{traits}::\text{eq}((\text{at})(\text{xpos}), \text{str}.\text{at}(\text{I})) \) for some element \( \text{I} \) of the string referenced by \( \text{str} \).

**Effects:** Determines \( \text{xpos} \).

**Returns:** \( \text{xpos} \) if the function can determine such a value for \( \text{xpos} \). Otherwise, returns \( \text{npos} \).

---

Let \( \text{xpos} \) be the lowest position, if possible, such that the following conditions hold:

- \( \text{pos} \leq \text{xpos} \)
- \( \text{xpos} < \text{size()} \)
- \( \text{traits}::\text{eq}((\text{at})(\text{xpos}), \text{str}.\text{at}(\text{I})) \) for no element \( \text{I} \) of the string referenced by \( \text{str} \).

**Effects:** Determines \( \text{xpos} \).

**Returns:** \( \text{xpos} \) if the function can determine such a value for \( \text{xpos} \). Otherwise, returns \( \text{npos} \).

---

Let \( \text{xpos} \) be the highest position, if possible, such that the following conditions hold:

- \( \text{xpos} \leq \text{pos} \)
- \( \text{xpos} < \text{size()} \)
- \( \text{traits}::\text{eq}((\text{at})(\text{xpos}), \text{str}.\text{at}(\text{I})) \) for no element \( \text{I} \) of the string referenced by \( \text{str} \).

**Effects:** Determines \( \text{xpos} \).

**Returns:** \( \text{xpos} \) if the function can determine such a value for \( \text{xpos} \). Otherwise, returns \( \text{npos} \).
20.4.3 Non-member comparison functions

1 Let \( S \) be `basic_string_view<charT, traits>`, and \( sv \) be an instance of \( S \). Implementations shall provide sufficient additional overloads marked `constexpr` and `noexcept` so that an object \( t \) with an implicit conversion to \( S \) can be compared according to Table 62.

Table 62 — Additional `basic_string_view` comparison overloads

<table>
<thead>
<tr>
<th>Expression</th>
<th>Equivalent to</th>
</tr>
</thead>
<tbody>
<tr>
<td>( t == sv )</td>
<td>( S(t) == sv )</td>
</tr>
<tr>
<td>( sv == t )</td>
<td>( sv == S(t) )</td>
</tr>
<tr>
<td>( t != sv )</td>
<td>( S(t) != sv )</td>
</tr>
<tr>
<td>( sv != t )</td>
<td>( sv != S(t) )</td>
</tr>
<tr>
<td>( t &lt; sv )</td>
<td>( S(t) &lt; sv )</td>
</tr>
<tr>
<td>( sv &lt; t )</td>
<td>( sv &lt; S(t) )</td>
</tr>
<tr>
<td>( t &gt; sv )</td>
<td>( S(t) &gt; sv )</td>
</tr>
<tr>
<td>( sv &gt; t )</td>
<td>( sv &gt; S(t) )</td>
</tr>
<tr>
<td>( t &lt;= sv )</td>
<td>( S(t) &lt;= sv )</td>
</tr>
<tr>
<td>( sv &lt;= t )</td>
<td>( sv &lt;= S(t) )</td>
</tr>
<tr>
<td>( t &gt;= sv )</td>
<td>( S(t) &gt;= sv )</td>
</tr>
<tr>
<td>( sv &gt;= t )</td>
<td>( sv &gt;= S(t) )</td>
</tr>
</tbody>
</table>

[Example: A sample conforming implementation for `operator==` would be:

```cpp
template<class T> using __identity = decay_t<T>;
template<class charT, class traits>
    constexpr bool operator==(basic_string_view<charT, traits> lhs,
        basic_string_view<charT, traits> rhs) noexcept {
    return lhs.compare(rhs) == 0;
}
template<class charT, class traits>
    constexpr bool operator==(basic_string_view<charT, traits> lhs,
        __identity<basic_string_view<charT, traits>> rhs) noexcept {
    return lhs.compare(rhs) == 0;
}
template<class charT, class traits>
    constexpr bool operator==(__identity<basic_string_view<charT, traits>> lhs,
        basic_string_view<charT, traits> rhs) noexcept {
    return lhs.compare(rhs) == 0;
}
```

—end example]

2 Returns: \( lhs \).compare(rhs) == 0.

3 Returns: `lhs.compare(rhs) != 0`.

4 Returns: \( lhs \).compare(rhs) < 0.

5 Returns: \( lhs \).compare(rhs) > 0.
template<class charT, class traits>
constexpr bool operator<=(basic_string_view<charT, traits> lhs,
basic_string_view<charT, traits> rhs) noexcept;

Returns: lhs.compare(rhs) <= 0.

template<class charT, class traits>
constexpr bool operator>=(basic_string_view<charT, traits> lhs,
basic_string_view<charT, traits> rhs) noexcept;

Returns: lhs.compare(rhs) >= 0.

20.4.4 Inserters and extractors

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, basic_string_view<charT, traits> str);

Effects: Behaves as a formatted output function (27.7.5.2.1) of os. Forms a character sequence seq, initially consisting of the elements defined by the range [str.begin(), str.end()). Determines padding for seq as described in 27.7.5.2.1. Then inserts seq as if by calling os.rdbuf()->sputn(seq, n), where n is the larger of os.width() and str.size(); then calls os.width(0).

Returns: os.

20.4.5 Hash support

template<> struct hash<string_view>;
template<> struct hash<u16string_view>;
template<> struct hash<u32string_view>;
template<> struct hash<wstring_view>;

The specialization is enabled (19.14.16). [Note: The hash value of a string view object is equal to the hash value of the corresponding string object (20.3.5). — end note]

20.4.6 Suffix for basic_string_view literals

constexpr string_view operator"sv(const char* str, size_t len) noexcept;

Returns: string_view(str, len).

costexpr u16string_view operator"sv(const char16_t* str, size_t len) noexcept;

Returns: u16string_view(str, len).

costexpr u32string_view operator"sv(const char32_t* str, size_t len) noexcept;

Returns: u32string_view(str, len).

costexpr wstring_view operator"sv(const wchar_t* str, size_t len) noexcept;

Returns: wstring_view(str, len).

    const char* strstr(const char* s1, const char* s2); // see 15.2
    size_t strspn(const char* s1, const char* s2);
    const char* strstr(const char* s1, const char* s2); // see 15.2
```

§ 20.5.3 722
The contents and meaning of the header `<cstring>` are the same as the C standard library header `<string.h>`.

The functions `strerror` and `strtok` are not required to avoid data races (15.5.5.9).

The functions `memcpy` and `memmove` are signal-safe (16.12.4).

[Note: The functions `strchr`, `strpbrk`, `strstr`, and `memchr`, have different signatures in this document, but they have the same behavior as in the C standard library (15.2). — end note]

21 Containers library

21.1 General

This Clause describes components that C++ programs may use to organize collections of information.

The following subclauses describe container requirements, and components for sequence containers and associative containers, as summarized in Table 63.

21.2 Container requirements

21.2.1 General container requirements

Containers are objects that store other objects. They control allocation and deallocation of these objects through constructors, destructors, insert and erase operations.

All of the complexity requirements in this Clause are stated solely in terms of the number of operations on the contained objects. [Example: The copy constructor of type vector<vector<int>> has linear complexity, even though the complexity of copying each contained vector<int> is itself linear. — end example]

For the components affected by this subclause that declare an allocator_type, objects stored in these components shall be constructed using the function allocator_traits<allocator_type>::rebind_traits<U>::construct and destroyed using the function allocator_traits<allocator_type>::rebind_traits<U>::destroy (19.10.9.2), where U is either allocator_type::value_type or an internal type used by the container. These functions are called only for the container’s element type, not for internal types used by the container. [Note: This means, for example, that a node-based container might need to construct nodes containing aligned buffers and call construct to place the element into the buffer. — end note]

In Tables 64, 65, and 66 X denotes a container class containing objects of type T, a and b denote values of type X, u denotes an identifier, r denotes a non-const value of type X, and rv denotes a non-const rvalue of type X.

<td></td>
<td>constant</td>
</tr>
</tbody>
</table>

Those entries marked “(Note A)” or “(Note B)” have linear complexity for `array` and have constant complexity for all other standard containers. [Note: The algorithm `equal()` is defined in Clause 23. — end note]

5 The member function `size()` returns the number of elements in the container. The number of elements is defined by the rules of constructors, inserts, and erases.

6 `begin()` returns an iterator referring to the first element in the container. `end()` returns an iterator which is the past-the-end value for the container. If the container is empty, then `begin()` == `end()`.

7 In the expressions

```
i == j
i != j
i < j
i <= j
i >= j
i > j
i - j
```

where i and j denote objects of a container’s `iterator` type, either or both may be replaced by an object of the container’s `const_iterator` type referring to the same element with no change in semantics.

8 Unless otherwise specified, all containers defined in this clause obtain memory using an allocator (see 15.5.3.5). [Note: In particular, containers and iterators do not store references to allocated elements other than through the allocator’s pointer type, i.e., as objects of type P or `pointer_traits<P>::template rebind<unspecified>`, where P is `allocator_traits<allocator_type>::pointer`. — end note] Copy constructors for these container types obtain an allocator by calling `allocator_traits<allocator_type>::select_on_container_copy_construction` on the allocator belonging to the container being copied. Move constructors obtain an allocator by move construction from the allocator belonging to the container being moved. Such move construction of the allocator shall not exit via an exception. All other constructors for these container types take a `const allocator_type&` argument. [Note: If an invocation of a
constructor uses the default value of an optional allocator argument, then the allocator type must support
value-initialization. —end note] A copy of this allocator is used for any memory allocation and element
construction performed, by these constructors and by all member functions, during the lifetime of each
container object or until the allocator is replaced. The allocator may be replaced only via assignment or
swap(). Allocator replacement is performed by copy assignment, move assignment, or swapping of the allocator
only if allocator_traits<allocator_type>::propagate_on_container_copy_assignment::value, allocator_traits<allocator_type>::propagate_on_container_move_assignment::value, or allocator_traits<allocator_type>::propagate_on_container_swap::value is true within the implementation of the corresponding container operation. In all container types defined in this Clause, the member get_allocator() returns a copy of the allocator used to construct the container or, if that allocator has been replaced, a copy of the most recent replacement.

The expression a.swap(b), for containers a and b of a standard container type other than array, shall exchange the values of a and b without invoking any move, copy, or swap operations on the individual container elements. Lvalues of any Compare, Pred, or Hash types belonging to a and b shall be swappable and shall be exchanged by calling swap as described in 15.5.3.2. If allocator_traits<allocator_type>::propagate_on_container_swap::value is true, then lvalues of type allocator_type shall be swappable and the allocators of a and b shall also be exchanged by calling swap as described in 15.5.3.2. Otherwise, the allocators shall not be swapped, and the behavior is undefined unless a.get_allocator() == b.get_allocator(). Every iterator referring to an element in one container before the swap shall refer to the same element in the other container after the swap. It is unspecified whether an iterator with value a.end() before the swap will have value b.end() after the swap.

If the iterator type of a container belongs to the bidirectional or random access iterator categories (22.2), the container is called reversible and satisfies the additional requirements in Table 65.

§ 21.2.1 729

11 Unless otherwise specified (see 21.2.6.1, 21.2.7.1, 21.3.8.4, and 21.3.11.5) all container types defined in this Clause meet the following additional requirements:

(11.1) — if an exception is thrown by an insert() or emplace() function while inserting a single element, that function has no effects.
(11.2) — if an exception is thrown by a push_back(), push_front(), emplace_back(), or emplace_front() function, that function has no effects.
(11.3) — no erase(), clear(), pop_back() or pop_front() function throws an exception.
(11.4) — no copy constructor or assignment operator of a returned iterator throws an exception.
(11.5) — no swap() function throws an exception.
(11.6) — no `swap()` function invalidates any references, pointers, or iterators referring to the elements of the containers being swapped. [Note: The `end()` iterator does not refer to any element, so it may be invalidated. — end note]

12 Unless otherwise specified (either explicitly or by defining a function in terms of other functions), invoking a container member function or passing a container as an argument to a library function shall not invalidate iterators to, or change the values of, objects within that container.

13 A contiguous container is a container that supports random access iterators (22.2.7) and whose member types `iterator` and `const_iterator` are contiguous iterators (22.2.1).

14 Table 66 lists operations that are provided for some types of containers but not others. Those containers for which the listed operations are provided shall implement the semantics described in Table 66 unless otherwise stated.

<table>
<thead>

<td>linear</td>
<td></td>
</tr>
<tr>
<td><code>a &gt;= b</code></td>
<td>convertible to <code>bool</code></td>
<td>!(a &lt; b)</td>
<td>linear</td>
<td></td>
</tr>
</tbody>
</table>

[Note: The algorithm `lexicographical_compare()` is defined in Clause 23. — end note]

15 All of the containers defined in this Clause and in 20.3.2 except `array` meet the additional requirements of an allocator-aware container, as described in Table 67.

Given an allocator type `A` and given a container type `X` having a value_type identical to `T` and an allocator_type identical to `allocator_traits<A>::rebind_alloc<T>` and given an lvalue `m` of type `A`, a pointer `p` of type `T*`, an expression `v` of type (possibly const) `T`, and an rvalue `rv` of type `T`, the following terms are defined. If `X` is not allocator-aware, the terms below are defined as if `A` were `allocator<T>` — no allocator object needs to be created and user specializations of `allocator<T>` are not instantiated:

(15.1) — `T` is `Cpp17DefaultInsertable into X` means that the following expression is well-formed:
```
allocator_traits<A>::construct(m, p)
```
(15.2) — An element of `X` is default-inserted if it is initialized by evaluation of the expression
```
allocator_traits<A>::construct(m, p)
```
where `p` is the address of the uninitialized storage for the element allocated within `X`.
(15.3) — `T` is `Cpp17MoveInsertable into X` means that the following expression is well-formed:
```
allocator_traits<A>::construct(m, p, rv)
```
and its evaluation causes the following postcondition to hold: The value of `*p` is equivalent to the value of `rv` before the evaluation. [Note: `rv` remains a valid object. Its state is unspecified — end note]
(15.4) — `T` is `Cpp17CopyInsertable into X` means that, in addition to `T` being `Cpp17MoveInsertable` into `X`, the following expression is well-formed:
```
allocator_traits<A>::construct(m, p, v)
```
and its evaluation causes the following postcondition to hold: The value of `v` is unchanged and is equivalent to `*p`.

§ 21.2.1
--- `T` is `Cpp17EmplaceConstructible into X from args`, for zero or more arguments `args`, means that the following expression is well-formed:

\[
\text{allocator_traits}<A>::\text{construct}(m, p, \text{args})
\]

--- `T` is `Cpp17Erasable from X` means that the following expression is well-formed:

\[
\text{allocator_traits}<A>::\text{destroy}(m, p)
\]

[Note: A container calls \text{allocator_traits}<A>::\text{construct}(m, p, \text{args}) to construct an element at `p` using `args`, with `m == \text{get_allocator()}`. The default construct in \text{allocator} will call `::\text{new}((\text{void}*)p) T(\text{args})`, but specialized allocators may choose a different definition. — end note]

16 In Table 67, `X` denotes an allocator-aware container class with a \text{value_type} of `T` using allocator of type `A`. `u` denotes a variable, `a` and `b` denote non-const lvalues of type `X`, `t` denotes an lvalue or a const rvalue of type `X`, `rv` denotes a non-const rvalue of type `X`, and `m` is a value of type `A`.

17 The behavior of certain container member functions and deduction guides depends on whether types qualify as input iterators or allocators. The extent to which an implementation determines that a type cannot be an input iterator is unspecified, except that as a minimum integral types shall not qualify as input iterators. Likewise, the extent to which an implementation determines that a type cannot be an allocator is unspecified, except that as a minimum a type A shall not qualify as an allocator unless it satisfies both of the following conditions:

17.1 The qualified-id A::value_type is valid and denotes a type (12.9.2).

17.2 The expression declval<A&>().allocate(size_t{}) is well-formed when treated as an unevaluated operand.

#### 21.2.2 Container data races

For purposes of avoiding data races (15.5.5.9), implementations shall consider the following functions to be const: begin, end, rbegin, rend, front, back, data, find, lower_bound, upper_bound, equal_range, at and, except in associative or unordered associative containers, operator[].

Notwithstanding 15.5.5.9, implementations are required to avoid data races when the contents of the contained object in different elements in the same container, excepting vector<bool>, are modified concurrently.

[Note: For a vector<int> x with a size greater than one, x[1] = 5 and *x.begin() = 10 can be executed concurrently without a data race, but x[0] = 5 and *x.begin() = 10 executed concurrently may result in a data race. As an exception to the general rule, for a vector<bool> y, y[0] = true may race with y[1] = true. — end note]

#### 21.2.3 Sequence containers

A sequence container organizes a finite set of objects, all of the same type, into a strictly linear arrangement. The library provides four basic kinds of sequence containers: vector, forward_list, list, and deque. In addition, array is provided as a sequence container which provides limited sequence operations because it has a fixed number of elements. The library also provides container adaptors that make it easy to construct abstract data types, such as stacks or queues, out of the basic sequence container kinds (or out of other kinds of sequence containers that the user might define).

[Note: The sequence containers offer the programmer different complexity trade-offs and should be used accordingly. vector is the type of sequence container that should be used by default. array should be used when the container has a fixed size known during translation. list or forward_list should be used when there are frequent insertions and deletions from the middle of the sequence. deque is the data structure of choice when most insertions and deletions take place at the beginning or at the end of the sequence. When choosing a container, remember vector is best; leave a comment to explain if you choose from the rest! — end note]

In Tables 68 and 69, X denotes a sequence container class, a denotes a value of type X containing elements of type T, u denotes the name of a variable being declared, A denotes X::allocator_type if the qualified-id of
X::allocator_type is valid and denotes a type (12.9.2) and allocator<T> if it doesn’t, i and j denote iterators satisfying input iterator requirements and refer to elements implicitly convertible to value_type, [i, j) denotes a valid range, il designates an object of type initializer_list<value_type>, n denotes a value of type X::size_type, p denotes a valid constant iterator to a, q denotes a valid dereferenceable constant iterator to a, t denotes a valid range of constant iterators in a, t denotes an lvalue or a const rvalue of X::value_type, and rv denotes a non-const rvalue of X::value_type. Args denotes a template parameter pack; args denotes a function parameter pack with the pattern Args&&.

The complexities of the expressions are sequence dependent.

</tr>
</tbody>
</table>

5 The iterator returned from a.insert(p, t) points to the copy of t inserted into a.

6 The iterator returned from a.insert(p, rv) points to the copy of rv inserted into a.
The iterator returned from \( a\.insert(p, n, t) \) points to the copy of the first element inserted into \( a \), or \( p \) if \( n == 0 \).

The iterator returned from \( a\.insert(p, i, j) \) points to the copy of the first element inserted into \( a \), or \( p \) if \( i == j \).

The iterator returned from \( a\.insert(p, il) \) points to the copy of the first element inserted into \( a \), or \( p \) if \( il \) is empty.

The iterator returned from \( a\.emplace(p, args) \) points to the new element constructed from \( args \) into \( a \).

The iterator returned from \( a\.erase(q) \) points to the element immediately following \( q \) prior to the element being erased. If no such element exists, \( a\.end() \) is returned.

The iterator returned by \( a\.erase(q1, q2) \) points to the element pointed to by \( q2 \) prior to any elements being erased. If no such element exists, \( a\.end() \) is returned.

For every sequence container defined in this Clause and in Clause 20:

13.1 — If the constructor

\[
\text{template<class InputIterator> } \\
X(\text{InputIterator first, InputIterator last,} \\
\text{const allocator_type& alloc = allocator_type();)}
\]

is called with a type \( \text{InputIterator} \) that does not qualify as an input iterator, then the constructor shall not participate in overload resolution.

13.2 — If the member functions of the forms:

\[
\text{template<class InputIterator> } \\
\text{return-type F(const_iterator p,} \\
\text{InputIterator first, InputIterator last);} \quad \text{ // such as insert}
\]

\[
\text{template<class InputIterator> } \\
\text{return-type F(InputIterator first, InputIterator last);} \quad \text{ // such as append, assign}
\]

\[
\text{template<class InputIterator> } \\
\text{return-type F(const_iterator il, const_iterator i2,} \\
\text{InputIterator first, InputIterator last);} \quad \text{ // such as replace}
\]

are called with a type \( \text{InputIterator} \) that does not qualify as an input iterator, then these functions shall not participate in overload resolution.

13.3 — A deduction guide for a sequence container shall not participate in overload resolution if it has an \( \text{InputIterator} \) template parameter and a type that does not qualify as an input iterator is deduced for that parameter, or if it has an \( \text{Allocator} \) template parameter and a type that does not qualify as an allocator is deduced for that parameter.

Table 69 lists operations that are provided for some types of sequence containers but not others. An implementation shall provide these operations for all container types shown in the “container” column, and shall implement them so as to take amortized constant time.

<td>reference; const_reference *(a.begin() + n)</td>
<td>basic_string, array, deque, vector</td>
<td></td>
</tr>
</tbody>
</table>

---

15 The member function `at()` provides bounds-checked access to container elements. `at()` throws `out_of_range` if n >= a.size().

### 21.2.4 Node handles

#### 21.2.4.1 Overview

A **node handle** is an object that accepts ownership of a single element from an associative container (21.2.6) or an unordered associative container (21.2.7). It may be used to transfer that ownership to another container with compatible nodes. Containers with compatible nodes have the same node handle type. Elements may be transferred in either direction between container types in the same row of Table 70.

1 If a node handle is not empty, then it contains an allocator that is equal to the allocator of the container when the element was extracted. If a node handle is empty, it contains no allocator.
### Table 70 — Container types with compatible nodes

</tbody>
</table>

3 Class `node_handle` is for exposition only. An implementation is permitted to provide equivalent functionality without providing a class with this name.

4 If a user-defined specialization of `pair` exists for `pair<const Key, T>` or `pair<Key, T>`, where `Key` is the container’s `key_type` and `T` is the container’s `mapped_type`, the behavior of operations involving node handles is undefined.

```cpp
template<unspecialized>
class node_handle {
  public:
    // These type declarations are described in Tables 71 and 72.
    using value_type = see below; // not present for map containers
    using key_type = see below; // not present for set containers
    using mapped_type = see below; // not present for set containers
    using allocator_type = see below;

    private:
    using container_node_type = unspecified;
    using ator_traits = allocator_traits<allocator_type>;

    typename ator_traits::rebind_traits<container_node_type>::pointer ptr_;
    optional<allocator_type> alloc_;

    public:
    // 21.2.4.2, constructors, copy, and assignment
    constexpr node_handle() noexcept : ptr_(), alloc_() {}
    node_handle(node_handle&&) noexcept;
    node_handle& operator=(node_handle&&);

    // 21.2.4.3, destructor
    ~node_handle();

    // 21.2.4.4, observers
    value_type& value() const; // not present for map containers
    key_type& key() const; // not present for set containers
    mapped_type& mapped() const; // not present for set containers

    allocator_type get_allocator() const;
    explicit operator bool() const noexcept;
    [[nodiscard]] bool empty() const noexcept;

    // 21.2.4.5, modifiers
    void swap(node_handle&&) noexcept(ator_traits::propagate_on_container_swap::value ||
                                        ator_traits::is_always_equal::value);

    friend void swap(node_handle& x, node_handle& y) noexcept(noexcept(x.swap(y))) {
      x.swap(y);
    }
};
```
21.2.4.2 Constructors, copy, and assignment

```cpp
node_handle(node_handle&& nh) noexcept;
```

1. **Effects:** Constructs a `node_handle` object initializing `ptr_` with `nh.ptr_`. Move constructs `alloc_` with `nh.alloc_`. Assigns `nullptr` to `nh.ptr_` and assigns `nullopt` to `nh.alloc_`.

```cpp
node_handle& operator=(node_handle&& nh);
```

2. **Requires:** Either `!alloc_`, or `ator_traits::propagate_on_container_move_assignment` is `true`, or `alloc_ == nh.alloc_`.

3. **Effects:**

   (3.1) — If `ptr_ != nullptr`, destroys the `value_type` subobject in the `container_node_type` object pointed to by `ptr_` by calling `ator_traits::destroy`, then deallocates `ptr_` by calling `ator_traits::rebind_traits<container_node_type>::deallocate`.

   (3.2) — Assigns `nh.ptr_` to `ptr_`.

   (3.3) — If `!alloc_` or `ator_traits::propagate_on_container_move_assignment` is `true`, move assigns `nh.alloc_` to `alloc_`.

   (3.4) — Assigns `nullptr` to `nh.ptr_` and assigns `nullopt` to `nh.alloc_`.

4. **Returns:** `*this`.

5. **Throws:** Nothing.

21.2.4.3 Destructor

```cpp
~node_handle();
```

1. **Effects:** If `ptr_ != nullptr`, destroys the `value_type` subobject in the `container_node_type` object pointed to by `ptr_` by calling `ator_traits::destroy`, then deallocates `ptr_` by calling `ator_traits::rebind_traits<container_node_type>::deallocate`.

21.2.4.4 Observers

```cpp
value_type& value() const;
```

1. **Requires:** `empty() == false`.

2. **Returns:** A reference to the `value_type` subobject in the `container_node_type` object pointed to by `ptr_`.

3. **Throws:** Nothing.

```cpp
key_type& key() const;
```

4. **Requires:** `empty() == false`.

5. **Returns:** A non-const reference to the `key_type` member of the `value_type` subobject in the `container_node_type` object pointed to by `ptr_`.

6. **Throws:** Nothing.

7. **Remarks:** Modifying the key through the returned reference is permitted.

```cpp
mapped_type& mapped() const;
```

8. **Requires:** `empty() == false`.

9. **Returns:** A reference to the `mapped_type` member of the `value_type` subobject in the `container_node_type` object pointed to by `ptr_`.

10. **Throws:** Nothing.

```cpp
allocator_type get_allocator() const;
```

11. **Requires:** `empty() == false`.

12. **Returns:** `*alloc_`.

13. **Throws:** Nothing.

§ 21.2.4.4
explicit operator bool() const noexcept;
   Returns: ptr_ != nullptr.
[[nodiscard]] bool empty() const noexcept;
   Returns: ptr_ == nullptr.

21.2.4.5 Modifiers

    void swap(node_handle& nh)
       noexcept(ator_traits::propagate_on_container_swap::value ||
                 ator_traits::is_always_equal::value);
   Requires: !alloc_, or !nh.alloc_, or ator_traits::propagate_on_container_swap is true, or
             alloc_ == nh.alloc_.
   Effects: Calls swap(ptr_, nh.ptr_). If !alloc_, or !nh.alloc_, or ator_traits::propagate_on_container_swap is true calls swap(alloc_, nh.alloc_).

21.2.5 Insert return type

    template<class Iterator, class NodeType>
    struct INSERT_RETURN_TYPE
    {
       Iterator position;
       bool inserted;
       NodeType node;
    };

2 The name INSERT_RETURN_TYPE is exposition only. INSERT_RETURN_TYPE has the template parameters,
data members, and special members specified above. It has no base classes or members other than those
specified.

21.2.6 Associative containers

1 Associative containers provide fast retrieval of data based on keys. The library provides four basic kinds of
associative containers: set, multiset, map and multimap.

2 Each associative container is parameterized on Key and an ordering relation Compare that induces a strict
weak ordering (23.7) on elements of Key. In addition, map and multimap associate an arbitrary mapped type
T with the Key. The object of type Compare is called the comparison object of a container.

3 The phrase “equivalence of keys” means the equivalence relation imposed by the comparison object. That
is, two keys k1 and k2 are considered to be equivalent if for the comparison object comp, comp(k1, k2)
== false && comp(k2, k1) == false. [Note: This is not necessarily the same as the result of k1 == k2.
—end note] For any two keys k1 and k2 in the same container, calling comp(k1, k2) shall always return the
same value.

4 An associative container supports unique keys if it may contain at most one element for each key. Otherwise,
it supports equivalent keys. The set and map classes support unique keys; the multiset and multimap
classes support equivalent keys. For multiset and multimap, insert, emplace, and erase preserve the
relative ordering of equivalent elements.

5 For set and multiset the value type is the same as the key type. For map and multimap it is equal to
pair<const Key, T>.

6 iterator of an associative container is of the bidirectional iterator category. For associative containers
where the value type is the same as the key type, both iterator and const_iterator are constant iterators.
It is unspecified whether or not iterator and const_iterator are the same type. [Note: iterator and
const_iterator have identical semantics in this case, and iterator is convertible to const_iterator.
Users can avoid violating the one-definition rule by always using const_iterator in their function parameter
lists. —end note]

7 The associative containers meet all the requirements of Allocator-aware containers (21.2.1), except that
for map and multimap, the requirements placed on value_type in Table 67 apply instead to key_type

§ 21.2.6
and mapped_type. [Note: For example, in some cases key_type and mapped_type are required to be Cpp17CopyAssignable even though the associated value_type, pair<const key_type, mapped_type>, is not Cpp17CopyAssignable. — end note]

In Table 71, X denotes an associative container class, a denotes a value of type X, a2 denotes a value of a type with nodes compatible with type X (Table 70), b denotes a possibly const value of type X, u denotes the name of a variable being declared, a_unique denotes a value of type X when X supports unique keys, a_eq denotes a value of type X when X supports multiple keys, a_tran denotes a possibly const value of type X when the qualified-id X::key_compare::is_transparent is valid and denotes a type (12.9.2), i and j satisfy input iterator requirements and refer to elements implicitly convertible to value_type, [i, j) denotes a valid range, p denotes a valid constant iterator to a, q denotes a valid dereferenceable constant iterator to a, r denotes a valid dereferenceable iterator to a, (q1, q2) denotes a valid range of constant iterators in a, il designates an object of type initializer_list<value_type>, t denotes a value of type X::value_type, k denotes a value of type X::key_type and c denotes a possibly const value of type X::key_compare; kl is a value such that a is partitioned (23.7) with respect to c(r, kl), with r the key value of e and e in a; ku is a value such that a is partitioned with respect to !c(ku, r); ke is a value such that a is partitioned with respect to c(r, ke) and !c(ke, r), with c(r, ke) implying !c(ke, r). A denotes the storage allocator used by X, if any, or allocator<X::value_type> otherwise, m denotes an allocator of a type convertible to A, and nh denotes a non-const rvalue of type X::node_type.

</tr>
</tbody>
</table>

9 The `insert` and `emplace` members shall not affect the validity of iterators and references to the container, and the `erase` members shall invalidate only iterators and references to the erased elements.

10 The `extract` members invalidate only iterators to the removed element; pointers and references to the removed element remain valid. However, accessing the element through such pointers and references while the element is owned by a `node_type` is undefined behavior. References and pointers to an element obtained while it is owned by a `node_type` are invalidated if the element is successfully inserted.

11 The fundamental property of iterators of associative containers is that they iterate through the containers in the non-descending order of keys where non-descending is defined by the comparison that was used to construct them. For any two dereferenceable iterators `i` and `j` such that distance from `i` to `j` is positive, the following condition holds:

   \[
   \text{value_comp}(\ast j, \ast i) = \text{false}
   \]

12 For associative containers with unique keys the stronger condition holds:

   \[
   \text{value_comp}(\ast i, \ast j) \neq \text{false}
   \]

13 When an associative container is constructed by passing a comparison object the container shall not store a pointer or reference to the passed object, even if that object is passed by reference. When an associative container is copied, either through a copy constructor or an assignment operator, the target container shall then use the comparison object from the container being copied, as if that comparison object had been passed to the target container in its constructor.
The member function templates `find`, `count`, `contains`, `lower_bound`, `upper_bound`, and `equal_range` shall not participate in overload resolution unless the qualified-id `Compare::is_transparent` is valid and denotes a type (12.9.2).

A deduction guide for an associative container shall not participate in overload resolution if any of the following are true:

1. It has an `InputIterator` template parameter and a type that does not qualify as an input iterator is deduced for that parameter.
2. It has an `Allocator` template parameter and a type that does not qualify as an allocator is deduced for that parameter.
3. It has a `Compare` template parameter and a type that qualifies as an allocator is deduced for that parameter.

### 21.2.7 Unordered associative containers

Unordered associative containers provide an ability for fast retrieval of data based on keys. The worst-case complexity for most operations is linear, but the average case is much faster. The library provides four unordered associative containers: `unordered_set`, `unordered_map`, `unordered_multiset`, and `unordered_multimap`.

Unordered associative containers conform to the requirements for Containers (21.2), except that the expressions `a == b` and `a != b` have different semantics than for the other container types.

Each unordered associative container is parameterized by `Key`, by a function object type `Hash` that meets the `Cpp17Hash` requirements (15.5.3.4) and acts as a hash function for argument values of type `Key`, and by a binary predicate `Pred` that induces an equivalence relation on values of type `Key`. Additionally, `unordered_map` and `unordered_multimap` associate an arbitrary `mapped` type `T` with the `Key`.

The container’s object of type `Hash` — denoted by `hash` — is called the `hash function` of the container. The container’s object of type `Pred` — denoted by `pred` — is called the `key equality predicate` of the container.

Two values `k1` and `k2` of type `Key` are considered equivalent if the container’s key equality predicate returns `true` when passed those values. If `k1` and `k2` are equivalent, the container’s hash function shall return the same value for both. [Note: Thus, when an unordered associative container is instantiated with a non-default `Pred` parameter it usually needs a non-default `Hash` parameter as well. — end note] For any two keys `k1` and `k2` in the same container, calling `pred(k1, k2)` shall always return the same value. For any key `k` in a container, calling `hash(k)` shall always return the same value.

An unordered associative container supports `unique keys` if it may contain at most one element for each key. Otherwise, it supports `equivalent keys`. `unordered_set` and `unordered_map` support unique keys. `unordered_multiset` and `unordered_multimap` support equivalent keys. In containers that support equivalent keys, elements with equivalent keys are adjacent to each other in the iteration order of the container. Thus, although the absolute order of elements in an unordered container is not specified, its elements are grouped into `equivalent-key groups` such that all elements of each group have equivalent keys. Mutating operations on unordered containers shall preserve the relative order of elements within each equivalent-key group unless otherwise specified.

For `unordered_set` and `unordered_multiset` the value type is the same as the key type. For `unordered_map` and `unordered_multimap` it is pair<const `Key`, `T`>.

For unordered containers where the value type is the same as the key type, both `iterator` and `const_iterator` are constant iterators. It is unspecified whether or not `iterator` and `const_iterator` are the same type. [Note: `iterator` and `const_iterator` have identical semantics in this case, and `iterator` is convertible to `const_iterator`. Users can avoid violating the one-definition rule by always using `const_iterator` in their function parameter lists. — end note]
The elements of an unordered associative container are organized into buckets. Keys with the same hash code appear in the same bucket. The number of buckets is automatically increased as elements are added to an unordered associative container, so that the average number of elements per bucket is kept below a bound. Rehashing invalidates iterators, changes ordering between elements, and changes which buckets elements appear in, but does not invalidate pointers or references to elements. For unordered_multiset and unordered_multimap, rehashing preserves the relative ordering of equivalent elements.

The unordered associative containers meet all the requirements of Allocator-aware containers (21.2.1), except that for unordered_map and unordered_multimap, the requirements placed on value_type in Table 67 apply instead to key_type and mapped_type. [Note: For example, key_type and mapped_type are sometimes required to be Cpp17CopyAssignable even though the associated value_type, pair<const key_type, mapped_type>, is not Cpp17CopyAssignable. — end note]

In Table 72: X denotes an unordered associative container class, a denotes a value of type X, a2 denotes a value of a type with nodes compatible with type X (Table 70), b denotes a possibly const value of type X, a_uniq denotes a value of type X when X supports unique keys, a_eq denotes a value of type X when X supports equivalent keys, i and j denote input iterators that refer to value_type, [i, j) denotes a valid range, p and q2 denote valid constant iterators to a, q and q1 denote valid dereferenceable constant iterators to a, r denotes a valid dereferenceable iterator to a, [q1, q2) denotes a valid range in a, il denotes a value of type initializer_list<value_type>, t denotes a value of type X::value_type, k denotes a value of type key_type, hf denotes a possibly const value of type hasher, eq denotes a possibly const value of type key_equal, n denotes a value of type size_type, z denotes a value of type float, and nh denotes a non-const rvalue of type X::node_type.

</tbody>
</table>
Two unordered containers `a` and `b` compare equal if `a.size() == b.size()` and, for every equivalent-key group `[Ea1, Ea2) obtained from `a.equal_range(Ea1)`], there exists an equivalent-key group `[Eb1, Eb2) obtained from `b.equal_range(Ea1)`, such that `is_permutation(Ea1, Ea2, Eb1, Eb2)` returns `true`. For `unordered_set` and `unordered_map`, the complexity of `operator==(i.e., the number of calls to the == operator of the value_type, to the predicate returned by `key_eq()`, and to the hasher returned by `hash_function()`) is proportional to `N` in the average case and to `N^2` in the worst case, where `N` is `a.size()`.

For `unordered_multiset` and `unordered_multimap`, the complexity of `operator==` is proportional to `\sum E_i^2` in the average case and to `N^2` in the worst case, where `N` is `a.size()`, and `E_i` is the size of the `i`th equivalent-key group in `a`. However, if the respective elements of each corresponding pair of equivalent-key groups `Ea_i` and `Eb_i` are arranged in the same order (as is commonly the case, e.g., if `a` and `b` are unmodified copies of the same container), then the average-case complexity for `unordered_multiset` and `unordered_multimap` becomes proportional to `N` (but worst-case complexity remains \(O(N^2)\), e.g., for a pathologically bad hash function).

The behavior of a program that uses `operator==` or `operator!=` on unordered containers is undefined unless the `Pred` function object has the same behavior for both containers and the equality comparison function for `Key` is a refinement\(^{231}\) of the partition into equivalent-key groups produced by `Pred`.

The iterator types `iterator` and `const_iterator` of an unordered associative container are of at least the forward iterator category. For unordered associative containers where the key type and value type are the same, both `iterator` and `const_iterator` are constant iterators.

The `insert` and `emplace` members shall not affect the validity of references to container elements, but may invalidate all iterators to the container. The `erase` members shall invalidate only iterators and references to the erased elements, and preserve the relative order of the elements that are not erased.

The `insert` and `emplace` members shall not affect the validity of iterators if `(N+n) <= z * B`, where `N` is the number of elements in the container prior to the insert operation, `n` is the number of elements inserted, `B` is the container’s bucket count, and `z` is the container’s maximum load factor.

The `extract` members invalidate only iterators to the removed element, and preserve the relative order of the elements that are not erased; pointers and references to the removed element remain valid. However, accessing the element through such pointers and references while the element is owned by a `node_type` is undefined behavior. References and pointers to an element obtained while it is owned by a `node_type` are invalidated if the element is successfully inserted.

A deduction guide for an unordered associative container shall not participate in overload resolution if any of the following are true:

- It has an `InputIterator` template parameter and a type that does not qualify as an input iterator is deduced for that parameter.
- It has an `Allocator` template parameter and a type that does not qualify as an allocator is deduced for that parameter.
- It has a `Hash` template parameter and an integral type or a type that qualifies as an allocator is deduced for that parameter.
- It has a `Pred` template parameter and a type that qualifies as an allocator is deduced for that parameter.

### 21.2.7.1 Exception safety guarantees

For unordered associative containers, no `clear()` function throws an exception. `erase(k)` does not throw an exception unless that exception is thrown by the container’s `Hash` or `Pred` object (if any).

For unordered associative containers, if an exception is thrown by any operation other than the container’s hash function from within an `insert` or `emplace` function inserting a single element, the insertion has no effect.

For unordered associative containers, no `swap` function throws an exception unless that exception is thrown by the swap of the container’s `Hash` or `Pred` object (if any).

For unordered associative containers, if an exception is thrown from within a `rehash()` function other than by the container’s hash function or comparison function, the `rehash()` function has no effect.

---

\(^{231}\) Equality comparison is a refinement of partitioning if no two objects that compare equal fall into different partitions.
21.3 Sequence containers

21.3.1 In general

The headers `<array>`, `<deque>`, `<forward_list>`, `<list>`, and `<vector>` define class templates that meet the requirements for sequence containers.

1 The following exposition-only alias template may appear in deduction guides for sequence containers:

```cpp
template<class InputIterator>
using iter_value_type = typename iterator_traits<InputIterator>::value_type;  // exposition only
```

21.3.2 Header `<array>` synopsis

```cpp
#include <initializer_list>

namespace std {

// 21.3.7, class template array
template<class T, size_t N> struct array;

template<class T, size_t N>
constexpr bool operator==(const array<T, N>& x, const array<T, N>& y);

template<class T, size_t N>
constexpr bool operator!=(const array<T, N>& x, const array<T, N>& y);

template<class T, size_t N>
constexpr bool operator<(const array<T, N>& x, const array<T, N>& y);

template<class T, size_t N>
constexpr bool operator>(const array<T, N>& x, const array<T, N>& y);

template<class T, size_t N>
void swap(array<T, N>& x, array<T, N>& y) noexcept(noexcept(x.swap(y)));

template<class T> class tuple_size;

template<size_t I, class T> class tuple_element;

template<class T, size_t N>
struct tuple_size<array<T, N>>;

template<size_t I, class T, size_t N>
struct tuple_element<I, array<T, N>>;

template<size_t I, class T, size_t N>
constexpr T& get(array<T, N>&) noexcept;

template<size_t I, class T, size_t N>
constexpr T&& get(array<T, N>&&) noexcept;

template<size_t I, class T, size_t N>
constexpr const T& get(const array<T, N>&) noexcept;

template<size_t I, class T, size_t N>
constexpr const T&& get(const array<T, N>&&) noexcept;

}
```

21.3.3 Header `<deque>` synopsis

```cpp
#include <initializer_list>

namespace std {

// 21.3.8, class template deque
template<class T, class Allocator = allocator<T>> class deque;

template<class T, class Allocator>
bool operator==(const deque<T, Allocator>& x, const deque<T, Allocator>& y);

template<class T, class Allocator>
bool operator!=(const deque<T, Allocator>& x, const deque<T, Allocator>& y);

template<class T, class Allocator>
bool operator<(const deque<T, Allocator>& x, const deque<T, Allocator>& y);

template<class T, class Allocator>
bool operator>(const deque<T, Allocator>& x, const deque<T, Allocator>& y);

```
template<class T, class Allocator>
  bool operator<(const deque<T, Allocator>& x, const deque<T, Allocator>& y);
template<class T, class Allocator>
  bool operator>=(const deque<T, Allocator>& x, const deque<T, Allocator>& y);

namespace pmr {
  template<class T>
  using deque = std::deque<T, polymorphic_allocator<T>>;
}

21.3.4 Header <forward_list> synopsis

#include <initializer_list>

namespace std {
  // 21.3.9, class template forward_list
  template<class T, class Allocator = allocator<T>> class forward_list;

  template<class T, class Allocator>
  bool operator==(const forward_list<T, Allocator>& x, const forward_list<T, Allocator>& y);
  template<class T, class Allocator>
  bool operator!=(const forward_list<T, Allocator>& x, const forward_list<T, Allocator>& y);
  template<class T, class Allocator>
  bool operator< (const forward_list<T, Allocator>& x, const forward_list<T, Allocator>& y);
  template<class T, class Allocator>
  bool operator> (const forward_list<T, Allocator>& x, const forward_list<T, Allocator>& y);
  template<class T, class Allocator>
  bool operator<=(const forward_list<T, Allocator>& x, const forward_list<T, Allocator>& y);
  template<class T, class Allocator>
  bool operator>=(const forward_list<T, Allocator>& x, const forward_list<T, Allocator>& y);

  namespace pmr {
    template<class T>
    using forward_list = std::forward_list<T, polymorphic_allocator<T>>;
  }
}

21.3.5 Header <list> synopsis

#include <initializer_list>

namespace std {
  // 21.3.10, class template list
  template<class T, class Allocator = allocator<T>> class list;

  template<class T, class Allocator>
  bool operator==(const list<T, Allocator>& x, const list<T, Allocator>& y);
  template<class T, class Allocator>
  bool operator!=(const list<T, Allocator>& x, const list<T, Allocator>& y);
  template<class T, class Allocator>

}

21.3.7 Class template array

21.3.7.1 Overview

The header <array> defines a class template for storing fixed-size sequences of objects. An array is a contiguous container (21.2.1). An instance of array<T, N> stores N elements of type T, so that size() == N is an invariant.

An array is an aggregate (9.3.1) that can be list-initialized with up to N elements whose types are convertible to T.

An array satisfies all of the requirements of a container and of a reversible container (21.2), except that a default constructed array object is not empty and that swap does not have constant complexity. An array satisfies some of the requirements of a sequence container (21.2.3). Descriptions are provided here only for
operations on array that are not described in one of these tables and for operations where there is additional semantic information.

4 The types iterator and const_iterator satisfy the constexpr iterator requirements (22.2.1).

namespace std {
  template<class T, size_t N>
  struct array {
    // types
    using value_type = T;
    using pointer = T*;
    using const_pointer = const T*;
    using reference = T&;
    using const_reference = const T&;
    using size_type = size_t;
    using difference_type = ptrdiff_t;
    using iterator = implementation-defined; // see 21.2
    using const_iterator = implementation-defined; // see 21.2
    using reverse_iterator = std::reverse_iterator<iterator>;
    using const_reverse_iterator = std::reverse_iterator<const_iterator>;

    // no explicit construct/copy/destroy for aggregate type
    void fill(const T& u);
    void swap(array&) noexcept(is_nothrow_swappable_v<T>);

    // iterators
    constexpr iterator begin() noexcept;
    constexpr const_iterator begin() const noexcept;
    constexpr iterator end() noexcept;
    constexpr const_iterator end() const noexcept;
    constexpr reverse_iterator rbegin() noexcept;
    constexpr const_reverse_iterator rbegin() const noexcept;
    constexpr reverse_iterator rend() noexcept;
    constexpr const_reverse_iterator rend() const noexcept;
    constexpr const_iterator cbegin() const noexcept;
    constexpr const_iterator cend() const noexcept;
    constexpr const_reverse_iterator crbegin() const noexcept;
    constexpr const_reverse_iterator crend() const noexcept;

    // capacity
    [[nodiscard]] constexpr bool empty() const noexcept;
    constexpr size_type size() const noexcept;
    constexpr size_type max_size() const noexcept;

    // element access
    constexpr reference operator[](size_type n);
    constexpr const_reference operator[](size_type n) const;
    constexpr reference at(size_type n);
    constexpr const_reference at(size_type n) const;
    constexpr reference front();
    constexpr const_reference front() const;
    constexpr reference back();
    constexpr const_reference back() const;
    
    constexpr T* data() noexcept;
    constexpr const T* data() const noexcept;
  };

  template<class T, class... U>
  array(T, U...) -> array<T, 1 + sizeof...(U)>;
};

§ 21.3.7.1
21.3.7.2 Constructors, copy, and assignment  [array.cons]

The conditions for an aggregate (9.3.1) shall be met. Class array relies on the implicitly-declared special member functions (10.3.4, 10.3.7, and 10.3.5) to conform to the container requirements table in 21.2. In addition to the requirements specified in the container requirements table, the implicit move constructor and move assignment operator for array require that T be Cpp17MoveConstructible or Cpp17MoveAssignable, respectively.

```cpp
template<class T, class... U>
array(T, U...) -> array<T, 1 + sizeof...(U)>;
```

Requires: (is_same_v<T, U> && ...) is true. Otherwise the program is ill-formed.

21.3.7.3 Member functions  [array.members]

```cpp
constexpr size_type size() const noexcept;

constexpr T* data() noexcept;
constexpr const T* data() const noexcept;
```

Returns: A pointer such that [data(), data() + size()) is a valid range. For a non-empty array, data() == addressof(front()).

void fill(const T& u);

Effects: As if by fill_n(begin(), N, u).

void swap(array& y) noexcept(is_nothrow_swappable_v<T>);

Effects: Equivalent to swap_ranges(begin(), end(), y.begin()).

[Note: Unlike the swap function for other containers, array::swap takes linear time, may exit via an exception, and does not cause iterators to become associated with the other container. —end note]

21.3.7.4 Specialized algorithms  [array.special]

```cpp
template<class T, size_t N>
void swap(array<T, N>& x, array<T, N>& y) noexcept(noexcept(x.swap(y)));
```

Remarks: This function shall not participate in overload resolution unless N == 0 or is_swappable_v<T> is true.

Effects: As if by x.swap(y).

Complexity: Linear in N.

21.3.7.5 Zero-sized arrays  [array.zero]

array shall provide support for the special case N == 0.

In the case that N == 0, begin() == end() == unique value. The return value of data() is unspecified.

The effect of calling front() or back() for a zero-sized array is undefined.

Member function swap() shall have a non-throwing exception specification.

21.3.7.6 Tuple interface  [array.tuple]

```cpp
template<class T, size_t N>
struct tuple_size<array<T, N>> : integral_constant<size_t, N> { };
```

```cpp
tuple_element<I, array<T, N>>::type
```

Requires: I < N. The program is ill-formed if I is out of bounds.

Value: The type T.

```cpp
template<size_t I, class T, size_t N>
constexpr T& get(array<T, N>&& a) noexcept;
```

```cpp
template<size_t I, class T, size_t N>
constexpr T&& get(array<T, N>&& a) noexcept;
```
template<
    size_t I, class T, size_t N>
constexpr const T& get(const array<T, N>& a) noexcept;

template<
    size_t I, class T, size_t N>
constexpr const T&& get(const array<T, N>&& a) noexcept;

3
Requires: I < N. The program is ill-formed if I is out of bounds.

4
Returns: A reference to the I\textsuperscript{th} element of a, where indexing is zero-based.

21.3.8 Class template deque [deque]
21.3.8.1 Overview [deque.overview]
1
A deque is a sequence container that supports random access iterators (22.2.7). In addition, it supports
constant time insert and erase operations at the beginning or the end; insert and erase in the middle take
linear time. That is, a deque is especially optimized for pushing and popping elements at the beginning and
end. Storage management is handled automatically.

2
A deque satisfies all of the requirements of a container, of a reversible container (given in tables in 21.2), of
a sequence container, including the optional sequence container requirements (21.2.3), and of an allocator-aware
container (Table 67). Descriptions are provided here only for operations on deque that are not described in
one of these tables or for operations where there is additional semantic information.

namespace std {
  template<class T, class Allocator = allocator<T>>
  class deque {
    public:
      // types
      using value_type = T;
      using allocator_type = Allocator;
      using pointer = typename allocator_traits<Allocator>::pointer;
      using const_pointer = typename allocator_traits<Allocator>::const_pointer;
      using reference = value_type&;
      using const_reference = const value_type&;
      using size_type = implementation-defined; // see 21.2
      using difference_type = implementation-defined; // see 21.2
      using iterator = implementation-defined; // see 21.2
      using const_iterator = implementation-defined; // see 21.2
      using reverse_iterator = std::reverse_iterator<iterator>;
      using const_reverse_iterator = std::reverse_iterator<const_iterator>;

      // 21.3.8.2, construct/copy/destroy
      deque() : deque(Allocator()) { }
      explicit deque(const Allocator&);
      explicit deque(size_type n, const Allocator& = Allocator());
      deque(size_type n, const T& value, const Allocator& = Allocator());
      template<class InputIterator>
      deque(InputIterator first, InputIterator last, const Allocator& = Allocator());
      deque(const deque& x);
      deque(deque&&);
      deque(const deque&, const Allocator&);
      deque(deque&, const Allocator&);
      deque(initializer_list<T>, const Allocator& = Allocator());

      ~deque();
      deque& operator=(const deque& x);
      deque& operator=(deque& x)
        noexcept(allocation_traits<Allocator>::is_always_equal::value);
      deque& operator=(initializer_list<T>);
      template<class InputIterator>
      void assign(InputIterator first, InputIterator last);
      void assign(size_type n, const T& t);
      void assign(initializer_list<T>);
      allocator_type get_allocator() const noexcept;

      // iterators
      iterator begin() noexcept;
const_iterator begin() const noexcept;
iterator end() noexcept;
const_iterator end() const noexcept;
reverse_iterator rbegin() noexcept;
const_reverse_iterator rbegin() const noexcept;
reverse_iterator rend() noexcept;
const_reverse_iterator rend() const noexcept;

const_iterator cbegin() const noexcept;
const_iterator cend() const noexcept;
const_reverse_iterator crbegin() const noexcept;
const_reverse_iterator crend() const noexcept;

// 21.3.8.3, capacity
[[nodiscard]] bool empty() const noexcept;
size_type size() const noexcept;
size_type max_size() const noexcept;
void resize(size_type sz);
void resize(size_type sz, const T& c);
void shrink_to_fit();

// element access
reference operator[](size_type n);
const_reference operator[](size_type n) const;
reference at(size_type n);
const_reference at(size_type n) const;
reference front();
const_reference front() const;
reference back();
const_reference back() const;

// 21.3.8.4, modifiers
template<class... Args> reference emplace_front(Args&&... args);
template<class... Args> reference emplace_back(Args&&... args);
template<class... Args> iterator emplace(const_iterator position, Args&&... args);  
void push_front(const T& x);
void push_front(T&& x);
void push_back(const T& x);
void push_back(T&& x);

iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
iterator insert(const_iterator position, InputIterator first, InputIterator last);
iterator insert(const_iterator position, initializer_list<T>);
void pop_front();
void pop_back();

iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);
void swap(deque&) noexcept(allocator_traits<Allocator>::is_always_equal::value);
void clear() noexcept;
};

template<class InputIterator, class Allocator = allocator<iter_value_type<InputIterator>>>
deque(InputIterator, InputIterator, Allocator = Allocator())
-> deque<iter_value_type<InputIterator>, Allocator>;

§ 21.3.8.1 765
template<class T, class Allocator>
void swap(deque<T, Allocator>& x, deque<T, Allocator>& y)
    noexcept(noexcept(x.swap(y)));
}

21.3.8.2 Constructors, copy, and assignment [deque.cons]

explicit deque(const Allocator&);
    Effects: Constructs an empty deque, using the specified allocator.
    Complexity: Constant.

explicit deque(size_type n, const Allocator& = Allocator());
    Effects: Constructs a deque with n default-inserted elements using the specified allocator.
    Requires: T shall be Cpp17DefaultInsertable into *this.
    Complexity: Linear in n.

dele(size_type n, const T& value, const Allocator& = Allocator());
    Effects: Constructs a deque with n copies of value, using the specified allocator.
    Requires: T shall be Cpp17CopyInsertable into *this.
    Complexity: Linear in n.

template<class InputIterator>
dele(InputIterator first, InputIterator last, const Allocator& = Allocator());
    Effects: Constructs a deque equal to the range [first, last), using the specified allocator.
    Complexity: Linear in distance(first, last).

21.3.8.3 Capacity [deque.capacity]

void resize(size_type sz);
    Effects: If sz < size(), erases the last size() - sz elements from the sequence. Otherwise, appends sz - size() default-inserted elements to the sequence.
    Requires: T shall be Cpp17MoveInsertable and Cpp17DefaultInsertable into *this.

void resize(size_type sz, const T& c);
    Effects: If sz < size(), erases the last size() - sz elements from the sequence. Otherwise, appends sz - size() copies of c to the sequence.
    Requires: T shall be Cpp17CopyInsertable into *this.

void shrink_to_fit();
    Requires: T shall be Cpp17MoveInsertable into *this.
    Effects: shrink_to_fit is a non-binding request to reduce memory use but does not change the size of the sequence. [Note: The request is non-binding to allow latitude for implementation-specific optimizations. —end note] If an exception is thrown other than by the move constructor of a non-Cpp17CopyInsertable T there are no effects.
    Complexity: Linear in the size of the sequence.
    Remarks: shrink_to_fit invalidates all the references, pointers, and iterators referring to the elements in the sequence as well as the past-the-end iterator.

21.3.8.4 Modifiers [deque.modifiers]

iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
    iterator insert(const_iterator position,
    InputIterator first, InputIterator last);

§ 21.3.8.4 766
iterator insert(const_iterator position, initializer_list<T>);

template<class... Args> reference emplace_front(Args&&... args);
template<class... Args> reference emplace_back(Args&&... args);
template<class... Args> iterator emplace(const_iterator position, Args&&... args);
void push_front(const T& x);
void push_front(T&& x);
void push_back(const T& x);
void push_back(T&& x);

1 Effects: An insertion in the middle of the deque invalidates all the iterators and references to elements of the deque. An insertion at either end of the deque invalidates all the iterators to the deque, but has no effect on the validity of references to elements of the deque.

2 Remarks: If an exception is thrown other than by the copy constructor, move constructor, assignment operator, or move assignment operator of T there are no effects. If an exception is thrown while inserting a single element at either end, there are no effects. Otherwise, if an exception is thrown by the move constructor of a non-Cpp17CopyInsertable T, the effects are unspecified.

3 Complexity: The complexity is linear in the number of elements inserted plus the lesser of the distances to the beginning and end of the deque. Inserting a single element either at the beginning or end of a deque always takes constant time and causes a single call to a constructor of T.

iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);
void pop_front();
void pop_back();

4 Effects: An erase operation that erases the last element of a deque invalidates only the past-the-end iterator and all iterators and references to the erased elements. An erase operation that erases the first element of a deque but not the last element invalidates only iterators and references to the erased elements. An erase operation that erases neither the first element nor the last element of a deque invalidates the past-the-end iterator and all iterators and references to all the elements of the deque. [Note: pop_front and pop_back are erase operations. — end note]

5 Complexity: The number of calls to the destructor of T is the same as the number of elements erased, but the number of calls to the assignment operator of T is no more than the lesser of the number of elements before the erased elements and the number of elements after the erased elements.

6 Throws: Nothing unless an exception is thrown by the assignment operator of T.

21.3.9 Class template forward_list [forwardlist]

21.3.9.1 Overview [forwardlist.overview]

1 A forward_list is a container that supports forward iterators and allows constant time insert and erase operations anywhere within the sequence, with storage management handled automatically. Fast random access to list elements is not supported. [Note: It is intended that forward_list have zero space or time overhead relative to a hand-written C-style singly linked list. Features that would conflict with that goal have been omitted. — end note]

2 A forward_list satisfies all of the requirements of a container (Table 64), except that the size() member function is not provided and operator== has linear complexity. A forward_list also satisfies all of the requirements for an allocator-aware container (Table 67). In addition, a forward_list provides the assign member functions (Table 68) and several of the optional container requirements (Table 69). Descriptions are provided here only for operations on forward_list that are not described in that table or for operations where there is additional semantic information.

3 [Note: Modifying any list requires access to the element preceding the first element of interest, but in a forward_list there is no constant-time way to access a preceding element. For this reason, ranges that are modified, such as those supplied to erase and splice, must be open at the beginning. — end note]
using allocator_type = Allocator;
using pointer = typename allocator_traits<Allocator>::pointer;
using const_pointer = typename allocator_traits<Allocator>::const_pointer;
using reference = value_type&;
using const_reference = const value_type&;
using size_type = implementation-defined; // see 21.2
using difference_type = implementation-defined; // see 21.2
using iterator = implementation-defined; // see 21.2
using const_iterator = implementation-defined; // see 21.2

// 21.3.9.2, construct/copy/destroy
forward_list() : forward_list(Allocator()) { }
explicit forward_list(const Allocator&);
explicit forward_list(size_type n, const Allocator& = Allocator());
forward_list(size_type n, const T& value, const Allocator& = Allocator());
template<class InputIterator>
  forward_list(InputIterator first, InputIterator last, const Allocator& = Allocator());

forward_list(const forward_list& x);
forward_list(forward_list&& x, const Allocator&);
forward_list(const forward_list& x, const Allocator&);
forward_list(initializer_list<T>, const Allocator& = Allocator());
~forward_list();
forward_list& operator=(const forward_list& x);
forward_list& operator=(forward_list&& x)
  noexcept(allocator_traits<Allocator>::is_always_equal::value);
forward_list& operator=(initializer_list<T>);
template<class InputIterator>
  void assign(InputIterator first, InputIterator last);
void assign(size_type n, const T& t);
void assign(initializer_list<T>);
allocator_type get_allocator() const noexcept;

// 21.3.9.3, iterators
iterator before_begin() noexcept;
const_iterator before_begin() const noexcept;
iterator begin() noexcept;
const_iterator begin() const noexcept;
iterator end() noexcept;
const_iterator end() const noexcept;
const_iterator cbegin() const noexcept;
const_iterator cbefore_begin() const noexcept;
const_iterator cend() const noexcept;

// capacity
[[nodiscard]] bool empty() const noexcept;
size_type max_size() const noexcept;

// 21.3.9.4, element access
reference front();
const_reference front() const;

// 21.3.9.5, modifiers
template<class... Args> reference emplace_front(Args&&... args);
void push_front(const T& x);
void push_front(T&& x);
void pop_front();
template<class... Args> iterator emplace_after(const_iterator position, Args&&... args);
iterator insert_after(const_iterator position, const T& x);
iterator insert_after(const_iterator position, T&& x);
iterator insert_after(const_iterator position, size_type n, const T& x);

template<class InputIterator>
iterator insert_after(const_iterator position, InputIterator first, InputIterator last);

iterator insert_after(const_iterator position, initializer_list<T> il);

iterator erase_after(const_iterator position);

iterator erase_after(const_iterator position, const_iterator last);

void swap(forward_list&)
   noexcept(allocation_traits<Allocator>::is_always_equal::value);

void resize(size_type sz);
void resize(size_type sz, const value_type& c);
void clear() noexcept;

// 21.3.9.6, forward_list operations
void splice_after(const_iterator position, forward_list& x);
void splice_after(const_iterator position, forward_list&& x);
void splice_after(const_iterator position, forward_list& x, const_iterator i);
void splice_after(const_iterator position, forward_list&& x, const_iterator i);
void splice_after(const_iterator position, forward_list& x,
                   const_iterator first, const_iterator last);
void splice_after(const_iterator position, forward_list&& x,
                   const_iterator first, const_iterator last);

size_type remove(const T& value);

template<class Predicate> size_type remove_if(Predicate pred);

size_type unique();

template<class BinaryPredicate> size_type unique(BinaryPredicate binary_pred);

void merge(forward_list& x);
void merge(forward_list&& x);

template<class Compare> void merge(forward_list& x, Compare comp);

void sort();

template<class Compare> void sort(Compare comp);

void reverse() noexcept;

};

template<class InputIterator, class Allocator = allocator<
   iter-value-type<InputIterator>>>
forward_list(InputIterator, InputIterator, Allocator = Allocator())
   -> forward_list<iter-value-type<InputIterator>>, Allocator>;

// swap
template<class T, class Allocator>
void swap(forward_list<T, Allocator>& x, forward_list<T, Allocator>& y)
   noexcept(noexcept(x.swap(y)));

An incomplete type T may be used when instantiating forward_list if the allocator satisfies the allocator completeness requirements (15.5.3.5.1). T shall be complete before any member of the resulting specialization of forward_list is referenced.

21.3.9.2 Constructors, copy, and assignment [forwardlist.cons]

explicit forward_list(const Allocator&);

   Effects: Constructs an empty forward_list object using the specified allocator.

   Complexity: Constant.

explicit forward_list(size_type n, const Allocator& = Allocator());

   Effects: Constructs a forward_list object with n default-inserted elements using the specified allocator.
Requires: $T$ shall be `Cpp17DefaultInsertable` into `*this`.

Complexity: Linear in $n$.

```cpp
forward_list(size_type n, const T& value, const Allocator& = Allocator());
```

Effects: Constructs a `forward_list` object with $n$ copies of `value` using the specified allocator.

Requires: $T$ shall be `Cpp17CopyInsertable` into `*this`.

Complexity: Linear in $n$.

```cpp
template<class InputIterator>
forward_list(InputIterator first, InputIterator last, const Allocator& = Allocator());
```

Effects: Constructs a `forward_list` object equal to the range `[first, last)`.

Complexity: Linear in `distance(first, last)`.

21.3.9.3 Iterators

```cpp
iterator before_begin() noexcept;
const_iterator before_begin() const noexcept;
const_iterator cbefore_begin() const noexcept;
```

Returns: A non-dereferenceable iterator that, when incremented, is equal to the iterator returned by `begin()`.

Effects: `cbefore_begin()` is equivalent to `const_cast<forward_list const&>(*this).before_begin()`.

Remarks: `before_begin()` == `end()` shall equal `false`.

21.3.9.4 Element access

```cpp
reference front();
const_reference front() const;
```

Returns: `*begin()`.

21.3.9.5 Modifiers

None of the overloads of `insert_after` shall affect the validity of iterators and references, and `erase_after` shall invalidate only iterators and references to the erased elements. If an exception is thrown during `insert_after` there shall be no effect. Inserting $n$ elements into a `forward_list` is linear in $n$, and the number of calls to the copy or move constructor of $T$ is exactly equal to $n$. Erasing $n$ elements from a `forward_list` is linear in $n$ and the number of calls to the destructor of type $T$ is exactly equal to $n$.

```cpp
template<class... Args> reference emplace_front(Args&&... args);
```

Effects: Inserts an object of type `value_type` constructed with `value_type(std::forward<Args>(args)...)` at the beginning of the list.

```cpp
void push_front(const T& x);
void push_front(T&& x);
```

Effects: Inserts a copy of $x$ at the beginning of the list.

```cpp
void pop_front();
```

Effects: As if by `erase_after(before_begin())`.

```cpp
iterator insert_after(const_iterator position, const T& x);
iterator insert_after(const_iterator position, T&& x);
```

Requires: `position` is `before_begin()` or is a dereferenceable iterator in the range `[begin(), end())`.

Effects: Inserts a copy of $x$ after `position`.

Returns: An iterator pointing to the copy of $x$.

```cpp
iterator insert_after(const_iterator position, size_type n, const T& x);
```

Requires: `position` is `before_begin()` or is a dereferenceable iterator in the range `[begin(), end())`.

Effects: Inserts $n$ copies of $x$ after `position`. 

§ 21.3.9.5
Returns: An iterator pointing to the last inserted copy of \( x \) or \( \text{position} \) if \( n == 0 \).

```cpp
template<class InputIterator>
iterator insert_after(const_iterator position, InputIterator first, InputIterator last);
```

Requires: \( \text{position} \) is \( \text{before\_begin}() \) or is a dereferenceable iterator in the range \([\text{begin}(), \text{end}())\). \( \text{first} \) and \( \text{last} \) are not iterators in \( \ast \text{this} \).

Effects: Inserts copies of elements in \([\text{first}, \text{last})\) after \( \text{position} \).

Returns: An iterator pointing to the last inserted element or \( \text{position} \) if \( \text{first} == \text{last} \).

```cpp
iterator insert_after(const_iterator position, initializer_list<T> il);
```

Effects: \( \text{insert\_after}(p, \text{il.begin}(), \text{il.end}()) \).

Returns: An iterator pointing to the last inserted element or \( \text{position} \) if \( \text{il} \) is empty.

```cpp
template<class... Args>
iterator emplace_after(const_iterator position, Args&&... args);
```

Requires: \( \text{position} \) is \( \text{before\_begin}() \) or is a dereferenceable iterator in the range \([\text{begin}(), \text{end}())\).

Effects: Inserts an object of type \( \text{value\_type} \) constructed with \( \text{value\_type}(/\ast \text{forward<Args>}(\text{args})\ldots) \) after \( \text{position} \).

Returns: An iterator pointing to the new object.

```cpp
iterator erase_after(const_iterator position);
```

Requires: The iterator following \( \text{position} \) is dereferenceable.

Effects: Erases the element pointed to by the iterator following \( \text{position} \).

Returns: An iterator pointing to the element following the one that was erased, or \( \text{end}() \) if no such element exists.

Throws: Nothing.

```cpp
iterator erase_after(const_iterator position, const_iterator last);
```

Requires: All iterators in the range \((\text{position}, \text{last})\) are dereferenceable.

Effects: Erases the elements in the range \((\text{position}, \text{last})\).

Returns: \( \text{last} \).

Throws: Nothing.

```cpp
void resize(size_type sz);
```

Effects: If \( sz < \text{distance}((\text{begin}(), \text{end}())) \), erases the last \( \text{distance}((\text{begin}(), \text{end}())) - sz \) elements from the list. Otherwise, inserts \( sz - \text{distance}((\text{begin}(), \text{end}())) \) default-inserted elements at the end of the list.

Requires: \( T \) shall be \( \text{Cpp17DefaultInsertable} \) into \( \ast \text{this} \).

```cpp
void resize(size_type sz, const value_type& c);
```

Effects: If \( sz < \text{distance}((\text{begin}(), \text{end}())) \), erases the last \( \text{distance}((\text{begin}(), \text{end}())) - sz \) elements from the list. Otherwise, inserts \( sz - \text{distance}((\text{begin}(), \text{end}())) \) copies of \( c \) at the end of the list.

Requires: \( T \) shall be \( \text{Cpp17CopyInsertable} \) into \( \ast \text{this} \).

```cpp
void clear() noexcept;
```

Effects: Erases all elements in the range \((\text{begin}(), \text{end}())\).

Remarks: Does not invalidate past-the-end iterators.

### 21.3.9.6 Operations

In this subclause, arguments for a template parameter named \( \text{Predicate} \) or \( \text{BinaryPredicate} \) shall satisfy the corresponding requirements in 23.2. For \( \text{merge} \) and \( \text{sort} \), the definitions and requirements in 23.7 apply.
void splice_after(const_iterator position, forward_list&& x);

Requires: position is before_begin() or is a dereferenceable iterator in the range [begin(), end()).
get_allocator() == x.get_allocator(). addressof(x) != this.

Effects: Inserts the contents of x after position, and x becomes empty. Pointers and references to the
moved elements of x now refer to those same elements but as members of *this. Iterators referring
to the moved elements will continue to refer to their elements, but they now behave as iterators into
*this, not into x.

Throws: Nothing.

Complexity: $O(distance(x.begin(), x.end()))$

void splice_after(const_iterator position, forward_list& x, const_iterator i);
void splice_after(const_iterator position, forward_list&& x, const_iterator i);

Requires: position is before_begin() or is a dereferenceable iterator in the range [begin(), end()).
The iterator following i is a dereferenceable iterator in x. get_allocator() == x.get_allocator().

Effects: Inserts the element following i into *this, following position, and removes it from x. The
result is unchanged if position == i or position == ++i. Pointers and references to ++i continue
to refer to the same element but as a member of *this. Iterators to +++i continue to refer to the same
element, but now behave as iterators into *this, not into x.

Throws: Nothing.

Complexity: $O(1)$

void splice_after(const_iterator position, forward_list& x,
const_iterator first, const_iterator last);
void splice_after(const_iterator position, forward_list&& x,
const_iterator first, const_iterator last);

Requires: position is before_begin() or is a dereferenceable iterator in the range [begin(), end()).
(first, last) is a valid range in x, and all iterators in the range (first, last) are dereferenceable.
position is not an iterator in the range (first, last). get_allocator() == x.get_allocator().

Effects: Inserts elements in the range (first, last) after position and removes the elements from x.
Pointers and references to the moved elements of x now refer to those same elements but as members of
*this. Iterators referring to the moved elements will continue to refer to their elements, but they
now behave as iterators into *this, not into x.

Complexity: $O(distance(first, last))$

size_type remove(const T& value);
template<class Predicate> size_type remove_if(Predicate pred);

Effects: Erases all the elements in the list referred to by a list iterator i for which the following
conditions hold: *i == value (for remove()), pred(*i) is true (for remove_if()). Invalidates only
the iterators and references to the erased elements.

Returns: The number of elements erased.

Throws: Nothing unless an exception is thrown by the equality comparison or the predicate.

Remarks: Stable (15.5.5.7).

Complexity: Exactly distance(begin(), end()) applications of the corresponding predicate.

size_type unique();
template<class BinaryPredicate> size_type unique(BinaryPredicate pred);

Effects: Erases all but the first element from every consecutive group of equal elements referred to
by the iterator i in the range [first + 1, last) for which *i == *(i-1) (for the version with no
arguments) or pred(*i, *(i - 1)) (for the version with a predicate argument) holds. Invalidates
only the iterators and references to the erased elements.

Returns: The number of elements erased.

Throws: Nothing unless an exception is thrown by the equality comparison or the predicate.
Complexity: If the range \([\text{first}, \text{last})\) is not empty, exactly \((\text{last} - \text{first}) - 1\) applications of the corresponding predicate, otherwise no applications of the predicate.

```c++
void merge(forward_list& x);
void merge(forward_list&& x);
template<class Compare> void merge(forward_list& x, Compare comp);
template<class Compare> void merge(forward_list&& x, Compare comp);
```

Requires: \(*this\) and \(x\) are both sorted with respect to the comparator \(\text{operator}<\) (for the first two overloads) or \(\text{comp}\) (for the last two overloads), and \(\text{get_allocator}() == x.\text{get_allocator}()\) is true.

Effects: Merges the two sorted ranges \([\text{begin()}, \text{end}())\) and \([x.\text{begin}(), x.\text{end}())\). \(x\) is empty after the merge. If an exception is thrown other than by a comparison there are no effects. Pointers and references to the moved elements of \(x\) now refer to those same elements but as members of \(*this\). Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into \(*this\), not into \(x\).

Remarks: Stable (15.5.5.7). The behavior is undefined if \(\text{get_allocator}() != x.\text{get_allocator}()\).

Complexity: At most \(\text{distance}(<\text{begin}(), \text{end}()) + \text{distance}(x.\text{begin}(), x.\text{end}()) - 1\) comparisons.

```c++
void sort();
template<class Compare> void sort(Compare comp);
```

Effects: Sorts the list according to the \(\text{operator}<\) or the \(\text{comp}\) function object. If an exception is thrown, the order of the elements in \(*this\) is unspecified. Does not affect the validity of iterators and references.

Remarks: Stable (15.5.5.7).

Complexity: Approximately \(N \log N\) comparisons, where \(N\) is \(\text{distance}(<\text{begin}(), \text{end}())\).

```c++
void reverse() noexcept;
```

Effects: Reverses the order of the elements in the list. Does not affect the validity of iterators and references.

Complexity: Linear time.

## 21.3.10 Class template list

### 21.3.10.1 Overview

A list is a sequence container that supports bidirectional iterators and allows constant time insert and erase operations anywhere within the sequence, with storage management handled automatically. Unlike vectors (21.3.11) and deques (21.3.8), fast random access to list elements is not supported, but many algorithms only need sequential access anyway.

A list satisfies all of the requirements of a container, of a reversible container (given in two tables in 21.2), of a sequence container, including most of the optional sequence container requirements (21.2.3), and of an allocator-aware container (Table 67). The exceptions are the \(\text{operator}[]\) and \(\text{at}\) member functions, which are not provided.\(^{232}\) Descriptions are provided here only for operations on list that are not described in one of these tables or for operations where there is additional semantic information.

```c++
namespace std {
    template<class T, class Allocator = allocator<T>>
    class list {
        public:
            // types
            using value_type = T;
            using allocator_type = Allocator;
            using pointer = typename allocator_traits<Allocator>::pointer;
            using const_pointer = typename allocator_traits<Allocator>::const_pointer;
            using reference = value_type&;
            using const_reference = const value_type&;
            using size_type = implementation-defined; // see 21.2
            using difference_type = implementation-defined; // see 21.2
```
using iterator = implementation-defined; // see 21.2
using const_iterator = implementation-defined; // see 21.2
using reverse_iterator = std::reverse_iterator<iterator>;
using const_reverse_iterator = std::reverse_iterator<const_iterator>;

// 21.3.10.2, construct/copy/destroy
list() : list(Allocator()) {} explicit list(const Allocator&);
explicit list(size_type n, const Allocator& = Allocator());
list(initializer_list<T>, const Allocator& = Allocator());
template<class InputIterator>
list(InputIterator first, InputIterator last, const Allocator& = Allocator());
list(const list&, const Allocator&);
list(list&& x);
list(const list&, const Allocator&); list(list&&, const Allocator&);
list(initializer_list<T>, const Allocator& = Allocator());
~list(); list& operator=(const list& x);
list& operator=(list&& x) noexcept;
noexcept(allocator_traits<Allocator>::is_always_equal::value);
list& operator=(initializer_list<T>);
template<class InputIterator>
void assign(InputIterator first, InputIterator last);
void assign(size_type n, const T& t);
void assign(initializer_list<T>);
allocator_type get_allocator() const noexcept;

// iterators
iterator begin() noexcept;
const_iterator begin() const noexcept;
iterator end() noexcept;
const_iterator end() const noexcept;
reverse_iterator rbegin() noexcept;
const_reverse_iterator rbegin() const noexcept;
reverse_iterator rend() noexcept;
const_reverse_iterator rend() const noexcept;
const_iterator cbegin() const noexcept;
const_iterator cend() const noexcept;
const_reverse_iterator crbegin() const noexcept;
const_reverse_iterator crend() const noexcept;

// 21.3.10.3, capacity
[[nodiscard]] bool empty() const noexcept;
size_type size() const noexcept;
size_type max_size() const noexcept;
void resize(size_type sz);
void resize(size_type sz, const T& c);

// element access
reference front();
const_reference front() const;
reference back();
const_reference back() const;

// 21.3.10.4, modifiers
template<class... Args> reference emplace_front(Args&&... args);
template<class... Args> reference emplace_back(Args&&... args);
void push_front(const T& x);
void push_front(T&& x);
void pop_front();
void push_back(const T& x);
void push_back(T&& x);
void pop_back();

template<class... Args> iterator emplace(const_iterator position, Args&&... args);
iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);

template<class InputIterator>
iterator insert(const_iterator position, InputIterator first, InputIterator last);
iterator insert(const_iterator position, initializer_list<T> il);

iterator erase(const_iterator position);
iterator erase(const_iterator position, const_iterator last);

void swap(list&) noexcept(allocator_traits<Allocator>::is_always_equal::value);
void clear() noexcept;

// 21.3.10.5, list operations
void splice(const_iterator position, list& x);
void splice(const_iterator position, list&& x);
void splice(const_iterator position, list& x, const_iterator i);
void splice(const_iterator position, list&& x, const_iterator i);
void splice(const_iterator position, list& x, const_iterator first, const_iterator last);
void splice(const_iterator position, list&& x, const_iterator first, const_iterator last);

size_type remove(const T& value);
template<class Predicate> size_type remove_if(Predicate pred);

size_type unique();
template<class BinaryPredicate>
size_type unique(BinaryPredicate binary_pred);

void merge(list& x);
void merge(list&& x);

template<class Compare>
void merge(list& x, Compare comp);

size_type unique();
template<class BinaryPredicate>
size_type unique(BinaryPredicate binary_pred);

void merge(list& x);

void sort();

void reverse() noexcept;

};

template<class InputIterator, class Allocator = allocator<iter-value-type<InputIterator>>> list(InputIterator, InputIterator, Allocator = Allocator())
-> list<iter-value-type<InputIterator>, Allocator>;

// swap

template<class T, class Allocator>

void swap(list<T, Allocator>& x, list<T, Allocator>& y)
noexcept(noexcept(x.swap(y)));

An incomplete type T may be used when instantiating list if the allocator satisfies the allocator completeness requirements (15.5.3.5.1). T shall be complete before any member of the resulting specialization of list is referenced.

21.3.10.2 Constructors, copy, and assignment

explicit list(const Allocator&);

Effects: Constructs an empty list, using the specified allocator.

Complexity: Constant.

explicit list(size_type n, const Allocator& = Allocator());

Effects: Constructs a list with n default-inserted elements using the specified allocator.
4  Requires: T shall be Cpp17DefaultInsertable into *this.
5  Complexity: Linear in n.

list(size_type n, const T& value, const Allocator& = Allocator());

6  Effects: Constructs a list with n copies of value, using the specified allocator.
7  Requires: T shall be Cpp17CopyInsertable into *this.
8  Complexity: Linear in n.

template<class InputIterator>
list(InputIterator first, InputIterator last, const Allocator& = Allocator());

9  Effects: Constructs a list equal to the range [first, last).
10  Complexity: Linear in distance(first, last).

21.3.10.3 Capacity

void resize(size_type sz);

1  Effects: If size() < sz, appends sz - size() default-inserted elements to the sequence. If sz <=
size(), equivalent to:
   list<T>::iterator it = begin();
   advance(it, sz);
   erase(it, end());
2  Requires: T shall be Cpp17DefaultInsertable into *this.

void resize(size_type sz, const T& c);

3  Effects: As if by:
   if (sz > size())
      insert(end(), sz-size(), c);
   else if (sz < size()) {
      iterator i = begin();
      advance(i, sz);
      erase(i, end());
   } else
   // do nothing
4  Requires: T shall be Cpp17CopyInsertable into *this.

21.3.10.4 Modifiers

iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
iterator insert(const_iterator position, InputIterator first,
   InputIterator last);
iterator insert(const_iterator position, initializer_list<T>);
template<class... Args> reference emplace_front(Args&&... args);
template<class... Args> reference emplace_back(Args&&... args);
template<class... Args> iterator emplace(const_iterator position, Args&&... args);
void push_front(const T& x);
void push_front(T&& x);
void push_back(const T& x);
void push_back(T&& x);

1  Remarks: Does not affect the validity of iterators and references. If an exception is thrown there are no
effects.

2  Complexity: Insertion of a single element into a list takes constant time and exactly one call to a
constructor of T. Insertion of multiple elements into a list is linear in the number of elements inserted,
and the number of calls to the copy constructor or move constructor of \( T \) is exactly equal to the number of elements inserted.

```
iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);
```

```
void pop_front();
void pop_back();
void clear() noexcept;
```

**Effects:** Invalidates only the iterators and references to the erased elements.

**Throws:** Nothing.

**Complexity:** Erasing a single element is a constant time operation with a single call to the destructor of \( T \). Erasing a range in a list is linear time in the size of the range and the number of calls to the destructor of type \( T \) is exactly equal to the size of the range.

### 21.3.10.5 Operations

Since lists allow fast insertion and erasing from the middle of a list, certain operations are provided specifically for them.\(^{233}\) In this subclause, arguments for a template parameter named `Predicate` or `BinaryPredicate` shall satisfy the corresponding requirements in 23.2. For `merge` and `sort`, the definitions and requirements in 23.7 apply.

`list` provides three splice operations that destructively move elements from one list to another. The behavior of splice operations is undeﬁned if `get_allocator()` \(!= x.get_allocator()\).

```
void splice(const_iterator position, list& x);
void splice(const_iterator position, list&& x);
```

**Requires:** `addressof(x) != this`.

**Effects:** Inserts the contents of \( x \) before `position` and \( x \) becomes empty. Pointers and references to the moved elements of \( x \) now refer to those same elements but as members of `*this`. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into `*this`, not into \( x \).

**Throws:** Nothing.

**Complexity:** Constant time.

```
void splice(const_iterator position, list& x, const_iterator i);
void splice(const_iterator position, list&& x, const_iterator i);
```

**Requires:** `i` is a valid dereferenceable iterator of \( x \).

**Effects:** Inserts an element pointed to by `i` from list \( x \) before `position` and removes the element from \( x \). The result is unchanged if `position == i` or `position == ++i`. Pointers and references to `*i` continue to refer to this same element but as a member of `*this`. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into `*this`, not into \( x \).

**Throws:** Nothing.

**Complexity:** Constant time.

```
void splice(const_iterator position, list& x, const_iterator first, const_iterator last);
void splice(const_iterator position, list&& x, const_iterator first, const_iterator last);
```

**Requires:** \([first, last)\) is a valid range in \( x \). The program has undeﬁned behavior if `position` is an iterator in the range \([first, last)\).

**Effects:** Inserts elements in the range \([first, last)\) before `position` and removes the elements from \( x \). Pointers and references to the moved elements of \( x \) now refer to those same elements but as members of `*this`. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into `*this`, not into \( x \).

**Throws:** Nothing.

\(^{233}\) As specified in 15.5.3.5, the requirements in this Clause apply only to lists whose allocators compare equal.
**Complexity:** Constant time if &x == this; otherwise, linear time.

```cpp
size_type remove(const T& value);
template<class Predicate> size_type remove_if(Predicate pred);
```

**Effects:** Erases all the elements in the list referred to by a list iterator i for which the following conditions hold: *i == value, pred(*i) != false. Invalidates only the iterators and references to the erased elements.

**Returns:** The number of elements erased.

**Throws:** Nothing unless an exception is thrown by *i == value or pred(*i) != false.

**Remarks:** Stable (15.5.5.7).

**Complexity:** Exactly size() applications of the corresponding predicate.

```cpp
size_type unique();
template<class BinaryPredicate> size_type unique(BinaryPredicate binary_pred);
```

**Effects:** Erases all but the first element from every consecutive group of equal elements referred to by the iterator i in the range [first + 1, last) for which *i == *(i - 1) (for the version of unique with no arguments) or pred(*i, *(i - 1)) (for the version of unique with a predicate argument) holds. Invalidates only the iterators and references to the erased elements.

**Returns:** The number of elements erased.

**Throws:** Nothing unless an exception is thrown by *i == *(i - 1) or pred(*i, *(i - 1))

**Complexity:** If the range [first, last) is not empty, exactly (last - first) - 1 applications of the corresponding predicate, otherwise no applications of the predicate.

```cpp
void merge(list& x);
void merge(list&& x);
template<class Compare> void merge(list& x, Compare comp);
template<class Compare> void merge(list&& x, Compare comp);
```

**Requires:** Both the list and the argument list shall be sorted with respect to the comparator operator< (for the first two overloads) or comp (for the last two overloads).

**Effects:** If addressof(x) == this, does nothing; otherwise, merges the two sorted ranges [begin(), end()) and [x.begin(), x.end()). The result is a range in which the elements will be sorted in non-decreasing order according to the ordering defined by comp; that is, for every iterator i, in the range other than the first, the condition comp(*i, *(i - 1)) will be false. Pointers and references to the moved elements of x now refer to those same elements but as members of *this. Iterators referring to the moved elements will continue to refer to their elements, but they now behave as iterators into *this, not into x.

**Remarks:** Stable (15.5.5.7). If addressof(x) != this, the range [x.begin(), x.end()) is empty after the merge. No elements are copied by this operation. The behavior is undefined if get_allocator() != x.get_allocator().

**Complexity:** At most size() + x.size() - 1 applications of comp if addressof(x) != this; otherwise, no applications of comp are performed. If an exception is thrown other than by a comparison there are no effects.

```cpp
void reverse() noexcept;
```

**Effects:** Reverses the order of the elements in the list. Does not affect the validity of iterators and references.

**Complexity:** Linear time.

```cpp
void sort();
template<class Compare> void sort(Compare comp);
```

**Effects:** Sorts the list according to the operator< or a Compare function object. If an exception is thrown, the order of the elements in *this is unspecified. Does not affect the validity of iterators and references.

**Remarks:** Stable (15.5.5.7).
Complexity: Approximately $N \log N$ comparisons, where $N = \text{size()}$.

21.3.11 Class template vector

21.3.11.1 Overview

A vector is a sequence container that supports (amortized) constant time insert and erase operations at the end; insert and erase in the middle take linear time. Storage management is handled automatically, though hints can be given to improve efficiency.

A vector satisfies all of the requirements of a container and of a reversible container (given in two tables in 21.2), of a sequence container, including most of the optional sequence container requirements (21.2.3), of an allocator-aware container (Table 67), and, for an element type other than bool, of a contiguous container (21.2.1). The exceptions are the push_front, pop_front, and emplace_front member functions, which are not provided. Descriptions are provided here only for operations on vector that are not described in one of these tables or for operations where there is additional semantic information.

```cpp
namespace std {
    template<class T, class Allocator = allocator<T>>
    class vector {
    public:
        // types
        using value_type = T;
        using allocator_type = Allocator;
        using pointer = typename allocator_traits<Allocator>::pointer;
        using const_pointer = typename allocator_traits<Allocator>::const_pointer;
        using reference = value_type&;
        using const_reference = const value_type&;
        using size_type = implementation-defined; // see 21.2
        using difference_type = implementation-defined; // see 21.2
        using iterator = implementation-defined; // see 21.2
        using const_iterator = implementation-defined; // see 21.2
        using reverse_iterator = std::reverse_iterator<iterator>;
        using const_reverse_iterator = std::reverse_iterator<const_iterator>;

        // 21.3.11.2, construct/copy/destroy
        vector() noexcept(noexcept(Allocator())) : vector(Allocator()) { }
        explicit vector(const Allocator&) noexcept;
        explicit vector(size_type n, const Allocator& = Allocator());
        vector(size_type n, const T& value, const Allocator& = Allocator());
        template<class InputIterator>
        vector(InputIterator first, InputIterator last, const Allocator& = Allocator());
        vector(const vector& x);
        vector(vector&&) noexcept;
        vector(const vector&, const Allocator&);
        vector(vector&&, const Allocator&);
        vector(initializer_list<T>, const Allocator& = Allocator());
        ~vector();
        vector& operator=(const vector& x);
        vector& operator=(vector&& x) noexcept;
        vector& operator=(const vector& x);
        vector& operator=(vector&& x) noexcept;
        noexcept(allocator_traits<Allocator>::propagate_on_container_move_assignment::value ||
            allocator_traits<Allocator>::is_always_equal::value);
        vector& operator=(initializer_list<T>);
        template<class InputIterator>
        void assign(InputIterator first, InputIterator last);
        void assign(size_type n, const T& u);
        void assign(initializer_list<T>);
        allocator_type get_allocator() const noexcept;

        // iterators
        iterator begin() noexcept;
        const_iterator begin() const noexcept;
        iterator end() noexcept;
        const_iterator end() const noexcept;
        reverse_iterator rbegin() noexcept;
    };
```
const_reverse_iterator rbegin() const noexcept;
reverse_iterator rend() noexcept;
const_reverse_iterator rend() const noexcept;

const_iterator cbegin() const noexcept;
const_iterator cend() const noexcept;
const_reverse_iterator crbegin() const noexcept;
const_reverse_iterator crend() const noexcept;

// 21.3.11.3, capacity
[[nodiscard]] bool empty() const noexcept;
size_type size() const noexcept;
size_type max_size() const noexcept;
size_type capacity() const noexcept;
void resize(size_type sz);
void resize(size_type sz, const T& c);
void reserve(size_type n);
void shrink_to_fit();

// element access
reference operator[](size_type n);
const_reference operator[](size_type n) const;
const_reference at(size_type n) const;
reference at(size_type n);
reference front();
const_reference front() const;
reference back();
const_reference back() const;

// 21.3.11.4, data access
T* data() noexcept;
const T* data() const noexcept;

// 21.3.11.5, modifiers
template<class... Args> reference emplace_back(Args&&... args);
void push_back(const T& x);
void push_back(T&& x);
void pop_back();
template<class... Args> iterator emplace(const_iterator position, Args&&... args);
iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
iterator insert(const_iterator position, InputIterator first, InputIterator last);
iterator insert(const_iterator position, initializer_list<T> il);
iterator erase(const_iterator position);
iterator erase(const_iterator position, const_iterator last);
void swap(vector&);
noexcept(algorithm::propagate_on_container_swap::value ||
algorithm::is_always_equal::value);
void clear() noexcept;

};

template<class InputIterator, class Allocator = allocator<iter_value_type<InputIterator>>>
vector<InputIterator, Allocator, Allocator> vector(InputIterator, InputIterator, Allocator = Allocator());
-> vector<iter_value_type<InputIterator>, Allocator>;

// swap
template<class T, class Allocator>
void swap(vector<T, Allocator>& x, vector<T, Allocator>& y)
noexcept(noexcept(x.swap(y)));
}
An incomplete type \( T \) may be used when instantiating \( \text{vector} \) if the allocator satisfies the allocator completeness requirements (15.5.3.5.1). \( T \) shall be complete before any member of the resulting specialization of \( \text{vector} \) is referenced.

### 21.3.11.2 Constructors, copy, and assignment

[vector.cons]

```cpp
explicit vector(const Allocator&) noexcept;
```

**Effects:** Constructs an empty \( \text{vector} \), using the specified allocator.

**Complexity:** Constant.

```cpp
explicit vector(size_type n, const Allocator& = Allocator());
```

**Effects:** Constructs a \( \text{vector} \) with \( n \) default-inserted elements using the specified allocator.

**Requires:** \( T \) shall be \( \text{Cpp17DefaultInsertable} \) into \(*\text{this}\).*

**Complexity:** Linear in \( n \).

```cpp
vector(size_type n, const T& value, const Allocator& = Allocator());
```

**Effects:** Constructs a \( \text{vector} \) with \( n \) copies of \( \text{value} \), using the specified allocator.

**Requires:** \( T \) shall be \( \text{Cpp17CopyInsertable} \) into \(*\text{this}\).*

**Complexity:** Linear in \( n \).

```cpp
template<class InputIterator>
vector(InputIterator first, InputIterator last, const Allocator& = Allocator());
```

**Effects:** Constructs a \( \text{vector} \) equal to the range \([\text{first}, \text{last})\), using the specified allocator.

**Complexity:** Makes only \( N \) calls to the copy constructor of \( T \) (where \( N \) is the distance between \( \text{first} \) and \( \text{last} \)) and no reallocations if iterators \( \text{first} \) and \( \text{last} \) are of forward, bidirectional, or random access categories. It makes order \( N \) calls to the copy constructor of \( T \) and order \( \log N \) reallocations if they are just input iterators.

### 21.3.11.3 Capacity

[vector.capacity]

```cpp
size_type capacity() const noexcept;
```

**Returns:** The total number of elements that the vector can hold without requiring reallocation.

**Complexity:** Constant time.

```cpp
void reserve(size_type n);
```

**Requires:** \( T \) shall be \( \text{Cpp17MoveInsertable} \) into \(*\text{this}\).*

**Effects:** A directive that informs a \( \text{vector} \) of a planned change in size, so that it can manage the storage allocation accordingly. After \( \text{reserve}() \), \( \text{capacity}() \) is greater or equal to the argument of \( \text{reserve} \) if reallocation happens; and equal to the previous value of \( \text{capacity}() \) otherwise. Reallocation happens at this point if and only if the current capacity is less than the argument of \( \text{reserve}() \). If an exception is thrown other than by the move constructor of a non-\( \text{Cpp17CopyInsertable} \) type, there are no effects.

**Complexity:** It does not change the size of the sequence and takes at most linear time in the size of the sequence.

**Throws:** \( \text{length_error} \) if \( n > \text{max_size}() \).

**Remarks:** Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence. No reallocation shall take place during insertions that happen after a call to \( \text{reserve}() \) until the time when an insertion would make the size of the vector greater than the value of \( \text{capacity}() \).

```cpp
void shrink_to_fit();
```

**Requires:** \( T \) shall be \( \text{Cpp17MoveInsertable} \) into \(*\text{this}\).*

**Effects:** \( \text{shrink_to_fit} \) is a non-binding request to reduce \( \text{capacity}() \) to \( \text{size}() \). [Note: The request is non-binding to allow latitude for implementation-specific optimizations. — end note] It does not
increase `capacity()` but may reduce `capacity()` by causing reallocation. If an exception is thrown other than by the move constructor of a non-`Cpp17CopyInsertable` `T` there are no effects.

**Complexity:** Linear in the size of the sequence.

**Remarks:** Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence as well as the past-the-end iterator. If no reallocation happens, they remain valid.

```cpp
void swap(vector& x)
    noexcept(algorithm_traits<Allocator>::propagate_on_container_swap::value ||
             algorithm_traits<Allocator>::is_always_equal::value);
```

**Effects:** Exchanges the contents and `capacity()` of `*this` with that of `x`.

**Complexity:** Constant time.

```cpp
void resize(size_type sz);
```

**Effects:** If `sz < size()`, erases the last `size() - sz` elements from the sequence. Otherwise, appends `sz - size()` default-inserted elements to the sequence.

**Requires:** `T` shall be `Cpp17MoveInsertable` and `Cpp17DefaultInsertable` into `*this`.

**Remarks:** If an exception is thrown other than by the move constructor of a non-`Cpp17CopyInsertable` `T` there are no effects.

```cpp
void resize(size_type sz, const T& c);
```

**Effects:** If `sz < size()`, erases the last `size() - sz` elements from the sequence. Otherwise, appends `sz - size()` copies of `c` to the sequence.

**Requires:** `T` shall be `Cpp17CopyInsertable` into `*this`.

**Remarks:** If an exception is thrown there are no effects.

### 21.3.11.4 Data

```
T* data() noexcept;
const T* data() const noexcept;
```

**Returns:** A pointer such that `[data(), data() + size())` is a valid range. For a non-empty vector, `data() == addressof(front())`.

**Complexity:** Constant time.

### 21.3.11.5 Modifiers

```
iterator insert(const_iterator position, const T& x);
iterator insert(const_iterator position, T&& x);
iterator insert(const_iterator position, size_type n, const T& x);
template<class InputIterator>
    iterator insert(const_iterator position, InputIterator first, InputIterator last);
iterator insert(const_iterator position, initializer_list<T>);
template<class... Args> reference emplace_back(Args&&... args);
template<class... Args> iterator emplace(const_iterator position, Args&&... args);
void push_back(const T& x);
void push_back(T&& x);
```

**Remarks:** Causes reallocation if the new size is greater than the old capacity. Reallocation invalidates all the references, pointers, and iterators referring to the elements in the sequence. If no reallocation happens, all the iterators and references before the insertion point remain valid. If an exception is thrown other than by the copy constructor, move constructor, assignment operator, or move assignment operator of `T` or by any `InputIterator` operation there are no effects. If an exception is thrown while inserting a single element at the end and `T` is `Cpp17CopyInsertable` or `is_nothrow_move_constructible_v<T>` is `true`, there are no effects. Otherwise, if an exception is thrown by the move constructor of a non-`Cpp17CopyInsertable` `T`, the effects are unspecified.

**Complexity:** The complexity is linear in the number of elements inserted plus the distance to the end of the vector.
iterator erase(const_iterator position);
iterator erase(const_iterator first, const_iterator last);
void pop_back();

Effects: Invalidates iterators and references at or after the point of the erase.

Complexity: The destructor of T is called the number of times equal to the number of the elements erased, but the assignment operator of T is called the number of times equal to the number of elements in the vector after the erased elements.

Throws: Nothing unless an exception is thrown by the assignment operator or move assignment operator of T.

21.3.12 Class vector<bool> [vector.bool]

To optimize space allocation, a specialization of vector for bool elements is provided:

```cpp
namespace std {
    template<class Allocator>
    class vector<bool, Allocator> {
        public:
            using value_type = bool;
            using allocator_type = Allocator;
            using pointer = implementation-defined;
            using const_pointer = implementation-defined;
            using const_reference = bool;
            using size_type = implementation-defined;
            using difference_type = implementation-defined;
            using iterator = std::reverse_iterator<iterator>;
            using const_iterator = std::reverse_iterator<const_iterator>;

            // bit reference
            class reference {
                friend class vector;
                reference() noexcept;
                reference(const reference&) = default;
                ~reference();
                operator bool() const noexcept;
                reference& operator=(const bool x) noexcept;
                reference& operator=(const reference& x) noexcept;
                void flip() noexcept;  // flips the bit
            };

            // construct/copy/destroy
            vector() : vector(Allocator()) { }
            explicit vector(const Allocator&);
            explicit vector(size_type n, const Allocator& = Allocator());
            vector(size_type n, const bool& value, const Allocator& = Allocator());
            template<class InputIterator>
            vector(InputIterator first, InputIterator last, const Allocator& = Allocator());
            vector(const vector& x);
            vector(const vector&, const Allocator&);
            vector(vector&& x);
            vector(vector&&, const Allocator&);
            vector(initializer_list<bool>, const Allocator& = Allocator());
            ~vector();
            vector& operator=(const vector& x);
            vector& operator=(vector&& x);
            vector& operator=(initializer_list<bool>);
            template<class InputIterator>
            void assign(InputIterator first, InputIterator last);
            void assign(size_type n, const bool& t);
```
```cpp
void assign(initializer_list<bool>);
allocator_type get_allocator() const noexcept;

// iterators
iterator begin() noexcept;
const_iterator begin() const noexcept;
iterator end() noexcept;
const_iterator end() const noexcept;
reverse_iterator rbegin() noexcept;
const_reverse_iterator rbegin() const noexcept;
reverse_iterator rend() noexcept;
const_reverse_iterator rend() const noexcept;
const_iterator cbegin() const noexcept;
const_iterator cend() const noexcept;
const_reverse_iterator crbegin() const noexcept;
const_reverse_iterator crend() const noexcept;

// capacity
[[nodiscard]] bool empty() const noexcept;
size_type size() const noexcept;
size_type max_size() const noexcept;
size_type capacity() const noexcept;
void resize(size_type sz, bool c = false);
void reserve(size_type n);
void shrink_to_fit();

// element access
reference operator[](size_type n);
const_reference operator[](size_type n) const;
const_reference at(size_type n) const;
reference at(size_type n);
reference front();
const_reference front() const;
reference back();
const_reference back() const;

// modifiers
template<
    class... Args>
    reference emplace_back(Args&&... args);
void push_back(const bool& x);
void pop_back();

// iterators
iterator insert(const_iterator position, const_iterator position, Args&&... args);
iterator insert(const_iterator position, size_type n, const bool& x);
template<class InputIterator>
    iterator insert(const_iterator position, InputIterator first, InputIterator last);
    iterator insert(const_iterator position, initializer_list<bool> il);
    iterator erase(const_iterator position);
    iterator erase(const_iterator first, const_iterator last);
    void swap(vector&);
    static void swap(reference x, reference y) noexcept;
    void flip() noexcept;  // flips all bits
    void clear() noexcept;
};

2 Unless described below, all operations have the same requirements and semantics as the primary vector template, except that operations dealing with the bool value type map to bit values in the container storage and allocator_traits::construct (19.10.9.2) is not used to construct these values.

3 There is no requirement that the data be stored as a contiguous allocation of bool values. A space-optimized representation of bits is recommended instead.

§ 21.3.12
```
4 reference is a class that simulates the behavior of references of a single bit in vector<bool>. The conversion function returns true when the bit is set, and false otherwise. The assignment operator sets the bit when the argument is (convertible to) true and clears it otherwise. flip reverses the state of the bit.

void flip() noexcept;

5 Effects: Replaces each element in the container with its complement.

static void swap(reference x, reference y) noexcept;

6 Effects: Exchanges the contents of x and y as if by:

    bool b = x;
    x = y;
    y = b;

template<class Allocator> struct hash<vector<bool, Allocator>>;

7 The specialization is enabled (19.14.16).

21.4 Associative containers

21.4.1 In general

The header <map> defines the class templates map and multimap; the header <set> defines the class templates set and multiset.

2 The following exposition-only alias templates may appear in deduction guides for associative containers:

    template<class InputIterator>
    using iter_value_type =
        typename iterator_traits<InputIterator>::value_type; // exposition only

    template<class InputIterator>
    using iter_key_type = remove_const_t<
        typename iterator_traits<InputIterator>::value_type::first_type>; // exposition only

    template<class InputIterator>
    using iter_mapped_type =
        typename iterator_traits<InputIterator>::value_type::second_type; // exposition only

    template<class InputIterator>
    using iter_to_alloc_type = pair<
        add_const_t<typename iterator_traits<InputIterator>::value_type::first_type>,
        typename iterator_traits<InputIterator>::value_type::second_type>; // exposition only

21.4.2 Header <map> synopsis

#include <initializer_list>

namespace std {

    // 21.4.4, class template map
    template<class Key, class T, class Compare = less<Key>,
             class Allocator = allocator<pair<const Key, T>>>
    class map;

    template<class Key, class T, class Compare, class Allocator>
    bool operator==(const map<Key, T, Compare, Allocator>& x,
                    const map<Key, T, Compare, Allocator>& y);

    template<class Key, class T, class Compare, class Allocator>
    bool operator!=(const map<Key, T, Compare, Allocator>& x,
                    const map<Key, T, Compare, Allocator>& y);

    template<class Key, class T, class Compare, class Allocator>
    bool operator< (const map<Key, T, Compare, Allocator>& x,
                    const map<Key, T, Compare, Allocator>& y);

    template<class Key, class T, class Compare, class Allocator>
    bool operator> (const map<Key, T, Compare, Allocator>& x,
                    const map<Key, T, Compare, Allocator>& y);

    template<class Key, class T, class Compare, class Allocator>

21.4.4 Class template map

21.4.4.1 Overview

A map is an associative container that supports unique keys (contains at most one of each key value) and provides for fast retrieval of values of another type T based on the keys. The map class supports bidirectional iterators.

A map satisfies all of the requirements of a container, of a reversible container (21.2), of an associative container (21.2.6), and of an allocator-aware container (Table 67). A map also provides most operations
described in 21.2.6 for unique keys. This means that a map supports the a_uniq operations in 21.2.6 but not the a_eq operations. For a map<Key,T> the key_type is Key and the value_type is pair<const Key,T>.

Descriptions are provided here only for operations on map that are not described in one of those tables or for operations where there is additional semantic information.

namespace std {
    template<class Key, class T, class Compare = less<Key>,
     class Allocator = allocator<pair<const Key, T>>>
    class map {
    public:
        // types
        using key_type = Key;
        using mapped_type = T;
        using value_type = pair<const Key, T>;
        using key_compare = Compare;
        using allocator_type = Allocator;
        using pointer = typename allocator_traits<Allocator>::pointer;
        using const_pointer = typename allocator_traits<Allocator>::const_pointer;
        using reference = value_type&;
        using const_reference = const value_type&;
        using size_type = implementation-defined; // see 21.2
        using difference_type = implementation-defined; // see 21.2
        using iterator = implementation-defined; // see 21.2
        using const_iterator = implementation-defined; // see 21.2
        using reverse_iterator = std::reverse_iterator<iterator>;
        using const_reverse_iterator = std::reverse_iterator<const_iterator>;
        using node_type = unspecified;
        using insert_return_type = INSERT_RETURN_TYPE<iterator, node_type>;
    
    class value_compare {
        friend class map;
    protected:
        Compare comp;
    public:
        bool operator()(const value_type& x, const value_type& y) const {
            return comp(x.first, y.first);
        }
    }

    // 21.4.4.2, construct/copy/destroy
    map() : map(Compare()) {} 
    explicit map(const Compare& comp, const Allocator& = Allocator());
    template<class InputIterator>
    map(InputIterator first, InputIterator last,

void swap(map<Key, T, Compare, Allocator>& x,
  map<Key, T, Compare, Allocator>& y)
  noexcept(noexcept(x.swap(y)));

21.4.4.2 Constructors, copy, and assignment
[map.cons]
explicit map(const Compare& comp, const Allocator& = Allocator());
  Effects: Constructs an empty map using the specified comparison object and allocator.
  Complexity: Constant.

template<class InputIterator>
  map(InputIterator first, InputIterator last,
  const Compare& comp = Compare(), const Allocator& = Allocator());
  Effects: Constructs an empty map using the specified comparison object and allocator, and inserts elements from the range [first, last).
  Complexity: Linear in \( N \) if the range [first, last) is already sorted using \( \text{comp} \) and otherwise \( N \log N \), where \( N \) is last - first.

21.4.4.3 Element access
[map.access]
T& operator[](const key_type& x);
  Effects: Equivalent to: return try_emplace(x).first->second;
  Remarks: These signatures shall not participate in overload resolution unless is_constructible_v<value_type, P&&> is true.

T& operator[](key_type&& x);
  Effects: Equivalent to: return try_emplace(move(x)).first->second;

T&
  at(const key_type& x);
  Returns: A reference to the mapped_type corresponding to \( x \) in *this.
  Throws: An exception object of type out_of_range if no such element is present.
  Complexity: Logarithmic.

21.4.4.4 Modifiers
[map.modifiers]
template<class P>
  pair<iterator, bool> insert(P&& x);
template<class P>
  iterator insert(const_iterator position, P&& x);
  Effects: The first form is equivalent to return emplace(std::forward<P>(x)).
The second form is equivalent to return emplace_hint(position, std::forward<P>(x)).
  Requires: \( \text{value_type} \) shall be Cpp17EmplaceConstructible into map from piecewise_construct, forward_as_tuple(k), forward_as_tuple(std::forward<Args>(args)...).

§ 21.4.4.4 791
Effects: If the map already contains an element whose key is equivalent to \( k \), there is no effect. Otherwise inserts an object of type `value_type` constructed with `piecewise_construct`, `forward_as_tuple(k)`.

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to \( k \).

Complexity: The same as `emplace` and `emplace_hint`, respectively.

```cpp
template<class... Args>
pair<iterator, bool> try_emplace(key_type&& k, Args&&... args);
```

```cpp
template<class... Args>
iterator try_emplace(const_iterator hint, key_type&& k, Args&&... args);
```

Requires: `value_type` shall be `Cpp17EmplaceConstructible` into map from `piecewise_construct, forward_as_tuple(std::move(k)), forward_as_tuple(std::forward<Args>(args))...`.

Effects: If the map already contains an element whose key is equivalent to \( k \), there is no effect. Otherwise inserts an object of type `value_type` constructed with `piecewise_construct, forward_as_tuple(std::move(k)), forward_as_tuple(std::forward<Args>(args))...`.

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to \( k \).

Complexity: The same as `emplace` and `emplace_hint`, respectively.

```cpp
template<class M>
pair<iterator, bool> insert_or_assign(const key_type& k, M&& obj);
```

```cpp
template<class M>
iterator insert_or_assign(const_iterator hint, const key_type& k, M&& obj);
```

Requires: `is_assignable_v<mapped_type&, M&&>` shall be true. `value_type` shall be `Cpp17EmplaceConstructible` into map from `k, forward<M>(obj)`.

Effects: If the map already contains an element \( e \) whose key is equivalent to \( k \), assigns `std::forward<M>(obj)` to \( e.second \). Otherwise inserts an object of type `value_type` constructed with \( k, std::forward<M>(obj) \).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to \( k \).

Complexity: The same as `emplace` and `emplace_hint`, respectively.

```cpp
template<class M>
pair<iterator, bool> insert_or_assign(key_type&& k, M&& obj);
```

```cpp
template<class M>
iterator insert_or_assign(const_iterator hint, key_type&& k, M&& obj);
```

Requires: `is_assignable_v<mapped_type&, M&&>` shall be true. `value_type` shall be `Cpp17EmplaceConstructible` into map from `move(k), forward<M>(obj)`.

Effects: If the map already contains an element \( e \) whose key is equivalent to \( k \), assigns `std::forward<M>(obj)` to \( e.second \). Otherwise inserts an object of type `value_type` constructed with `std::move(k), std::forward<M>(obj)`.

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to \( k \).

Complexity: The same as `emplace` and `emplace_hint`, respectively.

### 21.4.5 Class template `multimap` [multimap]

#### 21.4.5.1 Overview [multimap.overview]

A `multimap` is an associative container that supports equivalent keys (possibly containing multiple copies of the same key value) and provides for fast retrieval of values of another type \( T \) based on the keys. The `multimap` class supports bidirectional iterators.

A `multimap` satisfies all of the requirements of a container and of a reversible container (21.2), of an associative container (21.2.6), and of an allocator-aware container (Table 67). A `multimap` also provides most operations described in 21.2.6 for equal keys. This means that a `multimap` supports the `a_eq` operations in 21.2.6 but not the `a_uniq` operations. For a `multimap<Key,T>` the `key_type` is `Key` and the `value_type` is `pair<const...`
key,T> Descriptions are provided here only for operations on multimap that are not described in one of those tables or for operations where there is additional semantic information.

namespace std {
    template<class Key, class T, class Compare = less<Key>,
        class Allocator = allocator<pair<const Key, T>>>

21.4.5.2 Constructors [multimap.cons]

explicit multimap(const Compare& comp, const Allocator& = Allocator());

Effects: Constructs an empty multimap using the specified comparison object and allocator.

Complexity: Constant.
const Allocator& = Allocator());

Effects: Constructs an empty multimap using the specified comparison object and allocator, and inserts elements from the range [first, last).

Complexity: Linear in N if the range [first, last) is already sorted using comp and otherwise $N \log N$, where $N$ is last - first.

21.4.5.3 Modifiers

template<class P> iterator insert(P&& x);
template<class P> iterator insert(const_iterator position, P&& x);

Effects: The first form is equivalent to return emplace(std::forward<P>(x)). The second form is equivalent to return emplace_hint(position, std::forward<P>(x)).

Remarks: These signatures shall not participate in overload resolution unless is_constructible_v<value_type, P&&> is true.

21.4.6 Class template set

21.4.6.1 Overview

A set is an associative container that supports unique keys (contains at most one of each key value) and provides for fast retrieval of the keys themselves. The set class supports bidirectional iterators.

A set satisfies all of the requirements of a container, of a reversible container (21.2), of an associative container (21.2.6), and of an allocator-aware container (Table 67). A set also provides most operations described in 21.2.6 for unique keys. This means that a set supports the a_eq operations but not the a_uniq operations. For a set<Key> both the key_type and value_type are Key. Descriptions are provided here only for operations on set that are not described in one of these tables and for operations where there is additional semantic information.

namespace std {

    template<class Key, class Compare = less<Key>,
            class Allocator = allocator<Key>>
    class set {
        public:
            // types
            using key_type = Key;
            using key_compare = Compare;
            using value_type = Key;
            using value_compare = Compare;

set(initializer_list<Key>, Allocator) -> set<Key, less<Key>, Allocator>;

// swap
template<class Key, class Compare, class Allocator>
void swap(set<Key, Compare, Allocator>& x,
  set<Key, Compare, Allocator>& y)
noexcept(noexcept(x.swap(y)));
}

21.4.6.2 Constructors, copy, and assignment

explicit set(const Compare& comp, const Allocator& = Allocator());

Effects: Constructs an empty set using the specified comparison objects and allocator.

Complexity: Constant.

template<class InputIterator>
set(InputIterator first, InputIterator last,
    const Compare& comp = Compare(), const Allocator& = Allocator());

Effects: Constructs an empty set using the specified comparison object and allocator, and inserts elements from the range [first, last).

Complexity: Linear in N if the range [first, last) is already sorted using comp and otherwise N log N, where N is last - first.

21.4.7 Class template multiset

21.4.7.1 Overview

A multiset is an associative container that supports equivalent keys (possibly contains multiple copies of the same key value) and provides for fast retrieval of the keys themselves. The multiset class supports bidirectional iterators.

A multiset satisfies all of the requirements of a container, of a reversible container (21.2), of an associative container (21.2.6), and of an allocator-aware container (Table 67). multiset also provides most operations described in 21.2.6 for duplicate keys. This means that a multiset supports the a_eq operations in 21.2.6 but not the a_uniq operations. For a multiset<Key> both the key_type and value_type are Key. Descriptions are provided here only for operations on multiset that are not described in one of these tables and for operations where there is additional semantic information.

namespace std {
    template<class Key, class Compare = less<Key>,
             class Allocator = allocator<Key>>
    class multiset {
        public:
            // types
            using key_type = Key;
            using key_compare = Compare;
            using value_type = Key;
            using value_compare = Compare;

801
template<class Key, class Compare, class Allocator>
void swap(multiset<Key, Compare, Allocator>& x,
          multiset<Key, Compare, Allocator>& y)
    noexcept(noexcept(x.swap(y)));
}

21.4.7.2 Constructors

explicit multiset(const Compare& comp, const Allocator& = Allocator());

1 Effects: Constructs an empty multiset using the specified comparison object and allocator.
2 Complexity: Constant.

template<class InputIterator>
multiset(InputIterator first, InputIterator last,
         const Compare& comp = Compare(), const Allocator& = Allocator());

3 Effects: Constructs an empty multiset using the specified comparison object and allocator, and inserts
elements from the range [first, last).
4 Complexity: Linear in \( N \) if the range [first, last) is already sorted using \( \text{comp} \) and otherwise
\( N \log N \), where \( N \) is last - first.

21.5 Unordered associative containers

21.5.1 In general

1 The header \texttt{<unordered\_map>} defines the class templates \texttt{unordered\_map} and \texttt{unordered\_multimap}; the
header \texttt{<unordered\_set>} defines the class templates \texttt{unordered\_set} and \texttt{unordered\_multiset}.
2 The exposition-only alias templates \texttt{iter-value-type}, \texttt{iter-key-type}, \texttt{iter-mapped-type}, and \texttt{iter-to-alloc-type}
defined in 21.4.1 may appear in deduction guides for unordered containers.

21.5.2 Header \texttt{<unordered\_map>} synopsis

21.5.4 Class template unordered_map

21.5.4.1 Overview

1 An unordered_map is an unordered associative container that supports unique keys (an unordered_map contains at most one of each key value) and that associates values of another type mapped_type with the keys. The unordered_map class supports forward iterators.

2 An unordered_map satisfies all of the requirements of a container, of an unordered associative container, and of an allocator-aware container (Table 67). It provides the operations described in the preceding requirements table for unique keys; that is, an unordered_map supports the a_uniq operations in that table, not the a_eq operations. For an unordered_map<Key, T> the key type is Key, the mapped type is T, and the value type is pair<const Key, T>.

3 This subclause only describes operations on unordered_map that are not described in one of the requirement tables, or for which there is additional semantic information.

namespace std {
    template<class Key, class T, class Hash = hash<Key>,
             class Pred = equal_to<Key>,
             class Allocator = allocator<pair<const Key, T>>>
    class unordered_map {
        public:
            // types
            using key_type = Key;
            using mapped_type = T;
            using value_type = pair<const Key, T>;

explicit unordered_map(size_type n,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());

Effects: Constructs an empty unordered_map using the specified hash function, key equality predicate, and allocator, and using at least n buckets. For the default constructor, the number of buckets is implementation-defined. max_load_factor() returns 1.0.
Complexity: Constant.

template<class InputIterator>
unordered_map(InputIterator f, InputIterator l,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());
unordered_map(initializer_list<value_type> il,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());

Effects: Constructs an empty unordered_map using the specified hash function, key equality predicate, and allocator, and using at least n buckets. If n is not provided, the number of buckets is implementation-defined. Then inserts elements from the range [f, l) for the first form, or from the range [il.begin(), il.end()) for the second form. max_load_factor() returns 1.0.
Complexity: Average case linear, worst case quadratic.

21.5.4.3 Element access

mapped_type& operator[](const key_type& k);

Effects: Equivalent to: return try_emplace(k).first->second;

mapped_type& operator[](key_type&& k);

Effects: Equivalent to: return try_emplace(move(k)).first->second;

mapped_type& at(const key_type& k);
const mapped_type& at(const key_type& k) const;

Returns: A reference to x.second, where x is the (unique) element whose key is equivalent to k.

Throws: An exception object of type out_of_range if no such element is present.
21.5.4.4 Modifiers

```cpp
template<class P>
pair<iterator, bool> insert(P&& obj);
```

1. **Effects:** Equivalent to: `return emplace(std::forward<P>(obj));`
2. **Remarks:** This signature shall not participate in overload resolution unless `is_constructible_\-
   v<value_type, P&&>` is true.

```cpp
template<class P>
iterator insert(const_iterator hint, P&& obj);
```

3. **Effects:** Equivalent to: `return emplace_hint(hint, std::forward<P>(obj));`
4. **Remarks:** This signature shall not participate in overload resolution unless `is_constructible_-
   v<value_type, P&&>` is true.

```cpp
template<class... Args>
pair<iterator, bool> try_emplace(const key_type& k, Args&&... args);
```

5. **Requires:** `value_type` shall be `Cpp17EmplaceConstructible` into unordered_map from `piecewise_construct, forward_as_tuple(k), forward_as_tuple(std::forward<Args>(args))...`.
6. **Effects:** If the map already contains an element whose key is equivalent to `k`, there is no effect. Otherwise inserts an object of type `value_type` constructed with `piecewise_construct, forward_as_tuple(k), forward_as_tuple(std::forward<Args>(args))...`.
7. **Returns:** In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.
8. **Complexity:** The same as `emplace` and `emplace_hint`, respectively.

```cpp
template<class... Args>
iterator try_emplace(const_iterator hint, const key_type& k, Args&&... args);
```

9. **Requires:** `value_type` shall be `Cpp17EmplaceConstructible` into unordered_map from `piecewise_construct, forward_as_tuple(k), forward_as_tuple(std::forward<Args>(args))...`.
10. **Effects:** If the map already contains an element whose key is equivalent to `k`, there is no effect. Otherwise inserts an object of type `value_type` constructed with `piecewise_construct, forward_as_tuple(std::move(k)), forward_as_tuple(std::forward<Args>(args))...`.
11. **Returns:** In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.
12. **Complexity:** The same as `emplace` and `emplace_hint`, respectively.

```cpp
template<class M>
pair<iterator, bool> insert_or_assign(const key_type& k, M&& obj);
```

13. **Requires:** `is_assignable_v<mapped_type&, M&&>` shall be `true`. `value_type` shall be `Cpp17EmplaceConstructible` into unordered_map from `k, std::forward<M>(obj)`.
14. **Effects:** If the map already contains an element `e` whose key is equivalent to `k`, assigns `std::for-
   ward<M>(obj)` to `e.second`. Otherwise inserts an object of type `value_type` constructed with `k, std::forward<M>(obj)`.
15. **Returns:** In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.
16. **Complexity:** The same as `emplace` and `emplace_hint`, respectively.

```cpp
template<class M>
iterator insert_or_assign(const_iterator hint, const key_type& k, M&& obj);
```

17. **Requires:** `is_assignable_v<mapped_type&, M&&>` shall be `true`. `value_type` shall be `Cpp17EmplaceConstructible` into unordered_map from `k, std::forward<M>(obj)`.
18. **Effects:** If the map already contains an element `e` whose key is equivalent to `k`, assigns `std::for-
   ward<M>(obj)` to `e.second`. Otherwise inserts an object of type `value_type` constructed with `k, std::forward<M>(obj)`.
19. **Returns:** In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.
20. **Complexity:** The same as `emplace` and `emplace_hint`, respectively.

```cpp
template<class M>
pair<iterator, bool> insert_or_assign(key_type&& k, M&& obj);
```

21. **Requires:** `is_assignable_v<mapped_type&, M&&>` shall be `true`. `value_type` shall be `Cpp17EmplaceConstructible` into unordered_map from `k, std::forward<M>(obj)`.
22. **Effects:** If the map already contains an element `e` whose key is equivalent to `k`, assigns `std::for-
   ward<M>(obj)` to `e.second`. Otherwise inserts an object of type `value_type` constructed with `k, std::forward<M>(obj)`.
23. **Returns:** In the first overload, the `bool` component of the returned pair is `true` if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to `k`.
24. **Complexity:** The same as `emplace` and `emplace_hint`, respectively.
template<class M>
iterator insert_or_assign(const_iterator hint, key_type&& k, M&& obj);

Requires: is_assignable_v<mapped_type&, M&&> shall be true. value_type shall be Cpp17Emplace-Constructible into unordered_map from std::move(k), std::forward<M>(obj).

Effects: If the map already contains an element e whose key is equivalent to k, assigns std::forward<M>(obj) to e.second. Otherwise inserts an object of type value_type constructed with std::move(k), std::forward<M>(obj).

Returns: In the first overload, the bool component of the returned pair is true if and only if the insertion took place. The returned iterator points to the map element whose key is equivalent to k.

Complexity: The same as emplace and emplace_hint, respectively.

21.5.5 Class template unordered_multimap

21.5.5.1 Overview

An unordered_multimap is an unordered associative container that supports equivalent keys (an instance of unordered_multimap may contain multiple copies of each key value) and that associates values of another type mapped_type with the keys. The unordered_multimap class supports forward iterators.

An unordered_multimap satisfies all of the requirements of a container, of an unordered associative container, and of an allocator-aware container (Table 67). It provides the operations described in the preceding requirements table for equivalent keys; that is, an unordered_multimap supports the a_eq operations in that table, not the a_uniq operations. For an unordered_multimap<Key, T> the key type is Key, the mapped type is T, and the value type is pair<const Key, T>.

This subclause only describes operations on unordered_multimap that are not described in one of the requirement tables, or for which there is additional semantic information.

namespace std {
    template<class Key, 
             class T, 
             class Hash = hash<Key>, 
             class Pred = equal_to<Key>, 
             class Allocator = allocator<pair<const Key, T>>>
    class unordered_multimap {
        public:
            // types
            using key_type = Key;
            using mapped_type = T;
            using value_type = pair<const Key, T>;
            using hasher = Hash;
            using key_equal = Pred;
            using allocator_type = Allocator;
            using pointer = typename allocator_traits<Allocator>::pointer;
            using const_pointer = typename allocator_traits<Allocator>::const_pointer;
            using reference = value_type&;
            using const_reference = const value_type&;
            using size_type = implementation-defined;  // see 21.2
            using difference_type = implementation-defined;  // see 21.2
            using iterator = implementation-defined;  // see 21.2
            using const_iterator = implementation-defined;  // see 21.2
            using local_iterator = implementation-defined;  // see 21.2
            using const_local_iterator = implementation-defined;  // see 21.2
            using node_type = unspecified;

            // 21.5.5.2, construct/copy/destroy
            unordered_multimap();
            explicit unordered_multimap(size_type n,
                                           const hasher& hf = hasher(),

void swap(unordered_multimap<Key, T, Hash, Pred, Alloc>& x, unordered_multimap<Key, T, Hash, Pred, Alloc>& y)
noexcept(noexcept(x.swap(y)));

A size_type parameter type in an unordered_multimap deduction guide refers to the size_type
member type of the type deduced by the deduction guide.

21.5.5.2 Constructors

unordered_multimap() : unordered_multimap(size_type(see below)) { }
explicit unordered_multimap(size_type n,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());

Effects: Constructs an empty unordered_multimap using the specified hash function, key equality
predicate, and allocator, and using at least n buckets. For the default constructor, the number of
buckets is implementation-defined. max_load_factor() returns 1.0.

Complexity: Constant.
template<class InputIterator>
unordered_multimap(InputIterator f, InputIterator l,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());
unordered_multimap(initializer_list<value_type> il,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());

Effects: Constructs an empty unordered_multimap using the specified hash function, key equality predicate, and allocator, and using at least n buckets. If n is not provided, the number of buckets is implementation-defined. Then inserts elements from the range [f, l) for the first form, or from the range [il.begin(), il.end()) for the second form. max_load_factor() returns 1.0.

Complexity: Average case linear, worst case quadratic.

21.5.5.3 Modifiers

template<class P>
iterator insert(P&& obj);

Effects: Equivalent to: return emplace(std::forward<P>(obj));
Remarks: This signature shall not participate in overload resolution unless is_constructible_<value_type, P&&> is true.

template<class P>
iterator insert(const_iterator hint, P&& obj);

Effects: Equivalent to: return emplace_hint(hint, std::forward<P>(obj));
Remarks: This signature shall not participate in overload resolution unless is_constructible_<value_type, P&&> is true.

21.5.6 Class template unordered_set

21.5.6.1 Overview

An unordered_set is an unordered associative container that supports unique keys (an unordered_set contains at most one of each key value) and in which the elements’ keys are the elements themselves. The unordered_set class supports forward iterators.

An unordered_set satisfies all of the requirements of a container, of an unordered associative container, and of an allocator-aware container (Table 67). It provides the operations described in the preceding requirements table for unique keys; that is, an unordered_set supports the a_uniq operations in that table, not the a_eq operations. For an unordered_set<Key> the key type and the value type are both Key. The iterator and const_iterator types are both constant iterator types. It is unspecified whether they are the same type.

This subclause only describes operations on unordered_set that are not described in one of the requirement tables, or for which there is additional semantic information.

namespace std {
    template<class Key,
        class Hash = hash<Key>,
        class Pred = equal_to<Key>,
        class Allocator = allocator<Key>>
    class unordered_set {
        public:
            // types
            using key_type = Key;
            using value_type = Key;
            using hasher = Hash;
            using key_equal = Pred;

float max_load_factor() const noexcept;
void max_load_factor(float z);
void rehash(size_type n);
void reserve(size_type n);
};

template<class InputIterator,
class Hash = hash<iter_value_type<InputIterator>>,
class Pred = equal_to<iter_value_type<InputIterator>>,
class Allocator = allocator<iter_value_type<InputIterator>>>
unordered_set(InputIterator, InputIterator, typename see below::size_type = see below,
    Hash = Hash(), Pred = Pred(), Allocator = Allocator())
    -> unordered_set<iter_value_type<InputIterator> ,
    Hash, Pred, Allocator>;

template<class T, class Hash = hash<T>,
class Pred = equal_to<T>, class Allocator = allocator<T>>
unordered_set(initializer_list<T>, typename see below::size_type = see below,
    Hash = Hash(), Pred = Pred(), Allocator = Allocator())
    -> unordered_set<T, Hash, Pred, Allocator>;

template<class InputIterator, class Allocator>
unordered_set(InputIterator, InputIterator, typename see below::size_type,
    Hash, Allocator)
    -> unordered_set<iter_value_type<InputIterator> ,
    hash<iter_value_type<InputIterator>>,
    equal_to<iter_value_type<InputIterator>>,
    Allocator>;

template<class InputIterator, class Hash, class Allocator>
unordered_set(InputIterator, InputIterator, typename see below::size_type,
    Hash, Allocator)
    -> unordered_set<iter_value_type<InputIterator> ,
    Hash, equal_to<iter_value_type<InputIterator>>,
    Allocator>;

// swap
void swap(unordered_set<Key, Hash, Pred, Alloc>& x,
    unordered_set<Key, Hash, Pred, Alloc>& y)
    noexcept(noexcept(x.swap(y)));
}

4 A size_type parameter type in an unordered_set deduction guide refers to the size_type member type
of the type deduced by the deduction guide.

21.5.6.2 Constructors

unordered_set() : unordered_set(size_type(see below)) {} 
explicit unordered_set(size_type n,
    const hasher& hf = hasher(),
    const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type();

Effects: Constructs an empty unordered_set using the specified hash function, key equality predicate, and allocator, and using at least n buckets. For the default constructor, the number of buckets is implementation-defined. max_load_factor() returns 1.0.

Complexity: Constant.

template<class InputIterator>
unordered_set(InputIterator f, InputIterator l,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());

unordered_set(initializer_list<value_type> il,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());

Effects: Constructs an empty unordered_set using the specified hash function, key equality predicate, and allocator, and using at least n buckets. If n is not provided, the number of buckets is implementation-defined. Then inserts elements from the range [f, 1) for the first form, or from the range [il.begin(), il.end()) for the second form. max_load_factor() returns 1.0.

Complexity: Average case linear, worst case quadratic.

21.5.7 Class template unordered_multiset

An unordered_multiset is an unordered associative container that supports equivalent keys (an instance of unordered_multiset may contain multiple copies of the same key value) and in which each element’s key is the element itself. The unordered_multiset class supports forward iterators.

An unordered_multiset satisfies all of the requirements of a container, of an unordered associative container, and of an allocator-aware container (Table 67). It provides the operations described in the preceding requirements table for equivalent keys; that is, an unordered_multiset supports the a_eq operations in that table, not the a_uniq operations. For an unordered_multiset<Key> the key type and the value type are both Key. The iterator and const_iterator types are both constant iterator types. It is unspecified whether they are the same type.

This subclause only describes operations on unordered_multiset that are not described in one of the requirement tables, or for which there is additional semantic information.

namespace std {
  template<class Key,
           class Hash = hash<Key>,
           class Pred = equal_to<Key>,
           class Allocator = allocator<Key>>
  class unordered_multiset {
    public:
      // types

4 A size_type parameter type in an unordered_multiset deduction guide refers to the size_type member type of the type deduced by the deduction guide.

21.5.7.2 Constructors

unordered_multiset() : unordered_multiset(size_type(see below)) { }
explicit unordered_multiset(size_type n, 
    const hasher& hf = hasher(), 
    const key_equal& eql = key_equal(), 
    const allocator_type& a = allocator_type());
1 Effects: Constructs an empty unordered_multiset using the specified hash function, key equality predicate, and allocator, and using at least n buckets. For the default constructor, the number of buckets is implementation-defined. max_load_factor() returns 1.0.

2 Complexity: Constant.
template<class InputIterator>
unordered_multiset(InputIterator f, InputIterator l,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());
unordered_multiset(initializer_list<value_type> il,
size_type n = see below,
const hasher& hf = hasher(),
const key_equal& eql = key_equal(),
const allocator_type& a = allocator_type());

Effects: Constructs an empty unordered_multiset using the specified hash function, key equality predicate, and allocator, and using at least n buckets. If n is not provided, the number of buckets is implementation-defined. Then inserts elements from the range [f, l) for the first form, or from the range [il.begin(), il.end()) for the second form. max_load_factor() returns 1.0.

Complexity: Average case linear, worst case quadratic.

21.6 Container adaptors

21.6.1 In general

The headers <queue> and <stack> define the container adaptors queue, priority_queue, and stack.

The container adaptors each take a Container template parameter, and each constructor takes a Container reference argument. This container is copied into the Container member of each adaptor. If the container takes an allocator, then a compatible allocator may be passed in to the adaptor's constructor. Otherwise, normal copy or move construction is used for the container argument. The first template parameter T of the container adaptors shall denote the same type as Container::value_type.

For container adaptors, no swap function throws an exception unless that exception is thrown by the swap of the adaptor's Container or Compare object (if any).

A deduction guide for a container adaptor shall not participate in overload resolution if any of the following are true:

- It has an InputIterator template parameter and a type that does not qualify as an input iterator is deduced for that parameter.
- It has a Compare template parameter and a type that qualifies as an allocator is deduced for that parameter.
- It has a Container template parameter and a type that qualifies as an allocator is deduced for that parameter.
- It has an Allocator template parameter and a type that does not qualify as an allocator is deduced for that parameter.
- It has both Container and Allocator template parameters, and uses_allocator_v<Container, Allocator> is false.

21.6.2 Header <queue> synopsis

#include <initializer_list>

namespace std {
    template<class T, class Container = deque<T>> class queue;
    template<class T, class Container = vector<T>,
             class Compare = less<typename Container::value_type>>
             class priority_queue;
    template<class T, class Container>
    bool operator==(const queue<T, Container>& x, const queue<T, Container>& y);
    template<class T, class Container>
    bool operator!=(const queue<T, Container>& x, const queue<T, Container>& y);
    template<class T, class Container>
    bool operator< (const queue<T, Container>& x, const queue<T, Container>& y);
    template<class T, class Container>
    bool operator> (const queue<T, Container>& x, const queue<T, Container>& y);
}
template<class T, class Container>
bool operator<=(const queue<T, Container>& x, const queue<T, Container>& y);
template<class T, class Container>
bool operator>=(const queue<T, Container>& x, const queue<T, Container>& y);

template<class T, class Container>
void swap(queue<T, Container>& x, queue<T, Container>& y) noexcept(noexcept(x.swap(y)));
template<class T, class Container, class Compare>
void swap(priority_queue<T, Container, Compare>& x, priority_queue<T, Container, Compare>& y) noexcept(noexcept(x.swap(y)));

21.6.3 Header <stack> synopsis

namespace std {
  template<class T, class Container = deque<T>> class stack;
}

21.6.4 Class template queue

1 Any sequence container supporting operations front(), back(), push_back() and pop_front() can be used to instantiate queue. In particular, list (21.3.10) and deque (21.3.8) can be used.
// [nodiscard] bool empty() const { return c.empty(); }
size_type size() const { return c.size(); }
reference front() { return c.front(); }
const_reference front() const { return c.front(); }
reference back() { return c.back(); }
const_reference back() const { return c.back(); }
void push(const value_type& x) { c.push_back(x); }
void push(value_type&& x) { c.push_back(std::move(x)); }
template<class... Args>
decltype(auto) emplace(Args&&... args)
    { return c.emplace_back(std::forward<Args>(args)...); }
void pop() { c.pop_front(); }
void swap(queue& q) noexcept(is_nothrow_swappable_v<Container>)
    { using std::swap; swap(c, q.c); }
};

template<class Container>
queue(Container) -> queue<typename Container::value_type, Container>;

template<class Container, class Allocator>
queue(Container, Allocator) -> queue<typename Container::value_type, Container>;

template<class T, class Container>
struct uses_allocator<queue<T, Container>, Allocator>
    : uses_allocator<Container, Allocator>::type { };
template<class T, class Container>
bool operator!=(const queue<T, Container>& x, const queue<T, Container>& y);

Returns: x.c != y.c.

template<class T, class Container>
bool operator< (const queue<T, Container>& x, const queue<T, Container>& y);

Returns: x.c < y.c.

template<class T, class Container>
bool operator> (const queue<T, Container>& x, const queue<T, Container>& y);

Returns: x.c > y.c.

template<class T, class Container>
bool operator<=(const queue<T, Container>& x, const queue<T, Container>& y);

Returns: x.c <= y.c.

template<class T, class Container>
bool operator>=(const queue<T, Container>& x, const queue<T, Container>& y);

Returns: x.c >= y.c.

21.6.4.5 Specialized algorithms
[queue.special]

template<class T, class Container>
void swap(queue<T, Container>& x, queue<T, Container>& y) noexcept(noexcept(x.swap(y)));

Remarks: This function shall not participate in overload resolution unless is_swappable_v<Container>
is true.

Effects: As if by x.swap(y).

21.6.5 Class template priority_queue
[priority.queue]

21.6.5.1 Overview
[priqueue.overview]

Any sequence container with random access iterator and supporting operations `front()`, `push_back()` and`pop_back()` can be used to instantiate `priority_queue`. In particular, `vector` (21.3.11) and `deque` (21.3.8)can be used. Instantiating `priority_queue` also involves supplying a function or function object for making priority comparisons; the library assumes that the function or function object defines a strict weakordering (23.7).

namespace std {
    template<class T, class Container = vector<T>,
             class Compare = less<typename Container::value_type>>
class priority_queue {
    public:
        using value_type = typename Container::value_type;
        using reference = typename Container::reference;
        using const_reference = typename Container::const_reference;
        using size_type = typename Container::size_type;
        using container_type = Container;
        using value_compare = Compare;

    protected:
        Container c;
        Compare comp;

    public:
        priority_queue() : priority_queue(Compare()) {}
        explicit priority_queue(const Compare& x) : priority_queue(x, Container()) {}
        priority_queue(const Compare& x, const Container&);
        priority_queue(const Compare& x, Container&&);
        template<class InputIterator>
        priority_queue(InputIterator first, InputIterator last, const Compare& x,
                        const Container&);
template<class InputIterator>
  priority_queue(InputIterator first, InputIterator last,  
  const Compare& x = Compare(), Container&& = Container());

template<class Alloc> explicit priority_queue(const Alloc&);

template<class Alloc> priority_queue(const Compare&, const Alloc&);

template<class Alloc> priority_queue(const Compare&, Container&&, const Alloc&);

template<class Alloc> priority_queue(const priority_queue&, const Alloc&);

template<class Alloc> priority_queue(priority_queue&&, const Alloc&);

[[nodiscard]] bool empty() const { return c.empty(); }

size_type size() const { return c.size(); }

top() const { return c.front(); }

push(const value_type& x);

push(value_type&& x);

template<class... Args> emplace(Args&&... args);

pop();

swap(priority_queue& q) noexcept(is_nothrow_swappable_v<Container> &&
                     is_nothrow_swappable_v<Compare>)
  { using std::swap; swap(c, q.c); swap(comp, q.comp); }

};

template<class Compare, class Container>
  priority_queue(Compare, Container)
  -> priority_queue<typename Container::value_type, Container, Compare>;

template<class InputIterator,  
         class Compare = less<typename iterator_traits<InputIterator>::value_type>,  
         class Container = vector<typename iterator_traits<InputIterator>::value_type>>
  priority_queue(InputIterator, InputIterator, Compare = Compare(), Container = Container())
  -> priority_queue<typename iterator_traits<InputIterator>::value_type, Container, Compare>;

template<class Compare, class Container, class Allocator>
  priority_queue(Compare, Container, Allocator)
  -> priority_queue<typename Container::value_type, Container, Compare>;

// no equality is provided

template<class T, class Container, class Compare>
  swap(priority_queue<T, Container, Compare>& x,  
        priority_queue<T, Container, Compare>& y) noexcept(noexcept(x.swap(y)));

template<class T, class Container, class Compare, class Alloc>
  struct uses_allocator<priority_queue<T, Container, Compare>, Alloc>  
  : uses_allocator<Container, Alloc>::type { };
Effects: Initializes comp with x and c with y (copy constructing or move constructing as appropriate); calls c.insert(c.end(), first, last); and finally calls make_heap(c.begin(), c.end(), comp).

21.6.5.3 Constructors with allocators

If uses_allocator_v<container_type, Alloc> is false the constructors in this subclause shall not participate in overload resolution.

```cpp
template<class Alloc> explicit priority_queue(const Alloc& a);
Effects: Initializes c with a and value-initializes comp.
```

```cpp
template<class Alloc> priority_queue(const Compare& compare, const Alloc& a);
Effects: Initializes c with a and initializes comp with compare.
```

```cpp
template<class Alloc>
priority_queue(const Compare& compare, const Container& cont, const Alloc& a);
Effects: Initializes c with cont as the first argument and a as the second argument, and initializes comp with compare; calls make_heap(c.begin(), c.end(), comp).
```

```cpp
template<class Alloc>
priority_queue(const Compare& compare, Container&& cont, const Alloc& a);
Effects: Initializes c with std::move(cont) as the first argument and a as the second argument, and initializes comp with compare; calls make_heap(c.begin(), c.end(), comp).
```

```cpp
template<class Alloc> priority_queue(const priority_queue& q, const Alloc& a);
Effects: Initializes c with q.c as the first argument and a as the second argument, and initializes comp with q.comp.
```

```cpp
template<class Alloc> priority_queue(priority_queue&& q, const Alloc& a);
Effects: Initializes c with std::move(q.c) as the first argument and a as the second argument, and initializes comp with std::move(q.comp).
```

21.6.5.4 Members

```cpp
void push(const value_type& x);
Effects: As if by:
c.push_back(x);
push_heap(c.begin(), c.end(), comp);
```

```cpp
void push(value_type&& x);
Effects: As if by:
c.push_back(std::move(x));
push_heap(c.begin(), c.end(), comp);
```

```cpp
template<class... Args> void emplace(Args&&... args)
Effects: As if by:
c.emplace_back(std::forward<Args>(args)...);
push_heap(c.begin(), c.end(), comp);
```

```cpp
void pop();
Effects: As if by:
pop_heap(c.begin(), c.end(), comp);
c.pop_back();
```

21.6.5.5 Specialized algorithms

```cpp
template<class T, class Container, class Compare>
void swap(priority_queue<T, Container, Compare>& x,}
```
priority_queue<T, Container, Compare>& y) noexcept(noexcept(x.swap(y)));  

Remarks: This function shall not participate in overload resolution unless is_swappable_v<Container> is true and is_swappable_v<Compare> is true.

Effects: As if by x.swap(y).

21.6.6 Class template stack

Any sequence container supporting operations back(), push_back() and pop_back() can be used to instantiate stack. In particular, vector (21.3.11), list (21.3.10) and deque (21.3.8) can be used.

21.6.6.1 Definition

namespace std {
    template<class T, class Container = deque<T>>
    class stack {
        public:
            using value_type = typename Container::value_type;
            using reference = typename Container::reference;
            using const_reference = typename Container::const_reference;
            using size_type = typename Container::size_type;
            using container_type = Container;

            protected:
                Container c;

            public:
                stack() : stack(Container()) {}
                explicit stack(const Container&);
                explicit stack(Container&&);
                template<class Alloc> explicit stack(const Alloc&);
                template<class Alloc> stack(const Container&, const Alloc&);
                template<class Alloc> stack(Container&&, const Alloc&);
                template<class Alloc> stack(const stack&, const Alloc&);
                template<class Alloc> stack(stack&&, const Alloc&);

                [[nodiscard]] bool empty() const { return c.empty(); }
                size_type size() const { return c.size(); }
                reference top() { return c.back(); }
                const_reference top() const { return c.back(); }
                void push(const value_type& x) { c.push_back(x); }
                void push(value_type&& x) { c.push_back(std::move(x)); }
                template<class... Args>
                    decltype(auto) emplace(Args&&... args)
                    { return c.emplace_back(std::forward<Args>(args)...); }
                void pop() { c.pop_back(); }
                void swap(stack& s) noexcept(is_nothrow_swappable_v<Container>)
                    { using std::swap; swap(c, s.c); }
            };

    template<class Container>
        stack(Container) -> stack<typename Container::value_type, Container>;

    template<class Container, class Allocator>
        stack(Container, Allocator) -> stack<typename Container::value_type, Container>;

    template<class T, class Container, class Alloc>
        struct uses_allocator<stack<T, Container>, Alloc>
            : uses_allocator<Container, Alloc>::type { };}

21.6.6.2 Constructors

explicit stack(const Container& cont);

Effects: Initializes c with cont.
explicit stack(Container&& cont);  
Effects: Initializes c with std::move(cont).

21.6.6.3 Constructors with allocators  
[stack.cons.alloc]

1 If uses_allocator_v<container_type, Alloc> is false the constructors in this subclause shall not participate in overload resolution.

template<class Alloc> explicit stack(const Alloc& a);
Effects: Initializes c with a.

template<class Alloc> stack(const container_type& cont, const Alloc& a);
Effects: Initializes c with cont as the first argument and a as the second argument.

template<class Alloc> stack(container_type&& cont, const Alloc& a);
Effects: Initializes c with std::move(cont) as the first argument and a as the second argument.

template<class Alloc> stack(const stack& s, const Alloc& a);
Effects: Initializes c with s.c as the first argument and a as the second argument.

template<class Alloc> stack(stack&& s, const Alloc& a);
Effects: Initializes c with std::move(s.c) as the first argument and a as the second argument.

21.6.6.4 Operators  
[stack.ops]

template<class T, class Container>
bool operator==(const stack<T, Container>& x, const stack<T, Container>& y);
Returns: x.c == y.c.

template<class T, class Container>
bool operator!=(const stack<T, Container>& x, const stack<T, Container>& y);
Returns: x.c != y.c.

template<class T, class Container>
bool operator< (const stack<T, Container>& x, const stack<T, Container>& y);
Returns: x.c < y.c.

template<class T, class Container>
bool operator> (const stack<T, Container>& x, const stack<T, Container>& y);
Returns: x.c > y.c.

template<class T, class Container>
bool operator<=(const stack<T, Container>& x, const stack<T, Container>& y);
Returns: x.c <= y.c.

template<class T, class Container>
bool operator>=(const stack<T, Container>& x, const stack<T, Container>& y);
Returns: x.c >= y.c.

21.6.6.5 Specialized algorithms  
[stack.special]

template<class T, class Container>
void swap(stack<T, Container>& x, stack<T, Container>& y) noexcept(noexcept(x.swap(y)));  
Remarks: This function shall not participate in overload resolution unless is_swappable_v<Container> is true.
Effects: As if by x.swap(y).

21.7 Views  
[views]

21.7.1 General  
[views.general]

The header <span> defines the view span.
21.7.2 Header <span> synopsis

    template<class ElementType, ptrdiff_t Extent>
    span<byte, Extent == dynamic_extent ? dynamic_extent :
    (static_cast<ptrdiff_t>(sizeof(ElementType)) * Extent)> as_writable_bytes(span<ElementType, Extent> s) noexcept;

} // namespace std

21.7.3 Class template span

21.7.3.1 Overview

1 A span is a view over a contiguous sequence of objects, the storage of which is owned by some other object.

2 ElementType is required to be a complete object type that is not an abstract class type.

3 If Extent is negative and not equal to dynamic_extent, the program is ill-formed.

4 The iterator types span::iterator and span::const_iterator are random access iterators (22.2.7), contiguous iterators (22.2.1), and constexpr iterators (22.2.1). All requirements on container iterators (21.2) apply to span::iterator and span::const_iterator as well.

5 All member functions of span have constant time complexity.

namespace std {

    template<class ElementType, ptrdiff_t Extent = dynamic_extent>
    class span {

    public:

        // constants and types
        using element_type = ElementType;
        using value_type = remove_cv_t<ElementType>;
        using index_type = ptrdiff_t;
        using difference_type = ptrdiff_t;
        using pointer = element_type*;
        using reference = element_type&;
        using iterator = implementation-defined;
        using const_iterator = implementation-defined;
        using reverse_iterator = std::reverse_iterator<iterator>;

} // namespace std

§ 21.7.3.1
using const_reverse_iterator = std::reverse_iterator<const_iterator>;
static constexpr index_type extent = Extent;

template<class Container>
span(const Container&) -> span<const typename Container::value_type>;

21.7.3.2 Constructors, copy, and assignment

constexpr span() noexcept;

Ensures: size() == 0 && data() == nullptr.

Remarks: This constructor shall not participate in overload resolution unless Extent <= 0 is true.

constexpr span(pointer ptr, index_type count);

Requires: [ptr, ptr + count) shall be a valid range. If extent is not equal to dynamic_extent, then count shall be equal to extent.

Effects: Constructs a span that is a view over the range [ptr, ptr + count).

Ensures: size() == count && data() == ptr.

Throws: Nothing.

constexpr span(pointer first, pointer last);

Requires: [first, last) shall be a valid range. If extent is not equal to dynamic_extent, then last - first shall be equal to extent.

Effects: Constructs a span that is a view over the range [first, last).

Ensures: size() == last - first && data() == first.

Throws: Nothing.

template<size_t N> constexpr span(element_type (&arr)[N]) noexcept;

template<size_t N> constexpr span(array<value_type, N>& arr) noexcept;

template<size_t N> constexpr span(const array<value_type, N>& arr) noexcept;

Effects: Constructs a span that is a view over the supplied array.

Ensures: size() == N && data() == data(arr).

Remarks: These constructors shall not participate in overload resolution unless:

- extent == dynamic_extent || N == extent is true, and
- remove_pointer_t<decltype(data(arr))>(*)[] is convertible to ElementType(*)[].

template<class Container> constexpr span(Container& cont);

template<class Container> constexpr span(const Container& cont);

Requires: [data(cont), data(cont) + size(cont)) shall be a valid range. If extent is not equal to dynamic_extent, then size(cont) shall be equal to extent.

Effects: Constructs a span that is a view over the range [data(cont), data(cont) + size(cont)).

Ensures: size() == size(cont) && data() == data(cont).

Throws: What and when data(cont) and size(cont) throw.

Remarks: These constructors shall not participate in overload resolution unless:

- Container is not a specialization of span,
- Container is not a specialization of array,
- is_array_v<Container> is false,
- data(cont) and size(cont) are both well-formed, and
— remove_pointer_t<decltype(data(cont))>(*)[] is convertible to ElementType(*)[].

constexpr span(const span& other) noexcept = default;

Ensures: other.size() == size() & other.data() == data().

template<class OtherElementType, ptrdiff_t OtherExtent>
constexpr span(const span<OtherElementType, OtherExtent>& s) noexcept;

Effects: Constructs a span that is a view over the range [s.data(), s.data() + s.size()).

Ensures: size() == s.size() & data() == s.data().

Remarks: This constructor shall not participate in overload resolution unless:

— Extent == dynamic_extent || Extent == OtherExtent is true, and

— OtherElementType(*)[] is convertible to ElementType(*)[].

constexpr span& operator=(const span& other) noexcept = default;

Ensures: size() == other.size() & data() == other.data().

21.7.3.3 Subviews

template<ptrdiff_t Count> constexpr span<element_type, Count> first() const;

Requires: 0 <= Count && Count <= size().

Effects: Equivalent to: return {data(), Count};

template<ptrdiff_t Count> constexpr span<element_type, Count> last() const;

Requires: 0 <= Count && Count <= size().

Effects: Equivalent to: return {data() + (size() - Count), Count};

template<ptrdiff_t Offset, ptrdiff_t Count = dynamic_extent>
constexpr span<element_type, see below> subspan() const;

Requires:

(0 <= Offset && Offset <= size())
&& (Count == dynamic_extent || Count >= 0 && Offset + Count <= size())

Effects: Equivalent to:

return span<ElementType, see below>(
    data() + Offset, Count != dynamic_extent ? Count : size() - Offset);

Remarks: The second template argument of the returned span type is:

Count != dynamic_extent ? Count :
    (Extent != dynamic_extent ? Extent - Offset :
        dynamic_extent)

constexpr span<element_type, dynamic_extent> first(index_type count) const;

Requires: 0 <= count && count <= size().

Effects: Equivalent to: return {data(), count};

constexpr span<element_type, dynamic_extent> last(index_type count) const;

Requires: 0 <= count 0 && count <= size().

Effects: Equivalent to: return {data() + (size() - count), count};

constexpr span<element_type, dynamic_extent> subspan(
    index_type offset, index_type count = dynamic_extent) const;

Requires:

(0 <= offset && offset <= size())
&& (count == dynamic_extent || count >= 0 && offset + count <= size())

Effects: Equivalent to:

return {data() + offset, count == dynamic_extent ? size() - offset : count};
21.7.3.4 Observers

constexpr index_type size() const noexcept;
  Effects: Equivalent to: return size_;
constexpr index_type size_bytes() const noexcept;
  Effects: Equivalent to: return size() * sizeof(element_type);
constexpr bool empty() const noexcept;
  Effects: Equivalent to: return size() == 0;

21.7.3.5 Element access

constexpr reference operator[](index_type idx) const;
constexpr reference operator()(index_type idx) const;
  Requires: 0 <= idx && idx < size().
  Effects: Equivalent to: return *(data() + idx);
constexpr pointer data() const noexcept;
  Effects: Equivalent to: return data_;

21.7.3.6 Iterator support

constexpr iterator begin() const noexcept;
  Returns: An iterator referring to the first element in the span. If empty() is true, then it returns the same value as end().
constexpr iterator end() const noexcept;
  Returns: An iterator which is the past-the-end value.
constexpr reverse_iterator rbegin() const noexcept;
  Effects: Equivalent to: return reverse_iterator(end());
constexpr reverse_iterator rend() const noexcept;
  Returns: Equivalent to: return reverse_iterator(begin());
constexpr const_iterator cbegin() const noexcept;
  Returns: A constant iterator referring to the first element in the span. If empty() is true, then it returns the same value as cend().
constexpr const_iterator cend() const noexcept;
  Returns: A constant iterator which is the past-the-end value.
constexpr const_reverse_iterator crbegin() const noexcept;
  Effects: Equivalent to: return const_reverse_iterator(cend());
constexpr const_reverse_iterator crend() const noexcept;
  Effects: Equivalent to: return const_reverse_iterator(cbegin());

21.7.3.7 Comparison operators

template<class T, ptrdiff_t X, class U, ptrdiff_t Y>
constexpr bool operator==(span<T, X> l, span<U, Y> r);
  Effects: Equivalent to: return equal(l.begin(), l.end(), r.begin(), r.end());
template<class T, ptrdiff_t X, class U, ptrdiff_t Y>
constexpr bool operator!=(span<T, X> l, span<U, Y> r);
  Effects: Equivalent to: return !(l == r);
template<class T, ptrdiff_t X, class U, ptrdiff_t Y>
constexpr bool operator<(span<T, X> l, span<U, Y> r);

Effects: Equivalent to:
return lexicographical_compare(l.begin(), l.end(), r.begin(), r.end());

template<class T, ptrdiff_t X, class U, ptrdiff_t Y>
constexpr bool operator>(span<T, X> l, span<U, Y> r);

Effects: Equivalent to: return (r < l);

template<class T, ptrdiff_t X, class U, ptrdiff_t Y>
constexpr bool operator<=(span<T, X> l, span<U, Y> r);

Effects: Equivalent to: return !(r < l);

template<class T, ptrdiff_t X, class U, ptrdiff_t Y>
constexpr bool operator>=(span<T, X> l, span<U, Y> r);

Effects: Equivalent to: return !(l < r);

21.7.3.8 Views of object representation
[span.objectrep]

template <class ElementType, ptrdiff_t Extent>
span<const byte, Extent == dynamic_extent ? dynamic_extent : static_cast<ptrdiff_t>(sizeof(ElementType)) * Extent>
as_bytes(span<ElementType, Extent> s) noexcept;

Effects: Equivalent to: return {reinterpret_cast<const byte*>(s.data()), s.size_bytes()};

template<class ElementType, ptrdiff_t Extent>
span<byte, Extent == dynamic_extent ? dynamic_extent : static_cast<ptrdiff_t>(sizeof(ElementType)) * Extent>
as_writable_bytes(span<ElementType, Extent> s) noexcept;

Effects: Equivalent to: return {reinterpret_cast<byte*>(s.data()), s.size_bytes()};

Remarks: This function shall not participate in overload resolution unless is_const_v<ElementType> is false.
22 Iterators library

22.1 General

This Clause describes components that C++ programs may use to perform iterations over containers (Clause 21), streams (27.7), and stream buffers (27.6).

The following subclauses describe iterator requirements, and components for iterator primitives, predefined iterators, and stream iterators, as summarized in Table 73.

Table 73 — Iterators library summary

<table>
<thead>
<tr>

<td>Predefined iterators</td>
</tr>
<tr>
<td>22.6</td>
<td>Stream iterators</td>
</tr>
</tbody>
</table>

22.2 Iterator requirements

Iterators are a generalization of pointers that allow a C++ program to work with different data structures (containers) in a uniform manner. To be able to construct template algorithms that work correctly and efficiently on different types of data structures, the library formalizes not just the interfaces but also the semantics and complexity assumptions of iterators. An input iterator \( i \) supports the expression \( *i \), resulting in a value of some object type \( T \), called the value type of the iterator. An output iterator \( i \) has a non-empty set of types that are writable to the iterator; for each such type \( T \), the expression \( *i = o \) is valid where \( o \) is a value of type \( T \). An iterator \( i \) for which the expression \( (*i).m \) is well-defined supports the expression \( i->m \) with the same semantics as \( (*i).m \). For every iterator type \( X \) for which equality is defined, there is a corresponding signed integer type called the difference type of the iterator.

Since iterators are an abstraction of pointers, their semantics is a generalization of most of the semantics of pointers in C++. This ensures that every function template that takes iterators works as well with regular pointers. This document defines five categories of iterators, according to the operations defined on them: input iterators, output iterators, forward iterators, bidirectional iterators and random access iterators, as shown in Table 74.

Table 74 — Relations among iterator categories

<table>
<thead>
<tr>
<th>Random Access</th>
<th>Bidirectional</th>
<th>Forward</th>
<th>Input</th>
<th>Output</th>
</tr>
</thead>
</table>

Forward iterators satisfy all the requirements of input iterators and can be used whenever an input iterator is specified; Bidirectional iterators also satisfy all the requirements of forward iterators and can be used whenever a forward iterator is specified; Random access iterators also satisfy all the requirements of bidirectional iterators and can be used whenever a bidirectional iterator is specified.

Iterators that further satisfy the requirement that, for integral values \( n \) and dereferenceable iterator values \( a \) and \( (a + n) \), \( *(a + n) \) is equivalent to \( *(addressof(*a) + n) \), are called contiguous iterators. [Note: For example, the type “pointer to int” is a contiguous iterator, but reverse_iterator<int *> is not. — end note]

§ 22.2.1
For a valid iterator range \([a, b)\) with dereferenceable \(a\), the corresponding range denoted by pointers is 
\[
 \text{addressof(*a), addressof(*a) + (b - a)); b might not be dereferenceable. — end note}
\]

Just as a regular pointer to an array guarantees that there is a pointer value pointing past the last element of the array, so for any iterator type there is an iterator value that points past the last element of a corresponding sequence. These values are called *past-the-end* values. Values of an iterator \(i\) for which the expression \(*i\) is defined are called *dereferenceable*. The library never assumes that past-the-end values are dereferenceable. Iterators can also have singular values that are not associated with any sequence. [Example: After the declaration of an uninitialized pointer \(x\) (as with \(\text{int* x;}\)), \(x\) must always be assumed to have a singular value of a pointer. — end example] Results of most expressions are undefined for singular values; the only exceptions are destroying an iterator that holds a singular value, the assignment of a non-singular value to an iterator that holds a singular value, and, for iterators that satisfy the \(\text{Cpp17DefaultConstructible}\) requirements, using a value-initialized iterator as the source of a copy or move operation. [Note: This guarantee is not offered for default-initialization, although the distinction only matters for types with trivial default constructors such as pointers or aggregates holding pointers. — end note] In these cases the singular value is overwritten the same way as any other value. Dereferenceable values are always non-singular.

An iterator \(j\) is called *reachable* from an iterator \(i\) if and only if there is a finite sequence of applications of the expression ++\(i\) that makes \(i == j\). If \(j\) is reachable from \(i\), they refer to elements of the same sequence.

Most of the library’s algorithmic templates that operate on data structures have interfaces that use ranges. A range is a pair of iterators that designate the beginning and end of the computation. A range \([i, j)\) is an empty range; in general, a range \([i, j)\) refers to the elements in the data structure starting with the element pointed to by \(i\) and up to but not including the element pointed to by \(j\). Range \([i, j)\) is valid if and only if \(j\) is reachable from \(i\). The result of the application of functions in the library to invalid ranges is undefined.

All the categories of iterators require only those functions that are realizable for a given category in constant time (amortized). Therefore, requirement tables for the iterators do not have a complexity column.

Destruction of an iterator may invalidate pointers and references previously obtained from that iterator.

An *invalid* iterator is an iterator that may be singular.\(^{235}\)

Iterators are called *constexpr iterators* if all operations provided to satisfy iterator category operations are constexpr functions, except for

\[\text{(13.1)}\]

— a pseudo-destructor call \((7.6.1.4)\), and

\[\text{(13.2)}\]

— the construction of an iterator with a singular value.

[Note: For example, the types “pointer to int” and \(\text{reverse_iterator<int*>}\) are constexpr iterators. — end note]

In the following subclauses, \(a\) and \(b\) denote values of type \(X\) or \(\text{const } X\), \(\text{difference_type}\) and \(\text{reference}\) refer to the types \(\text{iterator_traits<}\text{X>:::difference_type}\) and \(\text{iterator_traits<}\text{X>:::reference}\), respectively, \(n\) denotes a value of \(\text{difference_type}\), \(u, t, m, r\) denote identifiers, \(x, t\) denotes a value of type \(T\), \(o\) denotes a value of some type that is writable to the output iterator. [Note: For an iterator type \(X\) there must be an instantiation of \(\text{iterator_traits<}\text{X}>\) \((22.4.1)\). — end note]

### 22.2.2 \(\text{Cpp17Iterator}\)

The \(\text{Cpp17Iterator}\) requirements form the basis of the iterator taxonomy; every iterator satisfies the \(\text{Cpp17Iterator}\) requirements. This set of requirements specifies operations for dereferencing and incrementing an iterator. Most algorithms will require additional operations to read \((22.2.3)\) or write \((22.2.4)\) values, or to provide a richer set of iterator movements \((22.2.5, 22.2.6, 22.2.7)\).

A type \(X\) satisfies the \(\text{Cpp17Iterator}\) requirements if:

\[\text{(2.1)}\]

— \(X\) satisfies the \(\text{Cpp17CopyConstructible}, \text{Cpp17CopyAssignable}, \text{and Cpp17Destructible}\) requirements \((15.5.3.1)\) and \(1\)values of type \(X\) are swappable \((15.5.3.2)\), and

\[\text{(2.2)}\]

— the expressions in Table 75 are valid and have the indicated semantics.

---

\(^{235}\) This definition applies to pointers, since pointers are iterators. The effect of dereferencing an iterator that has been invalidated is undefined.
Table 75 — Cpp17Iterator requirements

<td></td>
<td></td>
</tr>
</tbody>
</table>

22.2.3 Input iterators

A class or pointer type X satisfies the requirements of an input iterator for the value type T if X satisfies the Cpp17Iterator (22.2.2) and Cpp17EqualityComparable (Table 22) requirements and the expressions in Table 76 are valid and have the indicated semantics.

In Table 76, the term the domain of == is used in the ordinary mathematical sense to denote the set of values over which == is (required to be) defined. This set can change over time. Each algorithm places additional requirements on the domain of == for the iterator values it uses. These requirements can be inferred from the uses that algorithm makes of == and !=. [Example: The call find(a,b,x) is defined only if the value of a has the property p defined as follows: b has property p and a value i has property p if (*i==x) or if (*i!=x and ++i has property p). — end example]

Table 76 — Cpp17InputIterator requirements (in addition to Cpp17Iterator)

<td>If a == b and (a, b) is in the domain of == then *a is equivalent to *b.</td>
</tr>
<tr>
<td>a-&gt;m</td>
<td></td>
<td>(*a).m</td>
<td>Requires: a is dereferenceable.</td>
</tr>
<tr>
<td>++r</td>
<td>x&amp;</td>
<td></td>
<td>Requires: r is dereferenceable. Ensures: r is dereferenceable or r is past-the-end; any copies of the previous value of r are no longer required to be dereferenceable nor to be in the domain of ==.</td>
</tr>
<tr>
<td>(void)r++</td>
<td>equivalent to (void)++r</td>
<td></td>
<td></td>
</tr>
<tr>
<td>*r++</td>
<td>convertible to T</td>
<td>{ T tmp = *r; ++r; return tmp; }</td>
<td></td>
</tr>
</tbody>
</table>

[Note: For input iterators, a == b does not imply ++a == ++b. (Equality does not guarantee the substitution property or referential transparency.) Algorithms on input iterators should never attempt to pass through the same iterator twice. They should be single pass algorithms. Value type T is not required to be a Cpp17CopyAssignable type (Table 28). These algorithms can be used with istreams as the source of the input data through the istream_iterator class template. — end note]
22.2.4 Output iterators

A class or pointer type \( X \) satisfies the requirements of an output iterator if \( X \) satisfies the \texttt{Cpp17Iterator} requirements (22.2.2) and the expressions in Table 77 are valid and have the indicated semantics.

Table 77 — \texttt{Cpp17OutputIterator} requirements (in addition to \texttt{Cpp17Iterator})

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note</th>
</tr>
</thead>
<tbody>
<tr>
<td>(*r = o)</td>
<td>result is not used</td>
<td>Remarks: After this operation ( r ) is not required to be dereferenceable. Ensures: ( r ) is incrementable.</td>
<td></td>
</tr>
<tr>
<td>(++r)</td>
<td>( X &amp; )</td>
<td>&amp;( r ) == &amp;( ++r ). Remarks: After this operation ( r ) is not required to be dereferenceable. Ensures: ( r ) is incrementable.</td>
<td></td>
</tr>
<tr>
<td>(r++)</td>
<td>convertible to const ( X &amp; ) ( { X \ tmp = r; \ ++r; \ return \ tmp; } )</td>
<td>Remarks: After this operation ( r ) is not required to be dereferenceable. Ensures: ( r ) is incrementable.</td>
<td></td>
</tr>
<tr>
<td>(*r++ = o)</td>
<td>result is not used</td>
<td>Remarks: After this operation ( r ) is not required to be dereferenceable. Ensures: ( r ) is incrementable.</td>
<td></td>
</tr>
</tbody>
</table>

2 [Note: The only valid use of an \texttt{operator*} is on the left side of the assignment statement. \textit{Assignment through the same value of the iterator happens only once.} Algorithms on output iterators should never attempt to pass through the same iterator twice. They should be \textit{single pass} algorithms. Equality and inequality might not be defined. — end note]

22.2.5 Forward iterators

A class or pointer type \( X \) satisfies the requirements of a forward iterator if

1. \( X \) satisfies the \texttt{Cpp17InputIterator} requirements (22.2.3),
2. \( X \) satisfies the \texttt{Cpp17DefaultConstructible} requirements (15.5.3.1),
3. if \( X \) is a mutable iterator, \texttt{reference} is a reference to \( T \); if \( X \) is a constant iterator, \texttt{reference} is a reference to const \( T \),
4. the expressions in Table 78 are valid and have the indicated semantics, and
5. objects of type \( X \) offer the multi-pass guarantee, described below.

The domain of == for forward iterators is that of iterators over the same underlying sequence. However, value-initialized iterators may be compared and shall compare equal to other value-initialized iterators of the same type. [Note: Value-initialized iterators behave as if they refer past the end of the same empty sequence. — end note]

Two dereferenceable iterators \( a \) and \( b \) of type \( X \) offer the \textit{multi-pass guarantee} if:

1. \( a == b \) implies \(+a == +b \) and
2. \( X \) is a pointer type or the expression (\texttt{void})\(+X(a)\), \(*a\) is equivalent to the expression \(*a\).

3 [Note: The requirement that \( a == b \) implies \(+a == +b \) (which is not true for input and output iterators) and the removal of the restrictions on the number of the assignments through a mutable iterator (which applies to output iterators) allows the use of multi-pass one-directional algorithms with forward iterators. — end note]
Table 78 — `Cpp17ForwardIterator` requirements (in addition to `Cpp17InputIterator`)

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note pre-/post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>r++</code></td>
<td>convertible to <code>const X&amp;</code></td>
<td><code>{ X tmp = r;</code> <code>const X&amp; ++r;</code> <code>return tmp; }</code></td>
<td></td>
</tr>
<tr>
<td><code>*r++</code></td>
<td>reference</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5 If `a` and `b` are equal, then either `a` and `b` are both dereferenceable or else neither is dereferenceable.

6 If `a` and `b` are both dereferenceable, then `a == b` if and only if `*a` and `*b` are bound to the same object.

22.2.6 Bidirectional iterators

A class or pointer type `X` satisfies the requirements of a bidirectional iterator if, in addition to satisfying the `Cpp17ForwardIterator` requirements, the following expressions are valid as shown in Table 79.

Table 79 — `Cpp17BidirectionalIterator` requirements (in addition to `Cpp17ForwardIterator`)

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Operational semantics</th>
<th>Assertion/note pre-/post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--r</code></td>
<td><code>X&amp;</code></td>
<td></td>
<td>Requires: there exists <code>s</code> such that <code>r == ++s</code>. Ensures: <code>r</code> is dereferenceable. <code>--(++r) == r</code> <code>--r == --s</code> implies <code>r == s</code>. <code>&amp;r == &amp;--r</code></td>
</tr>
<tr>
<td><code>r--</code></td>
<td>convertible to <code>const X&amp;</code></td>
<td><code>{ X tmp = r;</code> <code>const X&amp; --r;</code> <code>return tmp; }</code></td>
<td></td>
</tr>
<tr>
<td><code>*r--</code></td>
<td>reference</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

2 [Note: Bidirectional iterators allow algorithms to move iterators backward as well as forward. — end note]

22.2.7 Random access iterators

A class or pointer type `X` satisfies the requirements of a random access iterator if, in addition to satisfying the `Cpp17BidirectionalIterator` requirements, the following expressions are valid as shown in Table 80.

Table 80 — `Cpp17RandomAccessIterator` requirements (in addition to `Cpp17BidirectionalIterator`)

<table>
<thead>
<tr>

// 22.6, stream iterators

// 22.7, range access
22.4 Iterator primitives

To simplify the task of defining iterators, the library provides several classes and functions:

22.4.1 Iterator traits

To implement algorithms only in terms of iterators, it is often necessary to determine the value and difference types that correspond to a particular iterator type. Accordingly, it is required that if Iterator is the type of an iterator, the types

```cpp
iterator_traits<Iterator>::difference_type
iterator_traits<Iterator>::value_type
iterator_traits<Iterator>::iterator_category
```

be defined as the iterator’s difference type, value type and iterator category, respectively. In addition, the types

```cpp
iterator_traits<Iterator>::reference
iterator_traits<Iterator>::pointer
```

shall be defined as the iterator’s reference and pointer types, that is, for an iterator object `a`, the same type as the type of `*a` and `a->`, respectively. In the case of an output iterator, the types

```cpp
iterator_traits<Iterator>::difference_type
iterator_traits<Iterator>::value_type
iterator_traits<Iterator>::reference
iterator_traits<Iterator>::pointer
```

may be defined as void.

If Iterator has valid (12.9.2) member types difference_type, value_type, pointer, reference, and iterator_category, iterator_traits<Iterator> shall have the following as publicly accessible members:

```cpp
using difference_type = typename Iterator::difference_type;
using value_type = typename Iterator::value_type;
using pointer = typename Iterator::pointer;
using reference = typename Iterator::reference;
using iterator_category = typename Iterator::iterator_category;
```

Otherwise, iterator_traits<Iterator> shall have no members by any of the above names.

It is specialized for pointers as

```cpp
namespace std {
    template<class T> struct iterator_traits<T*> {
        using difference_type = ptrdiff_t;
        using value_type = remove_cv_t<T>;
        using pointer = T*;
        using reference = T;
        using iterator_category = random_access_iterator_tag;
    };
}
```

Example: To implement a generic reverse function, a C++ program can do the following:

```cpp
template<class BidirectionalIterator>
void reverse(BidirectionalIterator first, BidirectionalIterator last) {
    typename iterator_traits<BidirectionalIterator>::difference_type n = distance(first, last);
    --n;
}
```
while(n > 0) {
  typename iterator_traits<BidirectionalIterator>::value_type
tmp = *first;
  *first++ = ***last;
  *last = tmp;
  n -= 2;
}

— end example]

22.4.2 Standard iterator tags

It is often desirable for a function template specialization to find out what is the most specific category of its iterator argument, so that the function can select the most efficient algorithm at compile time. To facilitate this, the library introduces category tag classes which are used as compile time tags for algorithm selection. They are: input_iterator_tag, output_iterator_tag, forward_iterator_tag, bidirectional_iterator_tag and random_access_iterator_tag. For every iterator of type Iterator, iterator_traits<Iterator>::iterator_category shall be defined to be the most specific category tag that describes the iterator’s behavior.

namespace std {
  struct input_iterator_tag { }
  struct output_iterator_tag { }
  struct forward_iterator_tag: public input_iterator_tag { }
  struct bidirectional_iterator_tag: public forward_iterator_tag { }
  struct random_access_iterator_tag: public bidirectional_iterator_tag { }
}

[Example: For a program-defined iterator BinaryTreeIterator, it could be included into the bidirectional iterator category by specializing the iterator_traits template:

template<class T> struct iterator_traits<BinaryTreeIterator<T>> {
  using iterator_category = bidirectional_iterator_tag;
  using difference_type = ptrdiff_t;
  using value_type = T;
  using pointer = T*;
  using reference = T&;
};
— end example]

[Example: If evolve() is well-defined for bidirectional iterators, but can be implemented more efficiently for random access iterators, then the implementation is as follows:

template<class BidirectionalIterator>
inline void evolve(BidirectionalIterator first, BidirectionalIterator last) {
evolve(first, last,
  typename iterator_traits<BidirectionalIterator>::iterator_category());
}

template<class BidirectionalIterator>
void evolve(BidirectionalIterator first, BidirectionalIterator last,
  bidirectional_iterator_tag) {
  // more generic, but less efficient algorithm
}

template<class RandomAccessIterator>
void evolve(RandomAccessIterator first, RandomAccessIterator last,
  random_access_iterator_tag) {
  // more efficient, but less generic algorithm
}
— end example]
22.4.3 Iterator operations

Since only random access iterators provide + and − operators, the library provides two function templates advance and distance. These function templates use + and − for random access iterators (and are, therefore, constant time for them); for input, forward and bidirectional iterators they use ++ to provide linear time implementations.

```
template<class InputIterator, class Distance>  
constexpr void advance(InputIterator& i, Distance n);  
```

Requires: n shall be negative only for bidirectional and random access iterators.

Effects: Increments (or decrements for negative n) iterator reference i by n.

```
template<class InputIterator>  
constexpr typename iterator_traits<InputIterator>::difference_type  
distance(InputIterator first, InputIterator last);  
```

Effects: If InputIterator meets the Cpp17RandomAccessIterator requirements, returns (last − first); otherwise, returns the number of increments needed to get from first to last.

Requires: If InputIterator meets the Cpp17RandomAccessIterator requirements, last shall be reachable from first or first shall be reachable from last; otherwise, last shall be reachable from first.

```
template<class InputIterator>  
constexpr InputIterator next(InputIterator x,  
typename iterator_traits<InputIterator>::difference_type n = 1);  
```

Effects: Equivalent to: advance(x, n); return x;

```
template<class BidirectionalIterator>  
constexpr BidirectionalIterator prev(BidirectionalIterator x,  
typename iterator_traits<BidirectionalIterator>::difference_type n = 1);  
```

Effects: Equivalent to: advance(x, −n); return x;

22.5 Iterator adaptors

22.5.1 Reverse iterators

Class template reverse_iterator is an iterator adaptor that iterates from the end of the sequence defined by its underlying iterator to the beginning of that sequence. The fundamental relation between a reverse iterator and its corresponding iterator i is established by the identity: &*(reverse_iterator(i)) == &*(i − 1).

```
namespace std {  
    template<class Iterator>  
    class reverse_iterator {  
    public:  
        using iterator_type = Iterator;  
        using iterator_category = typename iterator_traits<Iterator>::iterator_category;  
        using value_type = typename iterator_traits<Iterator>::value_type;  
        using difference_type = typename iterator_traits<Iterator>::difference_type;  
        using pointer = typename iterator_traits<Iterator>::pointer;  
        using reference = typename iterator_traits<Iterator>::reference;  
        constexpr reverse_iterator();  
        constexpr explicit reverse_iterator(Iterator x);  
        template<class U> constexpr reverse_iterator(const reverse_iterator<U>& u);  
        template<class U> constexpr reverse_iterator& operator=(const reverse_iterator<U>& u);  
        constexpr Iterator base() const;  
        // explicit  
        constexpr reference operator*() const;  
        constexpr pointer operator->() const;  
    };  
};  
```

§ 22.5.1.1
22.5.1.2 reverse_iterator requirements

1 The template parameter Iterator shall satisfy all the requirements of a Cpp17BidirectionalIterator (22.2.6).

2 Additionally, Iterator shall satisfy the requirements of a Cpp17RandomAccessIterator (22.2.7) if any of the members operator+, operator-, operator++, operator-- (22.5.1.6), operator[] (22.5.1.5), or the non-member operators (22.5.1.7) operator<, operator>, operator<, operator>-, or operator+ (22.5.1.8) are referenced in a way that requires instantiation (12.8.1).

22.5.1.3 reverse_iterator construction and assignment

1 Effects: Value-initializes current. Iterator operations applied to the resulting iterator have defined
behavior if and only if the corresponding operations are defined on a value-initialized iterator of type `Iterator`.

```cpp
constexpr explicit reverse_iterator(Iterator x);
```

**Effects:** Initializes `current` with `x`.

```cpp
template<class U> constexpr explicit reverse_iterator(const reverse_iterator<U>& u);
```

**Effects:** Initializes `current` with `u.current`.

```cpp
template<class U>
constexpr reverse_iterator&
operator=(const reverse_iterator<U>& u);
```

**Effects:** Assigns `u.base()` to `current`.

**Returns:** *this.

### 22.5.1.4 Conversion [reverse.iter.conv]

```cpp
constexpr Iterator base() const;
```

**Returns:** `current`.

### 22.5.1.5 reverse_iterator element access [reverse.iter.elem]

```cpp
constexpr reference operator*() const;
```

**Effects:** As if by:

```cpp
Iterator tmp = current;
return *--tmp;
```

```cpp
constexpr pointer operator->() const;
```

**Returns:** `addressof(operator*())`.

```cpp
constexpr unspecified operator[](difference_type n) const;
```

**Returns:** `current[-n-1]`.

### 22.5.1.6 reverse_iterator navigation [reverse.iter.nav]

```cpp
constexpr reverse_iterator operator+(difference_type n) const;
```

**Returns:** `reverse_iterator(current-n)`.

```cpp
constexpr reverse_iterator operator-(difference_type n) const;
```

**Returns:** `reverse_iterator(current+n)`.

```cpp
constexpr reverse_iterator& operator++();
```

**Effects:** As if by:`--current`.

**Returns:** *this.

```cpp
constexpr reverse_iterator operator--(int);
```

**Effects:** As if by:

```cpp
reverse_iterator tmp = *this;
--current;
return tmp;
```

```cpp
constexpr reverse_iterator& operator--();
```

**Effects:** As if by `++current`.

**Returns:** *this.

```cpp
constexpr reverse_iterator operator--(int);
```

**Effects:** As if by:

```cpp
reverse_iterator tmp = *this;
```
constexpr reverse_iterator& operator+=(difference_type n);

Effects: As if by: current -= n;

Returns: *this.

constexpr reverse_iterator& operator-=(difference_type n);

Effects: As if by: current += n;

Returns: *this.

22.5.1.7 reverse_iterator comparisons

template<class Iterator1, class Iterator2>
constexpr bool operator==(const reverse_iterator<Iterator1>& x, const reverse_iterator<Iterator2>& y);

Returns: x.current == y.current.

template<class Iterator1, class Iterator2>
constexpr bool operator!=(const reverse_iterator<Iterator1>& x, const reverse_iterator<Iterator2>& y);

Returns: x.current != y.current.

template<class Iterator1, class Iterator2>
constexpr bool operator<(const reverse_iterator<Iterator1>& x, const reverse_iterator<Iterator2>& y);

Returns: x.current > y.current.

template<class Iterator1, class Iterator2>
constexpr bool operator<=(const reverse_iterator<Iterator1>& x, const reverse_iterator<Iterator2>& y);

Returns: x.current >= y.current.

template<class Iterator1, class Iterator2>
constexpr bool operator>=(const reverse_iterator<Iterator1>& x, const reverse_iterator<Iterator2>& y);

Returns: x.current <= y.current.

22.5.1.8 Non-member functions

template<class Iterator1, class Iterator2>
constexpr auto operator-(const reverse_iterator<Iterator1>& x, const reverse_iterator<Iterator2>& y) -> decltype(y.base() - x.base());

Returns: y.current - x.current.

§ 22.5.1.8
const reverse_iterator<Iterator>& x);

Returns: reverse_iterator<Iterator> (x.current - n).

template<class Iterator>
const reverse_iterator<Iterator> make_reverse_iterator(Iterator i);

Returns: reverse_iterator<Iterator>(i).

22.5.2 Insert iterators

To make it possible to deal with insertion in the same way as writing into an array, a special kind of iterator adaptors, called insert iterators, are provided in the library. With regular iterator classes,

while (first != last) *result++ = *first++;

causes a range [first, last) to be copied into a range starting with result. The same code with result being an insert iterator will insert corresponding elements into the container. This device allows all of the copying algorithms in the library to work in the insert mode instead of the regular overwrite mode.

An insert iterator is constructed from a container and possibly one of its iterators pointing to where insertion takes place if it is neither at the beginning nor at the end of the container. Insert iterators satisfy the requirements of output iterators. operator* returns the insert iterator itself. The assignment operator=(const T& x) is defined on insert iterators to allow writing into them, it inserts x right before where the insert iterator is pointing. In other words, an insert iterator is like a cursor pointing into the container where the insertion takes place. back_insert_iterator inserts elements at the end of a container, front_insert_iterator inserts elements at the beginning of a container, and insert_iterator inserts elements where the iterator points to in a container. back_inserter, front_inserter, and inserter are three functions making the insert iterators out of a container.

22.5.2.1 Class template back_insert_iterator

namespace std {
    template<class Container>
    class back_insert_iterator {
    protected:
        Container* container;

    public:
        using iterator_category = output_iterator_tag;
        using value_type = void;
        using difference_type = void;
        using pointer = void;
        using reference = void;
        using container_type = Container;

        explicit back_insert_iterator(Container& x);
        back_insert_iterator& operator=(const typename Container::value_type& value);
        back_insert_iterator& operator=(typename Container::value_type&& value);

        back_insert_iterator& operator*();
        back_insert_iterator& operator++();
        back_insert_iterator operator++(int);
    };
    template<class Container>
    back_insert_iterator<Container> back_inserter(Container& x);
}

22.5.2.1.1 back_insert_iterator operations

explicit back_insert_iterator(Container& x);

Effects: Initializes container with addressof(x).

back_insert_iterator& operator=(const typename Container::value_type& value);

Effects: As if by: container->push_back(value);

Returns: *this.
back_insert_iterator& operator=(typename Container::value_type&& value);

Effects: As if by: container->push_back(std::move(value));

Returns: *this.

back_insert_iterator& operator*();

Returns: *this.

back_insert_iterator& operator++();
back_insert_iterator operator++(int);

Returns: *this.

22.5.2.1.2 back_inserter

[back inserter]

template<class Container>
back_insert_iterator<Container> back_inserter(Container& x);

Returns: back_insert_iterator<Container>(x).

22.5.2.2 Class template front_insert_iterator

[front insert iterator]

namespace std {
    template<class Container>
    class front_insert_iterator {
    protected:
        Container* container;

    public:
        using iterator_category = output_iterator_tag;
        using value_type = void;
        using difference_type = void;
        using pointer = void;
        using reference = void;
        using container_type = Container;

        explicit front_insert_iterator(Container& x);
        front_insert_iterator& operator=(const typename Container::value_type& value);
        front_insert_iterator& operator=(typename Container::value_type&& value);
        front_insert_iterator& operator*();
        front_insert_iterator& operator++();
        front_insert_iterator operator++(int);
    }

    template<class Container>
    front_insert_iterator<Container> front_inserter(Container& x);
}

22.5.2.2.1 front_insert_iterator operations

[front insert iter ops]

explicit front_insert_iterator(Container& x);

Effects: Initializes container with addressof(x).

front_insert_iterator& operator=(const typename Container::value_type& value);

Effects: As if by: container->push_front(value);

Returns: *this.

front_insert_iterator& operator=(typename Container::value_type&& value);

Effects: As if by: container->push_front(std::move(value));

Returns: *this.

front_insert_iterator& operator*();

Returns: *this.
front_insert_iterator& operator++();
front_insert_iterator operator++(int);

Returns: *this.

22.5.2.2.2 front_inserter

template<class Container>
front_insert_iterator<Container> front_inserter(Container& x);

Returns: front_insert_iterator<Container>(x).

22.5.2.3 Class template insert_iterator

namespace std {
    template<class Container>
    class insert_iterator {
        protected:
            Container* container;
            typename Container::iterator iter;

        public:
            using iterator_category = output_iterator_tag;
            using value_type = void;
            using difference_type = void;
            using pointer = void;
            using reference = void;
            using container_type = Container;

            insert_iterator(Container& x, typename Container::iterator i);
            insert_iterator& operator=(const typename Container::value_type& value);
            insert_iterator& operator=(typename Container::value_type&& value);
            insert_iterator& operator*();
            insert_iterator& operator++();
            insert_iterator& operator++(int);
        };

        template<class Container>
        insert_iterator<Container> inserter(Container& x, typename Container::iterator i);
    }

22.5.2.3.1 insert_iterator operations

insert_iterator(Container& x, typename Container::iterator i);

Effects: Initializes container with addressof(x) and iter with i.

insert_iterator& operator=(const typename Container::value_type& value);

Effects: As if by:
iter = container->insert(iter, value);
++iter;

Returns: *this.

insert_iterator& operator=(typename Container::value_type&& value);

Effects: As if by:
iter = container->insert(iter, std::move(value));
++iter;

Returns: *this.

insert_iterator& operator*();

Returns: *this.

§ 22.5.2.3.1
insert_iterator& operator++();
insert_iterator& operator++(int);

Returns: *this.

22.5.2.3.2 inserter

template<class Container>
insert_iterator<Container> inserter(Container& x, typename Container::iterator i);

Returns: insert_iterator<Container>(x, i).

22.5.3 Move iterators

Class template move_iterator is an iterator adaptor with the same behavior as the underlying iterator except that its indirection operator implicitly converts the value returned by the underlying iterator’s indirection operator to an rvalue. Some generic algorithms can be called with move iterators to replace copying with moving.

[Example:

```cpp
list<string> s;
// populate the list s
vector<string> v1(s.begin(), s.end());  // copies strings into v1
vector<string> v2(make_move_iterator(s.begin()), make_move_iterator(s.end()));  // moves strings into v2
```
—end example]

22.5.3.1 Class template move_iterator

```cpp
namespace std {
    template<class Iterator>
    class move_iterator {
    public:
        using iterator_type = Iterator;
        using iterator_category = typename iterator_traits<Iterator>::iterator_category;
        using value_type = typename iterator_traits<Iterator>::value_type;
        using difference_type = typename iterator_traits<Iterator>::difference_type;
        using pointer = Iterator;
        using reference = see below;

        constexpr move_iterator();
        constexpr explicit move_iterator(Iterator i);
        template<class U> constexpr move_iterator(const move_iterator<U>& u);
        template<class U> constexpr move_iterator& operator=(const move_iterator<U>& u);

        constexpr iterator_type base() const;
        constexpr reference operator*() const;
        constexpr pointer operator->() const;
        constexpr move_iterator& operator++();
        constexpr move_iterator operator++(int);
        constexpr move_iterator& operator--();
        constexpr move_iterator operator--(int);

        constexpr move_iterator operator+(difference_type n) const;
        constexpr move_iterator& operator+=(difference_type n);
        constexpr move_iterator operator-(difference_type n) const;
        constexpr move_iterator& operator-=(difference_type n);
        constexpr unspecified operator[](difference_type n) const;

    private:
        Iterator current;  // exposition only
    };
```
template<class Iterator1, class Iterator2>
constexpr bool operator==(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

template<class Iterator1, class Iterator2>
constexpr bool operator!=(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

template<class Iterator1, class Iterator2>
constexpr bool operator<(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

template<class Iterator1, class Iterator2>
constexpr bool operator>(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

template<class Iterator1, class Iterator2>
constexpr bool operator<=(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

template<class Iterator1, class Iterator2>
constexpr bool operator>=(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

template<class Iterator1, class Iterator2>
constexpr auto operator- (const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y) -> decltype(x.base() - y.base());

template<class Iterator>
constexpr move_iterator<Iterator> operator+(typename move_iterator<Iterator>::difference_type n, const move_iterator<Iterator>& x);

template<class Iterator>
constexpr move_iterator<Iterator> make_move_iterator(Iterator i);

1 Let $R$ denote $\text{iterator_traits<Iterator>::reference}$. If is_reference_v<$R$> is true, the template specialization move_iterator<Iterator> shall define the nested type named reference as a synonym for remove_reference_t<$R$>&&, otherwise as a synonym for $R$.

### 22.5.3.2 move_iterator requirements

The template parameter $\text{Iterator}$ shall satisfy the Cpp17InputIterator requirements (22.2.3). Additionally, if any of the bidirectional or random access traversal functions are instantiated, the template parameter shall satisfy the Cpp17BidirectionalIterator requirements (22.2.6) or Cpp17RandomAccessIterator requirements (22.2.7), respectively.

### 22.5.3.3 move_iterator construction and assignment

constexpr move_iterator();

1 **Effects:** Constructs a move_iterator, value-initializing current. Iterator operations applied to the resulting iterator have defined behavior if and only if the corresponding operations are defined on a value-initialized iterator of type Iterator.

constexpr explicit move_iterator(Iterator i);

1 **Effects:** Constructs a move_iterator, initializing current with i.

template<class U> constexpr move_iterator(const move_iterator<U>& u);

1 **Effects:** Constructs a move_iterator, initializing current with u.base().

4 **Requires:** U shall be convertible to Iterator.

template<class U> constexpr move_iterator& operator=(const move_iterator<U>& u);

5 **Effects:** Assigns u.base() to current.

6 **Requires:** U shall be convertible to Iterator.

### 22.5.3.4 move_iterator conversion

constexpr Iterator base() const;

1 **Returns:** current.
22.5.3.5 move_iterator element access

constexpr reference operator*() const;

Returns: static_cast<reference>(*current).

constexpr pointer operator->() const;

Returns: current.

constexpr unspecified operator[](difference_type n) const;

Returns: std::move(current[n]).

22.5.3.6 move_iterator navigation

constexpr move_iterator& operator++();

Effects: As if by ++current.

Returns: *this.

constexpr move_iterator operator++(int);

Effects: As if by:

move_iterator tmp = *this;
++current;
return tmp;

constexpr move_iterator& operator--();

Effects: As if by --current.

Returns: *this.

constexpr move_iterator operator--(int);

Effects: As if by:

move_iterator tmp = *this;
--current;
return tmp;

constexpr move_iterator operator+(difference_type n) const;

Returns: move_iterator(current + n).

constexpr move_iterator& operator+=(difference_type n);

Effects: As if by: current += n;

Returns: *this.

constexpr move_iterator operator-(difference_type n) const;

Returns: move_iterator(current - n).

constexpr move_iterator& operator-=(difference_type n);

Effects: As if by: current -= n;

Returns: *this.

22.5.3.7 move_iterator comparisons

template<class Iterator1, class Iterator2>
constexpr bool operator==(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

Returns: x.base() == y.base().

template<class Iterator1, class Iterator2>
constexpr bool operator!=(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

Returns: !(x == y).
template<class Iterator1, class Iterator2>
constexpr bool operator<(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

Returns: x.base() < y.base().

template<class Iterator1, class Iterator2>
constexpr bool operator>(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

Returns: y < x.

template<class Iterator1, class Iterator2>
constexpr bool operator<=(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

Returns: !(y < x).

template<class Iterator1, class Iterator2>
constexpr bool operator>=(const move_iterator<Iterator1>& x, const move_iterator<Iterator2>& y);

Returns: !(x < y).

22.5.3.8 move_iterator non-member functions

template<class Iterator1, class Iterator2>
constexpr auto operator-(
    const move_iterator<Iterator1>& x,
    const move_iterator<Iterator2>& y) -> decltype(x.base() - y.base());

Returns: x.base() - y.base().

template<class Iterator>
constexpr move_iterator<Iterator> operator+(
    typename move_iterator<Iterator>::difference_type n, const move_iterator<Iterator>& x);

Returns: x + n.

template<class Iterator>
constexpr move_iterator<Iterator> make_move_iterator(Iterator i);

Returns: move_iterator<Iterator>(i).

22.6 Stream iterators

To make it possible for algorithmic templates to work directly with input/output streams, appropriate iterator-like class templates are provided.

[Example:
partial_sum(istream_iterator<double, char>(cin),
    istream_iterator<double, char>();//
    ostream_iterator<double, char>(cout, "\n"));
]
reads a file containing floating-point numbers from cin, and prints the partial sums onto cout. — end example

22.6.1 Class template istream_iterator

The class template istream_iterator is an input iterator (22.2.3) that reads (using operator>>) successive elements from the input stream for which it was constructed. After it is constructed, and every time ++ is used, the iterator reads and stores a value of T. If the iterator fails to read and store a value of T (fail() on the stream returns true), the iterator becomes equal to the end-of-stream iterator value. The constructor with no arguments istream_iterator() always constructs an end-of-stream input iterator object, which is the only legitimate iterator to be used for the end condition. The result of operator* on an end-of-stream iterator is not defined. For any other iterator value a const T& is returned. The result of operator-> on an end-of-stream iterator is not defined. For any other iterator value a const T* is returned. The behavior of a program that applies operator++() to an end-of-stream iterator is undefined. It is impossible to store things into istream iterators. The type T shall satisfy the Cpp17DefaultConstructible, Cpp17CopyConstructible, and Cpp17CopyAssignable requirements.

Two end-of-stream iterators are always equal. An end-of-stream iterator is not equal to a non-end-of-stream iterator. Two non-end-of-stream iterators are equal when they are constructed from the same stream.
namespace std {
    template<class T, class charT = char, class traits = char_traits<charT>,
             class Distance = ptrdiff_t>
    class istream_iterator {
    public:
    using iterator_category = input_iterator_tag;
    using value_type = T;
    using difference_type = Distance;
    using pointer = const T*;
    using reference = const T&;
    using char_type = charT;
    using traits_type = traits;
    using istream_type = basic_istream<charT, traits>;
    constexpr istream_iterator();
    istream_iterator(istream_type& s);
    istream_iterator(const istream_iterator& x) = default;
    ~istream_iterator() = default;
    istream_iterator& operator=(const istream_iterator&);
    const T& operator*() const;
    const T* operator->() const;
    istream_iterator& operator++();
    istream_iterator operator++(int);

    private:
    basic_istream<charT, traits>** in_stream; // exposition only
    T value; // exposition only
    }

    template<class T, class charT, class traits, class Distance>
    bool operator==(const istream_iterator<T, charT, traits, Distance>& x,
                    const istream_iterator<T, charT, traits, Distance>& y);

    template<class T, class charT, class traits, class Distance>
    bool operator!=(const istream_iterator<T, charT, traits, Distance>& x,
                    const istream_iterator<T, charT, traits, Distance>& y);
}

22.6.1.1 istream_iterator constructors and destructor

constexpr istream_iterator();

Effects: Constructs the end-of-stream iterator. If is_trivially_default_constructible_v<T> is true, then this constructor is a constexpr constructor.

Ensures: in_stream == 0.

istream_iterator(istream_type& s);

Effects: Initializes in_stream with addressof(s). value may be initialized during construction or the first time it is referenced.

Ensures: in_stream == addressof(s).

istream_iterator(const istream_iterator& x) = default;

Effects: Constructs a copy of x. If is_trivially_copy_constructible_v<T> is true, then this constructor is a trivial copy constructor.

Ensures: in_stream == x.in_stream.

~istream_iterator() = default;

Effects: The iterator is destroyed. If is_trivially_destructible_v<T> is true, then this destructor is trivial.

§ 22.6.1.1
22.6.1.2 istream_iterator operations

```cpp
const T& operator*() const;
```

Returns: value.

```cpp
const T* operator->() const;
```

Returns: addressof(operator*()).

```cpp
istream_iterator& operator++();
```

Requires: in_stream != 0.

Effects: As if by: *in_stream >> value;

Returns: *this.

```cpp
istream_iterator operator++(int);
```

Requires: in_stream != 0.

Effects: As if by:

```cpp
istream_iterator tmp = *this;
*in_stream >> value;
return (tmp);
```

template<class T, class charT, class traits, class Distance>
bool operator==(const istream_iterator<T,charT,traits,Distance>& x,
const istream_iterator<T,charT,traits,Distance>& y);

Returns: x.in_stream == y.in_stream.

template<class T, class charT, class traits, class Distance>
bool operator!=(const istream_iterator<T,charT,traits,Distance>& x,
const istream_iterator<T,charT,traits,Distance>& y);

Returns: !(x == y)

22.6.2 Class template ostream_iterator

```cpp
ostream_iterator writes (using operator<<) successive elements onto the output stream from which it was
constructed. If it was constructed with charT* as a constructor argument, this string, called a delimiter
string, is written to the stream after every T is written. It is not possible to get a value out of the output
iterator. Its only use is as an output iterator in situations like

while (first != last)
  *result++ = *first++;
```

ostream_iterator is defined as:

```cpp
namespace std {
  template<class T, class charT = char, class traits = char_traits<charT>>
  class ostream_iterator {
    public:
      using iterator_category = output_iterator_tag;
      using value_type = void;
      using difference_type = void;
      using pointer = void;
      using reference = void;
      using char_type = charT;
      using traits_type = traits;
      using ostream_type = basic_ostream<charT,traits>;

      ostream_iterator(ostream_type& s);
      ostream_iterator(ostream_type& s, const charT* delimiter);
      ostream_iterator(const ostream_iterator& x);
      ~ostream_iterator();
      ostream_iterator& operator=(const ostream_iterator& = default;
      ostream_iterator& operator=(const T& value);
```
22.6.2.1 `ostream_iterator` constructors and destructor

- `ostream_iterator(ostream_type& s);`
  
  **Effects:** Initializes `out_stream` with `addressof(s)` and `delim` with null.

- `ostream_iterator(ostream_type& s, const charT* delimiter);`
  
  **Effects:** Initializes `out_stream` with `addressof(s)` and `delim` with `delimiter`.

- `ostream_iterator(const ostream_iterator& x);`
  
  **Effects:** Constructs a copy of `x`.

- `~ostream_iterator();`
  
  **Effects:** The iterator is destroyed.

22.6.2.2 `ostream_iterator` operations

- `ostream_iterator& operator=(const T& value);`
  
  **Effects:** As if by:
  
  ```
  *out_stream << value;
  if (delim != 0)
    *out_stream << delim;
  return *this;
  ```

- `ostream_iterator& operator*();`
  
  **Returns:** `*this`.

- `ostream_iterator& operator++();`
  
  **Returns:** `*this`.

- `ostream_iterator& operator++(int);`
  
  **Returns:** `*this`.

22.6.3 Class template `istreambuf_iterator`

The class template `istreambuf_iterator` defines an input iterator (22.2.3) that reads successive `characters` from the streambuf for which it was constructed. `operator*` provides access to the current input character, if any. Each time `operator++` is evaluated, the iterator advances to the next input character. If the end of stream is reached (`streambuf_type::sgetc()` returns `traits::eof()`), the iterator becomes equal to the `end-of-stream` iterator value. The default constructor `istreambuf_iterator()` and the constructor `istreambuf_iterator(0)` both construct an end-of-stream iterator object suitable for use as an end-of-range. All specializations of `istreambuf_iterator` shall have a trivial copy constructor, a `constexpr` default constructor, and a trivial destructor.

- The result of `operator*()` on an end-of-stream iterator is undefined. For any other iterator value a `char_type` value is returned. It is impossible to assign a character via an input iterator.

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class istreambuf_iterator {
    public:
        using iterator_category = input_iterator_tag;
        using value_type = charT;
        using difference_type = typename traits::off_type;
        using pointer = unspecified;
        using reference = charT;
```
using char_type = charT;
using traits_type = traits;
using int_type = typename traits::int_type;
using streambuf_type = basic_streambuf<charT,traits>;
using istream_type = basic_istream<charT,traits>;

class proxy; // exposition only

constexpr istreambuf_iterator() noexcept;
istreambuf_iterator(const istreambuf_iterator&) noexcept = default;
-istreambuf_iterator() = default;
istreambuf_iterator(const streambuf_type* s) noexcept;
istreambuf_iterator(istream_type& s) noexcept = default;
charT operator*() const;
istreambuf_iterator& operator++();
proxy operator++(int);
bool equal(const istreambuf_iterator& b) const;

private:
  streambuf_type* sbuf_; // exposition only
};

namespace std {
  template<class charT, class traits>
  istreambuf_iterator<charT, traits>::proxy {
    proxy(charT c, basic_streambuf<charT,traits>* sbuf)
      : keep_(c), sbuf_(sbuf) { }
  public:
    charT operator*() { return keep_; }
  }
}

22.6.3.1 Class istreambuf_iterator::proxy
[istreambuf.iterator.proxy]

1 Class istreambuf_iterator<charT,traits>::proxy is for exposition only. An implementation is permitted to provide equivalent functionality without providing a class with this name. Class istreambuf_iterator<charT, traits>::proxy provides a temporary placeholder as the return value of the post-increment operator (operator++). It keeps the character pointed to by the previous value of the iterator for some possible future access to get the character.

22.6.3.2 istreambuf_iterator constructors
[istreambuf.iterator.cons]

1 For each istreambuf_iterator constructor in this subclause, an end-of-stream iterator is constructed if and only if the exposition-only member sbuf_ is initialized with a null pointer value.

constexpr istreambuf_iterator() noexcept;

2 Effects: Initializes sbuf_ with nullptr.

istreambuf_iterator(istream_type& s) noexcept;

3 Effects: Initializes sbuf_ with s.rdbuf().

istreambuf_iterator(streambuf_type* s) noexcept;

4 Effects: Initializes sbuf_ with s.
istreambuf_iterator(const proxy& p) noexcept;

**Effects:** Initializes sbuf_ with p.sbuf_.

### 22.6.3.3 istreambuf_iterator operations

**charT operator*() const**

**Returns:** The character obtained via the streambuf member sbuf_->sgetc().

**istreambuf_iterator& operator++();**

**Effects:** As if by sbuf_->sbumpc().

**Returns:** *this.

**proxy operator++(int);**

**Returns:** proxy(sbuf_->sbumpc(), sbuf_).

**bool equal(const istreambuf_iterator& b) const;**

**Returns:** true if and only if both iterators are at end-of-stream, or neither is at end-of-stream, regardless of what streambuf object they use.

**template<class charT, class traits>**

**bool operator==(const istreambuf_iterator[charT,traits]& a,**

**const istreambuf_iterator<charT,traits>& b);**

**Returns:** a.equal(b).

**template<class charT, class traits>**

**bool operator!=(const istreambuf_iterator<charT,traits>& a,**

**const istreambuf_iterator<charT,traits>& b);**

**Returns:** !a.equal(b).

### 22.6.4 Class template ostreambuf_iterator

**namespace std {**

**template<class charT, class traits>**

**class ostreambuf_iterator {**

**public:**

**using iterator_category = output_iterator_tag;**

**using value_type = void;**

**using difference_type = void;**

**using pointer = void;**

**using reference = void;**

**using char_type = charT;**

**using traits_type = traits;**

**using streambuf_type = basic_streambuf<charT,traits>;**

**using ostream_type = basic_ostream<charT,traits>;**

**ostreambuf_iterator(ostream_type& s) noexcept;**

**ostreambuf_iterator(streambuf_type* s) noexcept;**

**ostreambuf_iterator& operator=(charT c);**

**ostreambuf_iterator& operator*();**

**ostreambuf_iterator& operator++();**

**ostreambuf_iterator& operator++(int);**

**bool failed() const noexcept;**

**private:**

**streambuf_type* sbuf_;**

// exposition only

**};**

**}**

1 The class template `ostreambuf_iterator` writes successive `characters` onto the output stream from which it was constructed. It is not possible to get a character value out of the output iterator.
22.6.4.1 ostreambuf_iterator constructors

```cpp
ostreambuf_iterator(ostream_type& s) noexcept;
```

Requires: `s.rdbuf()` shall not be a null pointer.

Effects: Initializes `sbuf_` with `s.rdbuf()`.

```cpp
ostreambuf_iterator(streambuf_type* s) noexcept;
```

Requires: `s` shall not be a null pointer.

Effects: Initializes `sbuf_` with `s`.

22.6.4.2 ostreambuf_iterator operations

```cpp
ostreambuf_iterator& operator=(charT c);
```

Effects: If `failed()` yields `false`, calls `sbuf_->sputc(c)`; otherwise has no effect.

Returns: `*this`.

```cpp
ostreambuf_iterator& operator*();
```

Returns: `*this`.

```cpp
ostreambuf_iterator& operator++();
ostreambuf_iterator& operator++(int);
```

Returns: `*this`.

```cpp
bool failed() const noexcept;
```

Returns: `true` if in any prior use of member `operator=`, the call to `sbuf_->sputc()` returned `traits::eof()`; or `false` otherwise.

22.7 Range access

In addition to being available via inclusion of the `<iterator>` header, the function templates in 22.7 are available when any of the following headers are included: `<array>`, `<deque>`, `<forward_list>`, `<list>`, `<map>`, `<regex>`, `<set>`, `<span>`, `<string>`, `<string_view>`, `<unordered_map>`, `<unordered_set>`, and `<vector>`. Each of these templates is a designated customization point (15.5.4.2.1).

```cpp
template<class C> constexpr auto begin(C& c) -> decltype(c.begin());
template<class C> constexpr auto begin(const C& c) -> decltype(c.begin());
```

Returns: `c.begin()`.

```cpp
template<class C> constexpr auto end(C& c) -> decltype(c.end());
template<class C> constexpr auto end(const C& c) -> decltype(c.end());
```

Returns: `c.end()`.

```cpp
template<class T, size_t N> constexpr T* begin(T (&array)[N]) noexcept;
template<class T, size_t N> constexpr T* end(T (&array)[N]) noexcept;
```

Returns: `array`.

```cpp
template<class T, size_t N> constexpr T* begin(T (&array)[N]) noexcept( noexcept(std::begin(c)))
  -> decltype(std::begin(c));
template<class T, size_t N> constexpr T* end(T (&array)[N]) noexcept( noexcept(std::end(c)))
  -> decltype(std::end(c));
```

Returns: `std::begin(c)`.

```cpp
template<class C> constexpr auto cbegin(const C& c) noexcept( noexcept(std::begin(c)))
  -> decltype(std::begin(c));
template<class C> constexpr auto cend(const C& c) noexcept( noexcept(std::end(c)))
  -> decltype(std::end(c));
```

Returns: `std::end(c)`.

```cpp
template<class C> constexpr auto rbegin(C& c) -> decltype(c.rbegin());
template<class C> constexpr auto rend(const C& c) -> decltype(c.rend());
```

Returns: `c.rbegin()`.

§ 22.7
template<class C> constexpr auto rend(C& c) -> decltype(c.rend());
template<class C> constexpr auto rend(const C& c) -> decltype(c.rend());

Returns: c.rend().

template<class T, size_t N> constexpr reverse_iterator<T*> rbegin(T (&array)[N]);

Returns: reverse_iterator<T*>(array + N).

template<class T, size_t N> constexpr reverse_iterator<T*> rend(T (&array)[N]);

Returns: reverse_iterator<T*>(array).

template<class E> constexpr reverse_iterator<const E*> rbegin(initializer_list<E> il);

Returns: reverse_iterator<const E*>(il.end()).

template<class E> constexpr reverse_iterator<const E*> rend(initializer_list<E> il);

Returns: reverse_iterator<const E*>(il.begin()).

template<class C> constexpr auto crbegin(const C& c) -> decltype(std::rbegin(c));

Returns: std::rbegin(c).

template<class C> constexpr auto crend(const C& c) -> decltype(std::rend(c));

Returns: std::rend(c).

22.8 Container and view access

In addition to being available via inclusion of the <iterator> header, the function templates in 22.8 are available when any of the following headers are included: <array>, <deque>, <forward_list>, <list>, <map>, <regex>, <set>, <span>, <string>, <string_view>, <unordered_map>, <unordered_set>, and <vector>. Each of these templates is a designated customization point (15.5.4.2.1).

template<class C> constexpr auto size(const C& c) -> decltype(c.size());

Returns: c.size().

template<class T, size_t N> constexpr size_t size(const T (&array)[N]) noexcept;

Returns: N.

template<class C> [[nodiscard]] constexpr auto empty(const C& c) -> decltype(c.empty());

Returns: c.empty().

template<class T, size_t N> [[nodiscard]] constexpr bool empty(const T (&array)[N]) noexcept;

Returns: false.

template<class E> [[nodiscard]] constexpr bool empty(initializer_list<E> il) noexcept;

Returns: il.size() == 0.

template<class C> constexpr auto data(C& c) -> decltype(c.data());

template<class C> constexpr auto data(const C& c) -> decltype(c.data());

Returns: c.data().

template<class T, size_t N> constexpr T* data(T (&array)[N]) noexcept;

Returns: array.

template<class E> constexpr const E* data(initializer_list<E> il) noexcept;

Returns: il.begin().
23 Algorithms library

23.1 General

This Clause describes components that C++ programs may use to perform algorithmic operations on containers (Clause 21) and other sequences.

The following subclauses describe components for non-modifying sequence operations, mutating sequence operations, sorting and related operations, and algorithms from the ISO C library, as summarized in Table 81.

Table 81 — Algorithms library summary

<table>
<thead>
<tr>

23.2 Algorithms requirements

All of the algorithms are separated from the particular implementations of data structures and are parameterized by iterator types. Because of this, they can work with program-defined data structures, as long as these data structures have iterator types satisfying the assumptions on the algorithms.

For purposes of determining the existence of data races, algorithms shall not modify objects referenced through an iterator argument unless the specification requires such modification.

Throughout this Clause, the names of template parameters are used to express type requirements.

- If an algorithm’s template parameter is named InputIterator, InputIterator1, or InputIterator2, the template argument shall satisfy the Cpp17InputIterator requirements (22.2.3).
- If an algorithm’s template parameter is named OutputIterator, OutputIterator1, or OutputIterator2, the template argument shall satisfy the Cpp17OutputIterator requirements (22.2.4).
- If an algorithm’s template parameter is named ForwardIterator, ForwardIterator1, or ForwardIterator2, the template argument shall satisfy the Cpp17ForwardIterator requirements (22.2.5).
- If an algorithm’s template parameter is named BidirectionalIterator, BidirectionalIterator1, or BidirectionalIterator2, the template argument shall satisfy the Cpp17BidirectionalIterator requirements (22.2.6).
- If an algorithm’s template parameter is named RandomAccessIterator, RandomAccessIterator1, or RandomAccessIterator2, the template argument shall satisfy the Cpp17RandomAccessIterator requirements (22.2.7).

If an algorithm’s Effects: element specifies that a value pointed to by any iterator passed as an argument is modified, then that algorithm has an additional type requirement: The type of that argument shall satisfy the requirements of a mutable iterator (22.2). [Note: This requirement does not affect arguments that are named OutputIterator, OutputIterator1, or OutputIterator2, because output iterators must always be mutable. —end note]

Both in-place and copying versions are provided for certain algorithms. When such a version is provided for an algorithm it is called algorithm_copy. Algorithms that take predicates end with the suffix _if (which follows the suffix _copy).

The Predicate parameter is used whenever an algorithm expects a function object (19.14) that, when applied to the result of dereferencing the corresponding iterator, returns a value testable as true. In other words,
if an algorithm takes `Predicate pred` as its argument and `first` as its iterator argument, it should work correctly in the construct `pred(*first)` contextually converted to `bool` (7.3). The function object `pred` shall not apply any non-constant function through the dereferenced iterator.

The `BinaryPredicate` parameter is used whenever an algorithm expects a function object that when applied to the result of dereferencing two corresponding iterators or to dereferencing an iterator and type `T` when `T` is part of the signature returns a value testable as `true`. In other words, if an algorithm takes `BinaryPredicate binary_pred` as its argument and `first1` and `first2` as its iterator arguments, it should work correctly in the construct `binary_pred(*first1, *first2)` contextually converted to `bool` (7.3). `BinaryPredicate` always takes the first iterator’s `value_type` as its first argument, that is, in those cases when `T value` is part of the signature, it should work correctly in the construct `binary_pred(*first1, value)` contextually converted to `bool` (7.3). `binary_pred` shall not apply any non-constant function through the dereferenced iterators.

The parameters `UnaryOperation`, `BinaryOperation`, `BinaryOperation1`, and `BinaryOperation2` are used whenever an algorithm expects a function object (19.14).

[Note: Unless otherwise specified, algorithms that take function objects as arguments are permitted to copy those function objects freely. Programmers for whom object identity is important should consider using a wrapper class that points to a noncopied implementation object such as `reference_wrapper<T>` (19.14.5), or some equivalent solution. — end note]

When the description of an algorithm gives an expression such as `*first == value` for a condition, the expression shall evaluate to either `true` or `false` in boolean contexts.

In the description of the algorithms operators `+` and `-` are used for some of the iterator categories for which they do not have to be defined. In these cases the semantics of `a+n` is the same as that of

```cpp
X tmp = a;
advance(tmp, n);
return tmp;
```

and that of `b-a` is the same as of

```cpp
return distance(a, b);
```

## 23.3 Parallel algorithms

This subclause describes components that C++ programs may use to perform operations on containers and other sequences in parallel.

### 23.3.1 Terms and definitions

A parallel algorithm is a function template listed in this document with a template parameter named `ExecutionPolicy`.

Parallel algorithms access objects indirectly accessible via their arguments by invoking the following functions:

1. All operations of the categories of the iterators that the algorithm is instantiated with.
2. Operations on those sequence elements that are required by its specification.
3. User-provided function objects to be applied during the execution of the algorithm, if required by the specification.
4. Operations on those function objects required by the specification. [Note: See 23.2. — end note]

These functions are herein called element access functions. [Example: The `sort` function may invoke the following element access functions:

5. Operations of the random-access iterator of the actual template argument (as per 22.2.7), as implied by the name of the template parameter `RandomAccessIterator`.
6. The `swap` function on the elements of the sequence (as per the preconditions specified in 23.7.1.1).
7. The user-provided `Compare` function object.

— end example]

### 23.3.2 Requirements on user-provided function objects

Unless otherwise specified, function objects passed into parallel algorithms as objects of type `Predicate`, `BinaryPredicate`, `Compare`, `UnaryOperation`, `BinaryOperation`, `BinaryOperation1`, `BinaryOperation2`, `UnaryOperation1`, and `UnaryOperation2`, `BinaryOperation1`, and `BinaryOperation2` are used whenever an algorithm expects a function object (19.14).
and the operators used by the analogous overloads to these parallel algorithms that could be formed by the
invocation with the specified default predicate or operation (where applicable) shall not directly or indirectly
modify objects via their arguments, nor shall they rely on the identity of the provided objects.

23.3.3 Effect of execution policies on algorithm execution  [algorithms.parallel.exec]

Parallel algorithms have template parameters named ExecutionPolicy (19.18) which describe the manner in
which the execution of these algorithms may be parallelized and the manner in which they apply the element
access functions.

If an object is modified by an element access function, the algorithm will perform no other unsynchronized
accesses to that object. The modifying element access functions are those which are specified as modifying
the object. [Note: For example, swap(), ++, --, @=, and assignments modify the object. For the assignment
and @= operators, only the left argument is modified. —end note]

Unless otherwise stated, implementations may make arbitrary copies of elements (with type T) from sequences
where is_trivially_copy_constructible_v<T> and is_trivially_destructible_v<T> are true. [Note: This implies
that user-supplied function objects should not rely on object identity of arguments for such input sequences.
Users for whom the object identity of the arguments to these function objects is important should consider using
a wrapping iterator that returns a non-copied implementation object such as reference_wrapper<T> (19.14.5)
or some equivalent solution. —end note]

The invocations of element access functions in parallel algorithms invoked with an execution policy object of
type execution::sequenced_policy all occur in the calling thread of execution. [Note: The invocations
are not interleaved; see 6.8.1. —end note]

The invocations of element access functions in parallel algorithms invoked with an execution policy object
of type execution::parallel_policy are permitted to execute in either the invoking thread of execution
or in a thread of execution implicitly created by the library to support parallel algorithm execution. If the
threads of execution created by thread (30.3.2) provide concurrent forward progress guarantees (6.8.2.2),
then a thread of execution implicitly created by the library will provide parallel forward progress guarantees;
otherwise, the provided forward progress guarantee is implementation-defined. Any such invocations executing
in the same thread of execution are indeterminately sequenced with respect to each other. [Note: It is the
caller’s responsibility to ensure that the invocation does not introduce data races or deadlocks. —end note]

[Example:
int a[] = {0,1};
std::vector<int> v;
std::for_each(std::execution::par, std::begin(a), std::end(a), [&](int i) {
    v.push_back(i*2+1); // incorrect: data race
});
The program above has a data race because of the unsynchronized access to the container v. —end example]

[Example:
int a[] = {1,2};
std::atomic<int> x{0};
std::for_each(std::execution::par, std::begin(a), std::end(a), [&](int) {
    x.fetch_add(1, std::memory_order::relaxed);
    // spin wait for another iteration to change the value of x
    while (x.load(std::memory_order::relaxed) == 1) { } // incorrect: assumes execution order
});
The above example depends on the order of execution of the iterations, and will not terminate if both
iterations are executed sequentially on the same thread of execution. —end example]

The invocations of element access functions in parallel algorithms invoked with an execution policy of type
execution::parallel_unsequenced_policy are permitted to execute in an unordered fashion in unspecified

§ 23.3.3 866
threads of execution, and unsequenced with respect to one another within each thread of execution. These threads of execution are either the invoking thread of execution or threads of execution implicitly created by the library; the latter will provide weakly parallel forward progress guarantees. [Note: This means that multiple function object invocations may be interleaved on a single thread of execution, which overrides the usual guarantee from 6.8.1 that function executions do not interleave with one another. — end note] Since execution::parallel_unsequenced_policy allows the execution of element access functions to be interleaved on a single thread of execution, blocking synchronization, including the use of mutexes, risks deadlock. Thus, the synchronization with execution::parallel_unsequenced_policy is restricted as follows: A standard library function is vectorization-unsafe if it is specified to synchronize with another function invocation, or another function invocation is specified to synchronize with it, and if it is not a memory allocation or deallocation function. Vectorization-unsafe standard library functions may not be invoked by user code called from execution::parallel_unsequenced_policy algorithms. [Note: Implementations must ensure that internal synchronization inside standard library functions does not prevent forward progress when those functions are executed by threads of execution with weakly parallel forward progress guarantees. — end note] [Example:] int x = 0; std::mutex m; int a[] = {1, 2}; std::for_each(std::execution::par_unseq, std::begin(a), std::end(a), [&](int) { std::lock_guard<mutex> guard(m); // incorrect: lock_guard constructor calls m.lock() ++x; }); The above program may result in two consecutive calls to m.lock() on the same thread of execution (which may deadlock), because the applications of the function object are not guaranteed to run on different threads of execution. — end example] [Note: The semantics of the execution::parallel_policy or the execution::parallel_unsequenced_policy invocation allow the implementation to fall back to sequential execution if the system cannot parallelize an algorithm invocation due to lack of resources. — end note]

7 If an invocation of a parallel algorithm uses threads of execution implicitly created by the library, then the invoking thread of execution will either

(7.1) — temporarily block with forward progress guarantee delegation (6.8.2.2) on the completion of these library-managed threads of execution, or

(7.2) — eventually execute an element access function;

the thread of execution will continue to do so until the algorithm is finished. [Note: In blocking with forward progress guarantee delegation in this context, a thread of execution created by the library is considered to have finished execution as soon as it has finished the execution of the particular element access function that the invoking thread of execution logically depends on. — end note]

8 The semantics of parallel algorithms invoked with an execution policy object of implementation-defined type are implementation-defined.

### 23.3.4 Parallel algorithm exceptions

[algorithms.parallel.exceptions]

1 During the execution of a parallel algorithm, if temporary memory resources are required for parallelization and none are available, the algorithm throws a bad_alloc exception.

2 During the execution of a parallel algorithm, if the invocation of an element access function exits via an uncaught exception, the behavior is determined by the ExecutionPolicy.

### 23.3.5 ExecutionPolicy algorithm overloads

[algorithms.parallel.overloads]

1 Parallel algorithms are algorithm overloads. Each parallel algorithm overload has an additional template type parameter named ExecutionPolicy, which is the first template parameter. Additionally, each parallel algorithm overload has an additional function parameter of type ExecutionPolicy&&, which is the first function parameter. [Note: Not all algorithms have parallel algorithm overloads. — end note]

2 Unless otherwise specified, the semantics of ExecutionPolicy algorithm overloads are identical to their overloads without.

3 Unless otherwise specified, the complexity requirements of ExecutionPolicy algorithm overloads are relaxed from the complexity requirements of the overloads without as follows: when the guarantee says “at most
"expr" or “exactly expr” and does not specify the number of assignments or swaps, and expr is not already expressed with $O()$ notation, the complexity of the algorithm shall be $O(expr)$.

4 Parallel algorithms shall not participate in overload resolution unless is_execution_policy_v<remove_cvref_t<ExecutionPolicy>> is true.

23.4 Header <algorithm> synopsis

```
#include <initializer_list>

namespace std {
    // 23.5, non-modifying sequence operations
    // 23.5.1, all of
    template<class InputIterator, class Predicate>
    constexpr bool all_of(InputIterator first, InputIterator last, Predicate pred);
    template<class ExecutionPolicy, class ForwardIterator, class Predicate>
    bool all_of(ExecutionPolicy&& exec, // see 23.3.5
                ForwardIterator first, ForwardIterator last, Predicate pred);

    // 23.5.2, any of
    template<class InputIterator, class Predicate>
    constexpr bool any_of(InputIterator first, InputIterator last, Predicate pred);
    template<class ExecutionPolicy, class ForwardIterator, class Predicate>
    bool any_of(ExecutionPolicy&& exec, // see 23.3.5
                ForwardIterator first, ForwardIterator last, Predicate pred);

    // 23.5.3, none of
    template<class InputIterator, class Predicate>
    constexpr bool none_of(InputIterator first, InputIterator last, Predicate pred);
    template<class ExecutionPolicy, class ForwardIterator, class Predicate>
    bool none_of(ExecutionPolicy&& exec, // see 23.3.5
                 ForwardIterator first, ForwardIterator last, Predicate pred);

    // 23.5.4, for each
    template<class InputIterator, class Function>
    constexpr Function for_each(InputIterator first, InputIterator last, Function f);
    template<class ExecutionPolicy, class ForwardIterator, class Function>
    void for_each(ExecutionPolicy&& exec, // see 23.3.5
                  ForwardIterator first, ForwardIterator last, Function f);
    template<class InputIterator, class Size, class Function>
    constexpr InputIterator for_each_n(InputIterator first, Size n, Function f);
    template<class ExecutionPolicy, class ForwardIterator, class Size, class Function>
    ForwardIterator for_each_n(ExecutionPolicy&& exec, // see 23.3.5
                               ForwardIterator first, Size n, Function f);

§ 23.5 Non-modifying sequence operations

23.5.1 All of

template<class InputIterator, class Predicate>
constexpr bool all_of(InputIterator first, InputIterator last, Predicate pred);

template<class ExecutionPolicy, class ForwardIterator, class Predicate>
bool all_of(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last,
Predicate pred);

Returns: true if [first, last) is empty or if pred(*i) is true for every iterator i in the range
[first, last), and false otherwise.

Complexity: At most last - first applications of the predicate.

23.5.2 Any of

template<class InputIterator, class Predicate>
constexpr bool any_of(InputIterator first, InputIterator last, Predicate pred);

template<class ExecutionPolicy, class ForwardIterator, class Predicate>
bool any_of(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last,
Predicate pred);

Returns: false if [first, last) is empty or if there is no iterator i in the range [first, last)
such that pred(*i) is true, and true otherwise.

Complexity: At most last - first applications of the predicate.

23.5.3 None of

template<class InputIterator, class Predicate>
constexpr bool none_of(InputIterator first, InputIterator last, Predicate pred);

template<class ExecutionPolicy, class ForwardIterator, class Predicate>
bool none_of(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last,
Predicate pred);

Returns: true if [first, last) is empty or if pred(*i) is false for every iterator i in the range
[first, last), and false otherwise.

Complexity: At most last - first applications of the predicate.
23.5.4 For each

```
template<class InputIterator, class Function>
constexpr Function for_each(InputIterator first, InputIterator last, Function f);
```

1. Requires: Function shall satisfy the Cpp17MoveConstructible requirements (Table 25). [Note: Function need not meet the requirements of Cpp17CopyConstructible (Table 26). —end note]
2. Effects: Applies f to the result of dereferencing every iterator in the range [first, last), starting from first and proceeding to last - 1. [Note: If the type of first satisfies the requirements of a mutable iterator, f may apply non-constant functions through the dereferenced iterator. —end note]
5. Remarks: If f returns a result, the result is ignored.

```
template<class ExecutionPolicy, class ForwardIterator, class Function>
void for_each(ExecutionPolicy&& exec,
             ForwardIterator first, ForwardIterator last,
             Function f);
```

6. Requires: Function shall satisfy the Cpp17CopyConstructible requirements.
7. Effects: Applies f to the result of dereferencing every iterator in the range [first, last). [Note: If the type of first satisfies the requirements of a mutable iterator, f may apply non-constant functions through the dereferenced iterator. —end note]
8. Complexity: Applies f exactly last - first times.
9. Remarks: If f returns a result, the result is ignored. Implementations do not have the freedom granted under 23.3.3 to make arbitrary copies of elements from the input sequence. [Note: Does not return a copy of its Function parameter, since parallelization may not permit efficient state accumulation. —end note]

```
template<class InputIterator, class Size, class Function>
constexpr InputIterator for_each_n(InputIterator first, Size n, Function f);
```

10. Requires: Function shall satisfy the Cpp17MoveConstructible requirements [Note: Function need not meet the requirements of Cpp17CopyConstructible. —end note]
11. Requires: n >= 0.
12. Effects: Applies f to the result of dereferencing every iterator in the range [first, first + n) in order. [Note: If the type of first satisfies the requirements of a mutable iterator, f may apply non-constant functions through the dereferenced iterator. —end note]
14. Remarks: If f returns a result, the result is ignored.

```
template<class ExecutionPolicy, class ForwardIterator, class Size, class Function>
ForwardIterator for_each_n(ExecutionPolicy&& exec, ForwardIterator first, Size n, Function f);
```

15. Requires: Function shall satisfy the Cpp17CopyConstructible requirements.
16. Requires: n >= 0.
17. Effects: Applies f to the result of dereferencing every iterator in the range [first, first + n). [Note: If the type of first satisfies the requirements of a mutable iterator, f may apply non-constant functions through the dereferenced iterator. —end note]
18. Returns: first + n.
19. Remarks: If f returns a result, the result is ignored. Implementations do not have the freedom granted under 23.3.3 to make arbitrary copies of elements from the input sequence.

23.5.5 Find

```
template<class InputIterator, class T>
constexpr InputIterator find(InputIterator first, InputIterator last, T t);
```

§ 23.5.5
```cpp
const T& value);

template<class ExecutionPolicy, class ForwardIterator, class T>
ForwardIterator find(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last,
const T& value);

template<class InputIterator, class Predicate>
constexpr InputIterator find_if(InputIterator first, InputIterator last,
Predicate pred);

template<class ExecutionPolicy, class ForwardIterator, class Predicate>
ForwardIterator find_if(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last,
Predicate pred);

template<class InputIterator, class Predicate>
constexpr InputIterator find_if_not(InputIterator first, InputIterator last,
Predicate pred);

template<class ExecutionPolicy, class ForwardIterator, class Predicate>
ForwardIterator find_if_not(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last,
Predicate pred);

1 Returns: The first iterator \(i\) in the range \([first, last)\) for which the following corresponding
conditions hold: \(*i == value, pred(*i) != false, pred(*i) == false\). Returns \(last\) if no such
iterator is found.

2 Complexity: At most \(last - first\) applications of the corresponding predicate.

23.5.6 Find end

```cpp
template<class ForwardIterator1, class ForwardIterator2>
constexpr ForwardIterator1
find_end(ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator1
find_end(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2);

template<class ForwardIterator1, class ForwardIterator2,
class BinaryPredicate>
constexpr ForwardIterator1
find_end(ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2,
BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class BinaryPredicate>
ForwardIterator1
find_end(ExecutionPolicy&& exec,
ForwardIterator1 first1, ForwardIterator1 last1,
ForwardIterator2 first2, ForwardIterator2 last2,
BinaryPredicate pred);

1 Effects: Finds a subsequence of equal values in a sequence.

2 Returns: The last iterator \(i\) in the range \([first1, last1 - (last2 - first2))\) such that for every
non-negative integer \(n < (last2 - first2)\), the following corresponding conditions hold: 
\(*i + n == *(first2 + n), pred(*i + n, *(first2 + n)) != false\). Returns \(last1\) if \([first2,
last2)\) is empty or if no such iterator is found.

3 Complexity: At most \((last2 - first2) * (last1 - first1 - (last2 - first2)) + 1\) applica-
tions of the corresponding predicate.

23.5.7 Find first

```cpp
template<class InputIterator, class ForwardIterator>
constexpr InputIterator
find_first_of(InputIterator first1, InputIterator last1,
ForwardIterator first2, ForwardIterator last2);
```
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
  ForwardIterator1
  find_first_of(ExecutionPolicy&& exec,
  ForwardIterator1 first1, ForwardIterator1 last1,
  ForwardIterator2 first2, ForwardIterator2 last2);

template<class InputIterator, class ForwardIterator,
  class BinaryPredicate>
  constexpr InputIterator
  find_first_of(InputIterator first1, InputIterator last1,
  ForwardIterator first2, ForwardIterator last2,
  BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
  class BinaryPredicate>
  ForwardIterator1
  find_first_of(ExecutionPolicy&& exec,
  ForwardIterator1 first1, ForwardIterator1 last1,
  ForwardIterator2 first2, ForwardIterator2 last2,
  BinaryPredicate pred);

Effects: Finds an element that matches one of a set of values.

Returns: The first iterator \(i\) in the range \([\text{first1}, \text{last1})\) such that for some iterator \(j\) in the range \([\text{first2}, \text{last2})\) the following conditions hold: \(*i == *j\), \(\text{pred(*i,*j)} \neq \text{false}\). Returns \text{last1} if \([\text{first2}, \text{last2})\) is empty or no such iterator is found.

Complexity: At most \((\text{last1}-\text{first1}) \times (\text{last2}-\text{first2})\) applications of the corresponding predicate.

23.5.8 Adjacent find

template<class ForwardIterator>
  constexpr ForwardIterator
  adjacent_find(ForwardIterator first, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
  ForwardIterator
  adjacent_find(ExecutionPolicy&& exec,
  ForwardIterator first, ForwardIterator last);

template<class ForwardIterator, class BinaryPredicate>
  constexpr ForwardIterator
  adjacent_find(ForwardIterator first, ForwardIterator last,
  BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator, class BinaryPredicate>
  ForwardIterator
  adjacent_find(ExecutionPolicy&& exec,
  ForwardIterator first, ForwardIterator last,
  BinaryPredicate pred);

Returns: The first iterator \(i\) such that both \(i\) and \(i + 1\) are in the range \([\text{first}, \text{last})\) for which the following corresponding conditions hold: \(*i == *(i + 1)\), \(\text{pred(*i, *(i + 1))} \neq \text{false}\). Returns \text{last} if no such iterator is found.

Complexity: For the overloads with no ExecutionPolicy, exactly \(\min((i - \text{first}) + 1, (\text{last} - \text{first}) - 1)\) applications of the corresponding predicate, where \(i\) is \text{adjacent_find}'s return value. For the overloads with an ExecutionPolicy, \(\bigO(\text{last} - \text{first})\) applications of the corresponding predicate.

23.5.9 Count

template<class InputIterator, class T>
  constexpr typename iterator_traits<InputIterator>::difference_type
  count(InputIterator first, InputIterator last, const T & value);

template<class ExecutionPolicy, class ForwardIterator, class T>
  typename iterator_traits<ForwardIterator>::difference_type
  count(ExecutionPolicy&& exec,
  ForwardIterator first, ForwardIterator last, const T & value);
template<class InputIterator, class Predicate>  
constexpr typename iterator_traits<InputIterator>::difference_type  
count_if(InputIterator first, InputIterator last, Predicate pred);  
template<class ExecutionPolicy, class ForwardIterator, class Predicate>  
typename iterator_traits<ForwardIterator>::difference_type  
count_if(ExecutionPolicy&& exec,  
ForwardIterator first, ForwardIterator last, Predicate pred);  

Effects: Returns the number of iterators i in the range [first, last) for which the following
 corresponding conditions hold: *i == value, pred(*i) != false.

Complexity: Exactly last - first applications of the corresponding predicate.

23.5.10 Mismatch

template<class InputIterator1, class InputIterator2>  
constexpr pair<InputIterator1, InputIterator2>  
mismatch(InputIterator1 first1, InputIterator1 last1,
 InputIterator2 first2);  
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>  
pair<ForwardIterator1, ForwardIterator2>  
mismatch(ExecutionPolicy&& exec,
 ForwardIterator1 first1, ForwardIterator1 last1,
 ForwardIterator2 first2);  

Remarks: If last2 was not given in the argument list, it denotes first2 + (last1 - first1) below.

Returns: A pair of iterators first1 + n and first2 + n, where n is the smallest integer such that, respectively,

— !(first1 + n) == *(first2 + n)) or

§ 23.5.10
(2.2) \( \text{pred}(*(\text{first1} + n), *(\text{first2} + n)) \equiv \text{false} \), or \( \min(\text{last1} - \text{first1}, \text{last2} - \text{first2}) \) if no such integer exists.

3 Complexity: At most \( \min(\text{last1} - \text{first1}, \text{last2} - \text{first2}) \) applications of the corresponding predicate.

### 23.5.11 Equal

#### [alg.equal]

```cpp
template<class InputIterator1, class InputIterator2>
constexpr bool equal(InputIterator1 first1, InputIterator1 last1,
                     InputIterator2 first2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
bool equal(ExecutionPolicy&& exec,
           ForwardIterator1 first1, ForwardIterator1 last1,
           ForwardIterator2 first2);
```

```cpp
template<class InputIterator1, class InputIterator2,
         class BinaryPredicate>
constexpr bool equal(InputIterator1 first1, InputIterator1 last1,
                     InputIterator2 first2, BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
         class BinaryPredicate>
bool equal(ExecutionPolicy&& exec,
           ForwardIterator1 first1, ForwardIterator1 last1,
           ForwardIterator2 first2, BinaryPredicate pred);
```

```cpp
template<class InputIterator1, class InputIterator2>
constexpr bool equal(InputIterator1 first1, InputIterator1 last1,
                     InputIterator2 first2, InputIterator2 last2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
bool equal(ExecutionPolicy&& exec,
           ForwardIterator1 first1, ForwardIterator1 last1,
           ForwardIterator2 first2, ForwardIterator2 last2);
```

```cpp
template<class InputIterator1, class InputIterator2,
         class BinaryPredicate>
constexpr bool equal(InputIterator1 first1, InputIterator1 last1,
                     InputIterator2 first2, InputIterator2 last2,
                     BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
         class BinaryPredicate>
bool equal(ExecutionPolicy&& exec,
           ForwardIterator1 first1, ForwardIterator1 last1,
           ForwardIterator2 first2, ForwardIterator2 last2,
           BinaryPredicate pred);
```

---

**Remarks:** If \( \text{last2} \) was not given in the argument list, it denotes \( \text{first2} + (\text{last1} - \text{first1}) \) below.

**Returns:** If \( \text{last1} - \text{first1} != \text{last2} - \text{first2} \), return \text{false}. Otherwise return \text{true} if for every iterator \( i \) in the range \([\text{first1}, \text{last1})\) the following corresponding conditions hold: \( *i == *((\text{first2} + (i - \text{first1}))), \text{pred}(*i, *((\text{first2} + (i - \text{first1})))) \equiv \text{false} \). Otherwise, returns \text{false}.

**Complexity:**

(3.1) For the overloads with no \text{ExecutionPolicy},

(3.1.1) if \text{InputIterator1} and \text{InputIterator2} meet the \text{Cpp17RandomAccessIterator} requirements (22.2.7) and \( \text{last1} - \text{first1} != \text{last2} - \text{first2} \), then no applications of the corresponding predicate; otherwise,

(3.1.2) at most \( \min(\text{last1} - \text{first1}, \text{last2} - \text{first2}) \) applications of the corresponding predicate.

(3.2) For the overloads with an \text{ExecutionPolicy},

(3.2.1) if \text{ForwardIterator1} and \text{ForwardIterator2} meet the \text{Cpp17RandomAccessIterator} requirements and \( \text{last1} - \text{first1} != \text{last2} - \text{first2} \), then no applications of the corresponding predicate; otherwise,
23.5.12 Is permutation

```
template<class ForwardIterator1, class ForwardIterator2>
constexpr bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1,
                               ForwardIterator2 first2);
```

```
template<class ForwardIterator1, class ForwardIterator2,
         class BinaryPredicate>
constexpr bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1,
                               ForwardIterator2 first2, BinaryPredicate pred);
```

```
template<class ForwardIterator1, class ForwardIterator2>
constexpr bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1,
                               ForwardIterator2 first2, ForwardIterator2 last2);
```

```
template<class ForwardIterator1, class ForwardIterator2,
         class BinaryPredicate>
constexpr bool is_permutation(ForwardIterator1 first1, ForwardIterator1 last1,
                               ForwardIterator2 first2, ForwardIterator2 last2,
                               BinaryPredicate pred);
```

1 Requires: ForwardIterator1 and ForwardIterator2 shall have the same value type. The comparison function shall be an equivalence relation.

2 Remarks: If last2 was not given in the argument list, it denotes first2 + (last1 - first1) below.

3 Returns: If last1 - first1 != last2 - first2, return false. Otherwise return true if there exists a permutation of the elements in the range [first2, first2 + (last1 - first1)), beginning with ForwardIterator2 begin, such that equal(first1, last1, begin) returns true or equal(first1, last1, begin, pred) returns true; otherwise, returns false.

4 Complexity: No applications of the corresponding predicate if ForwardIterator1 and ForwardIterator2 meet the requirements of random access iterators and last1 - first1 != last2 - first2. Otherwise, exactly last1 - first1 applications of the corresponding predicate if equal(first1, last1, first2, last2) would return true if pred was not given in the argument list or equal(first1, last1, first2, last2, pred) would return true if pred was given in the argument list; otherwise, at worst $O(N^2)$, where $N$ has the value last1 - first1.

23.5.13 Search

```
template<class ForwardIterator1, class ForwardIterator2>
constexpr ForwardIterator1 search(ForwardIterator1 first1, ForwardIterator1 last1,
                                  ForwardIterator2 first2, ForwardIterator2 last2);
```

```
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator1 search(ExecutionPolicy&& exec,
                         ForwardIterator1 first1, ForwardIterator1 last1,
                         ForwardIterator2 first2, ForwardIterator2 last2);
```

```
template<class ForwardIterator1, class ForwardIterator2,
         class BinaryPredicate>
constexpr ForwardIterator1 search(ForwardIterator1 first1, ForwardIterator1 last1,
                                  ForwardIterator2 first2, ForwardIterator2 last2,
                                  BinaryPredicate pred);
```

```
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
         class BinaryPredicate>
ForwardIterator1 search(ExecutionPolicy&& exec,
                         ForwardIterator1 first1, ForwardIterator1 last1,
                         ForwardIterator2 first2, ForwardIterator2 last2,
                         BinaryPredicate pred);
```

1 Effects: Finds a subsequence of equal values in a sequence.

2 Returns: The first iterator $i$ in the range [first1, last1 - (last2 - first2)) such that for every non-negative integer $n$ less than last2 - first2 the following corresponding conditions hold: $*(i + n) =$
*(first2 + n), pred(*(i + n), *(first2 + n)) != false. Returns first1 if [first2, last2)
is empty, otherwise returns last1 if no such iterator is found.

**Complexity:** At most \((last1 - first1) \times (last2 - first2)\) applications of the corresponding predicate.

```cpp
template<class ForwardIterator, class Size, class T>
constexpr ForwardIterator
search_n(ForwardIterator first, ForwardIterator last,
        Size count, const T& value);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator, class Size, class T>
ForwardIterator
search_n(ExecutionPolicy&& exec,
        ForwardIterator first, ForwardIterator last,
        Size count, const T& value);
```

```cpp
template<class ForwardIterator, class Size, class T,
class BinaryPredicate>
constexpr ForwardIterator
search_n(ForwardIterator first, ForwardIterator last,
        Size count, const T& value,
        BinaryPredicate pred);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator, class Size, class T,
class BinaryPredicate>
ForwardIterator
search_n(ExecutionPolicy&& exec,
        ForwardIterator first, ForwardIterator last,
        Size count, const T& value,
        BinaryPredicate pred);
```

**Requires:** The type Size shall be convertible to integral type (7.3.8, 10.3.8).

**Effects:** Finds a subsequence of equal values in a sequence.

**Returns:** The first iterator \(i\) in the range \([first, last\text{-count})\) such that for every non-negative integer \(n\) less than \(count\) the following corresponding conditions hold: \(*(i + n) == value, pred(*(i + n),value) != false. Returns last if no such iterator is found.

**Complexity:** At most \(last - first\) applications of the corresponding predicate.

```cpp
template<class ForwardIterator, class Searcher>
constexpr ForwardIterator
search(ForwardIterator first, ForwardIterator last, const Searcher& searcher);
```

**Effects:** Equivalent to: return searcher(first, last).first;

**Remarks:** Searcher need not meet the Cpp17CopyConstructible requirements.

### 23.6 Mutating sequence operations

#### [alg.modifying.operations]

### 23.6.1 Copy

#### [alg.copy]

```cpp
template<class InputIterator, class OutputIterator>
constexpr OutputIterator copy(InputIterator first, InputIterator last,
                               OutputIterator result);
```

**Requires:** result shall not be in the range \([first, last)\).

**Effects:** Copies elements in the range \([first, last)\) into the range \([result, result + (last - first))\) starting from first and proceeding to last. For each non-negative integer \(n < (last - first)\), performs \(*(result + n) = *(first + n)\).

**Returns:** result + (last - first).

**Complexity:** Exactly last - first assignments.
template<class InputIterator, class Size, class OutputIterator>
constexpr OutputIterator copy_n(InputIterator first, Size n, OutputIterator result);

Effects: For each non-negative integer \(i < n\), performs \(*(result + i) = *(first + i)\).

Returns: result + n.

Complexity: Exactly \(n\) assignments.

template<class InputIterator, class OutputIterator, class Predicate>
constexpr OutputIterator copy_if(InputIterator first, InputIterator last, OutputIterator result, Predicate pred);

Requires: The ranges \([first, last)\) and \([result, result + (last - first))\) shall not overlap.

Effects: Copies all of the elements referred to by the iterator \(i\) in the range \([first, last)\) for which \(pred(*i)\) is true.

Returns: The end of the resulting range.

Complexity: Exactly \(last - first\) applications of the corresponding predicate.

Remarks: Stable (15.5.5.7).

23.6.2 Move [alg.move]
Effects: Moves elements in the range \([\text{first, last})\) into the range \([\text{result, result + (last - first)})\) starting from first and proceeding to last. For each non-negative integer \(n < (\text{last - first})\), performs \(*\text{(result + n)} = \text{std::move(*(first + n))}\).

Returns: \(\text{result + (last - first)}\).

Complexity: Exactly \(\text{last - first}\) move assignments.

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2 move(ExecutionPolicy&& policy,
    ForwardIterator1 first, ForwardIterator1 last,
    ForwardIterator2 result);

Requires: The ranges \([\text{first, last})\) and \([\text{result, result + (last - first)})\) shall not overlap.

Effects: Moves elements in the range \([\text{first, last})\) into the range \([\text{result, result + (last - first)})\). For each non-negative integer \(n < (\text{last - first})\), performs \(*\text{(result + n)} = \text{std::move(*(first + n))}\).

Returns: \(\text{result + (last - first)}\).

Complexity: Exactly \(\text{last - first}\) assignments.

template<class BidirectionalIterator1, class BidirectionalIterator2>
constexpr BidirectionalIterator2
move_backward(BidirectionalIterator1 first, BidirectionalIterator1 last,
    BidirectionalIterator2 result);

Requires: \(\text{result}\) shall not be in the range \([\text{first, last})\).

Effects: Moves elements in the range \([\text{first, last})\) into the range \([\text{result - (last-first), result})\) starting from \(\text{last - 1}\) and proceeding to first. For each positive integer \(n \leq (\text{last - first})\), performs \(*\text{(result - n)} = \text{std::move(*(last - n))}\).

Returns: \(\text{result - (last - first)}\).

Complexity: Exactly \(\text{last - first}\) assignments.

23.6.3 Swap

template<class ForwardIterator1, class ForwardIterator2>
constexpr ForwardIterator2
swap_ranges(ForwardIterator1 first1, ForwardIterator1 last1,
    ForwardIterator2 first2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2
swap_ranges(ExecutionPolicy&& exec,
    ForwardIterator1 first1, ForwardIterator1 last1,
    ForwardIterator2 first2);

Requires: The two ranges \([\text{first1, last1})\) and \([\text{first2, first2 + (last1 - first1)})\) shall not overlap. \(*\text{(first1 + n)}\) shall be swappable with \((15.5.3.2) \ast\text{(first2 + n)}\).

Effects: For each non-negative integer \(n < (\text{last1 - first1})\) performs: \text{swap(*(first1 + n)}, *(\text{first2 + n}))\).

Returns: \(\text{first2 + (last1 - first1)}\).

Complexity: Exactly last1 - first1 swaps.

template<class ForwardIterator1, class ForwardIterator2>
constexpr void iter_swap(ForwardIterator1 a, ForwardIterator2 b);

Requires: \(a\) and \(b\) shall be dereferenceable. \(*a\) shall be swappable with \((15.5.3.2) \ast b\).

Effects: As if by \text{swap(*a, *b)}.

move_backward should be used instead of move when last is in the range \([\text{result - (last - first)}, \text{result})\).
23.6.4 Transform \[\text{alg.transform}\]

\[
\text{template}<\text{class InputIterator}, \text{class OutputIterator}, \text{class UnaryOperation}>
\text{constexpr OutputIterator transform(InputIterator first, InputIterator last, OutputIterator result, UnaryOperation op);}
\]

\[
\text{template}<\text{class ExecutionPolicy}, \text{class ForwardIterator1}, \text{class ForwardIterator2}, \text{class UnaryOperation}>
\text{ForwardIterator2 transform(ExecutionPolicy&& exec, ForwardIterator1 first, ForwardIterator1 last, ForwardIterator2 result, UnaryOperation op);}
\]

\[
\text{template}<\text{class InputIterator1}, \text{class InputIterator2}, \text{class OutputIterator}, \text{class BinaryOperation}>
\text{constexpr OutputIterator transform(InputIterator1 first1, InputIterator1 last1, InputIterator2 first2, OutputIterator result, BinaryOperation binary_op);}
\]

\[
\text{template}<\text{class ExecutionPolicy}, \text{class ForwardIterator1}, \text{class ForwardIterator2}, \text{class BinaryOperation}>
\text{ForwardIterator transform(ExecutionPolicy&& exec, ForwardIterator1 first1, ForwardIterator1 last1, ForwardIterator2 first2, ForwardIterator result, BinaryOperation binary_op);}
\]

\text{Requires: op and binary\_op shall not invalidate iterators or subranges, or modify elements in the ranges}

\begin{align*}
(1.1) & \quad [\text{first1}, \text{last1}], \\
(1.2) & \quad [\text{first2}, \text{first2 + (last1 - first1)}], \text{and} \\
(1.3) & \quad [\text{result}, \text{result + (last1 - first1)}]. \tag{239}
\end{align*}

\text{Effects: Assigns through every iterator i in the range } [\text{result}, \text{result + (last1 - first1)}] \text{ a new corresponding value equal to } \text{op}\left((\text{first1 + (i - result)})\right) \text{ or } \text{binary\_op}(\text{first1 + (i - result)}), \text{ or } \text{binary\_op}(\text{first2 + (i - result)}).

\text{Returns: result + (last1 - first1).}

\text{Complexity: Exactly last1 - first1 applications of op or binary\_op. This requirement also applies to the overload with an ExecutionPolicy.}

\text{Remarks: result may be equal to first in case of unary transform, or to first1 or first2 in case of binary transform.}

23.6.5 Replace \[\text{alg.replace}\]

\[
\text{template}<\text{class ForwardIterator}, \text{class T}>
\text{constexpr void replace(ForwardIterator first, ForwardIterator last, const T& old_value, const T& new_value);}
\]

\[
\text{template}<\text{class ExecutionPolicy}, \text{class ForwardIterator}, \text{class T}>
\text{void replace(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last, const T& old_value, const T& new_value);}
\]

\[
\text{template}<\text{class ForwardIterator}, \text{class Predicate, class T}>
\text{constexpr void replace\_if(ForwardIterator first, ForwardIterator last, Predicate pred, const T& new_value);}
\]

\text{239} The use of fully closed ranges is intentional.

§ 23.6.5

895
template<class ExecutionPolicy, class ForwardIterator, class Predicate, class T>
void replace_if(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last,
Predicate pred, const T& new_value);

1. Requires: The expression *first = new_value shall be valid.

2. Effects: Substitutes elements referred by the iterator i in the range [first, last) with new_value, when the following corresponding conditions hold: *i == old_value, pred(*i) != false.

3. Complexity: Exactly last - first applications of the corresponding predicate.

template<class InputIterator, class OutputIterator, class T>
constexpr OutputIterator
replace_copy(InputIterator first, InputIterator last,
OutputIterator result,
const T& old_value, const T& new_value);

4. Requires: The results of the expressions *first and new_value shall be writable (22.2.1) to the result output iterator. The ranges [first, last) and [result, result + (last - first)) shall not overlap.

5. Effects: Assigns to every iterator i in the range [result, result + (last - first)) either new_value or *(first + (i - result)) depending on whether the following corresponding conditions hold:
   *first + (i - result)) == old_value
   pred(*first + (i - result))) != false

6. Returns: result + (last - first).

7. Complexity: Exactly last - first applications of the corresponding predicate.

23.6.6 Fill [alg.fill]

template<class ForwardIterator, class T>
constexpr void fill(ForwardIterator first, ForwardIterator last, const T& value);

template<class ExecutionPolicy, class ForwardIterator, class T>
void fill(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last, const T& value);

template<class OutputIterator, class Size, class T>
constexpr OutputIterator fill_n(OutputIterator first, Size n, const T& value);

template<class ExecutionPolicy, class ForwardIterator, class Size, class T>
ForwardIterator fill_n(ExecutionPolicy&& exec,
ForwardIterator first, Size n, const T& value);

1. Requires: The expression value shall be writable (22.2.1) to the output iterator. The type Size shall be convertible to an integral type (7.3.8, 10.3.8).
Effects: The fill algorithms assign value through all the iterators in the range \([\text{first}, \text{last})\). The fill_n algorithms assign value through all the iterators in the range \([\text{first}, \text{first} + n)\) if \(n\) is positive, otherwise they do nothing.

Returns: fill_n returns \(\text{first} + n\) for non-negative values of \(n\) and \(\text{first}\) for negative values.

Complexity: Exactly \(\text{last} - \text{first}\), \(n\), or 0 assignments, respectively.

### 23.6.7 Generate

```cpp
template<class ForwardIterator, class Generator>
constexpr void generate(ForwardIterator first, ForwardIterator last,
    Generator gen);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator, class Generator>
    void generate(ExecutionPolicy&& exec,
    ForwardIterator first, ForwardIterator last,
    Generator gen);
```

```cpp
template<class OutputIterator, class Size, class Generator>
constexpr OutputIterator generate_n(OutputIterator first, Size n, Generator gen);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator, class Size, class Generator>
    ForwardIterator generate_n(ExecutionPolicy&& exec,
    ForwardIterator first, Size n, Generator gen);
```

1 Requires: \(\text{gen}\) takes no arguments, \(\text{Size}\) shall be convertible to an integral type (7.3.8, 10.3.8).

2 Effects: The generate algorithms invoke the function object \(\text{gen}\) and assign the return value of \(\text{gen}\) through all the iterators in the range \([\text{first}, \text{last})\). The generate_n algorithms invoke the function object \(\text{gen}\) and assign the return value of \(\text{gen}\) through all the iterators in the range \([\text{first}, \text{first} + n)\) if \(n\) is positive, otherwise they do nothing.

3 Returns: generate_n returns \(\text{first} + n\) for non-negative values of \(n\) and \(\text{first}\) for negative values.

4 Complexity: Exactly \(\text{last} - \text{first}\), \(n\), or 0 invocations of \(\text{gen}\) and assignments, respectively.

### 23.6.8 Remove

```cpp
template<class ForwardIterator, class T>
constexpr ForwardIterator remove(ForwardIterator first, ForwardIterator last,
    const T& value);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator, class T>
ForwardIterator remove(ExecutionPolicy&& exec,
    ForwardIterator first, ForwardIterator last,
    const T& value);
```

```cpp
template<class ForwardIterator, class Predicate>
constexpr ForwardIterator remove_if(ForwardIterator first, ForwardIterator last,
    Predicate pred);
```

```cpp
template<class ExecutionPolicy, class ForwardIterator, class Predicate>
    ForwardIterator remove_if(ExecutionPolicy&& exec,
    ForwardIterator first, ForwardIterator last,
    Predicate pred);
```

1 Requires: The type of \(*\text{first}\) shall satisfy the Cpp17MoveAssignable requirements (Table 27).

2 Effects: Eliminates all the elements referred to by iterator \(i\) in the range \([\text{first}, \text{last})\) for which the following corresponding conditions hold: \(*i == \text{value}, \text{pred}(*i) != \text{false}\).

3 Returns: The end of the resulting range.

4 Remarks: Stable (15.5.5.7).

5 Complexity: Exactly \(\text{last} - \text{first}\) applications of the corresponding predicate.

6 [Note: Each element in the range \([\text{ret}, \text{last})\), where \(\text{ret}\) is the returned value, has a valid but unspecified state, because the algorithms can eliminate elements by moving from elements that were originally in that range. — end note]
template<class InputIterator, class OutputIterator, class T>
constexpr OutputIterator
remove_copy(InputIterator first, InputIterator last,
OutputIterator result, const T& value);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class T>
ForwardIterator2
remove_copy(ExecutionPolicy&& exec,
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result, const T& value);

template<class InputIterator, class OutputIterator, class Predicate>
constexpr OutputIterator
remove_copy_if(InputIterator first, InputIterator last,
OutputIterator result, Predicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
class Predicate>
ForwardIterator2
remove_copy_if(ExecutionPolicy&& exec,
ForwardIterator1 first, ForwardIterator1 last,
ForwardIterator2 result, Predicate pred);

7  Requires: The ranges [first, last) and [result, result + (last - first)) shall not overlap.
The expression *result = *first shall be valid. [Note: For the overloads with an ExecutionPolicy,
there may be a performance cost if iterator_traits<ForwardIterator1>::value_type is not Cpp17-
MoveConstructible (Table 25). — end note]

8  Effects: Copies all the elements referred to by the iterator i in the range [first, last) for which the
following corresponding conditions do not hold: *i == value, pred(*i) != false.

9  Returns: The end of the resulting range.

10 Complexity: Exactly last - first applications of the corresponding predicate.

11 Remarks: Stable (15.5.5.7).

23.6.9 Unique [alg.unique]

template<class ForwardIterator>
constexpr ForwardIterator
unique(ForwardIterator first, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator unique(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last);

template<class ForwardIterator, class BinaryPredicate>
constexpr ForwardIterator
unique(ForwardIterator first, ForwardIterator last,
BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator, class BinaryPredicate>
ForwardIterator unique(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last,
BinaryPredicate pred);

1  Requires: The comparison function shall be an equivalence relation. The type of *first shall satisfy
the Cpp17MoveAssignable requirements (Table 27).

2  Effects: For a nonempty range, eliminates all but the first element from every consecutive group
of equivalent elements referred to by the iterator i in the range [first + 1, last) for which the
following conditions hold: *(i - 1) == *i or pred(*(i - 1), *i) != false.

3  Returns: The end of the resulting range.

4  Complexity: For nonempty ranges, exactly (last - first) - 1 applications of the corresponding predicate.
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2
unique_copy(ExecutionPolicy&& exec,
    ForwardIterator1 first, ForwardIterator1 last,
    ForwardIterator2 result);

template<class InputIterator, class OutputIterator,
    class BinaryPredicate>
constexpr OutputIterator
unique_copy(InputIterator first, InputIterator last,
    OutputIterator result, BinaryPredicate pred);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
    class BinaryPredicate>
ForwardIterator2
unique_copy(ExecutionPolicy&& exec,
    ForwardIterator1 first, ForwardIterator1 last,
    ForwardIterator2 result, BinaryPredicate pred);

Requires:

(5.1) The comparison function shall be an equivalence relation.
(5.2) The ranges \([first, last)\) and \([result, result+(last-first))\) shall not overlap.
(5.3) The expression \(*result = *first\) shall be valid.
(5.4) For the overloads with no \(\text{ExecutionPolicy}\), let \(T\) be the value type of \(\text{InputIterator}\). If \(\text{InputIterator}\) meets the \(\text{Cpp17ForwardIterator}\) requirements, then there are no additional requirements for \(T\). Otherwise, if \(\text{OutputIterator}\) meets the \(\text{Cpp17ForwardIterator}\) requirements and its value type is the same as \(T\), then \(T\) shall be \(\text{Cpp17CopyAssignable}\) (Table 28). Otherwise, \(T\) shall be both \(\text{Cpp17CopyConstructible}\) (Table 26) and \(\text{Cpp17CopyAssignable}\). [Note: For the overloads with an \(\text{ExecutionPolicy}\), there may be a performance cost if the value type of \(\text{ForwardIterator1}\) is not both \(\text{Cpp17CopyConstructible}\) and \(\text{Cpp17CopyAssignable}\). —end note]

Effects: Copies only the first element from every consecutive group of equal elements referred to by the iterator \(i\) in the range \([first, last)\) for which the following corresponding conditions hold: \(\ast i = \ast(i - 1)\) or \(\text{pred}(\ast i, \ast(i - 1)) \neq \text{false}\).

Returns: The end of the resulting range.

Complexity: For nonempty ranges, exactly \(last - first - 1\) applications of the corresponding predicate.

23.6.10 Reverse

\[\text{alg.reverse}\]

template<class BidirectionalIterator>
constexpr void reverse(BidirectionalIterator first, BidirectionalIterator last);

template<class ExecutionPolicy, class BidirectionalIterator>
void reverse(ExecutionPolicy&& exec,
    BidirectionalIterator first, BidirectionalIterator last);

Requires: \(\text{BidirectionalIterator}\) shall satisfy the \(\text{Cpp17ValueSwappable}\) requirements (15.5.3.2).

Effects: For each non-negative integer \(i < (last - first) / 2\), applies \text{iter_swap} to all pairs of iterators \(\ast\ i, (last - i) - 1\).

Complexity: Exactly \((last - first)/2\) swaps.

template<class BidirectionalIterator, class OutputIterator>
constexpr OutputIterator
reverse_copy(BidirectionalIterator first, BidirectionalIterator last,
    OutputIterator result);

template<class ExecutionPolicy, class BidirectionalIterator, class ForwardIterator>
ForwardIterator
reverse_copy(ExecutionPolicy&& exec,
    BidirectionalIterator first, BidirectionalIterator last,
    ForwardIterator result);

Requires: The ranges \([first, last)\) and \([result, result + (last - first))\) shall not overlap.
Effects: Copies the range \([\text{first}, \text{last})\) to the range \([\text{result}, \text{result} + (\text{last} - \text{first}))\) such that for every non-negative integer \(i < (\text{last} - \text{first})\) the following assignment takes place: \(*(\text{result} + (\text{last} - \text{first}) - 1 - i) = *(\text{first} + i)\).

Returns: \(\text{result} + (\text{last} - \text{first})\).

Complexity: Exactly \(\text{last} - \text{first}\) assignments.

23.6.11 Rotate

\[
\begin{align*}
\text{template<class ForwardIterator>} & \\
\hspace{1em} & \text{constexpr ForwardIterator} \\
\hspace{2em} & \text{rotate(ForwardIterator first, ForwardIterator middle, ForwardIterator last);} \\
\text{template<class ExecutionPolicy, class ForwardIterator>} & \\
\hspace{1em} & \text{ForwardIterator} \\
\hspace{2em} & \text{rotate(ExecutionPolicy&& exec,} \\
\hspace{3em} & \text{ForwardIterator first, ForwardIterator middle, ForwardIterator last);} \\
\end{align*}
\]

Requires: \([\text{first}, \text{middle})\) and \([\text{middle}, \text{last})\) shall be valid ranges. \text{ForwardIterator} shall satisfy the Cpp17ValueSwappable requirements (15.5.3.2). The type of \(*\text{first}\) shall satisfy the Cpp17MoveConstructible (Table 25) and Cpp17MoveAssignable (Table 27) requirements.

Effects: For each non-negative integer \(i < (\text{last} - \text{first})\), places the element from the position \(\text{first} + i\) into position \(\text{first} + (i + (\text{last} - \text{middle})) \% (\text{last} - \text{first})\).

Returns: \(\text{first} + (\text{last} - \text{middle})\).

Remarks: This is a left rotate.

Complexity: At most \(\text{last} - \text{first}\) swaps.

\[
\begin{align*}
\text{template<class ForwardIterator, class OutputIterator>} & \\
\hspace{1em} & \text{constexpr OutputIterator} \\
\hspace{2em} & \text{rotate_copy(ForwardIterator first, ForwardIterator middle, ForwardIterator last,} \\
\hspace{3em} & \text{OutputIterator result);} \\
\text{template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>} & \\
\hspace{1em} & \text{ForwardIterator2} \\
\hspace{2em} & \text{rotate_copy(ExecutionPolicy&& exec,} \\
\hspace{3em} & \text{ForwardIterator1 first, ForwardIterator1 middle, ForwardIterator1 last,} \\
\hspace{4em} & \text{ForwardIterator2 result);} \\
\end{align*}
\]

Requires: The ranges \([\text{first}, \text{last})\) and \([\text{result}, \text{result} + (\text{last} - \text{first}))\) shall not overlap.

Effects: Copies the range \([\text{first}, \text{last})\) to the range \([\text{result}, \text{result} + (\text{last} - \text{first}))\) such that for each non-negative integer \(i < (\text{last} - \text{first})\) the following assignment takes place: \(*(\text{result} + i) = *(\text{first} + (i + (\text{middle} - \text{first})) \% (\text{last} - \text{first})).\)

Returns: \(\text{result} + (\text{last} - \text{first})\).

Complexity: Exactly \(\text{last} - \text{first}\) assignments.

23.6.12 Sample

\[
\begin{align*}
\text{template<class PopulationIterator, class SampleIterator,} & \\
\hspace{1em} & \text{class Distance, class UniformRandomBitGenerator>} \\
\hspace{2em} & \text{SampleIterator sample(PopulationIterator first, PopulationIterator last,} \\
\hspace{3em} & \text{SampleIterator out, Distance n,} \\
\hspace{4em} & \text{UniformRandomBitGenerator&& g);} \\
\end{align*}
\]

Requires:

(1.1) \text{PopulationIterator} shall satisfy the Cpp17InputIterator requirements (22.2.3).

(1.2) \text{SampleIterator} shall satisfy the Cpp17OutputIterator requirements (22.2.4).

(1.3) \text{SampleIterator} shall satisfy the Cpp17RandomAccessIterator requirements (22.2.7) unless PopulationIterator satisfies the Cpp17ForwardIterator requirements (22.2.5).

(1.4) \text{PopulationIterator}’s value type shall be writable (22.2.1) to out.

(1.5) \text{Distance} shall be an integer type.
(1.6) — `remove_reference_t<UniformRandomBitGenerator>` shall satisfy the requirements of a uniform random bit generator type (24.7.2.3) whose return type is convertible to `Distance`.

(1.7) — `out` shall not be in the range `[first, last).

Effects: Copies \(\min(last - first, n)\) elements (the sample) from `[first, last)` (the population) to `out` such that each possible sample has equal probability of appearance. [Note: Algorithms that obtain such effects include selection sampling and reservoir sampling. — end note]

Returns: The end of the resulting sample range.

Complexity: \(\Theta(last - first)\).

Remarks:

— Stable if and only if `PopulationIterator` satisfies the `Cpp17ForwardIterator` requirements.

— To the extent that the implementation of this function makes use of random numbers, the object \(g\) shall serve as the implementation’s source of randomness.

23.6.13 Shuffle [alg.random.shuffle]

```cpp
template<class RandomAccessIterator, class UniformRandomBitGenerator>
void shuffle(RandomAccessIterator first,
    RandomAccessIterator last,
    UniformRandomBitGenerator&& g);
```

1 Requires: `RandomAccessIterator` shall satisfy the `Cpp17ValueSwappable` requirements (15.5.3.2). The type `remove_reference_t<UniformRandomBitGenerator>` shall satisfy the requirements of a uniform random bit generator (24.7.2.3) type whose return type is convertible to `iterator_traits<RandomAccessIterator>::difference_type`.

2 Effects: Permutes the elements in the range `[first, last)` such that each possible permutation of those elements has equal probability of appearance.

3 Complexity: Exactly \((last - first) - 1\) swaps.

4 Remarks: To the extent that the implementation of this function makes use of random numbers, the object \(g\) shall serve as the implementation’s source of randomness.

23.6.14 Shift [alg.shift]

```cpp
template<class ForwardIterator>
constexpr ForwardIterator
shift_left(ForwardIterator first, ForwardIterator last,
    typename iterator_traits<ForwardIterator>::difference_type n);
```

1 Requires: The type of *first shall satisfy the `Cpp17MoveAssignable` requirements.

2 Effects: If \(n \leq 0\) or \(n \geq last - first\), does nothing. Otherwise, moves the element from position `first + n + i` into position `first + i` for each non-negative integer \(i < (last - first) - n\). In the first overload case, does so in order starting from \(i = 0\) and proceeding to \(i = (last - first) - n - 1\).

3 Returns: `first + (last - first - n)` if \(n\) is positive and \(n < last - first\), otherwise `first` if \(n\) is positive, otherwise `last`.

4 Complexity: At most \((last - first) - n\) assignments.

```cpp
template<class ForwardIterator>
constexpr ForwardIterator
shift_right(ForwardIterator first, ForwardIterator last,
    typename iterator_traits<ForwardIterator>::difference_type n);
```
template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator
    shift_right(ExecutionPolicy&& exec, ForwardIterator first, ForwardIterator last,
        typename iterator_traits<ForwardIterator>::difference_type n);

Requires: The type of *first shall satisfy the Cpp17MoveAssignable requirements. ForwardIterator shall meet the Cpp17BidirectionalIterator requirements (22.2.6) or the Cpp17ValueSwappable requirements.

Effects: If n <= 0 or n >= last - first, does nothing. Otherwise, moves the element from position first + i into position first + n + i for each non-negative integer i < (last - first) - n. In the first overload case, if ForwardIterator satisfies the Cpp17BidirectionalIterator requirements, does so in order starting from i = (last - first) - n - 1 and proceeding to i = 0.

Returns: first + n if n is positive and n < last - first, otherwise last if n is positive, otherwise first.

Complexity: At most (last - first) - n assignments or swaps.

23.7 Sorting and related operations

All the operations in 23.7 have two versions: one that takes a function object of type Compare and one that uses an operator<.

Compare is a function object type (19.14). The return value of the function call operation applied to an object of type Compare, when contextually converted to bool (7.3), yields true if the first argument of the call is less than the second, and false otherwise. Compare comp is used throughout for algorithms assuming an ordering relation. It is assumed that comp will not apply any non-constant function through the dereferenced iterator.

For all algorithms that take Compare, there is a version that uses operator< instead. That is, comp(*i, *j) != false defaults to *i < *j != false. For algorithms other than those described in 23.7.3, comp shall induce a strict weak ordering on the values.

The term strict refers to the requirement of an irreflexive relation (!comp(x, x) for all x), and the term weak to requirements that are not as strong as those for a total ordering, but stronger than those for a partial ordering. If we define equiv(a, b) as !comp(a, b) && !comp(b, a), then the requirements are that comp and equiv both be transitive relations:

- comp(a, b) && comp(b, c) implies comp(a, c)
- equiv(a, b) && equiv(b, c) implies equiv(a, c)

[Note: Under these conditions, it can be shown that

- equiv is an equivalence relation,
- comp induces a well-defined relation on the equivalence classes determined by equiv, and
- the induced relation is a strict total ordering.

-end note]

A sequence is sorted with respect to a comparator comp if for every iterator i pointing to the sequence and every non-negative integer n such that i + n is a valid iterator pointing to an element of the sequence, comp(*i+n, *i) == false.

A sequence [start, finish) is partitioned with respect to an expression f(e) if there exists an integer n such that for all 0 <= i < (finish - start), f(*(start + i)) is true if and only if i < n.

In the descriptions of the functions that deal with ordering relationships we frequently use a notion of equivalence to describe concepts such as stability. The equivalence to which we refer is not necessarily an operator==, but an equivalence relation induced by the strict weak ordering. That is, two elements a and b are considered equivalent if and only if !(a < b) && !(b < a).

23.7.1 Sorting

23.7.1.1 sort

template<class RandomAccessIterator>
    constexpr void sort(RandomAccessIterator first, RandomAccessIterator last);

§ 23.7.1.1 902
template<class ExecutionPolicy, class RandomAccessIterator>
void sort(ExecutionPolicy&& exec,
    RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
constexpr void sort(RandomAccessIterator first, RandomAccessIterator last,
    Compare comp);

template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
void sort(ExecutionPolicy&& exec,
    RandomAccessIterator first, RandomAccessIterator last,
    Compare comp);

Requires: RandomAccessIterator shall satisfy the Cpp17ValueSwappable requirements (15.5.3.2).
The type of *first shall satisfy the Cpp17MoveConstructible (Table 25) and Cpp17MoveAssignable
(Table 27) requirements.

Effects: Sorts the elements in the range [first, last).

Complexity: $O(N \log N)$ comparisons, where $N = last - first$.

23.7.1.2  stable_sort

template<class RandomAccessIterator>
void stable_sort(RandomAccessIterator first, RandomAccessIterator last);

template<class ExecutionPolicy, class RandomAccessIterator>
void stable_sort(ExecutionPolicy&& exec,
    RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
void stable_sort(RandomAccessIterator first, RandomAccessIterator last,
    Compare comp);

template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
void stable_sort(ExecutionPolicy&& exec,
    RandomAccessIterator first, RandomAccessIterator last,
    Compare comp);

Requires: RandomAccessIterator shall satisfy the Cpp17ValueSwappable requirements (15.5.3.2).
The type of *first shall satisfy the Cpp17MoveConstructible (Table 25) and Cpp17MoveAssignable
(Table 27) requirements.

Effects: Sorts the elements in the range [first, last).

Complexity: At most $N \log_2^2(N)$ comparisons, where $N = last - first$, but only $N \log N$ comparisons
if there is enough extra memory.

Remarks: Stable (15.5.5.7).

23.7.1.3  partial_sort

template<class RandomAccessIterator>
constexpr void partial_sort(RandomAccessIterator first,
    RandomAccessIterator middle,
    RandomAccessIterator last);

template<class ExecutionPolicy, class RandomAccessIterator>
void partial_sort(ExecutionPolicy&& exec,
    RandomAccessIterator first,
    RandomAccessIterator middle,
    RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
constexpr void partial_sort(RandomAccessIterator first,
    RandomAccessIterator middle,
    RandomAccessIterator last,
    Compare comp);

template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
void partial_sort(ExecutionPolicy&& exec,
    RandomAccessIterator first,
    RandomAccessIterator middle,
    RandomAccessIterator last,
    Compare comp);

Requirements: RandomAccessIterator shall satisfy the Cpp17ValueSwappable requirements (15.5.3.2).
The type of *first shall satisfy the Cpp17MoveConstructible (Table 25) and Cpp17MoveAssignable
(Table 27) requirements.

Effects: Sorts the elements in the range [first, last).

Complexity: At most $N \log^2(N)$ comparisons, where $N = last - first$, but only $N \log N$ comparisons
if there is enough extra memory.

Remarks: Stable (15.5.5.7).
template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
void partial_sort(ExecutionPolicy&& exec,
    RandomAccessIterator first,
    RandomAccessIterator middle,
    RandomAccessIterator last,
    Compare comp);

1 Requires: RandomAccessIterator shall satisfy the Cpp17ValueSwappable requirements (15.5.3.2). The type of *first shall satisfy the Cpp17MoveConstructible (Table 25) and Cpp17MoveAssignable (Table 27) requirements.

2 Effects: Places the first middle - first sorted elements from the range [first, last) into the range [first, middle). The rest of the elements in the range [middle, last) are placed in an unspecified order.

3 Complexity: Approximately (last - first) * log(middle - first) comparisons.

23.7.1.4 partial_sort_copy

template<class InputIterator, class RandomAccessIterator>
constexpr RandomAccessIterator
partial_sort_copy(InputIterator first, InputIterator last,
    RandomAccessIterator result_first,
    RandomAccessIterator result_last);

template<class ExecutionPolicy, class ForwardIterator, class RandomAccessIterator>
RandomAccessIterator
partial_sort_copy(ExecutionPolicy&& exec,
    ForwardIterator first, ForwardIterator last,
    RandomAccessIterator result_first,
    RandomAccessIterator result_last);

template<class InputIterator, class RandomAccessIterator,
    class Compare>
constexpr RandomAccessIterator
partial_sort_copy(InputIterator first, InputIterator last,
    RandomAccessIterator result_first,
    RandomAccessIterator result_last,
    Compare comp);

template<class ExecutionPolicy, class ForwardIterator, class RandomAccessIterator,
    class Compare>
RandomAccessIterator
partial_sort_copy(ExecutionPolicy&& exec,
    ForwardIterator first, ForwardIterator last,
    RandomAccessIterator result_first,
    RandomAccessIterator result_last,
    Compare comp);

1 Requires: RandomAccessIterator shall satisfy the Cpp17ValueSwappable requirements (15.5.3.2). The type of *result_first shall satisfy the Cpp17MoveConstructible (Table 25) and Cpp17MoveAssignable (Table 27) requirements.

2 Effects: Places the first min(last - first, result_last - result_first) sorted elements into the range [result_first, result_first + min(last - first, result_last - result_first)).

3 Returns: The smaller of: result_last or result_first + (last - first).

4 Complexity: Approximately (last - first) * log(min(last - first, result_last - result_first)) comparisons.

23.7.1.5 is_sorted

template<class ForwardIterator>
constexpr bool is_sorted(ForwardIterator first, ForwardIterator last);

1 Returns: is_sorted_until(first, last) == last.
template<class ExecutionPolicy, class ForwardIterator>
bool is_sorted(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last);

Returns: is_sorted_until(std::forward<ExecutionPolicy>(exec), first, last) == last.

template<class ExecutionPolicy, class ForwardIterator, class Compare>
bool is_sorted(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last,
Compare comp);

Returns: is_sorted_until(first, last, comp) == last.

template<class ExecutionPolicy, class ForwardIterator, class Compare>
bool is_sorted(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last,
Compare comp);

Returns:
is_sorted_until(std::forward<ExecutionPolicy>(exec), first, last, comp) == last

template<class ForwardIterator, class Compare>
constexpr bool is_sorted(ForwardIterator first, ForwardIterator last,
Compare comp);

Returns: is_sorted_until(first, last, comp) == last.

template<class ForwardIterator>
constexpr ForwardIterator
is_sorted_until(ForwardIterator first, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator
is_sorted_until(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last);

Returns: If (last - first) < 2, returns last. Otherwise, returns the last iterator i in [first, last] for which the range [first, i) is sorted.

Complexity: Linear.

23.7.2 Nth element

template<class RandomAccessIterator>
constexpr void nth_element(RandomAccessIterator first, RandomAccessIterator nth,
RandomAccessIterator last);

template<class ExecutionPolicy, class RandomAccessIterator>
void nth_element(ExecutionPolicy&& exec,
RandomAccessIterator first, RandomAccessIterator nth,
RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
constexpr void nth_element(RandomAccessIterator first, RandomAccessIterator nth,
RandomAccessIterator last, Compare comp);

template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
void nth_element(ExecutionPolicy&& exec,
RandomAccessIterator first, RandomAccessIterator nth,
RandomAccessIterator last, Compare comp);

Requires: RandomAccessIterator shall satisfy the Cpp17ValueSwappable requirements (15.5.3.2). The type of *first shall satisfy the Cpp17MoveConstructible (Table 25) and Cpp17MoveAssignable (Table 27) requirements.

Effects: After nth_element the element in the position pointed to by nth is the element that would be in that position if the whole range were sorted, unless nth == last. Also for every iterator i in
the range \([\text{first}, \text{nth})\) and every iterator \(j\) in the range \([\text{nth}, \text{last})\) it holds that: \(!(*j < *i)\) or \(\text{comp}(*j, *i) == \text{false}\).

**Complexity:** For the overloads with no **ExecutionPolicy**, linear on average. For the overloads with an **ExecutionPolicy**, \(O(N)\) applications of the predicate, and \(O(N \log N)\) swaps, where \(N = \text{last} - \text{first}\).

### 23.7.3 Binary search

All of the algorithms in this subclause are versions of binary search and assume that the sequence being searched is partitioned with respect to an expression formed by binding the search key to an argument of the implied or explicit comparison function. They work on non-random access iterators minimizing the number of comparisons, which will be logarithmic for all types of iterators. They are especially appropriate for random access iterators, because these algorithms do a logarithmic number of steps through the data structure. For non-random access iterators they execute a linear number of steps.

#### 23.7.3.1 lower_bound

\[
\text{lower_bound}(\text{first}, \text{last}, \text{value});
\]

**Requires:** The elements \(e\) of \([\text{first}, \text{last})\) shall be partitioned with respect to the expression \(e < \text{value}\) or \(\text{comp}(e, \text{value})\).

**Returns:** The furthermost iterator \(i\) in the range \([\text{first}, \text{last})\) such that for every iterator \(j\) in the range \([\text{first}, i)\) the following corresponding conditions hold: \(*j < \text{value}\) or \(\text{comp}(*j, \text{value}) \neq \text{false}\).

**Complexity:** At most \(\log_2(\text{last} - \text{first}) + O(1)\) comparisons.

#### 23.7.3.2 upper_bound

\[
\text{upper_bound}(\text{first}, \text{last}, \text{value});
\]

**Requires:** The elements \(e\) of \([\text{first}, \text{last})\) shall be partitioned with respect to the expression \(!!(\text{value} < e)\) or \(!\text{comp}(\text{value}, e)\).

**Returns:** The furthermost iterator \(i\) in the range \([\text{first}, \text{last})\) such that for every iterator \(j\) in the range \([\text{first}, i)\) the following corresponding conditions hold: \(!(\text{value} < *j)\) or \(\text{comp(\text{value}, *j)} \neq \text{false}\).

**Complexity:** At most \(\log_2(\text{last} - \text{first}) + O(1)\) comparisons.

#### 23.7.3.3 equal_range

\[
\text{equal_range}(\text{first}, \text{last}, \text{value});
\]
template<class ForwardIterator, class T, class Compare>
constexpr pair<ForwardIterator, ForwardIterator>
equal_range(ForwardIterator first, ForwardIterator last, const T& value, Compare comp);

**Requires:** The elements e of [first, last) shall be partitioned with respect to the expressions e < value and !(value < e) or comp(e, value) and !comp(value, e). Also, for all elements e of [first, last), e < value shall imply !(value < e) or comp(e, value) shall imply !comp(value, e).

**Returns:**
make_pair(lower_bound(first, last, value),
upper_bound(first, last, value))
or
make_pair(lower_bound(first, last, value, comp),
upper_bound(first, last, value, comp))

**Complexity:** At most 2 * log₂(last - first) + O(1) comparisons.

---

### 23.7.3.4 `binary_search`

**template<class ForwardIterator, class T>**

```cpp
constexpr bool binary_search(ForwardIterator first, ForwardIterator last, const T& value);
```

**Requires:** The elements e of [first, last) shall be partitioned with respect to the expressions e < value and !(value < e) or comp(e, value) and !comp(value, e). Also, for all elements e of [first, last), e < value shall imply !(value < e) or comp(e, value) shall imply !comp(value, e).

**Returns:** true if there is an iterator i in the range [first, last) that satisfies the corresponding conditions: !(i < value) && !(value < i) or comp(*i, value) == false && comp(value, *i) == false.

**Complexity:** At most log₂(last - first) + O(1) comparisons.

---

### 23.7.4 Partitions

**template<class InputIterator, class Predicate>**

```cpp
constexpr bool is_partitioned(InputIterator first, InputIterator last, Predicate pred);
```

**Requires:** For the overload with no `ExecutionPolicy`, `InputIterator`'s value type shall be convertible to `Predicate`'s argument type. For the overload with an `ExecutionPolicy`, `ForwardIterator`'s value type shall be convertible to `Predicate`'s argument type.

**Returns:** true if [first, last) is empty or if the elements e of [first, last) are partitioned with respect to the expression pred(e).

**Complexity:** Linear. At most last - first applications of pred.

**template<class ForwardIterator, class Predicate>**

```cpp
constexpr ForwardIterator partition(ForwardIterator first, ForwardIterator last, Predicate pred);
```
template<class ExecutionPolicy, class ForwardIterator, class Predicate>
ForwardIterator
partition(ExecutionPolicy&& exec,
    ForwardIterator first, ForwardIterator last, Predicate pred);

Requires: ForwardIterator shall satisfy the Cpp17ValueSwappable requirements (15.5.3.2).

Effects: Places all the elements in the range [first, last) that satisfy pred before all the elements
that do not satisfy it.

Returns: An iterator i such that for every iterator j in the range [first, i) pred(*j) != false, and for
every iterator k in the range [i, last), pred(*k) == false.

Complexity: Let \( N = \text{last} - \text{first} \):
(7.1) For the overload with no ExecutionPolicy, exactly \( N \) applications of the predicate. At most \( N/2 \) swaps if ForwardIterator meets the Cpp17BidirectionalIterator requirements and at most \( N \) swaps otherwise.
(7.2) For the overload with an ExecutionPolicy, \( \Theta(N \log N) \) swaps and \( \Theta(N) \) applications of the predicate.

template<class BidirectionalIterator, class Predicate>
BidirectionalIterator
stable_partition(BidirectionalIterator first, BidirectionalIterator last, Predicate pred);

Requires: BidirectionalIterator shall satisfy the Cpp17ValueSwappable requirements (15.5.3.2). The type of *first shall satisfy the Cpp17MoveConstructible (Table 25) and Cpp17MoveAssignable (Table 27) requirements.

Effects: Places all the elements in the range [first, last) that satisfy pred before all the elements
that do not satisfy it.

Returns: An iterator i such that for every iterator j in the range [first, i), pred(*j) != false, and for
every iterator k in the range [i, last), pred(*k) == false. The relative order of the elements
in both groups is preserved.

Complexity: Let \( N = \text{last} - \text{first} \):
(11.1) For the overload with no ExecutionPolicy, at most \( N \log N \) swaps, but only \( \Theta(N) \) swaps if there
is enough extra memory. Exactly \( N \) applications of the predicate.
(11.2) For the overload with an ExecutionPolicy, \( \Theta(N \log N) \) swaps and \( \Theta(N) \) applications of the predicate.

template<class InputIterator1, class OutputIterator1, 
    class OutputIterator2, class Predicate>
constexpr pair<OutputIterator1, OutputIterator2>
partition_copy(InputIterator first, InputIterator last, 
    OutputIterator1 out_true, OutputIterator2 out_false, Predicate pred);

Requires:
(12.1) For the overload with no ExecutionPolicy, InputIterator’s value type shall be Cpp17Copy-
Assignable (Table 28), and shall be writable (22.2.1) to the out_true and out_false OutputIter-
ators, and shall be convertible to Predicate’s argument type.
(12.2) For the overload with an ExecutionPolicy, ForwardIterator’s value type shall be Cpp17Copy-
Assignable, and shall be writable to the out_true and out_false ForwardIterators, and shall
be convertible to Predicate's argument type. [Note: There may be a performance cost if ForwardIterator's value type is not Cpp17CopyConstructible. — end note]

(12.3)

Effects: For each iterator i in \([\text{first}, \text{last})\), copies \(*i\) to the output range beginning with out_true if \(\text{pred}(\ast i)\) is true, or to the output range beginning with out_false otherwise.

Returns: A pair p such that p.first is the end of the output range beginning at out_true and p.second is the end of the output range beginning at out_false.

Complexity: Exactly \(\text{last} - \text{first}\) applications of \(\text{pred}\).

template<class ForwardIterator, class Predicate>
constexpr ForwardIterator
\(\text{partition\_point}(\text{ForwardIterator first}, \text{ForwardIterator last}, \text{Predicate pred})\);

Requires: ForwardIterator's value type shall be convertible to Predicate's argument type. The elements \(e\) of \([\text{first}, \text{last})\) shall be partitioned with respect to the expression \(\text{pred}(e)\).

Returns: An iterator mid such that all_of\((\text{first}, \text{mid}, \text{pred})\) and none_of\((\text{mid}, \text{last}, \text{pred})\) are both true.

Complexity: \(\Theta(\log((\text{last} - \text{first}))\) applications of \(\text{pred}\).

23.7.5 Merge

"alg.merge"

\text{template}<\text{class InputIterator1, class InputIterator2, class OutputIterator}>
\text{constexpr OutputIterator}
\text{merge}(\text{InputIterator1 first1, InputIterator1 last1, InputIterator2 first2, InputIterator2 last2, OutputIterator result});

\text{template}<\text{class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class ForwardIterator}>
\text{ForwardIterator}
\text{merge(ExecutionPolicy&& exec, ForwardIterator1 first1, ForwardIterator1 last1, ForwardIterator2 first2, ForwardIterator2 last2, ForwardIterator result});

\text{template}<\text{class InputIterator1, class InputIterator2, class OutputIterator, class Compare}>
\text{constexpr OutputIterator}
\text{merge}(\text{InputIterator1 first1, InputIterator1 last1, InputIterator2 first2, InputIterator2 last2, OutputIterator result, Compare comp});

\text{template}<\text{class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class Compare}>
\text{ForwardIterator}
\text{merge(ExecutionPolicy&& exec, ForwardIterator1 first1, ForwardIterator1 last1, ForwardIterator2 first2, ForwardIterator2 last2, ForwardIterator result, Compare comp});

Requires: The ranges \([\text{first1}, \text{last1})\) and \([\text{first2}, \text{last2})\) shall be sorted with respect to operator< or comp. The resulting range shall not overlap with either of the original ranges.

Effects: Copies all the elements of the two ranges \([\text{first1}, \text{last1})\) and \([\text{first2}, \text{last2})\) into the range \([\text{result}, \text{result}\_\text{last})\), where \(\text{result}\_\text{last}\) is \(\text{result} + (\text{last1} - \text{first1}) + (\text{last2} - \text{first2})\), such that the resulting range satisfies is_sorted\((\text{result}, \text{result}\_\text{last}, \text{comp})\), respectively.

Returns: \(\text{result} + (\text{last1} - \text{first1}) + (\text{last2} - \text{first2})\).

Complexity: Let \(N = (\text{last1} - \text{first1}) + (\text{last2} - \text{first2})\):

— For the overloads with no ExecutionPolicy, at most \(N - 1\) comparisons.

— For the overloads with an ExecutionPolicy, \(\Theta(N)\) comparisons.
5  Remarks: Stable (15.5.5.7).

```cpp
template<class BidirectionalIterator>
void inplace_merge(BidirectionalIterator first,
                  BidirectionalIterator middle,
                  BidirectionalIterator last);
```

```cpp
template<class ExecutionPolicy, class BidirectionalIterator>
void inplace_merge(ExecutionPolicy&& exec,
                  BidirectionalIterator first,
                  BidirectionalIterator middle,
                  BidirectionalIterator last);
```

```cpp
template<class BidirectionalIterator, class Compare>
void inplace_merge(BidirectionalIterator first,
                  BidirectionalIterator middle,
                  BidirectionalIterator last, Compare comp);
```

```cpp
template<class ExecutionPolicy, class BidirectionalIterator, class Compare>
void inplace_merge(ExecutionPolicy&& exec,
                  BidirectionalIterator first,
                  BidirectionalIterator middle,
                  BidirectionalIterator last, Compare comp);
```

6  Requires: The ranges \([\text{first}, \text{middle})\) and \([\text{middle}, \text{last})\) shall be sorted with respect to \texttt{operator<}

\ orm \texttt{comp}. \texttt{BidirectionalIterator} shall satisfy the \texttt{Cpp17ValueSwappable} requirements (15.5.3.2).
The type of \texttt{*first} shall satisfy the \texttt{Cpp17MoveConstructible} (Table 25) and \texttt{Cpp17MoveAssignable}

\orm (Table 27) requirements.

7  Effects: Merges two sorted consecutive ranges \([\text{first}, \text{middle})\) and \([\text{middle}, \text{last})\), putting the result of the merge into the range \([\text{first}, \text{last})\). The resulting range will be in non-decreasing order; that is, for every iterator \(i\) in \([\text{first}, \text{last})\) other than \texttt{first}, the condition \(*i < *(i - 1)\) or,

\orm \texttt{comp(*i, *(i - 1))} will be false.

8  Complexity: Let \(N = \text{last} - \text{first}:

\(\text{(8.1)}\)

\orm — For the overloads with no \texttt{ExecutionPolicy}, if enough additional memory is available, exactly \(N - 1\) comparisons.

\(\text{(8.2)}\)

\orm — For the overloads with no \texttt{ExecutionPolicy} if no additional memory is available, \(\Theta(N \log N)\) comparisons.

\(\text{(8.3)}\)

\orm — For the overloads with an \texttt{ExecutionPolicy}, \(\Theta(N \log N)\) comparisons.

9  Remarks: Stable (15.5.5.7).

### 23.7.6 Set operations on sorted structures

This subclause defines all the basic set operations on sorted structures. They also work with \texttt{multisets} (21.4.7) containing multiple copies of equivalent elements. The semantics of the set operations are generalized to \texttt{multisets} in a standard way by defining \texttt{set_union()} to contain the maximum number of occurrences of every element, \texttt{set_intersection()} to contain the minimum, and so on.

#### 23.7.6.1 includes

```cpp
#include<includes>
```
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class Compare>
bool includes(ExecutionPolicy&& exec,
            ForwardIterator1 first1, ForwardIterator1 last1,
            ForwardIterator2 first2, ForwardIterator2 last2,
            Compare comp);

Returns: true if \([\text{first2}, \text{last2})\) is empty or if every element in the range \([\text{first2}, \text{last2})\) is contained in the range \([\text{first1}, \text{last1})\). Returns false otherwise.

Complexity: At most \(2 \times ((\text{last1} - \text{first1}) + (\text{last2} - \text{first2})) - 1\) comparisons.

23.7.6.2 set_union

template<class InputIterator1, class InputIterator2, class OutputIterator>
constexpr OutputIterator
set_union(InputIterator1 first1, InputIterator1 last1,
          InputIterator2 first2, InputIterator2 last2,
          OutputIterator result);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class ForwardIterator>
ForwardIterator
set_union(ExecutionPolicy&& exec,
          ForwardIterator1 first1, ForwardIterator1 last1,
          ForwardIterator2 first2, ForwardIterator2 last2,
          ForwardIterator result);

template<class InputIterator1, class InputIterator2, class OutputIterator, class Compare>
constexpr OutputIterator
set_union(InputIterator1 first1, InputIterator1 last1,
          InputIterator2 first2, InputIterator2 last2,
          OutputIterator result, Compare comp);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class ForwardIterator, class Compare>
ForwardIterator
set_union(ExecutionPolicy&& exec,
          ForwardIterator1 first1, ForwardIterator1 last1,
          ForwardIterator2 first2, ForwardIterator2 last2,
          ForwardIterator result, Compare comp);

Requires: The resulting range shall not overlap with either of the original ranges.

Effects: Constructs a sorted union of the elements from the two ranges; that is, the set of elements that are present in one or both of the ranges.

Returns: The end of the constructed range.

Complexity: At most \(2 \times ((\text{last1} - \text{first1}) + (\text{last2} - \text{first2})) - 1\) comparisons.

Remarks: If \([\text{first1}, \text{last1})\) contains \(m\) elements that are equivalent to each other and \([\text{first2}, \text{last2})\) contains \(n\) elements that are equivalent to them, then all \(m\) elements from the first range shall be copied to the output range, in order, and then \(\max(n - m, 0)\) elements from the second range shall be copied to the output range, in order.

23.7.6.3 set_intersection

template<class InputIterator1, class InputIterator2, class OutputIterator>
constexpr OutputIterator
set_intersection(InputIterator1 first1, InputIterator1 last1,
                 InputIterator2 first2, InputIterator2 last2,
                 OutputIterator result);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class ForwardIterator>
ForwardIterator
set_intersection(ExecutionPolicy&& exec,
                 ForwardIterator1 first1, ForwardIterator1 last1,
template<class InputIterator1, class InputIterator2, 
        class OutputIterator, class Compare>
constexpr OutputIterator
    set_intersection(InputIterator1 first1, InputIterator1 last1, 
                    InputIterator2 first2, InputIterator2 last2, 
                    OutputIterator result, Compare comp);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, 
        class ForwardIterator, class Compare>
ForwardIterator
    set_intersection(ExecutionPolicy&& exec, 
                    ForwardIterator1 first1, ForwardIterator1 last1, 
                    ForwardIterator2 first2, ForwardIterator2 last2, 
                    ForwardIterator result, Compare comp);

Requires: The resulting range shall not overlap with either of the original ranges.

Effects: Constructs a sorted intersection of the elements from the two ranges; that is, the set of elements 
that are present in both of the ranges.

Returns: The end of the constructed range.

Complexity: At most \(2 \times ((last1 - first1) + (last2 - first2)) - 1\) comparisons.

Remarks: If \([first1, last1)\) contains \(m\) elements that are equivalent to each other and \([first2, last2)\) contains \(n\) elements that are equivalent to them, the first \(\min(m, n)\) elements shall be copied 
from the first range to the output range, in order.

23.7.6.4 set_difference

template<class InputIterator1, class InputIterator2, 
        class OutputIterator>
constexpr OutputIterator
    set_difference(InputIterator1 first1, InputIterator1 last1, 
                   InputIterator2 first2, InputIterator2 last2, 
                   OutputIterator result);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, 
        class ForwardIterator>
ForwardIterator
    set_difference(ExecutionPolicy&& exec, 
                   ForwardIterator1 first1, ForwardIterator1 last1, 
                   ForwardIterator2 first2, ForwardIterator2 last2, 
                   ForwardIterator result);

Requires: The resulting range shall not overlap with either of the original ranges.

Effects: Copies the elements of the range \([first1, last1)\) which are not present in the range 
\([first2, last2)\) to the range beginning at \(result\). The elements in the constructed range are sorted.

Returns: The end of the constructed range.

Complexity: At most \(2 \times ((last1 - first1) + (last2 - first2)) - 1\) comparisons.
Remarks: If \([\text{first}_1, \text{last}_1)\) contains \(m\) elements that are equivalent to each other and \([\text{first}_2, \text{last}_2)\) contains \(n\) elements that are equivalent to them, the last \(\max(m-n, 0)\) elements from \([\text{first}_1, \text{last}_1)\) shall be copied to the output range.

23.7.6.5 \textbf{set\_symmetric\_difference} \[set.symmetric.difference\]

\[
\begin{align*}
\text{template<} & \text{class InputIterator1, class InputIterator2,} \\
& \text{class OutputIterator}\}\text{> constexpr OutputIterator} \\
& \text{set\_symmetric\_difference(InputIterator1 \text{first}_1, \text{InputIterator1 last}_1,} \\
& \text{InputIterator2 \text{first}_2, \text{InputIterator2 last}_2,} \\
& \text{OutputIterator result);} \\
\text{template<} & \text{class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,} \\
& \text{class ForwardIterator}\}\text{> ForwardIterator} \\
& \text{set\_symmetric\_difference(ExecutionPolicy&& \text{exec,} } \\
& \text{ForwardIterator1 \text{first}_1, \text{ForwardIterator1 last}_1,} \\
& \text{ForwardIterator2 \text{first}_2, \text{ForwardIterator2 last}_2,} \\
& \text{ForwardIterator result);} \\
\text{template<} & \text{class InputIterator1, class InputIterator2,} \\
& \text{class OutputIterator, class Compare}\}\text{> constexpr OutputIterator} \\
& \text{set\_symmetric\_difference(InputIterator1 \text{first}_1, \text{InputIterator1 last}_1,} \\
& \text{InputIterator2 \text{first}_2, \text{InputIterator2 last}_2,} \\
& \text{OutputIterator result, Compare \text{comp);} \\
\text{template<} & \text{class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,} \\
& \text{class ForwardIterator, class Compare}\}\text{> ForwardIterator} \\
& \text{set\_symmetric\_difference(ExecutionPolicy&& \text{exec,} } \\
& \text{ForwardIterator1 \text{first}_1, \text{ForwardIterator1 last}_1,} \\
& \text{ForwardIterator2 \text{first}_2, \text{ForwardIterator2 last}_2,} \\
& \text{ForwardIterator result, Compare \text{comp);} \\
\end{align*}
\]

\textit{Requires}: The resulting range shall not overlap with either of the original ranges.

\textit{Effects}: Copies the elements of the range \([\text{first}_1, \text{last}_1)\) that are not present in the range \([\text{first}_2, \text{last}_2)\), and the elements of the range \([\text{first}_2, \text{last}_2)\) that are not present in the range \([\text{first}_1, \text{last}_1)\) to the range beginning at \textit{result}. The elements in the constructed range are sorted.

\textit{Returns}: The end of the constructed range.

\textit{Complexity}: At most \(2 * ((\text{last}_1 - \text{first}_1) + (\text{last}_2 - \text{first}_2)) - 1\) comparisons.

Remarks: If \([\text{first}_1, \text{last}_1)\) contains \(m\) elements that are equivalent to each other and \([\text{first}_2, \text{last}_2)\) contains \(n\) elements that are equivalent to them, then \(|m-n|\) of those elements shall be copied to the output range: the last \(m-n\) of these elements from \([\text{first}_1, \text{last}_1)\) if \(m>n\), and the last \(n-m\) of these elements from \([\text{first}_2, \text{last}_2)\) if \(m<n\).

23.7.7 \textbf{Heap operations} \[alg.heap.operations\]

A \textit{heap} is a particular organization of elements in a range between two random access iterators \([a, b)\) such that:

\begin{enumerate}
\item With \(N = b - a\), for all \(i, 0 < i < N, \text{comp}(a[\left\lfloor \frac{i-1}{2} \right\rfloor], a[i])\) is \textit{false}.
\item \(*a\) may be removed by \textit{pop\_heap()}\), or a new element added by \textit{push\_heap()}\), in \(O(\log N)\) time.
\end{enumerate}

These properties make heaps useful as priority queues.

\textit{make\_heap()} converts a range into a heap and \textit{sort\_heap()} turns a heap into a sorted sequence.

23.7.7.1 \textbf{push\_heap} \[push.heap\]

\[
\begin{align*}
\text{template<} & \text{class RandomAccessIterator}\}\text{> constexpr void push\_heap(RandomAccessIterator \text{first}, \text{RandomAccessIterator last)};} \\
\end{align*}
\]
23.7.7.2 pop_heap

```cpp
template<class RandomAccessIterator>
constexpr void pop_heap(RandomAccessIterator first, RandomAccessIterator last);
```

1. **Requires**: The range \([\text{first}, \text{last})\) shall be a valid non-empty heap.\(^1\) RandomAccessIterator shall satisfy the Cpp17ValueSwappable requirements (15.5.3.2). The type of *first shall satisfy the Cpp17MoveConstructible (Table 25) and Cpp17MoveAssignable (Table 27) requirements.

2. **Effects**: Swaps the value in the location first with the value in the location last - 1 and makes [first, last - 1) into a heap.

3. **Complexity**: At most \(2 \log(last - first)\) comparisons.

23.7.7.3 make_heap

```cpp
template<class RandomAccessIterator>
constexpr void make_heap(RandomAccessIterator first, RandomAccessIterator last);
```

1. **Requires**: The type of *first shall satisfy the Cpp17MoveConstructible requirements (Table 25) and the Cpp17MoveAssignable requirements (Table 27).

2. **Effects**: Constructs a heap out of the range [first, last).

3. **Complexity**: At most \(3(last - first)\) comparisons.

23.7.7.4 sort_heap

```cpp
template<class RandomAccessIterator>
constexpr void sort_heap(RandomAccessIterator first, RandomAccessIterator last);
```

1. **Requires**: The range \([\text{first}, \text{last})\) shall be a valid heap. RandomAccessIterator shall satisfy the Cpp17ValueSwappable requirements (15.5.3.2). The type of *first shall satisfy the Cpp17MoveConstructible (Table 25) and Cpp17MoveAssignable (Table 27) requirements.

2. **Effects**: Sorts elements in the heap [first, last).

3. **Complexity**: At most \(2N \log N\) comparisons, where \(N = last - first\).

23.7.7.5 is_heap

```cpp
template<class RandomAccessIterator>
constexpr bool is_heap(RandomAccessIterator first, RandomAccessIterator last);
```

1. **Returns**: is_heap_until(first, last) == last.
template<class ExecutionPolicy, class RandomAccessIterator>
bool is_heap(ExecutionPolicy&& exec,
            RandomAccessIterator first, RandomAccessIterator last);

Returns: is_heap_until(std::forward<ExecutionPolicy>(exec), first, last) == last.

template<class RandomAccessIterator, class Compare>
constexpr bool is_heap(RandomAccessIterator first, RandomAccessIterator last,
                        Compare comp);

Returns: is_heap_until(first, last, comp) == last.

template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
bool is_heap(ExecutionPolicy&& exec,
             RandomAccessIterator first, RandomAccessIterator last,
             Compare comp);

Returns: is_heap_until(std::forward<ExecutionPolicy>(exec), first, last, comp) == last.

template<class RandomAccessIterator>
constexpr RandomAccessIterator
is_heap_until(RandomAccessIterator first, RandomAccessIterator last);

template<class ExecutionPolicy, class RandomAccessIterator>
RandomAccessIterator
is_heap_until(ExecutionPolicy&& exec,
              RandomAccessIterator first, RandomAccessIterator last);

template<class RandomAccessIterator, class Compare>
constexpr RandomAccessIterator
is_heap_until(RandomAccessIterator first, RandomAccessIterator last, Compare comp);

template<class ExecutionPolicy, class RandomAccessIterator, class Compare>
RandomAccessIterator
is_heap_until(ExecutionPolicy&& exec,
              RandomAccessIterator first, RandomAccessIterator last,
              Compare comp);

Returns: If (last - first) < 2, returns last. Otherwise, returns the last iterator i in [first, last] for which the range [first, i) is a heap.

Complexity: Linear.

23.7.8 Minimum and maximum

template<class T> constexpr const T& min(const T& a, const T& b);

template<class T, class Compare>
constexpr const T& min(const T& a, const T& b, Compare comp);

Requires: For the first form, type T shall be Cpp17LessThanComparable (Table 23).

Returns: The smaller value.

Remarks: Returns the first argument when the arguments are equivalent.

Complexity: Exactly one comparison.

template<class T>
constexpr T min(initializer_list<T> t);

template<class T, class Compare>
constexpr T min(initializer_list<T> t, Compare comp);

Requires: T shall be Cpp17CopyConstructible and t.size() > 0. For the first form, type T shall be Cpp17LessThanComparable.

Returns: The smallest value in the initializer list.

Remarks: Returns a copy of the leftmost argument when several arguments are equivalent to the smallest.

Complexity: Exactly t.size() – 1 comparisons.
template<class T> constexpr const T& max(const T& a, const T& b);
template<class T, class Compare>
constexpr const T& max(const T& a, const T& b, Compare comp);

Requires: For the first form, type T shall be Cpp17LessThanComparable (Table 23).
Returns: The larger value.
Remarks: Returns the first argument when the arguments are equivalent.
Complexity: Exactly one comparison.

template<class T>
constexpr T max(initializer_list<T> t);
template<class T, class Compare>
constexpr T max(initializer_list<T> t, Compare comp);

Requires: T shall be Cpp17CopyConstructible and t.size() > 0. For the first form, type T shall be Cpp17LessThanComparable.
Returns: The largest value in the initializer list.
Remarks: Returns a copy of the leftmost argument when several arguments are equivalent to the largest.
Complexity: Exactly t.size() - 1 comparisons.

template<class T> constexpr pair<const T&, const T&> minmax(const T& a, const T& b);
template<class T, class Compare>
constexpr pair<const T&, const T&> minmax(const T& a, const T& b, Compare comp);

Requires: For the first form, type T shall be Cpp17LessThanComparable (Table 23).
Returns: pair<const T&, const T&>(b, a) if b is smaller than a, and pair<const T&, const T&>(a, b) otherwise.
Remarks: Returns pair<const T&, const T&>(a, b) when the arguments are equivalent.
Complexity: Exactly one comparison.

template<class T>
constexpr pair<T, T> minmax(initializer_list<T> t);
template<class T, class Compare>
constexpr pair<T, T> minmax(initializer_list<T> t, Compare comp);

Requires: T shall be Cpp17CopyConstructible and t.size() > 0. For the first form, type T shall be Cpp17LessThanComparable.
Returns: pair<T, T>(x, y), where x has the smallest and y has the largest value in the initializer list.
Remarks: x is a copy of the leftmost argument when several arguments are equivalent to the smallest. y is a copy of the rightmost argument when several arguments are equivalent to the largest.
Complexity: At most (3/2)t.size() applications of the corresponding predicate.

template<class ForwardIterator>
constexpr ForwardIterator min_element(ForwardIterator first, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator min_element(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last);

template<class ForwardIterator, class Compare>
constexpr ForwardIterator min_element(ForwardIterator first, ForwardIterator last,
Compare comp);

template<class ExecutionPolicy, class ForwardIterator, class Compare>
ForwardIterator min_element(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last,
Compare comp);

Returns: The first iterator i in the range [first, last) such that for every iterator j in the range [first, last) the following corresponding conditions hold: !(j < *i) or comp(*j, *i) == false. Returns last if first == last.
template<class ForwardIterator>
constexpr ForwardIterator max_element(ForwardIterator first, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
ForwardIterator max_element(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last);

template<class ForwardIterator, class Compare>
constexpr ForwardIterator max_element(ForwardIterator first, ForwardIterator last,
Compare comp);

template<class ExecutionPolicy, class ForwardIterator, class Compare>
ForwardIterator max_element(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last,
Compare comp);

Returns: The first iterator i in the range [first, last) such that for every iterator j in the range [first, last) the following corresponding conditions hold: !(i < j) or comp(*i, *j) == false. Returns last if first == last.

Complexity: Exactly max(last - first - 1, 0) applications of the corresponding comparisons.

template<class ForwardIterator>
constexpr pair<ForwardIterator, ForwardIterator> minmax_element(ForwardIterator first, ForwardIterator last);

template<class ExecutionPolicy, class ForwardIterator>
pair<ForwardIterator, ForwardIterator> minmax_element(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last);

template<class ForwardIterator, class Compare>
constexpr pair<ForwardIterator, ForwardIterator> minmax_element(ForwardIterator first, ForwardIterator last, Compare comp);

template<class ExecutionPolicy, class ForwardIterator, class Compare>
pair<ForwardIterator, ForwardIterator> minmax_element(ExecutionPolicy&& exec,
ForwardIterator first, ForwardIterator last, Compare comp);

Returns: make_pair(first, first) if [first, last) is empty, otherwise make_pair(m, M), where m is the first iterator in [first, last) such that no iterator in the range refers to a smaller element, and where M is the last iterator in [first, last) such that no iterator in the range refers to a larger element.

Complexity: At most max(\(\lceil \frac{3}{2}(N - 1) \rceil, 0\)) applications of the corresponding predicate, where N is last - first.

23.7.9 Bounded value

template<class T>
constexpr const T& clamp(const T& v, const T& lo, const T& hi);

template<class T, class Compare>
constexpr const T& clamp(const T& v, const T& lo, const T& hi, Compare comp);

Requires: The value of lo shall be no greater than hi. For the first form, type T shall be Cpp17LessThanComparable (Table 23).

Returns: lo if v is less than lo, hi if hi is less than v, otherwise v.

[Note: If NaN is avoided, T can be a floating-point type. — end note]

Complexity: At most two comparisons.

23.7.10 Lexicographical comparison

template<class InputIterator1, class InputIterator2>
constexpr bool
lexicographical_compare(InputIterator1 first1, InputIterator1 last1, 
InputIterator2 first2, InputIterator2 last2);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
bool
lexicographical_compare(ExecutionPolicy&& exec, 
ForwardIterator1 first1, ForwardIterator1 last1, 
ForwardIterator2 first2, ForwardIterator2 last2);

template<class InputIterator1, class InputIterator2, class Compare>
constexpr bool
lexicographical_compare(InputIterator1 first1, InputIterator1 last1, 
InputIterator2 first2, InputIterator2 last2, 
Compare comp);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, 
class Compare>
bool
lexicographical_compare(ExecutionPolicy&& exec, 
ForwardIterator1 first1, ForwardIterator1 last1, 
ForwardIterator2 first2, ForwardIterator2 last2, 
Compare comp);

1 Returns: true if the sequence of elements defined by the range [first1, last1) is lexicographically less than the sequence of elements defined by the range [first2, last2) and false otherwise.

2 Complexity: At most $2 \min(last1 - first1, last2 - first2)$ applications of the corresponding comparison.

3 Remarks: If two sequences have the same number of elements and their corresponding elements (if any) are equivalent, then neither sequence is lexicographically less than the other. If one sequence is a prefix of the other, then the shorter sequence is lexicographically less than the longer sequence. Otherwise, the lexicographical comparison of the sequences yields the same result as the comparison of the first corresponding pair of elements that are not equivalent.

4 [Example: The following sample implementation satisfies these requirements:

```cpp
for ( ; first1 != last1 && first2 != last2 ; ++first1, (void) ++first2) {
    if (*first1 < *first2) return true;
    if (*first2 < *first1) return false;
}
return first1 == last1 && first2 != last2;

— end example]
```

5 [Note: An empty sequence is lexicographically less than any non-empty sequence, but not less than any empty sequence. — end note]

### 23.7.11 Three-way comparison algorithms

[alg.3way]

template<class T, class U> constexpr auto compare_3way(const T& a, const U& b);

1 Effects: Compares two values and produces a result of the strongest applicable comparison category type:

(1.1) Returns a <=> b if that expression is well-formed.

(1.2) Otherwise, if the expressions a == b and a < b are each well-formed and convertible to bool, returns strong_ordering::equal when a == b is true, otherwise returns strong_ordering::less when a < b is true, and otherwise returns strong_ordering::greater.

(1.3) Otherwise, if the expression a == b is well-formed and convertible to bool, returns strong_equality::equal when a == b is true, and otherwise returns strong_equality::nonequal.

(1.4) Otherwise, the function is defined as deleted.

template<class InputIterator1, class InputIterator2, class Cmp>
constexpr auto
lexicographical_compare_3way(InputIterator1 b1, InputIterator1 e1, 
InputIterator2 b2, InputIterator2 e2, 
Cmp comp)
-> common_comparison_category_t<decltype(comp(*b1, *b2)), strong_ordering>;

Requires: Cmp shall be a function object type whose return type is a comparison category type.

Effects: Lexicographically compares two ranges and produces a result of the strongest applicable comparison category type. Equivalent to:

```cpp
for ( ; b1 != e1 && b2 != e2; void(++b1), void(++b2) )
    if (auto cmp = comp(*b1,*b2); cmp != 0)
        return cmp;
    return b1 != e1 ? strong_ordering::greater :
                    b2 != e2 ? strong_ordering::less :
                           strong_ordering::equal;
```

```cpp
template<class InputIterator1, class InputIterator2>
constexpr auto lexicographical_compare_3way(InputIterator1 b1, InputIterator1 e1,
                                           InputIterator2 b2, InputIterator2 e2);
```

Effects: Equivalent to:

```cpp
return lexicographical_compare_3way(b1, e1, b2, e2,
    [](const auto& t, const auto& u) { return compare_3way(t, u); });
```

### 23.7.12 Permutation generators

```cpp
template<class BidirectionalIterator>
constexpr bool next_permutation(BidirectionalIterator first,
                                 BidirectionalIterator last);
```

Requires: BidirectionalIterator shall satisfy the Cpp17ValueSwappable requirements (15.5.3.2).

Effects: Takes a sequence defined by the range [first, last) and transforms it into the next permutation. The next permutation is found by assuming that the set of all permutations is lexicographically sorted with respect to operator< or comp.

Returns: true if such a permutation exists. Otherwise, it transforms the sequence into the smallest permutation, that is, the ascendingly sorted one, and returns false.

Complexity: At most (last - first) / 2 swaps.

```cpp
template<class BidirectionalIterator, class Compare>
constexpr bool next_permutation(BidirectionalIterator first,
                                 BidirectionalIterator last, Compare comp);
```

### 23.8 Header <numeric> synopsis

```cpp
namespace std {
    // 23.9.1, accumulate
    template<class InputIterator, class T>
    T accumulate(InputIterator first, InputIterator last, T init);
}
```
template<class InputIterator, class T, class BinaryOperation>
T accumulate(InputIterator first, InputIterator last, T init, BinaryOperation binary_op);

// 23.9.2, reduce
template<class InputIterator>
typename iterator_traits<InputIterator>::value_type
reduce(InputIterator first, InputIterator last);
template<class InputIterator, class T>
T reduce(InputIterator first, InputIterator last, T init);
template<class InputIterator, class T, class BinaryOperation>
T reduce(InputIterator first, InputIterator last, T init, BinaryOperation binary_op);
template<class ExecutionPolicy, class ForwardIterator>
type name iterator_traits<ForwardIterator>::value_type
reduce(ExecutionPolicy&& exec, // see 23.3.5
ForwardIterator first, ForwardIterator last);
template<class ExecutionPolicy, class ForwardIterator, class T>
T reduce(ExecutionPolicy&& exec, // see 23.3.5
ForwardIterator first, ForwardIterator last, T init);
template<class ExecutionPolicy, class ForwardIterator, class T, class BinaryOperation>
T reduce(ExecutionPolicy&& exec, // see 23.3.5
ForwardIterator first, ForwardIterator last, T init, BinaryOperation binary_op);

// 23.9.3, inner product
template<class InputIterator1, class InputIterator2, class T>
T inner_product(InputIterator1 first1, InputIterator1 last1,
InputIterator2 first2, T init);
template<class InputIterator1, class InputIterator2, class T,
class BinaryOperation1, class BinaryOperation2>
T inner_product(InputIterator1 first1, InputIterator1 last1,
InputIterator2 first2, T init,
BinaryOperation1 binary_op1,
BinaryOperation2 binary_op2);

// 23.9.4, transform reduce
template<class InputIterator1, class InputIterator2, class T>
T transform_reduce(InputIterator1 first1, InputIterator1 last1,
InputIterator2 first2,

     ForwardIterator1 first,
     ForwardIterator1 last,
     ForwardIterator2 result);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class BinaryOperation>
ForwardIterator2 adjacent_difference(ExecutionPolicy& exec, // see 23.3.5
     ForwardIterator1 first,
     ForwardIterator1 last,
     ForwardIterator2 result,
     BinaryOperation binary_op);

// 23.9.11, iota
template<class ForwardIterator, class T>
void iota(ForwardIterator first, ForwardIterator last, T value);

// 23.9.12, greatest common divisor
template<class M, class N>
constexpr common_type_t<M,N> gcd(M m, N n);

// 23.9.13, least common multiple
template<class M, class N>
constexpr common_type_t<M,N> lcm(M m, N n);

23.9 Generalized numeric operations [numeric.ops]

1 [Note: The use of closed ranges as well as semi-open ranges to specify requirements throughout this subclause
is intentional. — end note]

23.9.1 Accumulate [accumulate]

template<class InputIterator, class T>
T accumulate(InputIterator first, InputIterator last, T init);

template<class InputIterator, class T, class BinaryOperation>
T accumulate(InputIterator first, InputIterator last, T init,
               BinaryOperation binary_op);

1 Requires: T shall satisfy the Cpp17CopyConstructible (Table 26) and Cpp17CopyAssignable (Table 28)
requirements. In the range [first, last], binary_op shall neither modify elements nor invalidate
iterators or subranges.

2 Effects: Computes its result by initializing the accumulator acc with the initial value init and then
modifies it with acc = std::move(acc) + *i or acc = binary_op(std::move(acc), *i) for every
iterator i in the range [first, last) in order.

23.9.2 Reduce [reduce]

template<class InputIterator>
typename iterator_traits<InputIterator>::value_type
reduce(InputIterator first, InputIterator last);

1 Effects: Equivalent to:

    return reduce(first, last,
                   typename iterator_traits<InputIterator>::value_type());

241) The use of fully closed ranges is intentional.

242) accumulate is similar to the APL reduction operator and Common Lisp reduce function, but it avoids the difficulty of
defining the result of reduction on an empty sequence by always requiring an initial value.
template<class ExecutionPolicy, class ForwardIterator>
type_name iterator_traits<ForwardIterator>::value_type
    reduce(ExecutionPolicy&& exec,
           ForwardIterator first, ForwardIterator last);

Effects: Equivalent to:
    return reduce(std::forward<ExecutionPolicy>(exec), first, last,
                   typename iterator_traits<ForwardIterator>::value_type());

template<class InputIterator, class T>
T reduce(InputIterator first, InputIterator last, T init);

Effects: Equivalent to:
    return reduce(first, last, init, plus<>());

template<class ExecutionPolicy, class ForwardIterator, class T>
    T reduce(ExecutionPolicy&& exec,
             ForwardIterator first, ForwardIterator last, T init);

Effects: Equivalent to:
    return reduce(std::forward<ExecutionPolicy>(exec), first, last, init, plus<>());

template<class InputIterator, class T, class BinaryOperation>
    T reduce(InputIterator first, InputIterator last, T init,
             BinaryOperation binary_op);

Returns: GENERALIZED_SUM(binary_op, init, *i, ...) for every i in [first, last).

Complexity: O(last - first) applications of binary_op.

[Note: The difference between reduce and accumulate is that reduce applies binary_op in an
unspecified order, which yields a nondeterministic result for non-associative or non-commutative
binary_op such as floating-point addition. — end note]

23.9.3 Inner product

template<class InputIterator1, class InputIterator2, class T>
    T inner_product(InputIterator1 first1, InputIterator1 last1, InputIterator2 first2, T init);

template<class InputIterator1, class InputIterator2, class T, class BinaryOperation1, class BinaryOperation2>
    T inner_product(InputIterator1 first1, InputIterator1 last1, InputIterator2 first2, T init,
                    BinaryOperation1 binary_op1, BinaryOperation2 binary_op2);

Requires: T shall satisfy the Cpp17CopyConstructible (Table 26) and Cpp17CopyAssignable (Table 28)
requirements. In the ranges [first1, last1] and [first2, first2 + (last1 - first1)] binary_op1 and binary_op2
shall neither modify elements nor invalidate iterators or subranges.

Effects: Computes its result by initializing the accumulator acc with the initial value init and then
modifying it with acc = std::move(acc) + (*i1) * (*i2) or acc = binary_op1(std::move(acc),

243) The use of fully closed ranges is intentional.
binary_op2(*i1, *i2)) for every iterator i1 in the range [first1, last1) and iterator i2 in the range [first2, first2 + (last1 - first1)) in order.

23.9.4 Transform reduce

```
template<class InputIterator1, class InputIterator2, class T>
T transform_reduce(InputIterator1 first1, InputIterator1 last1,
     InputIterator2 first2, T init);
```

1. **Effects:** Equivalent to:

```
return transform_reduce(first1, last1, first2, init, plus<>(), multiplies<>());
```

```
template<class ExecutionPolicy, 
     class ForwardIterator1, class ForwardIterator2, class T>
T transform_reduce(ExecutionPolicy& exec,
     ForwardIterator1 first1, ForwardIterator1 last1,
     ForwardIterator2 first2, T init);
```

2. **Effects:** Equivalent to:

```
return transform_reduce(std::forward<ExecutionPolicy>(exec),
     first1, last1, first2, init, plus<>(), multiplies<>());
```

```
template<class InputIterator1, class InputIterator2, class T, 
     class BinaryOperation1, class BinaryOperation2>
T transform_reduce(InputIterator1 first1, InputIterator1 last1,
     InputIterator2 first2, T init,
     BinaryOperation1 binary_op1, 
     BinaryOperation2 binary_op2);
```

3. **Requires:**

1. T shall be `Cpp17MoveConstructible` (Table 25).
2. All of
   1. binary_op1(init, init),
   2. binary_op1(init, binary_op2(*first1, *first2)),
   3. binary_op1(binary_op2(*first1, *first2), init), and
   4. binary_op1(binary_op2(*first1, *first2), binary_op2(*first1, *first2))
      shall be convertible to T.
   5. Neither binary_op1 nor binary_op2 shall invalidate subranges, or modify elements in the ranges [first1, last1] and [first2, first2 + (last1 - first1)].

4. **Returns:**

```
GENERALIZED_SUM(binary_op1, init, binary_op2(*i, *(first2 + (i - first1))), ...)
```

for every iterator i in [first1, last1).

5. **Complexity:** \(O(last1 - first1)\) applications each of binary_op1 and binary_op2.

```
template<class InputIterator, class T, 
     class BinaryOperation, class UnaryOperation>
T transform_reduce(InputIterator first, InputIterator last, T init,
     BinaryOperation binary_op, UnaryOperation unary_op);
```
template<class ExecutionPolicy,
class ForwardIterator, class T,
class BinaryOperation, class UnaryOperation>
T transform_reduce(ExecutionPolicy&& exec,
    ForwardIterator first, ForwardIterator last,
    T init, BinaryOperation binary_op, UnaryOperation unary_op);

Requires:

(6.1) — T shall be Cpp17MoveConstructible (Table 25).
(6.2) — All of
  (6.2.1) — binary_op(init, init),
  (6.2.2) — binary_op(init, unary_op(*first)),
  (6.2.3) — binary_op(unary_op(*first), init), and
  (6.2.4) — binary_op(unary_op(*first), unary_op(*first))
  shall be convertible to T.
(6.3) — Neither unary_op nor binary_op shall invalidate subranges, or modify elements in the range [first, last).

Returns:

GENERALIZED_SUM(binary_op, init, unary_op(*i), ...)
for every iterator i in [first, last).

Complexity: \( O(last - first) \) applications each of unary_op and binary_op.

[Note: transform_reduce does not apply unary_op to init. — end note]

23.9.5 Partial sum [partial.sum]

template<class InputIterator, class OutputIterator>
OutputIterator partial_sum(
    InputIterator first, InputIterator last,
    OutputIterator result);

template<class InputIterator, class OutputIterator, class BinaryOperation>
OutputIterator partial_sum(
    InputIterator first, InputIterator last,
    OutputIterator result, BinaryOperation binary_op);

Requires: InputIterator’s value type shall be constructible from the type of *first. The result of the expression std::move(acc) + *i or binary_op(std::move(acc), *i) shall be implicitly convertible to InputIterator’s value type. acc shall be writable (22.2.1) to the result output iterator. In the ranges [first, last] and [result, result + (last - first)] binary_op shall neither modify elements nor invalidate iterators or subranges.\(^{244}\)

Effects: For a non-empty range, the function creates an accumulator acc whose type is InputIterator’s value type, initializes it with *first, and assigns the result to *result. For every iterator i in (first + 1, last) in order, acc is then modified by acc = std::move(acc) + *i or acc = binary_op(std::move(acc), *i) and the result is assigned to *(result + (i - first)).

Returns: result + (last - first).

Complexity: Exactly (last - first) - 1 applications of the binary operation.

Remarks: result may be equal to first.

23.9.6 Exclusive scan [exclusive.scan]

template<class InputIterator, class OutputIterator, class T>
OutputIterator exclusive_scan(InputIterator first, InputIterator last,
    OutputIterator result, T init);

Effects: Equivalent to:

return exclusive_scan(first, last, result, init, plus<>());

\(^{244}\) The use of fully closed ranges is intentional.
template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class T>
ForwardIterator2 exclusive_scan(ExecutionPolicy&& exec,
    ForwardIterator1 first, ForwardIterator1 last,
    ForwardIterator2 result, T init);

Effects: Equivalent to:

    return exclusive_scan(std::forward<ExecutionPolicy>(exec),
        first, last, result, init, plus<>());

template<class InputIterator, class OutputIterator, class T, class BinaryOperation>
OutputIterator exclusive_scan(InputIterator first, InputIterator last,
    OutputIterator result, T init, BinaryOperation binary_op);

Effects: For each integer \(K\) in \([0, \text{last} - \text{first})\) assigns through \(\text{result} + K\) the value of:

\[
\text{GENERALIZED\_NONCOMMUTATIVE\_SUM} \\
\text{binary\_op, init, *(first + 0), *(first + 1), ... , *(first + K - 1)}
\]

Returns: The end of the resulting range beginning at \(\text{result}\).

Complexity: \(\Theta(\text{last} - \text{first})\) applications of \(\text{binary\_op}\).

Remarks: \(\text{result}\) may be equal to \(\text{first}\).

Note: The difference between \text{exclusive\_scan} and \text{inclusive\_scan} is that \text{exclusive\_scan} excludes the \(i\)th input element from the \(i\)th sum. If \(\text{binary\_op}\) is not mathematically associative, the behavior of \text{exclusive\_scan} may be nondeterministic. — end note

### 23.9.7 Inclusive scan

template<class InputIterator, class OutputIterator>
OutputIterator inclusive_scan(InputIterator first, InputIterator last, OutputIterator result);

Effects: Equivalent to:

    return inclusive_scan(first, last, result, plus<>());

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2 inclusive_scan(ExecutionPolicy&& exec,
    ForwardIterator1 first, ForwardIterator1 last,
    ForwardIterator2 result);

Effects: Equivalent to:

    return inclusive_scan(std::forward<ExecutionPolicy>(exec), first, last, result, plus<>());

template<class InputIterator, class OutputIterator, class BinaryOperation>
OutputIterator inclusive_scan(InputIterator first, InputIterator last,
    OutputIterator result, BinaryOperation binary_op);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2, class BinaryOperation>
ForwardIterator2 inclusive_scan(ExecutionPolicy&& exec,
    ForwardIterator1 first, ForwardIterator1 last,
    ForwardIterator2 result, BinaryOperation binary_op);
template<class InputIterator, class OutputIterator, class BinaryOperation, class T>
OutputIterator inclusive_scan(InputIterator first, InputIterator last,
OutputIterator result, BinaryOperation binary_op, T init);

requires:
(3.1) If init is provided, T shall be Cpp17MoveConstructible (Table 25);
otherwise, ForwardIterator1’s value type shall be Cpp17MoveConstructible.
(3.2) If init is provided, all of binary_op(init, init), binary_op(init, *first),
and binary_op(*first, *first) shall be convertible to T; otherwise, binary_op(*first, *first)
shall be convertible to ForwardIterator1’s value type.
(3.3) binary_op shall neither invalidate iterators or subranges, nor modify elements in
the ranges [first, last] or [result, result + (last - first)].

Effects: For each integer K in [0, last - first) assigns through result + K the value of
(4.1) GENERALIZED_NONCOMMUTATIVE_SUM
    binary_op, init, *(first + 0), *(first + 1), ..., *(first + K)
    if init is provided, or
(4.2) GENERALIZED_NONCOMMUTATIVE_SUM
    binary_op, *(first + 0), *(first + 1), ..., *(first + K)
    otherwise.

returns: The end of the resulting range beginning at result.

Complexity: Θ(last - first) applications of binary_op.

Remarks: result may be equal to first.

[Note: The difference between exclusive_scan and inclusive_scan is that
inclusive_scan includes the i-th input element in the i-th sum. If binary_op
is not mathematically associative, the behavior of inclusive_scan may be
nondeterministic. — end note]
Effects: For each integer \( K \) in \([0, \text{last} - \text{first})\) assigns through \( \text{result} + K \) the value of:

\[
\text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(
\quad \text{binary\_op}, \text{init},
\quad \text{unary\_op}(\text{*(first + 0)}), \text{unary\_op}(\text{*(first + 1)}), \ldots, \text{unary\_op}(\text{*(first + \(K - 1\)))}
\]

Returns: The end of the resulting range beginning at \( \text{result} \).

Complexity: \( \Theta(\text{last} - \text{first}) \) applications each of \( \text{unary\_op} \) and \( \text{binary\_op} \).

Remarks: \( \text{result} \) may be equal to \( \text{first} \).

[Notes: The difference between \( \text{transform\_exclusive\_scan} \) and \( \text{transform\_inclusive\_scan} \) is that \( \text{transform\_exclusive\_scan} \) excludes the \( i \text{th} \) input element from the \( i \text{th} \) sum. If \( \text{binary\_op} \) is not mathematically associative, the behavior of \( \text{transform\_exclusive\_scan} \) may be nondeterministic. \( \text{transform\_exclusive\_scan} \) does not apply \( \text{unary\_op} \) to \( \text{init} \). — end note]

23.9.9 Transform inclusive scan

\[ \quad \text{transform\_inclusive\_scan} \]

\[
\quad \text{OutputIterator} \quad \text{transform\_inclusive\_scan}(<\text{InputIterator} \text{first}, \text{InputIterator} \text{last}, \text{OutputIterator} \text{result}, \text{BinaryOperation} \text{binary\_op}, \text{UnaryOperation} \text{unary\_op});
\]

\[
\quad \text{template}<\text{class ExecutionPolicy}, \text{class ForwardIterator1, class ForwardIterator2}, \text{class BinaryOperation, class UnaryOperation}>
\quad \text{ForwardIterator2} \quad \text{transform\_inclusive\_scan}(<\text{ExecutionPolicy} \&\& \text{exec}, \text{ForwardIterator1} \text{first}, \text{ForwardIterator1} \text{last}, \text{ForwardIterator2} \text{result}, \text{BinaryOperation} \text{binary\_op}, \text{UnaryOperation} \text{unary\_op});
\]

\[
\quad \text{template}<\text{class InputIterator}, \text{class OutputIterator}, \text{class BinaryOperation, class UnaryOperation}>
\quad \text{OutputIterator} \quad \text{transform\_inclusive\_scan}(<\text{InputIterator} \text{first}, \text{InputIterator} \text{last}, \text{OutputIterator} \text{result}, \text{BinaryOperation} \text{binary\_op}, \text{UnaryOperation} \text{unary\_op}, \text{T} \text{init});
\]

\[
\quad \text{template}<\text{class ExecutionPolicy}, \text{class ForwardIterator1, class ForwardIterator2}, \text{class BinaryOperation, class UnaryOperation}, \text{class T}>
\quad \text{ForwardIterator2} \quad \text{transform\_inclusive\_scan}(<\text{ExecutionPolicy} \&\& \text{exec}, \text{ForwardIterator1} \text{first}, \text{ForwardIterator1} \text{last}, \text{ForwardIterator2} \text{result}, \text{BinaryOperation} \text{binary\_op}, \text{UnaryOperation} \text{unary\_op}, \text{T} \text{init});
\]

Requires:

(1.1) — If \( \text{init} \) is provided, \( \text{T} \) shall be \text{Cpp17MoveConstructible} (Table 25); otherwise, \text{ForwardIterator1}'s value type shall be \text{Cpp17MoveConstructible}.

(1.2) — If \( \text{init} \) is provided, all of

(1.2.1) — \text{binary\_op}(\text{init}, \text{init}),

(1.2.2) — \text{binary\_op}(\text{init}, \text{unary\_op}(\text{first})), and

(1.2.3) — \text{binary\_op}(\text{unary\_op}(\text{first}), \text{unary\_op}(\text{first}))

shall be convertible to \( \text{T} \); otherwise, \text{binary\_op}(\text{unary\_op}(\text{first}), \text{unary\_op}(\text{first})) shall be convertible to \text{ForwardIterator1}'s value type.

(1.3) — Neither \text{unary\_op} nor \text{binary\_op} shall invalidate iterators or subranges, nor modify elements in the ranges \([\text{first}, \text{last})\) or \([\text{result}, \text{result} + (\text{last} - \text{first})])

Effects: For each integer \( K \) in \([0, \text{last} - \text{first})\) assigns through \( \text{result} + K \) the value of

\[
\quad \text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(
\quad \text{binary\_op}, \text{init},
\quad \text{unary\_op}(\text{*(first + 0)}), \text{unary\_op}(\text{*(first + 1)}), \ldots, \text{unary\_op}(\text{*(first + \(K - 1\)))}
\]

if \( \text{init} \) is provided, or
23.9.10 Adjacent difference

template<class InputIterator, class OutputIterator>
OutputIterator
adjacent_difference(InputIterator first, InputIterator last, OutputIterator result);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2>
ForwardIterator2
adjacent_difference(ExecutionPolicy&& exec,
                  ForwardIterator1 first, ForwardIterator1 last, ForwardIterator2 result);

template<class InputIterator, class OutputIterator, class BinaryOperation>
OutputIterator
adjacent_difference(InputIterator first, InputIterator last,
                    OutputIterator result, BinaryOperation binary_op);

template<class ExecutionPolicy, class ForwardIterator1, class ForwardIterator2,
         class BinaryOperation>
ForwardIterator2
adjacent_difference(ExecutionPolicy&& exec,
                    ForwardIterator1 first, ForwardIterator1 last,
                    ForwardIterator2 result, BinaryOperation binary_op);

Let \( T \) be the value type of `decltype(first)`. For the overloads that do not take an argument `binary_op`, let `binary_op` be an lvalue that denotes an object of type `minus<\>`.

Requires:

(2.1) — For the overloads with no `ExecutionPolicy`, \( T \) shall be `Cpp17MoveAssignable` (Table 27) and shall be constructible from the type of `*first`. acc (defined below) shall be writable (22.2.1) to the `result` output iterator. The result of the expression `binary_op(val, std::move(acc))` shall be writable to the `result` output iterator.

(2.2) — For the overloads with an `ExecutionPolicy`, the result of the expressions `binary_op(*first, *first)` and `*first` shall be writable to `result`.

(2.3) — For all overloads, in the ranges \([first, last]\) and \([result, result + (last - first)]\), `binary_op` shall neither modify elements nor invalidate iterators or subranges.

Effects: For the overloads with no `ExecutionPolicy` and a non-empty range, the function creates an accumulator `acc` of type `T`, initializes it with `*first`, and assigns the result to `*result`. For every iterator `i` in `\([first + 1, last)\)` in order, creates an object `val` whose type is `T`, initializes it with `*i`, computes `binary_op(val, std::move(acc))`, assigns the result to `*(result + (i - first))`, and move assigns from `val` to `acc`.

For the overloads with an `ExecutionPolicy` and a non-empty range, performs `*result = *first`. Then, for every `d` in \([1, last - first - 1]\), performs `*(result + d) = binary_op(*(first + d), *(first + (d - 1)))`.

Returns: `result + (last - first)`.

Complexity: Exactly \((last - first) - 1\) applications of the binary operation.

\[\text{Note: The difference between } \text{transform}_\text{exclusive}_\text{scan} \text{ and } \text{transform}_\text{inclusive}_\text{scan} \text{ is that } \text{transform}_\text{inclusive}_\text{scan} \text{ includes the } i\text{th} \text{ input element in the } i\text{th} \text{ sum. If } \text{binary}_\text{op} \text{ is not mathematically associative, the behavior of } \text{transform}_\text{inclusive}_\text{scan} \text{ may be nondeterministic. } \text{transform}_\text{inclusive}_\text{scan} \text{ does not apply } \text{unary}_\text{op} \text{ to } \text{init} \text{.} \]
Remarks: For the overloads with no ExecutionPolicy, result may be equal to first. For the overloads with an ExecutionPolicy, the ranges \([\text{first}, \text{last})\) and \([\text{result}, \text{result} + (\text{last} - \text{first}))\) shall not overlap.

23.9.11 Iota

\[\text{template<class ForwardIterator, class T> void iota(ForwardIterator first, ForwardIterator last, T value);}\]

1 Requires: \(T\) shall be convertible to \(\text{ForwardIterator}^{3}\)’s value type. The expression ++val, where val has type \(T\), shall be well-formed.

2 Effects: For each element referred to by the iterator \(i\) in the range \([\text{first}, \text{last})\), assigns \(*i = \text{value}\) and increments value as if by ++value.

3 Complexity: Exactly \(\text{last} - \text{first}\) increments and assignments.

23.9.12 Greatest common divisor

\[\text{template<class M, class N> constexpr common_type_t<M,N> gcd(M m, N n);}\]

1 Requires: \(|m|\) and \(|n|\) shall be representable as a value of \(\text{common_type_t}\langle M,N\rangle\). [Note: These requirements ensure, for example, that \(\text{gcd}(m, m) = |m|\) is representable as a value of type \(M\). —end note]

2 Remarks: If either \(M\) or \(N\) is not an integer type, or if either is \(\text{cv bool}\), the program is ill-formed.

3 Returns: Zero when \(m\) and \(n\) are both zero. Otherwise, returns the greatest common divisor of \(|m|\) and \(|n|\).

4 Throws: Nothing.

23.9.13 Least common multiple

\[\text{template<class M, class N> constexpr common_type_t<M,N> lcm(M m, N n);}\]

1 Requires: \(|m|\) and \(|n|\) shall be representable as a value of \(\text{common_type_t}\langle M,N\rangle\). The least common multiple of \(|m|\) and \(|n|\) shall be representable as a value of type \(\text{common_type_t}\langle M,N\rangle\).

2 Remarks: If either \(M\) or \(N\) is not an integer type, or if either is \(\text{cv bool}\) the program is ill-formed.

3 Returns: Zero when either \(m\) or \(n\) is zero. Otherwise, returns the least common multiple of \(|m|\) and \(|n|\).

4 Throws: Nothing.

23.10 C library algorithms

\[\text{void* bsearch(const void* key, const void* base, size_t nmemb, size_t size,}\]

1 \[\text{c-compare-pred* compar);}\]

2 Effects: These functions have the semantics specified in the C standard library.

3 Remarks: The behavior is undefined unless the objects in the array pointed to by \(\text{base}\) are of trivial type.

4 Throws: Any exception thrown by \(\text{compar}\) () (15.5.5.12).

24 Numerics library  

24.1 General

This Clause describes components that C++ programs may use to perform seminumerical operations.

The following subclauses describe components for complex number types, random number generation, numeric (n-at-a-time) arrays, generalized numeric algorithms, and mathematical functions for floating-point types, as summarized in Table 82.

Table 82 — Numerics library summary

<table>
<thead>

24.2 Definitions

Define \( \text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(\text{op}, a_1, \ldots, a_N) \) as follows:

\[
\begin{align*}
(1.1) & \quad a_1 \text{ when } N = 1, \text{ otherwise} \\
(1.2) & \quad \text{op}(\text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(\text{op}, a_1, \ldots, a_K), \\
& \quad \text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(\text{op}, a_{M}, \ldots, a_N)) \text{ for any } K \text{ where } 1 < K + 1 = M \leq N.
\end{align*}
\]

Define \( \text{GENERALIZED\_SUM}(\text{op}, a_1, \ldots, a_N) \) as \( \text{GENERALIZED\_NONCOMMUTATIVE\_SUM}(\text{op}, b_1, \ldots, b_N) \), where \( b_1, \ldots, b_N \) may be any permutation of \( a_1, \ldots, a_N \).

24.3 Numeric type requirements  

The complex and valarray components are parameterized by the type of information they contain and manipulate. A C++ program shall instantiate these components only with a type \( T \) that satisfies the following requirements:

\[
\begin{align*}
(1.1) & \quad T \text{ is not an abstract class (it has no pure virtual member functions);} \\
(1.2) & \quad T \text{ is not a reference type;} \\
(1.3) & \quad T \text{ is not cv-qualified;} \\
(1.4) & \quad \text{If } T \text{ is a class, it has a public default constructor;} \\
(1.5) & \quad \text{If } T \text{ is a class, it has a public copy constructor with the signature } T::T(const T&) \\
(1.6) & \quad \text{If } T \text{ is a class, it has a public destructor;} \\
(1.7) & \quad \text{If } T \text{ is a class, it has a public assignment operator whose signature is either } T& T::operator=(const T&) \text{ or } T& T::operator=(T) \\
(1.8) & \quad \text{If } T \text{ is a class, its assignment operator, copy and default constructors, and destructor shall correspond to each other in the following sense:} \\
(1.8.1) & \quad \text{Initialization of raw storage using the copy constructor on the value of } T(), \text{ however obtained, is semantically equivalent to value-initialization of the same raw storage.}
\end{align*}
\]

\textsuperscript{246} In other words, value types. These include arithmetic types, pointers, the library class complex, and instantiations of valarray for value types.
Initialization of raw storage using the default constructor, followed by assignment, is semantically equivalent to initialization of raw storage using the copy constructor.

Destruction of an object, followed by initialization of its raw storage using the copy constructor, is semantically equivalent to assignment to the original object.

[Note: This rule states, in part, that there shall not be any subtle differences in the semantics of initialization versus assignment. This gives an implementation considerable flexibility in how arrays are initialized.]

[Example: An implementation is allowed to initialize a `valarray` by allocating storage using the `new` operator (which implies a call to the default constructor for each element) and then assigning each element its value. Or the implementation can allocate raw storage and use the copy constructor to initialize each element. — end example]

If the distinction between initialization and assignment is important for a class, or if it fails to satisfy any of the other conditions listed above, the programmer should use `vector` (21.3.11) instead of `valarray` for that class. — end note]

If `T` is a class, it does not overload unary `operator&`. If any operation on `T` throws an exception the effects are undefined.

In addition, many member and related functions of `valarray<T>` can be successfully instantiated and will exhibit well-defined behavior if and only if `T` satisfies additional requirements specified for each such member or related function.

[Example: It is valid to instantiate `valarray<complex>`, but `operator()` will not be successfully instantiated for `valarray<complex>` operands, since `complex` does not have any ordering operators. — end example]

24.4 The floating-point environment  

24.4.1 Header `<cfenv>` synopsis

```cpp
#define FE_ALL_EXCEPT see below
#define FE_DIVBYZERO see below // optional
#define FE_INEXACT see below  // optional
#define FE_INVALID see below  // optional
#define FE_OVERFLOW see below // optional
#define FE_UNDERFLOW see below // optional

#define FE_DOWNWARD see below // optional
#define FE_TONEAREST see below // optional
#define FE_TOWARDZERO see below // optional
#define FE_UPWARD see below  // optional
#define FE_DFL_ENV see below

namespace std {
  // types
  using fenv_t  = object type;
  using fexcept_t = integer type;
  // functions
  int feclearexcept(int except);
  int fegetexceptflag(fexcept_t* pflag, int except);
  int feraiseexcept(int except);
  int fesetexceptflag(const fexcept_t* pflag, int except);
  int fetestexcept(int except);
  int fegetround();
  int fesetround(int mode);

  int fegetenv(fenv_t* penv);
  int feholdexcept(fenv_t* penv);
  int fesetenv(const fenv_t* penv);
  int feupdateenv(const fenv_t* penv);
}
```
The contents and meaning of the header `<cfenv>` are the same as the C standard library header `<fenv.h>`. [Note: This document does not require an implementation to support the FENV_ACCESS pragma; it is implementation-defined (14.6) whether the pragma is supported. As a consequence, it is implementation-defined whether these functions can be used to test floating-point status flags, set floating-point control modes, or run under non-default mode settings. If the pragma is used to enable control over the floating-point environment, this document does not specify the effect on floating-point evaluation in constant expressions. — end note]

The floating-point environment has thread storage duration (6.6.4.2). The initial state for a thread’s floating-point environment is the state of the floating-point environment of the thread that constructs the corresponding thread object (30.3.2) at the time it constructed the object. [Note: That is, the child thread gets the floating-point state of the parent thread at the time of the child’s creation. — end note]

A separate floating-point environment shall be maintained for each thread. Each function accesses the environment corresponding to its calling thread.

See also: ISO C 7.6

### 24.5 Complex numbers

The header `<complex>` defines a class template, and numerous functions for representing and manipulating complex numbers.

The effect of instantiating the template `complex` for any type other than `float`, `double`, or `long double` is unspecified. The specializations `complex<float>`, `complex<double>`, and `complex<long double>` are literal types (6.7).

If the result of a function is not mathematically defined or not in the range of representable values for its type, the behavior is undefined.

If `z` is an lvalue of type `cv complex<T>` then:

1. The expression `reinterpret_cast<cv T(&)[2]>(z)` shall be well-formed,
2. `reinterpret_cast<cv T(&)[2]>(z)[0]` shall designate the real part of `z`, and
3. `reinterpret_cast<cv T(&)[2]>(z)[1]` shall designate the imaginary part of `z`.

Moreover, if `a` is an expression of type `cv complex<T>*` and the expression `a[i]` is well-defined for an integer expression `i`, then:

1. `reinterpret_cast<cv T*>(a)[2*i]` shall designate the real part of `a[i]`, and
2. `reinterpret_cast<cv T*>(a)[2*i + 1]` shall designate the imaginary part of `a[i]`.

### 24.5.1 Header `<complex>` synopsis

```cpp
namespace std {
  // 24.5.2, class template complex
  template<class T> class complex;

  // 24.5.3, complex specializations
  template<> class complex<float>;
  template<> class complex<double>;
  template<> class complex<long double>;

  // 24.5.6, operators
  template<class T> constexpr complex<T> operator+(const complex<T>&, const complex<T>&);
  template<class T> constexpr complex<T> operator+(const complex<T>&, const T&);
  template<class T> constexpr complex<T> operator+(const T&, const complex<T>&);
  template<class T> constexpr complex<T> operator-(const complex<T>&, const complex<T>&);
  template<class T> constexpr complex<T> operator-(const complex<T>&, const T&);
  template<class T> constexpr complex<T> operator-(const T&, const complex<T>&);
  template<class T> constexpr complex<T> operator*(const complex<T>&, const complex<T>&);
  template<class T> constexpr complex<T> operator*(const complex<T>&, const T&);
  template<class T> constexpr complex<T> operator*(const T&, const complex<T>&);
  template<class T> constexpr complex<T> operator/(const complex<T>&, const complex<T>&);
  template<class T> constexpr complex<T> operator/(const complex<T>&, const T&);
  template<class T> constexpr complex<T> operator/(const T&, const complex<T>&);

  // 24.5.7, constructions
  template<class T> complex<T>::complex();
  template<class T> complex<T>::complex(const T&);
  template<class T> complex<T>::complex(const complex<T>&);
  template<class T> complex<T>::~complex();
}
```
template<class T> constexpr complex<T> operator/(const complex<T>&, const complex<T>&);
template<class T> constexpr complex<T> operator/(const complex<T>&, const T&);
template<class T> constexpr complex<T> operator/(const T&, const complex<T>&);
template<class T> constexpr complex<T> operator+(const complex<T>&);
template<class T> constexpr complex<T> operator-(const complex<T>&);
template<class T> constexpr bool operator==(const complex<T>&, const complex<T>&);
template<class T> constexpr bool operator==(const complex<T>&, const T&);
template<class T> constexpr bool operator==(const T&, const complex<T>&);
template<class T> constexpr bool operator!=(const complex<T>&, const complex<T>&);
template<class T> constexpr bool operator!=(const complex<T>&, const T&);
template<class T> constexpr bool operator!=(const T&, const complex<T>&);

template<class T, class charT, class traits>
    basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>&, complex<T>&);

template<class T, class charT, class traits>
    basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>&, const complex<T>&);

// 24.5.7, values
    template<class T> constexpr T real(const complex<T>&);
    template<class T> constexpr T imag(const complex<T>&);
    template<class T> T abs(const complex<T>&);
    template<class T> T arg(const complex<T>&);
    template<class T> constexpr T norm(const complex<T>&);
    template<class T> constexpr complex<T> conj(const complex<T>&);
    template<class T> complex<T> proj(const complex<T>&);
    template<class T> complex<T> polar(const T&, const T& = T());

// 24.5.8, transcendentals
    template<class T> complex<T> acos(const complex<T>&);
    template<class T> complex<T> asin(const complex<T>&);
    template<class T> complex<T> atan(const complex<T>&);
    template<class T> complex<T> acosh(const complex<T>&);
    template<class T> complex<T> asinh(const complex<T>&);
    template<class T> complex<T> atanh(const complex<T>&);
    template<class T> complex<T> cos (const complex<T>&);
    template<class T> complex<T> cosh (const complex<T>&);
    template<class T> complex<T> exp (const complex<T>&);
    template<class T> complex<T> log (const complex<T>&);
    template<class T> complex<T> log10(const complex<T>&);
    template<class T> complex<T> pow (const complex<T>&, const T&);
    template<class T> complex<T> pow (const complex<T>&, const complex<T>&);
    template<class T> complex<T> pow (const T&, const complex<T>&);
    template<class T> complex<T> sin (const complex<T>&);
    template<class T> complex<T> sinh (const complex<T>&);
    template<class T> complex<T> sqrt (const complex<T>&);
    template<class T> complex<T> tan (const complex<T>&);
    template<class T> complex<T> tanh (const complex<T>&);

// 24.5.10, complex literals
    inline namespace literals {
        inline namespace complex_literals {
            constexpr complex<long double> operator""i1(long double);
            constexpr complex<long double> operator""i1(unsigned long);
            constexpr complex<double> operator""i1(long double);
24.5.2 Class template complex

namespace std {
    template<class T> class complex {
        public:
            using value_type = T;
            constexpr complex(const T& re = T(), const T& im = T());
            constexpr complex(const complex&);
            template<class X> constexpr complex(const complex<X>&);
            constexpr T real() const;
            constexpr void real(T);
            constexpr T imag() const;
            constexpr void imag(T);
            constexpr complex& operator= (const T&);
            constexpr complex& operator+=(const T&);
            constexpr complex& operator-=(const T&);
            constexpr complex& operator*=(const T&);
            constexpr complex& operator/=(const T&);
            template<class X> constexpr complex& operator= (const complex<X>&);
            template<class X> constexpr complex& operator+=(const complex<X>&);
            template<class X> constexpr complex& operator-=(const complex<X>&);
            template<class X> constexpr complex& operator*=(const complex<X>&);
            template<class X> constexpr complex& operator/=(const complex<X>&);
    };
}

The class complex describes an object that can store the Cartesian components, real() and imag(), of a complex number.

24.5.3 complex specializations

namespace std {
    template<> class complex<float> {
        public:
            using value_type = float;
            constexpr complex(float re = 0.0f, float im = 0.0f);
            constexpr complex(const complex<float>&) = default;
            constexpr explicit complex(const complex<double>&);
            constexpr explicit complex(const complex<long double>&);
            constexpr float real() const;
            constexpr void real(float);
            constexpr float imag() const;
            constexpr void imag(float);
            constexpr complex& operator= (float);
            constexpr complex& operator+=(float);
            constexpr complex& operator-=(float);
            constexpr complex& operator*=(float);
            constexpr complex& operator/=(float);
    };
}
constexpr complex& operator=(const complex&);
template<class X> constexpr complex& operator=(const complex<X>&);
template<class X> constexpr complex& operator+=(const complex<X>&);
template<class X> constexpr complex& operator-=(const complex<X>&);
template<class X> constexpr complex& operator*=(const complex<X>&);
template<class X> constexpr complex& operator/=(const complex<X>&);

};
template<> class complex<double> {
public:
  using value_type = double;
  constexpr complex(double re = 0.0, double im = 0.0);
  constexpr complex(const complex<float>&);
  constexpr complex(const complex<double>&) = default;
  constexpr explicit complex(const complex<long double>&);

  constexpr double real() const;
  constexpr void real(double);
  constexpr double imag() const;
  constexpr void imag(double);

  constexpr complex& operator=(double);
  constexpr complex& operator+=(double);
  constexpr complex& operator-=(double);
  constexpr complex& operator*=(double);
  constexpr complex& operator/=(double);

};
template<> class complex<long double> {
public:
  using value_type = long double;
  constexpr complex(long double re = 0.0L, long double im = 0.0L);
  constexpr complex(const complex<float>&);
  constexpr complex(const complex<double>&);
  constexpr complex(const complex<long double>&) = default;

  constexpr long double real() const;
  constexpr void real(long double);
  constexpr long double imag() const;
  constexpr void imag(long double);

  constexpr complex& operator=(long double);
  constexpr complex& operator+=(long double);
  constexpr complex& operator-=(long double);
  constexpr complex& operator*=(long double);
  constexpr complex& operator/=(long double);

};

§ 24.5.3
24.5.4 complex member functions

```cpp
template<class T> constexpr complex(const T& re = T(), const T& im = T());
```

Effects: Constructs an object of class complex.

Ensures: real() == re && imag() == im.

```cpp
constexpr T real() const;
```

Returns: The value of the real component.

```cpp
constexpr void real(T val);
```

Effects: Assigns val to the real component.

```cpp
constexpr T imag() const;
```

Returns: The value of the imaginary component.

```cpp
constexpr void imag(T val);
```

Effects: Assigns val to the imaginary component.

24.5.5 complex member operators

```cpp
constexpr complex& operator+=(const T& rhs);
```

Effects: Adds the scalar value rhs to the real part of the complex value *this and stores the result in the real part of *this, leaving the imaginary part unchanged.

Returns: *this.

```cpp
constexpr complex& operator-=(const T& rhs);
```

Effects: Subtracts the scalar value rhs from the real part of the complex value *this and stores the result in the real part of *this, leaving the imaginary part unchanged.

Returns: *this.

```cpp
constexpr complex& operator*=(const T& rhs);
```

Effects: Multiplies the scalar value rhs by the complex value *this and stores the result in *this.

Returns: *this.

```cpp
constexpr complex& operator/=(const T& rhs);
```

Effects: Divides the scalar value rhs into the complex value *this and stores the result in *this.

Returns: *this.

```cpp
template<class X> constexpr complex& operator+=(const complex<X>& rhs);
```

Effects: Adds the complex value rhs to the complex value *this and stores the sum in *this.

Returns: *this.

```cpp
template<class X> constexpr complex& operator-=(const complex<X>& rhs);
```

Effects: Subtracts the complex value rhs from the complex value *this and stores the difference in *this.

Returns: *this.

```cpp
template<class X> constexpr complex& operator*=(const complex<X>& rhs);
```

Effects: Multiplies the complex value rhs by the complex value *this and stores the product in *this.

Returns: *this.

```cpp
template<class X> constexpr complex& operator/=(const complex<X>& rhs);
```

Effects: Divides the complex value rhs into the complex value *this and stores the quotient in *this.

Returns: *this.
24.5.6 complex non-member operations

```c++
template<class T> constexpr complex<T> operator+(const complex<T>& lhs);

Returns: complex<T>(lhs).
Remarks: unary operator.

template<class T> constexpr complex<T> operator+(const complex<T>& lhs, const complex<T>& rhs);
template<class T> constexpr complex<T> operator+(const complex<T>& lhs, const T& rhs);
template<class T> constexpr complex<T> operator+(const T& lhs, const complex<T>& rhs);

Returns: complex<T>(lhs) += rhs.

template<class T> constexpr complex<T> operator-(const complex<T>& lhs);

Returns: complex<T>(-lhs.real(),-lhs.imag()).
Remarks: unary operator.

template<class T> constexpr complex<T> operator-(const complex<T>& lhs, const complex<T>& rhs);
template<class T> constexpr complex<T> operator-(const complex<T>& lhs, const T& rhs);
template<class T> constexpr complex<T> operator-(const T& lhs, const complex<T>& rhs);

Returns: complex<T>(lhs) -= rhs.

template<class T> constexpr complex<T> operator*(const complex<T>& lhs, const complex<T>& rhs);
template<class T> constexpr complex<T> operator*(const complex<T>& lhs, const T& rhs);
template<class T> constexpr complex<T> operator*(const T& lhs, const complex<T>& rhs);

Returns: complex<T>(lhs) *= rhs.

template<class T> constexpr bool operator==(const complex<T>& lhs, const complex<T>& rhs);
template<class T> constexpr bool operator==(const complex<T>& lhs, const T& rhs);
template<class T> constexpr bool operator==(const T& lhs, const complex<T>& rhs);

Returns: lhs.real() == rhs.real() && lhs.imag() == rhs.imag().
Remarks: The imaginary part is assumed to be T(), or 0.0, for the T arguments.

template<class T> constexpr bool operator!=(const complex<T>& lhs, const complex<T>& rhs);
template<class T> constexpr bool operator!=(const complex<T>& lhs, const T& rhs);
template<class T> constexpr bool operator!=(const T& lhs, const complex<T>& rhs);

Returns: rhs.real() != lhs.real() || rhs.imag() != lhs.imag().

template<class T, class charT, class traits>
basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& is, complex<T>& x);

Requires: The input values shall be convertible to T.
Effects: Extracts a complex number x of the form: u, (u), or (u,v), where u is the real part and v is the imaginary part (27.7.4.2).
If bad input is encountered, calls is.setstate(ios_base::failbit) (which may throw ios::failure (27.5.5.4)).
Returns: is.
Remarks: This extraction is performed as a series of simpler extractions. Therefore, the skipping of whitespace is specified to be the same for each of the simpler extractions.

template<class T, class charT, class traits>
basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& o, const complex<T>& x);

Effects: Inserts the complex number x onto the stream o as if it were implemented as follows:
  basic_ostringstream<charT, traits> s;
s.flags(o.flags());
```
Note: In a locale in which comma is used as a decimal point character, the use of comma as a field separator can be ambiguous. Inserting `showpoint` into the output stream forces all outputs to show an explicit decimal point character; as a result, all inserted sequences of complex numbers can be extracted unambiguously. — end note]

### 24.5.7 complex value operations

**template<class T> constexpr T real(const complex<T>& x);**

*Returns:* \( x.\text{real}() \).

**template<class T> constexpr T imag(const complex<T>& x);**

*Returns:* \( x.\text{imag}() \).

**template<class T> T abs(const complex<T>& x);**

*Returns:* The magnitude of \( x \).

**template<class T> T arg(const complex<T>& x);**

*Returns:* The phase angle of \( x \), or \( \text{atan2}(\text{imag}(x), \text{real}(x)) \).

**template<class T> constexpr T norm(const complex<T>& x);**

*Returns:* The squared magnitude of \( x \).

**template<class T> constexpr complex<T> conj(const complex<T>& x);**

*Returns:* The complex conjugate of \( x \).

**template<class T> complex<T> proj(const complex<T>& x);**

*Returns:* The projection of \( x \) onto the Riemann sphere.

*Remarks:* Behaves the same as the C function `cproj`. See also: ISO C 7.3.9.5

**template<class T> complex<T> polar(const T& rho, const T& theta = T());**

*Requires:* \( \text{rho} \) shall be non-negative and non-NaN. \( \text{theta} \) shall be finite.

*Returns:* The complex value corresponding to a complex number whose magnitude is \( \text{rho} \) and whose phase angle is \( \text{theta} \).

### 24.5.8 complex transcedentals

**template<class T> complex<T> acos(const complex<T>& x);**

*Returns:* The complex arc cosine of \( x \).

*Remarks:* Behaves the same as the C function `cacos`. See also: ISO C 7.3.5.1

**template<class T> complex<T> asin(const complex<T>& x);**

*Returns:* The complex arc sine of \( x \).

*Remarks:* Behaves the same as the C function `casin`. See also: ISO C 7.3.5.2

**template<class T> complex<T> atan(const complex<T>& x);**

*Returns:* The complex arc tangent of \( x \).

*Remarks:* Behaves the same as the C function `catan`. See also: ISO C 7.3.5.3

**template<class T> complex<T> acosh(const complex<T>& x);**

*Returns:* The complex arc hyperbolic cosine of \( x \).

*Remarks:* Behaves the same as the C function `cacosh`. See also: ISO C 7.3.6.1

§ 24.5.8
template<class T> complex<T> asinh(const complex<T>& x);

Returns: The complex arc hyperbolic sine of x.
Remarks: Behaves the same as the C function casinh. See also: ISO C 7.3.6.2

template<class T> complex<T> atanh(const complex<T>& x);

Returns: The complex arc hyperbolic tangent of x.
Remarks: Behaves the same as the C function catanh. See also: ISO C 7.3.6.3

template<class T> complex<T> cos(const complex<T>& x);

Returns: The complex cosine of x.

template<class T> complex<T> cosh(const complex<T>& x);

Returns: The complex hyperbolic cosine of x.

template<class T> complex<T> exp(const complex<T>& x);

Returns: The complex base-e exponential of x.

template<class T> complex<T> log(const complex<T>& x);

Returns: The complex natural (base-e) logarithm of x. For all x, imag(log(x)) lies in the interval [−π, π]. [Note: The semantics of this function are intended to be the same in C++ as they are for clog in C. — end note]
Remarks: The branch cuts are along the negative real axis.

template<class T> complex<T> log10(const complex<T>& x);

Returns: The complex common (base-10) logarithm of x, defined as log(x) / log(10).
Remarks: The branch cuts are along the negative real axis.

template<class T> complex<T> pow(const complex<T>& x, const complex<T>& y);
template<class T> complex<T> pow(const complex<T>& x, const T& y);
template<class T> complex<T> pow(const T& x, const complex<T>& y);

Returns: The complex power of base x raised to the yth power, defined as exp(y * log(x)). The value returned for pow(0, 0) is implementation-defined.
Remarks: The branch cuts are along the negative real axis.

template<class T> complex<T> sin(const complex<T>& x);

Returns: The complex sine of x.

template<class T> complex<T> sinh(const complex<T>& x);

Returns: The complex hyperbolic sine of x.

template<class T> complex<T> sqrt(const complex<T>& x);

Returns: The complex square root of x, in the range of the right half-plane. [Note: The semantics of this function are intended to be the same in C++ as they are for csqrt in C. — end note]
Remarks: The branch cuts are along the negative real axis.

template<class T> complex<T> tan(const complex<T>& x);

Returns: The complex tangent of x.

template<class T> complex<T> tanh(const complex<T>& x);

Returns: The complex hyperbolic tangent of x.

24.5.9 Additional overloads

The following function templates shall have additional overloads:
arg norm
conj proj
imag real
where \texttt{norm}, \texttt{conj}, \texttt{imag}, and \texttt{real} are \texttt{constexpr} overloads.

The additional overloads shall be sufficient to ensure:

1. If the argument has type \texttt{long double}, then it is effectively cast to \texttt{complex<long double>}.
2. Otherwise, if the argument has type \texttt{double} or an integer type, then it is effectively cast to \texttt{complex<double>}.
3. Otherwise, if the argument has type \texttt{float}, then it is effectively cast to \texttt{complex<float>}.

Function template \texttt{pow} shall have additional overloads sufficient to ensure, for a call with at least one argument of type \texttt{complex<T>}:

1. If either argument has type \texttt{complex<long double>} or \texttt{long double}, then both arguments are effectively cast to \texttt{complex<long double>}.
2. Otherwise, if either argument has type \texttt{complex<double>}, \texttt{double}, or an integer type, then both arguments are effectively cast to \texttt{complex<double>}.
3. Otherwise, if either argument has type \texttt{complex<float>} or \texttt{float}, then both arguments are effectively cast to \texttt{complex<float>}.

### 24.5.10 Suffixes for complex number literals

This subclause describes literal suffixes for constructing complex number literals. The suffixes \texttt{i}, \texttt{il}, and \texttt{if} create complex numbers of the types \texttt{complex<double>}, \texttt{complex<long double>}, and \texttt{complex<float>} respectively, with their imaginary part denoted by the given literal number and the real part being zero.

```cpp
constexpr complex<long double> operator""il(long double d);
constexpr complex<long double> operator""il(unsigned long long d);
```

Returns: \texttt{complex<long double>\{0.0L, static_cast<long double>(d)\}}.

```cpp
constexpr complex<double> operator""i(long double d);
constexpr complex<double> operator""i(unsigned long long d);
```

Returns: \texttt{complex<double>\{0.0, static_cast<double>(d)\}}.

```cpp
constexpr complex<float> operator""if(long double d);
constexpr complex<float> operator""if(unsigned long long d);
```

Returns: \texttt{complex<float>\{0.0f, static_cast<float>(d)\}}.

### 24.6 Bit manipulation

#### 24.6.1 General

The header \texttt{<bit>} provides components to access, manipulate and process both individual bits and bit sequences.

#### 24.6.2 Header \texttt{<bit>} synopsis

```cpp
namespace std {
  // 24.6.3, bit_cast
  template<typename To, typename From>
  constexpr To bit_cast(const From& from) noexcept;

  // 24.6.4, integral powers of 2
  template <class T>
  constexpr bool ispow2(T x) noexcept;
  template <class T>
  constexpr T ceil2(T x) noexcept;
  template <class T>
  constexpr T floor2(T x) noexcept;
  template <class T>
  constexpr T log2p1(T x) noexcept;
}
```
24.6.3 Function template bit_cast

template<typename To, typename From>
constexpr To bit_cast(const From& from) noexcept;

Returns: An object of type To. Each bit of the value representation of the result is equal to the corresponding bit in the object representation of from. Padding bits of the To object are unspecified. If there is no value of type To corresponding to the value representation produced, the behavior is undefined. If there are multiple such values, which value is produced is unspecified.

Remarks: This function shall not participate in overload resolution unless:

1. sizeof(To) == sizeof(From) is true;
2. is_trivially_copyable_v<To> is true; and
3. is_trivially_copyable_v<From> is true.

This function shall be constexpr if and only if To, From, and the types of all subobjects of To and From are types T such that:

1. is_union_v<T> is false;
2. is_pointer_v<T> is false;
3. is_member_pointer_v<T> is false;
4. is_volatile_v<T> is false;
5. T has no non-static data members of reference type.

24.6.4 Integral powers of 2

template <class T>
constexpr bool ispow2(T x) noexcept;

Returns: true if x is an integral power of two; false otherwise.

Remarks: This function shall not participate in overload resolution unless T is an unsigned integer type (6.7.1).

template <class T>
constexpr T ceil2(T x) noexcept;

Returns: The minimal value y such that ispow2(y) is true and y >= x; if y is not representable as a value of type T, the result is an unspecified value.

Remarks: This function shall not participate in overload resolution unless T is an unsigned integer type (6.7.1).

template <class T>
constexpr T floor2(T x) noexcept;

Returns: If x == 0, 0; otherwise the maximal value y such that ispow2(y) is true and y <= x.

Remarks: This function shall not participate in overload resolution unless T is an unsigned integer type (6.7.1).

template <class T>
constexpr T log2p1(T x) noexcept;

Returns: If x == 0, 0; otherwise one plus the base-2 logarithm of x, with any fractional part discarded.

Remarks: This function shall not participate in overload resolution unless T is an unsigned integer type (6.7.1).

24.7 Random number generation

This subclause defines a facility for generating (pseudo-)random numbers.

In addition to a few utilities, four categories of entities are described: uniform random bit generators, random number engines, random number engine adaptors, and random number distributions. These categorizations are applicable to types that satisfy the corresponding requirements, to objects instantiated from such types, and to templates producing such types when instantiated. [Note: These entities are specified in such a way as to permit the binding of any uniform random bit generator object e as the argument to any random number
distribution object \( d \), thus producing a zero-argument function object such as given by \( \text{bind}(d,e) \). — end note

Each of the entities specified via this subclause has an associated arithmetic type (6.7.1) identified as \texttt{result_type}. With \( T \) as the \texttt{result_type} thus associated with such an entity, that entity is characterized:

a) as \texttt{boolean} or equivalently as \texttt{boolean-valued}, if \( T \) is \texttt{bool};

b) otherwise as \texttt{integral} or equivalently as \texttt{integer-valued}, if \texttt{numeric_limits<T>::is_integer} is \texttt{true};

c) otherwise as \texttt{floating} or equivalently as \texttt{real-valued}.

If integer-valued, an entity may optionally be further characterized as \texttt{signed} or \texttt{unsigned}, according to \texttt{numeric_limits<T>::is_signed}.

4 Unless otherwise specified, all descriptions of calculations in this subclause use mathematical real numbers.

5 Throughout this subclause, the operators \texttt{bitand}, \texttt{bitor}, and \texttt{xor} denote the respective conventional bitwise operations. Further:

a) the operator \texttt{rshift} denotes a bitwise right shift with zero-valued bits appearing in the high bits of the result, and

b) the operator \texttt{lshift} denotes a bitwise left shift with zero-valued bits appearing in the low bits of the result, and whose result is always taken modulo \( 2^w \).

24.7.1 Header \texttt{<random>} synopsis

```cpp
#include <initializer_list>

namespace std {

// 24.7.2.3, uniform random bit generator requirements

    class extreme_value_distribution;

// 24.7.8.5.1, class template normal_distribution
template<class RealType = double>
    class normal_distribution;
24.7.2 Requirements [rand.req]

24.7.2.1 General requirements [rand.req.genl]

Throughout this subclause 24.7, the effect of instantiating a template:

a) that has a template type parameter named Sseq is undefined unless the corresponding template argument is cv-unqualified and satisfies the requirements of seed sequence (24.7.2.2).

b) that has a template type parameter named URBG is undefined unless the corresponding template argument is cv-unqualified and satisfies the requirements of uniform random bit generator (24.7.2.3).

c) that has a template type parameter named Engine is undefined unless the corresponding template argument is cv-unqualified and satisfies the requirements of random number engine (24.7.2.4).

d) that has a template type parameter named RealType is undefined unless the corresponding template argument is cv-unqualified and is one of float, double, or long double.

e) that has a template type parameter named IntType is undefined unless the corresponding template argument is cv-unqualified and is one of short, int, long, long long, unsigned short, unsigned int, unsigned long, or unsigned long long.

f) that has a template type parameter named UIntType is undefined unless the corresponding template argument is cv-unqualified and is one of unsigned short, unsigned int, unsigned long, or unsigned long long.

2 Throughout this subclause 24.7, phrases of the form “x is an iterator of a specific kind” shall be interpreted as equivalent to the more formal requirement that “x is a value of a type satisfying the requirements of the specified iterator type”.

3 Throughout this subclause 24.7, any constructor that can be called with a single argument and that satisfies a requirement specified in this subclause shall be declared explicit.
24.7.2.2 Seed sequence requirements

A seed sequence is an object that consumes a sequence of integer-valued data and produces a requested number of unsigned integer values \(0 \leq i < 2^{32}\), based on the consumed data. [Note: Such an object provides a mechanism to avoid replication of streams of random variates. This can be useful, for example, in applications requiring large numbers of random number engines. — end note]

A class \(S\) satisfies the requirements of a seed sequence if the expressions shown in Table 83 are valid and have the indicated semantics, and if \(S\) also satisfies all other requirements of this subclause 24.7.2.2. In that Table and throughout this subclause:

- a) \(T\) is the type named by \(S\)’s associated `result_type`;
- b) \(q\) is a value of \(S\) and \(r\) is a possibly const value of \(S\);
- c) \(ib\) and \(ie\) are input iterators with an unsigned integer `value_type` of at least 32 bits;
- d) \(rb\) and \(re\) are mutable random access iterators with an unsigned integer `value_type` of at least 32 bits;
- e) \(ob\) is an output iterator; and
- f) \(il\) is a value of `initializer_list<T>`.

Table 83 — Seed sequence requirements

<td><code>void</code></td>
<td>Copies to the given destination a sequence of 32-bit units that can be provided to the constructor of a second object of type (S), and that would reproduce in that second object a state indistinguishable from the state of the first object.</td>
<td>(O(r.size()))</td>
</tr>
</tbody>
</table>
24.7.2.3 Uniform random bit generator requirements

A uniform random bit generator \( g \) of type \( G \) is a function object returning unsigned integer values such that each value in the range of possible results has (ideally) equal probability of being returned. \[ \text{Note: The degree to which \( g \)'s results approximate the ideal is often determined statistically. — end note} \]

```cpp
template<class G>
concept UniformRandomBitGenerator =
Invocable<G&> && UnsignedIntegral<invoke_result_t<G&>> &&
requires {
  G::min(); requires Same<decltype(G::min()), invoke_result_t<G&>>;
  G::max(); requires Same<decltype(G::max()), invoke_result_t<G&>>;
};
```

Let \( g \) be an object of type \( G \). \( G \) models \texttt{UniformRandomBitGenerator} only if

1. \( \text{both } G::\text{min}() \text{ and } G::\text{max}() \text{ are constant expressions (7.7)}, \)
2. \( G::\text{min}() \text{ < } G::\text{max}() \),
3. \( G::\text{min}() \text{ <= } g() \),
4. \( g() \text{ <= } G::\text{max}() \), and
5. \( g() \) has amortized constant complexity.

A class \( G \) meets the uniform random bit generator requirements if \( G \) models \texttt{UniformRandomBitGenerator}, \texttt{invoke_result_t<G&>} is an unsigned integer type (6.7.1), and \( G \) provides a nested \texttt{typedef-name result_type} that denotes the same type as \texttt{invoke_result_t<G&>}.

24.7.2.4 Random number engine requirements

A random number engine (commonly shortened to engine) \( e \) of type \( E \) is a uniform random bit generator that additionally meets the requirements (e.g., for seeding and for input/output) specified in this subclause.

At any given time, \( e \) has a state \( e_i \) for some integer \( i \geq 0 \). Upon construction, \( e \) has an initial state \( e_0 \). An engine’s state may be established via a constructor, a seed function, assignment, or a suitable \texttt{operator>>}.

\( E \)'s specification shall define:

a) the size of \( E \)'s state in multiples of the size of \texttt{result_type}, given as an integral constant expression;
b) the transition algorithm \( TA \) by which \( e \)'s state \( e_i \) is advanced to its successor state \( e_{i+1} \); and
c) the generation algorithm \( GA \) by which an engine’s state is mapped to a value of type \texttt{result_type}.

A class \( E \) that satisfies the requirements of a uniform random bit generator (24.7.2.3) also satisfies the requirements of a random number engine if the expressions shown in Table 84 are valid and have the indicated semantics, and if \( E \) also satisfies all other requirements of this subclause 24.7.2.4. In that Table and throughout this subclause:

a) \( T \) is the type named by \( E \)'s associated \texttt{result_type};
b) \( e \) is a value of \( E \), \( v \) is an lvalue of \( E \), \( x \) and \( y \) are (possibly \texttt{const}) values of \( E \);
c) \( u \) is a value of \( T \);
d) \( q \) is an lvalue satisfying the requirements of a seed sequence (24.7.2.2);
e) \( z \) is a value of type \texttt{unsigned long long}:
f) \( os \) is an lvalue of the type of some class template specialization \texttt{basic_ostream<charT, traits>}; and
g) \( is \) is an lvalue of the type of some class template specialization \texttt{basic_istream<charT, traits>}.

where \texttt{charT} and \texttt{traits} are constrained according to Clause 20 and Clause 27.

### Table 84 — Random number engine requirements

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Pre/post-condition</th>
<th>Complexity</th>
</tr>
</thead>
<tbody>
<tr>
<td>( E() )</td>
<td>Creates an engine with the same ( O(\text{size of state}) ) initial state as all other default-constructed engines of type ( E ).</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Expression</td>
<td>Return type</td>
<td>Pre/post-condition</td>
<td>Complexity</td>
</tr>
<tr>
<td>------------</td>
<td>-------------</td>
<td>---------------------</td>
<td>------------</td>
</tr>
<tr>
<td>E(x)</td>
<td></td>
<td>Creates an engine that compares equal to x.</td>
<td>(\mathcal{O}(\text{size of state}))</td>
</tr>
<tr>
<td>E(s)</td>
<td></td>
<td>Creates an engine with initial state determined by s.</td>
<td>(\mathcal{O}(\text{size of state}))</td>
</tr>
<tr>
<td>E(q)</td>
<td></td>
<td>Creates an engine with an initial state that depends on a sequence produced by one call to q.generate.</td>
<td>same as complexity of q.generate called on a sequence whose length is size of state</td>
</tr>
</tbody>
</table>

| e.seed()   | void        | Ensures: \(e == E()\). | same as E() |
| e.seed(s)  | void        | Ensures: \(e == E(s)\). | same as E(s) |
| e.seed(q)  | void        | Ensures: \(e == E(q)\). | same as E(q) |

| e()        | T           | Advances e’s state \(e_i\) to \(e_{i+1} = T \text{A}(e_i)\) and returns \(G \text{A}(e_i)\). | per 24.7.2.3 |

| e.discard(z) | void   | Advances e’s state \(e_i\) to \(e_{i+z}\) by any means equivalent to \(z\) consecutive calls e(). | no worse than the complexity of \(z\) consecutive calls e() |

| x == y      | bool       | This operator is an equivalence relation. With \(S_x\) and \(S_y\) as the infinite sequences of values that would be generated by repeated future calls to x() and y(), respectively, returns true if \(S_x = S_y\); else returns false. | \(\mathcal{O}(\text{size of state})\) |

| x != y      | bool       | \(! (x == y)\). | \(\mathcal{O}(\text{size of state})\) |

| os << x     | reference to the type of os | With os.fmtflags set to ios_base::dec|ios_base::left and the fill character set to the space character, writes to os the textual representation of x’s current state. In the output, adjacent numbers are separated by one or more space characters. Ensures: The os.fmtflags and fill character are unchanged. | \(\mathcal{O}(\text{size of state})\) |

---

247 This constructor (as well as the subsequent corresponding seed() function) may be particularly useful to applications requiring a large number of independent random sequences.

248 This operation is common in user code, and can often be implemented in an engine-specific manner so as to provide significant performance improvements over an equivalent naive loop that makes \(z\) consecutive calls e().
<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Pre/post-condition</th>
<th>Complexity</th>
</tr>
</thead>
<tbody>
<tr>
<td>is &gt;&gt; v</td>
<td>reference to the type of is</td>
<td>With is.fmtflags set to ios_base::dec, sets v’s state as determined by reading its textual representation from is. If bad input is encountered, ensures that v’s state is unchanged by the operation and calls is.setstate(ios::failbit) (which may throw ios::failure (27.5.5.4)). If a textual representation written via os &lt;&lt; x was subsequently read via is &gt;&gt; v, then x == v provided that there have been no intervening invocations of x or of v. Requires: is provides a textual representation that was previously written using an output stream whose imbued locale was the same as that of is, and whose type’s template specialization arguments charT and traits were respectively the same as those of is. Ensures: The is.fmtflags are unchanged.</td>
<td>$\mathcal{O}(\text{size of state})$</td>
</tr>
</tbody>
</table>

5 E shall satisfy the Cpp17CopyConstructible (Table 26) and Cpp17CopyAssignable (Table 28) requirements. These operations shall each be of complexity no worse than $\mathcal{O}(\text{size of state})$.

24.7.2.5 Random number engine adaptor requirements [rand.req.adapt]

1 A random number engine adaptor (commonly shortened to adaptor) a of type A is a random number engine that takes values produced by some other random number engine, and applies an algorithm to those values in order to deliver a sequence of values with different randomness properties. An engine b of type B adapted in this way is termed a base engine in this context. The expression a.base() shall be valid and shall return a const reference to a’s base engine.

2 The requirements of a random number engine type shall be interpreted as follows with respect to a random number engine adaptor type.

A::A();

3 Effects: The base engine is initialized as if by its default constructor.

bool operator==(const A& a1, const A& a2);

4 Returns: true if a1’s base engine is equal to a2’s base engine. Otherwise returns false.

A::A(result_type s);

5 Effects: The base engine is initialized with s.

template<class Sseq> A::A(Sseq& q);

6 Effects: The base engine is initialized with q.

void seed();

7 Effects: With b as the base engine, invokes b.seed().
void seed(result_type s);
8  Effects: With \( b \) as the base engine, invokes \( b \cdot \text{seed}(s) \).

template<class Sseq> void seed(Sseq& q);
9  Effects: With \( b \) as the base engine, invokes \( b \cdot \text{seed}(q) \).

A shall also satisfy the following additional requirements:

a) The complexity of each function shall not exceed the complexity of the corresponding function applied to the base engine.

b) The state of \( A \) shall include the state of its base engine. The size of \( A \)'s state shall be no less than the size of the base engine.

c) Copying \( A \)'s state (e.g., during copy construction or copy assignment) shall include copying the state of the base engine of \( A \).

d) The textual representation of \( A \) shall include the textual representation of its base engine.

### 24.7.2.6 Random number distribution requirements [rand.req.dist]

1 A random number distribution (commonly shortened to distribution) \( d \) of type \( D \) is a function object returning values that are distributed according to an associated mathematical probability density function \( p(z) \) or according to an associated discrete probability function \( P(z_i) \). A distribution’s specification identifies its associated probability function \( p(z) \) or \( P(z_i) \).

2 An associated probability function is typically expressed using certain externally-supplied quantities known as the parameters of the distribution. Such distribution parameters are identified in this context by writing, for example, \( p(z | a, b) \) or \( P(z_i | a, b) \), to name specific parameters, or by writing, for example, \( p(z | \{p\}) \) or \( P(z_i | \{p\}) \), to denote a distribution’s parameters \( p \) taken as a whole.

3 A class \( D \) satisfies the requirements of a random number distribution if the expressions shown in Table 85 are valid and have the indicated semantics, and if \( D \) and its associated types also satisfy all other requirements of this subclause 24.7.2.6. In that Table and throughout this subclause,

a) \( T \) is the type named by \( D \)'s associated result_type;

b) \( P \) is the type named by \( D \)'s associated param_type;

c) \( d \) is a value of \( D \), and \( x \) and \( y \) are (possibly const) values of \( D \);

d) \( \text{glb} \) and \( \text{lub} \) are values of \( T \) respectively corresponding to the greatest lower bound and the least upper bound on the values potentially returned by \( d \)'s operator(), as determined by the current values of \( d \)'s parameters;

e) \( p \) is a (possibly const) value of \( P \);

f) \( g, g1, \) and \( g2 \) are lvalues of a type satisfying the requirements of a uniform random bit generator (24.7.2.3);

g) \( \text{os} \) is an lvalue of the type of some class template specialization basic_ostream<charT, traits>; and

h) \( \text{is} \) is an lvalue of the type of some class template specialization basic_istream<charT, traits>;

where charT and traits are constrained according to Clause 20 and Clause 27.

</tbody>
</table>

4. D shall satisfy the `Cpp17CopyConstructible` (Table 26) and `Cpp17CopyAssignable` (Table 28) requirements.

5. The sequence of numbers produced by repeated invocations of `d(g)` shall be independent of any invocation of `os << d` or of any `const` member function of D between any of the invocations `d(g)`.

6. If a textual representation is written using `os << x` and that representation is restored into the same or a different object `y` of the same type using `is >> y`, repeated invocations of `y(g)` shall produce the same sequence of numbers as would repeated invocations of `x(g)`.

7. It is unspecified whether `D::param_type` is declared as a (nested) class or via a `typedef`. In this subclause 24.7, declarations of `D::param_type` are in the form of `typedefs` for convenience of exposition only.

8. P shall satisfy the `Cpp17CopyConstructible` (Table 26), `Cpp17CopyAssignable` (Table 28), and `Cpp17EqualityComparable` (Table 22) requirements.

9. For each of the constructors of D taking arguments corresponding to parameters of the distribution, P shall have a corresponding constructor subject to the same requirements and taking arguments identical in number, type, and default values. Moreover, for each of the member functions of D that return values corresponding to parameters of the distribution, P shall have a corresponding member function with the identical name, type, and semantics.

10. P shall have a declaration of the form

    ```
    using distribution_type = D;
    ```

### 24.7.3 Random number engine class templates

1. Each type instantiated from a class template specified in this subclause 24.7.3 satisfies the requirements of a random number engine (24.7.2.4) type.

2. Except where specified otherwise, the complexity of each function specified in this subclause 24.7.3 is constant.

3. Except where specified otherwise, no function described in this subclause 24.7.3 throws an exception.

4. Every function described in this subclause 24.7.3 that has a function parameter `q` of type `Sseq&` for a template type parameter named `Sseq` that is different from type `seed_seq` throws what and when the invocation of `q.generate` throws.

5. Descriptions are provided in this subclause 24.7.3 only for engine operations that are not described in 24.7.2.4 or for operations where there is additional semantic information. In particular, declarations for copy constructors, for copy assignment operators, for streaming operators, and for equality and inequality operators are not shown in the synopses.

6. Each template specified in this subclause 24.7.3 requires one or more relationships, involving the value(s) of its non-type template parameter(s), to hold. A program instantiating any of these templates is ill-formed if any such required relationship fails to hold.
For every random number engine and for every random number engine adaptor \(X\) defined in this subclause (24.7.3) and in subclause 24.7.4:

(7.1) — if the constructor

\[
\text{template<typename Sseq> explicit } X(Sseq& q);
\]

is called with a type \(Sseq\) that does not qualify as a seed sequence, then this constructor shall not participate in overload resolution;

(7.2) — if the member function

\[
\text{template<typename Sseq> void seed(Sseq& q);}
\]

is called with a type \(Sseq\) that does not qualify as a seed sequence, then this function shall not participate in overload resolution.

The extent to which an implementation determines that a type cannot be a seed sequence is unspecified, except that as a minimum a type shall not qualify as a seed sequence if it is implicitly convertible to \(X::\text{result\_type}\).

24.7.3.1 Class template linear_congruential_engine

A linear_congruential_engine random number engine produces unsigned integer random numbers. The state \(x_i\) of a linear_congruential_engine object \(x\) is of size 1 and consists of a single integer. The transition algorithm is a modular linear function of the form \(T_A(x_i) = (a \cdot x_i + c) \mod m\); the generation algorithm is \(G_A(x_i) = x_i + 1\).

\[
\text{template<typename UIntType, UIntType a, UIntType c, UIntType m>}
\]

\[
\text{class linear_congruential_engine }
\]

\[
\text{public: }
\]

\[
\text{// types}
\]

\[
\text{using result\_type = UIntType;}
\]

\[
\text{// engine characteristics}
\]

\[
\text{static constexpr result\_type multiplier = a;}
\]

\[
\text{static constexpr result\_type increment = c;}
\]

\[
\text{static constexpr result\_type modulus = m;}
\]

\[
\text{static constexpr result\_type min() \{ return c == 0u ? 1u : 0u; \}}
\]

\[
\text{static constexpr result\_type max() \{ return m - 1u; \}}
\]

\[
\text{static constexpr result\_type default\_seed = 1u;}
\]

\[
\text{// constructors and seeding functions}
\]

\[
\text{linear_congruential_engine() : linear_congruential_engine(default\_seed) \{}
\]

\[
\text{explicit linear_congruential_engine(result\_type s);}
\]

\[
\text{template<typename Sseq> explicit linear_congruential_engine(Sseq& q);}
\]

\[
\text{void seed(result\_type s = default\_seed);}
\]

\[
\text{template<typename Sseq> void seed(Sseq& q);}
\]

\[
\text{// generating functions}
\]

\[
\text{result\_type operator()();}
\]

\[
\text{void discard(unsigned long long z);}
\]

1 If the template parameter \(m\) is 0, the modulus \(m\) used throughout this subclause 24.7.3.1 is numeric\_limits<result\_type>::max() plus 1. [Note: \(m\) need not be representable as a value of type result\_type. — end note]

2 If the template parameter \(m\) is not 0, the following relations shall hold: \(a < m\) and \(c < m\).

3 The textual representation consists of the value of \(x_i\).

4 The textual representation consists of the value of \(x_i\).

\[
\text{explicit linear_congruential_engine(result\_type s);}
\]

5 \[Effects: \] Constructs a linear_congruential_engine object. If \(c\) mod \(m\) is 0 and \(s\) mod \(m\) is 0, sets the engine’s state to 1, otherwise sets the engine’s state to \(s\) mod \(m\).
template<class Sseq> explicit linear_congruential_engine(Sseq& q);

Effects: Constructs a \texttt{linear_congruential_engine} object. With \(k = \left\lceil \log_2 m \right\rceil\) and \(a\) an array (or equivalent) of length \(k + 3\), invokes \texttt{q.generate(a + 0, a + k + 3)} and then computes

\[ S = \left( \sum_{j=0}^{k-1} a_{j+3} \cdot 2^{2j} \right) \mod m. \]

If \(c \mod m = 0\) and \(S = 0\), sets the engine's state to 1, else sets the engine's state to \(S\).

### 24.7.3.2 Class template \texttt{mersenne_twister_engine} [rand.eng.mers]

A \texttt{mersenne_twister_engine} random number engine\(^{249}\) produces unsigned integer random numbers in the closed interval \([0, 2^w - 1]\). The state \(x_i\) of a \texttt{mersenne_twister_engine} object \(x\) is of size \(n\) and consists of a sequence \(X\) of \(n\) values of the type delivered by \(x\); all subscripts applied to \(X\) are to be taken modulo \(n\).

The transition algorithm employs a twisted generalized feedback shift register defined by shift values \(n\) and \(m\), a twist value \(r\), and a conditional xor-mask \(a\). To improve the uniformity of the result, the bits of the raw shift register are additionally \textit{tempered} (i.e., scrambled) according to a bit-scrambling matrix defined by values \(u, d, s, b, t, c,\) and \(l\).

The state transition is performed as follows:

1. Concatenate the upper \(w - r\) bits of \(X_{i-n}\) with the lower \(r\) bits of \(X_{i+1-n}\) to obtain an unsigned integer value \(Y\).
2. With \(\alpha = a \cdot (Y \text{ bitand } 1)\), set \(X_i\) to \(X_{i+m-n} \text{ xor } (Y \text{ rshift } 1) \text{ xor } \alpha\).

The sequence \(X\) is initialized with the help of an initialization multiplier \(f\).

The generation algorithm determines the unsigned integer values \(z_1, z_2, z_3, z_4\) as follows, then delivers \(z_4\) as its result:

1. Let \(z_1 = X_i \text{ xor } ((X_i \text{ rshift } u) \text{ bitand } d)\).
2. Let \(z_2 = z_1 \text{ xor } ((z_1 \text{ lshift } s) \text{ bitand } b)\).
3. Let \(z_3 = z_2 \text{ xor } ((z_2 \text{ lshift } t) \text{ bitand } c)\).
4. Let \(z_4 = z_3 \text{ xor } (z_3 \text{ rshift } l)\).

\[template<class UIntType, size_t w, size_t n, size_t m, size_t r, \]
[\hspace{1em} UIntType a, size_t u, UIntType d, size_t s, \]
[\hspace{1em} UIntType b, size_t t, \]
[\hspace{1em} UIntType c, size_t l, UIntType f> \]
\[class mersenne_twister_engine { \]
public:
\hspace{1em} using result_type = UIntType;
\hspace{1em} // types
\hspace{1em} // engine characteristics
\hspace{1em} static constexpr size_t word_size = w;
\hspace{1em} static constexpr size_t state_size = n;
\hspace{1em} static constexpr size_t shift_size = m;
\hspace{1em} static constexpr size_t mask_bits = r;
\hspace{1em} static constexpr UIntType xor_mask = a;
\hspace{1em} static constexpr size_t tempering_u = u;
\hspace{1em} static constexpr UIntType tempering_d = d;
\hspace{1em} static constexpr size_t tempering_s = s;
\hspace{1em} static constexpr UIntType tempering_b = b;
\hspace{1em} static constexpr size_t tempering_t = t;
\hspace{1em} static constexpr UIntType tempering_c = c;
\hspace{1em} static constexpr size_t tempering_l = l;
\hspace{1em} static constexpr UIntType initialization_multiplier = f;
\hspace{1em} static constexpr result_type min() { return 0; }\]
\hspace{1em} static constexpr result_type max() { return \(2^w - 1\); }
\hspace{1em} static constexpr result_type default_seed = 5489u;

\(^{249}\) The name of this engine refers, in part, to a property of its period: For properly-selected values of the parameters, the period is closely related to a large Mersenne prime number.
Effects: Constructs a `mersenne_twister_engine` object. Sets $X_{-n}$ to value $\text{mod } 2^w$. Then, iteratively for $i = 1 - n, \ldots, -1$, sets $X_i$ to

$$[f \cdot (X_{i-1} \text{xor } (X_{i-1} \text{rshift } (w - 2))) + i \text{ mod } n] \text{ mod } 2^w.$$  

Complexity: $O(n)$. 

Effects: Constructs a `mersenne_twister_engine` object. With $k = [w/32]$ and $a$ an array (or equivalent) of length $n \cdot k$, invokes $\text{q.generate}(a + 0, a + n \cdot k)$ and then, iteratively for $i = -n, \ldots, -1$, sets $X_i$ to $(\sum_{j=0}^{k-1} a_{k(i+n)+j} \cdot 2^{32j}) \text{ mod } 2^w$. Finally, if the most significant $w - r$ bits of $X_{-n}$ are zero, and if each of the other resulting $X_i$ is 0, changes $X_{-n}$ to $2^{w-1}$. 

24.7.3.3 Class template subtract_with_carry_engine

A `subtract_with_carry_engine` random number engine produces unsigned integer random numbers.

2 The state $x_i$ of a `subtract_with_carry_engine` object $x$ is of size $O(r)$, and consists of a sequence $X$ of $r$ integer values $0 \leq X_i < m = 2^w$; all subscripts applied to $X$ are to be taken modulo $r$. The state $x_i$ additionally consists of an integer $c$ (known as the carry) whose value is either 0 or 1.

3 The state transition is performed as follows:

a) Let $Y = X_{i-x} - X_{i-r} - c$.

b) Set $X_i$ to $y \text{ mod } m$. Set $c$ to 1 if $Y < 0$, otherwise set $c$ to 0.

[Note: This algorithm corresponds to a modular linear function of the form $TA(x_i) = (a \cdot x_i) \text{ mod } b$, where $b$ is of the form $m^r - m^s + 1$ and $a = b - (b - 1)/m$. — end note]

4 The generation algorithm is given by $GA(x_i) = y$, where $y$ is the value produced as a result of advancing the engine’s state as described above.
// constructors and seeding functions
subtract_with_carry_engine() : subtract_with_carry_engine(default_seed) {} explicit subtract_with_carry_engine(result_type value); template<class Sseq> explicit subtract_with_carry_engine(Sseq& q); void seed(result_type value = default_seed); template<class Sseq> void seed(Sseq& q);

// generating functions
result_type operator()(); void discard(unsigned long long z);

The following relations shall hold: 0u < s, s < r, 0 < w, and w <= numeric_limits<UIntType>::digits.

The textual representation consists of the values of \(X_i-r,...,X_{i-1}\), in that order, followed by \(c\).

explicit subtract_with_carry_engine(result_type value);

Effects: Constructs a subtract_with_carry_engine object. Sets the values of \(X_i-r,...,X_{i-1}\), in that order, as specified below. If \(X_{i-1}\) is then 0, sets \(c\) to 1; otherwise sets \(c\) to 0.

To set the values \(X_k\), first construct \(e\), a linear_congruential_engine object, as if by the following definition:

\[
\text{linear_congruential_engine<result_type, 40014u,0u,2147483563u> e(value == 0u ? default_seed : value);}
\]

Then, to set each \(X_k\), obtain new values \(z_0,...,z_{n-1}\) from \(n = \lceil w/32 \rceil\) successive invocations of \(e\) taken modulo \(2^{32}\). Set \(X_k\) to \((\sum_{j=0}^{n-1} z_j \cdot 2^{32j}) \mod m\).

Complexity: Exactly \(n \cdot r\) invocations of \(e\).

template<class Sseq> explicit subtract_with_carry_engine(Sseq& q);

Effects: Constructs a subtract_with_carry_engine object. With \(k = \lceil w/32 \rceil\) and \(a\) an array (or equivalent) of length \(r \cdot k\), invokes \(q.generate(a+0, a+r \cdot k)\) and then, iteratively for \(i = -r,...,-1\), sets \(X_i\) to \((\sum_{j=0}^{k-1} a_k(i+r+j) \cdot 2^{32j}) \mod m\). If \(X_{-1}\) is then 0, sets \(c\) to 1; otherwise sets \(c\) to 0.

24.7.4 Random number engine adaptor class templates [rand.adapt]

24.7.4.1 In general [rand.adapt.general]

1 Each type instantiated from a class template specified in this subclause 24.7.4 satisfies the requirements of a random number engine adaptor (24.7.2.5) type.

2 Except where specified otherwise, the complexity of each function specified in this subclause 24.7.4 is constant.

3 Except where specified otherwise, no function described in this subclause 24.7.4 throws an exception.

4 Every function described in this subclause 24.7.4 that has a function parameter \(q\) of type \(Sseq\) and a template type parameter named \(Sseq\) that is different from type \(seed_seq\) throws what and when the invocation of \(q.generate\) throws.

5 Descriptions are provided in this subclause 24.7.4 only for adaptor operations that are not described in subclause 24.7.2.5 or for operations where there is additional semantic information. In particular, declarations for copy constructors, for copy assignment operators, for streaming operators, and for equality and inequality operators are not shown in the synopses.

6 Each template specified in this subclause 24.7.4 requires one or more relationships, involving the value(s) of its non-type template parameter(s), to hold. A program instantiating any of these templates is ill-formed if any such required relationship fails to hold.

24.7.4.2 Class template discard_block_engine [rand.adapt.disc]

1 A discard_block_engine random number engine adaptor produces random numbers selected from those produced by some base engine \(e\). The state \(x_i\) of a discard_block_engine engine adaptor object \(x\) consists of the state \(e_i\) of its base engine \(e\) and an additional integer \(n\). The size of the state is the size of \(e\)'s state plus 1.
The transition algorithm discards all but \( r > 0 \) values from each block of \( p \geq r \) values delivered by \( e \). The state transition is performed as follows: If \( n \geq r \), advance the state of \( e \) from \( e_i \) to \( e_{i+p-r} \) and set \( n \) to 0. In any case, then increment \( n \) and advance \( e \)'s then-current state \( e_j \) to \( e_{j+1} \).

The generation algorithm yields the value returned by the last invocation of \( e() \) while advancing \( e \)'s state as described above.

```cpp
template<class Engine, size_t p, size_t r>
class discard_block_engine {
  public:
    // types
    using result_type = typename Engine::result_type;

    // engine characteristics
    static constexpr size_t block_size = p;
    static constexpr size_t used_block = r;
    static constexpr result_type min() { return Engine::min(); }
    static constexpr result_type max() { return Engine::max(); }

    // constructors and seeding functions
    discard_block_engine();
    explicit discard_block_engine(const Engine& e);
    explicit discard_block_engine(Engine&& e);
    explicit discard_block_engine(result_type s);
    template<class Sseq> explicit discard_block_engine(Sseq& q);
    void seed();
    void seed(result_type s);
    template<class Sseq> void seed(Sseq& q);

    // generating functions
    result_type operator()();
    void discard(unsigned long long z);

    // property functions
    const Engine& base() const noexcept { return e; }

private:
  Engine e; // exposition only
  int n; // exposition only
};
```

The following relations shall hold: \( 0 < r \) and \( r \leq p \).

The textual representation consists of the textual representation of \( e \) followed by the value of \( n \).

In addition to its behavior pursuant to subclause 24.7.2.5, each constructor that is not a copy constructor sets \( n \) to 0.

### 24.7.4.3 Class template independent_bits_engine

An `independent_bits_engine` random number engine adaptor combines random numbers that are produced by some base engine \( e \), so as to produce random numbers with a specified number of bits \( w \). The state \( x_i \) of an `independent_bits_engine` engine adaptor object \( x \) consists of the state \( e_i \) of its base engine \( e \); the size of the state is the size of \( e \)'s state.

The transition and generation algorithms are described in terms of the following integral constants:

- a) Let \( R = e.\max() - e.\min() + 1 \) and \( m = \lceil \log_2 R \rceil \).
- b) With \( n \) as determined below, let \( w_0 = \lfloor w/n \rfloor \), \( n_0 = n - w \mod n \), \( y_0 = 2^{w_0} \lfloor R/2^{w_0} \rfloor \), and \( y_1 = 2^{w_0+1} \lfloor R/2^{w_0+1} \rfloor \).
- c) Let \( n = \lfloor w/m \rfloor \) if and only if the relation \( R-y_0 \leq \lfloor y_0/n \rfloor \) holds as a result. Otherwise let \( n = 1 + \lfloor w/m \rfloor \).

[Note: The relation \( w = n_0w_0 + (n - n_0)(w_0 + 1) \) always holds. — end note]

The transition algorithm is carried out by invoking \( e() \) as often as needed to obtain \( n_0 \) values less than \( y_0 + e.\min() \) and \( n - n_0 \) values less than \( y_1 + e.\min() \).
The generation algorithm uses the values produced while advancing the state as described above to yield a quantity \( S \) obtained as if by the following algorithm:

\[
S = 0;
\]

for \((k = 0; k \neq n_0; k ++ = 1)\) {
  
do \( u = e() - e.\min() \); while \((u \geq y_0)\);
  \( S = 2^{w_0} \cdot S + u \mod 2^{w_0}; \)
}

for \((k = n_0; k \neq n; k ++ = 1)\) {
  
do \( u = e() - e.\min() \); while \((u \geq y_1)\);
  \( S = 2^{w_0+1} \cdot S + u \mod 2^{w_0+1}; \)
}

```
template<class Engine, size_t w, class UIntType>
  class independent_bits_engine {
    public:
      // types
      using result_type = UIntType;

      // engine characteristics
      static constexpr result_type min() { return 0; }
      static constexpr result_type max() { return \(2^w - 1\); }

      // constructors and seeding functions
      independent_bits_engine();
      explicit independent_bits_engine(const Engine& e);
      explicit independent_bits_engine(Engine&& e);
      explicit independent_bits_engine(result_type s);
      template<class Sseq> explicit independent_bits_engine(Sseq& q);
      void seed();
      void seed(result_type s);
      template<class Sseq> void seed(Sseq& q);

      // generating functions
      result_type operator()();
      void discard(unsigned long long z);

    // property functions
    const Engine& base() const noexcept { return e; }

  private:
    Engine e;  // exposition only
  };
```
// engine characteristics
static constexpr size_t table_size = k;
static constexpr result_type min() { return Engine::min(); }
static constexpr result_type max() { return Engine::max(); }

// constructors and seeding functions
shuffle_order_engine();
explicit shuffle_order_engine(const Engine& e);
explicit shuffle_order_engine(Engine&& e);
explicit shuffle_order_engine(result_type s);
template<class Sseq> explicit shuffle_order_engine(Sseq& q);
void seed();
void seed(result_type s);
template<class Sseq> void seed(Sseq& q);

// generating functions
result_type operator()();
void discard(unsigned long long z);

// property functions
const Engine& base() const noexcept { return e; }

private:
    Engine e; // exposition only
    result_type V[k]; // exposition only
    result_type Y; // exposition only
};

The following relation shall hold: 0 < k.
The textual representation consists of the textual representation of e, followed by the k values of V, followed by the value of Y.
In addition to its behavior pursuant to subclause 24.7.2.5, each constructor that is not a copy constructor initializes V[0],...,V[k-1] and Y, in that order, with values returned by successive invocations of e().

24.7.5 Engines and engine adaptors with predefined parameters

using minstd_rand0 =
    linear_congruential_engine<uint_fast32_t, 16807, 0, 2147483647>;

Required behavior: The 10000th consecutive invocation of a default-constructed object of type minstd_rand0 shall produce the value 1043618065.

using minstd_rand =
    linear_congruential_engine<uint_fast32_t, 48271, 0, 2147483647>;

Required behavior: The 10000th consecutive invocation of a default-constructed object of type minstd_rand shall produce the value 399268537.

using mt19937 =
    mersenne_twister_engine<uint_fast32_t,
        32,624,397,31,0x9908b0df,11,0xffffffff,7,0x9d2c5680,15,0xefc60000,17,0x71d67fffeda60000,37,0xfff7eee00000000,43,
        6364136223846793005>;

Required behavior: The 10000th consecutive invocation of a default-constructed object of type mt19937 shall produce the value 4123659995.

using mt19937_64 =
    mersenne_twister_engine<uint_fast64_t,
        64,312,156,31,0xb5026f5aa96619e9,29,
        0x5555555555555555,17,
        0x71d67ffeda60000,37,
        0xff7eee0000000000,43,
        6364136223846793005>;

Required behavior: The 10000th consecutive invocation of a default-constructed object of type mt19937_64 shall produce the value 9981545732273789042.
5 Required behavior: The 10000th consecutive invocation of a default-constructed object of type ranlux24_base shall produce the value 7937952.

6 Required behavior: The 10000th consecutive invocation of a default-constructed object of type ranlux48_base shall produce the value 61839128582725.

7 Required behavior: The 10000th consecutive invocation of a default-constructed object of type ranlux24 shall produce the value 9901578.

8 Required behavior: The 10000th consecutive invocation of a default-constructed object of type ranlux48 shall produce the value 249142670248501.

9 Required behavior: The 10000th consecutive invocation of a default-constructed object of type knuth_b shall produce the value 111239016.

10 Remarks: The choice of engine type named by this typedef is implementation-defined. [Note: The implementation may select this type on the basis of performance, size, quality, or any combination of such factors, so as to provide at least acceptable engine behavior for relatively casual, inexpert, and/or lightweight use. Because different implementations may select different underlying engine types, code that uses this typedef need not generate identical sequences across implementations. —end note]

24.7.6 Class random_device

1 A random_device uniform random bit generator produces nondeterministic random numbers.

2 If implementation limitations prevent generating nondeterministic random numbers, the implementation may employ a random number engine.

```cpp
class random_device {
public:
  // types
  using result_type = unsigned int;

  // generator characteristics
  static constexpr result_type min() { return numeric_limits<result_type>::min(); }
  static constexpr result_type max() { return numeric_limits<result_type>::max(); }

  // constructors
  random_device() : random_device(implementation-defined) {};
  explicit random_device(const string& token);

  // generating functions
  result_type operator()();

  // property functions
  double entropy() const noexcept;

  // no copy functions
  random_device(const random_device& ) = delete;
  void operator=(const random_device& ) = delete;
};
```
explicit random_device(const string& token);

3 Effects: Constructs a random_device nondeterministic uniform random bit generator object. The semantics of the token parameter and the token value used by the default constructor are implementation-defined.\textsuperscript{250}

4 Throws: A value of an implementation-defined type derived from exception if the random_device could not be initialized.

double entropy() const noexcept;

5 Returns: If the implementation employs a random number engine, returns 0.0. Otherwise, returns an entropy estimate\textsuperscript{251} for the random numbers returned by operator(), in the range min() to log₂(max() + 1).

result_type operator()();

6 Returns: A nondeterministic random value, uniformly distributed between min() and max(), inclusive. It is implementation-defined how these values are generated.

7 Throws: A value of an implementation-defined type derived from exception if a random number could not be obtained.

24.7.7 Utilities [rand.util]

24.7.7.1 Class seed_seq [rand.util.seedseq]

```cpp
class seed_seq {
    public:
        // types
        using result_type = uint_least32_t;

        // constructors
        seed_seq();
        template<class T>
        seed_seq(initializer_list<T> il);
        template<class InputIterator>
        seed_seq(InputIterator begin, InputIterator end);

        // generating functions
        template<class RandomAccessIterator>
        void generate(RandomAccessIterator begin, RandomAccessIterator end);

        // property functions
        size_t size() const noexcept;
        template<class OutputIterator>
        void param(OutputIterator dest) const;

        // no copy functions
        seed_seq(const seed_seq&) = delete;
        void operator=(const seed_seq&) = delete;

    private:
        vector<result_type> v;  // exposition only
};
```

1 Effects: Constructs a seed_seq object as if by default-constructing its member v.

2 Throws: Nothing.

```cpp
template<class T>
seed_seq(initializer_list<T> il);
```

3 Requires: T shall be an integer type.

\textsuperscript{250} The parameter is intended to allow an implementation to differentiate between different sources of randomness.

\textsuperscript{251} If a device has \( n \) states whose respective probabilities are \( P_0, \ldots, P_{n-1} \), the device entropy \( S \) is defined as

\[
S = - \sum_{i=0}^{n-1} P_i \cdot \log P_i.
\]
Effects: Same as \texttt{seed\_seq}(il.begin(), il.end()).

\begin{verbatim}
template<class InputIterator>
seed_seq(InputIterator begin, InputIterator end);
\end{verbatim}

Requires: \texttt{InputIterator} shall satisfy the \texttt{Cpp17InputIterator} requirements (22.2.3). Moreover, \texttt{iterator\_traits<InputIterator>::value\_type} shall denote an integer type.

Effects: Constructs a \texttt{seed\_seq} object by the following algorithm:

\begin{verbatim}
for( InputIterator s = begin; s != end; ++s)
v.push\_back((s)\%mod2^32);
\end{verbatim}

\begin{verbatim}
template<class RandomAccessIterator>
void generate(RandomAccessIterator begin, RandomAccessIterator end);
\end{verbatim}

Requires: \texttt{RandomAccessIterator} shall satisfy the \texttt{Cpp17RandomAccessIterator} requirements (22.2.7) and the requirements of a mutable iterator. Moreover, \texttt{iterator\_traits<RandomAccessIterator>::value\_type} shall denote an integer type capable of accommodating 32-bit quantities.

Effects: Does nothing if \texttt{begin == end}. Otherwise, with \(s = v\text{.size()}\) and \(n = \text{end} - \text{begin}\), fills the supplied range \([\text{begin}, \text{end}]\) according to the following algorithm in which each operation is to be carried out modulo \(2^{32}\), each indexing operator applied to \texttt{begin} is to be taken modulo \(n\), and \(T(x)\) is defined as \(x \text{xor} (x \text{rshift} 27)\):

a) By way of initialization, set each element of the range to the value \(0x8b8b8b8b\). Additionally, for use in subsequent steps, let \(p = (n - t)/2\) and let \(q = p + t\), where

\[
t = (n \geq 623) \oplus 11 : (n \geq 68) \oplus 7 : (n \geq 39) \oplus 5 : (n \geq 7) \oplus 3 : (n - 1)/2;
\]

b) With \(m\) as the larger of \(s + 1\) and \(n\), transform the elements of the range: iteratively for \(k = 0, \ldots, m - 1\), calculate values

\[
\begin{align*}
    r_1 &= 1664525 \cdot T(\text{begin}[k] \text{xor} \text{begin}[k + p] \text{xor} \text{begin}[k - 1]) \\
    r_2 &= r_1 + \begin{cases} \\
    s, & k = 0 \\
    k \text{mod} n + v[k - 1], & 0 < k \leq s \\
    k \text{mod} n, & s < k \\
    \end{cases}
\end{align*}
\]

and, in order, increment \texttt{begin}[k + p] by \(r_1\), increment \texttt{begin}[k + q] by \(r_2\), and set \texttt{begin}[k] to \(r_2\).

c) Transform the elements of the range again, beginning where the previous step ended: iteratively for \(k = m, \ldots, m + n - 1\), calculate values

\[
\begin{align*}
    r_3 &= 1566083941 \cdot T(\text{begin}[k] + \text{begin}[k + p] + \text{begin}[k - 1]) \\
    r_4 &= r_3 - (k \text{mod} n)
\end{align*}
\]

and, in order, update \texttt{begin}[k + p] by xoring it with \(r_3\), update \texttt{begin}[k + q] by xoring it with \(r_4\), and set \texttt{begin}[k] to \(r_4\).

Throws: What and when \texttt{RandomAccessIterator} operations of \texttt{begin} and \texttt{end} throw.

\begin{verbatim}
size_t size() const noexcept;
\end{verbatim}

Returns: The number of 32-bit units that would be returned by a call to \texttt{param()}.

Complexity: Constant time.

\begin{verbatim}
template<class OutputIterator>
void param(OutputIterator dest) const;
\end{verbatim}

Requires: \texttt{OutputIterator} shall satisfy the \texttt{Cpp17OutputIterator} requirements (22.2.4). Moreover, the expression \*\texttt{dest} = \texttt{rt} shall be valid for a value \texttt{rt} of type \texttt{result\_type}.

Effects: Copies the sequence of prepared 32-bit units to the given destination, as if by executing the following statement:

\begin{verbatim}
copy(v.begin(), v.end(), dest);
\end{verbatim}

Throws: What and when \texttt{OutputIterator} operations of \texttt{dest} throw.
24.7.7.2 Function template generate_canonical

1 Each function instantiated from the template described in this subclause 24.7.7.2 maps the result of one or more invocations of a supplied uniform random bit generator g to one member of the specified RealType such that, if the values \(g_i\) produced by g are uniformly distributed, the instantiation’s results \(t_j, 0 \leq t_j < 1\), are distributed as uniformly as possible as specified below.

2 [Note: Obtaining a value in this way can be a useful step in the process of transforming a value generated by a uniform random bit generator into a value that can be delivered by a random number distribution. — end note]

```cpp
template<class RealType, size_t bits, class URBG>
RealType generate_canonical(URBG& g);
```

3 Complexity: Exactly \(k = \max(1, \lceil b/\log_2 R \rceil)\) invocations of \(g\), where \(b\) is the lesser of \text{numeric_limits<RealType>::digits} and \(bits\), and \(R\) is the value of \(g\).max() - g.min() + 1.

4 Effects: Invokes \(g()\) \(k\) times to obtain values \(g_0, \ldots, g_{k-1}\), respectively. Calculates a quantity

\[
S = \sum_{i=0}^{k-1} (g_i - g\text{.min()} \times R^i
\]

using arithmetic of type RealType.

5 Returns: \(S/R^k\).

6 Throws: What and when \(g\) throws.

24.7.8 Random number distribution class templates

24.7.8.1 In general

1 Each type instantiated from a class template specified in this subclause 24.7.8 satisfies the requirements of a random number distribution (24.7.2.6) type.

2 Descriptions are provided in this subclause 24.7.8 only for distribution operations that are not described in 24.7.2.6 or for operations where there is additional semantic information. In particular, declarations for copy constructors, for copy assignment operators, for streaming operators, and for equality and inequality operators are not shown in the synopses.

3 The algorithms for producing each of the specified distributions are implementation-defined.

4 The value of each probability density function \(p(z)\) and of each discrete probability function \(P(z_i)\) specified in this subclause is 0 everywhere outside its stated domain.

24.7.8.2 Uniform distributions

24.7.8.2.1 Class template uniform_int_distribution

1 A uniform_int_distribution random number distribution produces random integers \(i, a \leq i \leq b\), distributed according to the constant discrete probability function

\[
P(i | a, b) = 1/(b - a + 1).
\]

```cpp
template<class IntType = int>
class uniform_int_distribution {
public:
   // types
   using result_type = IntType;
   using param_type = unspecified;

   // constructors and reset functions
   uniform_int_distribution() : uniform_int_distribution(0) {}
   explicit uniform_int_distribution(IntType a, IntType b = numeric_limits<IntType>::max());
   explicit uniform_int_distribution(const param_type& parm);
   void reset();
};
```

252) \(b\) is introduced to avoid any attempt to produce more bits of randomness than can be held in RealType.
// generating functions
template<class URBG>
    result_type operator()(URBG& g);
template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

// property functions
result_type a() const;
result_type b() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;
};

explicit uniform_int_distribution(IntType a, IntType b = numeric_limits<IntType>::max());

Requires: a ≤ b.

Effects: Constructs a uniform_int_distribution object; a and b correspond to the respective parameters of the distribution.

result_type a() const;
Returns: The value of the a parameter with which the object was constructed.

result_type b() const;
Returns: The value of the b parameter with which the object was constructed.

24.7.8.2.2 Class template uniform_real_distribution [rand.dist.uni.real]
A uniform_real_distribution random number distribution produces random numbers x, a ≤ x < b, distributed according to the constant probability density function

\[ p(x | a, b) = \frac{1}{b - a} . \]

[Note: This implies that p(x | a, b) is undefined when a == b. —end note]

template<class RealType = double>
    class uniform_real_distribution {
        public:
            using result_type = RealType;
            using param_type = unspecified;

            // constructors and reset functions
            uniform_real_distribution() : uniform_real_distribution(0.0) {}
            explicit uniform_real_distribution(RealType a, RealType b = 1.0); explicit uniform_real_distribution(const param_type& parm);
            void reset();

            // generating functions
            template<class URBG>
                result_type operator()(URBG& g);
            template<class URBG>
                result_type operator()(URBG& g, const param_type& parm);

            // property functions
            result_type a() const;
            result_type b() const;
            param_type param() const;
            void param(const param_type& parm);
            result_type min() const;
            result_type max() const;
    };
explicit uniform_real_distribution(RealType a, RealType b = 1.0);

Requires: \( a \leq b \) and \( b - a \leq \text{numeric\_limits<RealType>::max()} \).

Effects: Constructs a uniform_real_distribution object; \( a \) and \( b \) correspond to the respective parameters of the distribution.

result_type a() const;

Returns: The value of the \( a \) parameter with which the object was constructed.

result_type b() const;

Returns: The value of the \( b \) parameter with which the object was constructed.

24.7.8.3 Bernoulli distributions

24.7.8.3.1 Class bernoulli_distribution

A bernoulli_distribution random number distribution produces bool values \( b \) distributed according to the discrete probability function

\[
P(b | p) = \begin{cases} 
  p & \text{if } b = \text{true}, \\
  1 - p & \text{if } b = \text{false}.
\end{cases}
\]

class bernoulli_distribution {
  public:
    // types
    using result_type = bool;
    using param_type = unspecified;

    // constructors and reset functions
    bernoulli_distribution() : bernoulli_distribution(0.5) {} // unspecified
    explicit bernoulli_distribution(double p);
    explicit bernoulli_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

    // property functions
    double p() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
  };

explicit bernoulli_distribution(double p);

Requires: \( 0 \leq p \leq 1 \).

Effects: Constructs a bernoulli_distribution object; \( p \) corresponds to the parameter of the distribution.

double p() const;

Returns: The value of the \( p \) parameter with which the object was constructed.

24.7.8.3.2 Class template binomial_distribution

A binomial_distribution random number distribution produces integer values \( i \geq 0 \) distributed according to the discrete probability function

\[
P(i | t, p) = \binom{t}{i} \cdot p^i \cdot (1 - p)^{t-i}.
\]
template<class IntType = int>
class binomial_distribution {
public:
    // types
    using result_type = IntType;
    using param_type = unspecified;

    // constructors and reset functions
    binomial_distribution() : binomial_distribution(1) {}
    explicit binomial_distribution(IntType t, double p = 0.5);
    explicit binomial_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

    // property functions
    IntType t() const;
    double p() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};

explicit binomial_distribution(IntType t, double p = 0.5);

Requires: 0 ≤ p ≤ 1 and 0 ≤ t.
Effects: Constructs a binomial_distribution object; t and p correspond to the respective parameters of the distribution.

IntType t() const;
Returns: The value of the t parameter with which the object was constructed.

double p() const;
Returns: The value of the p parameter with which the object was constructed.

24.7.8.3.3 Class template geometric_distribution
A geometric_distribution random number distribution produces integer values i ≥ 0 distributed according to the discrete probability function
\[ P(i \mid p) = p \cdot (1 - p)^i. \]
24.7.8.3.4 Class template negative_binomial_distribution

A negative_binomial_distribution random number distribution produces random integers \( i \geq 0 \) distributed according to the discrete probability function

\[
P(i \mid k, p) = \binom{k + i - 1}{i} \cdot p^k \cdot (1 - p)^i.
\]

[Note: This implies that \( P(i \mid k, p) \) is undefined when \( p = 1 \). —end note]

```cpp
template<class IntType = int>
class negative_binomial_distribution {
public:
    // types
    using result_type = IntType;
    using param_type = unspecified;

    // constructor and reset functions
    negative_binomial_distribution() : negative_binomial_distribution(1) {}
    explicit negative_binomial_distribution(IntType k, double p = 0.5);
    explicit negative_binomial_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

    // property functions
    IntType k() const;
    double p() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

explicit negative_binomial_distribution(IntType k, double p = 0.5);

Requires: \( 0 < p \leq 1 \) and \( 0 < k \).

Effects: Constructs a negative_binomial_distribution object; \( k \) and \( p \) correspond to the respective parameters of the distribution.

IntType k() const;

Returns: The value of the \( k \) parameter with which the object was constructed.
double p() const;

Returns: The value of the p parameter with which the object was constructed.

24.7.8.4 Poisson distributions

24.7.8.4.1 Class template poisson_distribution

A poisson_distribution random number distribution produces integer values \( i \geq 0 \) distributed according to the discrete probability function

\[
P(i | \mu) = \frac{e^{-\mu} \mu^i}{i!}.
\]

The distribution parameter \( \mu \) is also known as this distribution’s mean.

```cpp
// 24.7.8.4.2 969
```

template<class IntType = int>
    class poisson_distribution
{
  public:
    // types
    using result_type = IntType;
    using param_type = unspecified;
    // constructors and reset functions
    poisson_distribution() : poisson_distribution(1.0) {}
    explicit poisson_distribution(double mean);
    explicit poisson_distribution(const param_type& parm);
    void reset();
    // generating functions
    template<class URBG>
        result_type operator()(URBG& g);
    template<class URBG>
        result_type operator()(URBG& g, const param_type& parm);
    // property functions
    double mean() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};

explicit poisson_distribution(double mean);

Requires: \( 0 < \text{mean} \).

Effects: Constructs a poisson_distribution object; \text{mean} corresponds to the parameter of the distribution.

```cpp
double mean() const;

Returns: The value of the mean parameter with which the object was constructed.
```

24.7.8.4.2 Class template exponential_distribution

An exponential_distribution random number distribution produces random numbers \( x > 0 \) distributed according to the probability density function

\[
p(x | \lambda) = \lambda e^{-\lambda x}.
\]

```cpp
template<class RealType = double>
    class exponential_distribution {
  public:
    // types
    using result_type = RealType;
    using param_type = unspecified;
```
// constructors and reset functions
exponential_distribution() : exponential_distribution(1.0) {}
explicit exponential_distribution(RealType lambda);
explicit exponential_distribution(const param_type& parm);
void reset();

// generating functions
template<class URBG>
result_type operator()(URBG& g);
template<class URBG>
result_type operator()(URBG& g, const param_type& parm);

// property functions
RealType lambda() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;
};

explicit exponential_distribution(RealType lambda);

// Requires: 0 < lambda.
// Effects: Constructs an exponential_distribution object; lambda corresponds to the parameter of the distribution.
RealType lambda() const;

Returns: The value of the lambda parameter with which the object was constructed.

24.7.8.4.3 Class template gamma_distribution

A gamma_distribution random number distribution produces random numbers \( x > 0 \) distributed according to the probability density function

\[
p(x | \alpha, \beta) = \frac{e^{-x/\beta}}{\beta^\alpha \Gamma(\alpha)} \cdot x^{\alpha-1}.
\]

template<class RealType = double>
class gamma_distribution {
public:
    using result_type = RealType;
    using param_type = unspecified;

    // constructors and reset functions
gamma_distribution() : gamma_distribution(1.0) {}
exPLICIT gamma_distribution(RealType alpha, RealType beta = 1.0);
exPLICIT gamma_distribution(const param_type& parm);
void reset();

    // generating functions
template<class URBG>
result_type operator()(URBG& g);
template<class URBG>
result_type operator()(URBG& g, const param_type& parm);

    // property functions
RealType alpha() const;
RealType beta() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;
};

§ 24.7.8.4.3
explicit gamma_distribution(RealType alpha, RealType beta = 1.0);

2 Requires: 0 < alpha and 0 < beta.

3 Effects: Constructs a gamma_distribution object; alpha and beta correspond to the parameters of the distribution.

RealType alpha() const;

4 Returns: The value of the alpha parameter with which the object was constructed.

RealType beta() const;

5 Returns: The value of the beta parameter with which the object was constructed.

24.7.8.4.4 Class template weibull_distribution [rand.dist.poi.weibull]

A weibull_distribution random number distribution produces random numbers $x \geq 0$ distributed according to the probability density function

$$p(x \mid a, b) = \frac{a}{b} \left(\frac{x}{b}\right)^{a-1} \cdot \exp\left(-\left(\frac{x}{b}\right)^a\right).$$

```cpp
template<class RealType = double>
class weibull_distribution {
public:
  // types
  using result_type = RealType;
  using param_type = unspecified;

  // constructor and reset functions
  weibull_distribution() : weibull_distribution(1.0) {}
  explicit weibull_distribution(RealType a, RealType b = 1.0);
  explicit weibull_distribution(const param_type& parm);
  void reset();

  // generating functions
  template<class URBG>
  result_type operator()(URBG& g);
  template<class URBG>
  result_type operator()(URBG& g, const param_type& parm);

  // property functions
  RealType a() const;
  RealType b() const;
  param_type param() const;
  void param(const param_type& parm);
  result_type min() const;
  result_type max() const;
};
```

explicit weibull_distribution(RealType a, RealType b = 1.0);

2 Requires: 0 < a and 0 < b.

3 Effects: Constructs a weibull_distribution object; a and b correspond to the respective parameters of the distribution.

RealType a() const;

4 Returns: The value of the a parameter with which the object was constructed.

RealType b() const;

5 Returns: The value of the b parameter with which the object was constructed.
24.7.8.4.5 Class template extreme_value_distribution

An extreme_value_distribution random number distribution produces random numbers \( x \) distributed according to the probability density function:

\[
p(x \mid a, b) = \frac{1}{b} \exp \left( \frac{a - x}{b} - \exp \left( \frac{a - x}{b} \right) \right).
\]

```
template<class RealType = double>
class extreme_value_distribution {
  public:
    // types
    using result_type = RealType;
    using param_type = unspecified;

    // constructor and reset functions
    extreme_value_distribution() : extreme_value_distribution(0.0) {}  
    explicit extreme_value_distribution(RealType a, RealType b = 1.0);  
    explicit extreme_value_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

    // property functions
    RealType a() const;
    RealType b() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};
```

```
extreme_value_distribution(RealType a, RealType b = 1.0);
```

---

24.7.8.5 Normal distributions

24.7.8.5.1 Class template normal_distribution

A normal_distribution random number distribution produces random numbers \( x \) distributed according to the probability density function:

\[
p(x \mid \mu, \sigma) = \frac{1}{\sigma \sqrt{2\pi}} \exp \left( - \frac{(x - \mu)^2}{2\sigma^2} \right).
\]

The distribution parameters \( \mu \) and \( \sigma \) are also known as this distribution’s mean and standard deviation.

```
template<class RealType = double>
class normal_distribution {
  public:
    // types
    using result_type = RealType;

    // constructors
    normal_distribution();
    explicit normal_distribution(RealType mu, RealType sigma);
    explicit normal_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

    // property functions
    RealType mu() const;
    RealType sigma() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type mean() const;
    result_type stddev() const;
};
```

---

The distribution corresponding to this probability density function is also known (with a possible change of variable) as the Gumbel Type I, the log-Weibull, or the Fisher-Tippett Type I distribution.
using param_type = unspecified;

// constructors and reset functions
normal_distribution() : normal_distribution(0.0) {}
explicit normal_distribution(RealType mean, RealType stddev = 1.0);
explicit normal_distribution(const param_type& parm);
void reset();

// generating functions
template<class URBG>
result_type operator()(URBG& g);
template<class URBG>
result_type operator()(URBG& g, const param_type& parm);

// property functions
RealType mean() const;
RealType stddev() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;

explicit normal_distribution(RealType mean, RealType stddev = 1.0);

Requires: 0 < stddev.
Effects: Constructs a normal_distribution object; mean and stddev correspond to the respective parameters of the distribution.

RealType mean() const;
Returns: The value of the mean parameter with which the object was constructed.

RealType stddev() const;
Returns: The value of the stddev parameter with which the object was constructed.

24.7.8.5.2 Class template lognormal_distribution

A lognormal_distribution random number distribution produces random numbers \( x > 0 \) distributed according to the probability density function

\[
p(x \mid m, s) = \frac{1}{sx\sqrt{2\pi}} \cdot \exp\left(\frac{-(\ln x - m)^2}{2s^2}\right).
\]

template<class RealType = double>
class lognormal_distribution {
public:
    using result_type = RealType;
    using param_type = unspecified;

    // constructor and reset functions
    lognormal_distribution() : lognormal_distribution(0.0) {}
    explicit lognormal_distribution(RealType m, RealType s = 1.0);
    explicit lognormal_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);
// property functions
RealType m() const;
RealType s() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;
};

explicit lognormal_distribution(RealType m, RealType s = 1.0);

Requires: 0 < s.
Effects: Constructs a lognormal_distribution object; m and s correspond to the respective parameters of the distribution.

RealType m() const;
Returns: The value of the m parameter with which the object was constructed.

RealType s() const;
Returns: The value of the s parameter with which the object was constructed.

24.7.8.5.3 Class template chi_squared_distribution [rand.dist.norm.chisq]
A chi_squared_distribution random number distribution produces random numbers \( x > 0 \) distributed according to the probability density function
\[
p(x \mid n) = \frac{x^{(n/2)-1} \cdot e^{-x/2}}{\Gamma(n/2) \cdot 2^{n/2}}.
\]

template<class RealType = double>
class chi_squared_distribution {
public:
    // types
    using result_type = RealType;
    using param_type = unspecified;

    // constructor and reset functions
    chi_squared_distribution() : chi_squared_distribution(1) {} // default
    explicit chi_squared_distribution(RealType n);
    explicit chi_squared_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
    result_type operator()(URBG& g);
    template<class URBG>
    result_type operator()(URBG& g, const param_type& parm);

    // property functions
    RealType n() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};

explicit chi_squared_distribution(RealType n);

Requires: 0 < n.
Effects: Constructs a chi_squared_distribution object; n corresponds to the parameter of the distribution.

RealType n() const;
Returns: The value of the n parameter with which the object was constructed.
24.7.8.5.4 Class template cauchy_distribution

A `cauchy_distribution` random number distribution produces random numbers \( x \) distributed according to the probability density function

\[
p(x \mid a, b) = \left( \pi b \left( 1 + \left( \frac{x - a}{b} \right)^2 \right) \right)^{-1}.
\]

```cpp
template<class RealType = double>
class cauchy_distribution {
public:
  // types
  using result_type = RealType;
  using param_type = unspecified;

  // constructor and reset functions
  cauchy_distribution();
  cauchy_distribution(RealType a, RealType b = 1.0);
  explicit cauchy_distribution(const param_type& parm);
  void reset();

  // generating functions
  template<class URBG>
  result_type operator()(URBG& g);
  template<class URBG>
  result_type operator()(URBG& g, const param_type& parm);

  // property functions
  RealType a() const;
  RealType b() const;
  param_type param() const;
  void param(const param_type& parm);
  result_type min() const;
  result_type max() const;
};
```

### Requires: \( 0 < b \).

### Effects: Constructs a `cauchy_distribution` object; \( a \) and \( b \) correspond to the respective parameters of the distribution.

#### RealType a() const;

**Returns:** The value of the \( a \) parameter with which the object was constructed.

#### RealType b() const;

**Returns:** The value of the \( b \) parameter with which the object was constructed.

24.7.8.5.5 Class template fisher_f_distribution

A `fisher_f_distribution` random number distribution produces random numbers \( x \geq 0 \) distributed according to the probability density function

\[
p(x \mid m, n) = \frac{\Gamma((m + n)/2)}{\Gamma(m/2) \Gamma(n/2)} \cdot \left( \frac{m}{n} \right)^{m/2} \cdot x^{(m/2)-1} \cdot \left( 1 + \frac{mx}{n} \right)^{-(m+n)/2}.
\]

```cpp
template<class RealType = double>
class fisher_f_distribution {
public:
  // types
  using result_type = RealType;
  using param_type = unspecified;
```
// constructor and reset functions
fisher_f_distribution() : fisher_f_distribution(1) {}
explicit fisher_f_distribution(RealType m, RealType n = 1);
explicit fisher_f_distribution(const param_type& parm);
void reset();

// generating functions
template<class URBG>
result_type operator()(URBG& g);  
template<class URBG>
result_type operator()(URBG& g, const param_type& parm);

// property functions
RealType m() const;
RealType n() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;

explicit fisher_f_distribution(RealType m, RealType n = 1);

2  Requires: 0 < m and 0 < n.
3  Effects: Constructs a fisher_f_distribution object; m and n correspond to the respective parameters of the distribution.

RealType m() const;
4  Returns: The value of the m parameter with which the object was constructed.

RealType n() const;
5  Returns: The value of the n parameter with which the object was constructed.

24.7.8.5.6 Class template student_t_distribution

A student_t_distribution random number distribution produces random numbers x distributed according to the probability density function

\[ p(x|n) = \frac{1}{\sqrt{n\pi}} \frac{\Gamma((n+1)/2)}{\Gamma(n/2)} \cdot \left(1 + \frac{x^2}{n}\right)^{-(n+1)/2} \]

template<class RealType = double>
class student_t_distribution {
public:
  // types
using result_type = RealType;
using param_type = unspecified;

  // constructor and reset functions
student_t_distribution() : student_t_distribution(1) {}
explicit student_t_distribution(RealType n);
explicit student_t_distribution(const param_type& parm);
void reset();

  // generating functions
template<class URBG>
result_type operator()(URBG& g);  
template<class URBG>
result_type operator()(URBG& g, const param_type& parm);

  // property functions
RealType n() const;
param_type param() const;
void param(const param_type& parm);
explicit student_t_distribution(RealType n);

Requires: 0 < n.

Effects: Constructs a student_t_distribution object; n corresponds to the parameter of the distribution.

RealType n() const;

Returns: The value of the n parameter with which the object was constructed.

### 24.7.8.6 Sampling distributions

#### 24.7.8.6.1 Class template discrete_distribution

A discrete_distribution random number distribution produces random integers \( i, 0 \leq i < n \), distributed according to the discrete probability function

\[
P(i | p_0, \ldots, p_{n-1}) = p_i.
\]

Unless specified otherwise, the distribution parameters are calculated as: \( p_k = w_k / S \) for \( k = 0, \ldots, n - 1 \), in which the values \( w_k \), commonly known as the weights, shall be non-negative, non-NaN, and non-infinity. Moreover, the following relation shall hold: \( 0 < S = w_0 + \cdots + w_{n-1} \).

template<class IntType = int>
class discrete_distribution {
public:
    // types
    using result_type = IntType;
    using param_type = unspecified;

    // constructor and reset functions
    discrete_distribution();
    template<class InputIterator>
        discrete_distribution(InputIterator firstW, InputIterator lastW);
    discrete_distribution(initializer_list<double> w);
    template<class UnaryOperation>
        discrete_distribution(size_t nw, double xmin, double xmax, UnaryOperation fw);
    explicit discrete_distribution(const param_type& parm);
    void reset();

    // generating functions
    template<class URBG>
        result_type operator()(URBG& g);
    template<class URBG>
        result_type operator()(URBG& g, const param_type& parm);

    // property functions
    vector<double> probabilities() const;
    param_type param() const;
    void param(const param_type& parm);
    result_type min() const;
    result_type max() const;
};

Effects: Constructs a discrete_distribution object with \( n = 1 \) and \( p_0 = 1 \). [Note: Such an object will always deliver the value 0. — end note]

template<class InputIterator>
    discrete_distribution(InputIterator firstW, InputIterator lastW);

Requires: InputIterator shall satisfy the Cpp17InputIterator requirements (22.2.3). Moreover, iterator_traits<InputIterator>::value_type shall denote a type that is convertible to double.
If first\(W\) == last\(W\), let \(n = 1\) and \(w_0 = 1\). Otherwise, \([\text{first}W, \text{last}W)\) shall form a sequence \(w\) of length \(n > 0\).

**Effects:** Constructs a discrete_distribution object with probabilities given by the formula above.

discrete_distribution(initializer_list<double> \(wl\));

**Effects:** Same as discrete_distribution(wl.begin(), wl.end()).

```cpp
template<class UnaryOperation>
 discrete_distribution(size_t nw, double xmin, double xmax, UnaryOperation \(fw\));
```

**Requires:** Each instance of type **UnaryOperation** shall be a function object (19.14) whose return type shall be convertible to double. Moreover, double shall be convertible to the type of **UnaryOperation**’s sole parameter. If \(nw = 0\), let \(n = 1\), otherwise let \(n = nw\). The relation \(0 < \delta = (xmax - xmin)/n\) shall hold.

**Effects:** Constructs a discrete_distribution object with probabilities given by the formula above, using the following values: If \(nw = 0\), let \(w_0 = 1\). Otherwise, let \(w_k = fw(xmin + k \cdot \delta + \delta/2)\) for \(k = 0, \ldots, n - 1\).

**Complexity:** The number of invocations of \(fw\) shall not exceed \(n\).

```cpp
vector<double> probabilities() const;
```

**Returns:** A vector<double> whose size member returns \(n\) and whose operator[] member returns \(p_k\) when invoked with argument \(k\) for \(k = 0, \ldots, n - 1\).

### 24.7.8.6.2 Class template piecewise_constant_distribution

A piecewise_constant_distribution random number distribution produces random numbers \(x, b_0 \leq x < b_n\), uniformly distributed over each subinterval \([b_i, b_{i+1})\) according to the probability density function

\[
p(x | b_0, \ldots, b_n, \rho_0, \ldots, \rho_{n-1}) = \rho_i, \quad \text{for} \ b_i \leq x < b_{i+1}.
\]

The \(n + 1\) distribution parameters \(b_i\), also known as this distribution’s interval boundaries, shall satisfy the relation \(b_i < b_{i+1}\) for \(i = 0, \ldots, n - 1\). Unless specified otherwise, the remaining \(n\) distribution parameters are calculated as:

\[
\rho_k = \frac{w_k}{S - (b_{k+1} - b_k)} \quad \text{for} \ k = 0, \ldots, n - 1,
\]

in which the values \(w_k\), commonly known as the weights, shall be non-negative, non-NaN, and non-infinity. Moreover, the following relation shall hold: \(0 < S = w_0 + \cdots + w_{n-1}\).

```cpp
template<class RealType = double>
 class piecewise_constant_distribution {
 public:
     // types
     using result_type = RealType;
     using param_type = unspecified;

     // constructor and reset functions
     piecewise_constant_distribution();
     template<class InputIteratorB, class InputIteratorW>
     piecewise_constant_distribution(InputIteratorB firstB, InputIteratorB lastB,
                                     InputIteratorW firstW);
     template<class UnaryOperation>
     piecewise_constant_distribution(initializer_list<RealType> bl, UnaryOperation \(fw\));
     template<class UnaryOperation>
     piecewise_constant_distribution(size_t nw, RealType xmin, RealType xmax,
                                     UnaryOperation \(fw\));
     explicit piecewise_constant_distribution(const param_type& parm);
     void reset();

     // generating functions
     template<URBG>
     result_type operator()(URBG& g);
     template<URBG>
     result_type operator()(URBG& g, const param_type& parm);

§ 24.7.8.6.2
// property functions
vector<result_type> intervals() const;
vector<result_type> densities() const;
param_type param() const;
void param(const param_type& parm);
result_type min() const;
result_type max() const;

piecewise_constant_distribution();

Effects: Constructs a piecewise_constant_distribution object with n = 1, ρ0 = 1, b0 = 0, and b1 = 1.

template<class InputIteratorB, class InputIteratorW>

piecewise_constant_distribution(InputIteratorB firstB, InputIteratorB lastB,
InputIteratorW firstW);

Requires: InputIteratorB and InputIteratorW shall each satisfy the Cpp17InputIterator requirements (22.2.3). Moreover, iterator_traits<InputIteratorB>::value_type and iterator_traits<InputIteratorW>::value_type shall each denote a type that is convertible to double. If firstB == lastB or ++firstB == lastB, let n = 1, w0 = 1, b0 = 0, and b1 = 1. Otherwise, [firstB, lastB] shall form a sequence b of length n + 1, the length of the sequence w starting from firstW shall be at least n, and any wk for k ≥ n shall be ignored by the distribution.

Effects: Constructs a piecewise_constant_distribution object with parameters as specified above.

template<class UnaryOperation>

piecewise_constant_distribution(initializer_list<RealType> bl, UnaryOperation fw);

Requires: Each instance of type UnaryOperation shall be a function object (19.14) whose return type shall be convertible to double. Moreover, double shall be convertible to the type of UnaryOperation's sole parameter.

Effects: Constructs a piecewise_constant_distribution object with parameters taken or calculated from the following values: If bl.size() < 2, let n = 1, w0 = 1, b0 = 0, and b1 = 1. Otherwise, let [bl.begin(), bl.end()] form a sequence b0,...,bn, and let wk = fw((bk+1+bk)/2) for k = 0,...,n-1.

Complexity: The number of invocations of fw shall not exceed n.

template<class UnaryOperation>

piecewise_constant_distribution(size_t nw, RealType xmin, RealType xmax, UnaryOperation fw);

Requires: Each instance of type UnaryOperation shall be a function object (19.14) whose return type shall be convertible to double. Moreover, double shall be convertible to the type of UnaryOperation's sole parameter. If nw = 0, let n = 1, otherwise let n = nw. The relation 0 < δ = (xmax − xmin)/n shall hold.

Effects: Constructs a piecewise_constant_distribution object with parameters taken or calculated from the following values: Let bk = xmin + k·δ for k = 0,...,n, and wk = fw(bk+δ/2) for k = 0,...,n-1.

Complexity: The number of invocations of fw shall not exceed n.

vector<result_type> intervals() const;

Returns: A vector<result_type> whose size member returns n + 1 and whose operator[] member returns bk when invoked with argument k for k = 0,...,n.

vector<result_type> densities() const;

Returns: A vector<result_type> whose size member returns n and whose operator[] member returns ρk when invoked with argument k for k = 0,...,n − 1.

24.7.8.6.3 Class template piecewise_linear_distribution

A piecewise_linear_distribution random number distribution produces random numbers x, b0 ≤ x < b0, distributed over each subinterval [bi, bi+1) according to the probability density function

\[ p(x | b_0, \ldots, b_n, \rho_0, \ldots, \rho_n) = \rho_i \cdot \frac{b_{i+1} - x}{b_{i+1} - b_i} + \rho_{i+1} \cdot \frac{x - b_i}{b_{i+1} - b_i}, \text{ for } b_i \leq x < b_{i+1}. \]
The \( n + 1 \) distribution parameters \( b_i \), also known as this distribution’s \textit{interval boundaries}, shall satisfy the relation \( b_i < b_{i+1} \) for \( i = 0, \ldots, n - 1 \). Unless specified otherwise, the remaining \( n + 1 \) distribution parameters are calculated as \( \rho_k = w_k / S \) for \( k = 0, \ldots, n \), in which the values \( w_k \), commonly known as the \textit{weights at boundaries}, shall be non-negative, non-NaN, and non-infinity. Moreover, the following relation shall hold:

\[
0 < S = \frac{1}{2} \sum_{k=0}^{n-1} (w_k + w_{k+1}) \cdot (b_{k+1} - b_k).
\]

```
template<class RealType = double>
    class piecewise_linear_distribution {
    public:
        // types
        using result_type = RealType;
        using param_type = unspecified;

        // constructor and reset functions
        piecewise_linear_distribution();
        template<class InputIteratorB, class InputIteratorW>
            piecewise_linear_distribution(InputIteratorB firstB, InputIteratorB lastB,
                                            InputIteratorW firstW);
        template<class UnaryOperation>
            piecewise_linear_distribution(initializer_list<RealType> bl, UnaryOperation fw);
        template<class UnaryOperation>
            piecewise_linear_distribution(size_t nw, RealType xmin, RealType xmax,
                                            UnaryOperation fw);
        explicit piecewise_linear_distribution(const param_type& parm);
        void reset();

        // generating functions
        template<class URBG>
            result_type operator()(URBG& g);
        template<class URBG>
            result_type operator()(URBG& g, const param_type& parm);

        // property functions
        vector<result_type> intervals() const;
        vector<result_type> densities() const;
        param_type param() const;
        void param(const param_type& parm);
        result_type min() const;
        result_type max() const;
    };
```

\( \text{Effects:} \) Constructs a \texttt{piecewise_linear_distribution} object with \( n = 1 \), \( \rho_0 = \rho_1 = 1 \), \( b_0 = 0 \), and \( b_1 = 1 \).
template<class UnaryOperation>
    piecewise_linear_distribution(size_t nw, RealType xmin, RealType xmax, UnaryOperation fw);

Requires: Each instance of type UnaryOperation shall be a function object (19.14) whose return type shall be convertible to double. Moreover, double shall be convertible to the type of UnaryOperation’s sole parameter.

Effects: Constructs a piecewise_linear_distribution object with parameters taken or calculated from the following values: If nw = 0, let n = 1, otherwise let n = nw. The relation 0 < δ = (xmax − xmin)/n shall hold.

Complexity: The number of invocations of fw shall not exceed n + 1.

vector<result_type> intervals() const;

Returns: A vector<result_type> whose size member returns n + 1 and whose operator[] member returns bk when invoked with argument k for k = 0, ..., n.

vector<result_type> densities() const;

Returns: A vector<result_type> whose size member returns n and whose operator[] member returns ρk when invoked with argument k for k = 0, ..., n.

24.7.9  Low-quality random number generation [c.math.rand]

[Note: The header <cstdlib> (16.2.2) declares the functions described in this subclause. — end note]

int rand();
void srand(unsigned int seed);

Effects: The rand and srand functions have the semantics specified in the C standard library.

Remarks: The implementation may specify that particular library functions may call rand. It is implementation-defined whether the rand function may introduce data races (15.5.5.9). [Note: The other random number generation facilities in this document (24.7) are often preferable to rand, because rand’s underlying algorithm is unspecified. Use of rand therefore continues to be non-portable, with unpredictable and oft-questionable quality and performance. — end note]

template<class T> unspecified begin(valarray<T>& v);
template<class T> unspecified begin(const valarray<T>& v);
template<class T> unspecified end(valarray<T>& v);
template<class T> unspecified end(const valarray<T>& v);
}

1 The header `<valarray>` defines five class templates (`valarray`, `slice_array`, `gslice_array`, `mask_array`, and `indirect_array`), two classes (`slice` and `gslice`), and a series of related function templates for representing and manipulating arrays of values.

2 The `valarray` array classes are defined to be free of certain forms of aliasing, thus allowing operations on these classes to be optimized.

3 Any function returning a `valarray<T>` is permitted to return an object of another type, provided all the const member functions of `valarray<T>` are also applicable to this type. This return type shall not add more than two levels of template nesting over the most deeply nested argument type.

4 Implementations introducing such replacement types shall provide additional functions and operators as follows:

(4.1) — for every function taking a `const valarray<T>&` other than `begin` and `end (24.8.10)`, identical functions taking the replacement types shall be added;

(4.2) — for every function taking two `const valarray<T>&` arguments, identical functions taking every combination of `const valarray<T>&` and replacement types shall be added.

5 In particular, an implementation shall allow a `valarray<T>` to be constructed from such replacement types and shall allow assignments and compound assignments of such types to `valarray<T>`, `slice_array<T>`, `gslice_array<T>`, `mask_array<T>` and `indirect_array<T>` objects.

6 These library functions are permitted to throw a `bad_alloc (16.6.3.1)` exception if there are not sufficient resources available to carry out the operation. Note that the exception is not mandated.

### 24.8.2 Class template valarray [template.valarray]

#### 24.8.2.1 Class template valarray overview [template.valarray.overview]

```c++
namespace std {
    template<class T> class valarray {
        using value_type = T;

        // 24.8.2.2, construct/destroy
        valarray();
        explicit valarray(size_t);
        valarray(const T&, size_t);
        valarray(const T*, size_t);
        valarray(const valarray&);
        valarray(valarray&&) noexcept;
        valarray(const slice_array<T>&);
        valarray(const gslice_array<T>&);
        valarray(const mask_array<T>&);
        valarray(const indirect_array<T>&);
        valarray(initializer_list<T>);
        ~valarray();

        // 24.8.2.3, assignment
        valarray& operator=(const valarray&);
        valarray& operator=(valarray&&) noexcept;
        valarray& operator=(initializer_list<T>);
        valarray& operator=(const T&);
        valarray& operator=(const slice_array<T>&);
    }
}
```

---

254) Annex B recommends a minimum number of recursively nested template instantiations. This requirement thus indirectly suggests a minimum allowable complexity for valarray expressions.
valarray& operator=(const gslice_array<T>&);
valarray& operator=(const mask_array<T>&);
valarray& operator=(const indirect_array<T>&);

// 24.8.2.4, element access
const T& operator[](size_t) const;
T& operator[](size_t);

// 24.8.2.5, subset operations
valarray operator[](slice) const;

void swap(valarray&) noexcept;
size_t size() const;
T sum() const;
T min() const;
T max() const;
valarray shift (int) const;
valarray cshift(int) const;
valarray apply(T func(T)) const;
valarray apply(T func(const T&)) const;
void resize(size_t sz, T c = T());

§ 24.8.2.1
template<typename T, size_t cnt> valarray(const T(&)[cnt], size_t) -> valarray<T>;

1 The class template valarray<T> is a one-dimensional smart array, with elements numbered sequentially from zero. It is a representation of the mathematical concept of an ordered set of values. For convenience, an object of type valarray<T> is referred to as an “array” throughout the remainder of 24.8. The illusion of higher dimensionality may be produced by the familiar idiom of computed indices, together with the powerful subsetting capabilities provided by the generalized subscript operators.\textsuperscript{255}

24.8.2.2 valarray constructors [valarray.cons]

valarray();
\hspace{1em}1 Effects: Constructs a valarray that has zero length.\textsuperscript{256}

explicit valarray(size_t n);
\hspace{1em}2 Effects: Constructs a valarray that has length n. Each element of the array is value-initialized (9.3).

valarray(const T\& v, size_t n);
\hspace{1em}3 Effects: Constructs a valarray that has length n. Each element of the array is initialized with v.

valarray(const T* p, size_t n);
\hspace{1em}4 Requires: p points to an array (9.2.3.4) of at least n elements.
\hspace{1em}Effects: Constructs a valarray that has length n. The values of the elements of the array are initialized with the first n values pointed to by the first argument.\textsuperscript{257}

valarray(const valarray& v);
\hspace{1em}5 Effects: Constructs a valarray that has the same length as v. The elements are initialized with the values of the corresponding elements of v.\textsuperscript{258}

valarray(valarray&& v) noexcept;
\hspace{1em}6 Effects: Constructs a valarray that has the same length as v. The elements are initialized with the values of the corresponding elements of v.
\hspace{1em}Complexity: Constant.

valarray(initializer_list<T> il);
\hspace{1em}7 Effects: Equivalent to valarray(il.begin(), il.size()).

valarray(const slice_array<T>&);
valarray(const gslice_array<T>&);
valarray(const mask_array<T>&);
valarray(const indirect_array<T>&);
\hspace{1em}8 These conversion constructors convert one of the four reference templates to a valarray.

~valarray();
\hspace{1em}9 Effects: The destructor is applied to every element of *this; an implementation may return all allocated memory.

24.8.2.3 valarray assignment [valarray.assign]

valarray& operator=(const valarray& v);
\hspace{1em}1 Effects: Each element of the *this array is assigned the value of the corresponding element of v. If the length of v is not equal to the length of *this, resizes *this to make the two arrays the same length, as if by calling resize(v.size()), before performing the assignment.

\textsuperscript{255}The intent is to specify an array template that has the minimum functionality necessary to address aliasing ambiguities and the proliferation of temporary objects. Thus, the valarray template is neither a matrix class nor a field class. However, it is a very useful building block for designing such classes.

\textsuperscript{256}This default constructor is essential, since arrays of valarray may be useful. After initialization, the length of an empty array can be increased with the resize member function.

\textsuperscript{257}This constructor is the preferred method for converting a C array to a valarray object.

\textsuperscript{258}This copy constructor creates a distinct array rather than an alias. Implementations in which arrays share storage are permitted, but they would need to implement a copy-on-reference mechanism to ensure that arrays are conceptually distinct.
Ensures: size() == v.size().

Returns: *this.

valarray& operator=(valarray&& v) noexcept;

Effects: *this obtains the value of v. The value of v after the assignment is not specified.

Returns: *this.

Complexity: Linear.

valarray& operator=(initializer_list<T> il);

Effects: Equivalent to: return *this = valarray(il);

valarray& operator=(const T& v);

Effects: Assigns v to each element of *this.

Returns: *this.

valarray& operator=(const slice_array<T>&);
valarray& operator=(const gslice_array<T>&);
valarray& operator=(const mask_array<T>&);
valarray& operator=(const indirect_array<T>&);

Requires: The length of the array to which the argument refers equals size(). The value of an element in the left-hand side of a valarray assignment operator does not depend on the value of another element in that left-hand side.

These operators allow the results of a generalized subscripting operation to be assigned directly to a valarray.

24.8.2.4 valarray element access

const T& operator[](size_t n) const;
T& operator[](size_t n);

Requires: n < size().

Returns: A reference to the corresponding element of the array. [Note: The expression (a[i] = q, a[i]) == q evaluates to true for any non-constant valarray<T> a, any T q, and for any size_t i such that the value of i is less than the length of a. — end note]

Remarks: The expression &a[i+j] == &a[i] + j evaluates to true for all size_t i and size_t j such that i+j < a.size().

The expression &a[i] != &b[j] evaluates to true for any two arrays a and b and for any size_t i and size_t j such that i < a.size() and j < b.size(). [Note: This property indicates an absence of aliasing and may be used to advantage by optimizing compilers. Compilers may take advantage of inlining, constant propagation, loop fusion, tracking of pointers obtained from operator new, and other techniques to generate efficient valarrays. — end note]

The reference returned by the subscript operator for an array shall be valid until the member function resize(size_t, T) (24.8.2.8) is called for that array or until the lifetime of that array ends, whichever happens first.

24.8.2.5 valarray subset operations

valarray operator[](slice slicearr) const;

Returns: A valarray containing those elements of the controlled sequence designated by slicearr.

[Example:

const valarray<char> v0("abcdefghijkmnop", 16);]
slice_array<T> operator[](slice slicearr);

Returns: An object that holds references to elements of the controlled sequence selected by slicearr.

Example:
valarray<char> v0("abcdefgijklmnop", 16);
valarray<char> v1("ABCDE", 5);
v0[slice(2, 5, 3)] = v1;
// v0 == valarray<char>("abAdeBghCjkDmnEp", 16);

valarray operator[](const gslice& gslicearr) const;

Returns: A valarray containing those elements of the controlled sequence designated by gslicearr.

Example:
const valarray<char> v0("abcdefgijklmnop", 16);
const size_t lv[] = { 2, 3 };  // len(v0, 2)
const size_t dv[] = { 7, 2 };  // str(v0, 2)
const valarray<size_t> len(lv, 2), str(dv, 2);
v0[gslice(3, len, str)] = v1;
// v0 == valarray<char>("dfhkmo", 6)

valarray operator[](const valarray<bool>& boolarr) const;

Returns: A valarray containing those elements of the controlled sequence designated by boolarr.

Example:
const valarray<char> v0("abcdefgijklmnop", 16);
const bool vb[] = { false, false, true, true, false, true };
// v0[valarray<bool>(vb, 6)] = v1;
// v0 == valarray<char>("cdf", 3)

mask_array<T> operator[](const valarray<bool>& boolarr);

Returns: An object that holds references to elements of the controlled sequence selected by boolarr.

Example:
valarray<char> v0("abcdefgijklmnop", 16);
valarray<char> v1("ABC", 3);
const bool vb[] = { false, false, true, true, false, true };
v0[valarray<bool>(vb, 6)] = v1;
// v0 == valarray<char>("sbAbEgghijklmnop", 16)

valarray operator[](const valarray<size_t>& indarr) const;

Returns: A valarray containing those elements of the controlled sequence designated by indarr.

Example:
const valarray<char> v0("abcdefghijklmnop", 16);
const size_t vi[] = { 7, 5, 2, 3, 8 };
// v0[valarray<size_t>(vi, 5)] returns
// valarray<char>('hfcdi', 5)
— end example

indirect_array<T> operator[](const valarray<size_t>& indarr);

Returns: An object that holds references to elements of the controlled sequence selected by indarr.

[Example:
valarray<char> v0("abcdefghijklmnopqrstuvwxyz", 26);
valarray<char> v1("ABCDEFGHIJKLMNOPQRSTUVWXYZ", 26);
const size_t vi[] = { 7, 5, 2, 3, 8 };
v0[valarray<size_t>(vi, 5)] = v1;
// v0 == valarray<char>("abCDeBgAEjklmnop", 16)
— end example]

24.8.2.6 valarray unary operators

valarray operator+() const;
valarray operator-() const;
valarray operator~() const;
valarray<bool> operator!(const valarray& v) const;

1 Requires: Each of these operators may only be instantiated for a type T to which the indicated operator
can be applied and for which the indicated operator returns a value which is of type T (bool for
operator!) or which may be unambiguously implicitly converted to type T (bool for operator!).

2 Returns: A valarray whose length is size(). Each element of the returned array is initialized with
the result of applying the indicated operator to the corresponding element of the array.

24.8.2.7 valarray compound assignment

valarray& operator*= (const valarray& v);
valarray& operator/= (const valarray& v);
valarray& operator%= (const valarray& v);
valarray& operator+= (const valarray& v);
valarray& operator-= (const valarray& v);
valarray& operator^= (const valarray& v);
valarray& operator&= (const valarray& v);
valarray& operator|= (const valarray& v);
valarray& operator<<=(const valarray& v);
valarray& operator>>=(const valarray& v);

1 Requires: size() == v.size(). Each of these operators may only be instantiated for a type T if the
indicated operator can be applied to two operands of type T. The value of an element in the left-hand
side of a valarray compound assignment operator does not depend on the value of another element in
that left hand side.

2 Effects: Each of these operators performs the indicated operation on each of the elements of *this and
the corresponding element of v.

3 Returns: *this.

4 Remarks: The appearance of an array on the left-hand side of a compound assignment does not
invalidate references or pointers.

valarray& operator*= (const T& v);
valarray& operator/= (const T& v);
valarray& operator%= (const T& v);
valarray& operator+= (const T& v);
valarray& operator-= (const T& v);
valarray& operator^= (const T& v);
valarray& operator&= (const T& v);
valarray& operator|= (const T& v);
valarray& operator<<=(const T& v);
valarray& operator>>=(const T& v);
valarray& operator>>=(const T& v);

Requires: Each of these operators may only be instantiated for a type T if the indicated operator can be applied to two operands of type T.

Effects: Each of these operators applies the indicated operation to each element of *this and v.

Returns: *this

Remarks: The appearance of an array on the left-hand side of a compound assignment does not invalidate references or pointers to the elements of the array.

24.8.2.8 valarray member functions

void swap(valarray& v) noexcept;

Effects: *this obtains the value of v. v obtains the value of *this.

Complexity: Constant.

size_t size() const;

Returns: The number of elements in the array.

Complexity: Constant time.

T sum() const;

Requires: size() > 0. This function may only be instantiated for a type T to which operator+= can be applied.

Returns: The sum of all the elements of the array. If the array has length 1, returns the value of element 0. Otherwise, the returned value is calculated by applying operator+= to a copy of an element of the array and all other elements of the array in an unspecified order.

T min() const;

Requires: size() > 0

Returns: The minimum value contained in *this. For an array of length 1, the value of element 0 is returned. For all other array lengths, the determination is made using operator<.

T max() const;

Requires: size() > 0.

Returns: The maximum value contained in *this. For an array of length 1, the value of element 0 is returned. For all other array lengths, the determination is made using operator<.

valarray shift(int n) const;

Returns: A valarray of length size(), each of whose elements I is (*this)[I + n] if I + n is non-negative and less than size(), otherwise T(). [Note: If element zero is taken as the leftmost element, a positive value of n shifts the elements left n places, with zero fill. — end note]

[Example: If the argument has the value -2, the first two elements of the result will be value-initialized (9.3); the third element of the result will be assigned the value of the first element of the argument; etc. — end example]

valarray cshift(int n) const;

Returns: A valarray of length size() that is a circular shift of *this. If element zero is taken as the leftmost element, a non-negative value of n shifts the elements circularly left n places and a negative value of n shifts the elements circularly right −n places.

valarray apply(T func(T)) const;
valarray apply(T func(const T&)) const;

Returns: A valarray whose length is size(). Each element of the returned array is assigned the value returned by applying the argument function to the corresponding element of *this.
void resize(size_t sz, T c = T());

15 Effects: Changes the length of the *this array to sz and then assigns to each element the value of the second argument. Resizing invalidates all pointers and references to elements in the array.

24.8.3 valarray non-member operations

24.8.3.1 valarray binary operators

template<class T> valarray<T> operator* (const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T>& operator/ (const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T>& operator% (const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T>& operator+ (const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T>& operator- (const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T>& operator^ (const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T>& operator& (const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T>& operator| (const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T>& operator<<(const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T>& operator>>(const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T> operator>>(const typename valarray<T>::value_type&, const valarray<T>&);

3 Requires: Each of these operators may only be instantiated for a type T to which the indicated operator can be applied and for which the indicated operator returns a value which is of type T or which can be unambiguously implicitly converted to type T.

4 Returns: A valarray whose length is equal to the length of the array argument. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding element of the array argument and the non-array argument.

24.8.3.2 valarray logical operators

[valarray.comparison]

template<class T> valarray<bool> operator==(const valarray<T>&, const valarray<T>&);

template<class T> valarray<bool> operator!=(const valarray<T>&, const valarray<T>&);

template<class T> valarray<bool> operator<(const valarray<T>&, const valarray<T>&);

template<class T> valarray<bool> operator>(const valarray<T>&, const valarray<T>&);

template<class T> valarray<bool> operator<=(const valarray<T>&, const valarray<T>&);

template<class T> valarray<bool> operator>=(const valarray<T>&, const valarray<T>&);

template<class T> valarray<bool> operator&&(const valarray<T>&, const valarray<T>&);

template<class T> valarray<bool> operator||(const valarray<T>&, const valarray<T>&);

1 Requires: Each of these operators may only be instantiated for a type T to which the indicated operator can be applied and for which the indicated operator returns a value which is of type bool or which can be unambiguously implicitly converted to type bool. The two array arguments have the same length.

2 Returns: A valarray<bool> whose length is equal to the length of the array arguments. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding elements of the array arguments.

template<class T> valarray<bool> operator==(const valarray<T>&, const typename valarray<T>::value_type&);

template<class T> valarray<bool> operator==(const typename valarray<T>::value_type&, const valarray<T>&);

template<class T> valarray<bool> operator!=(const valarray<T>&, const typename valarray<T>::value_type&);

template<class T> valarray<bool> operator!=(const typename valarray<T>::value_type&, const valarray<T>&);

template<class T> valarray<bool> operator<(const valarray<T>&, const typename valarray<T>::value_type&);

template<class T> valarray<bool> operator<(const typename valarray<T>::value_type&, const valarray<T>&);

template<class T> valarray<bool> operator>(const valarray<T>&, const typename valarray<T>::value_type&);

template<class T> valarray<bool> operator>(const typename valarray<T>::value_type&, const valarray<T>&);

template<class T> valarray<bool> operator<=(const valarray<T>&, const typename valarray<T>::value_type&);

template<class T> valarray<bool> operator<=(const typename valarray<T>::value_type&, const valarray<T>&);

3 Requires: Each of these operators may only be instantiated for a type T to which the indicated operator can be applied and for which the indicated operator returns a value which is of type bool or which can be unambiguously implicitly converted to type bool.
Returns: A `valarray<bool>` whose length is equal to the length of the array argument. Each element of the returned array is initialized with the result of applying the indicated operator to the corresponding element of the array and the non-array argument.

### 24.8.3.3 valarray transcendental functions

```cpp
template<class T> valarray<T> abs (const valarray<T>&);
template<class T> valarray<T> acos (const valarray<T>&);
template<class T> valarray<T> asin (const valarray<T>&);
template<class T> valarray<T> atan (const valarray<T>&);
template<class T> valarray<T> atan2(const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> atan2(const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T> atan2(const typename valarray<T>::value_type&, const valarray<T>&);
template<class T> valarray<T> cos (const valarray<T>&);
template<class T> valarray<T> cosh (const valarray<T>&);
template<class T> valarray<T> exp (const valarray<T>&);
template<class T> valarray<T> log (const valarray<T>&);
template<class T> log10(const valarray<T>&);
template<class T> valarray<T> pow (const valarray<T>&, const valarray<T>&);
template<class T> valarray<T> pow (const valarray<T>&, const typename valarray<T>::value_type&);
template<class T> valarray<T> pow (const typename valarray<T>::value_type&, const valarray<T>&);
template<class T> valarray<T> sin (const valarray<T>&);
template<class T> sinh (const valarray<T>&);
template<class T> sqrt (const valarray<T>&);
template<class T> tan (const valarray<T>&);
template<class T> tanh (const valarray<T>&);
```

Requires: Each of these functions may only be instantiated for a type `T` to which a unique function with the indicated name can be applied (unqualified). This function shall return a value which is of type `T` or which can be unambiguously implicitly converted to type `T`.

### 24.8.3.4 valarray specialized algorithms

```cpp
template<class T> void swap(valarray<T>& x, valarray<T>& y) noexcept;
```

Effects: Equivalent to `x.swap(y)`.

### 24.8.4 Class slice

#### 24.8.4.1 Class slice overview

```cpp
namespace std {

class slice {

public:

    slice();
    slice(size_t_t start, size_t_t length, size_t_t stride);

    size_t_t start() const;
    size_t_t length() const;
    size_t_t stride() const;

};
}
```

The `slice` class represents a BLAS-like slice from an array. Such a slice is specified by a starting index, a length, and a stride.\(^{259}\)

#### 24.8.4.2 slice constructors

```cpp
slice();

slice(size_t_t start, size_t_t length, size_t_t stride);

slice(const slice&);
```

The default constructor is equivalent to `slice(0, 0, 0)`. A default constructor is provided only to permit the declaration of arrays of slices. The constructor with arguments for a slice takes a start, length, and stride parameter.

---

\(^{259}\) BLAS stands for Basic Linear Algebra Subprograms. C++ programs may instantiate this class. See, for example, Dongarra, Du Croz, Duff, and Hammarling: *A set of Level 3 Basic Linear Algebra Subprograms*; Technical Report MCS-P1-0888, Argonne National Laboratory (USA), Mathematics and Computer Science Division, August, 1988.

24.8.4.3 slice access functions

size_t start() const;
size_t size() const;
size_t stride() const;

1 Returns: The start, length, or stride specified by a slice object.
2 Complexity: Constant time.

24.8.5 Class template slice_array

24.8.5.1 Class template slice_array overview

namespace std {
    template<class T> class slice_array {
    public:
        using value_type = T;

        void operator= (const valarray<T>&) const;
        void operator*= (const valarray<T>&) const;
        void operator/= (const valarray<T>&) const;
        void operator%=(const valarray<T>&) const;
        void operator+=(const valarray<T>&) const;
        void operator-=(const valarray<T>&) const;
        void operator^=(const valarray<T>&) const;
        void operator&=(const valarray<T>&) const;
        void operator|=(const valarray<T>&) const;
        void operator<<=(const valarray<T>&) const;
        void operator>>=(const valarray<T>&) const;
        slice_array(const slice_array&);
        ~slice_array();
        const slice_array& operator=(const slice_array&) const;
        void operator=(const T&) const;
    slice_array() = delete; // as implied by declaring copy constructor above
    }
}

1 This template is a helper template used by the slice subscript operator

slice_array<T> valarray<T>::operator[] (slice);

2 It has reference semantics to a subset of an array specified by a slice object. [Example: The expression

a[slice(1, 5, 3)] = b; has the effect of assigning the elements of b to a slice of the elements in a. For

the slice shown, the elements selected from a are 1, 4, ..., 13. — end example]

24.8.5.2 slice_array assignment

void operator=(const valarray<T>&) const;
const slice_array& operator=(const slice_array&) const;

1 These assignment operators have reference semantics, assigning the values of the argument array

elements to selected elements of the valarray<T> object to which the slice_array object refers.

24.8.5.3 slice_array compound assignment

void operator=(const T&) const;
void operator+=(const valarray<T>&) const;
void operator-=(const valarray<T>&) const;
void operator^=(const valarray<T>&) const;
void operator&=(const valarray<T>&) const;
void operator|=(const valarray<T>&) const;
void operator<<=(const valarray<T>&) const;
void operator>>=(const valarray<T>&) const;

[Example: slice(3, 8, 2) constructs a slice which selects elements 3, 5, 7, ... 17 from an array.
—end example]
void operator<<=(const valarray<T>&) const;
void operator>>=(const valarray<T>&) const;

1 These compound assignments have reference semantics, applying the indicated operation to the elements of the argument array and selected elements of the valarray<T> object to which the slice_array object refers.

24.8.5.4 slice_array fill function

void operator=(const T&) const;

1 This function has reference semantics, assigning the value of its argument to the elements of the valarray<T> object to which the slice_array object refers.

24.8.6 The gslice class

24.8.6.1 The gslice class overview

namespace std {
  class gslice {
    public:
      gslice();
      gslice(size_t s, const valarray<size_t>& l, const valarray<size_t>& d);
      size_t start() const;
      valarray<size_t> size() const;
      valarray<size_t> stride() const;
  };
}

1 This class represents a generalized slice out of an array. A gslice is defined by a starting offset (s), a set of lengths (l_j), and a set of strides (d_j). The number of lengths shall equal the number of strides.

2 A gslice represents a mapping from a set of indices (i_j), equal in number to the number of strides, to a single index k. It is useful for building multidimensional array classes using the valarray template, which is one-dimensional. The set of one-dimensional index values specified by a gslice are

\[ k = s + \sum_{j} i_j d_j \]

where the multidimensional indices i_j range in value from 0 to l_{ij} - 1.

3 [Example: The gslice specification

\[
\begin{align*}
\text{start} &= 3 \\
\text{length} &= \{2, 4, 3\} \\
\text{stride} &= \{19, 4, 1\}
\end{align*}
\]

yields the sequence of one-dimensional indices

\[ k = 3 + (0, 1) \times 19 + (0, 1, 2, 3) \times 4 + (0, 1, 2) \times 1 \]

which are ordered as shown in the following table:

\[
\begin{align*}
(i_0, \quad i_1, \quad i_2, \quad k) &= \\
(0, \quad 0, \quad 0, \quad 3), & (0, \quad 0, \quad 1, \quad 4), & (0, \quad 0, \quad 2, \quad 5), & (0, \quad 1, \quad 0, \quad 7), & (0, \quad 1, \quad 1, \quad 8), & (0, \quad 1, \quad 2, \quad 9), & (0, \quad 2, \quad 0, \quad 11), & (0, \quad 2, \quad 1, \quad 12), & (0, \quad 2, \quad 2, \quad 13), & (0, \quad 3, \quad 0, \quad 15), & (0, \quad 3, \quad 1, \quad 16), & (0, \quad 3, \quad 2, \quad 17), & (1, \quad 0, \quad 0, \quad 22),
\end{align*}
\]
(1, 0, 1, 23),
... (1, 3, 2, 36)

That is, the highest-ordered index turns fastest. — end example

4 It is possible to have degenerate generalized slices in which an address is repeated.

5 [Example: If the stride parameters in the previous example are changed to \{1, 1, 1\}, the first few elements of the resulting sequence of indices will be

\[
(0, 0, 0, 3), \\
(0, 0, 1, 4), \\
(0, 0, 2, 5), \\
(0, 1, 0, 4), \\
(0, 1, 1, 5), \\
(0, 1, 2, 6), \\
...
\]

— end example]

6 If a degenerate slice is used as the argument to the non-const version of operator[](const gslice&), the behavior is undefined.

24.8.6.2 gslice constructors

[gslice.cons]

gslice();
gslice(size_t start, const valarray<size_t>& lengths, const valarray<size_t>& strides);
gslice(const gslice&);

1 The default constructor is equivalent to gslice(0, valarray<size_t>(), valarray<size_t>()).

2 The constructor with arguments builds a gslice based on a specification of start, lengths, and strides, as explained in the previous subclause.

24.8.6.3 gslice access functions

[gslice.access]

size_t start() const;
valarray<size_t> size() const;
valarray<size_t> stride() const;

1 Returns: The representation of the start, lengths, or strides specified for the gslice.

2 Complexity: start() is constant time. size() and stride() are linear in the number of strides.

24.8.7 Class template gslice_array

[template.gslice.array]

24.8.7.1 Class template gslice_array overview

[template.gslice.array.overview]

namespace std {

template<class T> class gslice_array {

public:

using value_type = T;

void operator= (const valarray<T>&) const;
void operator*= (const valarray<T>&) const;
void operator/= (const valarray<T>&) const;
void operator%= (const valarray<T>&) const;
void operator^= (const valarray<T>&) const;
void operator&= (const valarray<T>&) const;
void operator|= (const valarray<T>&) const;
void operator<<=(const valarray<T>&) const;
void operator>>=(const valarray<T>&) const;

§ 24.8.7.1 996
gslice_array(const gslice_array&);
-gslice_array();
const gslice_array& operator=(const gslice_array&)
const;
void operator=(const T&)
const;

gslice_array() = delete;  // as implied by declaring copy constructor above
};

1 This template is a helper template used by the gslice subscript operator
gslice_array<T> valarray<T>::operator[](const gslice);

2 It has reference semantics to a subset of an array specified by a gslice object. Thus, the expression
a[gslice(1, length, stride)] = b has the effect of assigning the elements of b to a generalized slice of
the elements in a.

24.8.7.2 gslice_array assignment [gslice.array.assign]

void operator=(const valarray<T>&) const;
const gslice_array& operator=(const gslice_array&)
const;

1 These assignment operators have reference semantics, assigning the values of the argument array
elements to selected elements of the valarray<T> object to which the gslice_array refers.

24.8.7.3 gslice_array compound assignment [gslice.array.comp.assign]

void operator== (const valarray<T>&) const;
void operator/= (const valarray<T>&) const;
void operator%= (const valarray<T>&) const;
void operator-= (const valarray<T>&) const;
void operator*= (const valarray<T>&) const;
void operator%= (const valarray<T>&) const;
void operator|= (const valarray<T>&) const;
void operator<<=(const valarray<T>&) const;
void operator>>=(const valarray<T>&) const;

1 These compound assignments have reference semantics, applying the indicated operation to the elements
of the argument array and selected elements of the valarray<T> object to which the gslice_array
object refers.

24.8.7.4 gslice_array fill function [gslice.array.fill]

void operator=(const T&)
const;

1 This function has reference semantics, assigning the value of its argument to the elements of the
valarray<T> object to which the gslice_array object refers.

24.8.8 Class template mask_array [template.mask.array]

24.8.8.1 Class template mask_array overview [template.mask.array.overview]

namespace std {

template<class T>
class mask_array {
public:

    using value_type = T;

    void operator== (const valarray<T>&) const;
    void operator/= (const valarray<T>&) const;
    void operator%= (const valarray<T>&) const;
    void operator-= (const valarray<T>&) const;
    void operator*= (const valarray<T>&) const;
    void operator%= (const valarray<T>&) const;
    void operator|= (const valarray<T>&) const;
    void operator<<=(const valarray<T>&) const;
    void operator>>=(const valarray<T>&) const;

§ 24.8.8.1 997
mask_array(const mask_array&);
~mask_array();
const mask_array& operator=(const mask_array&) const;
void operator=(const T&) const;
mask_array() = delete; // as implied by declaring copy constructor above
};

This template is a helper template used by the mask subscript operator:

```
mask_array<T> valarray<T>::operator[] (const valarray<bool>&).
```

It has reference semantics to a subset of an array specified by a boolean mask. Thus, the expression `a[mask] = b;` has the effect of assigning the elements of `b` to the masked elements in `a` (those for which the corresponding element in `mask` is `true`.)

### 24.8.8.2 `mask_array` assignment

```
void operator=(const valarray<T>&) const;
const mask_array& operator=(const mask_array&) const;
```

These assignment operators have reference semantics, assigning the values of the argument array elements to selected elements of the `valarray<T>` object to which it refers.

### 24.8.8.3 `mask_array` compound assignment

```
void operator*= (const valarray<T>&) const;
void operator/= (const valarray<T>&) const;
void operator%= (const valarray<T>&) const;
void operator+= (const valarray<T>&) const;
void operator-= (const valarray<T>&) const;
void operator^= (const valarray<T>&) const;
void operator&= (const valarray<T>&) const;
void operator|= (const valarray<T>&) const;
void operator<<=(const valarray<T>&) const;
void operator>>=(const valarray<T>&) const;
```

These compound assignments have reference semantics, applying the indicated operation to the elements of the argument array and selected elements of the `valarray<T>` object to which the mask object refers.

### 24.8.8.4 `mask_array` fill function

```
void operator=(const T&) const;
```

This function has reference semantics, assigning the value of its argument to the elements of the `valarray<T>` object to which the `mask_array` object refers.

### 24.8.9 Class template `indirect_array`

#### 24.8.9.1 Class template `indirect_array` overview

```
namespace std {
  template<class T> class indirect_array {
    public:
      using value_type = T;
      ...
    void operator= (const valarray<T>&) const;
    void operator+= (const valarray<T>&) const;
    void operator-= (const valarray<T>&) const;
    void operator^= (const valarray<T>&) const;
    void operator&= (const valarray<T>&) const;
    void operator|= (const valarray<T>&) const;
    void operator<<= (const valarray<T>&) const;
    void operator>>= (const valarray<T>&) const;
  }
}
```

§ 24.8.9.1 998
This template is a helper template used by the indirect subscript operator

```cpp
indirect_array<T> valarray<T>::operator[] (const valarray<size_t>&).
```

It has reference semantics to a subset of an array specified by an `indirect_array`. Thus, the expression `a[indirect] = b;` has the effect of assigning the elements of `b` to the elements in `a` whose indices appear in `indirect`.

### 24.8.9.2 `indirect_array` assignment

```cpp
void operator=(const valarray<T>&) const;
const indirect_array& operator=(const indirect_array&) const;
```

These assignment operators have reference semantics, assigning the values of the argument array elements to selected elements of the `valarray<T>` object to which it refers.

1. If the `indirect_array` specifies an element in the `valarray<T>` object to which it refers more than once, the behavior is undefined.

**Example:**
```cpp
int addr[] = {2, 3, 1, 4, 4};
valarray<size_t> indirect(addr, 5);
valarray<double> a(0., 10), b(1., 5);
a[indirect] = b;
```

results in undefined behavior since element 4 is specified twice in the indirection. — end example]

### 24.8.9.3 `indirect_array` compound assignment

```cpp
void operator*= (const valarray<T>&) const;
void operator/= (const valarray<T>&) const;
void operator%= (const valarray<T>&) const;
void operator+= (const valarray<T>&) const;
void operator-= (const valarray<T>&) const;
void operator^= (const valarray<T>&) const;
void operator&= (const valarray<T>&) const;
void operator|= (const valarray<T>&) const;
void operator<<=(const valarray<T>&) const;
void operator>>=(const valarray<T>&) const;
```

1. These compound assignments have reference semantics, applying the indicated operation to the elements of the argument array and selected elements of the `valarray<T>` object to which the `indirect_array` object refers.

2. If the `indirect_array` specifies an element in the `valarray<T>` object to which it refers more than once, the behavior is undefined.

### 24.8.9.4 `indirect_array` fill function

```cpp
void operator=(const T&) const;
```

1. This function has reference semantics, assigning the value of its argument to the elements of the `valarray<T>` object to which the `indirect_array` object refers.

### 24.8.10 `valarray` range access

1. In the `begin` and `end` function templates that follow, `unspecified1` is a type that meets the requirements of a mutable random access iterator (22.2.7) and of a contiguous iterator (22.2.1) whose `value_type` is the template parameter `T` and whose `reference` type is `T&`. `unspecified2` is a type that meets the requirements...
of a constant random access iterator (22.2.7) and of a contiguous iterator (22.2.1) whose \texttt{value\_type} is the template parameter \texttt{T} and whose \texttt{reference} type is \texttt{const T\&}.

The iterators returned by \texttt{begin} and \texttt{end} for an array are guaranteed to be valid until the member function \texttt{resize(size\_t, T)} (24.8.2.8) is called for that array or until the lifetime of that array ends, whichever happens first.

\begin{verbatim}
template<class T> unspecified1 begin(valarray<T>& v);
template<class T> unspecified2 begin(const valarray<T>& v);

Returns: An iterator referencing the first value in the array.
\end{verbatim}

\begin{verbatim}
template<class T> unspecified1 end(valarray<T>& v);
template<class T> unspecified2 end(const valarray<T>& v);

Returns: An iterator referencing one past the last value in the array.
\end{verbatim}

### 24.9 Mathematical functions for floating-point types

#### 24.9.1 Header \texttt{<cmath>} synopsis

```cpp
namespace std {
  using float_t = see below;
  using double_t = see below;
}

#define HUGE_VAL see below
#define HUGE_VALF see below
#define HUGE_VALL see below
#define INFINITY see below

double ellint_3(double k, double nu, double phi);
float ellint_3f(float k, float nu, float phi);
The contents and meaning of the header `<cmath>` are the same as the C standard library header `<math.h>`, with the addition of a three-dimensional hypotenuse function (24.9.3) and the mathematical special functions described in 24.9.5. [Note: Several functions have additional overloads in this document, but they have the same behavior as in the C standard library (15.2). — end note]

For each set of overloaded functions within `<cmath>`, with the exception of `abs`, there shall be additional overloads sufficient to ensure:

1. If any argument of arithmetic type corresponding to a `double` parameter has type `long double`, then all arguments of arithmetic type (6.7.1) corresponding to `double` parameters are effectively cast to `long double`.
2. Otherwise, if any argument of arithmetic type corresponding to a `double` parameter has type `double` or an integer type, then all arguments of arithmetic type corresponding to `double` parameters are effectively cast to `double`.
3. Otherwise, all arguments of arithmetic type corresponding to `double` parameters have type `float`.

[Note: `abs` is exempted from these rules in order to stay compatible with C. — end note]

---

```
long double ellint_3l(long double k, long double nu, long double phi);

// 24.9.5.14, exponential integral
double expint(double x);
float expintf(float x);
long double expintl(long double x);

// 24.9.5.15, Hermite polynomials
double hermite(unsigned n, double x);
float hermitef(unsigned n, float x);
long double hermitel(unsigned n, long double x);

// 24.9.5.16, Laguerre polynomials
double laguerre(unsigned n, double x);
float laguerref(unsigned n, float x);
long double laguerrel(unsigned n, long double x);

// 24.9.5.17, Legendre polynomials
double legendre(unsigned l, double x);
float legendref(unsigned l, float x);
long double legendrel(unsigned l, long double x);

// 24.9.5.18, Riemann zeta function
double riemann_zeta(double x);
float riemann_zetaf(float x);
long double riemann_zetal(long double x);

// 24.9.5.19, spherical Bessel functions of the first kind
double sph_bessel(unsigned n, double x);
float sph_besself(unsigned n, float x);
long double sph_bessell(unsigned n, long double x);

// 24.9.5.20, spherical associated Legendre functions
double sph_legendre(unsigned l, unsigned m, double theta);
float sph_legendref(unsigned l, unsigned m, float theta);
long double sph_legendrel(unsigned l, unsigned m, long double theta);

// 24.9.5.21, spherical Neumann functions;
// spherical Bessel functions of the second kind
double sph_neumann(unsigned n, double x);
float sph_neumannf(unsigned n, float x);
long double sph_neumannl(unsigned n, long double x);
```
24.9.2 Absolute values

\[ \text{abs}(j) \]
\[ \text{long abs}(\text{long } j) \]
\[ \text{long long abs}(\text{long long } j) \]
\[ \text{float abs}(\text{float } j) \]
\[ \text{double abs}(\text{double } j) \]
\[ \text{long double abs}(\text{long double } j) \]

1 Note: The headers `<cstdlib>` (16.2.2) and `<cmath>` (24.9.1) declare the functions described in this subclause.

2 Effects: The abs functions have the semantics specified in the C standard library for the functions abs, labs, llabs, fabsl, fabsf, and fabsd.

3 Remarks: If abs() is called with an argument of type X for which is_unsigned_v<X> is true and if X cannot be converted to int by integral promotion (7.3.6), the program is ill-formed. [Note: Arguments that can be promoted to int are permitted for compatibility with C. —end note]

See also: ISO C 7.12.7.2, 7.22.6.1

24.9.3 Three-dimensional hypotenuse

\[ \text{hypot}(x, y, z) \]
\[ \text{double hypot}(\text{double } x, \text{double } y, \text{double } z) \]
\[ \text{long double hypot}(\text{long double } x, \text{long double } y, \text{long double } z) \]

1 Returns: \( \sqrt{x^2 + y^2 + z^2} \).

24.9.4 Classification / comparison functions

24.9.5 Mathematical special functions

If any argument value to any of the functions specified in this subclause is a NaN (Not a Number), the function shall return a NaN but it shall not report a domain error. Otherwise, the function shall report a domain error for just those argument values for which:

1.1 the function description’s Returns: clause explicitly specifies a domain and those argument values fall outside the specified domain, or

1.2 the corresponding mathematical function value has a nonzero imaginary component, or

1.3 the corresponding mathematical function is not mathematically defined.\(^{260}\)

2 Unless otherwise specified, each function is defined for all finite values, for negative infinity, and for positive infinity.

24.9.5.1 Associated Laguerre polynomials

\[ \text{assoc_laguerre}(n, m, x) \]
\[ \text{assoc_laguerref}(n, m, x) \]
\[ \text{assoc_laguerrel}(n, m, x) \]

1 Effects: These functions compute the associated Laguerre polynomials of their respective arguments n, m, and x.

2 Returns:
\[ L^m_n(x) = (-1)^m \frac{d^m}{dx^m} L_{n+m}(x), \quad \text{for } x \geq 0, \]

where \( n \) is n, \( m \) is m, and \( x \) is x.

3 Remarks: The effect of calling each of these functions is implementation-defined if \( n \geq 128 \) or if \( m \geq 128 \).

\(^{260}\) A mathematical function is mathematically defined for a given set of argument values (a) if it is explicitly defined for that set of argument values, or (b) if its limiting value exists and does not depend on the direction of approach.
24.9.5.2 Associated Legendre functions [sf.cmath.assoc_legendre]

\begin{verbatim}
double assoc_legendre(unsigned l, unsigned m, double x);
float assoc_legendref(unsigned l, unsigned m, float x);
long double assoc_legendrel(unsigned l, unsigned m, long double x);
\end{verbatim}

1 Effects: These functions compute the associated Legendre functions of their respective arguments \( l, m, \) and \( x. \)

2 Returns:

\[ P^m_\ell(x) = (1 - x^2)^{m/2} \frac{d^m}{dx^m} P_\ell(x), \quad \text{for } |x| \leq 1, \]

where \( l \) is \( l, \) \( m \) is \( m, \) and \( x \) is \( x. \)

3 Remarks: The effect of calling each of these functions is implementation-defined if \( l \geq 128. \)

24.9.5.3 Beta function [sf.cmath.beta]

\begin{verbatim}
double beta(double x, double y);
float betaf(float x, float y);
long double betal(long double x, long double y);
\end{verbatim}

1 Effects: These functions compute the beta function of their respective arguments \( x \) and \( y. \)

2 Returns:

\[ B(x,y) = \frac{\Gamma(x)\Gamma(y)}{\Gamma(x+y)}, \quad \text{for } x > 0, y > 0, \]

where \( x \) is \( x \) and \( y \) is \( y. \)

24.9.5.4 Complete elliptic integral of the first kind [sf.cmath.comp_ellint_1]

\begin{verbatim}
double comp_ellint_1(double k);
float comp_ellint_1f(float k);
long double comp_ellint_1l(long double k);
\end{verbatim}

1 Effects: These functions compute the complete elliptic integral of the first kind of their respective arguments \( k. \)

2 Returns:

\[ K(k) = F(k,\pi/2), \quad \text{for } |k| \leq 1, \]

where \( k \) is \( k. \)

3 See also 24.9.5.11.

24.9.5.5 Complete elliptic integral of the second kind [sf.cmath.comp_ellint_2]

\begin{verbatim}
double comp_ellint_2(double k);
float comp_ellint_2f(float k);
long double comp_ellint_2l(long double k);
\end{verbatim}

1 Effects: These functions compute the complete elliptic integral of the second kind of their respective arguments \( k. \)

2 Returns:

\[ E(k) = E(k,\pi/2), \quad \text{for } |k| \leq 1, \]

where \( k \) is \( k. \)

3 See also 24.9.5.12.

24.9.5.6 Complete elliptic integral of the third kind [sf.cmath.comp_ellint_3]

\begin{verbatim}
double comp_ellint_3(double k, double nu);
float comp_ellint_3f(float k, float nu);
long double comp_ellint_3l(long double k, long double nu);
\end{verbatim}

1 Effects: These functions compute the complete elliptic integral of the third kind of their respective arguments \( k \) and \( nu. \)

2 Returns:

\[ \Pi(\nu,k) = \Pi(\nu,k,\pi/2), \quad \text{for } |k| \leq 1, \]
where $k$ is $k$ and $\nu$ is $\text{nu}$.

See also 24.9.13.

### 24.9.5.7 Regular modified cylindrical Bessel functions

```c
double cyl_bessel_i(double nu, double x);
float cyl_bessel_if(float nu, float x);
long double cyl_bessel_il(long double nu, long double x);
```

1. **Effects:** These functions compute the regular modified cylindrical Bessel functions of their respective arguments $\nu$ and $x$.

2. **Returns:**

$$I_{\nu}(x) = i^{-\nu}J_{\nu}(ix) = \sum_{k=0}^{\infty} \frac{(x/2)^{\nu+2k}}{k! \Gamma(\nu + k + 1)}, \text{ for } x \geq 0,$$

where $\nu$ is $\text{nu}$ and $x$ is $x$.

3. **Remarks:** The effect of calling each of these functions is implementation-defined if $\nu \geq 128$.

### 24.9.5.8 Cylindrical Bessel functions of the first kind

```c
double cyl_bessel_j(double nu, double x);
float cyl_bessel_jf(float nu, float x);
long double cyl_bessel_jl(long double nu, long double x);
```

1. **Effects:** These functions compute the cylindrical Bessel functions of the first kind of their respective arguments $\nu$ and $x$.

2. **Returns:**

$$J_{\nu}(x) = \sum_{k=0}^{\infty} \frac{(-1)^k(x/2)^{\nu+2k}}{k! \Gamma(\nu + k + 1)}, \text{ for } x \geq 0,$$

where $\nu$ is $\text{nu}$ and $x$ is $x$.

3. **Remarks:** The effect of calling each of these functions is implementation-defined if $\nu \geq 128$.

### 24.9.5.9 Irregular modified cylindrical Bessel functions

```c
double cyl_bessel_k(double nu, double x);
float cyl_bessel_kf(float nu, float x);
long double cyl_bessel_kl(long double nu, long double x);
```

1. **Effects:** These functions compute the irregular modified cylindrical Bessel functions of their respective arguments $\nu$ and $x$.

2. **Returns:**

$$K_{\nu}(x) = (\pi/2)i^{\nu+1}(J_{\nu}(ix) + iN_{\nu}(ix)) = \begin{cases} \pi I_{\nu}(x) - L_{\nu}(x) & \text{for } x \geq 0 \text{ and non-integral } \nu \\
\pi \lim_{\mu \to \nu} \frac{1 - L_{\nu}(x)}{\mu \sin \pi \mu} & \text{for } x \geq 0 \text{ and integral } \nu \end{cases},$$

where $\nu$ is $\text{nu}$ and $x$ is $x$.

3. **Remarks:** The effect of calling each of these functions is implementation-defined if $\nu \geq 128$.

See also 24.9.5.7, 24.9.5.8, 24.9.5.10.

### 24.9.5.10 Cylindrical Neumann functions

```c
double cyl_neumann(double nu, double x);
float cyl_neumannf(float nu, float x);
long double cyl_neumannl(long double nu, long double x);
```

1. **Effects:** These functions compute the cylindrical Neumann functions, also known as the cylindrical Bessel functions of the second kind, of their respective arguments $\nu$ and $x$. 

§ 24.9.5.10
Returns:
\[ N_\nu(x) = \begin{cases} 
\frac{J_\nu(x) \cos \nu \pi - J_{-\nu}(x)}{\sin \nu \pi} & \text{for } x \geq 0 \text{ and non-integral } \nu \\
\lim_{\mu \to \nu} \frac{J_\mu(x) \cos \mu \pi - J_{-\mu}(x)}{\sin \mu \pi} & \text{for } x \geq 0 \text{ and integral } \nu
\end{cases} \]

where \( \nu \) is \( \nu \) and \( x \) is \( x \).

Remarks: The effect of calling each of these functions is implementation-defined if \( \nu \geq 128 \).

See also 24.9.5.8.

### 24.9.5.11 Incomplete elliptic integral of the first kind

\[ \text{double} \quad \text{ellint}_1(\text{double } k, \text{double } \phi); \]
\[ \text{float} \quad \text{ellint}_1f(\text{float } k, \text{float } \phi); \]
\[ \text{long double} \quad \text{ellint}_1l(\text{long double } k, \text{long double } \phi); \]

Effects: These functions compute the incomplete elliptic integral of the first kind of their respective arguments \( k \) and \( \phi \) (\( \phi \) measured in radians).

Returns:
\[ F(k, \phi) = \int_0^\phi \frac{d\theta}{\sqrt{1 - k^2 \sin^2 \theta}}, \text{ for } |k| \leq 1, \]

where \( k \) is \( k \) and \( \phi \) is \( \phi \).

### 24.9.5.12 Incomplete elliptic integral of the second kind

\[ \text{double} \quad \text{ellint}_2(\text{double } k, \text{double } \phi); \]
\[ \text{float} \quad \text{ellint}_2f(\text{float } k, \text{float } \phi); \]
\[ \text{long double} \quad \text{ellint}_2l(\text{long double } k, \text{long double } \phi); \]

Effects: These functions compute the incomplete elliptic integral of the second kind of their respective arguments \( k \) and \( \phi \) (\( \phi \) measured in radians).

Returns:
\[ E(k, \phi) = \int_0^\phi \sqrt{1 - k^2 \sin^2 \theta} \, d\theta, \text{ for } |k| \leq 1, \]

where \( k \) is \( k \) and \( \phi \) is \( \phi \).

### 24.9.5.13 Incomplete elliptic integral of the third kind

\[ \text{double} \quad \text{ellint}_3(\text{double } k, \text{double } \nu, \text{double } \phi); \]
\[ \text{float} \quad \text{ellint}_3f(\text{float } k, \text{float } \nu, \text{float } \phi); \]
\[ \text{long double} \quad \text{ellint}_3l(\text{long double } k, \text{long double } \nu, \text{long double } \phi); \]

Effects: These functions compute the incomplete elliptic integral of the third kind of their respective arguments \( k, \nu, \) and \( \phi \) (\( \phi \) measured in radians).

Returns:
\[ \Pi(\nu, k, \phi) = \int_0^\phi \frac{d\theta}{(1 - \nu \sin^2 \theta)\sqrt{1 - k^2 \sin^2 \theta}}, \text{ for } |k| \leq 1, \]

where \( \nu \) is \( \nu \), \( k \) is \( k \), and \( \phi \) is \( \phi \).

### 24.9.5.14 Exponential integral

\[ \text{double} \quad \text{expint}(\text{double } x); \]
\[ \text{float} \quad \text{expintf}(\text{float } x); \]
\[ \text{long double} \quad \text{expintl}(\text{long double } x); \]

Effects: These functions compute the exponential integral of their respective arguments \( x \).

Returns:
\[ \text{Ei}(x) = -\int_{-x}^{\infty} \frac{e^{-t}}{t} \, dt \]

where \( x \) is \( x \).
24.9.5.15 Hermite polynomials

\texttt{double hermite(unsigned n, double x);}  
\texttt{float hermitef(unsigned n, float x);}  
\texttt{long double hermitel(unsigned n, long double x);}  

\begin{enumerate}
\item **Effects:** These functions compute the Hermite polynomials of their respective arguments \(n\) and \(x\).
\item **Returns:**  
\[ H_n(x) = (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2} \]
where \(n\) is \(n\) and \(x\) is \(x\).
\item **Remarks:** The effect of calling each of these functions is implementation-defined if \(n \geq 128\).
\end{enumerate}

24.9.5.16 Laguerre polynomials

\texttt{double laguerre(unsigned n, double x);}  
\texttt{float laguerref(unsigned n, float x);}  
\texttt{long double laguerrel(unsigned n, long double x);}  

\begin{enumerate}
\item **Effects:** These functions compute the Laguerre polynomials of their respective arguments \(n\) and \(x\).
\item **Returns:**  
\[ L_n(x) = e^x \frac{n!}{n^n} \frac{d^n}{dx^n} (x^n e^{-x}) \], for \(x \geq 0\),
where \(n\) is \(n\) and \(x\) is \(x\).
\item **Remarks:** The effect of calling each of these functions is implementation-defined if \(n \geq 128\).
\end{enumerate}

24.9.5.17 Legendre polynomials

\texttt{double legendre(unsigned l, double x);}  
\texttt{float legendref(unsigned l, float x);}  
\texttt{long double legendrel(unsigned l, long double x);}  

\begin{enumerate}
\item **Effects:** These functions compute the Legendre polynomials of their respective arguments \(l\) and \(x\).
\item **Returns:**  
\[ P_l(x) = \frac{1}{2^l l!} \frac{d^l}{dx^l} (x^2 - 1)^l \], for \(|x| \leq 1\),
where \(l\) is \(l\) and \(x\) is \(x\).
\item **Remarks:** The effect of calling each of these functions is implementation-defined if \(l \geq 128\).
\end{enumerate}

24.9.5.18 Riemann zeta function

\texttt{double \texttt{riemann\_zeta(double x);}}  
\texttt{float \texttt{riemann\_zetaf(float x);}}  
\texttt{long double \texttt{riemann\_zetal(long double x);}}  

\begin{enumerate}
\item **Effects:** These functions compute the Riemann zeta function of their respective arguments \(x\).
\item **Returns:**  
\[ \zeta(x) = \begin{cases} 
\sum_{k=1}^{\infty} k^{-x}, & \text{for } x > 1 \\
\frac{1}{1 - 2^{1-x}} \sum_{k=1}^{\infty} (-1)^{k-1} k^{-x}, & \text{for } 0 \leq x \leq 1 \\
2^x \pi^{x-1} \sin\left(\frac{\pi x}{2}\right) \Gamma(1-x) \zeta(1-x), & \text{for } x < 0 
\end{cases} \]
where \(x\) is \(x\).
\end{enumerate}
24.9.5.19 Spherical Bessel functions of the first kind

double sph_bessel(unsigned n, double x);
float sph_besself(unsigned n, float x);
long double sph_bessell(unsigned n, long double x);

1 Effects: These functions compute the spherical Bessel functions of the first kind of their respective arguments \( n \) and \( x \).

2 Returns:

\[ j_n(x) = (\pi/2x)^{1/2}J_{n+1/2}(x), \quad \text{for } x \geq 0, \]

where \( n \) is \( n \) and \( x \) is \( x \).

3 Remarks: The effect of calling each of these functions is implementation-defined if \( n \geq 128 \).

See also 24.9.5.8.

24.9.5.20 Spherical associated Legendre functions

double sph_legendre(unsigned l, unsigned m, double theta);
float sph_legendref(unsigned l, unsigned m, float theta);
long double sph_legendrel(unsigned l, unsigned m, long double theta);

1 Effects: These functions compute the spherical associated Legendre functions of their respective arguments \( l, m, \) and \( \theta \) (\( \theta \) measured in radians).

2 Returns:

\[ Y^m_l(\theta, 0) \]

where

\[ Y^m_l(\theta, \phi) = (-1)^m \left[ \frac{(2\ell + 1)(\ell - m)!}{4\pi (\ell + m)!} \right]^{1/2} P^m_l(\cos \theta) e^{im\phi}, \quad \text{for } |m| \leq \ell, \]

and \( l \) is \( l \), \( m \) is \( m \), and \( \theta \) is \( \theta \).

3 Remarks: The effect of calling each of these functions is implementation-defined if \( l \geq 128 \).

See also 24.9.5.2.

24.9.5.21 Spherical Neumann functions

double sph_neumann(unsigned n, double x);
float sph_neumannf(unsigned n, float x);
long double sph_neumannl(unsigned n, long double x);

1 Effects: These functions compute the spherical Neumann functions, also known as the spherical Bessel functions of the second kind, of their respective arguments \( n \) and \( x \).

2 Returns:

\[ n_n(x) = (\pi/2x)^{1/2}N_{n+1/2}(x), \quad \text{for } x \geq 0, \]

where \( n \) is \( n \) and \( x \) is \( x \).

3 Remarks: The effect of calling each of these functions is implementation-defined if \( n \geq 128 \).

See also 24.9.5.10.
25 Time library

25.1 General

This Clause describes the chrono library (25.2) and various C functions (25.13) that provide generally useful time utilities, as summarized in Table 86.

25.3 **Cpp17Clock requirements**

A clock is a bundle consisting of a duration, a time_point, and a function now() to get the current time_point. The origin of the clock’s time_point is referred to as the clock’s epoch. A clock shall satisfy the requirements in Table 87.

In Table 87 C1 and C2 denote clock types. t1 and t2 are values returned by C1::now() where the call returning t1 happens before (6.8.2) the call returning t2 and both of these calls occur before C1::time_point::max().

*Note: This means C1 did not wrap around between t1 and t2. — end note*

3 [Note: The relative difference in durations between those reported by a given clock and the SI definition is a measure of the quality of implementation. — end note]

4 A type TC meets the Cpp17TrivialClock requirements if:

(4.1) — TC satisfies the Cpp17Clock requirements (25.3),
(4.2) — the types TC::rep, TC::duration, and TC::time_point satisfy the Cpp17EqualityComparable (Table 22), Cpp17LessThanComparable (Table 23), Cpp17DefaultConstructible (Table 24), Cpp17CopyConstructible (Table 26), Cpp17CopyAssignable (Table 28), and Cpp17Destructible (Table 29) requirements and the requirements of numeric types (24.3). [Note: This means, in particular, that operations on these types will not throw exceptions. — end note]
(4.3) — lvalues of the types TC::rep, TC::duration, and TC::time_point are swappable (15.5.3.2),
(4.4) — the function TC::now() does not throw exceptions, and
(4.5) — the type TC::time_point::clock meets the Cpp17TrivialClock requirements, recursively.

25.4 Time-related traits

25.4.1 treat_as_floating_point

template<class Rep> struct treat_as_floating_point : is_floating_point<Rep> { };

1 The duration template uses the treat_as_floating_point trait to help determine if a duration object can be converted to another duration with a different tick period. If treat_as_floating_point_v<Rep> is true, then implicit conversions are allowed among durations. Otherwise, the implicit convertibility depends on the tick periods of the durations. [Note: The intention of this trait is to indicate whether a given class behaves like a floating-point type, and thus allows division of one value by another with acceptable loss of precision. If treat_as_floating_point_v<Rep> is false, Rep will be treated as if it behaved like an integral type for the purpose of these conversions. — end note]

25.4.2 duration_values

template<class Rep>
struct duration_values {
public:
    static constexpr Rep zero();
    static constexpr Rep min();
    static constexpr Rep max();
};

1 The duration template uses the duration_values trait to construct special values of the duration’s representation (Rep). This is done because the representation might be a class type with behavior which requires some other implementation to return these special values. In that case, the author of that class type should specialize duration_values to return the indicated values.

25.4.3

static constexpr Rep zero();

1 Returns: Rep(0). [Note: Rep(0) is specified instead of Rep() because Rep() may have some other meaning, such as an uninitialized value. — end note]

2 Remarks: The value returned shall be the additive identity.

static constexpr Rep min();

1 Returns: numeric_limits<Rep>::lowest().

3 Remarks: The value returned shall compare less than or equal to zero().

§ 25.4.2

1031
static constexpr Rep max();

Returns: numeric_limits<Rep>::max().

Remarks: The value returned shall compare greater than zero.

25.4.3 Specializations of common_type

template<class Rep1, class Period1, class Rep2, class Period2>
struct common_type<chrono::duration<Rep1, Period1>, chrono::duration<Rep2, Period2>> {  
  using type = chrono::duration<common_type_t<Rep1, Rep2>, see below>;  
};

The period of the duration indicated by this specialization of common_type shall be the greatest common divisor of Period1 and Period2. [Note: This can be computed by forming a ratio of the greatest common divisor of Period1::num and Period2::num and the least common multiple of Period1::den and Period2::den. —end note]

[Note: The typedef name type is a synonym for the duration with the largest tick period possible where both duration arguments will convert to it without requiring a division operation. The representation of this type is intended to be able to hold any value resulting from this conversion with no truncation error, although floating-point durations may have round-off errors. —end note]

template<class Clock, class Duration1, class Duration2>
struct common_type<chrono::time_point<Clock, Duration1>, chrono::time_point<Clock, Duration2>> {  
  using type = chrono::time_point<Clock, common_type_t<Duration1, Duration2>>;  
};

The common type of two time_point types is a time_point with the same clock as the two types and the common type of their two durations.

25.4.4 Class template is_clock

template<class T> struct is_clock;

1 is_clock is a Cpp17UnaryTypeTrait (19.15.1) with a base characteristic of true_type if T meets the Cpp17Clock requirements (25.3), otherwise false_type. For the purposes of the specification of this trait, the extent to which an implementation determines that a type cannot meet the Cpp17Clock requirements is unspecified, except that as a minimum a type T shall not qualify as a Cpp17Clock unless it satisfies all of the following conditions:

(1.1) — the qualified-ids T::rep, T::period, T::duration, and T::time_point are valid and each denotes a type (12.9.2),

(1.2) — the expression T::is_steady is well-formed when treated as an unevaluated operand,

(1.3) — the expression T::now() is well-formed when treated as an unevaluated operand.

2 The behavior of a program that adds specializations for is_clock is undefined.

25.5 Class template duration

A duration type measures time between two points in time (time_points). A duration has a representation which holds a count of ticks and a tick period. The tick period is the amount of time which occurs from one tick to the next, in units of seconds. It is expressed as a rational constant using the template ratio.
template<class Rep2>
    constexpr explicit duration(const Rep2& r);

template<class Rep2, class Period2>
    constexpr duration(const duration<Rep2, Period2>& d);
~duration() = default;
duration(duration&) = default;
duration& operator=(const duration&) = default;

  // 25.5.2, observer
  constexpr rep count() const;

  // 25.5.3, arithmetic
  constexpr common_type_t<duration> operator+() const;
  constexpr common_type_t<duration> operator-() const;
  constexpr duration& operator++();
  constexpr duration operator++(int);
  constexpr duration& operator--();
  constexpr duration operator--(int);
  constexpr duration& operator+=(const duration& d);
  constexpr duration& operator-=(const duration& d);
  constexpr duration& operator*=(const rep& rhs);
  constexpr duration& operator/=(const rep& rhs);
  constexpr duration& operator%=(const rep& rhs);
  constexpr duration& operator%=(const duration& rhs);

  // 25.5.4, special values
  static constexpr duration zero();
  static constexpr duration min();
  static constexpr duration max();
};

2 Rep shall be an arithmetic type or a class emulating an arithmetic type. If duration is instantiated with a duration type as the argument for the template parameter Rep, the program is ill-formed.

3 If Period is not a specialization of ratio, the program is ill-formed. If Period::num is not positive, the program is ill-formed.

4 Members of duration shall not throw exceptions other than those thrown by the indicated operations on their representations.

5 The defaulted copy constructor of duration shall be a constexpr function if and only if the required initialization of the member rep_ for copy and move, respectively, would satisfy the requirements for a constexpr function.

6 [Example:

   duration<long, ratio<60>> d0;  // holds a count of minutes using a long
   duration<long long, milli> d1; // holds a count of milliseconds using a long long
   duration<double, ratio<1, 30>> d2; // holds a count with a tick period of \(\frac{1}{30}\) of a second
                        // (30 Hz) using a double

   — end example]

25.5.1 Constructors

The duration template is declared in the header <chrono>.

template<class Rep2>
    constexpr explicit duration(const Rep2& r);

1 Remarks: This constructor shall not participate in overload resolution unless Rep2 is implicitly convertible to rep and

(1.1)    — treat_as_floating_point_v<rep> is true or
(1.2)    — treat_as_floating_point_v<Rep2> is false.

[Example:

duration<int, milli> d(3);  // OK

§ 25.5.1 1033
within a function and ensure that the value of the duration is not modified.

§ 25.5.3 1034
constexpr duration& operator*=(const rep& rhs);
  Effects: As if by: rep_ *= rhs;
  Returns: *this.

constexpr duration& operator/=(const rep& rhs);
  Effects: As if by: rep_ /= rhs;
  Returns: *this.

constexpr duration& operator%=(const rep& rhs);
  Effects: As if by: rep_ %= rhs;
  Returns: *this.

constexpr duration& operator%=(const duration& rhs);
  Effects: As if by: rep_ %= rhs.count();
  Returns: *this.

25.5.4 Special values

static constexpr duration zero();
  Returns: duration(duration_values<rep>::zero()).

static constexpr duration min();
  Returns: duration(duration_values<rep>::min()).

static constexpr duration max();
  Returns: duration(duration_values<rep>::max()).

25.5.5 Non-member arithmetic

In the function descriptions that follow, unless stated otherwise, let CD represent the return type of the function.

template<class Rep1, class Period1, class Rep2, class Period2>
constexpr common_type_t<duration<Rep1, Period1>, duration<Rep2, Period2>>
operator+(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);
  Returns: CD(CD(lhs).count() + CD(rhs).count()).

template<class Rep1, class Period1, class Rep2, class Period2>
constexpr common_type_t<duration<Rep1, Period1>, duration<Rep2, Period2>>
operator-(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);
  Returns: CD(CD(lhs).count() - CD(rhs).count()).

template<class Rep1, class Period, class Rep2>
constexpr duration<common_type_t<Rep1, Rep2>, Period>
operator*(const duration<common_type_t<Rep1, Rep2>, Period>& d, const Rep2& s);
  Remarks: This operator shall not participate in overload resolution unless Rep2 is implicitly convertible
to common_type_t<Rep1, Rep2>.
  Returns: CD(CD(d).count() * s).

template<class Rep1, class Rep2, class Period>
constexpr duration<common_type_t<Rep1, Rep2>, Period>
operator*(const Rep1& s, const duration<Rep2, Period>& d);
  Remarks: This operator shall not participate in overload resolution unless Rep1 is implicitly convertible
to common_type_t<Rep1, Rep2>.
  Returns: d * s.
template<class Rep1, class Period, class Rep2>
constexpr duration<common_type_t<Rep1, Rep2>, Period>
operator/(const duration<Rep1, Period>& d, const Rep2& s);

Remarks: This operator shall not participate in overload resolution unless Rep2 is implicitly convertible to common_type_t<Rep1, Rep2> and Rep2 is not a specialization of duration.

Returns: CD(CD(d).count() / s).

template<class Rep1, class Rep2, class Period2>
constexpr common_type_t<Rep1, Rep2>
operator%(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

Let CD be common_type_t<duration<Rep1, Period1>, duration<Rep2, Period2>>.

25.5.6 Comparisons

In the function descriptions that follow, CT represents common_type_t<A, B>, where A and B are the types of the two arguments to the function.

template<class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator==(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

Returns: CT(lhs).count() == CT(rhs).count().

template<class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator!=(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

Returns: !(lhs == rhs).

template<class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator<(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

Returns: rhs < lhs.

template<class Rep1, class Period1, class Rep2, class Period2>
constexpr bool operator<=(const duration<Rep1, Period1>& lhs, const duration<Rep2, Period2>& rhs);

Returns: !(rhs < lhs).

25.5.7 duration_cast

```cpp
template<class ToDuration, class Rep, class Period>
constexpr ToDuration duration_cast(const duration<Rep, Period>& d);
```

1. **Remarks:** This function shall not participate in overload resolution unless ToDuration is a specialization of duration.
2. **Returns:** Let CF be ratio_divide<Period, typename ToDuration::period>, and CR be common_type<typename ToDuration::rep, Rep, intmax_t>::type.
   1. If CF::num == 1 and CF::den == 1, returns:
      ```cpp
      ToDuration(static_cast<typename ToDuration::rep>(d.count()))
      ```
   2. Otherwise, if CF::num != 1 and CF::den == 1, returns:
      ```cpp
      ToDuration(static_cast<typename ToDuration::rep>(
                  static_cast<CR>(d.count()) * static_cast<CR>(CF::num)))
      ```
   3. Otherwise, if CF::num == 1 and CF::den != 1, returns:
      ```cpp
      ToDuration(static_cast<typename ToDuration::rep>(
                  static_cast<CR>(d.count()) / static_cast<CR>(CF::den)))
      ```
   4. Otherwise, returns:
      ```cpp
      ToDuration(static_cast<typename ToDuration::rep>(
                  static_cast<CR>(d.count()) * static_cast<CR>(CF::num) / static_cast<CR>(CF::den)))
      ```

[Note: This function does not use any implicit conversions; all conversions are done with static_cast. It avoids multiplications and divisions when it is known at compile time that one or more arguments is 1. Intermediate computations are carried out in the widest representation and only converted to the destination representation at the final step. —end note]

3. **template<class ToDuration, class Rep, class Period>**
   ```cpp
   constexpr ToDuration floor(const duration<Rep, Period>& d);
   ```

4. **Remarks:** This function shall not participate in overload resolution unless ToDuration is a specialization of duration.
5. **Returns:** The greatest result t representable in ToDuration for which t <= d.

6. **template<class ToDuration, class Rep, class Period>**
   ```cpp
   constexpr ToDuration ceil(const duration<Rep, Period>& d);
   ```

7. **Remarks:** This function shall not participate in overload resolution unless ToDuration is a specialization of duration.
8. **Returns:** The least result t representable in ToDuration for which t >= d.

9. **template<class ToDuration, class Rep, class Period>**
   ```cpp
   constexpr ToDuration round(const duration<Rep, Period>& d);
   ```

8. **Remarks:** This function shall not participate in overload resolution unless ToDuration is a specialization of duration, and treat_as_floating_point_v<typename ToDuration::rep> is false.
9. **Returns:** The value of ToDuration that is closest to d. If there are two closest values, then return the value t for which t % 2 == 0.

25.5.8 Suffixes for duration literals

1. This subclause describes literal suffixes for constructing duration literals. The suffixes h, min, s, ms, us, ns denote duration values of the corresponding types hours, minutes, seconds, milliseconds, microseconds, and nanoseconds respectively if they are applied to integral literals.
2. If any of these suffixes are applied to a floating-point literal the result is a chrono::duration literal with an unspecified floating-point representation.
3. If any of these suffixes are applied to an integer literal and the resulting chrono::duration value cannot be represented in the result type because of overflow, the program is ill-formed.
4. **Example:** The following code shows some duration literals.
   ```cpp
   using namespace std::chrono_literals;
   ```

§ 25.5.8 1037
auto constexpr aday=24h;
auto constexpr lesson=45min;
auto constexpr halfanhour=0.5h;

constexpr chrono::hours operator"h(unsigned long long hours);
constexpr chrono::duration<unspecified, ratio<3600, 1>> operator"h(long double hours);

Returns: A duration literal representing hours hours.

constexpr chrono::minutes operator"min(unsigned long long minutes);
constexpr chrono::duration<unspecified, ratio<60, 1>> operator"min(long double minutes);

Returns: A duration literal representing minutes minutes.

constexpr chrono::seconds operator"s(unsigned long long sec);
constexpr chrono::duration<unspecified> operator"s(long double sec);

Returns: A duration literal representing sec seconds.

[Note: The same suffix s is used for basic_string but there is no conflict, since duration suffixes apply to numbers and string literal suffixes apply to character array literals. —end note]

constexpr chrono::milliseconds operator"ms(unsigned long long msec);
constexpr chrono::duration<unspecified, milli> operator"ms(long double msec);

Returns: A duration literal representing msec milliseconds.

constexpr chrono::microseconds operator"us(unsigned long long usec);
constexpr chrono::duration<unspecified, micro> operator"us(long double usec);

Returns: A duration literal representing usec microseconds.

constexpr chrono::nanoseconds operator"ns(unsigned long long nsec);
constexpr chrono::duration<unspecified, nano> operator"ns(long double nsec);

Returns: A duration literal representing nsec nanoseconds.

25.5.9 Algorithms

template<class Rep, class Period>
constexpr duration<Rep, Period> abs(duration<Rep, Period> d);

Remarks: This function shall not participate in overload resolution unless numeric_limits<Rep>::is_signed is true.

Returns: If d >= d.zero(), return d, otherwise return -d.

25.5.10 I/O

template<class charT, class traits, class Rep, class Period>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const duration<Rep, Period>& d);

Requires: Rep is an integral type whose integer conversion rank (6.7.4) is greater than or equal to that of short, or a floating point type. charT is char or wchar_t.

Effects: Forms a basic_string<charT, traits> from d.count() using to_string if charT is char, or to_wstring if charT is wchar_t. Appends the units suffix described below to the basic_string. Inserts the resulting basic_string into os. [Note: This specification ensures that the result of this streaming operation will obey the width and alignment properties of the stream. —end note]

The units suffix depends on the type Period::type as follows:

1. If Period::type is atto, the suffix is "as".
2. Otherwise, if Period::type is femto, the suffix is "fs".
3. Otherwise, if Period::type is pico, the suffix is "ps".
4. Otherwise, if Period::type is nano, the suffix is "ns".
5. Otherwise, if Period::type is micro, the suffix is "µs" ("\u00b5\u0073").
Otherwise, if \texttt{Period::type} is \texttt{milli}, the suffix is "ms".

Otherwise, if \texttt{Period::type} is \texttt{centi}, the suffix is "cs".

Otherwise, if \texttt{Period::type} is \texttt{deci}, the suffix is "ds".

Otherwise, if \texttt{Period::type} is \texttt{ratio<1>}, the suffix is "s".

Otherwise, if \texttt{Period::type} is \texttt{deca}, the suffix is "das".

Otherwise, if \texttt{Period::type} is \texttt{hecto}, the suffix is "hs".

Otherwise, if \texttt{Period::type} is \texttt{kilo}, the suffix is "ks".

Otherwise, if \texttt{Period::type} is \texttt{mega}, the suffix is "Ms".

Otherwise, if \texttt{Period::type} is \texttt{giga}, the suffix is "Gs".

Otherwise, if \texttt{Period::type} is \texttt{tera}, the suffix is "Ts".

Otherwise, if \texttt{Period::type} is \texttt{peta}, the suffix is "Ps".

Otherwise, if \texttt{Period::type} is \texttt{exa}, the suffix is "Es".

Otherwise, if \texttt{Period::type} is \texttt{ratio<60>}, the suffix is "min".

Otherwise, if \texttt{Period::type} is \texttt{ratio<3600>}, the suffix is "h".

Otherwise, if \texttt{Period::type::den} == 1, the suffix is "[num]s".

Otherwise, the suffix is "[num/den]s".

In the list above the use of \texttt{num} and \texttt{den} refer to the static data members of \texttt{Period::type}, which are converted to arrays of \texttt{charT} using a decimal conversion with no leading zeroes.

If \texttt{Period::type} is \texttt{micro}, but the character U+00B5 cannot be represented in the encoding used for \texttt{charT}, the unit suffix "us" is used instead of "µs".

Returns: \texttt{os}.

```cpp
template<class charT, class traits, class Rep, class Period>
basic_ostream<charT, traits>&
to_stream(basic_ostream<charT, traits>& os, const charT* fmt, const duration<Rep, Period>& d);
```

Effects: Streams \texttt{d} into \texttt{os} using the format specified by the NTCTS \texttt{fmt}. \texttt{fmt} encoding follows the rules specified in 25.11.

Returns: \texttt{os}.

```cpp
template<class charT, class traits, class Rep, class Period, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>& is, const charT* fmt, duration<Rep, Period>& d, basic_string<charT, traits, Alloc>* abbrev = nullptr, minutes* offset = nullptr);
```

Effects: Attempts to parse the input stream \texttt{is} into the duration \texttt{d} using the format flags given in the NTCTS \texttt{fmt} as specified in 25.12. If the parse parses everything specified by the parsing format flags without error, and yet none of the flags impacts a duration, \texttt{d} will be assigned a zero value. If \texttt{%Z} is used and successfully parsed, that value will be assigned to \*\texttt{abbrev} if \texttt{abbrev} is non-null. If \texttt{%z} (or a modified variant) is used and successfully parsed, that value will be assigned to \*\texttt{offset} if \texttt{offset} is non-null.

Returns: \texttt{is}.

### 25.6 Class template \texttt{time_point}

```cpp
namespace std::chrono {
    template<class Clock, class Duration = typename Clock::duration>
class time_point {
public:
    using clock = Clock;
    using duration = Duration;
    using rep = typename duration::rep;
    using period = typename duration::period;
    }
```
private:
    duration d_;           // exposition only

public:
    // 25.6.1, construct
    constexpr time_point();        // has value epoch
    constexpr explicit time_point(const duration& d); // same as time_point() + d
    template<class Duration2>
        constexpr time_point(const time_point<clock, Duration2>& t);

    // 25.6.2, observer
    constexpr duration time_since_epoch() const;

    // 25.6.3, arithmetic
    constexpr time_point& operator++();
    constexpr time_point operator++(int);
    constexpr time_point& operator--();
    constexpr time_point operator--(int);
    constexpr time_point& operator+=(const duration& d);
    constexpr time_point& operator-=(const duration& d);

    // 25.6.4, special values
    static constexpr time_point min();
    static constexpr time_point max();
};

1 Clock shall either satisfy the Cpp17Clock requirements (25.3) or be the type local_t.
2 If Duration is not an instance of duration, the program is ill-formed.

25.6.1 Constructors [time.point.cons]
    constexpr time_point();
1     Effects: Constructs an object of type time_point, initializing d_ with duration::zero(). Such a
time_point object represents the epoch.

    constexpr explicit time_point(const duration& d);
2     Effects: Constructs an object of type time_point, initializing d_ with d. Such a time_point object
represents the epoch + d.

    template<class Duration2>
        constexpr time_point(const time_point<clock, Duration2>& t);
3     Remarks: This constructor shall not participate in overload resolution unless Duration2 is implicitly
convertible to duration.
4     Effects: Constructs an object of type time_point, initializing d_ with t.time_since_epoch().

25.6.2 Observer [time.point.observer]
    constexpr duration time_since_epoch() const;
1     Returns: d_.

25.6.3 Arithmetic [time.point.arithmetic]
    constexpr time_point& operator++();
1     Effects: ++d_.
2     Returns: *this.

    constexpr time_point operator++(int);
3     Returns: time_point(d_++).
constexpr time_point& operator--();
  Effects: --d_.
  Returns: *this.

constexpr time_point operator--(int);
  Returns: time_point(d_--).

constexpr time_point& operator+=(const duration& d);
  Effects: As if by: d_ += d;
  Returns: *this.

constexpr time_point& operator-=(const duration& d);
  Effects: As if by: d_ -= d;
  Returns: *this.

25.6.4 Special values

static constexpr time_point min();
  Returns: time_point(duration::min()).

static constexpr time_point max();
  Returns: time_point(duration::max()).

25.6.5 Non-member arithmetic

template<class Clock, class Duration1, class Rep2, class Period2>
  constexpr time_point<Clock, common_type_t<Duration1, duration<Rep2, Period2>>>
    operator+(const time_point<Clock, Duration1>& lhs, const duration<Rep2, Period2>& rhs);
  Returns: CT(lhs.time_since_epoch() + rhs), where CT is the type of the return value.

template<class Rep1, class Period1, class Clock, class Duration2>
  constexpr time_point<Clock, common_type_t<duration<Rep1, Period1>, Duration2>>
    operator+(const duration<Rep1, Period1>& lhs, const time_point<Clock, Duration2>& rhs);
  Returns: rhs + lhs.

template<class Clock, class Duration1, class Rep2, class Period2>
  constexpr time_point<Clock, common_type_t<Duration1, duration<Rep2, Period2>>>
    operator-(const time_point<Clock, Duration1>& lhs, const duration<Rep2, Period2>& rhs);
  Returns: CT(lhs.time_since_epoch() - rhs), where CT is the type of the return value.

template<class Clock, class Duration1, class Duration2>
  constexpr common_type_t<Duration1, Duration2>
    operator-(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);
  Returns: lhs.time_since_epoch() - rhs.time_since_epoch().

25.6.6 Comparisons

template<class Clock, class Duration1, class Duration2>
  constexpr bool operator==(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);
  Returns: lhs.time_since_epoch() == rhs.time_since_epoch().

template<class Clock, class Duration1, class Duration2>
  constexpr bool operator!=(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);
  Returns: !(lhs == rhs).
template<class Clock, class Duration1, class Duration2>
constexpr bool operator<(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);

Returns: \( \text{lhs.time_since_epoch()} < \text{rhs.time_since_epoch()} \).

template<class Clock, class Duration1, class Duration2>
constexpr bool operator>(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);

Returns: \( \text{rhs} < \text{lhs} \).

template<class Clock, class Duration1, class Duration2>
constexpr bool operator<=(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);

Returns: \( !\left( \text{rhs} < \text{lhs} \right) \).

template<class Clock, class Duration1, class Duration2>
constexpr bool operator>=(const time_point<Clock, Duration1>& lhs, const time_point<Clock, Duration2>& rhs);

Returns: \( !\left( \text{lhs} < \text{rhs} \right) \).

25.6.7 time_point_cast

template<class ToDuration, class Clock, class Duration>
constexpr time_point<Clock, ToDuration> time_point_cast(const time_point<Clock, Duration>& t);

Remarks: This function shall not participate in overload resolution unless ToDuration is a specialization of duration.

Returns:
\( \text{time_point<Clock, ToDuration>}(\text{duration_cast<ToDuration>}(t.\text{time_since_epoch}())) \)

template<class ToDuration, class Clock, class Duration>
constexpr time_point<Clock, ToDuration> floor(const time_point<Clock, Duration>& tp);

Remarks: This function shall not participate in overload resolution unless ToDuration is a specialization of duration.

Returns:
\( \text{time_point<Clock, ToDuration>}(\text{floor<ToDuration>}(tp.\text{time_since_epoch}())) \).

template<class ToDuration, class Clock, class Duration>
constexpr time_point<Clock, ToDuration> ceil(const time_point<Clock, Duration>& tp);

Remarks: This function shall not participate in overload resolution unless ToDuration is a specialization of duration.

Returns:
\( \text{time_point<Clock, ToDuration>}(\text{ceil<ToDuration>}(tp.\text{time_since_epoch}())) \).

template<class ToDuration, class Clock, class Duration>
constexpr time_point<Clock, ToDuration> round(const time_point<Clock, Duration>& tp);

Remarks: This function shall not participate in overload resolution unless ToDuration is a specialization of duration, and \( \text{treat_as_floating_point_v<typename ToDuration::rep>} \) is false.

Returns:
\( \text{time_point<Clock, ToDuration>}(\text{round<ToDuration>}(tp.\text{time_since_epoch}())) \).

25.7 Clocks

The types defined in this subclause shall satisfy the Cpp17TrivialClock requirements (25.3) unless otherwise specified.

25.7.1 Class system_clock

namespace std::chrono {
    class system_clock {
    public:
        using rep = see below;
        using period = ratio<unspecified, unspecified>;
    }
using duration = chrono::duration<rep, period>;  
using time_point = chrono::time_point<system_clock>;  
static constexpr bool is_steady = unspecified;  
static time_point now() noexcept;  

// mapping to/from C type time_t  
static time_t to_time_t(const time_point& t) noexcept;  
static time_point from_time_t(time_t t) noexcept;  

1 Objects of type system_clock represent wall clock time from the system-wide realtime clock. Objects of type sys_time<Duration> measure time since (and before) 1970-01-01 00:00:00 UTC excluding leap seconds. This measure is commonly referred to as Unix time. This measure facilitates an efficient mapping between sys_time and calendar types (25.8).  
[Example:  
sys_seconds{sys_days{1970y/January/1}}.time_since_epoch() is 0s.  
sys_seconds{sys_days{2000y/January/1}}.time_since_epoch() is 946'684'800s, which is 10'957 * 86'400s.  
—end example]  

25.7.1.2 Members  

using system_clock::rep = unspecified;  

1 Requires: system_clock::duration::min() < system_clock::duration::zero() shall be true.  
[Note: This implies that rep is a signed type. — end note]  

static time_t to_time_t(const time_point& t) noexcept;  

2 Returns: A time_t object that represents the same point in time as t when both values are restricted to the coarser of the precisions of time_t and time_point. It is implementation-defined whether values are rounded or truncated to the required precision.  

static time_point from_time_t(time_t t) noexcept;  

3 Returns: A time_point object that represents the same point in time as t when both values are restricted to the coarser of the precisions of time_t and time_point. It is implementation-defined whether values are rounded or truncated to the required precision.  

25.7.1.3 Non-member functions  

template<class charT, class traits, class Duration>  
basic_ostream<charT, traits>&  
operator<<(basic_ostream<charT, traits>& os, const sys_time<Duration>& tp);  

1 Remarks: This operator shall not participate in overload resolution if treat_as_floating_point_v<typename Duration::rep> is true, or if Duration{1} >= days{1}.  

2 Effects:  
auto const dp = floor<days>(tp);  
os << year_month_day(dp) << ' ' << time_of_day(tp-dp);  

3 Returns: os.  

[Example:  
cout << sys_seconds{0s} << '\n'; // 1970-01-01 00:00:00  
cout << sys_seconds{946'684'800s} << '\n'; // 2000-01-01 00:00:00  
cout << sys_seconds{946'688'523s} << '\n'; // 2000-01-01 01:02:03  
—end example]  

template<class charT, class traits>  
basic_ostream<charT, traits>&  
operator<<(basic_ostream<charT, traits>& os, const sys_days& dp);  

5 Effects: os << year_month_day(dp).  

6 Returns: os.
template<class charT, class traits, class Duration>
    basic_ostream<charT, traits>&
    to_stream(basic_ostream<charT, traits>& os, const charT* fmt, const sys_time<Duration>& tp);

Effects: Streams tp into os using the format specified by the NTCTS fmt. The fmt encoding follows the
rules specified in 25.11. If %Z is used, it will be replaced with "UTC" widened to charT. If %z is used
(or a modified variant of %z), an offset of 0min will be formatted.

Returns: os.

template<class charT, class traits, class Duration, class Alloc = allocator<charT>>
    basic_istream<charT, traits>&
    from_stream(basic_istream<charT, traits>& is, const charT* fmt,
                sys_time<Duration>& tp, basic_string<charT, traits, Alloc>* abbrev = nullptr,
                minutes* offset = nullptr);

Effects: Attempts to parse the input stream is into the sys_time tp using the format flags given in
the NTCTS fmt as specified in 25.12. If the parse fails to decode a valid date, is.setstate(ios_base::failbit)
shall be called and tp shall not be modified. If %Z is used and successfully parsed,
that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used
and successfully parsed, that value will be assigned to *offset if offset is non-null. Additionally,
the parsed offset will be subtracted from the successfully parsed timestamp prior to assigning that
difference to tp.

Returns: is.

25.7.2 Class utc_clock

25.7.2.1 Overview

namespace std::chrono {
    class utc_clock {
        public:
            using rep = a signed arithmetic type;
            using period = ratio<unspecified, unspecified>;
            using duration = chrono::duration<rep, period>;
            using time_point = chrono::time_point<utc_clock>;
            static constexpr bool is_steady = unspecified;
            static time_point now();
        
    };
}

In contrast to sys_time, which does not take leap seconds into account, utc_clock and its associated
time_point, utc_time, count time, including leap seconds, since 1970-01-01 00:00:00 UTC. [Example:
clock_cast<utc_clock>(sys_seconds{sys_days{1970y/January/1}}).time_since_epoch() is 0s.
clock_cast<utc_clock>(sys_seconds{sys_days{2000y/January/1}}).time_since_epoch()

utc_clock is not a Cpp17TrivialClock unless the implementation can guarantee that utc_clock::now()
does not propagate an exception. [Note: noexcept(from_sys(system_clock::now())) is false. — end note]

25.7.2.2 Member functions

static time_point now();

Returns: from_sys(system_clock::now()), or a more accurate value of utc_time.
template<typename Duration>
static sys_time<common_type_t<Duration, seconds>>
to_sys(const utc_time<Duration>& u);

Returns: A sys_time t, such that from_sys(t) == u if such a mapping exists. Otherwise u represents
a time_point during a leap second insertion and the last representable value of sys_time prior to the
insertion of the leap second is returned.

template<typename Duration>
static utc_time<common_type_t<Duration, seconds>>
from_sys(const sys_time<Duration>& t);

Returns: A utc_time u, such that u.time_since_epoch() - t.time_since_epoch() is equal to the
number of leap seconds that were inserted between t and 1970-01-01. If t is exactly the date of leap
second insertion, then the conversion counts that leap second as inserted.

Example:
auto t = sys_days{July/1/2015} - 2ns;
auto u = utc_clock::from_sys(t);
assert(u.time_since_epoch() - t.time_since_epoch() == 25s);
t += 1ns;
u = utc_clock::from_sys(t);
assert(u.time_since_epoch() - t.time_since_epoch() == 25s);
t += 1ns;
u = utc_clock::from_sys(t);
assert(u.time_since_epoch() - t.time_since_epoch() == 26s);
t += 1ns;
u = utc_clock::from_sys(t);
assert(u.time_since_epoch() - t.time_since_epoch() == 26s);

— end example

§ 25.7.2.3 Non-member functions

template<class charT, class traits, class Duration>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const utc_time<Duration>& t);

Effects: Calls to_stream(os, fmt, t), where fmt is a string containing "%F %T" widened to charT.

Returns: os.

template<class charT, class traits, class Duration>
basic_ostream<charT, traits>&
to_stream(basic_ostream<charT, traits>& os, const charT* fmt, const utc_time<Duration>& tp);

Effects: Streams tp into os using the format specified by the NTCTS fmt. fmt encoding follows the
rules specified in 25.11. If %Z is used, it will be replaced with "UTC" widened to charT. If %z is used
(or a modified variant of %z), an offset of Omin will be formatted. If tp represents a time during a leap
second insertion, and if a seconds field is formatted, the integral portion of that format shall be "60"
widened to charT.

Returns: os.

Example:
auto t = sys_days{July/1/2015} - 500ms;
auto u = clock_cast<utc_clock>(t);
for (auto i = 0; i < 8; ++i, u += 250ms)
    cout << u << " UTC\n";

Produces this output:
2015-06-30 23:59:59.500 UTC
2015-06-30 23:59:59.750 UTC
2015-06-30 23:59:60.000 UTC
2015-06-30 23:59:60.250 UTC
2015-06-30 23:59:60.500 UTC
2015-06-30 23:59:60.750 UTC
2015-07-01 00:00:00.000 UTC

§ 25.7.2.3
template<class charT, class traits, class Duration, class Alloc = allocator<charT>>
    basic_istream<charT, traits>&
    from_stream(basic_istream<charT, traits>& is, const charT* fmt,
                utc_time<Duration>& tp, basic_string<charT, traits, Alloc>* abbrev = nullptr,
                minutes* offset = nullptr);

Effects: Attempts to parse the input stream is into the utc_time tp using the format flags given in
the NTCTS fmt as specified in 25.12. If the parse fails to decode a valid date, is.setstate(ios_base::failbit)
shall be called and tp shall not be modified. If %Z is used and successfully parsed,
that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used
and successfully parsed, that value will be assigned to *offset if offset is non-null. Additionally,
the parsed offset will be subtracted from the successfully parsed timestamp prior to assigning that
difference to tp.

Returns: is.

25.7.3 Class tai_clock

25.7.3.1 Overview

namespace std::chrono {
    class tai_clock {
        public:
            using rep = a signed arithmetic type;
            using period = ratio<unspecified, unspecified>;
            using duration = chrono::duration<rep, period>;
            using time_point = chrono::time_point<tai_clock>;
            static constexpr bool is_steady = unspecified;

            static time_point now();

            template<class Duration>
                static utc_time<common_type_t<Duration, seconds>>
                to_utc(const tai_time<Duration>& t) noexcept;
            template<class Duration>
                static tai_time<common_type_t<Duration, seconds>>
                from_utc(const utc_time<Duration>& t) noexcept;
    };
}

1 The clock tai_clock measures seconds since 1958-01-01 00:00:00 and is offset 10s ahead of UTC at this date.
That is, 1958-01-01 00:00:00 TAI is equivalent to 1957-12-31 23:59:50 UTC. Leap seconds are not inserted
into TAI. Therefore every time a leap second is inserted into UTC, UTC falls another second behind TAI.
For example by 2000-01-01 there had been 22 leap seconds inserted so 2000-01-01 00:00:00 UTC is equivalent
to 2000-01-01 00:00:32 TAI (22s plus the initial 10s offset).

tai_clock is not a Cpp17TrivialClock unless the implementation can guarantee that tai_clock::now() does not propagate an exception. [Note: noexcept(from_utc(utc_clock::now())) is false. — end note]

25.7.3.2 Member functions

static time_point now();

1 Returns: from_utc(utc_clock::now()), or a more accurate value of tai_time.

template<class Duration>
static utc_time<common_type_t<Duration, seconds>>
    to_utc(const tai_time<Duration>& t) noexcept;

2 Returns:
    utc_time<common_type_t<Duration, seconds>>{t.time_since_epoch()} - 378691210s
[Note:
    378691210s == sys_days{1970y/January/1} - sys_days{1958y/January/1} + 10s
template<class Duration>
static tai_time<common_type_t<Duration, seconds>>
  from_utc(const utc_time<Duration>& t) noexcept;

Returns:
  tai_time<common_type_t<Duration, seconds>>(t.time_since_epoch()) + 378691210s

[Note:
  378691210s == sys_days{1970y/January/1} - sys_days{1958y/January/1} + 10s
  — end note]

25.7.3.3 Non-member functions

template<class charT, class traits, class Duration>
basic_ostream<charT, traits>&
  operator<<(basic_ostream<charT, traits>& os, const tai_time<Duration>& t);

1
Effects: Calls to_stream(os, fmt, t), where fmt is a string containing "%F %T" widened to charT.

Returns: os.

template<class charT, class traits, class Duration>
basic_ostream<charT, traits>&
  to_stream(basic_ostream<charT, traits>& os, const charT* fmt, const tai_time<Duration>& tp);

3
Effects: Streams tp into os using the format specified by the NTCTS fmt. fmt encoding follows the rules specified in 25.11. If %Z is used, it will be replaced with "TAI". If %z is used (or a modified variant of %z), an offset of 0min will be formatted. The date and time formatted shall be equivalent to that formatted by a sys_time initialized with:

  sys_time<Duration>({tp.time_since_epoch()} -
  (sys_days{1970y/January/1} - sys_days{1958y/January/1}))

4
Returns: os.

[Example:
  auto st = sys_days{2000y/January/1};
  auto tt = clock_cast<tai_clock>(st);
  cout << format("%F %T %Z == ", st) << format("%F %T %Z\n", tt);

  Produces this output:
  2000-01-01 00:00:00 UTC == 2000-01-01 00:00:32 TAI
  — end example]

template<class charT, class traits, class Duration, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
  from_stream(basic_istream<charT, traits>& is, const charT* fmt, tai_time<Duration>& tp, basic_string<charT, traits, Alloc>* abbrev = nullptr, minutes* offset = nullptr);

6
Effects: Attempts to parse the input stream is into the tai_time tp using the format flags given in the NTCTS fmt as specified in 25.12. If the parse fails to decode a valid date, is.setstate(ios_base::failbit) shall be called and tp shall not be modified. If %Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used and successfully parsed, that value will be assigned to *offset if offset is non-null. Additionally, the parsed offset will be subtracted from the successfully parsed timestamp prior to assigning that difference to tp.

Returns: is.
using rep = a signed arithmetic type;
using period = ratio<unspecified, unspecified>;
using time_point = chrono::time_point<gps_clock>;
static constexpr bool is_steady = unspecified;
static time_point now();

template<class Duration>
static utc_time<common_type_t<Duration, seconds>>
to_utc(const gps_time<Duration>& t) noexcept;

template<class Duration>
static gps_time<common_type_t<Duration, seconds>>
from_utc(const utc_time<Duration>& t) noexcept;

The clock `gps_clock` measures seconds since the first Sunday of January, 1980 00:00:00 UTC. Leap seconds are not inserted into GPS. Therefore every time a leap second is inserted into UTC, UTC falls another second behind GPS. Aside from the offset from 1958y/January/1 to 1980y/January/Sunday[1], GPS is behind TAI by 19s due to the 10s offset between 1958 and 1970 and the additional 9 leap seconds inserted between 1970 and 1980.

gps_clock is not a `Cpp17TrivialClock` unless the implementation can guarantee that `gps_clock::now()` does not propagate an exception. [Note: `noexcept(from_utc(utc_clock::now()))` is false. —end note]

25.7.4.2 Member functions

Returns: from_utc(utc_clock::now()), or a more accurate value of `gps_time`.

template<class Duration>
static utc_time<common_type_t<Duration, seconds>>
to_utc(const gps_time<Duration>& t) noexcept;

Returns:
gps_time<common_type_t<Duration, seconds>>{t.time_since_epoch()} + 315964809s
[Note:
315964809s == sys_days{1980y/January/Sunday[1]} - sys_days{1970y/January/1} + 9s
—end note]

template<class Duration>
static gps_time<common_type_t<Duration, seconds>>
from_utc(const utc_time<Duration>& t) noexcept;

Returns:
gps_time<common_type_t<Duration, seconds>>{t.time_since_epoch()} - 315964809s
[Note:
315964809s == sys_days{1980y/January/Sunday[1]} - sys_days{1970y/January/1} + 9s
—end note]

25.7.4.3 Non-member functions

template<class charT, class traits, class Duration>
basic_ostream<charT, traits>&
to_stream(basic_ostream<charT, traits>& os, const gps_time<Duration>& t);

Effects: Calls `to_stream(os, fmt, t)`, where `fmt` is a string containing "%F %T" widened to `charT`.

Returns: `os`.
template<class charT, class traits, class Duration>
    basic_ostream<charT, traits>&
    to_stream(basic_ostream<charT, traits>& os, const charT* fmt, const gps_time<Duration>& tp);

Effects: Streams tp into os using the format specified by the NTCTS fmt. fmt encoding follows the
rules specified in 25.11. If %Z is used, it will be replaced with "GPS". If %z is used (or a modified variant
of %z), an offset of 0min will be formatted. The date and time formatted shall be equivalent to that
formatted by a sys_time initialized with:

    sys_time<Duration>{tp.time_since_epoch()} +
    (sys_days{1980y/January/Sunday[1]} - sys_days{1970y/January/1})

Returns: os.

Example:

    auto st = sys_days{2000y/January/1};
    auto gt = clock_cast<gps_clock>(st);
    cout << format("%F %T %Z == ", st) << format("%F %T %Z\n", gt);

Produces this output:

    2000-01-01 00:00:00 UTC == 2000-01-01 00:00:13 GPS

— end example]

template<class charT, class traits, class Duration, class Alloc = allocator<charT>>
    basic_istream<charT, traits>&
    from_stream(basic_istream<charT, traits>& is, const charT* fmt,
                gps_time<Duration>& tp, basic_string<charT, traits, Alloc>* abbrev = nullptr,
                minutes* offset = nullptr);

Effects: Attempts to parse the input stream is into the gps_time tp using the format flags given in
the NTCTS fmt as specified in 25.12. If the parse fails to decode a valid date, is.setstate(ios_base::failbit)
shall be called and tp shall not be modified. If %Z is used and successfully parsed,
that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used
and successfully parsed, that value will be assigned to *offset if offset is non-null. Additionally,
the parsed offset will be subtracted from the successfully parsed timestamp prior to assigning that
difference to tp.

Returns: is.

25.7.5 Class file_clock

25.7.5.1 Overview

namespace std::chrono {
    class file_clock {
    public:
        using rep = a signed arithmetic type;
        using period = ratio<unspecified, unspecified>;
        using duration = chrono::duration<rep, period>;
        using time_point = chrono::time_point<file_clock>;
        static constexpr bool is_steady = unspecified;

        static time_point now() noexcept;
    };
}

The clock file_clock is used to create the time_point system used for file_time_type (27.11). Its epoch
is unspecified.

25.7.5.2 Member functions

static time_point now();

Returns: A file_clock::time_point indicating the current time.
The class `file_clock` shall provide precisely one of the following two sets of static member functions:

```cpp
template<class Duration>
static sys_time<see below>
  to_sys(const file_time<Duration>&);

template<class Duration>
static file_time<see below>
  from_sys(const sys_time<Duration>&);

or:

template<class Duration>
static utc_time<see below>
  to_utc(const file_time<Duration>&);

template<class Duration>
static file_time<see below>
  from_utc(const utc_time<Duration>&);
```

These member functions shall provide `time_point` conversions consistent with those specified by `utc_clock`, `tai_clock`, and `gps_clock`. The `Duration` of the resultant `time_point` is computed from the `Duration` of the input `time_point`.

### 25.7.5.3 Non-member functions

#### [time.clock.file.nonmembers]

```cpp
template<class charT, class traits, class Duration>
basic_ostream<charT, traits>&
  operator<<(basic_ostream<charT, traits>& os, const file_time<Duration>& t);
```

1. **Effects:** Calls `to_stream(os, fmt, t)`, where `fmt` is a string containing "%F %T" widened to `charT`.
2. **Returns:** `os`.

```cpp
template<class charT, class traits, class Duration>
basic_ostream<charT, traits>&
  to_stream(basic_ostream<charT, traits>& os, const charT* fmt, const file_time<Duration>& tp);
```

3. **Effects:** Streams `tp` into `os` using the format specified by the NTCTS `fmt`. `fmt` encoding follows the rules specified in 25.11. If `%Z` is used, it will be replaced with "UTC" widened to `charT`. If `%z` is used (or a modified variant of `%z`), an offset of 0min will be formatted. The date and time formatted shall be equivalent to that formatted by a `sys_time` initialized with `clock_cast<system_clock>(tp)`, or by a `utc_time` initialized with `clock_cast<utc_clock>(tp)`. 
4. **Returns:** `os`.

```cpp
template<class charT, class traits, class Duration, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
  from_stream(basic_istream<charT, traits>& is, const charT* fmt, file_time<Duration>& tp, basic_string<charT, traits, Alloc>* abbrev = nullptr, minutes* offset = nullptr);
```

5. **Effects:** Attempts to parse the input stream `is` into the `file_time` `tp` using the format flags given in the NTCTS `fmt` as specified in 25.12. If the parse fails to decode a valid date, `is.setstate(ios_base::failbit)` shall be called and `tp` shall not be modified. If `%Z` is used and successfully parsed, that value will be assigned to `*abbrev` if `abbrev` is non-null. If `%z` (or a modified variant) is used and successfully parsed, that value will be assigned to `*offset` if `offset` is non-null. Additionally, the parsed offset will be subtracted from the successfully parsed timestamp prior to assigning that difference to `tp`.
6. **Returns:** `is`.

### 25.7.6 Class steady_clock

#### [time.clock.steady]

```cpp
namespace std::chrono {
  class steady_clock {
    public:
      using rep = unspecified;
      using period = ratio<unspecified, unspecified>;
      using duration = chrono::duration<rep, period>;
      using time_point = chrono::time_point<unspecified, duration>;
      static constexpr bool is_steady = true;
  }
}
```
static time_point now() noexcept;
}

1 Objects of class `steady_clock` represent clocks for which values of `time_point` never decrease as physical time advances and for which values of `time_point` advance at a steady rate relative to real time. That is, the clock may not be adjusted.

### 25.7.7 Class `high_resolution_clock` [time.clock.hires]

```cpp
namespace std::chrono {
    class high_resolution_clock {
        public:
            using rep = unspecified;
            using period = ratio<unspecified, unspecified>;
            using duration = duration<rep, period>;
            using time_point = time_point<unspecified, duration>;
            static constexpr bool is_steady = unspecified;
            static time_point now() noexcept;
    };
}
```

1 Objects of class `high_resolution_clock` represent clocks with the shortest tick period. `high_resolution_clock` may be a synonym for `system_clock` or `steady_clock`.

### 25.7.8 Local time [time.clock.local]

1 The family of time points denoted by `local_time<Duration>` are based on the pseudo clock `local_t`. `local_t` has no member `now()` and thus does not meet the clock requirements. Nevertheless `local_time<Duration>` serves the vital role of representing local time with respect to a not-yet-specified time zone. Aside from being able to get the current time, the complete `time_point` algebra is available for `local_time<Duration>` (just as for `sys_time<Duration>`).

```cpp
template<class charT, class traits, class Duration>
    basic_ostream<charT, traits>&
    operator<<(basic_ostream<charT, traits>& os, const local_time<Duration>& lt);
```

2 **Effects:**
   
   ```cpp
   os << sys_time<Duration>{lt.time_since_epoch()};
   ```

3 **Returns:**
   
   ```cpp
   os;
   ```

```cpp
template<class charT, class traits, class Duration>
    basic_ostream<charT, traits>&
    to_stream(basic_ostream<charT, traits>& os, const charT* fmt, const local_time<Duration>& tp,
            const string* abbrev = nullptr, const seconds* offset_sec = nullptr);
```

4 **Effects:** Streams `tp` into `os` using the format specified by the NTCTS `fmt`. `fmt` encoding follows the rules specified in 25.11. If `%Z` is used, it will be replaced with `*abbrev` if `abbrev` is not equal to `nullptr`. If `abbrev` is equal to `nullptr` (and `%Z` is used), `os.setstate(ios_base::failbit)` shall be called. If `%z` is used (or a modified variant of `%z`), it will be formatted with the value of `*offset_sec` if `offset_sec` is not equal to `nullptr`. If `%z` (or a modified variant of `%z`) is used, and `offset_sec` is equal to `nullptr`, then `os.setstate(ios_base::failbit)` shall be called.

5 **Returns:**
   
   ```cpp
   os;
   ```

```cpp
template<class charT, class traits, class Duration, class Alloc = allocator<charT>>
    basic_istream<charT, traits>&
    from_stream(basic_istream<charT, traits>& is, const charT* fmt, local_time<Duration>& tp, basic_string<charT, traits, Alloc>* abbrev = nullptr, minutes* offset = nullptr);
```

6 **Effects:** Attempts to parse the input stream `is` into the `local_time tp` using the format flags given in the NTCTS `fmt` as specified in 25.12. If the parse fails to decode a valid date, `is.setstate(ios_base::failbit)` shall be called and `tp` shall not be modified. If `%Z` is used and successfully parsed, that value will be assigned to `*abbrev` if `abbrev` is non-null. If `%Z` (or a modified variant) is used and successfully parsed, that value will be assigned to `*offset` if `offset` is non-null.

---

§ 25.7.8 1051
Returns: is.

25.7.9 time_point conversions

25.7.9.1 Class template clock_time_conversion

```cpp
namespace std::chrono {
    template<class DestClock, class SourceClock>
    struct clock_time_conversion {
    }
}
```

clock_time_conversion serves as a trait which can be used to specify how to convert a source time_point of type `time_point<SourceClock, Duration>` to a destination time_point of type `time_point<DestClock, Duration>` via a specialization: `clock_time_conversion<DestClock, SourceClock>`. A specialization of `clock_time_conversion<DestClock, SourceClock>` shall provide a const-qualified operator() that takes a parameter of type `time_point<SourceClock, Duration>` and returns a `time_point<DestClock, OtherDuration>` representing an equivalent point in time. OtherDuration is a chrono::duration whose specialization is computed from the input Duration in a manner which can vary for each clock_time_conversion specialization. A program may specialize `clock_time_conversion` if at least one of the template parameters is a user-defined clock type.

Several specializations are provided by the implementation, as described in 25.7.9.2, 25.7.9.3, 25.7.9.4, and 25.7.9.5.

25.7.9.2 Identity conversions

```cpp
template<typename Clock>
struct clock_time_conversion<Clock, Clock> {
    template<class Duration>
    time_point<Clock, Duration> operator()(const time_point<Clock, Duration>& t) const;
};
```

```cpp
template<class Duration>
time_point<Clock, Duration> operator()(const time_point<Clock, Duration>& t) const;
```

Returns: t.

```cpp
template<class Duration>
time_point<Clock, Duration> operator()(const time_point<Clock, Duration>& t) const;
```

Returns: t.

```cpp
template<class Duration>
sys_time<Duration> operator()(const sys_time<Duration>& t) const;
```

Returns: t.

```cpp
template<class Duration>
sys_time<Duration> operator()(const sys_time<Duration>& t) const;
```

Returns: t.

25.7.9.3 Conversions between system_clock and utc_clock

```cpp
template<class Duration>
sys_time<Duration> operator()(const sys_time<Duration>& t) const;
```

Returns: t.

```cpp
template<class Duration>
sys_time<Duration> operator()(const sys_time<Duration>& t) const;
```

Returns: t.

```cpp
template<class Duration>
sys_time<Duration> operator()(const sys_time<Duration>& t) const;
```

Returns: t.
utc_time<common_type_t<Duration, seconds>>
  operator()(const sys_time<Duration>& t) const;  
};

template<class Duration>
utc_time<common_type_t<Duration, seconds>>
  operator()(const sys_time<Duration>& t) const;

Returns: utc_clock::from_sys(t).

template<>
struct clock_time_conversion<system_clock, utc_clock> {
  template<class Duration>
  sys_time<common_type_t<Duration, seconds>>
    operator()(const utc_time<Duration>& t) const;
};

template<class Duration>
sys_time<common_type_t<Duration, seconds>>
  operator()(const utc_time<Duration>& t) const;

Returns: utc_clock::to_sys(t).

25.7.9.4 Conversions between system_clock and other clocks \[time.clock.cast.sys\]

template<class SourceClock>
struct clock_time_conversion<system_clock, SourceClock> {
  template<class Duration>
  auto operator()(const time_point<SourceClock, Duration>& t) const
  -> decltype(SourceClock::to_sys(t));
};

template<class Duration>
auto operator()(const time_point<SourceClock, Duration>& t) const
  -> decltype(SourceClock::to_sys(t));

Remarks: This function does not participate in overload resolution unless SourceClock::to_sys(t) is well-formed. If SourceClock::to_sys(t) does not return sys_time<Duration>, where Duration is a valid chrono::duration specialization, the program is ill-formed.

Returns: SourceClock::to_sys(t).

template<class DestClock>
struct clock_time_conversion<DestClock, system_clock> {
  template<class Duration>
  auto operator()(const sys_time<Duration>& t) const
  -> decltype(DestClock::from_sys(t));
};

template<class Duration>
auto operator()(const sys_time<Duration>& t) const
  -> decltype(DestClock::from_sys(t));

Remarks: This function does not participate in overload resolution unless DestClock::from_sys(t) is well-formed. If DestClock::from_sys(t) does not return time_point<DestClock, Duration>, where Duration is a valid chrono::duration specialization, the program is ill-formed.

Returns: DestClock::from_sys(t).

25.7.9.5 Conversions between utc_clock and other clocks \[time.clock.cast.utc\]

template<class SourceClock>
struct clock_time_conversion<utc_clock, SourceClock> {
  template<class Duration>
  auto operator()(const time_point<SourceClock, Duration>& t) const
  -> decltype(SourceClock::to_utc(t));
};
template<class Duration>
auto operator()(const time_point<SourceClock, Duration>& t) const
-> decltype(SourceClock::to_utc(t));

Remarks: This function does not participate in overload resolution unless SourceClock::to_utc(t) is well-formed. If SourceClock::to_utc(t) does not return utc_time<Duration>, where Duration is a valid chrono::duration specialization, the program is ill-formed.

Returns: SourceClock::to_utc(t).

template<class DestClock>
struct clock_time_conversion<DestClock, utc_clock> {
  template<class Duration>
  auto operator()(const utc_time<Duration>& t) const
  -> decltype(DestClock::from_utc(t));
};

template<class Duration>
auto operator()(const utc_time<Duration>& t) const
-> decltype(DestClock::from_utc(t));

Remarks: This function does not participate in overload resolution unless DestClock::from_utc(t) is well-formed. If DestClock::from_utc(t) does not return time_point<DestClock, Duration>, where Duration is a valid chrono::duration specialization, the program is ill-formed.

Returns: DestClock::from_utc(t).

25.7.9.6 Function template clock_cast

template<class DestClock, class SourceClock, class Duration>
auto clock_cast(const time_point<SourceClock, Duration>& t);

Remarks: This function does not participate in overload resolution unless at least one of the following clock time conversion expressions is well-formed:

(1.1) clock_time_conversion<DestClock, SourceClock>{}(t)
(1.2) clock_time_conversion<DestClock, system_clock>{}(
  clock_time_conversion<system_clock, SourceClock>{}(t))
(1.3) clock_time_conversion<DestClock, utc_clock>{}(
  clock_time_conversion<utc_clock, SystemClock>{}(t))
(1.4) clock_time_conversion<DestClock, utc_clock>{}(
  clock_time_conversion<utc_clock, system_clock>{}(
    clock_time_conversion<system_clock, SourceClock>{}(t))))
(1.5) clock_time_conversion<DestClock, system_clock>{}(
  clock_time_conversion<system_clock, utc_clock>{}(
    clock_time_conversion<utc_clock, SourceClock>{}(t))))

A clock time conversion expression is considered better than another clock time conversion expression if it involves fewer operator() calls on clock_time_conversion specializations. If, among the well-formed clock time conversion expressions from the above list, there is not a unique best expression, the clock_cast is ambiguous and the program is ill-formed.

Returns: The best well-formed clock time conversion expression in the above list.

25.8 The civil calendar

25.8.1 In general

The types in 25.8 describe the civil (Gregorian) calendar and its relationship to sys_days and local_days.

25.8.2 Class last_spec

namespace std::chrono {
  struct last_spec {
    explicit last_spec() = default;
  }
};
The type last_spec is used in conjunction with other calendar types to specify the last in a sequence. For example, depending on context, it can represent the last day of a month, or the last day of the week of a month.

25.8.3 Class day

25.8.3.1 Overview

namespace std::chrono {

    class day {
        unsigned char d_;  // exposition only
    
    public:
        day() = default;
        explicit constexpr day(unsigned d) noexcept;
        constexpr day& operator++() noexcept;
        constexpr day operator++(int) noexcept;
        constexpr day& operator--() noexcept;
        constexpr day operator--(int) noexcept;
        constexpr day& operator+=(const days& d) noexcept;
        constexpr day& operator-=(const days& d) noexcept;
        explicit constexpr operator unsigned() const noexcept;
        constexpr bool ok() const noexcept;
    };
}

day represents a day of a month. It normally holds values in the range 1 to 31, but may hold non-negative values outside this range. It can be constructed with any unsigned value, which will be subsequently truncated to fit into day’s unspecified internal storage. day is Cpp17EqualityComparable (Table 22) and Cpp17LessThanComparable (Table 23), and participates in basic arithmetic with days objects, which represent a difference between two day objects.

day is a trivially copyable and standard-layout class type.

25.8.3.2 Member functions

    explicit constexpr day(unsigned d) noexcept;
    Effects: Constructs an object of type day by initializing d_ with d. The value held is unspecified if d is not in the range [0, 255].

    constexpr day& operator++() noexcept;
    Effects: ++d_.
    Returns: *this.

    constexpr day operator++(int) noexcept;
    Effects: ++(*this).
    Returns: A copy of *this as it existed on entry to this member function.

    constexpr day& operator--() noexcept;
    Effects: --d_.
    Returns: *this.

    constexpr day operator--(int) noexcept;
    Effects: --(*this).
    Returns: A copy of *this as it existed on entry to this member function.

    constexpr day& operator+=(const days& d) noexcept;
    Effects: *this = *this + d.
    Returns: *this.
constexpr day & operator-=(const days & d) noexcept;

Effects: \this = \this - d.

Returns: \this.

explicit constexpr operator unsigned() const noexcept;

Returns: d_.

constexpr bool ok() const noexcept;

Returns: 1 <= d_ && d_ <= 31.

25.8.3.3 Non-member functions

constexpr bool operator==(const day & x, const day & y) noexcept;

Returns: unsigned{x} == unsigned{y}.

constexpr bool operator<(const day & x, const day & y) noexcept;

Returns: unsigned{x} < unsigned{y}.

constexpr day operator+(const day & x, const days & y) noexcept;

Returns: day(unsigned{x} + y.count()).

constexpr day operator+(const days & x, const day & y) noexcept;

Returns: y + x.

constexpr day operator-(const day & x, const days & y) noexcept;

Returns: x + -y.

constexpr days operator-(const day & x, const day & y) noexcept;

Returns: days{int(unsigned{x}) - int(unsigned{y})}.

template<class charT, class traits>
  basic_ostream<charT, traits>&
  operator<<(basic_ostream<charT, traits>& os, const day& d);

Effects: Inserts format(fmt, d) where fmt is "%d" widened to charT. If !d.ok(), appends with " is not a valid day".

Returns: os.

template<class charT, class traits>
  basic_ostream<charT, traits>&
  to_stream(basic_ostream<charT, traits>& os, const charT* fmt, const day& d);

Effects: Streams d into os using the format specified by the NTCTS fmt. fmt encoding follows the rules specified in 25.11.

Returns: os.

template<class charT, class traits, class Alloc = allocator<charT>>
  basic_istream<charT, traits>&
  from_stream(basic_istream<charT, traits>& is, const charT* fmt, days& d, basic_string<charT, traits, Alloc>* abbrev = nullptr, minutes* offset = nullptr);

Effects: Attempts to parse the input stream is into the day d using the format flags given in the NTCTS fmt as specified in 25.12. If the parse fails to decode a valid day, is.setstate(ios_base::failbit) shall be called and d shall not be modified. If %Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev is non-null. If %Z (or a modified variant) is used and successfully parsed, that value will be assigned to *offset if offset is non-null.

Returns: is.

constexpr day operator"d(unsigned long long d) noexcept;

Returns: day{static_cast<unsigned>(d)}.
25.8.4 Class month

25.8.4.1 Overview

namespace std::chrono {

    class month {
        unsigned char m_;  // exposition only
    public:
        month() = default;
        explicit constexpr month(unsigned m) noexcept;
        constexpr month& operator++() noexcept;
        constexpr month operator++(int) noexcept;
        constexpr month& operator--() noexcept;
        constexpr month operator--(int) noexcept;
        constexpr month& operator+=(const months& m) noexcept;
        constexpr month& operator-=(const months& m) noexcept;
        explicit constexpr operator unsigned() const noexcept;
        constexpr bool ok() const noexcept;
    };
}

1 month represents a month of a year. It normally holds values in the range 1 to 12, but may hold non-negative values outside this range. It can be constructed with any unsigned value, which will be subsequently truncated to fit into month’s unspecified internal storage. month is Cpp17EqualityComparable (Table 22) and Cpp17LessThanComparable (Table 23), and participates in basic arithmetic with months objects, which represent a difference between two month objects.

2 month is a trivially copyable and standard-layout class type.

25.8.4.2 Member functions

explicit constexpr month(unsigned m) noexcept;

1 Effects: Constructs an object of type month by initializing m_ with m. The value held is unspecified if m is not in the range [0, 255].

constexpr month& month::operator++() noexcept;

2 Effects: *this += months{1}.
3 Returns: *this.

constexpr month operator++(int) noexcept;

4 Effects: ++(*this).
5 Returns: A copy of *this as it existed on entry to this member function.

constexpr month& month::operator--() noexcept;

6 Effects: *this -= months{1}.
7 Returns: *this.

constexpr month operator--(int) noexcept;

8 Effects: --(*this).
9 Returns: A copy of *this as it existed on entry to this member function.

constexpr month& month::operator+=(const months& m) noexcept;

10 Effects: *this = *this + m.
11 Returns: *this.

constexpr month& month::operator-=(const months& m) noexcept;

12 Effects: *this = *this - m.
13 Returns: *this.
explicit constexpr month::operator unsigned() const noexcept;

Returns: m_.

constexpr bool month::ok() const noexcept;

Returns: 1 <= m_ && m_ <= 12.

25.8.4.3 Non-member functions

constexpr bool operator==(const month& x, const month& y) noexcept;

Returns: unsigned{x} == unsigned{y}.

constexpr bool operator<(const month& x, const month& y) noexcept;

Returns: unsigned{x} < unsigned{y}.

constexpr month operator+(const month& x, const months& y) noexcept;

Returns: month{modulo(static_cast<long long>(unsigned{x}) + (y.count() - 1), 12) + 1}

where modulo(n, 12) computes the remainder of n divided by 12 using Euclidean division. [Note: Given a divisor of 12, Euclidean division truncates towards negative infinity and always produces a remainder in the range of [0, 11]. Assuming no overflow in the signed summation, this operation results in a month holding a value in the range [1, 12] even if !x.ok(). —end note] [Example: February + months{11} == January. —end example]

constexpr month operator+(const months& x, const month& y) noexcept;

Returns: y + x.

constexpr month operator-(const month& x, const months& y) noexcept;

Returns: x + -y.

constexpr months operator-(const month& x, const month& y) noexcept;

Returns: If x.ok() == true and y.ok() == true, returns a value m in the range [months{0}, months{11}] satisfying y + m == x. Otherwise the value returned is unspecified. [Example: January - February == months{11}. —end example]

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const month& m);

Effects: If m.ok() == true inserts format(os.getloc(), fmt, m) where fmt is "%b" widened to charT. Otherwise inserts unsigned{m} << " is not a valid month".

Returns: os.

template<class charT, class traits>
basic_ostream<charT, traits>&
to_stream(basic_ostream<charT, traits>& os, const charT* fmt, const month& m);

Effects: Streams m into os using the format specified by the NTCTS fmt. fmt encoding follows the rules specified in 25.11.

Returns: os.

template<class charT, class traits, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>& is, const charT* fmt, 
month& m, basic_string<charT, traits, Alloc>* abbrev = nullptr,
minutes* offset = nullptr);

Effects: Attempts to parse the input stream is into the month m using the format flags given in the NTCTS fmt as specified in 25.12. If the parse fails to decode a valid month, is.setstate(ios_base::failbit) shall be called and m shall not be modified. If %Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used and successfully parsed, that value will be assigned to *offset if offset is non-null.

§ 25.8.4.3
25.8.5 Class year

25.8.5.1 Overview

namespace std::chrono {
  class year {
    short y_; // exposition only
    public:
      year() = default;
      explicit constexpr year(int y) noexcept;
      constexpr year& operator++() noexcept;
      constexpr year operator++(int) noexcept;
      constexpr year& operator--() noexcept;
      constexpr year operator--(int) noexcept;
      constexpr year& operator+=(const years& y) noexcept;
      constexpr year& operator-=(const years& y) noexcept;
      constexpr year operator+() const noexcept;
      constexpr year operator-() const noexcept;
      constexpr bool is_leap() const noexcept;
      explicit constexpr operator int() const noexcept;
      constexpr bool ok() const noexcept;
      static constexpr year min() noexcept;
      static constexpr year max() noexcept;
  };
}

1 year represents a year in the civil calendar. It can represent values in the range \([\text{min}(), \text{max}()]\). It can be constructed with any int value, which will be subsequently truncated to fit into year’s unspecified internal storage. year is Cpp17EqualityComparable (Table 22) and Cpp17LessThanComparable (Table 23), and participates in basic arithmetic with years objects, which represent a difference between two year objects.

2 year is a trivially copyable and standard-layout class type.

25.8.5.2 Member functions

explicit constexpr year(int y) noexcept;

1 Effects: Constructs an object of type year by initializing y_ with y. The value held is unspecified if y is not in the range \([-32767, 32767]\).

constexpr year& operator++() noexcept;

2 Effects: ++y_.
3 Returns: *this.

constexpr year operator++(int) noexcept;

4 Effects: ++(*this).
5 Returns: A copy of *this as it existed on entry to this member function.

constexpr year& operator--() noexcept;

6 Effects: --y_.
7 Returns: *this.

constexpr year operator--(int) noexcept;

8 Effects: --(*this).
9 Returns: A copy of *this as it existed on entry to this member function.
constexpr year& operator+=(const years& y) noexcept;
    Effects: *this = *this + y.
    Returns: *this.

constexpr year& operator-=(const years& y) noexcept;
    Effects: *this = *this - y.
    Returns: *this.

constexpr year operator+() const noexcept;
    Returns: *this.

castexpr year::operator-() const noexcept;
    Returns: year{-y_}.

castexpr bool is_leap() const noexcept;
    Returns: y_ % 4 == 0 && (y_ % 100 != 0 || y_ % 400 == 0).

explicit constexpr operator int() const noexcept;
    Returns: y_.

castexpr bool ok() const noexcept;
    Returns: min() <= y_ && y_ <= max().

static constexpr year min() noexcept;
    Returns: year{-32767}.

static constexpr year max() noexcept;
    Returns: year{32767}.

25.8.5.3 Non-member functions

constexpr bool operator==(const year& x, const year& y) noexcept;
    Returns: int{x} == int{y}.

constexpr bool operator<(const year& x, const year& y) noexcept;
    Returns: int{x} < int{y}.

constexpr year operator+(const year& x, const years& y) noexcept;
    Returns: year{int{x} + y.count()}.

constexpr year operator+(const years& x, const year& y) noexcept;
    Returns: y + x.

constexpr year operator-(const year& x, const years& y) noexcept;
    Returns: x + -y.

constexpr years operator-(const year& x, const years& y) noexcept;
    Returns: years{int{x} - int{y}}.

template<class charT, class traits>
    basic_ostream<charT, traits>&
        operator<<(basic_ostream<charT, traits>& os, const year& y);
        Effects: Inserts format(fmt, y) where fmt is "%Y" widened to charT. If !y.ok(), appends with " is not a valid year".
        Returns: os.
template<class charT, class traits>  
basic_ostream<charT, traits>&
  to_stream(basic_ostream<charT, traits>& os, const charT* fmt, const year& y);
9  
Effects: Streams y into os using the format specified by the NTCTS fmt. fmt encoding follows the
rules specified in 25.11.
10  
Returns: os.

template<class charT, class traits, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
  from_stream(basic_istream<charT, traits>& is, const charT* fmt,
year& y, basic_string<charT, traits, Alloc>* abbrev = nullptr,
  minutes* offset = nullptr);
11  
Effects: Attempts to parse the input stream is into the year y using the format flags given in the NTCTS
fmt as specified in 25.12. If the parse fails to decode a valid year, is.setstate(ios_base::failbit)
shall be called and y shall not be modified. If %Z is used and successfully parsed, that value will be
assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used and successfully parsed,
that value will be assigned to *offset if offset is non-null.
12  
Returns: is.

constexpr year operator"y(unsigned long long y) noexcept;
13  
Returns: year{static_cast<int>(y)}.

25.8.6 Class weekday
25.8.6.1 Overview

namespace std::chrono {
  class weekday {
    unsigned char wd_;  // exposition only
  public:
    weekday() = default;
    explicit constexpr weekday(unsigned wd) noexcept;
    constexpr weekday(const sys_days& dp) noexcept;
    explicit constexpr weekday(const local_days& dp) noexcept;
    constexpr weekday& operator++() noexcept;
    constexpr weekday operator++(int) noexcept;
    constexpr weekday& operator--() noexcept;
    constexpr weekday operator--(int) noexcept;
    constexpr weekday& operator+=(const days& d) noexcept;
    constexpr weekday& operator-=(const days& d) noexcept;
    explicit constexpr operator unsigned() const noexcept;
    constexpr bool ok() const noexcept;
    constexpr weekday_indexed operator[](unsigned index) const noexcept;
    constexpr weekday_last operator[](last_spec) const noexcept;
  };

1 weekday represents a day of the week in the civil calendar. It normally holds values in the range 0 to 6,
corresponding to Sunday through Saturday, but it may hold non-negative values outside this range. It
can be constructed with any unsigned value, which will be subsequently truncated to fit into weekday's
unspecified internal storage. weekday is Cpp17EqualityComparable (Table 22). [Note: weekday is not
Cpp17LessThanComparable because there is no universal consensus on which day is the first day of the week.
weekday's arithmetic operations treat the days of the week as a circular range, with no beginning and no
end. — end note]

2 weekday is a trivially copyable and standard-layout class type.
25.8.6.2 Member functions

explicit constexpr weekday(unsigned wd) noexcept;
   Effects: Constructs an object of type weekday by initializing \texttt{wd}_ with \texttt{wd}. The value held is unspecified if \texttt{wd} is not in the range \([0, 255]\).

constexpr weekday(const sys_days& dp) noexcept;
   Effects: Constructs an object of type weekday by computing what day of the week corresponds to the \texttt{sys_days} \texttt{dp}, and representing that day of the week in \texttt{wd}_.
   [Example: If \texttt{dp} represents 1970-01-01, the constructed weekday represents Thursday by storing 4 in \texttt{wd}. — end example]

explicit constexpr weekday(const local_days& dp) noexcept;
   Effects: Constructs an object of type weekday by computing what day of the week corresponds to the \texttt{local_days} \texttt{dp}, and representing that day of the week in \texttt{wd}_.
   Remarks: The value after construction is identical to that constructed from \texttt{sys_days}\texttt{dp.time_ - since_epoch()}.

constexpr weekday& operator++() noexcept;
   Effects: \texttt{*this} += days\{1\}.
   Returns: \texttt{*this}.

constexpr weekday operator++(int) noexcept;
   Effects: \texttt{++(*this)}.
   Returns: A copy of \texttt{*this} as it existed on entry to this member function.

constexpr weekday& operator--() noexcept;
   Effects: \texttt{*this} -= days\{1\}.
   Returns: \texttt{*this}.

constexpr weekday operator--(int) noexcept;
   Effects: \texttt{--(*this)}.
   Returns: A copy of \texttt{*this} as it existed on entry to this member function.

constexpr weekday& operator+=(const days& d) noexcept;
   Effects: \texttt{*this} = \texttt{*this} + d.
   Returns: \texttt{*this}.

constexpr weekday& operator-=(const days& d) noexcept;
   Effects: \texttt{*this} = \texttt{*this} - d.
   Returns: \texttt{*this}.

explicit constexpr operator unsigned() const noexcept;
   Returns: \texttt{wd}_.

constexpr bool ok() const noexcept;
   Returns: \texttt{wd}_ <= 6.

constexpr weekday_indexed operator[](unsigned index) const noexcept;
   Returns: \{	exttt{*this}, index\}.

constexpr weekday_last operator[](last_spec) const noexcept;
   Returns: weekday_last\{\texttt{*this}\}.
25.8.6.3 Non-member functions

constexpr bool operator==(const weekday& x, const weekday& y) noexcept;

Returns: unsigned{x} == unsigned{y}.

constexpr weekday operator+(const weekday& x, const days& y) noexcept;

Returns:
weekday(modulo(static_cast<long long>(unsigned{x}) + y.count(), 7))
where modulo(n, 7) computes the remainder of n divided by 7 using Euclidean division. [Note: Given a divisor of 7, Euclidean division truncates towards negative infinity and always produces a remainder in the range of [0, 6]. Assuming no overflow in the signed summation, this operation results in a weekday holding a value in the range [0, 6] even if !x.ok(). — end note] [Example: Monday + days{6} == Sunday. — end example]

constexpr weekday operator+(const days& x, const weekday& y) noexcept;

Returns: y + x.

constexpr weekday operator-(const weekday& x, const days& y) noexcept;

Returns: x + -y.

constexpr days operator-(const weekday& x, const weekday& y) noexcept;

Returns: If x.ok() == true and y.ok() == true, returns a value d in the range [days{0}, days{6}] satisfying y + d == x. Otherwise the value returned is unspecified. [Example: Sunday - Monday == days{6}. — end example]

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const weekday& wd);

Effects: If wd.ok() == true inserts format(os.getloc(), fmt, wd) where fmt is "%a" widened to charT. Otherwise inserts unsigned{wd} << " is not a valid weekday".

Returns: os.

template<class charT, class traits>
basic_ostream<charT, traits>&
to_stream(basic_ostream<charT, traits>& os, const charT* fmt, const weekday& wd);

Effects: Streams wd into os using the format specified by the NTCTS fmt. fmt encoding follows the rules specified in 25.11.

Returns: os.

template<class charT, class traits, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>&& is, const charT* fmt, const weekday& wd, basic_string<charT, traits, Alloc>* abbrev = nullptr, minutes* offset = nullptr);

Effects: Attempts to parse the input stream is into the weekday wd using the format flags given in the NTCTS fmt as specified in 25.12. If the parse fails to decode a valid weekday, is.setstate(ios_base::failbit) shall be called and wd shall not be modified. If %Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used and successfully parsed, that value will be assigned to *offset if offset is non-null.

Returns: is.

25.8.7 Class weekday_indexed

25.8.7.1 Overview
namespace std::chrono {

class weekday_indexed {
    chrono::weekday wd_; // exposition only
    unsigned char index_; // exposition only
}
public:
    weekday_indexed() = default;
    constexpr weekday_indexed(const chrono::weekday& wd, unsigned index) noexcept;
    constexpr chrono::weekday weekday() const noexcept;
    constexpr unsigned index() const noexcept;
    constexpr bool ok() const noexcept;
};

1 `weekday_indexed` represents a `weekday` and a small index in the range 1 to 5. This class is used to represent the first, second, third, fourth, or fifth weekday of a month.

2 [Note: A `weekday_indexed` object can be constructed by indexing a `weekday` with an `unsigned`. — end note] [Example:
    ```cpp
    constexpr auto wdi = Sunday[2]; // wdi is the second Sunday of an as yet unspecified month
    static_assert(wdi.weekday() == Sunday);
    static_assert(wdi.index() == 2);
    —end example]

3 `weekday_indexed` is a trivially copyable and standard-layout class type.

25.8.7.2 Member functions [time.cal.wdidx.members]
```cpp
constexpr weekday_indexed(const chrono::weekday& wd, unsigned index) noexcept;
```
1 Effects: Constructs an object of type `weekday_indexed` by initializing `wd_` with `wd` and `index_` with `index`. The values held are unspecified if `!wd.ok()` or `index` is not in the range `[1, 5]`.

```cpp
constexpr chrono::weekday weekday() const noexcept;
```
2 Returns: `wd_`.

```cpp
constexpr unsigned index() const noexcept;
```
3 Returns: `index_`.

```cpp
constexpr bool ok() const noexcept;
```
4 Returns: `wd_.ok() && 1 <= index_ && index_ <= 5`.

25.8.7.3 Non-member functions [time.cal.wdidx.nonmembers]
```cpp
constexpr bool operator==(const weekday_indexed& x, const weekday_indexed& y) noexcept;
```
1 Returns: `x.weekday() == y.weekday() && x.index() == y.index()`.

```cpp
template<class charT, class traits>
basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& os, const weekday_indexed& wdi);
```
2 Effects: `os << wdi.weekday() << '[' << wdi.index(). If wdi.index() is in the range `[1, 5]`, appends with ']', otherwise appends with " is not a valid index".

3 Returns: `os`.

25.8.8 Class weekday_last [time.cal.wdlast]
25.8.8.1 Overview [time.cal.wdlast.overview]
```cpp
namespace std::chrono {
    class weekday_last {
        chrono::weekday wd_;  // exposition only

        public:
            explicit constexpr weekday_last(const chrono::weekday& wd) noexcept;

            constexpr chrono::weekday weekday() const noexcept;
            constexpr bool ok() const noexcept;
    };
}
```

§ 25.8.8.1 1064
weekday_last represents the last weekday of a month.

[Note: A weekday_last object can be constructed by indexing a weekday with last. — end note] [Example:
constexpr auto wdl = Sunday[last]; // wdl is the last Sunday of an as yet unspecified month
static_assert(wdl.weekday() == Sunday);
— end example]

weekday_last is a trivially copyable and standard-layout class type.

25.8.8.2 Member functions

explicit constexpr weekday_last(const chrono::weekday& wd) noexcept;
1 Effects: Constructs an object of type weekday_last by initializing wd_ with wd.

constexpr chrono::weekday weekday() const noexcept;
2 Returns: wd_.

constexpr bool ok() const noexcept;
3 Returns: wd_.ok().

25.8.8.3 Non-member functions

constexpr bool operator==(const weekday_last& x, const weekday_last& y) noexcept;
1 Returns: x.weekday() == y.weekday().

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const weekday_last& wdl);
2 Returns: os << wdl.weekday() << "[last]".

25.8.9 Class month_day

25.8.9.1 Overview

namespace std::chrono {

class month_day {
    chrono::month m_; // exposition only
    chrono::day d_; // exposition only

public:
    month_day() = default;
    constexpr month_day(const chrono::month& m, const chrono::day& d) noexcept;

    constexpr chrono::month month() const noexcept;
    constexpr chrono::day day() const noexcept;
    constexpr bool ok() const noexcept;

};
}

month_day represents a specific day of a specific month, but with an unspecified year. month_day is Cpp17EqualityComparable (Table 22) and Cpp17LessThanComparable (Table 23).

month_day is a trivially copyable and standard-layout class type.

25.8.9.2 Member functions

constexpr month_day(const chrono::month& m, const chrono::day& d) noexcept;
1 Effects: Constructs an object of type month_day by initializing m_ with m, and d_ with d.

constexpr chrono::month month() const noexcept;
2 Returns: m_.

constexpr chrono::day day() const noexcept;
3 Returns: d_.
constexpr bool ok() const noexcept;

Returns: true if m_.ok() is true, 1d <= d_, and d_ is less than or equal to the number of days in month m_; otherwise returns false. When m_ == February, the number of days is considered to be 29.

25.8.9.3 Non-member functions

constexpr bool operator==(const month_day& x, const month_day& y) noexcept;

Returns: x.month() == y.month() && x.day() == y.day().

constexpr bool operator<(const month_day& x, const month_day& y) noexcept;

Returns: If x.month() < y.month() returns true. Otherwise, if x.month() > y.month() returns false. Otherwise, returns x.day() < y.day().

template<class charT, class traits>
  basic_ostream<charT, traits>&
      operator<<(basic_ostream<charT, traits>& os, const month_day& md);

Returns: os << md.month() << '/' << md.day().

template<class charT, class traits>
  basic_ostream<charT, traits>&
      to_stream(basic_ostream<charT, traits>& os, const charT* fmt, const month_day& md);

Effects: Streams md into os using the format specified by the NTCTS fmt. fmt encoding follows the rules specified in 25.11.

Returns: os.

template<class charT, class traits, class Alloc = allocator<charT>>
  basic_istream<charT, traits>&
      from_stream(basic_istream<charT, traits>& is, const charT* fmt, month_day& md, basic_string<charT, traits, Alloc>* abbrev = nullptr, minutes* offset = nullptr);

Effects: Attempts to parse the input stream is into the month_day md using the format flags given in the NTCTS fmt as specified in 25.12. If the parse fails to decode a valid month_day, is.setstate(ios_base::failbit) shall be called and md shall not be modified. If %Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used and successfully parsed, that value will be assigned to *offset if offset is non-null.

Returns: is.

25.8.10 Class month_day_last

namespace std::chrono {
  class month_day_last {
    chronon::month m_; // exposition only

  public:
    explicit constexpr month_day_last(const chronon::month& m) noexcept;

    constexpr chronon::month month() const noexcept;
    constexpr bool ok() const noexcept;

  };
}

1 month_day_last represents the last day of a month.

2 [Note: A month_day_last object can be constructed using the expression m/last or last/m, where m is an expression of type month. — end note] [Example:
    constexpr auto mdl = February/last; // mdl is the last day of February of an as yet unspecified year
    static_assert(mdl.month() == February);
    — end example]

3 month_day_last is a trivially copyable and standard-layout class type.
explicit constexpr month_day_last(const chrono::month& m) noexcept;

  \textit{Effects:} Constructs an object of type \texttt{month\_day\_last} by initializing \texttt{m} with \texttt{m}.

constexpr month month() const noexcept;

  \textit{Returns:} \texttt{m}.

constexpr bool ok() const noexcept;

  \textit{Returns:} \texttt{m\_ok}.

constexpr bool operator==(const month_day_last& x, const month_day_last& y) noexcept;

  \textit{Returns:} \texttt{x.month()} == \texttt{y.month}().

constexpr bool operator<(const month_day_last& x, const month_day_last& y) noexcept;

  \textit{Returns:} \texttt{x.month()} < \texttt{y.month}().

```cpp
template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const month_day_last& mdl);
```

  \textit{Returns:} \texttt{os << mdl.month()} << "/last".

### 25.8.11 Class \texttt{month\_weekday} [time.cal.mwd]

#### 25.8.11.1 Overview [time.cal.mwd.overview]

```cpp
namespace std::chrono {
  class month_weekday {
    chrono::month m_; // exposition only
    chrono::weekday_indexed wdi_; // exposition only
  public:
    constexpr month_weekday(const chrono::month& m, const chrono::weekday_indexed& wdi) noexcept;
    constexpr month month() const noexcept;
    constexpr weekday_indexed weekday_indexed() const noexcept;
    constexpr bool ok() const noexcept;
  }
}
```

\texttt{month\_weekday} represents the \texttt{n}th weekday of a month, of an as yet unspecified year. To do this the \texttt{month\_weekday} stores a \texttt{month} and a \texttt{weekday\_indexed}.

[Example:
```
castexpr auto mwd = February/Tuesday[3]; // mwd is the third Tuesday of February of an as yet unspecified year
static_assert(mwd.month() == February);
static_assert(mwd.weekday_indexed() == Tuesday[3]);
```
]

\texttt{month\_weekday} is a trivially copyable and standard-layout class type.

#### 25.8.11.2 Member functions [time.cal.mwd.members]

```cpp
constexpr month_weekday(const chrono::month& m, const chrono::weekday_indexed& wdi) noexcept;
```

  \textit{Effects:} Constructs an object of type \texttt{month\_weekday} by initializing \texttt{m} with \texttt{m}, and \texttt{wdi} with \texttt{wdi}.

```cpp
constexpr chrono::month month() const noexcept;
```

  \textit{Returns:} \texttt{m}.

```cpp
constexpr chrono::weekday_indexed weekday_indexed() const noexcept;
```

  \textit{Returns:} \texttt{wdi}.

```cpp
constexpr bool ok() const noexcept;
```

  \textit{Returns:} \texttt{m\_ok} && \texttt{wdi\_ok}.
25.8.11.3 Non-member functions

constexpr bool operator==(const month_weekday& x, const month_weekday& y) noexcept;
1  Returns: x.month() == y.month() && x.weekday_indexed() == y.weekday_indexed().

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const month_weekday& mwd);
2  Returns: os << mwd.month() << '/' << mwd.weekday_indexed().

25.8.12 Class month_weekday_last

25.8.12.1 Overview

namespace std::chrono {
    class month_weekday_last {
        chrono::month m_;  // exposition only
        chrono::weekday_last wdl_;  // exposition only
    public:
        constexpr month_weekday_last(const chrono::month& m,
                                   const chrono::weekday_last& wdl) noexcept;
        constexpr chrono::month month() const noexcept;
        constexpr chrono::weekday_last weekday_last() const noexcept;
        constexpr bool ok() const noexcept;
    }
};

1 month_weekday_last represents the last weekday of a month, of an as yet unspecified year. To do this the
month_weekday_last stores a month and a weekday_last.

2 [Example:
    constexpr auto mwd
        = February/Tuesday[last];  // mwd is the last Tuesday of February of an as yet unspecified year
    static_assert(mwd.month() == February);
    static_assert(mwd.weekday_last() == Tuesday[last]);
    — end example]

3 month_weekday_last is a trivially copyable and standard-layout class type.

25.8.12.2 Member functions

constexpr month_weekday_last(const chrono::month& m,
                             const chrono::weekday_last& wdl) noexcept;
1  Effects: Constructs an object of type month_weekday_last by initializing m_ with m, and wdl_ with wdl.

constexpr chrono::month month() const noexcept;
2  Returns: m_.

constexpr chrono::weekday_last weekday_last() const noexcept;
3  Returns: wdl_.

constexpr bool ok() const noexcept;
4  Returns: m_.ok() && wdl_.ok().

25.8.12.3 Non-member functions

constexpr bool operator==(const month_weekday_last& x, const month_weekday_last& y) noexcept;
1  Returns: x.month() == y.month() && x.weekday_last() == y.weekday_last().
template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const month_weekday_last& mwdl);

Returns: os \ll mwdl.month() \ll '/' \ll mwdl.weekday_last().

25.8.13 Class year_month

25.8.13.1 Overview

namespace std::chrono {

class year_month {
    chrono::year y_;       // exposition only
    chrono::month m_;       // exposition only

public:
    year_month() = default;
    constexpr year_month(const chrono::year& y, const chrono::month& m) noexcept;
    constexpr chrono::year year() const noexcept;
    constexpr chrono::month month() const noexcept;
    constexpr year_month& operator+=(const months& dm) noexcept;
    constexpr year_month& operator-=(const months& dm) noexcept;
    constexpr year_month& operator+=(const years& dy) noexcept;
    constexpr year_month& operator-=(const years& dy) noexcept;
    constexpr bool ok() const noexcept;
};
}

1 year_month represents a specific month of a specific year, but with an unspecified day. year_month is a
field-based time point with a resolution of months. year_month is Cpp17EqualityComparable (Table 22) and
Cpp17LessThanComparable (Table 23).

2 year_month is a trivially copyable and standard-layout class type.

25.8.13.2 Member functions

constexpr year_month(const chrono::year& y, const chrono::month& m) noexcept;

Effects: Constructs an object of type year_month by initializing y_ with y, and m_ with m.

constexpr chrono::year year() const noexcept;

Returns: y_.

constexpr chrono::month month() const noexcept;

Returns: m_.

constexpr year_month& operator+=(const months& dm) noexcept;

Effects: *this = *this + dm.

Returns: *this.

constexpr year_month& operator-=(const months& dm) noexcept;

Effects: *this = *this - dm.

Returns: *this.

constexpr year_month& operator+=(const years& dy) noexcept;

Effects: *this = *this + dy.

Returns: *this.

constexpr year_month& operator-=(const years& dy) noexcept;

Effects: *this = *this - dy.

Returns: *this.
constexpr bool ok() const noexcept;

Returns: \( y_.ok() \&\& m_.ok() \).

25.8.13.3 Non-member functions

constexpr bool operator==(const year_month& x, const year_month& y) noexcept;

Returns: \( x\cdot year() == y\cdot year() \&\& x\cdot month() == y\cdot month() \).

constexpr bool operator<(const year_month& x, const year_month& y) noexcept;

Returns: If \( x\cdot year() < y\cdot year() \) returns `true`. Otherwise, if \( x\cdot year() > y\cdot year() \) returns `false`. Otherwise, returns \( x\cdot month() < y\cdot month() \).

constexpr year_month operator+(const year_month& ym, const months& dm) noexcept;

Returns: A `year_month` value \( z \) such that \( z - ym == dm \).

Complexity: \( \Theta(1) \) with respect to the value of \( dm \).

constexpr year_month operator+(const months& dm, const year_month& ym) noexcept;

Returns: \( ym + dm \).

constexpr year_month operator-(const year_month& ym, const months& dm) noexcept;

Returns: \( ym + -dm \).

constexpr months operator-(const year_month& x, const year_month& y) noexcept;

Returns:
\[
\begin{align*}
& x\cdot year() - y\cdot year() + \text{months}\left(\text{static\_cast<string>}(\text{unsigned}(x\cdot month()))\right) - \\
& \text{static\_cast<string>}(\text{unsigned}(y\cdot month()))\right)
\end{align*}
\]

constexpr year_month operator+(const year_month& ym, const years& dy) noexcept;

Returns: \( (ym\cdot year() + dy) / ym\cdot month() \).

constexpr year_month operator+(const years& dy, const year_month& ym) noexcept;

Returns: \( ym + dy \).

constexpr year_month operator-(const year_month& ym, const years& dy) noexcept;

Returns: \( ym + -dy \).

template<class charT, class traits>

basic_ostream<charT, traits>&

operator<<(basic_ostream<charT, traits>& os, const year_month& ym);

Returns: \( os << ym\cdot year() << '/' << ym\cdot month() \).

template<class charT, class traits>

basic_ostream<charT, traits>&

to_stream(basic_ostream<charT, traits>& os, const charT* fmt, const year_month& ym);

Effects: Streams \( ym \) into \( os \) using the format specified by the NTCTS \( fmt \). \( fmt \) encoding follows the rules specified in 25.11.

Returns: \( os \).

template<class charT, class traits, class Alloc = allocator<charT>>

basic_istream<charT, traits>&

from_stream(basic_istream<charT, traits>& is, const charT* fmt, 

year_month& ym, basic_string<charT, traits, Alloc>* abbrev = nullptr,

minutes* offset = nullptr);

Effects: Attempts to parse the input stream \( is \) into the `year_month` \( ym \) using the format flags given in the NTCTS \( fmt \) as specified in 25.12. If the parse fails to decode a valid `year_month`, \( is\cdotsetstate(io\_base::failbit) \) shall be called and \( ym \) shall not be modified. If `%Z` is used and successfully parsed, that value will be assigned to `*abbrev` if `abbrev` is non-null. If `%z` (or a modified variant) is used and successfully parsed, that value will be assigned to `*offset` if `offset` is non-null.
25.8.14 Class year_month_day

25.8.14.1 Overview

namespace std::chrono {
    class year_month_day {
        chrono::year y_;      // exposition only
        chrono::month m_;     // exposition only
        chrono::day d_;       // exposition only

        public:
            year_month_day() = default;
            constexpr year_month_day(const chrono::year& y, const chrono::month& m,
                               const chrono::day& d) noexcept;
            constexpr year_month_day(const year_month_day_last& ymdl) noexcept;
            constexpr year_month_day(const sys_days& dp) noexcept;
            explicit constexpr year_month_day(const local_days& dp) noexcept;

            constexpr year_month_day& operator+=(const months& m) noexcept;
            constexpr year_month_day& operator-=(const months& m) noexcept;
            constexpr year_month_day& operator+=(const years& y) noexcept;
            constexpr year_month_day& operator-=(const years& y) noexcept;

            constexpr chrono::year year() const noexcept;
            constexpr chrono::month month() const noexcept;
            constexpr chrono::day day() const noexcept;
            constexpr operator sys_days() const noexcept;
            explicit constexpr operator local_days() const noexcept;

            constexpr bool ok() const noexcept;
    }
};

1. `year_month_day` represents a specific year, month, and day. `year_month_day` is a field-based time point
   with a resolution of `days`. [Note: `year_month_day` supports `years`- and `months`-oriented arithmetic, but not
   `days`-oriented arithmetic. For the latter, there is a conversion to `sys_days`, which efficiently supports
   `days`-oriented arithmetic. —end note] `year_month_day` is `Cpp17EqualityComparable` (Table 22) and
   `Cpp17LessThanComparable` (Table 23),

2. `year_month_day` is a trivially copyable and standard-layout class type.

25.8.14.2 Member functions

constexpr year_month_day(const chrono::year& y, const chrono::month& m,
                               const chrono::day& d) noexcept;

1. **Effects:** Constructs an object of type `year_month_day` by initializing `y` with `y`, `m` with `m`, and `d` with `d`.

constexpr year_month_day(const year_month_day_last& ymdl) noexcept;

2. **Effects:** Constructs an object of type `year_month_day` by initializing `y` with `ymdl.year()`, `m` with
   `ymdl.month()`, and `d` with `ymdl.day()`. [Note: This conversion from `year_month_day_last` to
   `year_month_day` may be more efficient than converting a `year_month_day_last` to a `sys_days`, and
   then converting that `sys_days` to a `year_month_day`. —end note]

constexpr year_month_day(const sys_days& dp) noexcept;

3. **Effects:** Constructs an object of type `year_month_day` that corresponds to the date represented by `dp`.

   Remarks: For any value `ymd` of type `year_month_day` for which `ymd.ok()` is true, `ymd == year_month_day(sys_days{ymd})` is true.

explicit constexpr year_month_day(const local_days& dp) noexcept;

4. **Effects:** Constructs an object of type `year_month_day` that corresponds to the date represented by `dp`.

   Remarks: Equivalent to constructing with `sys_days{dp.time_since_epoch()}`.
constexpr year_month_day& operator+=(const months& m) noexcept;

Effects: *this = *this + m.
Returns: *this.

constexpr year_month_day& operator-=(const months& m) noexcept;

Effects: *this = *this - m.
Returns: *this.

constexpr year_month_day& year_month_day::operator+=(const years& y) noexcept;

Effects: *this = *this + y.
Returns: *this.

constexpr year_month_day& year_month_day::operator-=(const years& y) noexcept;

Effects: *this = *this - y.
Returns: *this.

constexpr chrono::year year() const noexcept;
Returns: y_

constexpr chrono::month month() const noexcept;
Returns: m_

constexpr chrono::day day() const noexcept;
Returns: d_

constexpr operator sys_days() const noexcept;
Returns: If ok(), returns a sys_days holding a count of days from the sys_days epoch to *this (a negative value if *this represents a date prior to the sys_days epoch). Otherwise, if y_.ok() & m_.ok() is true, returns a sys_days which is offset from sys_days{y_/m_/last}.day() by the number of days d is offset from sys_days{y_/m_/last}.day(). Otherwise the value returned is unspecified.
Remarks: A sys_days in the range [days{-12687428}, days{11248737}] which is converted to a year_month_day shall have the same value when converted back to a sys_days.

[Example:
static_assert(year_month_day{sys_days{2017y/January/0}} == 2016y/December/31);
static_assert(year_month_day{sys_days{2017y/January/31}} == 2017y/January/31);
static_assert(year_month_day{sys_days{2017y/January/32}} == 2017y/February/1);
—end example]

explicit constexpr operator local_days() const noexcept;
Returns: local_days{sys_days{*this}.time_since_epoch()}. 

constexpr bool ok() const noexcept;
Returns: If y_.ok() is true, and m_.ok() is true, and d is in the range [1d, (y_/m_/last).day()], then returns true; otherwise returns false.

25.8.14.3 Non-member functions [time.cal.ymd.nonmembers]

constexpr bool operator==(const year_month_day& x, const year_month_day& y) noexcept;

Returns: x.year() == y.year() && x.month() == y.month() && x.day() == y.day().

constexpr bool operator<(const year_month_day& x, const year_month_day& y) noexcept;

Returns: If x.year() < y.year(), returns true. Otherwise, if x.year() > y.year(), returns false. Otherwise, if x.month() < y.month(), returns true. Otherwise, if x.month() > y.month(), returns false. Otherwise, returns x.day() < y.day().
constexpr year_month_day operator+(const year_month_day& ymd, const months& dm) noexcept;

Returns: (ymd.year() / ymd.month() + dm) / ymd.day().

[Note: If ymd.day() is in the range [1d, 28d], ok() will return true for the resultant year_month_day.
—end note]

constexpr year_month_day operator+(const months& dm, const year_month_day& ymd) noexcept;

Returns: ymd + dm.

constexpr year_month_day operator+(const year_month_day& ymd, const years& dy) noexcept;

Returns: (ymd.year() + dy) / ymd.month() / ymd.day().

[Note: If ymd.month() is February and ymd.day() is not in the range [1d, 28d], ok() may return false for the resultant year_month_day.
—end note]

Note: If ymd.month() is February and ymd.day() is not in the range [1d, 28d], ok() may return false for the resultant year_month_day.
—end note]

Note: If ymd.month() is February and ymd.day() is not in the range [1d, 28d], ok() may return false for the resultant year_month_day.
—end note]

constexpr year_month_day operator-(const years& dy, const year_month_day& ymd) noexcept;

Returns: ymd + dy.

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const year_month_day& ymd);

Effects: Inserts format(fmt, ymd) where fmt is "%F" widened to charT. If !ymd.ok(), appends with " is not a valid date".

Returns: os.

template<class charT, class traits>
basic_ostream<charT, traits>&
to_stream(basic_ostream<charT, traits>& os, const charT* fmt, const year_month_day& ymd);

Effects: Streams ymd into os using the format specified by the NTCTS fmt. fmt encoding follows the rules specified in 25.11.

Returns: os.

template<class charT, class traits, class Alloc = allocator<charT>>
basic_istream<charT, traits>&
from_stream(basic_istream<charT, traits>& is, const charT* fmt, year_month_day& ymd, basic_string<charT, traits, Alloc>* abbrev = nullptr, minutes* offset = nullptr);

Effects: Attempts to parse the input stream is into the year_month_day ymd using the format flags given in the NTCTS fmt as specified in 25.12. If the parse fails to decode a valid year_month_day, is.setstate(ios_base::failbit) shall be called and ymd shall not be modified. If %Z is used and successfully parsed, that value will be assigned to *abbrev if abbrev is non-null. If %z (or a modified variant) is used and successfully parsed, that value will be assigned to *offset if offset is non-null.

Returns: is.

25.8.15 Class year_month_day_last
25.8.15.1 Overview
public:
constexpr year_month_day_last(const chrono::year& y,
const chrono::month_day_last& mdl) noexcept;

constexpr year_month_day_last& operator+=(const months& m) noexcept;
constexpr year_month_day_last& operator-=(const months& m) noexcept;
constexpr year_month_day_last& operator+=(const years& y) noexcept;
constexpr year_month_day_last& operator-=(const years& y) noexcept;

constexpr chrono::year year() const noexcept;
constexpr chrono::month month() const noexcept;
constexpr chrono::month_day_last month_day_last() const noexcept;
constexpr chrono::day day() const noexcept;
constexpr operator sys_days() const noexcept;
explicit constexpr operator local_days() const noexcept;
constexpr bool ok() const noexcept;

};

year_month_day_last represents the last day of a specific year and month. year_month_day_last is a
field-based time point with a resolution of days, except that it is restricted to pointing to the last day
of a year and month. [Note: year_month_day_last supports years- and months-oriented arithmetic, but
not days-oriented arithmetic. For the latter, there is a conversion to sys_days, which efficiently supports
days-oriented arithmetic. — end note] year_month_day_last is Cpp17EqualityComparable (Table 22) and
Cpp17LessThanComparable (Table 23).

year_month_day_last is a trivially copyable and standard-layout class type.

25.8.15.2 Member functions

castexpr year_month_day_last(const chrono::year& y,
const chrono::month_day_last& mdl) noexcept;

Effects: Constructs an object of type year_month_day_last by initializing y_ with y and mdl_ with
mdl.

castexpr year_month_day_last& operator+=(const months& m) noexcept;

Effects: *this = *this + m.

Returns: *this.

castexpr year_month_day_last& operator-=(const months& m) noexcept;

Effects: *this = *this - m.

Returns: *this.

castexpr year_month_day_last& operator+=(const years& y) noexcept;

Effects: *this = *this + y.

Returns: *this.

castexpr year_month_day_last& operator-=(const years& y) noexcept;

Effects: *this = *this - y.

Returns: *this.

castexpr chrono::year year() const noexcept;

Returns: y_.

castexpr chrono::month month() const noexcept;

Returns: mdl_.month().

castexpr chrono::month_day_last month_day_last() const noexcept;

Returns: mdl_.

§ 25.8.15.2
constexpr chrono::day day() const noexcept;

Returns: A day representing the last day of the (year, month) pair represented by *this.

[Note: This value may be computed on demand. —end note]

constexpr operator sys_days() const noexcept;

Returns: sys_days{year()/month()/day()}. explicit constexpr operator local_days() const noexcept;

Returns: local_days{sys_days{*this}.time_since_epoch()}. constexpr bool ok() const noexcept;

Returns: y_.ok() && mdl_.ok().

25.8.15.3 Non-member functions

constexpr bool operator==(const year_month_day_last& x, const year_month_day_last& y) noexcept;

Returns: x.year() == y.year() && x.month_day_last() == y.month_day_last().

constexpr bool operator<(const year_month_day_last& x, const year_month_day_last& y) noexcept;

Returns: If x.year() < y.year(), returns true. Otherwise, if x.year() > y.year(), returns false. Otherwise, returns x.month_day_last() < y.month_day_last().

constexpr year_month_day_last
operator+(const year_month_day_last& ymdl, const months& dm) noexcept;

Returns: (ymdl.year() / ymdl.month() + dm) / last.

constexpr year_month_day_last
operator+(const months& dm, const year_month_day_last& ymdl) noexcept;

Returns: ymdl + dm.

constexpr year_month_day_last
operator-(const year_month_day_last& ymdl, const months& dm) noexcept;

Returns: ymdl + (-dm).

constexpr year_month_day_last
operator+(const years& dy, const year_month_day_last& ymdl) noexcept;

Returns: ymdl + dy.

25.8.16 Class year_month_weekday

25.8.16.1 Overview

namespace std::chrono {

class year_month_weekday {

    chrono::year y_;       // exposition only
    chrono::month m_;       // exposition only
    chrono::weekday_indexed wdi_;  // exposition only

     template<class charT, class traits>
    basic_ostream<charT, traits>&
    operator<<(basic_ostream<charT, traits>& os, const year_month_day_last& ymdl);

    Returns: os << ymdl.year() << '/' << ymdl.month_day_last().

} // namespace std::chrono

} // std::chrono

§ 25.8.16.1
public:
    year_month_weekday() = default;
    constexpr year_month_weekday(const chrono::year& y, const chrono::month& m,
        const chrono::weekday_indexed& wdi) noexcept;
    constexpr year_month_weekday(const sys_days& dp) noexcept;
    explicit constexpr year_month_weekday(const local_days& dp) noexcept;
    constexpr year_month_weekday& operator+=(const months& m) noexcept;
    constexpr year_month_weekday& operator-=(const months& m) noexcept;
    constexpr year_month_weekday& operator+=(const years& y) noexcept;
    constexpr year_month_weekday& operator-=(const years& y) noexcept;
    constexpr chrono::year year() const noexcept;
    constexpr chrono::month month() const noexcept;
    constexpr chrono::weekday weekday() const noexcept;
    constexpr unsigned index() const noexcept;
    constexpr chrono::weekday_indexed weekday_indexed() const noexcept;
    constexpr operator sys_days() const noexcept;
    explicit constexpr operator local_days() const noexcept;
    constexpr bool ok() const noexcept;
};

1 year_month_weekday represents a specific year, month, and \( n \)th weekday of the month. year_month_weekday is a field-based time point with a resolution of days. \[Note: year_month_weekday supports years- and months-oriented arithmetic, but not days-oriented arithmetic. For the latter, there is a conversion to sys_days, which efficiently supports days-oriented arithmetic. — end note\] year_month_weekday is \Cpp17EqualityComparable (Table 22).

2 year_month_weekday is a trivially copyable and standard-layout class type.

25.8.16.2 Member functions

1 constexpr year_month_weekday(const chrono::year& y, const chrono::month& m,
    const chrono::weekday_indexed& wdi) noexcept;

   Effects: Constructs an object of type year_month_weekday by initializing y_ with y, m_ with m, and wdi_ with wdi.

2 constexpr year_month_weekday(const sys_days& dp) noexcept;

   Effects: Constructs an object of type year_month_weekday which corresponds to the date represented by dp.

3 Remarks: For any value ymdl of type year_month_weekday for which ymdl.ok() is true, ymdl == year_month_weekday{sys_days{ymdl}} is true.

4 explicit constexpr year_month_weekday(const local_days& dp) noexcept;

   Effects: Constructs an object of type year_month_weekday that corresponds to the date represented by dp.

5 Remarks: Equivalent to constructing with sys_days{dp.time_since_epoch()}.

6 constexpr year_month_weekday& operator+=(const months& m) noexcept;

   Effects: *this = *this + m.

7 Returns: *this.

8 constexpr year_month_weekday& operator-=(const months& m) noexcept;

   Effects: *this = *this - m.

9 Returns: *this.

10 constexpr year_month_weekday& operator+=(const years& y) noexcept;

   Effects: *this = *this + y.
Returns: *this.

constexpr year_month_weekday& operator-=(const years& y) noexcept;

Effects: *this = *this - y.

Returns: *this.

constexpr chrono::year year() const noexcept;

Returns: y_.

constexpr chrono::month month() const noexcept;

Returns: m_.

constexpr chrono::weekday weekday() const noexcept;

Returns: wdi_.weekday().

constexpr unsigned index() const noexcept;

Returns: wdi_.index().

constexpr chrono::weekday_indexed weekday_indexed() const noexcept;

constexpr operator sys_days() const noexcept;
template<class charT, class traits>
basic_ostream<charT, traits>& 
operator<<(basic_ostream<charT, traits>& os, const year_month_weekday& ymwd);

Returns: os << ymwdi.year() << '/' << ymwdi.month() << '/' << ymwdi.weekday_indexed().

25.8.17 Class year_month_weekday_last

25.8.17.1 Overview

namespace std::chrono {
    class year_month_weekday_last {
    private:
        chrono::year y_;  // exposition only
        chrono::month m_;  // exposition only
        chrono::weekday_last wdl_;  // exposition only
    public:
        constexpr year_month_weekday_last(const chrono::year& y, const chrono::month& m, 
                                           const chrono::weekday_last& wdl) noexcept;
        constexpr year_month_weekday_last& operator+=(const months& m) noexcept;
        constexpr year_month_weekday_last& operator-=(const months& m) noexcept;
        constexpr year_month_weekday_last& operator+=(const years& y) noexcept;
        constexpr year_month_weekday_last& operator-=(const years& y) noexcept;
        constexpr chrono::year year() const noexcept;
        constexpr chrono::month month() const noexcept;
        constexpr chrono::weekday weekday() const noexcept;
        constexpr chrono::weekday_last weekday_last() const noexcept;
        constexpr operator sys_days() const noexcept;
        explicit constexpr operator local_days() const noexcept;
        constexpr bool ok() const noexcept;
    };
};

1 year_month_weekday_last represents a specific year, month, and last weekday of the month. year_-
month_weekday_last is a field-based time point with a resolution of days, except that it is restricted to 
pointing to the last weekday of a year and month. [Note: year_month_weekday_last supports years-
and months-oriented arithmetic, but not days-oriented arithmetic. For the latter, there is a conversion to 
sys_days, which efficiently supports days-oriented arithmetic. — end note] year_month_weekday_last is 
Cpp17EqualityComparable (Table 22).

25.8.17.2 Member functions

1 year_month_weekday_last is a trivially copyable and standard-layout class type.

constexpr year_month_weekday_last(const chrono::year& y, const chrono::month& m, 
                                   const chrono::weekday_last& wdl) noexcept;

2 Effects: Constructs an object of type year_month_weekday_last by initializing y_ with y, m_ with m, 
            and wdl_ with wdl.

constexpr year_month_weekday_last& operator+=(const months& m) noexcept;

3 Effects: *this = *this + m.

4 Returns: *this.

constexpr year_month_weekday_last& operator-=(const months& m) noexcept;

5 Effects: *this = *this - m.

6 Returns: *this.

constexpr year_month_weekday_last& operator+=(const years& y) noexcept;

7 Effects: *this = *this + y.

8 Returns: *this.
constexpr year_month_weekday_last& operator-=(const years& y) noexcept;

Effects: *this = *this - y.
Returns: *this.

constexpr chrono::year year() const noexcept;
Returns: y_.

constexpr chrono::month month() const noexcept;
Returns: m_.

constexpr chrono::weekday weekday() const noexcept;
Returns: wdl_.weekday().

constexpr chrono::weekday_last weekday_last() const noexcept;
Returns: wdl_.

constexpr operator sys_days() const noexcept;
Returns: If ok() == true, returns a sys_days that represents the last weekday() of year()/month(). Otherwise the returned value is unspecified.

explicit constexpr operator local_days() const noexcept;
Returns: local_days{sys_days{*this}.time_since_epoch()}. 

constexpr bool ok() const noexcept;
Returns: y_.ok() && m_.ok() && wdl_.ok().

25.8.17.3 Non-member functions

constexpr bool operator==(const year_month_weekday_last& x,
const year_month_weekday_last& y) noexcept;
Returns: x.year() == y.year() && x.month() == y.month() && x.weekday_last() == y.weekday_last()

constexpr year_month_weekday_last
operator+(const year_month_weekday_last& ymwdl, const months& dm) noexcept;
Returns: (ymwdl.year() / ymwdl.month() + dm) / ymwdl.weekday_last().

constexpr year_month_weekday_last
operator+(const months& dm, const year_month_weekday_last& ymwdl) noexcept;
Returns: ymwdl + dm.

constexpr year_month_weekday_last
operator-(const year_month_weekday_last& ymwdl, const months& dm) noexcept;
Returns: ymwdl + (-dm).

constexpr year_month_weekday_last
operator+(const year_month_weekday_last& ymwdl, const years& dy) noexcept;
Returns: {ymwdl.year()+dy, ymwdl.month(), ymwdl.weekday_last()}. 

constexpr year_month_weekday_last
operator+(const years& dy, const year_month_weekday_last& ymwdl) noexcept;
Returns: ymwdl + dy.

constexpr year_month_weekday_last
operator-(const year_month_weekday_last& ymwdl, const years& dy) noexcept;
Returns: ymwdl + (-dy).
template<class charT, class traits>
  basic_ostream<charT, traits>&
  operator<<(basic_ostream<charT, traits>& os, const year_month_weekday_last& ymwdl);

Returns: os << ymwdl.year() << '/' << ymwdl.month() << '/' << ymwdl.weekday_last().

25.8.18  Conventional syntax operators  
[time.cal.operators]

A set of overloaded operator/ functions provides a conventional syntax for the creation of civil calendar dates.

[Note: The year, month, and day are accepted in any of the following 3 orders:
  year/month/day
  month/day/year
  day/month/year

Anywhere a day is required, any of the following can also be specified:
  last
  weekday[i]
  weekday[last]
  —end note]

[Note: Partial-date types such as year_month and month_day can be created by not applying the second division operator for any of the three orders. For example:
  year_month ym = 2015y/April;
  month_day md1 = April/4;
  month_day md2 = 4d/April;
  —end note]

[Example:
  auto a = 2015/4/4;  // a == int(125)
  auto b = 2015y/4/4; // b == year_month_day{year(2015), month(4), day(4)}
  auto c = 2015y/4d/April;  // error: no viable operator/ for first /
  auto d = 2015/April/4;  // error: no viable operator/ for first /
  —end example]

constexpr year_month
  operator/(const year& y, const month& m) noexcept;

Returns: {y, m}.

constexpr year_month
  operator/(const year& y, int m) noexcept;

Returns: y / month(m).

constexpr month_day
  operator/(const month& m, const day& d) noexcept;

Returns: {m, d}.

constexpr month_day
  operator/(const month& m, int d) noexcept;

Returns: m / day(d).

constexpr month_day
  operator/(int m, const day& d) noexcept;

Returns: month(m) / d.

constexpr month_day
  operator/(const day& d, const month& m) noexcept;

Returns: m / d.
constexpr month_day
    operator/(const day& d, int m) noexcept;

    Returns: month(m) / d.

constexpr month_day_last
    operator/(const month& m, last_spec) noexcept;

    Returns: month_day_last(m).

constexpr month_day_last
    operator/(int m, last_spec) noexcept;

    Returns: month(m) / last.

constexpr month_day_last
    operator/(last_spec, const month& m) noexcept;

    Returns: m / last.

constexpr month_day_last
    operator/(last_spec, int m) noexcept;

    Returns: month(m) / last.

constexpr month_weekday
    operator/(const month& m, const weekday_indexed& wdi) noexcept;

    Returns: {m, wdi}.

constexpr month_weekday
    operator/(int m, const weekday_indexed& wdi) noexcept;

    Returns: month(m) / wdi.

constexpr month_weekday
    operator/(const weekday_indexed& wdi, const month& m) noexcept;

    Returns: m / wdi.

constexpr month_weekday
    operator/(const weekday_indexed& wdi, int m) noexcept;

    Returns: month(m) / wdi.

constexpr month_weekday_last
    operator/(const month& m, const weekday_last& wdl) noexcept;

    Returns: {m, wdl}.

constexpr month_weekday_last
    operator/(int m, const weekday_last& wdl) noexcept;

    Returns: month(m) / wdl.

constexpr month_weekday_last
    operator/(const weekday_last& wdl, const month& m) noexcept;

    Returns: m / wdl.

constexpr month_weekday_last
    operator/(const weekday_last& wdl, int m) noexcept;

    Returns: month(m) / wdl.

constexpr year_month_day
    operator/(const year_month& ym, const day& d) noexcept;

    Returns: {ym.year(), ym.month(), d}.

constexpr year_month_day
    operator/(const year_month& ym, int d) noexcept;

    Returns: ym / day(d).
constexpr year_month_day
    operator/(const year& y, const month_day& md) noexcept;
Returns: y / md.month() / md.day().

constexpr year_month_day
    operator/(int y, const month_day& md) noexcept;
Returns: year(y) / md.

constexpr year_month_day
    operator/(const month_day& md, const year& y) noexcept;
Returns: y / md.

constexpr year_month_day
    operator/(const month_day& md, int y) noexcept;
Returns: year(y) / md.

constexpr year_month_day_last
    operator/(const year_month& ym, last_spec) noexcept;
Returns: {ym.year(), month_day_last{ym.month()}}.

constexpr year_month_day_last
    operator/(const year& y, const month_day_last& mdl) noexcept;
Returns: {y, mdl}.

constexpr year_month_day_last
    operator/(int y, const month_day_last& mdl) noexcept;
Returns: year(y) / mdl.

constexpr year_month_day_last
    operator/(const month_day_last& mdl, const year& y) noexcept;
Returns: y / mdl.

constexpr year_month_day_last
    operator/(const month_day_last& mdl, int y) noexcept;
Returns: year(y) / mdl.

constexpr year_month_weekday
    operator/(const year_month& ym, const weekday_indexed& wdi) noexcept;
Returns: {ym.year(), ym.month(), wdi}.

constexpr year_month_weekday
    operator/(const year& y, const month_weekday& mwd) noexcept;
Returns: {y, mwd.month(), mwd.weekday_indexed()}.

constexpr year_month_weekday
    operator/(int y, const month_weekday& mwd) noexcept;
Returns: year(y) / mwd.

constexpr year_month_weekday
    operator/(const month_weekday& mwd, const year& y) noexcept;
Returns: y / mwd.

constexpr year_month_weekday
    operator/(const month_weekday& mwd, int y) noexcept;
Returns: year(y) / mwd.

constexpr year_month_weekday_last
    operator/(const year_month& ym, const weekday_last& wdl) noexcept;
Returns: {ym.year(), ym.month(), wdl}.

§ 25.8.18
constexpr year_month_weekday_last
operator/(const year& y, const month_weekday_last& mwdl) noexcept;
41
Returns: \{y, mwdl.month(), mwdl.weekday_last()\}.

constexpr year_month_weekday_last
operator/(int y, const month_weekday_last& mwdl) noexcept;
42
Returns: year(y) / mwdl.

constexpr year_month_weekday_last
operator/(const month_weekday_last& mwdl, const year& y) noexcept;
43
Returns: y / mwdl.

constexpr year_month_weekday_last
operator/(const month_weekday_last& mwdl, int y) noexcept;
44
Returns: year(y) / mwdl.

25.9 Class template time_of_day
[time.tod]
25.9.1 Overview
[time.tod.overview]
namespace std::chrono {
    template<class Duration> class time_of_day;
    template<> class time_of_day<hours>;
    template<> class time_of_day<minutes>;
    template<> class time_of_day<seconds>;
    template<class Rep, class Period> class time_of_day<duration<Rep, Period>>;
}

1 The time_of_day class template splits a duration representing the time elapsed since midnight into a
"broken down" time of day such as hours:minutes:seconds. The Duration template parameter dictates the
precision to which the time is broken down. [Note: This can vary from a coarse precision of hours to a very
fine precision of nanoseconds. — end note] A time_of_day object also tracks whether it should be output
as a 12-hour time format or a 24-hour time format.

2 The primary time_of_day template is not defined. Four specializations are provided to handle four different
levels of precision.

3 Each specialization of time_of_day is a trivially copyable and standard-layout class type.

25.9.2 Hours precision
[time.tod.hours]
namespace std::chrono {
    template<> class time_of_day<hours> {  
        public:
            using precision = chrono::hours;

            time_of_day() = default;
            explicit constexpr time_of_day(chrono::hours since_midnight) noexcept;

            constexpr chrono::hours hours() const noexcept;
            explicit constexpr operator precision() const noexcept;
            constexpr precision to_duration() const noexcept;

            constexpr void make24() noexcept;
            constexpr void make12() noexcept;
    };
}

1 [Note: This specialization handles hours since midnight. — end note]

explicit constexpr time_of_day(chrono::hours since_midnight) noexcept;

2 Effects: Constructs an object of type time_of_day in 24-hour format corresponding to since_midnight
hours after 00:00:00.
Ensures: \text{hours()} returns the integral number of hours \text{since_midnight} is after 00:00:00.

\begin{verbatim}
constexpr chrono::hours hours() const noexcept;
\end{verbatim}

Returns: The stored hour of \text{*this}.

\begin{verbatim}
explicit constexpr operator precision() const noexcept;
\end{verbatim}

Returns: The number of hours since midnight.

\begin{verbatim}
constexpr precision to_duration() const noexcept;
\end{verbatim}

Returns: \text{precision{*this}}.

\begin{verbatim}
constexpr void make24() noexcept;
\end{verbatim}

Effects: If \text{*this} is a 12-hour time, converts to a 24-hour time. Otherwise, no effects.

\begin{verbatim}
constexpr void make12() noexcept;
\end{verbatim}

Effects: If \text{*this} is a 24-hour time, converts to a 12-hour time. Otherwise, no effects.

25.9.3 Minutes precision

\begin{verbatim}
namespace std::chrono {
    template<class T>
    class time_of_day<T> {
    public:
        using precision = chrono::minutes;

        time_of_day() = default;
        explicit constexpr time_of_day(T since_midnight) noexcept;

        constexpr chrono::hours hours() const noexcept;
        constexpr chrono::minutes minutes() const noexcept;

        explicit constexpr operator precision() const noexcept;
        constexpr precision to_duration() const noexcept;

        constexpr void make24() noexcept;
        constexpr void make12() noexcept;
    };
}
\end{verbatim}

\begin{verbatim}
explicit constexpr time_of_day(minutes since_midnight) noexcept;
\end{verbatim}

Effects: Constructs an object of type \text{time_of_day} in 24-hour format corresponding to \text{since_midnight} minutes after 00:00:00.

Ensures: \text{hours()} returns the integral number of hours \text{since_midnight} is after 00:00:00. \text{minutes()} returns the integral number of minutes \text{since_midnight} is after (00:00:00 + \text{hours()}).

\begin{verbatim}
constexpr chrono::hours hours() const noexcept;
\end{verbatim}

Returns: The stored hour of \text{*this}.

\begin{verbatim}
constexpr chrono::minutes minutes() const noexcept;
\end{verbatim}

Returns: The stored minute of \text{*this}.

\begin{verbatim}
explicit constexpr operator precision() const noexcept;
\end{verbatim}

Returns: The number of minutes since midnight.

\begin{verbatim}
constexpr precision to_duration() const noexcept;
\end{verbatim}

Returns: \text{precision{*this}}.

\begin{verbatim}
constexpr void make24() noexcept;
\end{verbatim}

Effects: If \text{*this} is a 12-hour time, converts to a 24-hour time. Otherwise, no effects.
constexpr void make12() noexcept;

**Effects:** If *this is a 24-hour time, converts to a 12-hour time. Otherwise, no effects.

### 25.9.4 Seconds precision

```cpp
namespace std::chrono {
    template<>
    class time_of_day<seconds> {
        using precision = chrono::seconds;

        time_of_day() = default;
        explicit constexpr time_of_day(chrono::seconds since_midnight) noexcept;

        constexpr chrono::hours hours() const noexcept;
        constexpr chrono::minutes minutes() const noexcept;
        constexpr chrono::seconds seconds() const noexcept;
        explicit constexpr operator precision() const noexcept;
        constexpr precision to_duration() const noexcept;
        constexpr void make24() noexcept;
        constexpr void make12() noexcept;
    };
}
```

**Note:** This specialization handles hours, minutes, and seconds since midnight. — end note

```cpp
explicit constexpr time_of_day(seconds since_midnight) noexcept;
```

**Effects:** Constructs an object of type time_of_day in 24-hour format corresponding to since_midnight seconds after 00:00:00.

**Ensures:**
- hours() returns the integral number of hours since_midnight is after 00:00:00.
- minutes() returns the integral number of minutes since_midnight is after (00:00:00 + hours()).
- seconds() returns the integral number of seconds since_midnight is after (00:00:00 + hours() + minutes()).

```cpp
constexpr chrono::hours hours() const noexcept;
```

**Returns:** The stored hour of *this.

```cpp
constexpr chrono::minutes minutes() const noexcept;
```

**Returns:** The stored minute of *this.

```cpp
constexpr chrono::seconds seconds() const noexcept;
```

**Returns:** The stored second of *this.

```cpp
explicit constexpr operator precision() const noexcept;
```

**Returns:** The number of seconds since midnight.

```cpp
constexpr precision to_duration() const noexcept;
```

**Returns:** precision{*this}.

```cpp
constexpr void make24() noexcept;
```

**Effects:** If *this is a 12-hour time, converts to a 24-hour time. Otherwise, no effects.

```cpp
constexpr void make12() noexcept;
```

**Effects:** If *this is a 24-hour time, converts to a 12-hour time. Otherwise, no effects.

### 25.9.5 Sub-second precision

```cpp
namespace std::chrono {
    template<class Rep, class Period>
    class time_of_day<duration<Rep, Period>> {
        public:
```

```cpp
§ 25.9.5 1085
```
using precision = duration<Rep, Period>;

time_of_day() = default;
explicit constexpr time_of_day(precision since_midnight) noexcept;

constexpr chrono::hours hours() const noexcept;
constexpr chrono::minutes minutes() const noexcept;
constexpr chrono::seconds seconds() const noexcept;
constexpr precision subseconds() const noexcept;

explicit constexpr operator precision() const noexcept;
constexpr precision to_duration() const noexcept;

constexpr void make24() noexcept;
constexpr void make12() noexcept;

This specialization shall not exist unless `treat_as_floating_point_v<Rep>` is `false` and `duration<Rep, Period>` is not convertible to `seconds`. [Note: This specialization handles hours, minutes, seconds, and fractional seconds since midnight. Typical uses are with milliseconds, microseconds and nanoseconds. —end note]

effects:

Constructs an object of type `time_of_day` in 24-hour format corresponding to `since_midnight` fractional seconds after 00:00:00.

Ensures: `hours()` returns the integral number of hours `since_midnight` is after 00:00:00. `minutes()` returns the integral number of minutes `since_midnight` is after (00:00:00 + `hours()`). `seconds()` returns the integral number of seconds `since_midnight` is after (00:00:00 + `hours()` + `minutes()`). `subseconds()` returns the integral number of fractional seconds `since_midnight` is after (00:00:00 + `hours()` + `minutes()` + `seconds()`).

Returns: The stored hour of `*this`.

Returns: The stored minute of `*this`.

Returns: The stored second of `*this`.

Returns: The stored subsecond of `*this`.

Returns: The number of subseconds since midnight.

Returns: `precision{*this}`.

Effects: If `*this` is a 12-hour time, converts to a 24-hour time. Otherwise, no effects.

Effects: If `*this` is a 24-hour time, converts to a 12-hour time. Otherwise, no effects.
operator<<(basic_ostream<charT, traits>& os, const time_of_day<hours>& t);

Effects: If t is a 24-hour time, outputs to os according to the format "%H00" (25.11). Otherwise outputs to os according to the format "%I%p" (25.11).

Returns: os.

Example:
for (hours h : {1h, 18h}) {
    time_of_day<hours> tod(h);
    os << tod << 'n';
    tod.make12();
    os << tod << 'n';
}

Produces the output:
0100
1am
1800
6pm

— end example

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const time_of_day<minutes>& t);

Effects: If t is a 24-hour time, outputs to os according to the format "%H:%M" (25.11). Otherwise outputs to os according to the format "%I:%M%p" (25.11).

Returns: os.

Example:
for (minutes m : {68min, 1095min}) {
    time_of_day<minutes> tod(m);
    os << tod << 'n';
    tod.make12();
    os << tod << 'n';
}

Produces the output:
01:08
1:08am
18:15
6:15pm

— end example

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const time_of_day<seconds>& t);

Effects: If t is a 24-hour time, outputs to os according to the format "%T" (25.11). Otherwise outputs to os according to the format "%I:%M:%S%p" (25.11).

Returns: os.

Example:
for (seconds s : {4083s, 65745s}) {
    time_of_day<seconds> tod(s);
    os << tod << 'n';
    tod.make12();
    os << tod << 'n';
}

Produces the output:
01:08:03
1:08:03am
18:15:45

§ 25.9.6
template<class charT, class traits>
    basic_ostream<charT, traits>&
    operator<<(basic_ostream<charT, traits>& os, const time_of_day<duration<Rep, Period>>& t);

Effects: If \( t \) is a 24-hour time, outputs to \( os \) according to the format "\%T" (25.11). Otherwise outputs to \( os \) according to the format "\%I:\%M:\%S\%p" (25.11).

Returns: \( os \).

Example:

```cpp
for (milliseconds ms : {4083007ms, 65745123ms}) {
    time_of_day<seconds> tod(ms);
    os << tod << '\n';
    tod.make12();
    os << tod << '\n';
}
```

Produces the output:

```
01:08:03.007
1:08:03.007am
18:15:45.123
6:15:45.123pm
```

§ 25.10  Time zones

25.10.1  In general

25.10 describes an interface for accessing the IANA Time Zone database described in RFC 6557, that interoperates with `sys_time` and `local_time`. This interface provides time zone support to both the civil calendar types (25.8) and to user-defined calendars.

25.10.2  Time zone database

25.10.2.1  Class `tzdb`

```cpp
namespace std::chrono {
    struct tzdb {
        string version;
        vector<time_zone> zones;
        vector<link> links;
        vector<leap> leaps;

        const time_zone* locate_zone(string_view tz_name) const;
        const time_zone* current_zone() const;
    };
}
```

Each `vector` in a `tzdb` object is sorted to enable fast lookup.

```cpp
const time_zone* locate_zone(string_view tz_name) const;
```

Returns: If a `time_zone` is found for which `name()` == `tz_name`, returns a pointer to that `time_zone`. Otherwise if a link is found for which `tz_name == link.name()`, then a pointer is returned to the `time_zone` for which `zone.name() == link.target()`. [Note: A link specifies an alternative name for a `time_zone`. — end note]

Throws: If a `const time_zone*` cannot be found as described in the `Returns:` clause, throws a `runtime_error`. [Note: On non-exceptional return, the return value is always a pointer to a valid `time_zone`. — end note]

```cpp
const time_zone* current_zone() const;
```

Returns: A pointer to the time zone which the computer has set as its local time zone.
25.10.2.2 Class tzdb_list

namespace std::chrono {
    class tzdb_list {
        public:
            tzdb_list(const tzdb_list&) = delete;
            tzdb_list& operator=(const tzdb_list&) = delete;

            // unspecified additional constructors

            class const_iterator;

            const tzdb& front() const noexcept;
            const_iterator erase_after(const_iterator p);

            const_iterator begin() const noexcept;
            const_iterator end() const noexcept;

            const_iterator cbegin() const noexcept;
            const_iterator cend() const noexcept;
    };
}

1 The tzdb_list database is a singleton; the unique object of type tzdb_list can be accessed via the get_tzdb_list() function. [Note: This access is only needed for those applications that need to have long uptimes and have a need to update the time zone database while running. Other applications can implicitly access the front() of this list via the read-only namespace scope functions get_tzdb(), locate_zone(), and current_zone(). — end note] The tzdb_list object contains a list of tzdb objects.

2 tzdb_list::const_iterator is a constant iterator which meets the Cpp17ForwardIterator requirements and has a value type of tzdb.

const tzdb& front() const noexcept;

3 Returns: A reference to the first tzdb in the container.

Remarks: This operation is thread-safe with respect to reload_tzdb(). [Note: reload_tzdb() pushes a new tzdb onto the front of this container. — end note]

const_iterator erase_after(const_iterator p);

4 Requires: The iterator following p is dereferenceable.

5 Effects: Erases the tzdb referred to by the iterator following p.

6 Returns: An iterator pointing to the element following the one that was erased, or end() if no such element exists.

7 Remarks: No pointers, references, or iterators are invalidated except those referring to the erased tzdb. [Note: It is not possible to erase the tzdb referred to by begin(). — end note]

8 Throws: Nothing.

const_iterator begin() const noexcept;

9 Returns: An iterator referring to the first tzdb in the container.

const_iterator end() const noexcept;

10 Returns: An iterator referring to the position one past the last tzdb in the container.

const_iterator cbegin() const noexcept;

11 Returns: begin().

const_iterator cend() const noexcept;

12 Returns: end().
25.10.2.3 Time zone database access

```cpp
const tzdb& get_tzdb_list();

Effects: If this is the first access to the time zone database, initializes the database. If this call initializes
the database, the resulting database will be a tzdb_list holding a single initialized tzdb.

Returns: A reference to the database.

Remarks: It is safe to call this function from multiple threads at one time.

Throws: runtime_error if for any reason a reference cannot be returned to a valid tzdb_list containing
one or more valid tzdb.
```

```cpp
const tzdb& get_tzdb();

Returns: get_tzdb_list().front().
```

```cpp
const time_zone* locate_zone(string_view tz_name);

Returns: get_tzdb().locate_zone(tz_name).

[Note: The time zone database will be initialized if this is the first reference to the database. — end note]
```

```cpp
const time_zone* current_zone();

Returns: get_tzdb().current_zone().
```

25.10.2.4 Remote time zone database support

The local time zone database is that supplied by the implementation when the program first accesses the
database, for example via current_zone(). While the program is running, the implementation may choose
to update the time zone database. This update shall not impact the program in any way unless the program
calls the functions in this subclause. This potentially updated time zone database is referred to as the remote
time zone database.

```cpp
const tzdb& reload_tzdb();

Effects: This function first checks the version of the remote time zone database. If the versions of the
local and remote databases are the same, there are no effects. Otherwise the remote database is pushed
to the front of the tzdb_list accessed by get_tzdb_list().

Returns: get_tzdb_list().front().

Remarks: No pointers, references, or iterators are invalidated.

Remarks: This function is thread-safe with respect to get_tzdb_list().front() and get_tzdb_list().erase_after().

Throws: runtime_error if for any reason a reference cannot be returned to a valid tzdb.
```

```cpp
string remote_version();

Returns: The latest remote database version.

[Note: This can be compared with get_tzdb().version to discover if the local and remote databases
are equivalent. — end note]
```

25.10.3 Exception classes

25.10.3.1 Class nonexistent_local_time

```cpp
namespace std::chrono {
    class nonexistent_local_time : public runtime_error {
        public:
            template<class Duration>
                nonexistent_local_time(const local_time<Duration>& tp, const local_info& i);
    };
}
```

nonexistent_local_time is thrown when an attempt is made to convert a non-existent local_time to a
sys_time without specifying choose::earliest or choose::latest.
template<class Duration>
nonexistent_local_time(const local_time<Duration>& tp, const local_info& i);

2
Requires: i.result == local_info::nonexistent.
3
Effects: Constructs a nonexistent_local_time by initializing the base class with a sequence of char
equivalent to that produced by os.str() initialized as shown below:

ostringstream os;
os << tp << " is in a gap between\n" << local_seconds{i.first.end.time_since_epoch()} + i.first.offset << ',
<< i.first.abbrev << " and\n" << local_seconds{i.second.begin.time_since_epoch()} + i.second.offset << ',
<< i.second.abbrev
<< " which are both equivalent to\n" << i.first.end << " UTC";

4
[Example:
#include <chrono>
#include <iostream>

int main() {
    using namespace std::chrono;
    try {
        auto zt = zoned_time{"America/New_York",
                              local_days{Sunday[2]/March/2016} + 2h + 30min};
    } catch (const nonexistent_local_time& e) {
        std::cout << e.what() << '\n';
    }
}

Produces the output:
2016-03-13 02:30:00 is in a gap between
2016-03-13 02:00:00 EDT and
2016-03-13 03:00:00 EDT which are both equivalent to
2016-03-13 07:00:00 UTC
—end example]

25.10.3.2 Class ambiguous_local_time

namespace std::chrono {
    class ambiguous_local_time : public runtime_error {
        public:
            template<class Duration>
            ambiguous_local_time(const local_time<Duration>& tp, const local_info& i);
    };
} 1

ambiguous_local_time is thrown when an attempt is made to convert an ambiguous local_time to a
sys_time without specifying choose::earliest or choose::latest.

template<class Duration>
ambiguous_local_time(const local_time<Duration>& tp, const local_info& i);

2
Requires: i.result == local_info::ambiguous.
3
Effects: Constructs an ambiguous_local_time by initializing the base class with a sequence of char
equivalent to that produced by os.str() initialized as shown below:

ostringstream os;
os << tp << " is ambiguous. It could be\n" << tp << ', ' << i.first.abbrev << " == "
<< tp - i.first.offset << " UTC or\n" << tp << ', ' << i.second.abbrev << " == "
<< tp - i.second.offset << " UTC";

4
[Example:
#include <chrono>
#include <iostream>

int main() {
    using namespace std::chrono;
    try {
        auto zt = zoned_time("America/New_York",
                             local_days{Sunday[1]/November/2016} + 1h + 30min);
    } catch (const ambiguous_local_time& e) {
        std::cout << e.what() << '\n';
    }
}

Produces the output:
2016-11-06 01:30:00 is ambiguous. It could be
2016-11-06 01:30:00 EDT == 2016-11-06 05:30:00 UTC or
2016-11-06 01:30:00 EST == 2016-11-06 06:30:00 UTC
—end example

25.10.4 Information classes

25.10.4.1 Class sys_info

namespace std::chrono {
    struct sys_info {
        sys_seconds begin;
        sys_seconds end;
        seconds offset;
        minutes save;
        string abbrev;
    };
}

1 A sys_info structure can be obtained from the combination of a time_zone and either a sys_time or local_time. It can also be obtained from a zoned_time, which is effectively a pair of a time_zone and sys_time.

2 [Note: This type provides a low-level interface to time zone information. Typical conversions from sys_time to local_time will use this structure implicitly, not explicitly. —end note]

3 The begin and end data members indicate that, for the associated time_zone and time_point, the offset and abbrev are in effect in the range [begin, end). This information can be used to efficiently iterate the transitions of a time_zone.

4 The offset data member indicates the UTC offset in effect for the associated time_zone and time_point. The relationship between local_time and sys_time is:

    offset = local_time - sys_time

5 The save data member is extra information not normally needed for conversion between local_time and sys_time. If save != 0min, this sys_info is said to be on “daylight saving” time, and offset - save suggests what offset this time_zone might use if it were off daylight saving time. However, this information should not be taken as authoritative. The only sure way to get such information is to query the time_zone with a time_point that returns a sys_info where save == 0min. There is no guarantee what time_point might return such a sys_info except that it is guaranteed not to be in the range [begin, end) (if save != 0min for this sys_info).

6 The abbrev data member indicates the current abbreviation used for the associated time_zone and time_point. Abbreviations are not unique among the time_zones, and so one cannot reliably map abbreviations back to a time_zone and UTC offset.

    template<class charT, class traits>
    basic_ostream<charT, traits>&
    operator<<(basic_ostream<charT, traits>& os, const sys_info& r);

7 Effects: Streams out the sys_info object r in an unspecified format.
25.10.4.2 Class `local_info` [time.zone.info.local]

```cpp
namespace std::chrono {
    struct local_info {
        static constexpr int unique = 0;
        static constexpr int nonexistent = 1;
        static constexpr int ambiguous = 2;

        int result;
        sys_info first;
        sys_info second;
    };
}
```

1 [Note: This type provides a low-level interface to time zone information. Typical conversions from `local_time` to `sys_time` will use this structure implicitly, not explicitly. — end note]

2 Describes the result of converting a `local_time` to a `sys_time` as follows:

   (2.1) When a `local_time` to `sys_time` conversion is unique, `result == unique`, `first` will be filled out with the correct `sys_info`, and `second` will be zero-initialized.

   (2.2) If the conversion stems from a nonexistent `local_time` then `result == nonexistent`, `first` will be filled out with the `sys_info` that ends just prior to the `local_time`, and `second` will be filled out with the `sys_info` that begins just after the `local_time`.

   (2.3) If the conversion stems from an ambiguous `local_time`, then `result == ambiguous`, `first` will be filled out with the `sys_info` that ends just after the `local_time`, and `second` will be filled out with the `sys_info` that starts just before the `local_time`.

```cpp
template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const local_info& r);
```

3 Streams out the `local_info` object `r` in an unspecified format.

25.10.5 Class `time_zone` [time.zone.timezone]

25.10.5.1 Overview [time.zone.overview]

```cpp
namespace std::chrono {
    class time_zone {
        public:
            time_zone(time_zone&&) = default;
            time_zone& operator=(time_zone&&) = default;

            // unspecified additional constructors

            string_view name() const noexcept;

            template<class Duration> sys_info get_info(const sys_time<Duration>& st) const;
            template<class Duration> local_info get_info(const local_time<Duration>& tp) const;

            template<class Duration>
            sys_time<common_type_t<Duration, seconds>>
                to_sys(const local_time<Duration>& tp) const;

            template<class Duration>
            sys_time<common_type_t<Duration, seconds>>
                to_sys(const local_time<Duration>& tp, choose z) const;

            template<class Duration>
            local_time<common_type_t<Duration, seconds>>
                to_local(const sys_time<Duration>& tp) const;
    };
}
```
A `time_zone` represents all time zone transitions for a specific geographic area. `time_zone` construction is unspecified, and performed as part of database initialization. [Note: `const time_zone` objects can be accessed via functions such as `locate_zone`. — end note]

### 25.10.5.2 Member functions

**string_view name() const noexcept;**

- **Returns:** The name of the `time_zone`.

  [Example: "America/New_York". — end example]

**template<class Duration> sys_info get_info(const sys_time<Duration>& st) const;**

- **Returns:** A `sys_info` for which `st` is in the range `[i.begin, i.end)`.

**template<class Duration> local_info get_info(const local_time<Duration>& tp) const;**

- **Returns:** A `local_info` for `tp`.

**template<class Duration> sys_time<common_type_t<Duration, seconds>> to_sys(const local_time<Duration>& tp) const;**

- **Returns:** A `sys_time` that is at least as fine as `seconds`, and will be finer if the argument `tp` has finer precision. This `sys_time` is the UTC equivalent of `tp` according to the rules of this `time_zone`.

- **Throws:** If the conversion from `tp` to a `sys_time` is ambiguous, throws `ambiguous_local_time`. If the `tp` represents a non-existent time between two UTC `time_points`, throws `nonexistent_local_time`.

**template<class Duration> sys_time<common_type_t<Duration, seconds>> to_sys(const local_time<Duration>& tp, choose z) const;**

- **Returns:** A `sys_time` that is at least as fine as `seconds`, and will be finer if the argument `tp` has finer precision. This `sys_time` is the UTC equivalent of `tp` according to the rules of this `time_zone`. If the conversion from `tp` to a `sys_time` is ambiguous, returns the earlier `sys_time` if `z == choose::earliest`, and returns the later `sys_time` if `z == choose::latest`. If the `tp` represents a non-existent time between two UTC `time_points`, then the two UTC `time_points` will be the same, and that UTC `time_point` will be returned.

**template<class Duration> local_time<common_type_t<Duration, seconds>> to_local(const sys_time<Duration>& tp) const;**

- **Returns:** The `local_time` associated with `tp` and this `time_zone`.

### 25.10.5.3 Non-member functions

**bool operator==(const time_zone& x, const time_zone& y) noexcept;**

- **Returns:** `x.name() == y.name()`.

**bool operator<(const time_zone& x, const time_zone& y) noexcept;**

- **Returns:** `x.name() < y.name()`.

### 25.10.6 Class template zoned_traits

```cpp
namespace std::chrono {
    template<class T> struct zoned_traits {};  // zoned_traits provides a means for customizing the behavior of zoned_time<Duration, TimeZonePtr>
}
```

A specialization for `const time_zone*` is provided by the implementation:

```cpp
namespace std::chrono {
    template<> struct zoned_traits<const time_zone*> {
        static const time_zone* default_zone();
    }
}
```
static const time_zone* locate_zone(string_view name);
};

static const time_zone* default_zone();
// Returns: std::chrono::locate_zone("UTC").

static const time_zone* locate_zone(string_view name);
// Returns: std::chrono::locate_zone(name).

### 25.10.7 Class template zoned_time

#### 25.10.7.1 Overview

```cpp
namespace std::chrono {
    template<class Duration, class TimeZonePtr = const time_zone*> class zoned_time {
        public:
            using duration = common_type_t<Duration, seconds>;

        private:
            TimeZonePtr zone_; // exposition only
            sys_time<duration> tp_; // exposition only

        public:
            zoned_time();
            zoned_time(const zoned_time&) = default;
            zoned_time& operator=(const zoned_time&) = default;
            zoned_time(const sys_time<Duration>& st);
            explicit zoned_time(TimeZonePtr z);
            explicit zoned_time(string_view name);

            template<class Duration2>
                zoned_time(const zoned_time<Duration2, TimeZonePtr>& zt) noexcept;
            zoned_time(TimeZonePtr z, const sys_time<Duration>& st);
            zoned_time(string_view name, const sys_time<Duration>& st);
            zoned_time(TimeZonePtr z, const local_time<Duration>& tp);
            zoned_time(string_view name, const local_time<Duration>& tp);
            zoned_time(TimeZonePtr z, const local_time<Duration>& tp, choose c);
            zoned_time(string_view name, const local_time<Duration>& tp, choose c);

            template<class Duration2, class TimeZonePtr2>
                zoned_time(TimeZonePtr z, const zoned_time<Duration2, TimeZonePtr2>& zt);
            zoned_time(TimeZonePtr z, const zoned_time<Duration2, TimeZonePtr2>& zt, choose);
            zoned_time(string_view name, const zoned_time<Duration>& zt);
            zoned_time(string_view name, const zoned_time<Duration>& zt, choose);

            zoned_time& operator=(const sys_time<Duration>& st);
            zoned_time& operator=(const local_time<Duration>& ut);

            operator sys_time<duration>() const;
            explicit operator local_time<duration>() const;

            TimeZonePtr get_time_zone() const;
            local_time<duration> get_local_time() const;
            sys_time<duration> get_sys_time() const;
            sys_info get_info() const;
    };
```
\texttt{zoned\_time()} \rightarrow \texttt{zoned\_time<seconds>};

\texttt{template<class Duration>}
\texttt{zoned\_time(sys\_time<Duration>)}
\rightarrow \texttt{zoned\_time<common\_type\_t<Duration, seconds>>};

\texttt{template<class TimeZonePtr, class Duration>}
\texttt{zoned\_time(TimeZonePtr, sys\_time<Duration>)}
\rightarrow \texttt{zoned\_time<common\_type\_t<Duration, seconds>, TimeZonePtr>>;}

\texttt{template<class TimeZonePtr, class Duration>}
\texttt{zoned\_time(TimeZonePtr, local\_time<Duration>, choose = choose::earliest)}
\rightarrow \texttt{zoned\_time<common\_type\_t<Duration, seconds>, TimeZonePtr>>;}

\texttt{template<class TimeZonePtr, class Duration>}
\texttt{zoned\_time(TimeZonePtr, zoned\_time<Duration>, choose = choose::earliest)}
\rightarrow \texttt{zoned\_time<common\_type\_t<Duration, seconds>, TimeZonePtr>>;}
\texttt{zoned\_time(string\_view) \rightarrow \texttt{zoned\_time<seconds>};}

\texttt{template<class Duration>}
\texttt{zoned\_time(string\_view, sys\_time<Duration>)}
\rightarrow \texttt{zoned\_time<common\_type\_t<Duration, seconds>>;}

\texttt{template<class Duration>}
\texttt{zoned\_time(string\_view, local\_time<Duration>, choose = choose::earliest)}
\rightarrow \texttt{zoned\_time<common\_type\_t<Duration, seconds>>;}

\texttt{template<class Duration, class TimeZonePtr, class TimeZonePtr2>}
\texttt{zoned\_time(TimeZonePtr, zoned\_time<Duration, TimeZonePtr2>, choose = choose::earliest)}
\rightarrow \texttt{zoned\_time<Duration, TimeZonePtr>>;}

1 \texttt{zoned\_time} represents a logical pairing of a \texttt{time\_zone} and a \texttt{time\_point} with precision \texttt{Duration}. \texttt{zoned\_time<Duration>} maintains the invariant that it always refers to a valid time zone and represents a point in time that exists and is not ambiguous in that time zone.

2 If \texttt{Duration} is not a specialization of \texttt{chrono::duration}, the program is ill-formed.

\subsection*{25.10.7.2 Constructors}
\texttt{zoned\_time();}
\begin{enumerate}
\item \textit{Remarks}: This constructor does not participate in overload resolution unless \texttt{traits::default\_zone()} is a well-formed expression.
\item \textit{Effects}: Constructs a \texttt{zoned\_time} by initializing \texttt{zone\_} with \texttt{traits::default\_zone()} and default constructing \texttt{tp\_}.
\end{enumerate}
\texttt{zoned\_time(const sys\_time<Duration>& st);}  
\begin{enumerate}
\item \textit{Remarks}: This constructor does not participate in overload resolution unless \texttt{traits::default\_zone()} is a well-formed expression.
\item \textit{Effects}: Constructs a \texttt{zoned\_time} by initializing \texttt{zone\_} with \texttt{traits::default\_zone()} and \texttt{tp\_} with \texttt{st}.
\end{enumerate}
\texttt{explicit zoned\_time(TimeZonePtr z);}  
\begin{enumerate}
\item \textit{Requires}: \texttt{z} refers to a time zone.
\item \textit{Effects}: Constructs a \texttt{zoned\_time} by initializing \texttt{zone\_} with \texttt{std\::move(z)}.
\end{enumerate}
\texttt{explicit zoned\_time(string\_view name);}  
\begin{enumerate}
\item \textit{Remarks}: This constructor does not participate in overload resolution unless \texttt{traits::locate\_zone(string\_view{})} is a well-formed expression and \texttt{zoned\_time} is constructible from the return type of \texttt{traits::locate\_zone(string\_view{})}.
\end{enumerate}
Effects: Constructs a `zoned_time` by initializing `zone_` with `traits::locate_zone(name)` and default constructing `tp_`.

```
template<class Duration2>
zoned_time(const zoned_time<Duration2, TimeZonePtr>& y) noexcept;
```

Remarks: Does not participate in overload resolution unless `sys_time<Duration2>` is implicitly convertible to `sys_time<Duration>`.

Effects: Constructs a `zoned_time` by initializing `zone_` with `y.zone_` and `tp_` with `y.tp_`.

```
zoned_time(TimeZonePtr z, const sys_time<Duration>& st);
```

Requires: `z` refers to a time zone.

Effects: Constructs a `zoned_time` by initializing `zone_` with `std::move(z)` and `tp_` with `st`.

```
zoned_time(string_view name, const sys_time<Duration>& st);
```

Remarks: This constructor does not participate in overload resolution unless `zoned_time` is constructible from the return type of `traits::locate_zone(name)` and `st`.

Effects: Equivalent to construction with `{traits::locate_zone(name), st}`.

```
zoned_time(TimeZonePtr z, const local_time<Duration>& tp);
```

Remarks: This constructor does not participate in overload resolution unless

```
decltype(declval<TimeZonePtr&>()->to_sys(local_time<Duration>{}))
```

is convertible to `sys_time<duration>`.

Effects: Constructs a `zoned_time` by initializing `zone_` with `std::move(z)` and `tp_` with `std::move(z)`.

```
zoned_time(string_view name, const local_time<Duration>& tp);
```

Remarks: This constructor does not participate in overload resolution unless `zoned_time` is constructible from the return type of `traits::locate_zone(name)` and `tp`.

Effects: Equivalent to construction with `{traits::locate_zone(name), tp}`.

```
zoned_time(TimeZonePtr z, const local_time<Duration>& tp, choose c);
```

Remarks: This constructor does not participate in overload resolution unless

```
decltype(declval<TimeZonePtr&>()->to_sys(local_time<Duration>{}, choose::earliest))
```

is convertible to `sys_time<duration>`.

Effects: Constructs a `zoned_time` by initializing `zone_` with `std::move(z)` and `tp_` with `zone_->to_sys(tp, c)`.

```
zoned_time(string_view name, const local_time<Duration>& tp, choose c);
```

Remarks: This constructor does not participate in overload resolution unless `zoned_time` is constructible from the return type of `traits::locate_zone(name)`, `local_time<Duration>`, and `choose`.

Effects: Equivalent to construction with `{traits::locate_zone(name), tp, c}`.

```
template<class Duration2, class TimeZonePtr2>
zoned_time(TimeZonePtr z, const zoned_time<Duration2, TimeZonePtr2>& y);
```

Remarks: Does not participate in overload resolution unless `sys_time<Duration2>` is implicitly convertible to `sys_time<Duration>`.

Requires: `z` refers to a valid time zone.

Effects: Constructs a `zoned_time` by initializing `zone_` with `std::move(z)` and `tp_` with `y.tp_`.

```
template<class Duration2, class TimeZonePtr2>
§ 25.10.7.2 1097
zoned_time(TimeZonePtr z, const zoned_time<Duration2,TimeZonePtr2>& y, choose);

Remarks: Does not participate in overload resolution unless sys_time<Duration2> is implicitly convertible to sys_time<Duration>.

Requires: z refers to a valid time zone.

Effects: Equivalent to construction with {z, y}.

[Note: The choose parameter has no effect. — end note]

zoned_time(string_view name, const zoned_time<Duration>& y);

Remarks: This constructor does not participate in overload resolution unless zoned_time is constructible from the return type of traits::locate_zone(name) and zoned_time.

Effects: Equivalent to construction with {traits::locate_zone(name), y}.

zoned_time(string_view name, const zoned_time<Duration>& y, choose c);

Remarks: This constructor does not participate in overload resolution unless zoned_time is constructible from the return type of traits::locate_zone(name), zoned_time, and choose.

Effects: Equivalent to construction with {traits::locate_zone(name), y, c}.

[Note: The choose parameter has no effect. — end note]

25.10.7.3 Member functions

zoned_time& operator=(const sys_time<Duration>& st);

Effects: After assignment, get_sys_time() == st. This assignment has no effect on the return value of get_time_zone().

Returns: *this.

zoned_time& operator=(const local_time<Duration>& lt);

Effects: After assignment, get_local_time() == lt. This assignment has no effect on the return value of get_time_zone().

Returns: *this.

operator sys_time<duration>() const;

Returns: get_sys_time().

explicit operator local_time<duration>() const;

Returns: get_local_time().

TimeZonePtr get_time_zone() const;

Returns: zone_.

local_time<duration> get_local_time() const;

Returns: zone_->to_local(tp_).

sys_time<duration> get_sys_time() const;

Returns: tp_.

sys_info get_info() const;

Returns: zone_->get_info(tp_).

25.10.7.4 Non-member functions

template<class Duration1, class Duration2, class TimeZonePtr>
bool operator==(const zoned_time<Duration1, TimeZonePtr>& x,
                const zoned_time<Duration2, TimeZonePtr>& y);

Returns: x.zone_ == y.zone_ && x.tp_ == y.tp_.
template<class Duration1, class Duration2, class TimeZonePtr>
bool operator!=(const zoned_time<Duration1, TimeZonePtr>& x,
const zoned_time<Duration2, TimeZonePtr>& y);

Returns: !(x == y).

template<class charT, class traits, class Duration, class TimeZonePtr>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>&& os,
const zoned_time<Duration, TimeZonePtr>& t);

Effects: Streams the value returned from t.get_local_time() to os using the format "%F %T %Z".

Returns: os.

template<class charT, class traits, class Duration, class TimeZonePtr>
basic_ostream<charT, traits>&
to_stream(basic_ostream<charT, traits>& os, const charT* fmt,
const zoned_time<Duration, TimeZonePtr>& tp);

Effects: First obtains a sys_info via tp.get_info() which for exposition purposes will be referred to as info. Then calls to_stream(os, fmt, tp.get_local_time(), &info.abbrev, &info.offset).

Returns: os.

25.10.8 Class leap

25.10.8.1 Overview

namespace std::chrono {
    class leap {
        public:
        leap(const leap&) = default;
        leap& operator=(const leap&) = default;

        // unspecified additional constructors

        constexpr sys_seconds date() const noexcept;
    };
}

Objects of type leap representing the date of the leap second insertions are constructed and stored in the time zone database when initialized.

Example:
for (auto& l : get_tzdb().leaps)
    if (l <= 2018y/March/17d)
        cout << l.date() << '\n';
25.10.8.2 Member functions

```cpp
constexpr sys_seconds date() const noexcept;
```

*Returns:* The date and time at which the leap second was inserted.

25.10.8.3 Non-member functions

```cpp
constexpr bool operator==(const leap& x, const leap& y) noexcept;
```

*Returns:* `x.date() == y.date()`.

```cpp
constexpr bool operator<(const leap& x, const leap& y) noexcept;
```

*Returns:* `x.date() < y.date()`.

```cpp
template<class Duration>
constexpr bool operator==(const leap& x, const sys_time<Duration>& y) noexcept;
```

*Returns:* `x.date() == y`.

```cpp
template<class Duration>
constexpr bool operator==(const leap& x, const sys_time<Duration>& y) noexcept;
```

*Returns:* `y == x`.

```cpp
template<class Duration>
constexpr bool operator!=(const leap& x, const sys_time<Duration>& y) noexcept;
```

*Returns:* `!(x == y)`.

```cpp
template<class Duration>
constexpr bool operator!=(const sys_time<Duration>& x, const leap& y) noexcept;
```

*Returns:* `!(x == y)`.

```cpp
template<class Duration>
constexpr bool operator<(const leap& x, const sys_time<Duration>& y) noexcept;
```

*Returns:* `x.date() < y`.

```cpp
template<class Duration>
constexpr bool operator<(const sys_time<Duration>& x, const leap& y) noexcept;
```

*Returns:* `x < y.date()`.

```cpp
template<class Duration>
constexpr bool operator>(const leap& x, const sys_time<Duration>& y) noexcept;
```

*Returns:* `y < x`.

```cpp
template<class Duration>
constexpr bool operator>(const sys_time<Duration>& x, const leap& y) noexcept;
```

*Returns:* `y < x`.

```cpp
template<class Duration>
constexpr bool operator<=(const leap& x, const sys_time<Duration>& y) noexcept;
```

*Returns:* `!(y < x)`.

```cpp
template<class Duration>
constexpr bool operator<=(const sys_time<Duration>& x, const leap& y) noexcept;
```

*Returns:* `!(y < x)`.
template<class Duration>
constexpr bool operator<=(const sys_time<Duration>& x, const leap& y) noexcept;

Returns: !(y < x).

template<class Duration>
constexpr bool operator>=(const leap& x, const sys_time<Duration>& y) noexcept;

Returns: !(x < y).

template<class Duration>
constexpr bool operator>=(const sys_time<Duration>& x, const leap& y) noexcept;

Returns: !(x < y).

25.10.9 Class link

25.10.9.1 Overview

namespace std::chrono {
    class link {
        public:
            link(link&&) = default;
            link& operator=(link&&) = default;

            // unspecified additional constructors

        string_view name() const noexcept;
        string_view target() const noexcept;
    };
}

A link specifies an alternative name for a time_zone. Links are constructed when the time zone database is initialized.

25.10.9.2 Member functions

string_view name() const noexcept;

Returns: The alternative name for the time zone.

string_view target() const noexcept;

Returns: The name of the time_zone for which this link provides an alternative name.

25.10.9.3 Non-member functions

bool operator==(const link& x, const link& y) noexcept;

Returns: x.name() == y.name().

bool operator<(const link& x, const link& y) noexcept;

Returns: x.name() < y.name().

25.11 Formatting

Each format overload specified in this subclause calls to_stream unqualified, so as to enable argument dependent lookup (6.4.2).

template<class charT, class Streamable>
basic_string<charT>
format(const charT* fmt, const Streamable& s);

Remarks: This function shall not participate in overload resolution unless
to_stream(declval<basic_ostream<charT>&>(), fmt, s)
is a valid expression.

Effects: Constructs a local variable of type basic_ostringstream<charT>(named os for exposition purposes). Executes os.exceptions(ios::failbit | ios::badbit). Then calls to_stream(os, fmt, s).
Returns: os.str().

```cpp
template<class charT, class Streamable>
basic_string<charT>
format(const locale& loc, const charT* fmt, const Streamable& s);
```

Remarks: This function shall not participate in overload resolution unless
to_stream(declval<basic_ostream<charT>&>(), fmt, s)
is a valid expression.

Effects: Constructs a local variable of type basic_ostringstream<charT> (named os for exposition purposes). Executes os.exceptions(ios::failbit | ios::badbit). Then calls os.imbue(loc). Then calls to_stream(os, fmt, s).

Returns: os.str().

```cpp
template<class charT, class traits, class Alloc, class Streamable>
basic_string<charT, traits, Alloc>
format(const basic_string<charT, traits, Alloc>& fmt, const Streamable& s);
```

Remarks: This function shall not participate in overload resolution unless
to_stream(declval<basic_ostringstream<charT, traits, Alloc>&>(), fmt.c_str(), s)
is a valid expression.

Effects: Constructs a local variable of type basic_ostringstream<charT, traits, Alloc> (named os for exposition purposes). Executes os.exceptions(ios::failbit | ios::badbit). Then calls to_stream(os, fmt.c_str(), s).

Returns: os.str().

```cpp
template<class charT, class traits, class Alloc, class Streamable>
basic_string<charT, traits, Alloc>
format(const locale& loc, const basic_string<charT, traits, Alloc>& fmt, const Streamable& s);
```

Remarks: This function shall not participate in overload resolution unless
to_stream(declval<basic_ostringstream<charT, traits, Alloc>&>(), fmt.c_str(), s)
is a valid expression.

Effects: Constructs a local variable of type basic_ostringstream<charT, traits, Alloc> (named os for exposition purposes). Then calls os.imbue(loc). Executes os.exceptions(ios::failbit | ios::badbit). Then calls to_stream(os, fmt.c_str(), s).

Returns: os.str().

The format functions call a to_stream function with a basic_ostream, a formatting string specifier, and a Streamable argument. Each to_stream overload is customized for each Streamable type. However all to_stream overloads treat the formatting string specifier according to the following specification:

The fmt string consists of zero or more conversion specifiers and ordinary multibyte characters. A conversion specifier consists of a % character, possibly followed by an E or O modifier character (described below), followed by a character that determines the behavior of the conversion specifier. All ordinary multibyte characters (excluding the terminating null character) are streamed unchanged into the basic_ostream.

Each conversion specifier is replaced by appropriate characters as described in Table 88. Some of the conversion specifiers depend on the locale which is imbued to the basic_ostream. If the Streamable object does not contain the information the conversion specifier refers to, the value streamed to the basic_ostream is unspecified.

Unless explicitly specified, Streamable types will not contain time zone abbreviation and time zone offset information. If available, the conversion specifiers %Z and %z will format this information (respectively). If the information is not available, and %Z or %z are contained in fmt, os.setstate(ios_base::failbit) shall be called.

</table>

25.12 Parsing

1 Each parse overload specified in this subclause calls from_stream unqualified, so as to enable argument dependent lookup (6.4.2).

```cpp
template<class charT, class traits, class Alloc, class Parsable>
unspecified
parse(const basic_string<charT, traits, Alloc>& fmt, Parsable& tp);
```

2 Remarks: This function shall not participate in overload resolution unless

```cpp
from_stream(declval<basic_istream<charT, traits>&>(), fmt.c_str(), tp)
```

is a valid expression.

3 Returns: A manipulator that, when extracted from a basic_istream<charT, traits> is, calls from_stream(is, fmt.c_str(), tp).

```cpp
template<class charT, class traits, class Alloc, class Parsable>
unspecified
parse(const basic_string<charT, traits, Alloc>& fmt, Parsable& tp,
      basic_string<charT, traits, Alloc>& abbrev);
```

4 Remarks: This function shall not participate in overload resolution unless

```cpp
from_stream(declval<basic_istream<charT, traits>&>(), fmt.c_str(), tp, &abbrev)
```

is a valid expression.

5 Returns: A manipulator that, when extracted from a basic_istream<charT, traits> is, calls from_stream(is, fmt.c_str(), tp, &abbrev).
template<class charT, class traits, class Alloc, class Parsable>
unspecified
parse(const basic_string<charT, traits, Alloc>& fmt, Parsable& tp, minutes& offset);

6 Remarks: This function shall not participate in overload resolution unless
from_stream(declval<basic_istream<charT, traits>&>(), fmt.c_str(), tp, nullptr, &offset)
is a valid expression.

7 Returns: A manipulator that, when extracted from a basic_istream<charT, traits> is, calls
from_stream(is, fmt.c_str(), tp, nullptr, &offset).

template<class charT, class traits, class Alloc, class Parsable>
unspecified
parse(const basic_string<charT, traits, Alloc>& fmt, Parsable& tp, basic_string<charT, traits, Alloc>& abbrev, minutes& offset);

8 Remarks: This function shall not participate in overload resolution unless
from_stream(declval<basic_istream<charT, traits>&>(), fmt.c_str(), tp, &abbrev, &offset)
is a valid expression.

9 Returns: A manipulator that, when extracted from a basic_istream<charT, traits> is, calls
from_stream(is, fmt.c_str(), tp, &abbrev, &offset).

All from_stream overloads behave as unformatted input functions, except that they have an unspecified
effect on the value returned by subsequent calls to basic_istream<>::gcount(). Each overload takes a
format string containing ordinary characters and flags which have special meaning. Each flag begins with a %.
Some flags can be modified by E or O. During parsing each flag interprets characters as parts of date and time
types according to the table below. Some flags can be modified by a width parameter given as a positive
decimal integer called out as N below which governs how many characters are parsed from the stream in
interpreting the flag. All characters in the format string that are not represented in the table below, except
for white space, are parsed unchanged from the stream. A white space character matches zero or more white
space characters in the input stream.

11 If the from_stream overload fails to parse everything specified by the format string, or if insufficient
information is parsed to specify a complete duration, time point, or calendrical data structure, setstate(ios_-
base::failbit) is called on the basic_istream.

Table 89 — Meaning of parse flags

<table>
<thead>
<tr>
<th>Flag</th>
<th>Parsed value</th>
</tr>
</thead>
<tbody>
<tr>
<td>%a</td>
<td>The locale’s full or abbreviated case-insensitive weekday name.</td>

25.13 Header <ctime> synopsis

```cpp
# define NULL see 16.2.3
# define CLOCKS_PER_SEC see below
# define TIME_UTC see below
namespace std {
    using size_t = see 16.2.4;
    using clock_t = see below;
    using time_t = see below;

    struct timespec;
    struct tm;
    clock_t clock();
    double difftime(time_t time1, time_t time0);
    time_t mktime(struct tm* timeptr);
    time_t time(time_t* timer);
    int timespec_get(timespec* ts, int base);
    char* asctime(const struct tm* timeptr);
    char* ctime(const time_t* timer);
    struct tm* gmtime(const time_t* timer);
    struct tm* localtime(const time_t* timer);
    size_t strftime(char* s, size_t maxsize, const char* format, const struct tm* timeptr);
}
```

1 The contents of the header <ctime> are the same as the C standard library header <time.h>.\(^{261}\)

\(^{261}\) strftime supports the C conversion specifiers C, D, e, F, g, G, h, r, R, t, T, u, v, and z, and the modifiers E and O.
2 The functions `asctime`, `ctime`, `gmtime`, and `localtime` are not required to avoid data races (15.5.5.9).

26 Localization library

26.1 General

This Clause describes components that C++ programs may use to encapsulate (and therefore be more portable when confronting) cultural differences. The locale facility includes internationalization support for character classification and string collation, numeric, monetary, and date/time formatting and parsing, and message retrieval.

The following subclauses describe components for locales themselves, the standard facets, and facilities from the ISO C library, as summarized in Table 90.

// 26.4.7, message retrieval
    class messages_base;
    template<class charT> class messages;

1 The header <locale> defines classes and declares functions that encapsulate and manipulate the information peculiar to a locale.

263 Locales
263.1 Class locale

namespace std {
    class locale {
        public:
            // types
            class facet;
            class id;
            using category = int;

            static const category none = 0,
                  collate = 0x010, ctype = 0x020,
                  monetary = 0x040, numeric = 0x080,
                  time = 0x100, messages = 0x200,
                  all = collate | ctype | monetary | numeric | time | messages;

            // construct/copy/destroy
            locale() noexcept;
            locale(const locale& other) noexcept;
            explicit locale(const char* std_name);
            explicit locale(const string& std_name);
            locale(const locale& other, const char* std_name, category);
            locale(const locale& other, const string& std_name, category);
            template<class Facet> locale(const locale& other, Facet* f);

262) In this subclause, the type name struct tm is an incomplete type that is defined in <ctime>.
locale(const locale& other, const locale& one, category);
~locale();          // not virtual
const locale& operator=(const locale& other) noexcept;
template<class Facet> locale combine(const locale& other) const;

// locale operations
basic_string<char> name() const;

bool operator==(const locale& other) const;
bool operator!=(const locale& other) const;

template<class charT, class traits, class Allocator>
    bool operator()(const basic_string<charT, traits, Allocator>& s1,
                    const basic_string<charT, traits, Allocator>& s2) const;

// global locale objects
static locale global(const locale&);
static const locale& classic();
};

1 Class locale implements a type-safe polymorphic set of facets, indexed by facet type. In other words, a facet has a dual role: in one sense, it’s just a class interface; at the same time, it’s an index into a locale’s set of facets.

2 Access to the facets of a locale is via two function templates, use_facet<> and has_facet<>.

[Example: An iostream operator<< might be implemented as:]

```cpp
template<class charT, class traits>
basic_ostream<charT, traits>&
operator<< (basic_ostream<charT, traits>& s, Date d) {
    typename basic_ostream<charT, traits>::sentry cerberos(s);
    if (cerberos) {
        ios_base::iostate err = ios_base::iostate::goodbit;
        tm tmbuf; d.extract(tmbuf);
        use_facet<time_put<charT, ostreambuf_iterator<charT, traits>>>(
            s.getloc()).put(s, s, s.fill(), err, &tmbuf, 'x');
        s.setstate(err);
    }
    return s;
}
```

—end example

4 In the call to use_facet<Facet>(loc), the type argument chooses a facet, making available all members of the named type. If Facet is not present in a locale, it throws the standard exception bad_cast. A C++ program can check if a locale implements a particular facet with the function template has_facet<Facet>(). User-defined facets may be installed in a locale, and used identically as may standard facets.

5 [Note: All locale semantics are accessed via use_facet<> and has_facet<>], except that:

(5.1) — A member operator template operator()(const basic_string<C, T, A>&, const basic_string<C, T, A>&) is provided so that a locale may be used as a predicate argument to the standard collections, to collate strings.

(5.2) — Convenient global interfaces are provided for traditional ctype functions such as isdigit() and isspace(), so that given a locale object loc a C++ program can call isspace(c, loc). (This eases upgrading existing extractors (27.7.4.2).)

—end note

6 Once a facet reference is obtained from a locale object by calling use_facet<> that reference remains usable, and the results from member functions of it may be cached and re-used, as long as some locale object refers to that facet.

263) Note that in the call to put the stream is implicitly converted to an ostreambuf_iterator<charT, traits>.  

§ 26.3.1 1111
In successive calls to a locale facet member function on a facet object installed in the same locale, the returned result shall be identical.

A `locale` constructed from a name string (such as "POSIX"), or from parts of two named locales, has a name; all others do not. Named locales may be compared for equality; an unnamed locale is equal only to (copies of) itself. For an unnamed locale, `locale::name()` returns the string ":*".

Whether there is one global locale object for the entire program or one global locale object per thread is implementation-defined. Implementations should provide one global locale object per thread. If there is a single global locale object for the entire program, implementations are not required to avoid data races on it (15.5.5.9).

26.3.1.1 Types

26.3.1.1.1 Type `locale::category`

```cpp
using category = int;
```

1 Valid `category` values include the `locale` member bitmask elements `collate`, `ctype`, `monetary`, `numeric`, `time`, and `messages`, each of which represents a single locale category. In addition, `locale` member bitmask constant `none` is defined as zero and represents no category. And `locale` member bitmask constant `all` is defined such that the expression

```
(collate | ctype | monetary | numeric | time | messages | all) == all
```

is `true`, and represents the union of all categories. Further, the expression `(X | Y)`, where `X` and `Y` each represent a single category, represents the union of the two categories.

2 `locale` member functions expecting a `category` argument require one of the `category` values defined above, or the union of two or more such values. Such a `category` value identifies a set of locale categories. Each locale category, in turn, identifies a set of locale facets, including at least those shown in Table 91.

</tr>
</tbody>
</table>

3 For any locale `loc` either constructed, or returned by `locale::classic()`, and any facet `Facet` shown in Table 91, `has_facet<Facet>(loc)` is `true`. Each `locale` member function which takes a `locale::category` argument operates on the corresponding set of facets.

4 An implementation is required to provide those specializations for facet templates identified as members of a category, and for those shown in Table 92.

5 The provided implementation of members of facets `num_get<charT>` and `num_put<charT>` calls `use_facet<F>(l)` only for facet `F` of types `numpunct<charT>` and `ctype<charT>`, and for locale `l` the value obtained by calling member `getloc()` on the `ios_base&` argument to these functions.

6 In declarations of facets, a template parameter with name `InputIterator` or `OutputIterator` indicates the set of all possible specializations on parameters that satisfy the C++17 InputIterator requirements or...

</table>

Cpp17OutputIterator requirements, respectively (22.2). A template parameter with name C represents the set of types containing char, wchar_t, and any other implementation-defined character types that satisfy the requirements for a character on which any of the iostream components can be instantiated. A template parameter with name International represents the set of all possible specializations on a bool parameter.

26.3.1.1.2 Class locale::facet

namespace std {
    class locale::facet {
        protected:
            explicit facet(size_t refs = 0);
            virtual ~facet();
            facet(const facet&) = delete;
            void operator=(const facet&) = delete;
    };
}

1 Class facet is the base class for locale feature sets. A class is a facet if it is publicly derived from another facet, or if it is a class derived from locale::facet and contains a publicly accessible declaration as follows:

```
static ::std::locale::id id;
```

2 Template parameters in this Clause which are required to be facets are those named Facet in declarations. A program that passes a type that is not a facet, or a type that refers to a volatile-qualified facet, as an (explicit or deduced) template parameter to a locale function expecting a facet, is ill-formed. A const-qualified facet is a valid template argument to any locale function that expects a Facet template parameter.

3 The refs argument to the constructor is used for lifetime management. For refs == 0, the implementation performs delete static_cast<locale::facet*>(f) (where f is a pointer to the facet) when the last locale object containing the facet is destroyed; for refs == 1, the implementation never destroys the facet.

4 Constructors of all facets defined in this Clause take such an argument and pass it along to their facet base class constructor. All one-argument constructors defined in this Clause are explicit, preventing their participation in automatic conversions.

264) This is a complete list of requirements; there are no other requirements. Thus, a facet class need not have a public copy constructor, assignment, default constructor, destructor, etc.
For some standard facets a standard "..._byname" class, derived from it, implements the virtual function semantics equivalent to that facet of the locale constructed by(locale(const char*)) with the same name. Each such facet provides a constructor that takes a const char* argument, which names the locale, and a refs argument, which is passed to the base class constructor. Each such facet also provides a constructor that takes a string argument str and a refs argument, which has the same effect as calling the first constructor with the two arguments str.c_str() and refs. If there is no "..._byname" version of a facet, the base class implements named locale semantics itself by reference to other facets.

26.3.1.1.3 Class locale::id

namespace std {
    class locale::id {
        public:
            id();
            void operator=(const id&) = delete;
            id(const id&) = delete;
    };
}

1 The class locale::id provides identification of a locale facet interface, used as an index for lookup and to encapsulate initialization.

2 [Note: Because facets are used by iostreams, potentially while static constructors are running, their initialization cannot depend on programmed static initialization. One initialization strategy is for locale to initialize each facet’s id member the first time an instance of the facet is installed into a locale. This depends only on static storage being zero before constructors run (6.8.3.2). — end note]

26.3.1.2 Constructors and destructor

locale() noexcept;

1 Default constructor: a snapshot of the current global locale.

2 Effects: Constructs a copy of the argument last passed to locale::global(locale&), if it has been called; else, the resulting facets have virtual function semantics identical to those of locale::classic().

3 [Note: This constructor is commonly used as the default value for arguments of functions that take a const locale& argument. — end note]

locale(const locale& other) noexcept;

4 Effects: Constructs a locale which is a copy of other.

5 explicit locale(const char* std_name);

6 Effects: Constructs a locale using standard C locale names, e.g., "POSIX". The resulting locale implements semantics defined to be associated with that name.

7 Throws: runtime_error if the argument is not valid, or is null.

8 Remarks: The set of valid string argument values is "C", ",", and any implementation-defined values.

9 explicit locale(const string& std_name);

10 Effects: The same as locale(std_name.c_str()).

11 locale(const locale& other, const char* std_name, category);

12 Effects: Constructs a locale as a copy of other except for the facets identified by the category argument, which instead implement the same semantics as locale(std_name).

13 Throws: runtime_error if the argument is not valid, or is null.

14 Remarks: The locale has a name if and only if other has a name.

15 locale(const locale& other, const string& std_name, category cat);

16 Effects: The same as locale(other, std_name.c_str(), cat).
template<class Facet> locale(const locale& other, Facet* f);

**Effects:** Constructs a locale incorporating all facets from the first argument except that of type `Facet`, and installs the second argument as the remaining facet. If `f` is null, the resulting object is a copy of `other`.

**Remarks:** The resulting locale has no name.

locale(const locale& other, const locale& one, category cats);

**Effects:** Constructs a locale incorporating all facets from the first argument except those that implement `cats`, which are instead incorporated from the second argument.

**Remarks:** The resulting locale has a name if and only if the first two arguments have names.

const locale& operator=(const locale& other) noexcept;

**Effects:** Creates a copy of `other`, replacing the current value.

**Returns:** `*this`.

~locale();

A non-virtual destructor that throws no exceptions.

### 26.3.1.3 Members

```cpp
template<class Facet> locale combine(const locale& other) const;
```

**Effects:** Constructs a locale incorporating all facets from `*this` except for that one facet of `other` that is identified by `Facet`.

**Returns:** The newly created locale.

**Throws:** `runtime_error` if `has_facet<Facet>(other)` is false.

**Remarks:** The resulting locale has no name.

```cpp
basic_string<char> name() const;
```

**Returns:** The name of `*this`, if it has one; otherwise, the string "*".

### 26.3.1.4 Operators

```cpp
bool operator==(const locale& other) const;
```

**Returns:** `true` if both arguments are the same locale, or one is a copy of the other, or each has a name and the names are identical; `false` otherwise.

```cpp
bool operator!=(const locale& other) const;
```

**Returns:** `!(*this == other)`.

```cpp
template<class charT, class traits, class Allocator>
bool operator()(const basic_string<charT, traits, Allocator>& s1,
const basic_string<charT, traits, Allocator>& s2) const;
```

**Effects:** Compares two strings according to the `collate<charT>` facet.

**Remarks:** This member operator template (and therefore `locale` itself) satisfies requirements for a comparator predicate template argument (Clause 23) applied to strings.

**Returns:**

```cpp
use_facet<collate<charT>>(*this).compare(s1.data(), s1.data() + s1.size(),
s2.data(), s2.data() + s2.size()) < 0
```

[Example: A vector of strings `v` can be collated according to collation rules in locale `loc` simply by (23.7.1, 21.3.11):

```cpp
std::sort(v.begin(), v.end(), loc);
```

— end example]
26.3.1.5 Static members

static locale global(const locale& loc);

Sets the global locale to its argument.

Effects: Causes future calls to the constructor locale() to return a copy of the argument. If the argument has a name, does

setlocale(LC_ALL, loc.name().c_str());

otherwise, the effect on the C locale, if any, is implementation-defined. No library function other
than locale::global() shall affect the value returned by locale(). [Note: See 26.5 for data race
considerations when setlocale is invoked. — end note]

Returns: The previous value of locale().

static const locale& classic();

The "C" locale.

Returns: A locale that implements the classic "C" locale semantics, equivalent to the value locale("C").

Remarks: This locale, its facets, and their member functions, do not change with time.

26.3.2 locale globals

template<class Facet> const Facet& use_facet(const locale& loc);

Requires: Facet is a facet class whose definition contains the public static member id as defined
in 26.3.1.1.2.

Returns: A reference to the corresponding facet of loc, if present.

Throws: bad_cast if has_facet<Facet>(loc) is false.

Remarks: The reference returned remains valid at least as long as any copy of loc exists.

template<class Facet> bool has_facet(const locale& loc) noexcept;

Returns: true if the facet requested is present in loc; otherwise false.

26.3.3 Convenience interfaces

26.3.3.1 Character classification

template<class charT> bool isspace(charT c, const locale& loc);

template<class charT> bool isprint(charT c, const locale& loc);

template<class charT> bool iscntrl(charT c, const locale& loc);

template<class charT> bool isupper(charT c, const locale& loc);

template<class charT> bool islower(charT c, const locale& loc);

template<class charT> bool isalpha(charT c, const locale& loc);

template<class charT> bool isdigit(charT c, const locale& loc);

template<class charT> bool ispunct(charT c, const locale& loc);

template<class charT> bool isxdigit(charT c, const locale& loc);

template<class charT> bool isgraph(charT c, const locale& loc);

template<class charT> bool isblank(charT c, const locale& loc);

Each of these functions is\textit{F} returns the result of the expression:

\texttt{use_facet<ctype<charT>>(loc).is(ctype_base::\textit{F}, c)}

where \textit{F} is the \texttt{ctype_base::mask} value corresponding to that function (26.4.1).\textsuperscript{265}

26.3.3.2 Conversions

26.3.3.2.1 Character conversions

template<class charT> charT toupper(charT c, const locale& loc);

Returns: use_facet<ctype<charT>>(loc).toupper(c).

\textsuperscript{265} When used in a loop, it is faster to cache the \texttt{ctype<>} facet and use it directly, or use the vector form of \texttt{ctype<>::is}.
template<class charT> char tolower(charT c, const locale& loc);

Returns: use_facet<ctype<charT> >(loc).tolower(c).

26.4 Standard locale categories

Each of the standard categories includes a family of facets. Some of these implement formatting or parsing of a datum, for use by standard or users’ iostream operators << and >>, as members put() and get(), respectively. Each such member function takes an ios_base& argument whose members flags(), precision(), and width(), specify the format of the corresponding datum (27.5.3). Those functions which need to use other facets call its member getloc() to retrieve the locale imbued there. Formatting facets use the character argument fill to fill out the specified width where necessary.

2 The put() members make no provision for error reporting. (Any failures of the OutputIterator argument can be extracted from the returned iterator.) The get() members take an ios_base::iostate& argument whose value they ignore, but set to ios_base::failbit in case of a parse error.

3 Within this clause it is unspecified whether one virtual function calls another virtual function.

26.4.1 The ctype category

namespace std {
    class ctype_base {
        public:
            using mask = see below;

            // numeric values are for exposition only.
            static const mask space = 1 << 0;
            static const mask print = 1 << 1;
            static const mask cntrl = 1 << 2;
            static const mask upper = 1 << 3;
            static const mask lower = 1 << 4;
            static const mask alpha = 1 << 5;
            static const mask digit = 1 << 6;
            static const mask punct = 1 << 7;
            static const mask xdigit = 1 << 8;
            static const mask blank = 1 << 9;
            static const mask alnum = alpha | digit;
            static const mask graph = alnum | punct;
    }
}

1 The type mask is a bitmask type (15.4.2.1.4).

26.4.1.1 Class template ctype

namespace std {
    template<class charT> class ctype : public locale::facet, public ctype_base {
        public:
            using char_type = charT;

            explicit ctype(size_t refs = 0);

            bool is(mask m, charT c) const;
            const charT* is(const charT* low, const charT* high, mask* vec) const;
            const charT* scan_is(mask m, const charT* low, const charT* high) const;
            const charT* scan_not(mask m, const charT* low, const charT* high) const;
            charT toupper(charT c) const;
            const charT* toupper(charT* low, const charT* high) const;
            charT tolower(charT c) const;
            const charT* tolower(charT* low, const charT* high) const;

            charT widen(char c) const;
            const charT* widen(const charT* low, const charT* high) const;
            char narrow(charT c, char dfault) const;
            const charT* narrow(const charT* low, const charT* high, char dfault, char* to) const;

§ 26.4.1.1
static locale::id id;

protected:
-ctype();
virtual bool do_is(mask m, charT c) const;
virtual const charT* do_is(const charT* low, const charT* high, mask* vec) const;
virtual const charT* do_scan_is(mask m, const charT* low, const charT* high) const;
virtual const charT* do_scan_not(mask m, const charT* low, const charT* high) const;
virtual charT do_toupper(charT) const;
virtual const charT* do_toupper(charT* low, const charT* high) const;
virtual charT do_tolower(charT) const;
virtual const charT* do_tolower(charT* low, const charT* high) const;
virtual charT do_widen(char) const;
virtual const charT* do_widen(const charT* low, const charT* high, charT* dest) const;
virtual char do_narrow(charT, char dfault) const;
virtual const charT* do_narrow(const charT* low, const charT* high, char dfault, char* dest) const;
};

1. Class ctype encapsulates the C library <ctype> features. istream members are required to use ctype<> for character classing during input parsing.

2. The specializations required in Table 91 (26.3.1.1.1), namely ctype<char> and ctype<wchar_t>, implement character classing appropriate to the implementation’s native character set.

### 26.4.1.1.1 ctype members

[locale ctype members]

- bool is(mask m, charT c) const;
- const charT* scan_is(mask m, const charT* low, const charT* high) const;
- const charT* scan_not(mask m, const charT* low, const charT* high) const;
- charT toupper(charT) const;
- const charT* toupper(charT* low, const charT* high) const;
- charT tolower(charT c) const;
- const charT* tolower(charT* low, const charT* high) const;
- charT widen(char c) const;
- const char* widen(const char* low, const char* high, charT* to) const;
- char narrow(charT c, char dfault) const;
- const charT* narrow(const charT* low, const charT* high, char dfault, char* to) const;

### 26.4.1.1.2 ctype virtual functions

[locale ctype virtuals]

- bool do_is(mask m, charT c) const;
- const charT* do_is(const charT* low, const charT* high, mask* vec) const;

1. Effects: Classifies a character or sequence of characters. For each argument character, identifies a value $M$ of type ctype_base::mask. The second form identifies a value $M$ of type ctype_base::mask for each *p where (low <= p && p < high), and places it into vec[p - low].
Returns: The first form returns the result of the expression \((M \& m) \neq 0\); i.e., \textbf{true} if the character has the characteristics specified. The second form returns \textbf{high}.

\begin{verbatim}
const char* do_scan_is(mask m, const charT* low, const charT* high) const;
\end{verbatim}

Effects: Locates a character in a buffer that conforms to a classification \(m\).

Returns: The smallest pointer \(p\) in the range \([\text{low}, \text{high})\) such that \(\text{is}(m, *p)\) would return \textbf{true}; otherwise, returns \textbf{high}.

\begin{verbatim}
const char* do_scan_not(mask m, const charT* low, const charT* high) const;
\end{verbatim}

Effects: Locates a character in a buffer that fails to conform to a classification \(m\).

Returns: The smallest pointer \(p\), if any, in the range \([\text{low}, \text{high})\) such that \(\text{is}(m, *p)\) would return \textbf{false}; otherwise, returns \textbf{high}.

\begin{verbatim}
charT do_toupper(charT c) const;
const charT* do_toupper(charT* low, const charT* high) const;
\end{verbatim}

Effects: Converts a character or characters to upper case. The second form replaces each character \(*p\) in the range \([\text{low}, \text{high})\) for which a corresponding upper-case character exists, with that character.

Returns: The first form returns the corresponding upper-case character if it is known to exist, or its argument if not. The second form returns \textbf{high}.

\begin{verbatim}
charT do_tolower(charT c) const;
const charT* do_tolower(charT* low, const charT* high) const;
\end{verbatim}

Effects: Converts a character or characters to lower case. The second form replaces each character \(*p\) in the range \([\text{low}, \text{high})\) and for which a corresponding lower-case character exists, with that character.

Returns: The first form returns the corresponding lower-case character if it is known to exist, or its argument if not. The second form returns \textbf{high}.

\begin{verbatim}
charT do_widen(char c) const;
const char* do_widen(const char* low, const char* high, charT* dest) const;
\end{verbatim}

Effects: Applies the simplest reasonable transformation from a \texttt{char} value or sequence of \texttt{char} values to the corresponding \texttt{charT} value or values.\(^{266}\) The only characters for which unique transformations are required are those in the basic source character set (5.3).

For any named \texttt{ctype} category with a \texttt{ctype <charT>} facet \(ctc\) and valid \texttt{ctype_base::mask} value \(M\),
\begin{verbatim}(ctc.is(M, c) || !is(M, do_widen(c)) ) \end{verbatim} is \textbf{true}.\(^{267}\)

The second form transforms each character \(*p\) in the range \([\text{low}, \text{high})\), placing the result in \(\text{dest}[p - \text{low}]\).

Returns: The first form returns the transformed value. The second form returns \textbf{high}.

\begin{verbatim}
char do_narrow(charT c, char dfault) const;
const charT* do_narrow(const charT* low, const charT* high, charT* dest) const;
\end{verbatim}

Effects: Applies the simplest reasonable transformation from a \texttt{charT} value or sequence of \texttt{charT} values to the corresponding \texttt{char} value or values.

For any character \(c\) in the basic source character set (5.3) the transformation is such that
\begin{verbatim}do_widen(do_narrow(c, 0)) == c\end{verbatim}

For any named \texttt{ctype} category with a \texttt{ctype<char>} facet \(ctc\) however, and \texttt{ctype_base::mask} value \(M\),
\begin{verbatim}(is(M, c) || !ctc.is(M, do_narrow(c, dfault)) ) \end{verbatim} is \textbf{true} (unless \texttt{do_narrow} returns \texttt{dfault}). In addition, for any digit character \(c\), the expression \begin{verbatim}(do_narrow(c, dfault) - '0')\end{verbatim} evaluates to the digit value of the character. The second form transforms each character \(*p\) in the range \([\text{low}, \text{high})\), placing the result (or \texttt{dfault} if no simple transformation is readily available) in \(\text{dest}[p - \text{low}]\).

\(^{266}\) The \texttt{char} argument of \texttt{do_widen} is intended to accept values derived from character literals for conversion to the locale’s encoding.
\(^{267}\) In other words, the transformed character is not a member of any character classification that \(c\) is not also a member of.
Returns: The first form returns the transformed value; or default if no mapping is readily available. The second form returns high.

26.4.1.2 Class template ctype_byname

namespace std {
    template<class charT>
    class ctype_byname : public ctype<charT> {
        public:
            using mask = typename ctype<charT>::mask;
            explicit ctype_byname(const char*, size_t refs = 0);
            explicit ctype_byname(const string&, size_t refs = 0);

            protected:
                ~ctype_byname();
        }
    }

26.4.1.3 ctype specializations

namespace std {
    template<>
    class ctype<char> : public locale::facet, public ctype_base {
        public:
            using char_type = char;
            explicit ctype(const mask* tab = nullptr, bool del = false, size_t refs = 0);

            bool is(mask m, char c) const;
            const char* is(const char* low, const char* high, mask* vec) const;
            const char* scan_is (mask m, const char* low, const char* high) const;
            const char* scan_not(mask m, const char* low, const char* high) const;

            char toupper(char c) const;
            const char* toupper(char* low, const char* high) const;
            char tolower(char c) const;
            const char* tolower(char* low, const char* high) const;
            char widen(char c) const;
            const char* widen(const char* low, const char* high) const;
            char narrow(char c, char dfault) const;
            const char* narrow(const char* low, const char* high, char dfault, char* to) const;

            static locale::id id;
            static const size_t table_size = implementation-defined;

            const mask* table() const noexcept;
            static const mask* classic_table() noexcept;

            protected:
                ~ctype();
                virtual char do_toupper(char c) const;
                virtual const char* do_toupper(char* low, const char* high) const;
                virtual char do_tolower(char c) const;
                virtual const char* do_tolower(char* low, const char* high) const;

                virtual char do_widen(char c) const;
                virtual const char* do_widen(const char* low, const char* high, char* to) const;
                virtual char do_narrow(char c, char dfault) const;
                virtual const char* do_narrow(const char* low, const char* high, char dfault, char* to) const;
        }
    }

§ 26.4.1.3
A specialization `ctype<char>` is provided so that the member functions on type `char` can be implemented inline.\(^{268}\) The implementation-defined value of member `table_size` is at least 256.

26.4.1.3.1 `ctype<char>` destructor  

`~ctype();`  

*Effects:* If the constructor’s first argument was nonzero, and its second argument was `true`, does delete [] `table()`.

26.4.1.3.2 `ctype<char>` members  

In the following member descriptions, for `unsigned char` values \(v\) where \(v \geq table_size\), `table()[v]` is assumed to have an implementation-specific value (possibly different for each such value \(v\)) without performing the array lookup.

```cpp
explicit ctype(const mask* tbl = nullptr, bool del = false, size_t refs = 0);
```

*Requires:* \(tbl\) either 0 or an array of at least `table_size` elements.

*Effects:* Passes its `refs` argument to its base class constructor.

```cpp
bool is(mask m, char c) const;
const char* is(const char* low, const char* high, mask* vec) const;
```

*Effects:* The second form, for all \(*p\) in the range \([low, high)\), assigns into `vec[p - low]` the value `table()[((unsigned char)*p)]`.

*Returns:* The first form returns `table()[((unsigned char)c) & m]`; the second form returns `high`.

```cpp
const char* scan_is(mask m, const char* low, const char* high) const;
```

*Returns:* The smallest \(p\) in the range \([low, high)\) such that `table()[((unsigned char) *p) & m]` is `true`.

```cpp
const char* scan_not(mask m, const char* low, const char* high) const;
```

*Returns:* The smallest \(p\) in the range \([low, high)\) such that `table()[((unsigned char) *p) & m]` is `false`.

```cpp
toupper(char c) const;
const char* toupper(char* low, const char* high) const;
```

*Returns:* `do_toupper(c)` or `do_toupper(low, high)`, respectively.

```cpp
tolower(char c) const;
const char* tolower(char* low, const char* high) const;
```

*Returns:* `do_tolower(c)` or `do_tolower(low, high)`, respectively.

```cpp
widen(char c) const;
const char* widen(const char* low, const char* high, char* to) const;
```

*Returns:* `do_widen(c)` or `do_widen(low, high, to)`, respectively.

```cpp
narrow(char c, char dfault) const;
const char* narrow(const char* low, const char* high, char dfault, char* to) const;
```

*Returns:* `do_narrow(c, dfault)` or `do_narrow(low, high, dfault, to)`, respectively.

```cpp
const mask* table() const noexcept;
```

*Returns:* The first constructor argument, if it was nonzero, otherwise `classic_table()`.

\(^{268}\) Only the `char` (not `unsigned char` and `signed char`) form is provided. The specialization is specified in the standard, and not left as an implementation detail, because it affects the derivation interface for `ctype<char>`. 
26.4.1.3.3  

c-type<char> static members

static const mask* classic_table() noexcept;

1. Returns: A pointer to the initial element of an array of size table_size which represents the classifications of characters in the "C" locale.

26.4.1.3.4  
c-type<char> virtual functions

char do_toupper(char) const;
const char* do_toupper(char* low, const char* high) const;
char do_tolower(char) const;
const char* do_tolower(char* low, const char* high) const;

virtual char do_widen(char c) const;
virtual const char* do_widen(const char* low, const char* high, char* to) const;
virtual char do_narrow(char c, char dfault) const;
virtual const char* do_narrow(const char* low, const char* high, char dfault, char* to) const;

1. These functions are described identically as those members of the same name in the c-type class template (26.4.1.1.1).

26.4.1.4  
Class template codecvt

namespace std {

class codecvt_base {
    public:
        enum result { ok, partial, error, noconv };
    }

template<class internT, class externT, class stateT>

class codecvt : public locale::facet, public codecvt_base {
    public:
        using intern_type = internT;
        using extern_type = externT;
        using state_type = stateT;

        explicit codecvt(size_t refs = 0);

        result out(
            stateT& state,
            const internT* from, const internT* from_end, const internT*& from_next,
            externT* to, externT* to_end, externT*& to_next) const;

        result unshift(
            stateT& state,
            externT* to, externT* to_end, externT*& to_next) const;

        result in(
            stateT& state,
            const externT* from, const externT* from_end, const externT*& from_next,
            internT* to, internT* to_end, internT*& to_next) const;

        int encoding() const noexcept;
        bool always_noconv() const noexcept;
        int length(stateT&, const externT* from, const externT* end, size_t max) const;
        int max_length() const noexcept;

        static locale::id id;

    protected:
        ~codecvt();
        virtual result do_out(
            stateT& state,
            const internT* from, const internT* from_end, const internT*& from_next,
            externT* to, externT* to_end, externT*& to_next) const;

§ 26.4.1.4
The class `codecvt<internT, externT, stateT>` is for use when converting from one character encoding to another, such as from wide characters to multibyte characters or between wide character encodings such as Unicode and EUC.

The `stateT` argument selects the pair of character encodings being mapped between.

The specializations required in Table 91 (26.3.1.1.1) convert the implementation-defined native character set. `codecvt<char, char, mbstate_t>` implements a degenerate conversion; it does not convert at all. The specialization `codecvt<char16_t, char, mbstate_t>` converts between the UTF-16 and UTF-8 encoding forms, and the specialization `codecvt<char32_t, char, mbstate_t>` converts between the UTF-32 and UTF-8 encoding forms. `codecvt<wchar_t, char, mbstate_t>` converts between the native character sets for narrow and wide characters. Specializations on `mbstate_t` perform conversion between encodings known to the library implementer. Other encodings can be converted by specializing on a program-defined `stateT` type. Objects of type `stateT` can contain any state that is useful to communicate to or from the specialized `do_in` or `do_out` members.

### 26.4.1.4.1 codecvt members

```cpp
virtual result do_in(
    stateT& state,
    const externT* from, const externT* from_end, const externT*& from_next,
    internT* to, internT* to_end, internT*& to_next) const;
virtual result do_unshift(
    stateT& state,
    externT* to, externT* to_end, externT*& to_next) const;
virtual int do_encoding() const noexcept;
virtual bool do_always_noconv() const noexcept;
virtual int do_length(stateT&, const externT* from, const externT* end, size_t max) const;
virtual int do_max_length() const noexcept;
};
```

1. Returns: `do_out(state, from, from_end, from_next, to, to_end, to_next) const;`
2. Returns: `do_unshift(stateT& state, externT* to, externT* to_end, externT*& to_next) const;`
3. Returns: `do_in(stateT& state, externT* from, externT* from_end, externT*& from_next,
   internT* to, internT* to_end, internT*& to_next) const;`
4. Returns: `do_encoding();`
5. Returns: `do_always_noconv();`
6. Returns: `do_length(stateT& state, externT* from, externT* from_end, size_t max) const;`
7. Returns: `do_max_length();`
26.4.1.4.2 codecvt virtual functions

result do_out(
    stateT& state,
    const internT* from, const internT* from_end, const internT*& from_next,
    externT* to, externT* to_end, externT*& to_next) const;

result do_in(
    stateT& state,
    const externT* from, const externT* from_end, const externT*& from_next,
    internT* to, internT* to_end, internT*& to_next) const;

1 Requires: (from <= from_end && to <= to_end) well-defined and true; state initialized, if at the beginning of a sequence, or else equal to the result of converting the preceding characters in the sequence.

2 Effects: Translates characters in the source range [from, from_end), placing the results in sequential positions starting at destination to. Converts no more than (from_end - from) source elements, and stores no more than (to_end - to) destination elements.

   Stops if it encounters a character it cannot convert. It always leaves the from_next and to_next pointers pointing one beyond the last element successfully converted. If returns noconv, internT and externT are the same type and the converted sequence is identical to the input sequence [from, from_next). to_next is set equal to to, the value of state is unchanged, and there are no changes to the values in [to, to_end).

3 A codecvt facet that is used by basic_filebuf (27.9) shall have the property that if
do_out(state, from, from_end, from_next, to, to_end, to_next)
would return ok, where from != from_end, then
do_out(state, from, from + 1, from_next, to, to_end, to_next)
shall also return ok, and that if
do_in(state, from, from_end, from_next, to, to_end, to_next)
would return ok, where to != to_end, then
do_in(state, from, from_end, from_next, to, to + 1, to_next)
shall also return ok.\[269\] [Note: As a result of operations on state, it can return ok or partial and set from_next == from and to_next != to. — end note]

4 Remarks: Its operations on state are unspecified. [Note: This argument can be used, for example, to maintain shift state, to specify conversion options (such as count only), or to identify a cache of seek offsets. — end note]

5 Returns: An enumeration value, as summarized in Table 93.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ok</td>
<td>completed the conversion</td>
</tr>
<tr>
<td>partial</td>
<td>not all source characters converted</td>
</tr>
<tr>
<td>error</td>
<td>encountered a character in [from, from_end) that it could not convert</td>
</tr>
<tr>
<td>noconv</td>
<td>internT and externT are the same type, and input sequence is identical to converted sequence</td>
</tr>
</tbody>
</table>

A return value of partial, if (from_next == from_end), indicates that either the destination sequence has not absorbed all the available destination elements, or that additional source elements are needed before another destination element can be produced.

\[269\] Informally, this means that basic_filebuf assumes that the mappings from internal to external characters is 1 to N: a codecvt facet that is used by basic_filebuf must be able to translate characters one internal character at a time.
result do_unshift(stateT& state, externT* to, externT* to_end, externT*& to_next) const;

Requires: (to <= to_end) well-defined and true; state initialized, if at the beginning of a sequence, or else equal to the result of converting the preceding characters in the sequence.

Effects: Places characters starting at to that should be appended to terminate a sequence when the current stateT is given by state.
Stores no more than (to_end - to) destination elements, and leaves the to_next pointer pointing one beyond the last element successfully stored.

Returns: An enumeration value, as summarized in Table 94.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ok</td>
<td>completed the sequence</td>
</tr>
<tr>
<td>partial</td>
<td>space for more than to_end - to destination elements was needed to termi-</td>
</tr>
<tr>
<td></td>
<td>nate a sequence given the value of state</td>
</tr>
<tr>
<td>error</td>
<td>an unspecified error has occurred</td>
</tr>
<tr>
<td>noconv</td>
<td>no termination is needed for this state_type</td>
</tr>
</tbody>
</table>

int do_encoding() const noexcept;

Returns: -1 if the encoding of the externT sequence is state-dependent; else the constant number of externT characters needed to produce an internal character; or 0 if this number is not a constant.

bool do_always_noconv() const noexcept;

Returns: true if do_in() and do_out() return noconv for all valid argument values. codecvt<char, char, mbstate_t> returns true.

int do_length(stateT& state, const externT* from, const externT* from_end, size_t max) const;

Requires: (from <= from_end) well-defined and true; state initialized, if at the beginning of a sequence, or else equal to the result of converting the preceding characters in the sequence.

Effects: The effect on the state argument is “as if” it called do_in(state, from, from_end, from, to, to+max, to) for to pointing to a buffer of at least max elements.

Returns: (from_next-from) where from_next is the largest value in the range [from, from_end) such that the sequence of values in the range [from, from_next) represents max or fewer valid complete characters of type internT. The specialization codecvt<char, char, mbstate_t> returns the lesser of max and (from_end-from).

int do_max_length() const noexcept;

Returns: The maximum value that do_length(state, from, from_end, 1) can return for any valid range [from, from_end) and stateT value state. The specialization codecvt<char, char, mbstate_t>::do_max_length() returns 1.

26.4.1.5 Class template codecvt_byname

namespace std {
  template<class internT, class externT, class stateT>
  class codecvt_byname : public codecvt<internT, externT, stateT> {
    public:
      explicit codecvt_byname(const char*, size_t refs = 0);
      explicit codecvt_byname(const string&, size_t refs = 0);
      protected:
        ~codecvt_byname();
    }
}

270) Typically these will be characters to return the state to stateT().
271) If encoding() yields -1, then more than max_length() externT elements may be consumed when producing a single internT character, and additional externT elements may appear at the end of a sequence after those that yield the final internT character.
26.4.2 The numeric category

The classes `num_get<>` and `num_put<>` handle numeric formatting and parsing. Virtual functions are provided for several numeric types. Implementations may (but are not required to) delegate extraction of smaller types to extractors for larger types.\(^2\)

All specifications of member functions for `num_put` and `num_get` in the subclauses of 26.4.2 only apply to the specializations required in Tables 91 and 92 (26.3.1.1.1), namely `num_get<char>`, `num_get<wchar_t>`, `num_get<C, InputIterator>`, `num_put<char>`, `num_put<wchar_t>`, and `num_put<C, OutputIterator>`. These specializations refer to the `ios_base&` argument for formatting specifications (26.4), and to its imbued locale for the `numpunct<>` facet to identify all numeric punctuation preferences, and also for the `ctype<>` facet to perform character classification.

Extractor and inserter members of the standard iostreams use `num_get<>` and `num_put<>` member functions for formatting and parsing numeric values (27.7.4.2.1, 27.7.5.2.1).

26.4.2.1 Class template `num_get`

```cpp
namespace std {
    template<class charT, class InputIterator = istreambuf_iterator<charT>>
    class num_get : public locale::facet {
        public:
            using char_type = charT;
            using iter_type = InputIterator;
            explicit num_get(size_t refs = 0);
            iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, bool& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, long& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, long long& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, unsigned short& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, unsigned int& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, unsigned long& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, unsigned long long& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, float& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, double& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, long double& v) const;
            iter_type get(iter_type in, iter_type end, ios_base&, ios_base::iostate& err, void*& v) const;
            static locale::id id;
        protected:
            ~num_get();
            virtual iter_type do_get(iter_type, iter_type, ios_base&, ios_base::iostate& err, bool& v) const;
            virtual iter_type do_get(iter_type, iter_type, ios_base&, ios_base::iostate& err, long& v) const;
            virtual iter_type do_get(iter_type, iter_type, ios_base&, ios_base::iostate& err, long long& v) const;
            virtual iter_type do_get(iter_type, iter_type, ios_base&, ios_base::iostate& err, unsigned short& v) const;
            virtual iter_type do_get(iter_type, iter_type, ios_base&, ios_base::iostate& err, unsigned int& v) const;
            virtual iter_type do_get(iter_type, iter_type, ios_base&, ios_base::iostate& err, unsigned long& v) const;
            virtual iter_type do_get(iter_type, iter_type, ios_base&, ios_base::iostate& err, unsigned long long& v) const;
            virtual iter_type do_get(iter_type, iter_type, ios_base&, ios_base::iostate& err, float& v) const;
            virtual iter_type do_get(iter_type, iter_type, ios_base&, ios_base::iostate& err, double& v) const;
            virtual iter_type do_get(iter_type, iter_type, ios_base&, ios_base::iostate& err, long double& v) const;
            virtual iter_type do_get(iter_type, iter_type, ios_base&, ios_base::iostate& err, void*& v) const;
}
```

272) Parsing "-1" correctly into, e.g., an unsigned short requires that the corresponding member `get()` at least extract the sign before delegating.
virtual iter_type do_get(iter_type, iter_type, ios_base&,
  ios_base::iostate& err, unsigned int& v) const;
virtual iter_type do_get(iter_type, iter_type, ios_base&,
  ios_base::iostate& err, unsigned long& v) const;
virtual iter_type do_get(iter_type, iter_type, ios_base&,
  ios_base::iostate& err, unsigned long long& v) const;
virtual iter_type do_get(iter_type, iter_type, ios_base&,
  ios_base::iostate& err, float& v) const;
virtual iter_type do_get(iter_type, iter_type, ios_base&,
  ios_base::iostate& err, double& v) const;
virtual iter_type do_get(iter_type, iter_type, ios_base&,
  ios_base::iostate& err, long double& v) const;
virtual iter_type do_get(iter_type, iter_type, ios_base&,
  ios_base::iostate& err, void*& v) const;
};

The facet **num_get** is used to parse numeric values from an input sequence such as an istream.

### 26.4.2.1.1 num_get members

iter_type get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, bool& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, long& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, long long& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, unsigned short& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, unsigned int& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, unsigned long& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, unsigned long long& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, float& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, double& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, long double& val) const;
iter_type get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, void*& val) const;

Returns: do_get(in, end, str, err, val).

### 26.4.2.1.2 num_get virtual functions

iter_type do_get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, long& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, long long& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, unsigned short& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, unsigned int& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, unsigned long& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, unsigned long long& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, float& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, double& val) const;
iter_type do_get(iter_type in, iter_type end, ios_base& str,
  ios_base::iostate& err, long double& val) const;

§ 26.4.2.1.2 1127
iter_type do_get(iter_type in, iter_type end, ios_base& str,
    ios_base::iostate& err, void*& val) const;

1 Effects: Reads characters from in, interpreting them according to str.flags(), use_facet<ctype<charT>>(loc), and use_facet<numpunct<charT>>(loc), where loc is str.getloc().

2 The details of this operation occur in three stages

(2.1) — Stage 1: Determine a conversion specifier

(2.2) — Stage 2: Extract characters from in and determine a corresponding char value for the format expected by the conversion specification determined in stage 1.

(2.3) — Stage 3: Store results

3 The details of the stages are presented below.

Stage 1: The function initializes local variables via

    fmtflags flags = str.flags();
    fmtflags basefield = (flags & ios_base::basefield);
    fmtflags uppercase = (flags & ios_base::uppercase);
    fmtflags boolalpha = (flags & ios_base::boolalpha);

For conversion to an integral type, the function determines the integral conversion specifier as indicated in Table 95. The table is ordered. That is, the first line whose condition is true applies.

Table 95 — Integer conversions

<table>
<thead>
<tr>
<th>State</th>
<th>stdio equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>basefield == oct</td>
<td>%o</td>
</tr>
<tr>
<td>basefield == hex</td>
<td>%X</td>
</tr>
<tr>
<td>basefield == 0</td>
<td>%i</td>
</tr>
<tr>
<td>signed integral type</td>
<td>%d</td>
</tr>
<tr>
<td>unsigned integral type</td>
<td>%u</td>
</tr>
</tbody>
</table>

For conversions to a floating-point type the specifier is %g.
For conversions to void* the specifier is %p.
A length modifier is added to the conversion specification, if needed, as indicated in Table 96.

Table 96 — Length modifier

<table>
<thead>
<tr>
<th>Type</th>
<th>Length modifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>short</td>
<td>h</td>
</tr>
<tr>
<td>unsigned short</td>
<td>h</td>
</tr>
<tr>
<td>long</td>
<td>l</td>
</tr>
<tr>
<td>unsigned long</td>
<td>l</td>
</tr>
<tr>
<td>long long</td>
<td>ll</td>
</tr>
<tr>
<td>unsigned long long</td>
<td>ll</td>
</tr>
<tr>
<td>double</td>
<td>l</td>
</tr>
<tr>
<td>long double</td>
<td>L</td>
</tr>
</tbody>
</table>

Stage 2: If in == end then stage 2 terminates. Otherwise a charT is taken from in and local variables are initialized as if by

    char_type ct = *in;
    char c = src[find(atoms, atoms + sizeof(src) - 1, ct) - atoms];
    if (ct == use_facet<numpunct<charT>>(loc).decimal_point())
        c = '.';
    bool discard =
        ct == use_facet<numpunct<charT>>(loc).thousands_sep() && use_facet<numpunct<charT>>(loc).grouping().length() != 0;

where the values src and atoms are defined as if by:

    static const char src[] = "0123456789abcdefxABCDEFX+-";
    char_type atoms[sizeof(src)];
    use_facet<ctype<charT>>(loc).widen(src, src + sizeof(src), atoms);
for this value of loc.

If discard is true, then if '.' has not yet been accumulated, then the position of the character is remembered, but the character is otherwise ignored. Otherwise, if '.' has already been accumulated, the character is discarded and Stage 2 terminates. If it is not discarded, then a check is made to determine if c is allowed as the next character of an input field of the conversion specifier returned by Stage 1. If so, it is accumulated.

If the character is either discarded or accumulated then in is advanced by ++in and processing returns to the beginning of stage 2.

Stage 3: The sequence of chars accumulated in stage 2 (the field) is converted to a numeric value by the rules of one of the functions declared in the header <cstdlib>:

- For a signed integer value, the function strtoll.
- For an unsigned integer value, the function strtoull.
- For a float value, the function strtof.
- For a double value, the function strtod.
- For a long double value, the function strtold.

The numeric value to be stored can be one of:

- zero, if the conversion function does not convert the entire field.
- the most positive (or negative) representable value, if the field to be converted to a signed integer type represents a value too large positive (or negative) to be represented in val.
- the most positive representable value, if the field to be converted to an unsigned integer type represents a value that cannot be represented in val.
- the converted value, otherwise.

The resultant numeric value is stored in val. If the conversion function does not convert the entire field, or if the field represents a value outside the range of representable values, ios_base::failbit is assigned to err.

Digit grouping is checked. That is, the positions of discarded separators is examined for consistency with use_facet<numpunct<charT>>(loc).grouping(). If they are not consistent then ios_base::failbit is assigned to err.

In any case, if stage 2 processing was terminated by the test for in == end then err |= ios_base::eofbit is performed.

iter_type do_get(iter_type in, iter_type end, ios_base& str, ios_base::iostate& err, bool& val) const;

Effects: If (str.flags()&ios_base::boolalpha) == 0 then input proceeds as it would for a long except that if a value is being stored into val, the value is determined according to the following: If the value to be stored is 0 then false is stored. If the value is 1 then true is stored. Otherwise true is stored and ios_base::failbit is assigned to err.

Otherwise target sequences are determined “as if” by calling the members false-name() and true-name() of the facet obtained by use_facet<numpunct<charT>>(str.getloc()). Successive characters in the range [in, end) (see 21.2.3) are obtained and matched against corresponding positions in the target sequences only as necessary to identify a unique match. The input iterator in is compared to end only when necessary to obtain a character. If a target sequence is uniquely matched, val is set to the corresponding value. Otherwise false is stored and ios_base::failbit is assigned to err.

The in iterator is always left pointing one position beyond the last character successfully matched. If val is set, then err is set to str.goodbit; or to str.eofbit if, when seeking another character to match, it is found that (in == end). If val is not set, then err is set to str.failbit; or to (str.failbit|str.eofbit) if the reason for the failure was that (in == end). [Example: For targets true: "a" and false: "abb", the input sequence "a" yields val == true and err == str.eofbit; the input sequence "abc" yields err = str.failbit, with in ending at the 'c' element. For targets true: "1" and false: "0", the input sequence "1" yields val == true and err == str.goodbit. For empty targets (""), any input sequence yields err == str.failbit. — end example]

Returns: in.

                   — end example

§ 26.4.2.1.2
26.4.2.2 Class template num_put

namespace std {
    template<class charT, class OutputIterator = ostreambuf_iterator<charT>>
    class num_put : public locale::facet {
        public:
            using char_type = charT;
            using iter_type = OutputIterator;

            explicit num_put(size_t refs = 0);

            iter_type put(iter_type s, ios_base& f, char_type fill, bool v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, long v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, long long v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, unsigned long v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, unsigned long long v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, double v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, long double v) const;
            iter_type put(iter_type s, ios_base& f, char_type fill, const void* v) const;

            static locale::id id;

        protected:
            ~num_put();
            virtual iter_type do_put(iter_type out, ios_base& str, char_type fill, bool v) const;
            virtual iter_type do_put(iter_type out, ios_base& str, char_type fill, long v) const;
            virtual iter_type do_put(iter_type out, ios_base& str, char_type fill, long long v) const;
            virtual iter_type do_put(iter_type out, ios_base& str, char_type fill, unsigned long v) const;
            virtual iter_type do_put(iter_type out, ios_base& str, char_type fill, unsigned long long v) const;
            virtual iter_type do_put(iter_type out, ios_base& str, char_type fill, double v) const;
            virtual iter_type do_put(iter_type out, ios_base& str, char_type fill, long double v) const;
            virtual iter_type do_put(iter_type out, ios_base& str, char_type fill, const void* v) const;
    }

1 The facet num_put is used to format numeric values to a character sequence such as an ostream.

26.4.2.2.1 num_put members

iter_type put(iter_type out, ios_base& str, char_type fill, bool val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, long long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, unsigned long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, unsigned long long val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, double val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, long double val) const;
iter_type put(iter_type out, ios_base& str, char_type fill, const void* val) const;

1 Returns: do_put(out, str, fill, val).

26.4.2.2.2 num_put virtual functions

iter_type do_put(iter_type out, ios_base& str, char_type fill, long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, long long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, unsigned long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, unsigned long long val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, double val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, long double val) const;
iter_type do_put(iter_type out, ios_base& str, char_type fill, const void* val) const;

1 Effects: Writes characters to the sequence out, formatting val as desired. In the following description,
loc names a local variable initialized as
locale loc = str.getloc();

2 The details of this operation occur in several stages:

(2.1) — Stage 1: Determine a printf conversion specifier spec and determine the characters that would be
printed by printf (27.12) given this conversion specifier for
printf(spec, val)
assuming that the current locale is the "C" locale.

— Stage 2: Adjust the representation by converting each char determined by stage 1 to a charT
using a conversion and values returned by members of use_facet<numpunct<charT>>(loc)

— Stage 3: Determine where padding is required.

— Stage 4: Insert the sequence into the out.

Detailed descriptions of each stage follow.

Returns: out.

Stage 1: The first action of stage 1 is to determine a conversion specifier. The tables that describe
this determination use the following local variables

fmtflags flags = str.flags();
fmtflags basefield = (flags & (ios_base::basefield));
fmtflags uppercase = (flags & (ios_base::uppercase));
fmtflags floatfield = (flags & (ios_base::floatfield));
fmtflags showpos = (flags & (ios_base::showpos));
fmtflags showbase = (flags & (ios_base::showbase));
fmtflags showpoint = (flags & (ios_base::showpoint));

All tables used in describing stage 1 are ordered. That is, the first line whose condition is true
applies. A line without a condition is the default behavior when none of the earlier lines apply.
For conversion from an integral type other than a character type, the function determines the
integral conversion specifier as indicated in Table 97.

Table 97 — Integer conversions

<table>
<thead>
<tr>
<th>State</th>
<th>stdio equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>basefield == ios_base::oct</td>
<td>%o</td>
</tr>
<tr>
<td>(basefield == ios_base::hex) &amp;&amp; !uppercase</td>
<td>%x</td>
</tr>
<tr>
<td>(basefield == ios_base::hex)</td>
<td>%X</td>
</tr>
<tr>
<td>for a signed integral type</td>
<td>%d</td>
</tr>
<tr>
<td>for an unsigned integral type</td>
<td>%u</td>
</tr>
</tbody>
</table>

For conversion from a floating-point type, the function determines the floating-point conversion
specifier as indicated in Table 98.

Table 98 — Floating-point conversions

<table>
<thead>
<tr>
<th>State</th>
<th>stdio equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>floatfield == ios_base::fixed</td>
<td>%f</td>
</tr>
<tr>
<td>floatfield == ios_base::scientific &amp;&amp; !uppercase</td>
<td>%e</td>
</tr>
<tr>
<td>floatfield == ios_base::scientific</td>
<td>%E</td>
</tr>
<tr>
<td>floatfield == (ios_base::fixed</td>
<td>ios_base::scientific) &amp;&amp; !uppercase</td>
</tr>
<tr>
<td>floatfield == (ios_base::fixed</td>
<td>ios_base::scientific)</td>
</tr>
<tr>
<td>!uppercase</td>
<td>%g</td>
</tr>
<tr>
<td>otherwise</td>
<td>%G</td>
</tr>
</tbody>
</table>

For conversions from an integral or floating-point type a length modifier is added to the conversion
specifier as indicated in Table 99.

The conversion specifier has the following optional additional qualifiers prepended as indicated in
Table 100.

For conversion from a floating-point type, if floatfield != (ios_base::fixed | ios_base::
scientific), str.precision() is specified as precision in the conversion specification. Otherwise,
no precision is specified.
For conversion from void* the specifier is %p.
Table 99 — Length modifier

<table>
<thead>
<tr>
<th>Type</th>
<th>Length modifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>long</td>
<td>l</td>
</tr>
<tr>
<td>long long</td>
<td>ll</td>
</tr>
<tr>
<td>unsigned long</td>
<td>l</td>
</tr>
<tr>
<td>unsigned long long</td>
<td>ll</td>
</tr>
<tr>
<td>long double</td>
<td>L</td>
</tr>
<tr>
<td>otherwise</td>
<td>none</td>
</tr>
</tbody>
</table>

Table 100 — Numeric conversions

<table>
<thead>
<tr>
<th>Type(s)</th>
<th>State</th>
<th>stdio equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>an integral type</td>
<td>showpos</td>
<td>+</td>
</tr>
<tr>
<td></td>
<td>showbase</td>
<td>#</td>
</tr>
<tr>
<td>a floating-point type</td>
<td>showpos</td>
<td>+</td>
</tr>
<tr>
<td></td>
<td>showpoint</td>
<td>#</td>
</tr>
</tbody>
</table>

The representations at the end of stage 1 consists of the char’s that would be printed by a call of printf(s, val) where s is the conversion specifier determined above.

Stage 2: Any character c other than a decimal point(.) is converted to a charT via use_facet<ctype<charT>>(loc).widen(c)

A local variable punct is initialized via

```
const numpunct<charT>& punct = use_facet<numpunct<charT>>(loc);
```

For arithmetic types, punct.thousands_sep() characters are inserted into the sequence as determined by the value returned by punct.do_grouping() using the method described in 26.4.3.1.2 Decimal point characters(.) are replaced by punct.decimal_point()

Stage 3: A local variable is initialized as

```
fmtflags adjustfield = (flags & (ios_base::adjustfield));
```

The location of any padding is determined according to Table 101.

Table 101 — Fill padding

<table>
<thead>
<tr>
<th>State</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>adjustfield == ios_base::left</td>
<td>pad after</td>
</tr>
<tr>
<td>adjustfield == ios_base::right</td>
<td>pad before</td>
</tr>
<tr>
<td>adjustfield == internal and a sign occurs in the representation</td>
<td>pad after the sign</td>
</tr>
<tr>
<td>adjustfield == internal and representation after stage 1 began with 0x or 0X</td>
<td>pad after x or X</td>
</tr>
<tr>
<td>otherwise</td>
<td>pad before</td>
</tr>
</tbody>
</table>

If str.width() is nonzero and the number of charT’s in the sequence after stage 2 is less than str.width(), then enough fill characters are added to the sequence at the position indicated for padding to bring the length of the sequence to str.width(). str.width(0) is called.

Stage 4: The sequence of charT’s at the end of stage 3 are output via

```
*out++ = c
```

iter_type do_put(iter_type out, ios_base& str, char_type fill, bool val) const;

Returns: If (str.flags() & ios_base::boolalpha) == 0 returns do_put(out, str, fill, (int)val), otherwise obtains a string s as if by

273) The conversion specification #o generates a leading 0 which is not a padding character.
26.4.3 The numeric punctuation facet

26.4.3.1 Class template numpunct

namespace std {
template<class charT>
class numpunct : public locale::facet {
public:
  using char_type = charT;
  using string_type = basic_string<charT>;

  explicit numpunct(size_t refs = 0);

  char_type decimal_point() const;
  char_type thousands_sep() const;
  string grouping() const;
  string_type truename() const;
  string_type falsename() const;

  static locale::id id;

protected:
  ~numpunct();  // virtual
  virtual char_type do_decimal_point() const;
  virtual char_type do_thousands_sep() const;
  virtual string do_grouping() const;  // for bool
  virtual string_type do_truename() const;  // for bool
  virtual string_type do_falsename() const;  // for bool
};
}

1 numpunct<> specifies numeric punctuation. The specializations required in Table 91 (26.3.1.1.1), namely numpunct<wchar_t> and numpunct<char>, provide classic "C" numeric formats, i.e., they contain information equivalent to that contained in the "C" locale or their wide character counterparts as if obtained by a call to widen.

2 The syntax for number formats is as follows, where digit represents the radix set specified by the fmtflags argument value, and thousands-sep and decimal-point are the results of corresponding numpunct<charT> members. Integer values have the format:

integer ::= [sign] units
sign ::= plusminus
plusminus ::= '+' | '-'
units ::= digits [thousands-sep units]
digits ::= digit [digits]

and floating-point values have:

floatval ::= [sign] units [decimal-point [digits]] [e [sign] digits] | [sign] decimal-point digits [e [sign] digits]
e ::= 'e' | 'E'

where the number of digits between thousands-seps is as specified by do_grouping(). For parsing, if the digits portion contains no thousands-separators, no grouping constraint is applied.

26.4.3.1.1 numpunct members

char_type decimal_point() const;
  Returns: do_decimal_point().

char_type thousands_sep() const;
  Returns: do_thousands_sep().
26.4.3.1.2 numpunct virtual functions

string grouping() const;

Returns: do_grouping().

string_type truename() const;
string_type falsename() const;

Returns: do_truename() or do_falsename(), respectively.

26.4.3.2 Class template numpunct_byname

namepace std {

  template<class charT>
  class numpunct_byname : public numpunct<charT> {
    // this class is specialized for char and wchar_t.
    public:
    using char_type = charT;
    using string_type = basic_string<charT>;

    explicit numpunct_byname(const char*, size_t refs = 0);
    explicit numpunct_byname(const string&, size_t refs = 0);

    protected:
    ~numpunct_byname();
  };
}

26.4.4 The collate category

26.4.4.1 Class template collate

namepace std {

  template<class charT>
  class collate : public locale::facet {
    public:
    using char_type = charT;
    using string_type = basic_string<charT>;

    explicit collate(size_t refs = 0);
  };

  // This class is specialized for char and wchar_t.

  using char_type = charT;
  using string_type = basic_string<charT>;

  explicit collate(size_t refs = 0);

  // This class is specialized for char and wchar_t.

  string_type do_truename() const;
  string_type do_falsename() const;

  Returns: A string representing the name of the boolean value true or false, respectively.

  In the base class implementation these names are "true" and "false", or L"true" and L"false".

274) Thus, the string "\003" specifies groups of 3 digits each, and "3" probably indicates groups of 51 (!) digits each, because 51 is the ASCII value of "3".
The class `collate<charT>` provides features for use in the collation (comparison) and hashing of strings. A locale member function template, `operator()`, uses the collate facet to allow a locale to act directly as the predicate argument for standard algorithms (Clause 23) and containers operating on strings. The specializations required in Table 91 (26.3.1.1.1), namely `collate<char>` and `collate<wchar_t>`, apply lexicographic ordering (23.7.10).

Each function compares a string of characters `*p` in the range `[low, high)`.  

### 26.4.4.1.1 collate members

```cpp
int compare(const charT* low1, const charT* high1,
            const charT* low2, const charT* high2) const;
string_type transform(const charT* low, const charT* high) const;
long hash(const charT* low, const charT* high) const;
```

1 Returns: `do_compare(low1, high1, low2, high2)`.

2 Returns: `do_transform(low, high)`.

3 Returns: `do_hash(low, high)`.

### 26.4.4.1.2 collate virtual functions

```cpp
int do_compare(const charT* low1, const charT* high1,
               const charT* low2, const charT* high2) const;
string_type do_transform(const charT* low, const charT* high) const;
long do_hash(const charT* low, const charT* high) const;
```

1 Returns: 1 if the first string is greater than the second, -1 if less, zero otherwise. The specializations required in Table 91 (26.3.1.1.1), namely `collate<char>` and `collate<wchar_t>`, implement a lexicographical comparison (23.7.10).

2 Returns: A basic_string<charT> value that, compared lexicographically with the result of calling `transform()` on another string, yields the same result as calling `do_compare()` on the same two strings.

3 Returns: An integer value equal to the result of calling `hash()` on any other string for which `do_compare()` returns 0 (equal) when passed the two strings. [Note: The probability that the result equals that for another string which does not compare equal should be very small, approaching `(1.0/numeric_limits<unsigned long>::max()). —end note]`

### 26.4.4.2 Class template collatebyname

```cpp
namespace std {
    template<class charT>
    class collatebyname : public collate<charT> {
        public: 
            string_type = basic_string<charT>;
    }
}
```

275 This function is useful when one string is being compared to many other strings.
explicit collate_byname(const char*, size_t refs = 0);
explicit collate_byname(const string&, size_t refs = 0);

protected:
- collate_byname();
};

26.4.5 The time category [category.time]

Templates time_get<CharT, InputIterator> and time_put<CharT, OutputIterator> provide date and time formatting and parsing. All specifications of member functions for time_put and time_get in the subclauses of 26.4.5 only apply to the specializations required in Tables 91 and 92 (26.3.1.1.1). Their members use their ios_base&, ios_base::iostate&, and fill arguments as described in 26.4, and the ctype<> facet, to determine formatting details.

26.4.5.1 Class template time_get [locale.time.get]

namespace std {
  class time_base {
    public:
      enum dateorder { no_order, dmy, mdy, ymd, ydm };

    };

};

§ 26.4.5.1 1136
virtual iter_type do_get(iter_type s, iter_type end, ios_base& f,
    ios_base::iostate& err, tm* t, char format, char modifier) const;
};

1 time_get is used to parse a character sequence, extracting components of a time or date into a struct tm object. Each get member parses a format as produced by a corresponding format specifier to time_put<>::put. If the sequence being parsed matches the correct format, the corresponding members of the struct tm argument are set to the values used to produce the sequence; otherwise either an error is reported or unspecified values are assigned.276

2 If the end iterator is reached during parsing by any of the get() member functions, the member sets ios_base::eofbit in err.

26.4.5.1.1 time_get members

dateorder date_order() const;
1 Returns: do_date_order().

iter_type get_time(iter_type s, iter_type end, ios_base& str,
    ios_base::iostate& err, tm* t) const;
2 Returns: do_get_time(s, end, str, err, t).

iter_type get_date(iter_type s, iter_type end, ios_base& str,
    ios_base::iostate& err, tm* t) const;
3 Returns: do_get_date(s, end, str, err, t).

iter_type get_weekday(iter_type s, iter_type end, ios_base& str,
    ios_base::iostate& err, tm* t) const;
iter_type get_monthname(iter_type s, iter_type end, ios_base& str,
    ios_base::iostate& err, tm* t) const;
4 Returns: do_get_weekday(s, end, str, err, t) or do_get_monthname(s, end, str, err, t).

iter_type get_year(iter_type s, iter_type end, ios_base& str,
    ios_base::iostate& err, tm* t) const;
5 Returns: do_get_year(s, end, str, err, t).

iter_type get(iter_type s, iter_type end, ios_base& f, ios_base::iostate& err,
    tm* t, char format, char modifier = 0) const;
6 Returns: do_get(s, end, f, err, t, format, modifier).

iter_type get(iter_type s, iter_type end, ios_base& f, ios_base::iostate& err,
    tm* t, const char_type* fmt, const char_type* fmtend) const;
7 Requires: [fmt, fmtend) shall be a valid range.

Effects: The function starts by evaluating err = ios_base::goodbit. It then enters a loop, reading zero or more characters from s at each iteration. Unless otherwise specified below, the loop terminates when the first of the following conditions holds:

(8.1) The expression fmt == fmtend evaluates to true.
(8.2) The expression err == ios_base::goodbit evaluates to false.
(8.3) The expression s == end evaluates to true, in which case the function evaluates err = ios_base::eofbit | ios_base::failbit.
(8.4) The next element of fmt is equal to '%', optionally followed by a modifier character, followed by a conversion specifier character, format, together forming a conversion specification valid for the ISO/IEC 9945 function strptime. If the number of elements in the range [fmt, fmtend) is not sufficient to unambiguously determine whether the conversion specification is complete and valid, the function evaluates err = ios_base::failbit. Otherwise, the function evaluates s = do_get(s, end, f, err, t, format, modifier), where the value of modifier is '\0' when

276) In other words, user confirmation is required for reliable parsing of user-entered dates and times, but machine-generated formats can be parsed reliably. This allows parsers to be aggressive about interpreting user variations on standard formats.

§ 26.4.5.1.1
the optional modifier is absent from the conversion specification. If \( \text{err} == \text{ios}_\text{base}::\text{goodbit} \) holds after the evaluation of the expression, the function increments \( \text{fmt} \) to point just past the end of the conversion specification and continues looping.

(8.5) The expression \( \text{isspace}(*\text{fmt}, \text{f}.\text{getloc}()) \) evaluates to \text{true}, in which case the function first increments \( \text{fmt} \) until \( \text{fmt} == \text{fmtend} \) \text{!!isspace}(*\text{fmt}, \text{f}.\text{getloc}()) \) evaluates to \text{true}, then advances \( s \) until \( s == \text{end} \) \text{!!isspace}(*\(s\), \text{f}.\text{getloc}()) \) is \text{true}, and finally resumes looping.

(8.6) The next character read from \( s \) matches the element pointed to by \( \text{fmt} \) in a case-insensitive comparison, in which case the function evaluates \( ++\text{fmt}, ++s \) and continues looping. Otherwise, the function evaluates \( \text{err} == \text{ios}_\text{base}::\text{failbit} \).

[Note: The function uses the \text{ctype<charT>} facet installed in \text{f}'s locale to determine valid whitespace characters. It is unspecified by what means the function performs case-insensitive comparison or whether multi-character sequences are considered while doing so. — end note]

26.4.5.1.2 \text{time_get} virtual functions

\text{dateorder do_date_order()} \text{const};

1 \text{Returns:} An enumeration value indicating the preferred order of components for those date formats that are composed of day, month, and year.\textsuperscript{277} \text{Returns} \text{no_order} if the date format specified by \'x' contains other variable components (e.g., Julian day, week number, week day).

\text{iter_type do_get_time(iter_type s, iter_type end, ios_base& str,}
\text{ios_base::iostate& err, tm* t)} \text{const;}

2 \text{Effects:} Reads characters starting at \( s \) until it has extracted those \text{struct tm} members, and remaining format characters, used by \text{time_put<>::put} to produce the format specified by \"%H:%M:%S\", or until it encounters an error or end of sequence.

3 \text{Returns:} An iterator pointing immediately beyond the last character recognized as possibly part of a valid time.

\text{iter_type do_get_date(iter_type s, iter_type end, ios_base& str,}
\text{ios_base::iostate& err, tm* t)} \text{const;}

4 \text{Effects:} Reads characters starting at \( s \) until it has extracted those \text{struct tm} members and remaining format characters used by \text{time_put<>::put} to produce one of the following formats, or until it encounters an error. The format depends on the value returned by \text{date_order()} as shown in Table 102.

Table 102 — \text{do_get_date} effects

<table>
<thead>
<tr>
<th>\text{date_order()}</th>
<th>Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>no_order</td>
<td>&quot;%m%d%Y&quot;</td>
</tr>
<tr>
<td>dmy</td>
<td>&quot;%d%m%Y&quot;</td>
</tr>
<tr>
<td>mdy</td>
<td>&quot;%m%d%Y&quot;</td>
</tr>
<tr>
<td>ymd</td>
<td>&quot;%Y%m%d&quot;</td>
</tr>
<tr>
<td>ydm</td>
<td>&quot;%Y%d%m&quot;</td>
</tr>
</tbody>
</table>

5 An implementation may also accept additional implementation-defined formats.

6 \text{Returns:} An iterator pointing immediately beyond the last character recognized as possibly part of a valid date.

\text{iter_type do_get_weekday(iter_type s, iter_type end, ios_base& str,}
\text{ios_base::iostate& err, tm* t)} \text{const;}

\text{iter_type do_get_monthname(iter_type s, iter_type end, ios_base& str,}
\text{ios_base::iostate& err, tm* t)} \text{const;}

7 \text{Effects:} Reads characters starting at \( s \) until it has extracted the (perhaps abbreviated) name of a weekday or month. If it finds an abbreviation that is followed by characters that could match a full

\textsuperscript{277) This function is intended as a convenience only, for common formats, and may return \text{no_order} in valid locales.
name, it continues reading until it matches the full name or fails. It sets the appropriate `struct tm`
member accordingly.

Returns: An iterator pointing immediately beyond the last character recognized as part of a valid name.

```c
iter_type do_get_year(iter_type s, iter_type end, ios_base& str,
                   ios_base::iostate& err, tm* t) const;
```

Effects: Reads characters starting at `s` until it has extracted an unambiguous year identifier. It is
implementation-defined whether two-digit year numbers are accepted, and (if so) what century they
are assumed to lie in. Sets the `t->tm_year` member accordingly.

Returns: An iterator pointing immediately beyond the last character recognized as part of a valid year
identifier.

```c
iter_type do_get(iter_type s, iter_type end, ios_base& f,
                ios_base::iostate& err, tm* t, char format, char modifier) const;
```

Requires: `t` shall point to an object.

Effects: The function starts by evaluating `err = ios_base::goodbit`. It then reads characters starting
at `s` until it encounters an error, or until it has extracted and assigned those `struct tm` members, and
any remaining format characters, corresponding to a conversion directive appropriate for the ISO/IEC
9945 function `strptime`, formed by concatenating ‘%’, the `modifier` character, when non-NUL, and the
`format` character. When the concatenation fails to yield a complete valid directive the function
leaves the object pointed to by `t` unchanged and evaluates `err |= ios_base::failbit`. When `s ==
end` evaluates to `true` after reading a character the function evaluates `err |= ios_base::eofbit`.

For complex conversion directives such as ‘%c’, ‘%x’, or ‘%X’, or directives that involve the optional modifiers
E or O, when the function is unable to unambiguously determine some or all `struct tm` members from
the input sequence `[s, end)`, it evaluates `err |= ios_base::eofbit`. In such cases the values of
those `struct tm` members are unspecified and may be outside their valid range.

Remarks: It is unspecified whether multiple calls to `do_get()` with the address of the same `struct
tm` object will update the current contents of the object or simply overwrite its members. Portable
programs should zero out the object before invoking the function.

Returns: An iterator pointing immediately beyond the last character recognized as possibly part of a
valid input sequence for the given `format` and `modifier`.

### 26.4.5.2 Class template time_get_byname

```c
namespace std {
  template<class charT, class InputIterator = istreambuf_iterator<charT>>
  class time_get_byname : public time_get<charT, InputIterator> {
    public:
      using dateorder = time_base::dateorder;
      using iter_type = InputIterator;

      explicit time_get_byname(const char*, size_t refs = 0);
      explicit time_get_byname(const string&, size_t refs = 0);

      protected:
        ~time_get_byname();
    };
}
```

### 26.4.5.3 Class template time_put

```c
namespace std {
  template<class charT, class OutputIterator = ostreambuf_iterator<charT>>
  class time_put : public locale::facet {
    public:
      using char_type = charT;
      using iter_type = OutputIterator;

      explicit time_put(size_t refs = 0);
  };
}
```
// the following is implemented in terms of other member functions.
iter_type put(iter_type s, ios_base& f, char_type fill, const tm* tmb,
    const charT* pattern, const charT* pat_end) const;
iter_type put(iter_type s, ios_base& f, char_type fill,
    const tm* tmb, char format, char modifier = 0) const;

static locale::id id;

protected:
    ~time_put();
    virtual iter_type do_put(iter_type s, ios_base&, char_type, const tm* t,
        char format, char modifier) const;
};

26.4.5.3.1 time_put members

iter_type put(iter_type s, ios_base& str, char_type fill, const tm* t,
    const charT* pattern, const charT* pat_end) const;
iter_type put(iter_type s, ios_base& str, char_type fill, const tm* t,
    char format, char modifier = 0) const;

1 Effects: The first form steps through the sequence from pattern to pat_end, identifying characters that are part of a format sequence. Each character that is not part of a format sequence is written to s immediately, and each format sequence, as it is identified, results in a call to do_put; thus, format elements and other characters are interleaved in the output in the order in which they appear in the pattern. Format sequences are identified by converting each character c to a char value as if by ct.narrow(c, 0), where ct is a reference to ctype<charT> obtained from str.getloc(). The first character of each sequence is equal to '%', followed by an optional modifier character mod and a format specifier character spec as defined for the function strftime. If no modifier character is present, mod is zero. For each valid format sequence identified, calls do_put(s, str, fill, t, spec, mod).

The second form calls do_put(s, str, fill, t, format, modifier).

[Note: The fill argument may be used in the implementation-defined formats or by derivations. A space character is a reasonable default for this argument. —end note]

2 Returns: An iterator pointing immediately after the last character produced.

26.4.5.3.2 time_put virtual functions

iter_type do_put(iter_type s, ios_base& str, char_type fill, const tm* t,
    char format, char modifier) const;

1 Effects: Formats the contents of the parameter t into characters placed on the output sequence s. Formatting is controlled by the parameters format and modifier, interpreted identically as the format specifiers in the string argument to the standard library function strftime()279, except that the sequence of characters produced for those specifiers that are described as depending on the C locale are instead implementation-defined.280

2 Returns: An iterator pointing immediately after the last character produced. [Note: The fill argument may be used in the implementation-defined formats or by derivations. A space character is a reasonable default for this argument. —end note]

26.4.5.4 Class template time_put_byname

namespace std {
    template<class charT, class OutputIterator = ostreambuf_iterator<charT>>
    class time_put_byname : public time_put<charT, OutputIterator> {
        public:
            using char_type = charT;
            using iter_type = OutputIterator;
            
            278) Although the C programming language defines no modifiers, most vendors do.
            279) Interpretation of the modifier argument is implementation-defined, but should follow POSIX conventions.
            280) Implementations should refer to other standards such as POSIX for these definitions.

§ 26.4.5.4 1140
explicit time_put_byname(const char*, size_t refs = 0);
explicit time_put_byname(const string&, size_t refs = 0);

protected:
    ~time_put_byname();
};

26.4.6 The monetary category

These templates handle monetary formats. A template parameter indicates whether local or international
monetary formats are to be used.

All specifications of member functions for money_put and money_get in the subclauses of 26.4.6 only apply
to the specializations required in Tables 91 and 92 (26.3.1.1.1). Their members use their ios_base&, ios_base::iostate&, and fill arguments as described in 26.4, and the moneypunct<> and ctype<> facets, to
determine formatting details.

26.4.6.1 Class template money_get

namespace std {
    template<class charT, class InputIterator = istreambuf_iterator<charT>>
    class money_get : public locale::facet {

public:
    using char_type = charT;
    using iter_type = InputIterator;
    using string_type = basic_string<charT>;

    explicit money_get(size_t refs = 0);

    iter_type get(iter_type s, iter_type end, bool intl,
                  ios_base& f, ios_base::iostate& err,
                  long double& units) const;

    iter_type get(iter_type s, iter_type end, bool intl,
                  ios_base& f, ios_base::iostate& err,
                  string_type& digits) const;

    static locale::id id;

protected:
    ~money_get();

    virtual iter_type do_get(iter_type s, iter_type end, bool intl, ios_base& f,
                              ios_base::iostate& err, long double& units) const;

    virtual iter_type do_get(iter_type s, iter_type end, bool intl, ios_base& f,
                              ios_base::iostate& err, string_type& digits) const;

};

26.4.6.1.1 money_get members

iter_type get(iter_type s, iter_type end, bool intl, ios_base& f,
              ios_base::iostate& err, long double& units) const;

iter_type get(iter_type s, iter_type end, bool intl, ios_base& f,
              ios_base::iostate& err, string_type& digits) const;

Returns: do_get(s, end, intl, f, err, quant).

26.4.6.1.2 money_get virtual functions

iter_type do_get(iter_type s, iter_type end, bool intl, ios_base&& str,
                 ios_base::iostate&& err, long double&& units) const;

iter_type do_get(iter_type s, iter_type end, bool intl, ios_base&& str,
                 ios_base::iostate&& err, string_type&& digits) const;

Effects: Reads characters from s to parse and construct a monetary value according to the format
specified by a moneypunct<charT, Intl> facet reference mp and the character mapping specified by a
cctype<charT> facet reference ct obtained from the locale returned by str.getloc(), and str.flags().

§ 26.4.6.1.2 1141
If a valid sequence is recognized, does not change \texttt{err}; otherwise, sets \texttt{err} to \texttt{(err|str.failbit)}, or \texttt{(err|str.failbit|str.eofbit)} if no more characters are available, and does not change \texttt{units} or \texttt{digits}. Uses the pattern returned by \texttt{mp.neg_format()} to parse all values. The result is returned as an integral value stored in \texttt{units} or as a sequence of digits possibly preceded by a minus sign (as produced by \texttt{ct.widen(c)} where \texttt{c} is \texttt{"-`} or in the range from \texttt{`0'} through \texttt{`9'}, inclusive) stored in \texttt{digits}. [\textit{Example}: The sequence \$1,056.23\) in a common United States locale would yield, for \texttt{units}, 105623, or, for digits, \texttt{"105623"}. —\textit{end example}] If \texttt{mp.grouping()} indicates that no thousands separators are permitted, any such characters are not read, and parsing is terminated at the point where they first appear. Otherwise, thousands separators are optional; if present, they are checked for correct placement only after all format components have been read.

Where \texttt{money_base::space} or \texttt{money_base::none} appears as the last element in the format pattern, no white space is consumed. Otherwise, where \texttt{money_base::space} appears in any of the initial elements of the format pattern, at least one white space character is required. Where \texttt{money_base::none} appears in any of the initial elements of the format pattern, white space is allowed but not required. If \texttt{(str.flags() \& str.showbase)} is false, the currency symbol is optional and is consumed only if other characters are needed to complete the format; otherwise, the currency symbol is required.

If the first character (if any) in the string \texttt{pos} returned by \texttt{mp.positive_sign()} or the string \texttt{neg} returned by \texttt{mp.negative_sign()} is recognized in the position indicated by \texttt{sign} in the format pattern, it is consumed and any remaining characters in the string are required after all the other format components. [\textit{Example}: If \texttt{showbase} is off, then for a \texttt{neg} value of \texttt{"()"} and a currency symbol of \texttt{"L"} in \texttt{"(100 L)"} the \texttt{"L"} is consumed; but if \texttt{neg} is \texttt{"-"}, the \texttt{"L"} in \texttt{"-100 L"} is not consumed. —\textit{end example}] If \texttt{pos} or \texttt{neg} is empty, the sign component is optional, and if no sign is detected, the result is given the sign that corresponds to the source of the empty string. Otherwise, the character in the indicated position must match the first character of \texttt{pos} or \texttt{neg}, and the result is given the corresponding sign. If the first character of \texttt{pos} is equal to the first character of \texttt{neg}, or if both strings are empty, the result is given a positive sign.

Digits in the numeric monetary component are extracted and placed in \texttt{digits}, or into a character buffer \texttt{bufi} for conversion to produce a value for \texttt{units}, in the order in which they appear, preceded by a minus sign if and only if the result is negative. The value \texttt{units} is produced as if by

\begin{verbatim}
for (int i = 0; i < n; ++i)
    buf2[i] = src[(find(atoms, atoms+sizeof(src), buf1[i]) - atoms)];
buf2[n] = 0;
sscanf(buf2, "%Lf", &units);
\end{verbatim}

where \texttt{n} is the number of characters placed in \texttt{buf1}, \texttt{buf2} is a character buffer, and the values \texttt{src} and \texttt{atoms} are defined as if by

\begin{verbatim}
static const char src[] = "0123456789-";
charT atoms[sizeof(src)];
ct.widen(src, src + sizeof(src) - 1, atoms);
\end{verbatim}

Returns: An iterator pointing immediately beyond the last character recognized as part of a valid monetary quantity.

26.4.6.2 Class template \texttt{money_put} 

\begin{verbatim}
namespace std {
    template<class charT, class OutputIterator = ostreambuf_iterator<charT>>
    class money_put : public locale::facet {
        public:
            using char_type = charT;
            using iter_type = OutputIterator;
            using string_type = basic_string<charT>;

            explicit money_put(size_t refs = 0);

            iter_type put(iter_type s, bool intl, ios_base& f,
                           char_type fill, long double units) const;
            iter_type put(iter_type s, bool intl, ios_base& f,
                           char_type fill, const string_type& digits) const;
        }

261) The semantics here are different from \texttt{ct.narrow}.}
static locale::id id;

protected:
~money_put();
virtual iter_type do_put(iter_type, bool, ios_base&, char_type fill, long double units) const;
virtual iter_type do_put(iter_type, bool, ios_base&, char_type fill, const string_type& digits) const;
};

26.4.6.2.1 money_put members

iter_type put(iter_type s, bool intl, ios_base& f, char_type fill, long double quant) const;
iter_type put(iter_type s, bool intl, ios_base& f, char_type fill, const string_type& quant) const;

Returns: do_put(s, intl, f, loc, quant).

26.4.6.2.2 money_put virtual functions

iter_type do_put(iter_type s, bool intl, ios_base& str, char_type fill, long double units) const;
iter_type do_put(iter_type s, bool intl, ios_base& str, char_type fill, const string_type& digits) const;

Effects: Writes characters to s according to the format specified by a moneypunct<charT, Intl> facet reference mp and the character mapping specified by a ctype<charT> facet reference ct obtained from the locale returned by str.getloc() and str.flags(). The argument units is transformed into a sequence of wide characters as if by

ct.widen(buf1, buf1 + sprintf(buf1, "%.0Lf", units), buf2)

for character buffers buf1 and buf2. If the first character in digits or buf2 is equal to ct.widen('-'), then the pattern used for formatting is the result of mp.neg_format(); otherwise the pattern is the result of mp.pos_format(). Digit characters are written, interspersed with any thousands separators and decimal point specified by the format, in the order they appear (after the optional leading minus sign) in digits or buf2. In digits, only the optional leading minus sign and the immediately subsequent digit characters (as classified according to ct) are used; any trailing characters (including digits appearing after a non-digit character) are ignored. Calls str.width(0).

Remarks: The currency symbol is generated if and only if (str.flags() & str.showbase) is nonzero. If the number of characters generated for the specified format is less than the value returned by str.width() on entry to the function, then copies of fill are inserted as necessary to pad to the specified width. For the value af equal to (str.flags() & str.adjustfield), if (af == str.internal) is true, the fill characters are placed where none or space appears in the formatting pattern; otherwise if (af == str.left) is true, they are placed after the other characters; otherwise, they are placed before the other characters. [Note: It is possible, with some combinations of format patterns and flag values, to produce output that cannot be parsed using num_get<>::get. — end note]

Returns: An iterator pointing immediately after the last character produced.

26.4.6.3 Class template moneypunct

namespace std {
    class money_base {
        public:
            enum part { none, space, symbol, sign, value };
            struct pattern { char field[4]; };
    }

    template<class charT, bool International = false>
    class moneypunct : public locale::facet, public money_base {
        public:
            using char_type = charT;
            using string_type = basic_string<charT>;
            explicit moneypunct(size_t refs = 0);
        }
The `moneypunct<>` facet defines monetary formatting parameters used by `money_get<>` and `money_put<>`. A monetary format is a sequence of four components, specified by a `pattern` value `p`, such that the `part` value `static_cast<part>(p.field[i])` determines the `i`th component of the format.\(^1\) In the `field` member of a `pattern` object, each value `symbol`, `sign`, `value`, and either `space` or `none` appears exactly once. The value `none`, if present, is not first; the value `space`, if present, is neither first nor last.\(^2\)

Where `none` or `space` appears, white space is permitted in the format, except where `none` appears at the end, in which case no white space is permitted. The value `space` indicates that at least one space is required at that position. Where `symbol` appears, the sequence of characters returned by `curr_symbol()` is permitted, and can be required. Where `sign` appears, the first (if any) of the sequence of characters returned by `positive_sign()` or `negative_sign()` (respectively as the monetary value is non-negative or negative) is required. Any remaining characters of the sign sequence are required after all other format components. Where `value` appears, the absolute numeric monetary value is required.\(^3\)

The format of the numeric monetary value is a decimal number:

```
value ::= units [ decimal-point [ digits ]] |
    decimal-point digits
```

if `frac_digits()` returns a positive value, or

```
value ::= units
```

otherwise. The symbol `decimal-point` indicates the character returned by `decimal_point()`. The other symbols are defined as follows:

```
units ::= digits [ thousands-sep units ]
digits ::= adigit [ digits ]
```

In the syntax specification, the symbol `adigit` is any of the values `ct.widen(c)` for `c` in the range ‘0’ through ‘9’, inclusive, and `ct` is a reference of type `const ctype<charT>&` obtained as described in the definitions of `money_get<>` and `money_put<>`. The symbol `thousands-sep` is the character returned by `thousands_sep()`. The space character used is the value `ct.widen(' ')`. White space characters are those characters `c` for which `ci.is(space, c)` returns `true`. The number of digits required after the decimal point (if any) is exactly the value returned by `frac_digits()`.

The placement of thousands-separator characters (if any) is determined by the value returned by `grouping()`, defined identically as the member `numpunct<>::do_grouping()`.

\(^1\) An array of `char`, rather than an array of `part`, is specified for `pattern::field` purely for efficiency.
26.4.6.3.1 moneypunct members

charT decimal_point() const;
charT thousands_sep() const;
string grouping() const;
string_type curr_symbol() const;
string_type positive_sign() const;
string_type negative_sign() const;
int frac_digits() const;
pattern pos_format() const;
pattern neg_format() const;

1 Each of these functions F returns the result of calling the corresponding virtual member function do_F().

26.4.6.3.2 moneypunct virtual functions

charT do_decimal_point() const;

1 Returns: The radix separator to use in case do_frac_digits() is greater than zero. 283

charT do_thousands_sep() const;

2 Returns: The digit group separator to use in case do_grouping() specifies a digit grouping pattern. 284

string do_grouping() const;

3 Returns: A pattern defined identically as, but not necessarily equal to, the result of numpunct<charT>::

string_type do_curr_symbol() const;

4 Returns: A string to use as the currency identifier symbol. [Note: For specializations where the second

template parameter is true, this is typically four characters long: a three-letter code as specified by

ISO 4217 followed by a space. —end note]

string_type do_positive_sign() const;
string_type do_negative_sign() const;

5 Returns: do_positive_sign() returns the string to use to indicate a positive monetary value; 286

do_negative_sign() returns the string to use to indicate a negative value.

int do_frac_digits() const;

6 Returns: The number of digits after the decimal radix separator, if any. 287

pattern do_pos_format() const;
pattern do_neg_format() const;

7 Returns: The specializations required in Table 92 (26.3.1.1.1), namely moneypunct<char>, moneypunct<

wchar_t>, moneypunct<char, true>, and moneypunct<wchar_t, true>, return an object of type

pattern initialized to { symbol, sign, none, value }. 288

26.4.6.4 Class template moneypunct_byname

namespace std {

template<class charT, bool Intl = false>
class moneypunct_byname : public moneypunct<charT, Intl> {

283) In common U.S. locales this is ".".
284) In common U.S. locales this is ",".
285) To specify grouping by 3s, the value is "\003" not "3".
286) This is usually the empty string.
287) In common U.S. locales, this is 2.
288) Note that the international symbol returned by do_curr_symbol() usually contains a space, itself; for example, "USD ".

using pattern = money_base::pattern;
using string_type = basic_string<charT>;

explicit moneypunct_byname(const char*, size_t refs = 0);
explicit moneypunct_byname(const string&, size_t refs = 0);
protected:
    ~moneypunct_byname();
};

26.4.7 The message retrieval category [category.messages]

Class messages<charT> implements retrieval of strings from message catalogs.

26.4.7.1 Class template messages [locale.messages]

namespace std {
    class messages_base {
        public:
            using catalog = unspecified signed integer type;
    };

    template<class charT>
    class messages : public locale::facet, public messages_base {
        public:
            using char_type = charT;
            using string_type = basic_string<charT>;

            explicit messages(size_t refs = 0);
            catalog open(const basic_string<char>& fn, const locale&) const;
            string_type get(catalog c, int set, int msgid,
            const string_type& dfault) const;
            void close(catalog c) const;

            static locale::id id;
        protected:
            ~messages();
            virtual catalog do_open(const basic_string<char>&, const locale&) const;
            virtual string_type do_get(catalog, int set, int msgid,
            const string_type& dfault) const;
            virtual void do_close(catalog) const;
    };

    Values of type messages_base::catalog usable as arguments to members get and close can be obtained only by calling member open.

26.4.7.1.1 messages members [locale.messages.members]

catalog open(const basic_string<char>& name, const locale& loc) const;

    Returns: do_open(name, loc).

string_type get(catalog cat, int set, int msgid, const string_type& dfault) const;

    Returns: do_get(cat, set, msgid, dfault).

void close(catalog cat) const;

    Effects: Calls do_close(cat).

26.4.7.1.2 messages virtual functions [locale.messages.virtuals]

catalog do_open(const basic_string<char>& name, const locale& loc) const;

    Returns: A value that may be passed to get() to retrieve a message from the message catalog identified by the string name according to an implementation-defined mapping. The result can be used until it is passed to close().

Returns a value less than 0 if no such catalog can be opened.

Remarks: The locale argument loc is used for character set code conversion when retrieving messages, if needed.
string_type do_get(catalog cat, int set, intmsgid, const string_type& dfault) const;  

4  Requires: cat shall be a catalog obtained from open() and not yet closed.

5  Returns: A message identified by arguments set,msgid, and dfault, according to an implementation-defined mapping. If no such message can be found, returns dfault.

void do_close(catalog cat) const;  

6  Requires: cat shall be a catalog obtained from open() and not yet closed.

7  Effects: Releases unspecified resources associated with cat.

8  Remarks: The limit on such resources, if any, is implementation-defined.

26.4.7.2 Class template messages_byname  
namespace std {  
    template<class charT>  
    class messages_byname : public messages<charT> {  
        public:  
            using catalog = messages_base::catalog;  
            using string_type = basic_string<charT>;  

        explicit messages_byname(const char*, size_t refs = 0);  
        explicit messages_byname(const string&, size_t refs = 0);  

        protected:  
            ~messages_byname();  
    };  
}  

26.5 C library locales  

26.5.1 Header <clocale> synopsis  
namespace std {  
    struct lconv;  

    char* setlocale(int category, const char* locale);  
    lconv* localeconv();  
}  

#define NULL see 16.2.3  
#define LC_ALL see below  
#define LC_COLLATE see below  
#define LC_CTYPE see below  
#define LC_MONETARY see below  
#define LC_NUMERIC see below  
#define LC_TIME see below  

1 The contents and meaning of the header <clocale> are the same as the C standard library header <locale.h>.

2 Calls to the function setlocale may introduce a data race (15.5.5.9) with other calls to setlocale or with calls to the functions listed in Table 103.

27 Input/output library [input.output]

27.1 General [input.output.general]

This Clause describes components that C++ programs may use to perform input/output operations.

The following subclauses describe requirements for stream parameters, and components for forward declarations of iostreams, predefined iostreams objects, base iostreams classes, stream buffering, stream formatting and manipulators, string streams, and file streams, as summarized in Table 104.

Table 104 — Input/output library summary

Figure 7 illustrates relationships among various types described in this clause. A line from A to B indicates that A is an alias (e.g., a typedef) for B or that A is defined in terms of B.

27.2 Iostreams requirements [iostreams.requirements]

27.2.1 Imbue limitations [iostreams.requirements.imbue]

No function described in Clause 27 except for `ios_base::imbue` and `basic_filebuf::pubimbue` causes any instance of `basic_ios::imbue` or `basic_streambuf::imbue` to be called. If any user function called from a function declared in Clause 27 or as an overriding virtual function of any class declared in Clause 27 calls `imbue`, the behavior is undefined.
27.2.2 Positioning type limitations

The classes of Clause 27 with template arguments charT and traits behave as described if traits::pos_type and traits::off_type are streampos and streamoff respectively. Except as noted explicitly below, their behavior when traits::pos_type and traits::off_type are other types is implementation-defined.

In the classes of Clause 27, a template parameter with name charT represents a member of the set of types containing char, wchar_t, and any other implementation-defined character types that satisfy the requirements for a character on which any of the iostream components can be instantiated.

27.2.3 Thread safety

Concurrent access to a stream object (27.8, 27.9), stream buffer object (27.6), or C Library stream (27.12) by multiple threads may result in a data race (6.8.2) unless otherwise specified (27.4). [Note: Data races result in undefined behavior (6.8.2). — end note]

If one thread makes a library call a that writes a value to a stream and, as a result, another thread reads this value from the stream through a library call b such that this does not result in a data race, then a’s write synchronizes with b’s read.

27.3 Forward declarations

27.3.1 Header <iosfwd> synopsis

namespace std {
  template<class charT> class char_traits;

1 Default template arguments are described as appearing both in `<iosfwd>` and in the synopsis of other headers but it is well-formed to include both `<iosfwd>` and one or more of the other headers.\\n
\(^{289}\) It is the implementation’s responsibility to implement headers so that including `<iosfwd>` and other headers does not violate the rules about multiple occurrences of default arguments.

\(\text{§}\ 27.3.1\ 1151\)
27.3.2 Overview

The class template specialization `basic_ios<charT, traits>` serves as a virtual base class for the class templates `basic_istream`, `basic_ostream`, and class templates derived from them. `basic_iosstream` is a class template derived from both `basic_istream<charT, traits>` and `basic_ostream<charT, traits>`. The class template specialization `basic_streambuf<charT, traits>` serves as a base class for class templates `basic_stringbuf` and `basic_filebuf`. The class template specialization `basic_istream<charT, traits>` serves as a base class for class templates `basic_istringstream` and `basic_ifstream`. The class template specialization `basic_ostream<charT, traits>` serves as a base class for class templates `basic_ostringstream` and `basic_ofstream`. The class template specialization `basic_iostream<charT, traits>` serves as a base class for class templates `basic_stringstream` and `basic_fstream`. Other typedef-names define instances of class templates specialized for `char` or `wchar_t` types. Specializations of the class template `fpos` are used for specifying file position information. The types `streampos` and `wstreampos` are used for positioning streams specialized on `char` and `wchar_t` respectively.

[Note: This synopsis suggests a circularity between `streampos` and `char_traits<char>`_types. An implementation can avoid this circularity by substituting equivalent types. One way to do this might be

```cpp
template<class stateT> class fpos { /* ... */ }; // depends on nothing
using _STATE = /* ... */ ; // implementation private declaration of stateT
using streampos = fpos<_STATE>;

template<> struct char_traits<char> {
  using pos_type = streampos;
};
— end note]

27.4 Standard iostream objects

27.4.1 Header <iostream> synopsis

```cpp
#include <ios> // see 27.5.1
#include <streambuf> // see 27.6.1
#include <istream> // see 27.7.1
#include <ostream> // see 27.7.2

namespace std {
  extern istream cin;
  extern ostream cout;
  extern ostream cerr;
  extern ostream clog;

  extern wistream wcin;
  extern wostream wcout;
  extern wostream wcerr;
  extern wostream wclog;
}
```

27.4.2 Overview

In this Clause, the type name FILE refers to the type FILE declared in `<cstdio>` (27.12.1). The header `<iostream>` declares objects that associate objects with the standard C streams provided for by the functions declared in `<cstdio>` (27.12), and includes all the headers necessary to use these objects. The objects are constructed and the associations are established at some time prior to or during the first time an object of class `ios_base::Init` is constructed, and in any case before the body of `main` (6.8.3.1)
begins execution. The objects are not destroyed during program execution. The results of including `<iostream>` in a translation unit shall be as if `<iostream>` defined an instance of `ios_base::Init` with static storage duration.

Mixing operations on corresponding wide- and narrow-character streams follows the same semantics as mixing such operations on FILEs, as specified in the C standard library.

Concurrent access to a synchronized (27.5.3.4) standard iostream object’s formatted and unformatted input (27.7.4.1) and output (27.7.5.1) functions or a standard C stream by multiple threads shall not result in a data race (6.8.2). [Note: Users must still synchronize concurrent use of these objects and streams by multiple threads if they wish to avoid interleaved characters. — end note]

See also: ISO C 7.21.2

### 27.4.3 Narrow stream objects

**istream cin;**

1. The object `cin` controls input from a stream buffer associated with the object `stdin`, declared in `<cstdio>` (27.12.1).

2. After the object `cin` is initialized, `cin.tie()` returns `&cout`. Its state is otherwise the same as required for `basic_ios<char>::init` (27.5.5.2).

**ostream cout;**

3. The object `cout` controls output to a stream buffer associated with the object `stdout`, declared in `<cstdio>` (27.12.1).

**ostream cerr;**

4. The object `cerr` controls output to a stream buffer associated with the object `stderr`, declared in `<cstdio>` (27.12.1).

5. After the object `cerr` is initialized, `cerr.flags() & unitbuf` is nonzero and `cerr.tie()` returns `&cout`. Its state is otherwise the same as required for `basic_ios<char>::init` (27.5.5.2).

**ostream clog;**

6. The object `clog` controls output to a stream buffer associated with the object `stderr`, declared in `<cstdio>` (27.12.1).

### 27.4.4 Wide stream objects

**wistream wcin;**

1. The object `wcin` controls input from a stream buffer associated with the object `stdin`, declared in `<cstdio>` (27.12.1).

2. After the object `wcin` is initialized, `wcin.tie()` returns `&wcout`. Its state is otherwise the same as required for `basic_ios<wchar_t>::init` (27.5.5.2).

**wostream wcout;**

3. The object `wcout` controls output to a stream buffer associated with the object `stdout`, declared in `<cstdio>` (27.12.1).

**wostream wcerr;**

4. The object `wcerr` controls output to a stream buffer associated with the object `stderr`, declared in `<cstdio>` (27.12.1).

5. After the object `wcerr` is initialized, `wcerr.flags() & unitbuf` is nonzero and `wcerr.tie()` returns `&wcout`. Its state is otherwise the same as required for `basic_ios<wchar_t>::init` (27.5.5.2).

**wostream wclog;**

6. The object `wclog` controls output to a stream buffer associated with the object `stderr`, declared in `<cstdio>` (27.12.1).

If it is possible for them to do so, implementations should initialize the objects earlier than required.

Constructors and destructors for static objects can access these objects to read input from `stdin` or write output to `stdout` or `stderr`.

§ 27.4.4
27.5 Iostreams base classes

27.5.1 Header <ios> synopsis

```cpp
#include <iosfwd> // see 27.3.1

namespace std {

    using streamoff = implementation-defined;
    using streamsize = implementation-defined;

    template<class stateT> class fpos;

    class ios_base;
    template<class charT, class traits = char_traits<charT>>
        class basic_ios;

    // 27.5.6, manipulators
    ios_base& boolalpha (ios_base& str);
    ios_base& noboolalpha(ios_base& str);

§ 27.5.1
27.5.2 Types

using streamoff = implementation-defined;

1 The type streamoff is a synonym for one of the signed basic integral types of sufficient size to represent the maximum possible file size for the operating system.\(^\text{292}\)

using streamsize = implementation-defined;

2 The type streamsize is a synonym for one of the signed basic integral types. It is used to represent the number of characters transferred in an I/O operation, or the size of I/O buffers.\(^\text{293}\)

27.5.3 Class ios_base

namespace std {
    class ios_base {
        public:
            class failure; // see below

            // 27.5.3.1.2, fmtflags
            using fmtflags = T1;
            static constexpr fmtflags boolalpha = unspecified;
            static constexpr fmtflags dec = unspecified;
            static constexpr fmtflags fixed = unspecified;
            static constexpr fmtflags hex = unspecified;
            static constexpr fmtflags internal = unspecified;
            static constexpr fmtflags left = unspecified;
            static constexpr fmtflags oct = unspecified;
            static constexpr fmtflags right = unspecified;
            static constexpr fmtflags scientific = unspecified;
            static constexpr fmtflags showbase = unspecified;
            static constexpr fmtflags showpoint = unspecified;
            static constexpr fmtflags showpos = unspecified;
            static constexpr fmtflags skipws = unspecified;
            static constexpr fmtflags unitbuf = unspecified;
            static constexpr fmtflags uppercase = unspecified;
            static constexpr fmtflags adjustfield = see below;
            static constexpr fmtflags basefield = see below;
            static constexpr fmtflags floatfield = see below;

            // 27.5.3.1.3, iostate
            using iostate = T2;
            static constexpr iostate badbit = unspecified;
            static constexpr iostate eofbit = unspecified;
            static constexpr iostate failbit = unspecified;
            static constexpr iostate goodbit = see below;

            // 27.5.3.1.4, openmode
            using openmode = T3;
            static constexpr openmode app = unspecified;
            static constexpr openmode ate = unspecified;
            static constexpr openmode binary = unspecified;
            static constexpr openmode in = unspecified;
            static constexpr openmode out = unspecified;
            static constexpr openmode trunc = unspecified;

            // 27.5.3.1.5, seekdir
            using seekdir = T4;
            static constexpr seekdir beg = unspecified;
            static constexpr seekdir cur = unspecified;
            static constexpr seekdir end = unspecified;

        class Init;
    }

292) Typically \texttt{long long}.
293) \texttt{streamsize} is used in most places where ISO C would use \texttt{size_t}.

§ 27.5.3
// 27.5.3.2, fmtflags state
fmtflags flags() const;
fmtflags flags(fmtflags fmtfl);
fmtflags setf(fmtflags fmtfl);
fmtflags setf(fmtflags fmtfl, fmtflags mask);
void unsetf(fmtflags mask);

streamsize precision() const;
streamsize precision(streamsize prec);
streamsize width() const;
streamsize width(streamsize wide);

// 27.5.3.3, locales
locale imbue(const locale& loc);
locale getloc() const;

// 27.5.3.5, storage
static int xalloc();
long& iword(int idx);
void*& pword(int idx);

// destructor
virtual ~ios_base();

// 27.5.3.6, callbacks
enum event { erase_event, imbue_event, copyfmt_event };
using event_callback = void (*)(event, ios_base&, int idx);
void register_callback(event_callback fn, int idx);

ios_base(const ios_base&) = delete;
ios_base& operator=(const ios_base&) = delete;

static bool sync_with_stdio(bool sync = true);

protected:
ios_base();

private:
static int index; // exposition only
long* iarray; // exposition only
void** parray; // exposition only
};

1 ios_base defines several member types:

(1.1) — a type failure, defined as either a class derived from system_error or a synonym for a class derived from system_error;
(1.2) — a class Init;
(1.3) — three bitmask types, fmtflags, iostate, and openmode;
(1.4) — an enumerated type, seekdir.

2 It maintains several kinds of data:

(2.1) — state information that reflects the integrity of the stream buffer;
(2.2) — control information that influences how to interpret (format) input sequences and how to generate (format) output sequences;
(2.3) — additional information that is stored by the program for its private use.

3 [Note: For the sake of exposition, the maintained data is presented here as:

(3.1) — static int index, specifies the next available unique index for the integer or pointer arrays maintained for the private use of the program, initialized to an unspecified value;
— long* iarray, points to the first element of an arbitrary-length long array maintained for the private use of the program;

— void** parray, points to the first element of an arbitrary-length pointer array maintained for the private use of the program.

— end note]

27.5.3.1 Types

27.5.3.1.1 Class ios_base::failure

```cpp
namespace std {
    class ios_base::failure : public system_error {
        public:
            explicit failure(const string& msg, const error_code& ec = io_errc::stream);
            explicit failure(const char* msg, const error_code& ec = io_errc::stream);
    };
}
```

1 An implementation is permitted to define `ios_base::failure` as a synonym for a class with equivalent functionality to class `ios_base::failure` shown in this subclause. [Note: When `ios_base::failure` is a synonym for another type it shall provide a nested type `failure`, to emulate the injected class name. — end note] The class `failure` defines the base class for the types of all objects thrown as exceptions, by functions in the iostreams library, to report errors detected during stream buffer operations.

2 When throwing `ios_base::failure` exceptions, implementations should provide values of `ec` that identify the specific reason for the failure. [Note: Errors arising from the operating system would typically be reported as `system_category()` errors with an error value of the error number reported by the operating system. Errors arising from within the stream library would typically be reported as `error_code(io_errc::stream, iostream_category())`. — end note]

```cpp
explicit failure(const string& msg, const error_code& ec = io_errc::stream);
```

3 Effects: Constructs an object of class `failure` by constructing the base class with `msg` and `ec`.

```cpp
explicit failure(const char* msg, const error_code& ec = io_errc::stream);
```

4 Effects: Constructs an object of class `failure` by constructing the base class with `msg` and `ec`.

27.5.3.1.2 Type ios_base::fmtflags

```cpp
using fmtflags = T1;
```

1 The type `fmtflags` is a bitmask type (15.4.2.1.4). Setting its elements has the effects indicated in Table 105.

2 Type `fmtflags` also defines the constants indicated in Table 106.

27.5.3.1.3 Type ios_base::iostate

```cpp
using iostate = T2;
```

1 The type `iostate` is a bitmask type (15.4.2.1.4) that contains the elements indicated in Table 107.

2 Type `iostate` also defines the constant:

— goodbit, the value zero.

27.5.3.1.4 Type ios_base::openmode

```cpp
using openmode = T3;
```

1 The type `openmode` is a bitmask type (15.4.2.1.4). It contains the elements indicated in Table 108.

27.5.3.1.5 Type ios_base::seekdir

```cpp
using seekdir = T4;
```

1 The type `seekdir` is an enumerated type (15.4.2.1.3) that contains the elements indicated in Table 109.
Table 105 — fmtflags effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Effect(s) if set</th>

</tr>
<tr>
<td>cur</td>
<td>request a seek relative to the current position within the sequence</td>
</tr>
<tr>
<td>end</td>
<td>request a seek relative to the current end of the sequence</td>
</tr>
</tbody>
</table>
27.5.3.1.6 Class ios_base::Init

namespace std {
    class ios_base::Init {
    public:
        Init();
        Init(const Init&) = default;
        ~Init();
        Init& operator=(const Init&) = default;
    private:
        static int init_cnt; // exposition only
    }
}

The class Init describes an object whose construction ensures the construction of the eight objects declared in <iostream> (27.4) that associate file stream buffers with the standard C streams provided for by the functions declared in <cstdio> (27.12.1).

For the sake of exposition, the maintained data is presented here as:

— static int init_cnt, counts the number of constructor and destructor calls for class Init, initialized to zero.

Init();

Effects: Constructs an object of class Init. Constructs and initializes the objects cin, cout, cerr, clog, wcin, wcout, wcerr, and wclog if they have not already been constructed and initialized.

~Init();

Effects: Destroys an object of class Init. If there are no other instances of the class still in existence, calls cout.flush(), cerr.flush(), clog.flush(), wcout.flush(), wcerr.flush(), wclog.flush().

27.5.3.2 ios_base state functions

fmtflags flags() const;

Returns: The format control information for both input and output.

fmtflags flags(fmtflags fmtfl);

Ensures: fmtfl == flags().

Returns: The previous value of flags().

fmtflags setf(fmtflags fmtfl);

Effects: Sets fmtfl in flags().

Returns: The previous value of flags().

fmtflags setf(fmtflags fmtfl, fmtflags mask);

Effects: Clears mask in flags(), sets fmtfl & mask in flags().

Returns: The previous value of flags().

void unsetf(fmtflags mask);

Effects: Clears mask in flags().

streamsize precision() const;

Returns: The precision to generate on certain output conversions.

streamsize precision(streamsize prec);

Ensures: prec == precision().

Returns: The previous value of precision().

streamsize width() const;

Returns: The minimum field width (number of characters) to generate on certain output conversions.
streamsize width(streamsize wide);

Ensures: wide == width().
Returns: The previous value of width().

27.5.3.3 ios_base functions

locale imbue(const locale& loc);

Effects: Calls each registered callback pair \( (fn, idx) \) (27.5.3.6) as \( (*fn)(\text{imbue\_event}, *this, idx) \) at such a time that a call to \( \text{ios\_base\_getloc()} \) from within \( fn \) returns the new locale value \( loc \).

Returns: The previous value of \( \text{getloc()} \).

Ensures: \( loc == \text{getloc()} \).

locale getloc() const;

Returns: If no locale has been imbued, a copy of the global C++ locale, \( \text{locale()} \), in effect at the time of construction. Otherwise, returns the imbued locale, to be used to perform locale-dependent input and output operations.

27.5.3.4 ios_base static members

bool sync_with_stdio(bool sync = true);

Returns: \( true \) if the previous state of the standard iostream objects (27.4) was synchronized and otherwise returns \( false \). The first time it is called, the function returns \( true \).

Effects: If any input or output operation has occurred using the standard streams prior to the call, the effect is implementation-defined. Otherwise, called with a \( false \) argument, it allows the standard streams to operate independently of the standard C streams.

When a standard iostream object \( str \) is synchronized with a standard stdio stream \( f \), the effect of inserting a character \( c \) by

\[ \text{fputc}(f, c); \]

is the same as the effect of

\[ \text{str.rdbuf()\rightarrow sputc}(c); \]

for any sequences of characters; the effect of extracting a character \( c \) by

\[ c = \text{fgetc}(f); \]

is the same as the effect of

\[ c = \text{str.rdbuf()\rightarrow sbumpc}(); \]

for any sequences of characters; and the effect of pushing back a character \( c \) by

\[ \text{ungetc}(c, f); \]

is the same as the effect of

\[ \text{str.rdbuf()\rightarrow sputbackc}(c); \]

for any sequence of characters.\(^ {294} \)

27.5.3.5 ios_base storage functions

static int xalloc();

Returns: \( index ++ \).
Remarks: Concurrent access to this function by multiple threads shall not result in a data race (6.8.2).

long& iword(int idx);

Requires: \( idx \) is a value obtained by a call to \( xalloc() \).

Effects: If \( iarray \) is a null pointer, allocates an array of \( \text{long} \) of unspecified size and stores a pointer to its first element in \( iarray \). The function then extends the array pointed at by \( iarray \) as necessary

---

\(^ {294} \) This implies that operations on a standard iostream object can be mixed arbitrarily with operations on the corresponding stdio stream. In practical terms, synchronization usually means that a standard iostream object and a standard stdio object share a buffer.
to include the element `iarray[idx]`. Each newly allocated element of the array is initialized to zero. The reference returned is invalid after any other operations on the object. However, the value of the storage referred to is retained, so that until the next call to `copyfmt`, calling `ivord` with the same index yields another reference to the same value. If the function fails and `*this` is a base class subobject of a `basic_ios<>` object or subobject, the effect is equivalent to calling `basic_ios<>::setstate(badbit)` on the derived object (which may throw `failure`).

Returns: On success `iarray[idx]`. On failure, a valid `long` initialized to 0.

```cpp
void*& pword(int idx);
```

Returns: On success `parray[idx]`. On failure a valid `void*` initialized to 0.

Remarks: After a subsequent call to `pword(int)` for the same object, the earlier return value may no longer be valid.

### 27.5.3.6 `ios_base callbacks`

```cpp
void register_callback(event_callback fn, int idx);
```

Effects: Registers the pair `(fn, idx)` such that during calls to `imbue()` (27.5.3.3), `copyfmt()`, or `~ios_base()` (27.5.3.7), the function `fn` is called with argument `idx`. Functions registered are called when an event occurs, in opposite order of registration. Functions registered while a callback function is active are not called until the next event.

Returns: On success `parray[idx]`. On failure a valid `void*` initialized to 0.

Remarks: After a subsequent call to `pword(int)` for the same object, the earlier return value may no longer be valid.

### 27.5.3.7 `ios_base constructors/destructor`

```cpp
ios_base();
```

Effects: Each `ios_base` member has an indeterminate value after construction. The object’s members shall be initialized by calling `basic_ios::init` before the object’s first use or before it is destroyed, whichever comes first; otherwise the behavior is undefined.

```cpp
~ios_base();
```

Effects: Destroys an object of class `ios_base`. Calls each registered callback pair `(fn, idx)` (27.5.3.6) as `(*fn)(erase_event, *this, idx)` at such time that any `ios_base` member function called from within `fn` has well-defined results.

### 27.5.4 Class template `fpos`

```cpp
namespace std {
    template<class stateT> class fpos {
        public:
            // 27.5.4.1, members
            stateT state() const;
            void state(stateT);
        private;
            stateT st; // exposition only
    }
}
```

295) An implementation is free to implement both the integer array pointed at by `iarray` and the pointer array pointed at by `parray` as sparse data structures, possibly with a one-element cache for each.

296) For example, because it cannot allocate space.

297) For example, because it cannot allocate space.
27.5.4.1 fpos members

void state(stateT s);

1 Effects: Assigns s to st.

stateT state() const;

2 Returns: Current value of st.

27.5.4.2 fpos requirements

1 An fpos type specifies file position information. It holds a state object whose type is equal to the template parameter stateT. Type stateT shall meet the Cpp17DefaultConstructible (Table 24), Cpp17CopyConstructible (Table 26), Cpp17CopyAssignable (Table 28), and Cpp17Destructible (Table 29) requirements. If is_trivially_copy_constructible_v<stateT> is true, then fpos<stateT> has a trivial copy constructor. If is_trivially_copy_assignable<stateT> is true, then fpos<stateT> has a trivial copy assignment operator. If is_trivially_destructible_v<stateT> is true, then fpos<stateT> has a trivial destructor. All specializations of fpos satisfy the Cpp17DefaultConstructible, Cpp17CopyConstructible, Cpp17CopyAssignable, Cpp17Destructible, and Cpp17EqualityComparable (Table 22) requirements. In addition, the expressions shown in Table 110 are valid and have the indicated semantics. In that table,

(1.1) — P refers to an instance of fpos,
(1.2) — p and q refer to values of type P or const P,
(1.3) — pl and ql refer to modifiable lvalues of type P,
(1.4) — o refers to type streamoff, and
(1.5) — o refers to a value of type streamoff or const streamoff.

Table 110 — Position type requirements

<table>

</tbody>
</table>

2 Stream operations that return a value of type traits::pos_type return P(0(-1)) as an invalid value to signal an error. If this value is used as an argument to any istream, ostream, or streambuf member that accepts a value of type traits::pos_type then the behavior of that function is undefined.
27.5.5 Class template basic_ios

27.5.5.1 Overview

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_ios : public ios_base {
    public:
        using char_type = charT;
        using int_type = typename traits::int_type;
        using pos_type = typename traits::pos_type;
        using off_type = typename traits::off_type;
        using traits_type = traits;

        // 27.5.5.4, flags functions
        explicit operator bool() const;
        bool operator!() const;
        iostate rdstate() const;
        void clear(iostate state = goodbit);
        void setstate(iostate state);
        bool good() const;
        bool eof() const;
        bool fail() const;
        bool bad() const;

        iostate exceptions() const;
        void exceptions(iostate except);

        // 27.5.5.2, constructor/destructor
        explicit basic_ios(basic_streambuf<charT, traits>* sb);
        virtual ~basic_ios();

        // 27.5.5.3, members
        basic_ostream<charT, traits>* tie() const;
        basic_ostream<charT, traits>* tie(basic_ostream<charT, traits>* tiestr);

        basic_streambuf<charT, traits>* rdbuf() const;
        basic_streambuf<charT, traits>* rdbuf(basic_streambuf<charT, traits>* sb);

        basic_ios& copyfmt(const basic_ios& rhs);

        char_type fill() const;
        char_type fill(char_type ch);

        locale imbue(const locale& loc);

        char narrow(char_type c, char dfault) const;
        char_type widen(char c) const;

        basic_ios(const basic_ios&) = delete;
        basic_ios& operator=(const basic_ios&) = delete;

    protected:
        basic_ios();
        void init(basic_streambuf<charT, traits>* sb);
        void move(basic_ios& rhs);
        void move(basic_ios&& rhs);
        void swap(basic_ios& rhs) noexcept;
        void set_rdbuf(basic_streambuf<charT, traits>* sb);
    }
}
```
27.5.5.2 basic_ios constructors

**explicit basic_ios(basic_streambuf<charT, traits>* sb);**

*Effects:* Constructs an object of class `basic_ios`, assigning initial values to its member objects by calling `init(sb)`.

`basic_ios();`

*Effects:* Constructs an object of class `basic_ios` leaving its member objects uninitialized. The object shall be initialized by calling `basic_ios::init` before its first use or before it is destroyed, whichever comes first; otherwise the behavior is undefined.

`~basic_ios();`

*Remarks:* The destructor does not destroy `rdbuf()`.

`void init(basic_streambuf<charT, traits>* sb);`

*Ensures:* The postconditions of this function are indicated in Table 111.

27.5.5.3 Member functions

`basic_ostream<charT, traits>* tie() const;`

*Returns:* An output sequence that is tied to (synchronized with) the sequence controlled by the stream buffer.

`basic_ostream<charT, traits>* tie(basic_ostream<charT, traits>* tiestr);`

*Requires:* If `tiestr` is not null, `tiestr` shall not be reachable by traversing the linked list of tied stream objects starting from `tiestr->tie()`.

*Ensures:* `tiestr == tie()`.

*Returns:* The previous value of `tie()`.

`basic_streambuf<charT, traits>* rdbuf() const;`

*Returns:* A pointer to the `streambuf` associated with the stream.

`basic_streambuf<charT, traits>* rdbuf(basic_streambuf<charT, traits>* sb);`

*Ensures:* `sb == rdbuf()`.

*Effects:* Calls `clear()`.

*Returns:* The previous value of `rdbuf()`.

`locale imbue(const locale& loc);`

*Effects:* Calls `ios_base::imbue(loc)` and if `rdbuf() != 0` then `rdbuf() -> pubimbue(loc)`.
Returns: The prior value of `ios_base::imbue()`.

```cpp
char narrow(char_type c, char dfault) const;
```

Returns: `use_facet<ctype<char_type>>(getloc()).narrow(c, dfault)`

```cpp
char_type widen(char c) const;
```

Returns: `use_facet<ctype<char_type>>(getloc()).widen(c)`

```cpp
char_type fill() const;
```

Returns: The character used to pad (fill) an output conversion to the specified field width.

```cpp
char_type fill(char_type fillch);
```

Ensures: `traits::eq(fillch, fill())`.

Returns: The previous value of `fill()`.

basic_ios& copyfmt(const basic_ios& rhs);

Effects: If `(this == &rhs)` does nothing. Otherwise assigns to the member objects of `*this` the corresponding member objects of `rhs` as follows:

- calls each registered callback pair `(fn, idx)` as `(*fn)(erase_event, *this, idx)`;
- then, assigns to the member objects of `*this` the corresponding member objects of `rhs`, except that
  - `rdstate()`, `rdbuf()`, and `exceptions()` are left unchanged;
  - the contents of arrays pointed at by `pword` and `iword` are copied, not the pointers themselves;[^298]
  - if any newly stored pointer values in `*this` point at objects stored outside the object `rhs` and those objects are destroyed when `rhs` is destroyed, the newly stored pointer values are altered to point at newly constructed copies of the objects;
- then, calls each callback pair that was copied from `rhs` as `(*fn)(copyfmt_event, *this, idx)`;
- then, calls `exceptions(rhs.exceptions())`.

[Note: The second pass through the callback pairs permits a copied `pword` value to be zeroed, or to have its referent deep copied or reference counted, or to have other special action taken. — end note]

Ensures: The postconditions of this function are indicated in Table 112.

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>rdbuf()</td>
<td>unchanged</td>
</tr>
<tr>
<td>tie()</td>
<td>rhs.tie()</td>
</tr>
<tr>
<td>rdstate()</td>
<td>unchanged</td>
</tr>
<tr>
<td>exceptions()</td>
<td>rhs.exceptions()</td>
</tr>
<tr>
<td>flags()</td>
<td>rhs.flags()</td>
</tr>
<tr>
<td>width()</td>
<td>rhs.width()</td>
</tr>
<tr>
<td>precision()</td>
<td>rhs.precision()</td>
</tr>
<tr>
<td>fill()</td>
<td>rhs.fill()</td>
</tr>
<tr>
<td>getloc()</td>
<td>rhs.getloc()</td>
</tr>
</tbody>
</table>

Returns: `*this`.

void move(basic_ios& rhs);

[^298]: This suggests an infinite amount of copying, but the implementation can keep track of the maximum element of the arrays that is nonzero.
void move(basic_ios&& rhs);

Ensures: *this shall have the state that rhs had before the function call, except that rdbuf() shall return 0. rhs shall be in a valid but unspecified state, except that rhs.rdbuf() shall return the same value as it returned before the function call, and rhs.tie() shall return 0.

void swap(basic_ios& rhs) noexcept;

Effects: The states of *this and rhs shall be exchanged, except that rdbuf() shall return the same value as it returned before the function call, and rhs.rdbuf() shall return the same value as it returned before the function call.

void set_rdbuf(basic_streambuf<charT, traits>* sb);

Requires: sb != nullptr.

Effects: Associates the basic_streambuf object pointed to by sb with this stream without calling clear().

Ensures: rdbuf() == sb.

Throws: Nothing.

27.5.5.4 basic_ios flags functions

explicit operator bool() const;

Returns: !fail().

bool operator!() const;

Returns: fail().

iostate rdstate() const;

Returns: The error state of the stream buffer.

void clear(iostate state = goodbit);

Ensures: If rdbuf() != 0 then state == rdstate(); otherwise rdstate() == (state | ios_base::badbit).

Effects: If ((state | (rdbuf() ? goodbit : badbit)) & exceptions()) == 0, returns. Otherwise, the function throws an object of class basic_ios::failure (27.5.3.1.1), constructed with implementation-defined argument values.

void setstate(iostate state);

Effects: Calls clear(rdstate() | state) (which may throw basic_ios::failure (27.5.3.1.1)).

bool good() const;

Returns: rdstate() == 0

bool eof() const;

Returns: true if eofbit is set in rdstate().

bool fail() const;

Returns: true if failbit or badbit is set in rdstate().

bool bad() const;

Returns: true if badbit is set in rdstate().

iostate exceptions() const;

Returns: A mask that determines what elements set in rdstate() cause exceptions to be thrown.

void exceptions(iostate except);

Ensures: except == exceptions().

299) Checking badbit also for fail() is historical practice.
Effects: Calls `clear(rdstate())`.

### 27.5.6 ios_base manipulators

#### 27.5.6.1 fmtflags manipulators

Each function specified in this subclause is a designated addressable function (15.5.4.2.1).

```cpp
ios_base& boolalpha(ios_base& str);
Effects: Calls `str.setf(ios_base::boolalpha)`.
Returns: `str`.

ios_base& noboolalpha(ios_base& str);
Effects: Calls `str.unsetf(ios_base::boolalpha)`.
Returns: `str`.

ios_base& showbase(ios_base& str);
Effects: Calls `str.setf(ios_base::showbase)`.
Returns: `str`.

ios_base& noshowbase(ios_base& str);
Effects: Calls `str.unsetf(ios_base::showbase)`.
Returns: `str`.

ios_base& showpoint(ios_base& str);
Effects: Calls `str.setf(ios_base::showpoint)`.
Returns: `str`.

ios_base& noshowpoint(ios_base& str);
Effects: Calls `str.unsetf(ios_base::showpoint)`.
Returns: `str`.

ios_base& showpos(ios_base& str);
Effects: Calls `str.setf(ios_base::showpos)`.
Returns: `str`.

ios_base& noshowpos(ios_base& str);
Effects: Calls `str.unsetf(ios_base::showpos)`.
Returns: `str`.

ios_base& skipws(ios_base& str);
Effects: Calls `str.setf(ios_base::skipws)`.
Returns: `str`.

ios_base& noskipws(ios_base& str);
Effects: Calls `str.unsetf(ios_base::skipws)`.
Returns: `str`.

ios_base& uppercase(ios_base& str);
Effects: Calls `str.setf(ios_base::uppercase)`.
Returns: `str`.

ios_base& nouppercase(ios_base& str);
Effects: Calls `str.unsetf(ios_base::uppercase)`.
Returns: `str`.
```

§ 27.5.6.1
ios_base& unitbuf(ios_base& str);
   Effects: Calls str.setf(ios_base::unitbuf).
   Returns: str.

ios_base& nounitbuf(ios_base& str);
   Effects: Calls str.unsetf(ios_base::unitbuf).
   Returns: str.

27.5.6.2 adjustfield manipulators [adjustfield.manip]
1 Each function specified in this subclause is a designated addressable function (15.5.4.2.1).

ios_base& internal(ios_base& str);
  Effects: Calls str.setf(ios_base::internal, ios_base::adjustfield).
  Returns: str.

ios_base& left(ios_base& str);
  Effects: Calls str.setf(ios_base::left, ios_base::adjustfield).
  Returns: str.

ios_base& right(ios_base& str);
  Effects: Calls str.setf(ios_base::right, ios_base::adjustfield).
  Returns: str.

27.5.6.3 basefield manipulators [basefield.manip]
1 Each function specified in this subclause is a designated addressable function (15.5.4.2.1).

ios_base& dec(ios_base& str);
  Effects: Calls str.setf(ios_base::dec, ios_base::basefield).
  Returns: str.

ios_base& hex(ios_base& str);
  Effects: Calls str.setf(ios_base::hex, ios_base::basefield).
  Returns: str.

ios_base& oct(ios_base& str);
  Effects: Calls str.setf(ios_base::oct, ios_base::basefield).
  Returns: str.

27.5.6.4 floatfield manipulators [floatfield.manip]
1 Each function specified in this subclause is a designated addressable function (15.5.4.2.1).

ios_base& fixed(ios_base& str);
  Effects: Calls str.setf(ios_base::fixed, ios_base::floatfield).
  Returns: str.

ios_base& scientific(ios_base& str);
  Effects: Calls str.setf(ios_base::scientific, ios_base::floatfield).
  Returns: str.

ios_base& hexfloat(ios_base& str);
  Effects: Calls str.setf(ios_base::fixed | ios_base::scientific, ios_base::floatfield).
  Returns: str.

300) The function signature dec(ios_base&) can be called by the function signature basic_ostream< basic_ios& (*)(ios_base&) > to permit expressions of the form cout << dec to change the format flags stored in cout.

§ 27.5.6.4
[Note: The more obvious use of `ios_base::hex` to specify hexadecimal floating-point format would change the meaning of existing well-defined programs. C++ 2003 gives no meaning to the combination of `fixed` and `scientific`. — end note]

```cpp
ios_base& defaultfloat(ios_base& str);
```

Effects: Calls `str.unsetf(ios_base::floatfield)`.

Returns: `str`.

### 27.5.7 Error reporting

```cpp
error_code make_error_code(io_errc e) noexcept;
```

Returns: `error_code(static_cast<int>(e), iostream_category())`.

```cpp
error_condition make_error_condition(io_errc e) noexcept;
```

Returns: `error_condition(static_cast<int>(e), iostream_category())`.

```cpp
const error_category& iostream_category() noexcept;
```

Returns: A reference to an object of a type derived from class `error_category`.

The object’s `default_error_condition` and `equivalent` virtual functions shall behave as specified for the class `error_category`. The object’s `name` virtual function shall return a pointer to the string "iostream".

### 27.6 Stream buffers

#### 27.6.1 Header `<streambuf>` synopsis

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_streambuf;
    using streambuf = basic_streambuf<char>;
    using wstreambuf = basic_streambuf<wchar_t>;
}
```

The header `<streambuf>` defines types that control input from and output to character sequences.

#### 27.6.2 Stream buffer requirements

Stream buffers can impose various constraints on the sequences they control. Some constraints are:

1. The controlled input sequence can be not readable.
2. The controlled output sequence can be not writable.
3. The controlled sequences can be associated with the contents of other representations for character sequences, such as external files.
4. The controlled sequences can support operations `directly` to or from associated sequences.
5. The controlled sequences can impose limitations on how the program can read characters from a sequence, write characters to a sequence, put characters back into an input sequence, or alter the stream position.

Each sequence is characterized by three pointers which, if non-null, all point into the same `charT` array object. The array object represents, at any moment, a (sub)sequence of characters from the sequence. Operations performed on a sequence alter the values stored in these pointers, perform reads and writes directly to or from associated sequences, and alter "the stream position" and conversion state as needed to maintain this subsequence relationship. The three pointers are:

1. The `beginning pointer`, or lowest element address in the array (called `xbeg` here);
2. The `next pointer`, or next element address that is a current candidate for reading or writing (called `xnext` here);
3. The `end pointer`, or first element address beyond the end of the array (called `xend` here).

The following semantic constraints shall always apply for any set of three pointers for a sequence, using the pointer names given immediately above:
If `xnext` is not a null pointer, then `xbeg` and `xend` shall also be non-null pointers into the same `charT` array, as described above; otherwise, `xbeg` and `xend` shall also be null.

If `xnext` is not a null pointer and `xnext < xend` for an output sequence, then a `write position` is available. In this case, `*xnext` shall be assignable as the next element to write (to put, or to store a character value, into the sequence).

If `xnext` is not a null pointer and `xbeg < xnext` for an input sequence, then a `putback position` is available. In this case, `xnext[-1]` shall have a defined value and is the next (preceding) element to store a character that is put back into the input sequence.

If `xnext` is not a null pointer and `xnext < xend` for an input sequence, then a `read position` is available. In this case, `*xnext` shall have a defined value and is the next element to read (to get, or to obtain a character value, from the sequence).

### 27.6.3 Class template `basic_streambuf`

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_streambuf {
    public:
        using char_type = charT;
        using int_type = typename traits::int_type;
        using pos_type = typename traits::pos_type;
        using off_type = typename traits::off_type;
        using traits_type = traits;

        virtual ~basic_streambuf();

        // 27.6.3.2.1, locales
        locale pubimbue(const locale& loc);
        locale getloc() const;

        // 27.6.3.2.2, buffer and positioning
        basic_streambuf* pubsetbuf(char_type* s, streamsize n);
        pos_type pubseekoff(off_type off, ios_base::seekdir way,
                              ios_base::openmode which
                               = ios_base::in | ios_base::out);
        pos_type pubseekpos(pos_type sp,
                             ios_base::openmode which
                             = ios_base::in | ios_base::out);
        int pubsync();

        // get and put areas
        // 27.6.3.2.3, get area
        streamsize in_avail();
        int_type snextc();
        int_type sbumpc();
        int_type sgetc();
        streamsize sgetn(char_type* s, streamsize n);

        // 27.6.3.2.4, putback
        int_type sputbackc(char_type c);
        int_type sungetc();

        // 27.6.3.2.5, put area
        int_type  sputc(char_type c);
        streamsize sputn(const char_type* s, streamsize n);

    protected:
        basic_streambuf();
        basic_streambuf(const basic_streambuf& rhs);
        basic_streambuf& operator=(const basic_streambuf& rhs);

        void swap(basic_streambuf& rhs);
    }
}
```
The class template `basic_streambuf` serves as an abstract base class for deriving various stream buffers whose objects each control two character sequences:

- (1.1) a character input sequence;
- (1.2) a character output sequence.

### 27.6.3.1 `basic_streambuf` constructors

```cpp
basic_streambuf();
```

**Effects:** Constructs an object of class `basic_streambuf<charT, traits>` and initializes:

- (1.1) all its pointer member objects to null pointers,
- (1.2) the `getloc()` member to a copy the global locale, `locale()`, at the time of construction.

**Remarks:** Once the `getloc()` member is initialized, results of calling locale member functions, and of members of facets so obtained, can safely be cached until the next time the member `imbue` is called.

---

301) The default constructor is protected for class `basic_streambuf` to assure that only objects for classes derived from this class may be constructed.
basic_streambuf(const basic_streambuf& rhs);

3  Effects: Constructs a copy of rhs.
4  Ensures:

(4.1) — eback() == rhs.eback()
(4.2) — gptr() == rhs.gptr()
(4.3) — egptr() == rhs.egptr()
(4.4) — pbase() == rhs.pbase()
(4.5) — pptr() == rhs.pptr()
(4.6) — epptr() == rhs.epptr()
(4.7) — getloc() == rhs.getloc()

~basic_streambuf();

5  Effects: None.

27.6.3.2 basic_streambuf public member functions [streambuf.members]

27.6.3.2.1 Locales [streambuf.locales]
locale pubimbue(const locale& loc);

1  Ensures: loc == getloc().
2  Effects: Calls imbue(loc).
3  Returns: Previous value of getloc().

locale getloc() const;

4  Returns: If pubimbue() has ever been called, then the last value of loc supplied, otherwise the current global locale, locale(), in effect at the time of construction. If called after pubimbue() has been called but before pubimbue has returned (i.e., from within the call of imbue()) then it returns the previous value.

27.6.3.2.2 Buffer management and positioning [streambuf.buffer]
basic_streambuf* pubsetbuf(char_type* s, streamsize n);

1  Returns: setbuf(s, n).

pos_type pubseekoff(off_type off, ios_base::seekdir way,
                     ios_base::openmode which = ios_base::in | ios_base::out);

2  Returns: seekoff(off, way, which).

pos_type pubseekpos(pos_type sp,
                    ios_base::openmode which = ios_base::in | ios_base::out);

3  Returns: seekpos(sp, which).

int pubsync();

4  Returns: sync().

27.6.3.2.3 Get area [streambuf.pub.get]
streamsize in_avail();

1  Returns: If a read position is available, returns egptr() - gptr(). Otherwise returns showmanyc() (27.6.3.4.3).

int_type snextc();

2  Effects: Calls sbumpc().
3  Returns: If that function returns traits::eof(), returns traits::eof(). Otherwise, returns sgetc().

§ 27.6.3.2.3 1172
int_type sbumpc();

4 Returns: If the input sequence read position is not available, returns uflow(). Otherwise, returns traits::to_int_type(*gptr()) and increments the next pointer for the input sequence.

int_type sgetc();

5 Returns: If the input sequence read position is not available, returns underflow(). Otherwise, returns traits::to_int_type(*gptr()).

streamsize sgetn(char_type* s, streamsize n);

6 Returns: xsgetn(s, n).

27.6.3.2.4 Putback

[streambuf.pub.pback]

int_type sputbackc(char_type c);

1 Returns: If the input sequence putback position is not available, or if traits::eq(c, gptr()[-1]) is false, returns pbackfail(traits::to_int_type(c)). Otherwise, decrements the next pointer for the input sequence and returns traits::to_int_type(*gptr()).

int_type sungetc();

2 Returns: If the input sequence putback position is not available, returns pbackfail(). Otherwise, decrements the next pointer for the input sequence and returns traits::to_int_type(*gptr()).

27.6.3.2.5 Put area

[streambuf.pub.put]

int_type sputc(char_type c);

1 Returns: If the output sequence write position is not available, returns overflow(traits::to_int_type(c)). Otherwise, stores c at the next pointer for the output sequence, increments the pointer, and returns traits::to_int_type(c).

streamsize sputn(const char_type* s, streamsize n);

2 Returns: xsputn(s, n).

27.6.3.3 basic_streambuf protected member functions

[streambuf.protected]

27.6.3.3.1 Assignment

[streambuf.assign]

basic_streambuf& operator=(const basic_streambuf& rhs);

1 Effects: Assigns the data members of rhs to *this.

2 Ensures:

(2.1) eback() == rhs.eback()
(2.2) gptr() == rhs.gptr()
(2.3) egptr() == rhs.egptr()
(2.4) pbase() == rhs.pbase()
(2.5) pptr() == rhs.pptr()
(2.6) epptr() == rhs.epptr()
(2.7) getloc() == rhs.getloc()

3 Returns: *this.

void swap(basic_streambuf& rhs);

4 Effects: Swaps the data members of rhs and *this.

27.6.3.3.2 Get area access

[streambuf.get.area]

char_type* eback() const;

1 Returns: The beginning pointer for the input sequence.
char_type* gptr() const;  
Returns: The next pointer for the input sequence.

char_type* egptr() const;  
Returns: The end pointer for the input sequence.

void gbump(int n);  
Effects: Adds n to the next pointer for the input sequence.

void setg(char_type* gbeg, char_type* gnext, char_type* gend);  
Ensures: gbeg == eback(), gnext == gptr(), and gend == egptr().

27.6.3.3 Put area access

char_type* pbase() const;  
Returns: The beginning pointer for the output sequence.

char_type* pptr() const;  
Returns: The next pointer for the output sequence.

char_type* epptr() const;  
Returns: The end pointer for the output sequence.

void pbump(int n);  
Effects: Adds n to the next pointer for the output sequence.

void setp(char_type* pbeg, char_type* pend);  
Ensures: pbeg == pbase(), pbeg == pptr(), and pend == epptr().

27.6.3.4 basic_streambuf virtual functions

27.6.3.4.1 Locales

void imbue(const locale&);  
Effects: Change any translations based on locale.

Remarks: Allows the derived class to be informed of changes in locale at the time they occur. Between
invocations of this function a class derived from streambuf can safely cache results of calls to locale
functions and to members of facets so obtained.

Default behavior: Does nothing.

27.6.3.4.2 Buffer management and positioning

basic_streambuf* setbuf(char_type* s, streamsize n);  
Effects: Influences stream buffering in a way that is defined separately for each class derived from
basic_streambuf in this Clause (27.8.2.4, 27.9.2.4).

Default behavior: Does nothing. Returns this.

pos_type seekoff(off_type off, ios_base::seekdir way,
    ios_base::openmode which = ios_base::in | ios_base::out);  
Effects: Alters the stream positions within one or more of the controlled sequences in a way that is
defined separately for each class derived from basic_streambuf in this Clause (27.8.2.4, 27.9.2.4).

Default behavior: Returns pos_type(off_type(-1)).

pos_type seekpos(pos_type sp,
    ios_base::openmode which = ios_base::in | ios_base::out);  
Effects: Alters the stream positions within one or more of the controlled sequences in a way that is
defined separately for each class derived from basic_streambuf in this Clause (27.8.2, 27.9.2).
Default behavior: Returns `pos_type(off_type(-1))`.

```c
int sync();
```

**Effects:** Synchronizes the controlled sequences with the arrays. That is, if `pbase()` is non-null the characters between `pbase()` and `pptr()` are written to the controlled sequence. The pointers may then be reset as appropriate.

**Returns:** `-1` on failure. What constitutes failure is determined by each derived class (27.9.2.4).

Default behavior: Returns zero.

### 27.6.3.4.3 Get area

#### streamsize showmanyc();

**Returns:** An estimate of the number of characters available in the sequence, or `-1`. If it returns a positive value, then successive calls to `underflow()` will not return `traits::eof()` until at least that number of characters have been extracted from the stream. If `showmanyc()` returns `-1`, then calls to `underflow()` or `uflow()` will fail.

Default behavior: Returns zero.

Remarks: Uses `traits::eof()`.

```c
streamsize xsgetn(char_type* s, streamsize n);
```

**Effects:** Assigns up to `n` characters to successive elements of the array whose first element is designated by `s`. The characters assigned are read from the input sequence as if by repeated calls to `sbumpc()`. Assigning stops when either `n` characters have been assigned or a call to `sbumpc()` would return `traits::eof()`.

**Returns:** The number of characters assigned.

Remarks: Uses `traits::eof()`.

#### int_type underflow();

**Remarks:** The public members of `basic_streambuf` call this virtual function only if `gptr()` is null or `gptr() >= egptr()`.

**Returns:** `traits::to_int_type(c)`, where `c` is the first character of the pending sequence, without moving the input sequence position past it. If the pending sequence is null then the function returns `traits::eof()` to indicate failure.

The pending sequence of characters is defined as the concatenation of

1. the empty sequence if `gptr()` is null, otherwise the characters in `[gptr(), egptr())`, followed by
2. some (possibly empty) sequence of characters read from the input sequence.

The result character is the first character of the pending sequence if it is non-empty, otherwise the next character that would be read from the input sequence.

The backup sequence is the empty sequence if `eback()` is null, otherwise the characters in `[eback(), gptr())`.

**Effects:** The function sets up the `gptr()` and `egptr()` such that if the pending sequence is non-empty, then `egptr()` is non-null and the characters in `[gptr(), egptr())` are the characters in the pending sequence, otherwise either `gptr()` is null or `gptr() == egptr()`.

If `eback()` and `gptr()` are non-null then the function is not constrained as to their contents, but the “usual backup condition” is that either

1. the backup sequence contains at least `gptr() - eback()` characters, in which case the characters in `[eback(), gptr())` agree with the last `gptr() - eback()` characters of the backup sequence, or

---

302) The morphemes of `showmanyc` are “es-how-many-see”, not “show-manic”.

303) `underflow` or `uflow` might fail by throwing an exception prematurely. The intention is not only that the calls will not return `eof()` but that they will return “immediately”.

304) Classes derived from `basic_streambuf` can provide more efficient ways to implement `xsgetn()` and `xsputn()` by overriding these definitions from the base class.
the characters in \( \text{gptr}() - n, \text{gptr}() \) agree with the backup sequence (where \( n \) is the length of the backup sequence).

**Default behavior:** Returns \( \text{traits::eof()} \).

```cpp
int_type uflow();
```

**Requires:** The constraints are the same as for \( \text{underflow}() \), except that the result character shall be transferred from the pending sequence to the backup sequence, and the pending sequence shall not be empty before the transfer.

**Default behavior:** Calls \( \text{underflow}() \). If \( \text{underflow}() \) returns \( \text{traits::eof()} \), returns \( \text{traits::eof()} \). Otherwise, returns the value of \( \text{traits::to_int_type}(*\text{gptr()} \) and increment the value of the next pointer for the input sequence.

**Returns:** \( \text{traits::eof()} \) to indicate failure.

### 27.6.3.4.4 Putback

#### [streambuf.virt.pback]

```cpp
int_type pbackfail(int_type c = traits::eof());
```

**Remarks:** The public functions of \( \text{basic_streambuf} \) call this virtual function only when \( \text{gptr}() \) is null, \( \text{gptr}() == \text{eback()} \), or \( \text{traits::eq(traits::to_char_type(c), gptr()[\text{-}1])} \) returns false. Other calls shall also satisfy that constraint.

The **pending sequence** is defined as for \( \text{underflow}() \), with the modifications that

1. If \( \text{traits::eq_int_type(c, traits::eof())} \) returns true, then the input sequence is backed up one character before the pending sequence is determined.
2. If \( \text{traits::eq_int_type(c, traits::eof())} \) returns false, then \( c \) is prepended. Whether the input sequence is backed up or modified in any other way is unspecified.

**Ensures:** On return, the constraints of \( \text{gptr()}, \text{eback()} \), and \( \text{pptr()} \) are the same as for \( \text{underflow}() \).

**Returns:** \( \text{traits::eof()} \) to indicate failure. Failure may occur because the input sequence could not be backed up, or if for some other reason the pointers could not be set consistent with the constraints. \( \text{pbackfail()} \) is called only when put back has really failed.

**Returns some value other than \( \text{traits::eof()} \) to indicate success.**

**Default behavior:** Returns \( \text{traits::eof()} \).

### 27.6.3.4.5 Put area

#### [streambuf.virt.put]

```cpp
streamsize xsputn(const char_type* s, streamsize n);
```

**Effects:** Writes up to \( n \) characters to the output sequence as if by repeated calls to \( \text{sputc(c)} \). The characters written are obtained from successive elements of the array whose first element is designated by \( s \). Writing stops when either \( n \) characters have been written or a call to \( \text{sputc(c)} \) would return \( \text{traits::eof()} \). It is unspecified whether the function calls \( \text{overflow()} \) when \( \text{pptr()} == \text{epptr()} \) becomes true or whether it achieves the same effects by other means.

**Returns:** The number of characters written.

```cpp
int_type overflow(int_type c = traits::eof());
```

**Effects:** Consumes some initial subsequence of the characters of the **pending sequence**. The pending sequence is defined as the concatenation of

1. the empty sequence if \( \text{pbase()} \) is null, otherwise the \( \text{pptr()} - \text{pbase()} \) characters beginning at \( \text{pbase()} \), followed by
2. the empty sequence if \( \text{traits::eq_int_type(c, traits::eof())} \) returns true, otherwise the sequence consisting of \( c \).

**Remarks:** The member functions \( \text{sputc()} \) and \( \text{sputn()} \) call this function in case that no room can be found in the put buffer enough to accommodate the argument character sequence.

**Requires:** Every overriding definition of this virtual function shall obey the following constraints:
The effect of consuming a character on the associated output sequence is specified.\(^\text{305}\)

Let \(r\) be the number of characters in the pending sequence not consumed. If \(r\) is nonzero then \(\text{pbase()}\) and \(\text{pptr()}\) shall be set so that: \(\text{pptr()} - \text{pbase()} = r\) and the \(r\) characters starting at \(\text{pbase()}\) are the associated output stream. In case \(r\) is zero (all characters of the pending sequence have been consumed) then either \(\text{pbase()}\) is set to \(\text{nullptr}\), or \(\text{pbase()}\) and \(\text{pptr()}\) are both set to the same non-null value.

The function may fail if either appending some character to the associated output stream fails or if it is unable to establish \(\text{pbase()}\) and \(\text{pptr()}\) according to the above rules.

Returns: \(\text{traits::eof()}\) or throws an exception if the function fails.

Otherwise, returns some value other than \(\text{traits::eof()}\) to indicate success.\(^\text{306}\)

Default behavior: Returns \(\text{traits::eof()}\).

### 27.7 Formatting and manipulators

#### 27.7.1 Header <istream> synopsis

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_istream;

    using istream = basic_istream<char>;
    using wistream = basic_istream<wchar_t>;

    template<class charT, class traits = char_traits<charT>>
    class basic_iostream;

    using iostream = basic_iostream<char>;
    using wiostream = basic_iostream<wchar_t>;

    template<class charT, class traits = char_traits<charT>>
    basic_istream<charT, traits>& ws(basic_istream<charT, traits>& is);

    template<class charT, class traits, class T>
    basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>&& is, T&& x);
}
```

#### 27.7.2 Header <ostream> synopsis

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_ostream;

    using ostream = basic_ostream<char>;
    using wostream = basic_ostream<wchar_t>;

    template<class charT, class traits = char_traits<charT>>
    basic_ostream<charT, traits>& endl(basic_ostream<charT, traits>& os);

    template<class charT, class traits = char_traits<charT>>
    basic_ostream<charT, traits>& flush(basic_ostream<charT, traits>& os);

    template<class charT, class traits = char_traits<charT>>
    basic_ostream<charT, traits>& flush_emit(basic_ostream<charT, traits>& os);
}
```

\(^{305}\) That is, for each class derived from an instance of \texttt{basic\_streambuf} in this Clause (27.8.2, 27.9.2), a specification of how consuming a character effects the associated output sequence is given. There is no requirement on a program-defined class.

\(^{306}\) Typically, \texttt{overflow} returns \(\text{c}\) to indicate success, except when \(\text{traits::eq_int_type(c, traits::eof())}\) returns \(\text{true}\), in which case it returns \(\text{traits::not_eof(c)}\).
template<class charT, class traits, class T>
    basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>&& os, const T& x);
}

## 27.7.3 Header `<iomanip>` synopsis

```cpp
namespace std {
    // types T1, T2, ... are unspecified implementation types
    T1 resetiosflags(ios_base::fmtflags mask);
    T2 setiosflags (ios_base::fmtflags mask);
    T3 setbase(int base);
    template<class charT>
        T4 setfill(charT c);
    T5 setprecision(int n);
    T6 setw(int n);
    template<class moneyT>
        T7 get_money(moneyT& mon, bool intl = false);
    template<class moneyT>
        T8 put_money(const moneyT& mon, bool intl = false);
    template<class charT>
        T9 get_time(struct tm* tmb, const charT* fmt);
    template<class charT>
        T10 put_time(const struct tm* tmb, const charT* fmt);

    template<class charT>
        T11 quoted(const charT* s, charT delim = charT('"'), charT escape = charT('\'));
    template<class charT, class traits, class Allocator>
        T12 quoted(const basic_string<charT, traits, Allocator>& s,
                   charT delim = charT('"'), charT escape = charT('\'));
    template<class charT, class traits>
        T13 quoted(basic_string_view<charT, traits> s,
                   charT delim = charT('"'), charT escape = charT('\'));
}
```

## 27.7.4 Input streams

The header `<istream>` defines two types and a function signature that control input from a stream buffer along with a function template that extracts from stream rvalues.

### 27.7.4.1 Class template `basic_istream`

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_istream : virtual public basic_ios<charT, traits> {
    public:
        // types (inherited from basic_ios (27.5.5))
        using char_type = charT;
        using int_type = typename traits::int_type;
        using pos_type = typename traits::pos_type;
        using off_type = typename traits::off_type;
        using traits_type = traits;

        // 27.7.4.1.1, constructor/destructor
        explicit basic_istream(basic_streambuf<charT, traits>* sb);
        virtual ~basic_istream();

        // 27.7.4.1.3, prefix/suffix
        class sentry;

        // 27.7.4.2, formatted input
        basic_istream<charT, traits>&
            operator>>(basic_istream<charT, traits>&& (*pf)(basic_istream<charT, traits>&&));
        basic_istream<charT, traits>&
            operator>>(basic_ios<charT, traits>& (*pf)(basic_ios<charT, traits>&&));
    }
```
basic_istream<charT, traits>&
    operator>>(ios_base& (*pf)(ios_base&));

basic_istream<charT, traits>& operator>>(bool& n);
basic_istream<charT, traits>& operator>>(short& n);
basic_istream<charT, traits>& operator>>(unsigned short& n);
basic_istream<charT, traits>& operator>>(int& n);
basic_istream<charT, traits>& operator>>(unsigned int& n);
basic_istream<charT, traits>& operator>>(long& n);
basic_istream<charT, traits>& operator>>(unsigned long& n);
basic_istream<charT, traits>& operator>>(long long& n);
basic_istream<charT, traits>& operator>>(unsigned long long& n);
basic_istream<charT, traits>& operator>>(float& f);
basic_istream<charT, traits>& operator>>(double& f);
basic_istream<charT, traits>& operator>>(long double& f);

basic_istream<charT, traits>& operator>>(void*& p);
basic_istream<charT, traits>& operator>>(basic_streambuf<char_type, traits>* sb);

// 27.7.4.3, unformatted input
streamsize gcount() const;
int_type get();
basic_istream<charT, traits>& get(char_type& c);
basic_istream<charT, traits>& get(char_type* s, streamsize n);
basic_istream<charT, traits>& get(char_type* s, streamsize n, char_type delim);
basic_istream<charT, traits>& get(basic_streambuf<char_type, traits>& sb);
basic_istream<charT, traits>& get(basic_streambuf<char_type, traits>& sb, char_type delim);

basic_istream<charT, traits>& getline(char_type* s, streamsize n);
basic_istream<charT, traits>& getline(char_type* s, streamsize n, char_type delim);

basic_istream<charT, traits>& ignore(streamsize n = 1, int_type delim = traits::eof());
int_type peek();
basic_istream<charT, traits>& read (char_type* s, streamsize n);
streamsize readsome(char_type* s, streamsize n);

basic_istream<charT, traits>& putback(char_type c);
basic_istream<charT, traits>& umget();
int sync();

pos_type tellg();
basic_istream<charT, traits>& seekg(pos_type);
basic_istream<charT, traits>& seekg(off_type, ios_base::seekdir);

protected:
// 27.7.4.1.1, copy/move constructor
basic_istream(const basic_istream& rhs) = delete;
basic_istream(basic_istream&& rhs);

// 27.7.4.1.2, assign and swap
basic_istream& operator=(const basic_istream& rhs) = delete;
basic_istream& operator=(basic_istream&& rhs);
void swap(basic_istream& rhs);

// 27.7.4.2.3, character extraction templates
template<class charT, class traits>
basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>&, charT&);
template<class traits>
basic_istream<char, traits>& operator>>(basic_istream<char, traits>&, unsigned char&);
template<class traits>
basic_istream<char, traits>& operator>>(basic_istream<char, traits>&, signed char&);
The class template `basic_istream` defines a number of member function signatures that assist in reading and interpreting input from sequences controlled by a stream buffer.

Two groups of member function signatures share common properties: the formatted input functions (or extractors) and the unformatted input functions. Both groups of input functions are described as if they obtain (or extract) input characters by calling `rdbuf()->sbumpc()` or `rdbuf()->sgetc()`. They may use other public members of `istream`.

If `rdbuf()->sbumpc()` or `rdbuf()->sgetc()` returns `traits::eof()`, then the input function, except as explicitly noted otherwise, completes its actions and does `setstate(eofbit)`, which may throw `ios_base::failure` (27.5.5.4), before returning.

If one of these called functions throws an exception, then unless explicitly noted otherwise, the input function sets `badbit` in error state. If `badbit` is on in `exceptions()`, the input function rethrows the exception without completing its actions, otherwise it does not throw anything and proceeds as if the called function had returned a failure indication.

### 27.7.4.1.1 `basic_istream` constructors

```cpp
explicit basic_istream(basic_streambuf<charT, traits>* sb);
```

**Effects:** Constructs an object of class `basic_istream`, initializing the base class subobject with `basic_ios::init(sb)` (27.5.5.2).

**Ensures:** `gcount() == 0`.

```cpp
basic_istream(basic_istream&& rhs);
```

**Effects:** Move constructs from the rvalue `rhs`. This is accomplished by default constructing the base class, copying the `gcount()` from `rhs`, calling `basic_ios<charT, traits>::move(rhs)` to initialize the base class, and setting the `gcount()` for `rhs` to 0.

**Remarks:** Does not perform any operations of `rdbuf()`.

### 27.7.4.1.2 Class `basic_istream` assign and swap

```cpp
basic_istream& operator=(basic_istream&& rhs);
```

**Effects:** As if by `swap(rhs)`.

**Returns:** `*this`.

```cpp
void swap(basic_istream& rhs);
```

**Effects:** Calls `basic_ios<charT, traits>::swap(rhs)`. Exchanges the values returned by `gcount()` and `rhs.gcount()`.

### 27.7.4.1.3 Class `basic_istream::sentry`

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_istream<charT, traits>::sentry {
        using traits_type = traits;
        bool ok_; // exposition only
    public:
        explicit sentry(basic_istream<charT, traits>& is, bool noskipws = false);
        ~sentry();
        explicit operator bool() const { return ok_; }
        sentry(const sentry&) = delete;
    }
}
```
The class `sentry` defines a class that is responsible for doing exception safe prefix and suffix operations.

```cpp
sentry& operator=(const sentry&) = delete;
```

### Effects:

If `is.good()` is `false`, calls `is.setstate(failbit)`. Otherwise, prepares for formatted or unformatted input. First, if `is.tie()` is not a null pointer, the function calls `is.tie()->flush()` to synchronize the output sequence with any associated external C stream. Except that this call can be suppressed if the put area of `is.tie()` is empty. Further an implementation is allowed to defer the call to `flush` until a call of `is.rdbuf()->underflow()` occurs. If no such call occurs before the `sentry` object is destroyed, the call to `flush` may be eliminated entirely.\(^{307}\) If `noskipws` is zero and `is.flags() & ios_base::skipws` is nonzero, the function extracts and discards each character as long as the next available input character `c` is a whitespace character. If `is.rdbuf()->sbumpc()` or `is.rdbuf()->sgetc()` returns `traits::eof()`, the function calls `setstate(failbit | eofbit)` (which may throw `ios_base::failure`).

### Remarks:

The constructor

```cpp
explicit sentry(basic_istream<charT, traits>& is, bool noskipws = false);
```
uses the currently imbued locale in `is`, to determine whether the next input character is whitespace or not.

To decide if the character `c` is a whitespace character, the constructor performs as if it executes the following code fragment:

```cpp
const ctype<charT>& ctype = use_facet<ctype<charT>>(is.getloc());
if (ctype.is(ctype.space, c) != 0)
    // c is a whitespace character.
```

If, after any preparation is completed, `is.good()` is `true`, `ok_` != `false` otherwise, `ok_` == `false`. During preparation, the constructor may call `setstate(failbit)` (which may throw `ios_base::failure`)\(^{308}\)

~sentry();

### Effects:

None.

```cpp
explicit operator bool() const;
```

### Effects:

Returns `ok_`.

### 27.7.4.2 Formatted input functions

#### 27.7.4.2.1 Common requirements

Each formatted input function begins execution by constructing an object of class `sentry` with the `noskipws` (second) argument `false`. If the `sentry` object returns `true`, when converted to a value of type `bool`, the function endeavors to obtain the requested input. If an exception is thrown during input then `ios::badbit` is turned on\(^{309}\) in `*this`'s error state. If `(exceptions()&badbit) != 0` then the exception is rethrown. In any case, the formatted input function destroys the `sentry` object. If no exception has been thrown, it returns `*this`.

### 27.7.4.2.2 Arithmetic extractors

```cpp
operator>>(unsigned short& val);
operator>>(unsigned int& val);
operator>>(long& val);
operator>>(unsigned long& val);
operator>>(long long& val);
operator>>(unsigned long long& val);
operator>>(float& val);
operator>>(double& val);
```
operator>>(long double& val);
operator>>(bool& val);
operator>>(void*& val);

As in the case of the inserters, these extractors depend on the locale’s num_get<> (26.4.2.1) object to perform parsing the input stream data. These extractors behave as formatted input functions (as described in 27.7.4.2.1). After a sentry object is constructed, the conversion occurs as if performed by the following code fragment:

```
using numget = num_get<charT, istreambuf_iterator<charT, traits>>;
istate err = istate::goodbit;
use_facet<numget>(loc).get(*this, 0, *this, err, val);
setstate(err);
```

In the above fragment, loc stands for the private member of the basic_ios class. [Note: The first argument provides an object of the istreambuf_iterator class which is an iterator pointed to an input stream. It bypasses istreams and uses streambufs directly. — end note] Class locale relies on this type as its interface to istream, so that it does not need to depend directly on istream.

operator>>(short& val);

The conversion occurs as if performed by the following code fragment (using the same notation as for the preceding code fragment):

```
using numget = num_get<charT, istreambuf_iterator<charT, traits>>;
istate err = ios_base::goodbit;
long lval;
use_facet<numget>(loc).get(*this, 0, *this, err, lval);
if (lval < numeric_limits<short>::min()) {
   err |= ios_base::failbit;
   val = numeric_limits<short>::min();
} else if (numeric_limits<short>::max() < lval) {
   err |= ios_base::failbit;
   val = numeric_limits<short>::max();
} else
   val = static_cast<short>(lval);
setstate(err);
```

operator>>(int& val);

The conversion occurs as if performed by the following code fragment (using the same notation as for the preceding code fragment):

```
using numget = num_get<charT, istreambuf_iterator<charT, traits>>;
istate err = ios_base::goodbit;
long lval;
use_facet<numget>(loc).get(*this, 0, *this, err, lval);
if (lval < numeric_limits<int>::min()) {
   err |= ios_base::failbit;
   val = numeric_limits<int>::min();
} else if (numeric_limits<int>::max() < lval) {
   err |= ios_base::failbit;
   val = numeric_limits<int>::max();
} else
   val = static_cast<int>(lval);
setstate(err);
```

§ 27.7.4.2.3  basic_istream::operator>>

basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& (*pf)(basic_istream<charT, traits>&&));

Effects: None. This extractor does not behave as a formatted input function (as described in 27.7.4.2.1).

Returns: pf(*this).310

310) See, for example, the function signature ws(basic_istream&) (27.7.4.4).
basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& (*pf)(basic_istream<charT, traits>&&));

3  Effects: Calls pf(*this). This extractor does not behave as a formatted input function (as described in 27.7.4.2.1).

4  Returns: *this.

basic_istream<charT, traits>& operator>>(ios_base& (*pf)(ios_base&));

5  Effects: Calls pf(*this).3111 This extractor does not behave as a formatted input function (as described in 27.7.4.2.1).

6  Returns: *this.

template<class charT, class traits>
basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& in, charT* s);
template<class traits>
basic_istream<char, traits>& operator>>(basic_istream<char, traits>& in, unsigned char* s);
template<class traits>
basic_istream<char, traits>& operator>>(basic_istream<char, traits>& in, signed char* s);

7  Effects: Behaves like a formatted input member (as described in 27.7.4.2.1) of in. After a sentry object is constructed, operator>> extracts characters and stores them into successive locations of an array whose first element is designated by s. If width() is greater than zero, n is width(). Otherwise n is the number of elements of the largest array of char_type that can store a terminating charT(). n is the maximum number of characters stored.

8  Characters are extracted and stored until any of the following occurs:

8.1 — n-1 characters are stored;
8.2 — end of file occurs on the input sequence;
8.3 — letting ct be use_facet<ctype<charT>>(in.getloc())(in.getloc()), ct.is(ct.space, c) is true.

9  operator>> then stores a null byte (charT()) in the next position, which may be the first position if no characters were extracted. operator>> then calls width(0).

10 If the function extracted no characters, it calls setstate(failbit), which may throw ios_base::failure (27.5.5.4).

11 Returns: in.

template<class charT, class traits>
basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>& in, charT& c);
template<class traits>
basic_istream<char, traits>& operator>>(basic_istream<char, traits>& in, unsigned char& c);
template<class traits>
basic_istream<char, traits>& operator>>(basic_istream<char, traits>& in, signed char& c);

12 Effects: Behaves like a formatted input member (as described in 27.7.4.2.1) of in. After a sentry object is constructed a character is extracted from in, if one is available, and stored in c. Otherwise, the function calls in.setstate(failbit).

13 Returns: in.

basic_istream<charT, traits>& operator>>(basic_streambuf<charT, traits>* sb);

14 Effects: Behaves as an unformatted input function (27.7.4.3). If sb is null, calls setstate(failbit), which may throw ios_base::failure (27.5.5.4). After a sentry object is constructed, extracts characters from *this and inserts them in the output sequence controlled by sb. Characters are extracted and inserted until any of the following occurs:

14.1 — end-of-file occurs on the input sequence;
14.2 — inserting in the output sequence fails (in which case the character to be inserted is not extracted);
14.3 — an exception occurs (in which case the exception is caught).

3111) See, for example, the function signature dec(ios_base&) (27.5.6.3).
If the function inserts no characters, it calls `setstate(failbit)`, which may throw `ios_base::failure` [27.5.5.4]. If it inserted no characters because it caught an exception thrown while extracting characters from `*this` and `failbit` is on in `exceptions()` [27.5.5.4], then the caught exception is rethrown.

Returns: `*this`.

### 27.7.4.3 Unformatted input functions [istream.unformatted]

Each unformatted input function begins execution by constructing an object of class `sentry` with the default argument `noskipws` (second) argument `true`. If the `sentry` object returns `true`, when converted to a value of type `bool`, the function endeavors to obtain the requested input. Otherwise, if the `sentry` constructor exits by throwing an exception or if the `sentry` object returns `false`, when converted to a value of type `bool`, the function returns without attempting to obtain any input. In either case the number of extracted characters is set to 0; unformatted input functions taking a character array of nonzero size as an argument shall also store a null character (using `charT()`) in the first location of the array. If an exception is thrown during input then `ios::badbit` is turned on in `*this`’s error state. (Exceptions thrown from `basic_ios<>::clear()` are not caught or rethrown.) If `(exceptions()&badbit) != 0` then the exception is rethrown. It also counts the number of characters extracted. If no exception has been thrown it ends by storing the count in a member object and returning the value specified. In any event the `sentry` object is destroyed before leaving the unformatted input function.

```cpp
streamsize gcount() const;
```

**Effects:** None. This member function does not behave as an unformatted input function (as described above).

**Returns:** The number of characters extracted by the last unformatted input member function called for the object.

```cpp
int_type get();
```

**Effects:** Behaves as an unformatted input function (as described above). After constructing a `sentry` object, extracts a character `c`, if one is available. Otherwise, the function calls `setstate(failbit)`, which may throw `ios_base::failure` [27.5.5.4],

**Returns:** `c` if available, otherwise `traits::eof()`.

```cpp
basic_istream<charT, traits>& get(char_type& c);
```

**Effects:** Behaves as an unformatted input function (as described above). After constructing a `sentry` object, extracts a character `c`, if one is available, and assigns it to `c`. Otherwise, the function calls `setstate(failbit)` (which may throw `ios_base::failure` [27.5.5.4]).

**Returns:** `*this`.

```cpp
basic_istream<charT, traits>& get(char_type* s, streamsize n, char_type delim);
```

**Effects:** Behaves as an unformatted input function (as described above). After constructing a `sentry` object, extracts characters and stores them into successive locations of an array whose first element is designated by `s`. Characters are extracted and stored until any of the following occurs:

1. `n` is less than one or `n - 1` characters are stored;
2. end-of-file occurs on the input sequence (in which case the function calls `setstate(eofbit)`);
3. `traits::eq(c, delim)` for the next available input character `c` (in which case `c` is not extracted).

If the function stores no characters, it calls `setstate(failbit)` (which may throw `ios_base::failure` [27.5.5.4]). In any case, if `n` is greater than zero it then stores a null character into the next successive location of the array.

**Returns:** `*this`.

```cpp
basic_istream<charT, traits>& get(char_type* s, streamsize n);
```

**Effects:** Calls `get(s, n, widen(‘\n’))`.

---

312) This is done without causing an `ios::failure` to be thrown.
313) Note that this function is not overloaded on types `signed char` and `unsigned char`.
314) Note that this function is not overloaded on types `signed char` and `unsigned char`.

§ 27.7.4.3
Returns: Value returned by the call.

`basic_istream<charT, traits>& get(basic_streambuf<char_type, traits>& sb, char_type delim);`

Effects: Behaves as an unformatted input function (as described above). After constructing a sentry object, extracts characters and inserts them in the output sequence controlled by `sb`. Characters are extracted and inserted until any of the following occurs:

1. End-of-file occurs on the input sequence;
2. Inserting in the output sequence fails (in which case the character to be inserted is not extracted);
3. `traits::eq(c, delim)` for the next available input character `c` (in which case `c` is not extracted);
4. An exception occurs (in which case, the exception is caught but not rethrown).

If the function inserts no characters, it calls `setstate(failbit)`, which may throw `ios_base::failure`.

Returns: `*this`.

`basic_istream<charT, traits>& get(basic_streambuf<char_type, traits>& sb);`

Effects: Calls `get(sb, widen(\'\n\'))`.

Returns: Value returned by the call.

`basic_istream<charT, traits>& getline(char_type* s, streamsize n, char_type delim);`

Effects: Behaves as an unformatted input function (as described above). After constructing a sentry object, extracts characters and stores them into successive locations of an array whose first element is designated by `s`. Characters are extracted and stored until one of the following occurs:

1. End-of-file occurs on the input sequence (in which case the function calls `setstate(eofbit)`);
2. `traits::eq(c, delim)` for the next available input character `c` (in which case the input character is extracted but not stored);
3. `n` is less than one or `n - 1` characters are stored (in which case the function calls `setstate(failbit)`).

These conditions are tested in the order shown.

If the function extracts no characters, it calls `setstate(failbit)` (which may throw `ios_base::failure`).

In any case, if `n` is greater than zero, it then stores a null character (using `charT()`) into the next successive location of the array.

Returns: `*this`.

[Example:]

```cpp
#include <iostream>

int main() {
    using namespace std;
    const int line_buffer_size = 100;

    char buffer[line_buffer_size];
    int line_number = 0;
    while (cin.getline(buffer, line_buffer_size, '\n') || cin.gcount()) {
        int count = cin.gcount();
        if (cin.eof())
            cout << "Partial final line"; // cin.fail() is false
        else if (cin.fail()) {
            cout << "Partial long line";
            cin.clear(cin.rdstate() & ~ios_base::failbit);
        }
    }
}
```

---

315) Note that this function is not overloaded on types `signed char` and `unsigned char`.
316) Since the final input character is “extracted”, it is counted in the `gcount()`, even though it is not stored.
317) This allows an input line which exactly fills the buffer, without setting `failbit`. This is different behavior than the historical AT&T implementation.
318) This implies an empty input line will not cause `failbit` to be set.
basic_istream<charT, traits>& getline(char_type* s, streamsize n);

Returns: getline(s, n, widen(‘\n’))

basic_istream<charT, traits>& ignore(streamsize n = 1, int_type delim = traits::eof());

Effects: Behaves as an unformatted input function (as described above). After constructing a sentry object, extracts characters and discards them. Characters are extracted until any of the following occurs:

(25.1) \( n \neq \text{numeric_limits<streamsize>::max()} \) (16.3.4) and \( n \) characters have been extracted so far
(25.2) end-of-file occurs on the input sequence (in which case the function calls setstate(eofbit), which may throw ios_base::failure (27.5.5.4));
(25.3) \( \text{traits::eq_int_type(traits::to_int_type(c), delim)} \) for the next available input character \( c \) (in which case \( c \) is extracted).

Remarks: The last condition will never occur if \( \text{traits::eq_int_type(delim, traits::eof())} \).

Returns: *this.

int_type peek();

Effects: Behaves as an unformatted input function (as described above). After constructing a sentry object, reads but does not extract the current input character.

Returns: traits::eof() if good() is false. Otherwise, returns rdbuf()->sgetc().

basic_istream<charT, traits>& read(char_type* s, streamsize n);

Effects: Behaves as an unformatted input function (as described above). After constructing a sentry object, if !good() calls setstate(failbit) which may throw an exception, and return. Otherwise extracts characters and stores them into successive locations of an array whose first element is designated by \( s \). \( ^{319} \) Characters are extracted and stored until either of the following occurs:

(30.1) \( n \) characters are stored;
(30.2) end-of-file occurs on the input sequence (in which case the function calls setstate(failbit | eofbit), which may throw ios_base::failure (27.5.5.4)).

Returns: *this.

streamsize readsome(char_type* s, streamsize n);

Effects: Behaves as an unformatted input function (as described above). After constructing a sentry object, if !good() calls setstate(failbit) which may throw an exception, and return. Otherwise extracts characters and stores them into successive locations of an array whose first element is designated by \( s \). If \( \text{rdbuf()}->\text{in_avail()} == -1 \), calls setstate(eofbit) (which may throw ios_base::failure (27.5.5.4)), and extracts no characters;

(32.1) \( \text{if rdbuf()}->\text{in_avail()} == 0 \), extracts no characters
(32.2) \( \text{if rdbuf()}->\text{in_avail()} > 0 \), extracts \( \min(\text{rdbuf()}->\text{in_avail()}, n) \).

Returns: The number of characters extracted.

basic_istream<charT, traits>& putback(char_type c);

Effects: Behaves as an unformatted input function (as described above), except that the function first clears eofbit. After constructing a sentry object, if !good() calls setstate(failbit) which may

\( ^{319} \) Note that this function is not overloaded on types signed char and unsigned char.
throw an exception, and return. If rdbuf() is not null, calls rdbuf()->sputbackc(c). If rdbuf() is null, or if sputbackc returns traits::eof(), calls setstate(badbit) (which may throw ios_base::failure (27.5.5.4)). [Note: This function extracts no characters, so the value returned by the next call to gcount() is 0. — end note]

Returns: *this.

basic_istream<charT, traits>& unget();

Effects: Behaves as an unformatted input function (as described above), except that the function first clears eofbit. After constructing a sentry object, if !good() calls setstate(failbit) which may throw an exception, and return. If rdbuf() is not null, calls rdbuf()->sungetc(). If rdbuf() is null, or if sungetc returns traits::eof(), calls setstate(badbit) (which may throw ios_base::failure (27.5.5.4)). [Note: This function extracts no characters, so the value returned by the next call to gcount() is 0. — end note]

Returns: *this.

int sync();

Effects: Behaves as an unformatted input function (as described above), except that it does not count the number of characters extracted and does not affect the value returned by subsequent calls to gcount(). After constructing a sentry object, if rdbuf() is a null pointer, returns -1. Otherwise, calls rdbuf()->pubsync() and, if that function returns -1 calls setstate(badbit) (which may throw ios_base::failure (27.5.5.4), and returns -1. Otherwise, returns zero.

pos_type tellg();

Effects: Behaves as an unformatted input function (as described above), except that it does not count the number of characters extracted and does not affect the value returned by subsequent calls to gcount(). Returns: After constructing a sentry object, if fail() != false, returns pos_type(-1) to indicate failure. Otherwise, returns rdbuf()->pubseekoff(0, cur, in).

basic_istream<charT, traits>& seekg(pos_type pos);

Effects: Behaves as an unformatted input function (as described above), except that the function first clears eofbit, it does not count the number of characters extracted, and it does not affect the value returned by subsequent calls to gcount(). After constructing a sentry object, if fail() != true, executes rdbuf()->pubseekpos(pos, ios_base::in). In case of failure, the function calls setstate(failbit) (which may throw ios_base::failure).

Returns: *this.

basic_istream<charT, traits>& seekg(off_type off, ios_base::seekdir dir);

Effects: Behaves as an unformatted input function (as described above), except that the function first clears eofbit, does not count the number of characters extracted, and does not affect the value returned by subsequent calls to gcount(). After constructing a sentry object, if fail() != true, executes rdbuf()->pubseekoff(off, dir, ios_base::in). In case of failure, the function calls setstate(failbit) (which may throw ios_base::failure).

Returns: *this.

27.7.4.4 Standard basic_istream manipulators

Each instantiation of the function template specified in this subclause is a designated addressable function (15.5.4.2.1).

template<class charT, class traits>

basic_istream<charT, traits>& ws(basic_istream<charT, traits>& is);

Effects: Behaves as an unformatted input function (27.7.4.3), except that it does not count the number of characters extracted and does not affect the value returned by subsequent calls to is.gcount(). After constructing a sentry object extracts characters as long as the next available character c is whitespace or until there are no more characters in the sequence. Whitespace characters are distinguished with the same criterion as used by sentry::sentry (27.7.4.1.3). If ws stops extracting characters because there are no more available it sets eofbit, but not failbit.
Returns: is.

27.7.4.5 Rvalue stream extraction

```cpp
template<class charT, class traits, class T>
    basic_istream<charT, traits>& operator>>(basic_istream<charT, traits>&& is, T&& x);
```

1 Effects: Equivalent to:
   ```cpp
   is >> std::forward<T>(x);
   return is;
   ```

2 Remarks: This function shall not participate in overload resolution unless the expression `is >> std::forward<T>(x)` is well-formed.

27.7.4.6 Class template basic_iostream

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_iostream
        : public basic_istream<charT, traits>,
          public basic_ostream<charT, traits> {
    public:
        using char_type = charT;
        using int_type = typename traits::int_type;
        using pos_type = typename traits::pos_type;
        using off_type = typename traits::off_type;
        using traits_type = traits;

        // 27.7.4.6.1, constructor
        explicit basic_iostream(basic_streambuf<charT, traits>* sb);

        // 27.7.4.6.2, destructor
        virtual ~basic_iostream();

    protected:
        // 27.7.4.6.1, constructor
        basic_iostream(const basic_iostream& rhs) = delete;
        basic_iostream(basic_iostream&& rhs);

        // 27.7.4.6.3, assign and swap
        basic_iostream& operator=(const basic_iostream& rhs) = delete;
        basic_iostream& operator=(basic_iostream&& rhs);
        void swap(basic_iostream& rhs);
    }
}
```

1 The class template `basic_iostream` inherits a number of functions that allow reading input and writing output to sequences controlled by a stream buffer.

27.7.4.6.1 basic_iostream constructors

```cpp
explicit basic_iostream(basic_streambuf<charT, traits>* sb);
```

1 Effects: Constructs an object of class `basic_iostream`, initializing the base class subobjects with `basic_istream<charT, traits>(sb)` (27.7.4.1) and `basic_ostream<charT, traits>(sb)` (27.7.5.1).

2 Ensures: `rdbuf() == sb` and `gcount() == 0`.

3 Effects: Move constructs from the rvalue `rhs` by constructing the `basic_istream` base class with `move(rhs)`.

27.7.4.6.2 basic_iostream destructor

```cpp
virtual ~basic_iostream();
```

1 Effects: Destroys an object of class `basic_iostream`.

2 Remarks: Does not perform any operations on `rdbuf()`.
27.7.4.6.3 basic_iostream assign and swap

basic_iostream& operator=(basic_iostream&& rhs);

Effects: As if by swap(rhs).

void swap(basic_iostream& rhs);

Effects: Calls basic_istream<charr, traits>::swap(rhs).

27.7.5 Output streams

The header <ostream> defines a type and several function signatures that control output to a stream buffer along with a function template that inserts into stream values.

27.7.5.1 Class template basic_ostream

namespace std {
    template<class charr, class traits = char_traits<charT>>
    class basic_ostream : virtual public basic_ios<charT, traits> {
        public:
            // types (inherited from basic_ios (27.5.5))
            using char_type = charT;
            using int_type = typename traits::int_type;
            using pos_type = typename traits::pos_type;
            using off_type = typename traits::off_type;
            using traits_type = traits;

            // 27.7.5.1.1, constructor/destructor
            explicit basic_ostream(basic_streambuf<char_type, traits>* sb);
            virtual ~basic_ostream();

            // 27.7.5.1.3, prefix/suffix
            class sentry;

            // 27.7.5.2, formatted output
            basic_ostream<charT, traits>&
                operator<<(basic_ostream<charT, traits>& (*pf)(basic_ostream<charT, traits>&&));
            basic_ostream<charT, traits>&
                operator<<(basic_ios<charT, traits>& (*pf)(basic_ios<charT, traits>&&));
            basic_ostream<charT, traits>&
                operator<<(ios_base& (*pf)(ios_base&));
            basic_ostream<charT, traits>& operator<<(bool n);
            basic_ostream<charT, traits>& operator<<(short n);
            basic_ostream<charT, traits>& operator<<(unsigned short n);
            basic_ostream<charT, traits>& operator<<(int n);
            basic_ostream<charT, traits>& operator<<(unsigned int n);
            basic_ostream<charT, traits>& operator<<(long n);
            basic_ostream<charT, traits>& operator<<(unsigned long n);
            basic_ostream<charT, traits>& operator<<(long long n);
            basic_ostream<charT, traits>& operator<<(unsigned long long n);
            basic_ostream<charT, traits>& operator<<(float f);
            basic_ostream<charT, traits>& operator<<(double f);
            basic_ostream<charT, traits>& operator<<(const void* p);
            basic_ostream<charT, traits>& operator<<(nullptr_t);
            basic_ostream<charT, traits>& operator<<(basic_streambuf<char_type, traits>* sb);

            // 27.7.5.3, unformatted output
            basic_ostream<charT, traits>& put(char_type c);
            basic_ostream<charT, traits>& write(const char_type* s, streamsize n);
            basic_ostream<charT, traits>& flush();

§ 27.7.5.1 1189
The class template `basic_ostream` defines a number of member function signatures that assist in formatting and writing output to output sequences controlled by a stream buffer.

Two groups of member function signatures share common properties: the **formatted output functions** (or **inserters**) and the **unformatted output functions**. Both groups of output functions generate (or insert) output characters by actions equivalent to calling `rdbuf()->sputc(int_type)`. They may use other public members of `basic_ostream` except that they shall not invoke any virtual members of `rdbuf()` except `overflow()`, `xsputn()`, and `sync()`.

If one of these called functions throws an exception, then unless explicitly noted otherwise the output function sets `badbit` in error state. If `badbit` is on in `exceptions()`, the output function rethrows the exception without completing its actions, otherwise it does not throw anything and treat as an error.

### 27.7.5.1.1 `basic_ostream` constructors

```cpp
explicit basic_ostream(basic_streambuf<charT, traits>* sb);
```

1. **Effects:** Constructs an object of class `basic_ostream`, initializing the base class subobject with `basic_ios<charT, traits>::init(sb)` (27.5.5.2).
2. **Ensures:** `rdbuf() == sb`.

§ 27.7.5.1.1
basic_ostream(basic_ostream&& rhs);

Effects: Move constructs from the rvalue rhs. This is accomplished by default constructing the base class and calling basic_ios<

3

class: move(rhs) to initialize the base class.

virtual ~basic_ostream();

Effects: Destroys an object of class basic_ostream.

Remarks: Does not perform any operations on rdbuf().

27.7.5.1.2 Class basic_ostream assign and swap [ostream.assign]

basic_ostream& operator=(basic_ostream&& rhs);

1

Effects: As if by swap(rhs).

Returns: *this.

void swap(basic_ostream& rhs);

3

Effects: Calls basic_ios<charT, traits>::swap(rhs).

27.7.5.1.3 Class basic_ostream::sentry [ostream::sentry]

namespace std {

template<class charT, class traits = char_traits<charT>>

class basic_ostream<charT, traits>::sentry {

bool ok_; // exposition only

public:

explicit sentry(basic_ostream<charT, traits>& os);

~sentry();

explicit operator bool() const { return ok_; }

sentry(const sentry&) = delete;

sentry& operator=(const sentry&) = delete;

};

1

The class sentry defines a class that is responsible for doing exception safe prefix and suffix operations.

explicit sentry(basic_ostream<charT, traits>& os);

2

If os.good() is nonzero, prepares for formatted or unformatted output. If os.tie() is not a null pointer, calls os.tie() ->flush().

3

The call os.tie() ->flush() does not necessarily occur if the function can determine that no synchronization is necessary.

If, after any preparation is completed, os.good() is true, ok_ == true otherwise, ok_ == false. During preparation, the constructor may call setstate(failbit) (which may throw ios_base::

failure (27.5.5.4))

~sentry();

4

If (os.flags() & ios_base::unitbuf) && !uncaught_exceptions() && os.good() is true, calls os.rdbuf() ->pubsync(). If that function returns -1, sets badbit in os.rdstate() without propagating an exception.

explicit operator bool() const;

5

Effects: Returns ok_.

27.7.5.1.4 basic_ostream seek members [ostream.seeks]

Each seek member function begins execution by constructing an object of class sentry. It returns by destroying the sentry object.

pos_type tellp();

2

Returns: If fail() != false, returns pos_type(-1) to indicate failure. Otherwise, returns rdbuf() ->

pubseekoff(0, cur, out).

320) The call os.tie() ->flush() does not necessarily occur if the function can determine that no synchronization is necessary.

321) The sentry constructor and destructor can also perform additional implementation-dependent operations.

§ 27.7.5.1.4 1191
basic_ostream<charT, traits>& seekp(pos_type pos);
3
   Effects: If fail() != true, executes rdbuf()->pubseekpos(pos, ios_base::out). In case of failure, the function calls setstate(failbit) (which may throw ios_base::failure).
4
   Returns: *this.

basic_ostream<charT, traits>& seekp(off_type off, ios_base::seekdir dir);
5
   Effects: If fail() != true, executes rdbuf()->pubseekoff(off, dir, ios_base::out). In case of failure, the function calls setstate(failbit) (which may throw ios_base::failure).
6
   Returns: *this.

27.7.5.2 Formatted output functions

27.7.5.2.1 Common requirements

1 Each formatted output function begins execution by constructing an object of class sentry. If this object returns true when converted to a value of type bool, the function endeavors to generate the requested output. If the generation fails, then the formatted output function does setstate(ios_base::failbit), which might throw an exception. If an exception is thrown during output, then ios::badbit is turned on322 in *this’s error state. If (exceptions()&badbit) != 0 then the exception is rethrown. Whether or not an exception is thrown, the sentry object is destroyed before leaving the formatted output function. If no exception is thrown, the result of the formatted output function is *this.

2 The descriptions of the individual formatted output functions describe how they perform output and do not mention the sentry object.

3 If a formatted output function of a stream os determines padding, it does so as follows. Given a charT character sequence seq where charT is the character type of the stream, if the length of seq is less than os.width(), then enough copies of os.fill() are added to this sequence as necessary to pad to a width of os.width() characters. If (os.flags() & ios_base::adjustfield) == ios_base::left is true, the fill characters are placed after the character sequence; otherwise, they are placed before the character sequence.

27.7.5.2.2 Arithmetic inserters

operator<<(bool val);
operator<<(short val);
operator<<(unsigned short val);
operator<<(int val);
operator<<(long val);
operator<<(unsigned long val);
operator<<(long long val);
operator<<(unsigned long long val);
operator<<(float val);
operator<<(double val);
operator<<(long double val);
operator<<(const void* val);
1
   Effects: The classes num_get<> and num_put<> handle locale-dependent numeric formatting and parsing. These inserter functions use the imbued locale value to perform numeric formatting. When val is of type bool, long, unsigned long, long, unsigned long, double, long double, or const void*, the formatting conversion occurs as if it performed the following code fragment:
   
   bool failed = use_facet<
      num_put<charT, ostreambuf_iterator<charT, traits>>
   >(getloc()).put(*this, *this, fill(), val).failed();

   When val is of type short the formatting conversion occurs as if it performed the following code fragment:
   
   ios_base::fmtflags baseflags = ios_base::flags() & ios_base::basefield;

322) without causing an ios::failure to be thrown.
When \( \text{val} \) is of type `int` the formatting conversion occurs as if it performed the following code fragment:

\[
\text{ios\_base::fmtflags baseflags = ios\_base::flags() & ios\_base::basefield;}
\]

\[
\text{bool failed = use\_facet<}
\]

\[
\text{num\_put<charT, ostreambuf\_iterator<charT, traits>>}
\]

\[
\text{>(getloc()).put(*this, *this, fill(),}
\]

\[
\text{baseflags == ios\_base::oct || baseflags == ios\_base::hex}
\]

\[
? \text{static\_cast<long>(static\_cast<unsigned\_short>(val))}
\]

\[
: \text{static\_cast<long>(val)}.failed();
\]

When \( \text{val} \) is of type `unsigned short` or `unsigned int` the formatting conversion occurs as if it performed the following code fragment:

\[
\text{bool failed = use\_facet<}
\]

\[
\text{num\_put<charT, ostreambuf\_iterator<charT, traits>>}
\]

\[
\text{>(getloc()).put(*this, *this, fill(),}
\]

\[
\text{static\_cast<unsigned\_long>(val)}.failed();
\]

When \( \text{val} \) is of type `float` the formatting conversion occurs as if it performed the following code fragment:

\[
\text{bool failed = use\_facet<}
\]

\[
\text{num\_put<charT, ostreambuf\_iterator<charT, traits>>}
\]

\[
\text{>(getloc()).put(*this, *this, fill(),}
\]

\[
\text{static\_cast<double>(val)}.failed();
\]

The first argument provides an object of the `ostreambuf\_iterator< >` class which is an iterator for class `basic\_ostream< >`. It bypasses `ostreams` and uses `streambufs` directly. Class `locale` relies on these types as its interface to `iostreams`, since for flexibility it has been abstracted away from direct dependence on `ostream`. The second parameter is a reference to the base class subobject of type `ios\_base`. It provides formatting specifications such as field width, and a `locale` from which to obtain other facets. If `failed` is `true` then does `setstate(badbit)`, which may throw an exception, and returns.

Returns: \(*\text{this}\).
basic_ostream<charT, traits>& operator<<(basic_streambuf<charT, traits>* sb);

Effects: Behaves as an unformatted output function (27.7.5.3). After the sentry object is constructed, if sb is null calls setstate(badbit) (which may throw ios_base::failure).

Gets characters from sb and inserts them in *this. Characters are read from sb and inserted until any of the following occurs:

(8.1) — end-of-file occurs on the input sequence;
(8.2) — inserting in the output sequence fails (in which case the character to be inserted is not extracted);
(8.3) — an exception occurs while getting a character from sb.

If the function inserts no characters, it calls setstate(failbit) (which may throw ios_base::failure (27.5.5.4)). If an exception was thrown while extracting a character, the function sets failbit in error state, and if failbit is on in exceptions() the caught exception is rethrown.

Returns: *this.

basic_ostream<charT, traits>& operator<<(nullptr_t);

Effects: Equivalent to:

return *this << s;

where s is an implementation-defined NTCTS (15.3.17).

27.7.5.2.4 Character inserter function templates

[ostream.inserters.character]

```cpp
template<class charT, class traits>
  basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& out, charT c);
template<class charT, class traits>
  basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& out, char c);
  // specialization
  template<class traits>
  basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>& out, char c);
  // signed and unsigned
  template<class traits>
  basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>& out, signed char c);
template<class traits>
  basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>& out, unsigned char c);
```

1 Effects: Behaves as a formatted output function (27.7.5.2.1) of out. Constructs a character sequence seq. If c has type char and the character type of the stream is not char, then seq consists of out.widen(c); otherwise seq consists of c. Determines padding for seq as described in 27.7.5.2.1. Inserts seq into out. Calls os.width(0).

Returns: out.

```cpp
template<class charT, class traits>
  basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& out, const charT* s);
template<class charT, class traits>
  basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& out, const char* s);
  template<class traits>
  basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>& out, const signed char* s);
  template<class traits>
  basic_ostream<char, traits>& operator<<(basic_ostream<char, traits>& out, const unsigned char* s);
```

3 Requires: s shall not be a null pointer.

Effects: Behaves like a formatted inserter (as described in 27.7.5.2.1) of out. Creates a character sequence seq of n characters starting at s, each widened using out.widen() (27.5.5.3), where n is the number that would be computed as if by:

(4.1) — traits::length(s) for the overload where the first argument is of type basic_ostream<charT, traits>& and the second is of type const charT*, and also for the overload where the first argument is of type basic_ostream<char, traits>& and the second is of type const char*,
— char_traits<
  char>::length(s) for the overload where the first argument is of
  type basic_ostream<
  charT, traits>& and the second is of type const char*,
(4.2)
— traits::length(reinterpret_cast<const char*>(s)) for the other two
  overloads.
(4.3)

Determines padding for seq as described in 27.7.2.1. Inserts seq into
out. Calls width(0).

Returns: out.

27.7.5.3 Unformatted output functions
[ostream.unformatted]

Each unformatted output function begins execution by constructing an
object of class sentry. If this object returns true, while converting to a
value of type bool, the function endeavors to generate the requested
output. If an exception is thrown during output, then ios::badbit is
turned on\(^{325}\) in *this’s error state. If (exceptions() & badbit)
!= 0 then the exception is rethrown. In any case, the unformatted
output function ends by destroying the sentry object, then, if no exception
was thrown, returning the value specified for the unformatted output
function.

basic_ostream<
  charT, traits>& put(char_type c);

Effects: Behaves as an unformatted output function (as described above). After
constructing a sentry object, inserts the character c, if possible.\(^{326}\)

Otherwise, calls setstate(badbit) (which may throw ios_base::failure (27.5.5.4)).

Returns: *this.

basic_ostream& write(const char_type* s, streamsize n);

Effects: Behaves as an unformatted output function (as described above). After
constructing a sentry object, obtains characters to insert from successive
locations of an array whose first element is designated by s.\(^{327}\) Characters are
inserted until either of the following occurs:

— n characters are inserted;
(5.1)
— inserting in the output sequence fails (in which case the function calls
setstate(badbit), which may throw ios_base::failure (27.5.5.4)).
(5.2)

Returns: *this.

basic_ostream& flush();

Effects: Behaves as an unformatted output function (as described above). If
rdbuf() is not a null pointer, constructs a sentry object. If this object returns true
when converted to a value of type bool the function calls rdbuf()->pubsync(). If
that function returns -1 calls setstate(badbit) (which may throw
ios_base::failure (27.5.5.4)). Otherwise, if the sentry object returns false, does nothing.

Returns: *this.

27.7.5.4 Standard basic_ostream manipulators
[ostream.manip]

Each instantiation of any of the function templates specified in this subclause
is a designated addressable function (15.5.4.2.1).

template<class charT, class traits>
  basic_ostream<
  charT, traits>& endl(basic_ostream<
  charT, traits>& os);

Effects: Calls os.put(os.widen(‘\n’)), then os.flush().

Returns: os.

template<class charT, class traits>
  basic_ostream<
  charT, traits>& ends(basic_ostream<
  charT, traits>& os);

Effects: Inserts a null character into the output sequence: calls os.put(charT()).

Returns: os.

\(^{325}\) without causing an ios::failure to be thrown.

\(^{326}\) Note that this function is not overloaded on types signed char and unsigned char.

\(^{327}\) Note that this function is not overloaded on types signed char and unsigned char.
template<class charT, class traits>
    basic_ostream<charT, traits>& flush(basic_ostream<charT, traits>& os);

    Effects: Calls os.flush().

    Returns: os.

template<class charT, class traits>
    basic_ostream<charT, traits>& emit_on_flush(basic_ostream<charT, traits>& os);

    Effects: If os.rdbuf() is a basic_syncbuf<charT, traits, Allocator>*, called buf for the purpose of exposition, calls buf->set_emit_on_sync(true). Otherwise this manipulator has no effect. [Note: To work around the issue that the Allocator template argument cannot be deduced, implementations can introduce an intermediate base class to basic_syncbuf that manages its emit_on_sync flag. — end note]

    Returns: os.

template<class charT, class traits>
    basic_ostream<charT, traits>& noemit_on_flush(basic_ostream<charT, traits>& os);

    Effects: If os.rdbuf() is a basic_syncbuf<charT, traits, Allocator>*, called buf for the purpose of exposition, calls buf->set_emit_on_sync(false). Otherwise this manipulator has no effect.

    Returns: os.

template<class charT, class traits>
    basic_ostream<charT, traits>& flush_emit(basic_ostream<charT, traits>& os);

    Effects: Calls os.flush(). Then, if os.rdbuf() is a basic_syncbuf<charT, traits, Allocator>*, called buf for the purpose of exposition, calls buf->emit().

    Returns: os.

27.7.5.5 Rvalue stream insertion

    template<class charT, class traits, class T>
    basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>&& os, const T& x);

    Effects: As if by: os << x;

    Returns: os.

    Remarks: This function shall not participate in overload resolution unless the expression os << x is well-formed.

27.7.6 Standard manipulators

    The header <iomanip> defines several functions that support extractors and inserters that alter information maintained by class ios_base and its derived classes.

    unspecified resetiosflags(ios_base::fmtflags mask);

    Returns: An object of unspecified type such that if out is an object of type basic_ostream<charT, traits> then the expression out << resetiosflags(mask) behaves as if it called f(out, mask), or if in is an object of type basic_istream<charT, traits> then the expression in >> resetiosflags(mask) behaves as if it called f(in, mask), where the function f is defined as:\[328\]

    void f(ios_base& str, ios_base::fmtflags mask) {
        // reset specified flags
        str.setf(ios_base::fmtflags(0), mask);
    }

    The expression out << resetiosflags(mask) shall have type basic_ostream<charT, traits>& and value out. The expression in >> resetiosflags(mask) shall have type basic_istream<charT, traits>& and value in.

328 The expression cin >> resetiosflags(ios_base::skipws) clears ios_base::skipws in the format flags stored in the basic_istream<charT, traits> object cin (the same as cin >> noskipws), and the expression cout << resetiosflags(ios_base::showbase) clears ios_base::showbase in the format flags stored in the basic_ostream<charT, traits> object cout (the same as cout << noshowbase).
 unspecified setiosflags(ios_base::fmtflags mask);

3 Returns: An object of unspecified type such that if {out is an object of type basic_ostream<charT, traits> then the expression \( \text{out} \ll \text{setiosflags} \)\( \text{mask} \) behaves as if it called \( f(\text{out}, \text{mask}) \), or if in is an object of type basic_istream<charT, traits> then the expression \( \text{in} \gg \text{setiosflags} \)\( \text{mask} \) behaves as if it called \( f(\text{in}, \text{mask}) \), where the function \( f \) is defined as:

\[
\text{void } f(\text{ios_base}& \text{str}, \text{ios_base::fmtflags mask}) \{
    // set specified flags
    \text{str}.setf(mask);
\}
\]

The expression \( \text{out} \ll \text{setiosflags} \)\( \text{mask} \) shall have type basic_ostream<charT, traits>& and value out. The expression \( \text{in} \gg \text{setiosflags} \)\( \text{mask} \) shall have type basic_istream<charT, traits>& and value in.

 unspecified setbase(int base);

4 Returns: An object of unspecified type such that if {out is an object of type basic_ostream<charT, traits> then the expression \( \text{out} \ll \text{setbase} \)\( \text{base} \) behaves as if it called \( f(\text{out}, \text{base}) \), or if in is an object of type basic_istream<charT, traits> then the expression \( \text{in} \gg \text{setbase} \)\( \text{base} \) behaves as if it called \( f(\text{in}, \text{base}) \), where the function \( f \) is defined as:

\[
\text{void } f(\text{ios_base}& \text{str}, \text{int base}) \{
    // set basefield
    \text{str}.setf(base \== 8 ? \text{ios_base::oct} :
        base \== 10 ? \text{ios_base::dec} :
        base \== 16 ? \text{ios_base::hex} :
        \text{ios_base::fmtflags}(0), \text{ios_base::basefield});
\}
\]

The expression \( \text{out} \ll \text{setbase} \)\( \text{base} \) shall have type basic_ostream<charT, traits>& and value out. The expression \( \text{in} \gg \text{setbase} \)\( \text{base} \) shall have type basic_istream<charT, traits>& and value in.

 unspecified setfill(char_type c);

5 Returns: An object of unspecified type such that if {out is an object of type basic_ostream<charT, traits> and c has type charT then the expression \( \text{out} \ll \text{setfill} \)\( c \) behaves as if it called \( f(\text{out}, \text{c}) \), where the function \( f \) is defined as:

\[
\text{template<class charT, class traits>
    void } f(\text{basic_ios<charT, traits>>& str, charT c) \{
        // set fill character
        \text{str}.fill(c);
    \}
\]

The expression \( \text{out} \ll \text{setfill} \)\( c \) shall have type basic_ostream<charT, traits>& and value out.

 unspecified setprecision(int n);

6 Returns: An object of unspecified type such that if {out is an object of type basic_ostream<charT, traits> then the expression \( \text{out} \ll \text{setprecision} \)\( n \) behaves as if it called \( f(\text{out}, \text{n}) \), or if in is an object of type basic_istream<charT, traits> then the expression \( \text{in} \gg \text{setprecision} \)\( n \) behaves as if it called \( f(\text{in}, \text{n}) \), where the function \( f \) is defined as:

\[
\text{void } f(\text{ios_base}& \text{str}, \text{int n}) \{
    // set precision
    \text{str}.precision(n);
\}
\]

The expression \( \text{out} \ll \text{setprecision} \)\( n \) shall have type basic_ostream<charT, traits>& and value out. The expression \( \text{in} \gg \text{setprecision} \)\( n \) shall have type basic_istream<charT, traits>& and value in.

 unspecified setw(int n);

7 Returns: An object of unspecified type such that if {out is an instance of basic_ostream<charT, traits> then the expression \( \text{out} \ll \text{setw} \)\( n \) behaves as if it called \( f(\text{out}, \text{n}) \), or if in is an object
of type `basic_istream<charT, traits>` then the expression `in >> setw(n)` behaves as if it called `f(in, n)`, where the function `f` is defined as:

```cpp
void f(ios_base& str, int n) {
    // set width
    str.width(n);
}
```

The expression `out << setw(n)` shall have type `basic_ostream<charT, traits>&` and value `out`. The expression `in >> setw(n)` shall have type `basic_istream<charT, traits>&` and value `in`.

### 27.7.7 Extended manipulators

The header `<iomanip>` defines several functions that support extractors and inserters that allow for the parsing and formatting of sequences and values for money and time.

```cpp
template<class moneyT>
unspecified get_money(moneyT& mon, bool intl = false);
```

**Requires:** The type `moneyT` shall be either `long double` or a specialization of the `basic_string` template (Clause 20).

**Effects:** The expression `in >> get_money(mon, intl)` described below behaves as a formatted input function (27.7.4.2.1).

**Returns:** An object of unspecified type such that if `in` is an object of type `basic_istream<charT, traits>` then the expression `in >> get_money(mon, intl)` behaves as if it called `f(in, mon, intl)`, where the function `f` is defined as:

```cpp
template<class charT, class traits, class moneyT>
void f(basic_ios<charT, traits>& str, moneyT& mon, bool intl) {
    using Iter = istreambuf_iterator<charT, traits>;
    using MoneyGet = money_get<charT, Iter>;
    ios_base::iostate err = ios_base::goodbit;
    const MoneyGet& mg = use_facet<MoneyGet>(str.getloc());
    mg.get(Iter(str.rdbuf()), Iter(), intl, str, err, mon);
    if (ios_base::goodbit != err)
        str.setstate(err);
}
```

The expression `in >> get_money(mon, intl)` shall have type `basic_istream<charT, traits>&` and value `in`.

```cpp
template<class moneyT>
unspecified put_money(const moneyT& mon, bool intl = false);
```

**Requires:** The type `moneyT` shall be either `long double` or a specialization of the `basic_string` template (Clause 20).

**Returns:** An object of unspecified type such that if `out` is an object of type `basic_ostream<charT, traits>` then the expression `out << put_money(mon, intl)` behaves as a formatted output function (27.7.5.2.1) that calls `f(out, mon, intl)`, where the function `f` is defined as:

```cpp
template<class charT, class traits, class moneyT>
void f(basic_ios<charT, traits>& str, const moneyT& mon, bool intl) {
    using Iter = ostreambuf_iterator<charT, traits>;
    using MoneyPut = money_put<charT, Iter>;
    const MoneyPut& mp = use_facet<MoneyPut>(str.getloc());
    const Iter end = mp.put(Iter(str.rdbuf()), intl, str, str.fill(), mon);
    if (end.failed())
        str.setstate(ios::badbit);
}
```

The expression `out << put_money(mon, intl)` shall have type `basic_ostream<charT, traits>&` and value `out`. 

§ 27.7.7
template<class charT> unspecified get_time(struct tm* tmb, const charT* fmt);

7 Requi re s: The argument tmb shall be a valid pointer to an object of type struct tm. The argument fmt shall be a valid pointer to an array of objects of type charT with char_traits<charT>::length(fmt) elements.

8 Returns: An object of unspecified type such that if in is an object of type basic_istream<charT, traits> then the expression in >> get_time(tmb, fmt) behaves as if it called f(in, tmb, fmt), where the function f is defined as:

```cpp
template<class charT, class traits>
void f(basic_istream<charT, traits>& str, struct tm* tmb, const charT* fmt) {
    using Iter = istreambuf_iterator<charT, traits>;
    using TimeGet = time_get<charT, Iter>;

    ios_base::iostate err = ios_base::goodbit;
    const TimeGet& tg = use_facet<TimeGet>(str.getloc());

    tg.get(Iter(str.rdbuf()), Iter(), str, err, tmb,
           fmt, fmt + char_traits<charT>::length(fmt));

    if (err != ios_base::goodbit)
        str.setstate(err);
}
```

The expression in >> get_time(tmb, fmt) shall have type basic_istream<charT, traits>& and value in.

template<class charT> unspecified put_time(const struct tm* tmb, const charT* fmt);

9 Requires: The argument tmb shall be a valid pointer to an object of type struct tm, and the argument fmt shall be a valid pointer to an array of objects of type charT with char_traits<charT>::length(fmt) elements.

10 Returns: An object of unspecified type such that if out is an object of type basic_ostream<charT, traits> then the expression out << put_time(tmb, fmt) behaves as if it called f(out, tmb, fmt), where the function f is defined as:

```cpp
template<class charT, class traits>
void f(basic_ostream<charT, traits>& str, const struct tm* tmb, const charT* fmt) {
    using Iter = ostreambuf_iterator<charT, traits>;
    using TimePut = time_put<charT, Iter>;

    const TimePut& tp = use_facet<TimePut>(str.getloc());
    const Iter end = tp.put(Iter(str.rdbuf()), str, str.fill(), tmb,
                           fmt, fmt + traits::length(fmt));

    if (end.failed())
        str.setstate(ios_base::badbit);
}
```

The expression out << put_time(tmb, fmt) shall have type basic_ostream<charT, traits>& and value out.

27.7.8 Quoted manipulators

[quoted.manip]

1 Note: Quoted manipulators provide string insertion and extraction of quoted strings (for example, XML and CSV formats). Quoted manipulators are useful in ensuring that the content of a string with embedded spaces remains unchanged if inserted and then extracted via stream I/O. — end note]

```cpp
template<class charT>
    unspecified quoted(const charT* s, charT delim = charT('"'), charT escape = charT('\'));
```
template<class charT, class traits>
  unspecified quoted(basic_string_view<charT, traits> s, charT delim = charT('"'), charT escape = charT('\\'));

Returns: An object of unspecified type such that if out is an instance of basic_ostream with member type char_type the same as charT and with member type traits_type, which in the second and third forms is the same as traits, then the expression out << quoted(s, delim, escape) behaves as a formatted output function (27.7.5.2.1) of out. This forms a character sequence seq, initially consisting of the following elements:

(2.1) — delim.
(2.2) — Each character in s. If the character to be output is equal to escape or delim, as determined by traits_type::eq, first output escape.
(2.3) — delim.

Let x be the number of elements initially in seq. Then padding is determined for seq as described in 27.7.5.2.1, seq is inserted as if by calling out.rdbuf()->sputn(seq, n), where n is the larger of out.width() and x, and out.width(0) is called. The expression out << quoted(s, delim, escape) shall have type basic_ostream<charT, traits>& and value out.

template<class charT, class traits, class Allocator>
  unspecified quoted(basic_string<charT, traits, Allocator>& s, charT delim = charT('"'), charT escape = charT('\\'));

Returns: An object of unspecified type such that:

(3.1) — If in is an instance of basic_istream with member types char_type and traits_type the same as charT and traits, respectively, then the expression in >> quoted(s, delim, escape) behaves as if it extracts the following characters from in using operator>>(basic_istream<charT, traits>&, charT&) (27.7.4.2.3) which may throw ios_base::failure (27.5.3.1.1):

(3.1.1) — If the first character extracted is equal to delim, as determined by traits_type::eq, then:
  (3.1.1.1) — Turn off the skipws flag.
  (3.1.1.2) — s.clear()
  (3.1.1.3) — Until an unescaped delim character is reached or !in, extract characters from in and append them to s, except that if an escape is reached, ignore it and append the next character to s.
  (3.1.1.4) — Discard the final delim character.
  (3.1.1.5) — Restore the skipws flag to its original value.
(3.1.2) — Otherwise, in >> s.

(3.2) — If out is an instance of basic_ostream with member types char_type and traits_type the same as charT and traits, respectively, then the expression out << quoted(s, delim, escape) behaves as specified for the const basic_string<charT, traits, Allocator>& overload of the quoted function.

The expression in >> quoted(s, delim, escape) shall have type basic_istream<charT, traits>& and value in. The expression out << quoted(s, delim, escape) shall have type basic_ostream<charT, traits>& and value out.

27.8 String-based streams [string.streams]

27.8.1 Header <sstream> synopsis [sstream.syn]

namespace std {
  template<class charT, class traits = char_traits<charT>,
           class Allocator = allocator<charT>>
    class basic_stringbuf;

  using stringbuf = basic_stringbuf<char>;
  using wstringbuf = basic_stringbuf<wchar_t>;
}
template<
class charT, class traits = char_traits<charT>,
class Allocator = allocator<charT>>
class basic_istringstream;

using istringstream = basic_istringstream<char>;
using wistringstream = basic_istringstream<wchar_t>;

template<

protected:

    // 27.8.2.4, overridden virtual functions
    int_type underflow() override;
    int_type pbackfail(int_type c = traits::eof()) override;
    int_type overflow (int_type c = traits::eof()) override;
    basic_streambuf<charT, traits>* setbuf(charT*, streamsize) override;

    pos_type seekoff(off_type off, ios_base::seekdir way,
                     ios_base::openmode which
                     = ios_base::in | ios_base::out) override;

§ 27.8.2
```cpp
pos_type seekpos(pos_type sp,
    ios_base::openmode which
    = ios_base::in | ios_base::out) override;

private:
    ios_base::openmode mode;  // exposition only
};

template<class charT, class traits, class Allocator>
void swap(basic_stringbuf<charT, traits, Allocator>& x,
    basic_stringbuf<charT, traits, Allocator>& y);
```

The class `basic_stringbuf` is derived from `basic_streambuf` to associate possibly the input sequence and possibly the output sequence with a sequence of arbitrary characters. The sequence can be initialized from, or made available as, an object of class `basic_string`.

For the sake of exposition, the maintained data is presented here as:

(2.1) — `ios_base::openmode mode`, has in set if the input sequence can be read, and `out` set if the output sequence can be written.

### 27.8.2.1 basic_stringbuf constructors

**explicit basic_stringbuf(ios_base::openmode which);**

Effects: Constructs an object of class `basic_stringbuf`, initializing the base class with `basic_streambuf()` (27.6.3.1), and initializing `mode` with `which`.

Ensures: `str() == ""`.  

**explicit basic_stringbuf(
    const basic_string<charT, traits, Allocator>& s,
    ios_base::openmode which = ios_base::in | ios_base::out);**

Effects: Constructs an object of class `basic_stringbuf`, initializing the base class with `basic_streambuf()` (27.6.3.1), and initializing `mode` with `which`. Then calls `str(s)`.

**basic_stringbuf(basic_stringbuf&& rhs);**

Effects: Move constructs from the rvalue `rhs`. It is implementation-defined whether the sequence pointers in `*this` (`eback()`, `gptr()`, `egptr()`, `pbase()`, `pptr()`, `epptr()`) obtain the values which `rhs` had. Whether they do or not, `*this` and `rhs` reference separate buffers (if any at all) after the construction. The `openmode`, locale and any other state of `rhs` is also copied.

Ensures: Let `rhs_p` refer to the state of `rhs` just prior to this construction and let `rhs_a` refer to the state of `rhs` just after this construction.

(5.1) — `str() == rhs_p.str()`  
(5.2) — `gptr() - eback() == rhs_p.gptr() - rhs_p.eback()`  
(5.3) — `egptr() - eback() == rhs_p.egptr() - rhs_p.eback()`  
(5.4) — `pptr() - pbase() == rhs_p.pptr() - rhs_p.pbase()`  
(5.5) — `epptr() - pbase() == rhs_p.epptr() - rhs_p.pbase()`  
(5.6) — if (eback()) `eback()` != rhs_a.eback()  
(5.7) — if (gptr()) `gptr()` != rhs_a.gptr()  
(5.8) — if (egptr()) `egptr()` != rhs_a.egptr()  
(5.9) — if (pbase()) `pbase()` != rhs_a.pbase()  
(5.10) — if (pptr()) `pptr()` != rhs_a.pptr()  
(5.11) — if (epptr()) `epptr()` != rhs_a.epptr()
27.8.2.2 Assign and swap

basic_stringbuf& operator=(basic_stringbuf&& rhs);

Effects: After the move assignment *this has the observable state it would have had if it had been
move constructed from rhs (see 27.8.2.1).

Returns: *this.

void swap(basic_stringbuf& rhs);

Effects: Exchanges the state of *this and rhs.

template<class charT, class traits, class Allocator>
void swap(basic_stringbuf<charT, traits, Allocator>& x,
          basic_stringbuf<charT, traits, Allocator>& y);

Effects: As if by x.swap(y).

27.8.2.3 Member functions

basic_string<charT, traits, Allocator> str() const;

Returns: A basic_string object whose content is equal to the basic_stringbuf underlying character
sequence. If the basic_stringbuf was created only in input mode, the resultant basic_string
contains the character sequence in the range [eback(), egptr()). If the basic_stringbuf was
created with which & ios_base::out being nonzero then the resultant basic_string contains the
character sequence in the range [pbase(), high_mark), where high_mark represents the position one
past the highest initialized character in the buffer. Characters can be initialized by writing to the stream,
by constructing the basic_stringbuf with a basic_string, or by calling the str(basic_string)
member function. In the case of calling the str(basic_string) member function, all characters
initialized prior to the call are now considered uninitialized (except for those characters re-initialized
by the new basic_string). Otherwise the basic_stringbuf has been created in neither input nor
output mode and a zero length basic_string is returned.

void str(const basic_string<charT, traits, Allocator>& s);

Effects: Copies the content of s into the basic_stringbuf underlying character sequence and initializes
the input and output sequences according to mode.

Ensures: If mode & ios_base::out is nonzero, pbase() points to the first underlying character and
egptr() >= pbase() + s.size() holds; in addition, if mode & ios_base::ate is nonzero, pptr()
== pbase() + s.size() holds, otherwise pptr() == pbase() is true. If mode & ios_base::in is
nonzero, eback() points to the first underlying character, and both gptr() == eback() and egptr()
== eback() + s.size() hold.

27.8.2.4 Overridden virtual functions

int_type underflow() override;

Returns: If the input sequence has a read position available, returns traits::to_int_type(*gptr()).
 Otherwise, returns traits::eof(). Any character in the underlying buffer which has been initialized
is considered to be part of the input sequence.

int_type pbackfail(int_type c = traits::eof()) override;

Effects: Puts back the character designated by c to the input sequence, if possible, in one of three ways:

(2.1) If traits::eq_int_type(c, traits::eof()) returns false and if the input sequence has a
putback position available, and if traits::eq(to_char_type(c), gptr()[-1]) returns true,
assigns gptr() - 1 to gptr().

Returns: c.

(2.2) If traits::eq_int_type(c, traits::eof()) returns false and if the input sequence has a
putback position available, and if mode & ios_base::out is nonzero, assigns c to *--gptr().

Returns: c.

(2.3) If traits::eq_int_type(c, traits::eof()) returns true and if the input sequence has a
putback position available, assigns gptr() - 1 to gptr().

§ 27.8.2.4
Returns: traits::not_eof(c).

Returns: As specified above, or traits::eof() to indicate failure.

Remarks: If the function can succeed in more than one of these ways, it is unspecified which way is chosen.

int_type overflow(int_type c = traits::eof()) override;

Effects: Appends the character designated by c to the output sequence, if possible, in one of two ways:

1. If traits::eq_int_type(c, traits::eof()) returns false and if either the output sequence has a write position available or the function makes a write position available (as described below), the function calls sputc(c).
   Signals success by returning c.

2. If traits::eq_int_type(c, traits::eof()) returns true, there is no character to append.
   Signals success by returning a value other than traits::eof().

Remarks: The function can alter the number of write positions available as a result of any call.

Returns: As specified above, or traits::eof() to indicate failure.

The function can make a write position available only if (mode & ios_base::out) != 0. To make a write position available, the function reallocates (or initially allocates) an array object with a sufficient number of elements to hold the current array object (if any), plus at least one additional write position. If (mode & ios_base::in) != 0, the function alters the read end pointer egptr() to point just past the new write position.

pos_type seekoff(off_type off, ios_base::seekdir way,
                 ios_base::openmode which = ios_base::in | ios_base::out) override;

Effects: Alters the stream position within one of the controlled sequences, if possible, as indicated in Table 113.

<table>
<thead>
<tr>
<th>Conditions</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>(which &amp; ios_base::in) == ios_base::in</td>
<td>positions the input sequence</td>
</tr>
<tr>
<td>(which &amp; ios_base::out) == ios_base::out</td>
<td>positions the output sequence</td>
</tr>
<tr>
<td>(which &amp; (ios_base::in</td>
<td>ios_base::out)) == (ios_base::in</td>
</tr>
<tr>
<td>Otherwise</td>
<td>the positioning operation fails.</td>
</tr>
</tbody>
</table>

For a sequence to be positioned, the function determines newoff as indicated in Table 114. If the sequence’s next pointer (either gptr() or pptr()) is a null pointer and newoff is nonzero, the positioning operation fails.

If (newoff + off) < 0, or if newoff + off refers to an uninitialized character (27.8.2.3), the positioning operation fails. Otherwise, the function assigns xbeg + newoff + off to the next pointer xnext.

Returns: pos_type(newoff), constructed from the resultant offset newoff (of type off_type), that stores the resultant stream position, if possible. If the positioning operation fails, or if the constructed object cannot represent the resultant stream position, the return value is pos_type(off_type(-1)).
Table 114 — newoff values

<table>
<thead>
<tr>
<th>Condition</th>
<th>newoff Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>way == ios_base::beg</td>
<td>0</td>
</tr>
<tr>
<td>way == ios_base::cur</td>
<td>the next pointer minus the beginning pointer (xnext - xbeg).</td>
</tr>
<tr>
<td>way == ios_base::end</td>
<td>the high mark pointer minus the beginning pointer (high_mark - xbeg).</td>
</tr>
</tbody>
</table>

pos_type seekpos(pos_type sp,
    ios_base::openmode which
    = ios_base::in | ios_base::out) override;

Effects: Equivalent to seekoff(off_type(sp), ios_base::beg, which).

Returns: sp to indicate success, or pos_type(off_type(-1)) to indicate failure.

basic_stringbuf<charT, traits>* setbuf(charT* s, streamsize n);

Effects: implementation-defined, except that setbuf(0, 0) has no effect.

Returns: this.

### 27.8.3 Class template basic_istringstream

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>,
             class Allocator = allocator<charT>>
    class basic_istringstream : public basic_istream<charT, traits> {
        public:
            using char_type = charT;
            using int_type = typename traits::int_type;
            using pos_type = typename traits::pos_type;
            using off_type = typename traits::off_type;
            using traits_type = traits;
            using allocator_type = Allocator;

            // 27.8.3.1, constructors
            basic_istringstream() : basic_istringstream(ios_base::in) {} // exposition only
            explicit basic_istringstream(ios_base::openmode which);
            explicit basic_istringstream(
                const basic_string<charT, traits, Allocator>& str,
                ios_base::openmode which = ios_base::in);
            basic_istringstream(const basic_istringstream& rhs) = delete;
            basic_istringstream(basic_istringstream&& rhs);

            // 27.8.3.2, assign and swap
            basic_istringstream& operator=(const basic_istringstream& rhs) = delete;
            basic_istringstream& operator=(basic_istringstream&& rhs);
            void swap(basic_istringstream& rhs);

            // 27.8.3.3, members
            basic_stringbuf<charT, traits, Allocator>* rdbuf() const;
            basic_string<charT, traits, Allocator> str() const;
            void str(const basic_string<charT, traits, Allocator>& s);
            private:
                basic_stringbuf<charT, traits, Allocator> sb; // exposition only
        }
    }
}
```
The class basic_istringstream<charT, traits, Allocator> supports reading objects of class basic_string<charT, traits, Allocator>. It uses a basic_stringbuf<charT, traits, Allocator> object to control the associated storage. For the sake of exposition, the maintained data is presented here as:

— sb, the stringbuf object.

### 27.8.3.1 basic_istringstream constructors

**explicit basic_istringstream(ios_base::openmode which);**

*Effects:* Constructs an object of class basic_istringstream<charT, traits>, initializing the base class with basic_istream<charT, traits>(&sb) (27.7.4.1) and initializing sb with basic_stringbuf<charT, traits, Allocator>(which | ios_base::in) (27.8.2.1).

**explicit basic_istringstream(const basic_string<charT, traits, Allocator>& str, ios_base::openmode which = ios_base::in);**

*Effects:* Constructs an object of class basic_istringstream<charT, traits>, initializing the base class with basic_istream<charT, traits>(&sb) (27.7.4.1) and initializing sb with basic_stringbuf<charT, traits, Allocator>(str, which | ios_base::in) (27.8.2.1).

**basic_istringstream(basic_istringstream&& rhs);**

*Effects:* Move constructs from the rvalue rhs. This is accomplished by move constructing the base class, and the contained basic_stringbuf. Next basic_istream<charT, traits>::set_rdbuf(&sb) is called to install the contained basic_stringbuf.

### 27.8.3.2 Assign and swap

**basic_istringstream& operator=(basic_istringstream&& rhs);**

*Effects:* Move assigns the base and members of *this from the base and corresponding members of rhs.

**Returns:** *this.

**void swap(basic_istringstream& rhs);**

*Effects:* Exchanges the state of *this and rhs by calling basic_istream<charT, traits>::swap(rhs) and sb.swap(rhs.sb).

**template<class charT, class traits, class Allocator>**

**void swap(basic_istringstream<charT, traits, Allocator>& x, basic_istringstream<charT, traits, Allocator>& y);**

*Effects:* As if by x.swap(y).

### 27.8.3.3 Member functions

**basic_stringbuf<charT, traits, Allocator>* rdbuf() const;**

*Returns:* const_cast<basic_stringbuf<charT, traits, Allocator>*>(&sb).

**basic_string<charT, traits, Allocator> str() const;**

*Returns:* rdbuf() -> str().

**void str(const basic_string<charT, traits, Allocator>& s);**

*Effects:* Calls rdbuf() -> str(s).

### 27.8.4 Class template basic_ostringstream

**namespace std {**

**template<class charT, class traits = char_traits<charT>, class Allocator = allocator<charT>>**

**class basic_ostringstream : public basic_ostream<charT, traits> {**

**public:**

using char_type = charT;

using int_type = typename traits::int_type;

using pos_type = typename traits::pos_type;

```cpp
std::basic_ostringstream<charT, traits, Allocator> stringStream;
```
using off_type = typename traits::off_type;
using traits_type = traits;
using allocator_type = Allocator;

// 27.8.4.1, constructors
basic_ostringstream() : basic_ostringstream(ios_base::out) {}
explicit basic_ostringstream(ios_base::openmode which);
explicit basic_ostringstream(
    const basic_string<charT, traits, Allocator>& str,
    ios_base::openmode which = ios_base::out);
basic_ostringstream(const basic_ostringstream& rhs) = delete;
basic_ostringstream(basic_ostringstream&& rhs);

// 27.8.4.2, assign and swap
basic_ostringstream& operator=(const basic_ostringstream& rhs) = delete;
basic_ostringstream& operator=(basic_ostringstream&& rhs);
void swap(basic_ostringstream& rhs);

// 27.8.4.3, members
basic_stringbuf<charT, traits, Allocator>* rdbuf() const;
basic_string<charT, traits, Allocator> str() const;
void str(const basic_string<charT, traits, Allocator>& s);
private:
basic_stringbuf<charT, traits, Allocator> sb; // exposition only
};

template<class charT, class traits, class Allocator>
void swap(basic_ostringstream<charT, traits, Allocator>& x,
          basic_ostringstream<charT, traits, Allocator>& y);

1 The class basic_ostringstream<charT, traits, Allocator> supports writing objects of class basic_string<charT, traits, Allocator>. It uses a basic_stringbuf object to control the associated storage. For the sake of exposition, the maintained data is presented here as:

(1.1) — sb, the stringbuf object.

27.8.4.1 basic_ostringstream constructors

[ostringstream.cons]

explicit basic_ostringstream(ios_base::openmode which);

Effects: Constructs an object of class basic_ostringstream<charT, traits>, initializing the base class with basic_ostream<charT, traits>(&sb) (27.7.5.1) and initializing sb with basic_stringbuf<charT, traits, Allocator>(which | ios_base::out) (27.8.2.1).

explicit basic_ostringstream(
    const basic_string<charT, traits, Allocator>& str,
    ios_base::openmode which = ios_base::out);

Effects: Constructs an object of class basic_ostringstream<charT, traits>, initializing the base class with basic_ostream<charT, traits>(&sb) (27.7.5.1) and initializing sb with basic_stringbuf<charT, traits, Allocator>(str, which | ios_base::out) (27.8.2.1).

basic_ostringstream(basic_ostringstream&& rhs);

Effects: Move constructs from the rvalue rhs. This is accomplished by move constructing the base class, and the contained basic_stringbuf. Next basic_ostream<charT, traits>::set_rdbuf(&sb) is called to install the contained basic_stringbuf.

27.8.4.2 Assign and swap

[ostringstream.assign]

basic_ostringstream& operator=(basic_ostringstream&& rhs);

Effects: Move assigns the base and members of *this from the base and corresponding members of rhs.

Returns: *this.
void swap(basic_ostringstream& rhs);

Effects: Exchanges the state of *this and rhs by calling basic_ostream<charT, traits>::swap(rhs) and sb.swap(rhs.sb).

template<class charT, class traits, class Allocator>
void swap(basic_ostringstream<charT, traits, Allocator>& x,
          basic_ostringstream<charT, traits, Allocator>& y);

Effects: As if by x.swap(y).

27.8.4.3 Member functions

basic_stringbuf<charT, traits, Allocator>* rdbuf() const;

Returns: const_cast<basic_stringbuf<charT, traits, Allocator>*>(&sb).

basic_string<charT, traits, Allocator> str() const;

Returns: rdbuf()->str().

void str(const basic_string<charT, traits, Allocator>& s);

Effects: Calls rdbuf()->str(s).

27.8.5 Class template basic_stringstream

namespace std {
  template<class charT, class traits = char_traits<charT>,
           class Allocator = allocator<charT>>
  class basic_stringstream : public basic_iostream<charT, traits> {
    public:
      using char_type = charT;
      using int_type = typename traits::int_type;
      using pos_type = typename traits::pos_type;
      using off_type = typename traits::off_type;
      using traits_type = traits;
      using allocator_type = Allocator;

      basic_stringstream(); basic_stringstream(ios_base::out | ios_base::in) {} // 27.8.5.1, constructors
      explicit basic_stringstream(ios_base::openmode which);
      explicit basic_stringstream( const basic_stringstream<charT, traits, Allocator>& str,
                                  ios_base::openmode which = ios_base::out | ios_base::in);
      basic_stringstream(const basic_stringstream& rhs) = delete;
      basic_stringstream(basic_stringstream&& rhs);

      // 27.8.5.2, assign and swap
      basic_stringstream& operator=(const basic_stringstream& rhs) = delete;
      basic_stringstream& operator=(basic_stringstream&& rhs);
      void swap(basic_stringstream& rhs);

      // 27.8.5.3, members
      basic_stringbuf<charT, traits, Allocator>* rdbuf() const;
      basic_string<charT, traits, Allocator> str() const;
      void str(const basic_string<charT, traits, Allocator>& s);

    private:
      basic_stringbuf<charT, traits> sb; // exposition only
    };

  template<class charT, class traits, class Allocator>
  void swap(basic_stringstream<charT, traits, Allocator>& x,
            basic_stringstream<charT, traits, Allocator>& y);

}
The class template `basic_stringstream<charT, traits>` supports reading and writing from objects of class `basic_string<charT, traits, Allocator>`. It uses a `basic_stringbuf<charT, traits, Allocator>` object to control the associated sequence. For the sake of exposition, the maintained data is presented here as

g - sb, the stringbuf object.

27.8.5.1 `basic_stringstream` constructors [stringstream.cons]

explicit `basic_stringstream`(ios_base::openmode which);

**Effects:** Constructs an object of class `basic_stringstream<charT, traits>`, initializing the base class with `basic_iostream<charT, traits>(&sb)` (27.7.4.6.1) and initializing sb with `basic_stringbuf<charT, traits, Allocator>(which)`.

explicit `basic_stringstream`

`const basic_string<charT, traits, Allocator>& str,`  
ios_base::openmode which = ios_base::out | ios_base::in);

**Effects:** Constructs an object of class `basic_stringstream<charT, traits>`, initializing the base class with `basic_iostream<charT, traits>(&sb)` (27.7.4.6.1) and initializing sb with `basic_stringbuf<charT, traits, Allocator>(str, which)`.

`basic_stringstream(basic_stringstream&& rhs);`

**Effects:** Move constructs from the rvalue rhs. This is accomplished by move constructing the base class, and the contained `basic_stringbuf`. Next `basic_istream<charT, traits>::set_rdbuf(&sb)` is called to install the contained `basic_stringbuf`.

27.8.5.2 Assign and swap [stringstream.assign]

`basic_stringstream& operator=(basic_stringstream&& rhs);`

**Effects:** Move assigns the base and members of *this from the base and corresponding members of rhs.

```c
void swap(basic_stringstream& rhs);
```

**Effects:** Exchanges the state of *this and rhs by calling `basic_iostream<charT, traits>::swap(rhs)` and `sb.swap(rhs.sb)`.

```cpp
template<class charT, class traits, class Allocator>
void swap(basic_stringstream<charT, traits, Allocator>& x,`  
`basic_stringstream<charT, traits, Allocator>& y);
```

**Effects:** As if by `x.swap(y)`.

27.8.5.3 Member functions [stringstream.members]

```cpp
basic_stringbuf<charT, traits, Allocator>* rdbuf() const;
```

**Returns:** `const_cast<basic_stringbuf<charT, traits, Allocator>*>(&sb)`

```cpp
basic_string<charT, traits, Allocator> str() const;
```

**Returns:** `rdbuf()->str()`.

```cpp
void str(const basic_string<charT, traits, Allocator>& str);
```

**Effects:** Calls `rdbuf()->str(str)`.

27.9 File-based streams [file.streams]

27.9.1 Header `<fstream>` synopsis [fstream.syn]

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_filebuf;
    using filebuf = basic_filebuf<char>;
    using wfilebuf = basic_filebuf<wchar_t>;
}  // namespace std
```
template<
    class charT,
    class traits = char_traits<charT>>
class basic_ifstream;
using ifstream = basic_ifstream<char>;
using wifstream = basic_ifstream<wchar_t>;

template<
    class charT,
    class traits = char_traits<charT>>
class basic_ofstream;
using ofstream = basic_ofstream<char>;
using wofstream = basic_ofstream<wchar_t>;

template<
    class charT,
    class traits = char_traits<charT>>
class basic_fstream;
using fstream = basic_fstream<char>;
using wfstream = basic_fstream<wchar_t>;
}

1 The header `<fstream>` defines four class templates and eight types that associate stream buffers with files and assist reading and writing files.

2 [Note: The class template `basic_filebuf` treats a file as a source or sink of bytes. In an environment that uses a large character set, the file typically holds multibyte character sequences and the `basic_filebuf` object converts those multibyte sequences into wide character sequences. —end note]

3 In this subclause, member functions taking arguments of `const filesystem::path::value_type*` are only be provided on systems where `filesystem::path::value_type` (27.11.7) is not `char`. [Note: These functions enable class `path` support for systems with a wide native path character type, such as `wchar_t`. —end note]

27.9.2 Class template `basic_filebuf` [filebuf]

namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_filebuf : public basic_streambuf<charT, traits> {
    public:
        using char_type = charT;
        using int_type = typename traits::int_type;
        using pos_type = typename traits::pos_type;
        using off_type = typename traits::off_type;
        using traits_type = traits;

    // 27.9.2.1, constructors/destructor
        basic_filebuf();
        basic_filebuf(const basic_filebuf& rhs) = delete;
        basic_filebuf(basic_filebuf&& rhs);
        virtual ~basic_filebuf();

    // 27.9.2.2, assign and swap
        basic_filebuf& operator=(const basic_filebuf& rhs) = delete;
        basic_filebuf& operator=(basic_filebuf&& rhs);
        void swap(basic_filebuf& rhs);

    // 27.9.2.3, members
        bool is_open() const;
        basic_filebuf* open(const char* s, ios_base::openmode mode);
        basic_filebuf* open(const filesystem::path::value_type* s,
            ios_base::openmode mode); // wide systems only; see 27.9.1
        basic_filebuf* open(const string& s,
            ios_base::openmode mode);
        basic_filebuf* open(const filesystem::path& s,
            ios_base::openmode mode);
        basic_filebuf* close();

    protected:
        // 27.9.2.4, overridden virtual functions
        streamsize showmanyc() override;
        int_type underflow() override;
        int_type uflow() override;
    }
int_type pbackfail(int_type c = traits::eof()) override;
int_type overflow (int_type c = traits::eof()) override;

basic_streambuf<charT, traits>* setbuf(char_type* s,
    streamsize n) override;
pos_type seekoff(off_type off, ios_base::seekdir way,
    ios_base::openmode which
    = ios_base::in | ios_base::out) override;
pos_type seekpos(pos_type sp,
    ios_base::openmode which
    = ios_base::in | ios_base::out) override;
int sync() override;
void imbue(const locale& loc) override;

};

} // namespace std

template<class charT, class traits>
void swap(basic_filebuf<charT, traits>& x,
basic_filebuf<charT, traits>& y);

1 The class basic_filebuf<charT, traits> associates both the input sequence and the output sequence with a file.

2 The restrictions on reading and writing a sequence controlled by an object of class basic_filebuf<charT, traits> are the same as for reading and writing with the C standard library FILEs.

3 In particular:
   (3.1) — If the file is not open for reading the input sequence cannot be read.
   (3.2) — If the file is not open for writing the output sequence cannot be written.
   (3.3) — A joint file position is maintained for both the input sequence and the output sequence.

4 An instance of basic_filebuf behaves as described in 27.9.2 provided traits::pos_type is fpos<traits::state_type>. Otherwise the behavior is undefined.

5 In order to support file I/O and multibyte/wide character conversion, conversions are performed using members of a facet, referred to as a_codecvt in following subclauses, obtained as if by
   
   const codecvt<charT, char, typename traits::state_type>& a_codecvt =
       use_facet<codecvt<charT, char, typename traits::state_type>>(getloc());

27.9.2.1 basic_filebuf constructors

[filebuf.cons]

basic_filebuf();

1 Effects: Constructs an object of class basic_filebuf<charT, traits>, initializing the base class with basic_streambuf<charT, traits>() (27.6.3.1).

2 Ensures: is_open() == false.

basic_filebuf(basic_filebuf&& rhs);

3 Effects: Move constructs from the rvalue rhs. It is implementation-defined whether the sequence pointers in *this (eback(), gptr(), egptr(), pbase(), pptr(), epptr()) obtain the values which rhs had. Whether they do or not, *this and rhs reference separate buffers (if any at all) after the construction. Additionally *this references the file which rhs did before the construction, and rhs references no file after the construction. The openmode, locale and any other state of rhs is also copied.

4 Ensures: Let rhs_p refer to the state of rhs just prior to this construction and let rhs_a refer to the state of rhs just after this construction.

(4.1) — is_open() == rhs_p.is_open()
(4.2) — rhs_a.is_open() == false
(4.3) — gptr() - eback() == rhs_p.gptr() - rhs_p.eback()
(4.4) — egptr() - eback() == rhs_p.egptr() - rhs_p.eback()
(4.5) — pptr() - pbase() == rhs_p.pptr() - rhs_p.pbase()
(4.6) \[ \text{epptr() - pbase()} == \text{rhs_p.epptr() - rhs_p.pbase()} \]
(4.7) \[ \text{if (eback()) eback()} != \text{rhs_a.eback()} \]
(4.8) \[ \text{if (gptr()) gptr()} != \text{rhs_a.gptr()} \]
(4.9) \[ \text{if (egptr()) egptr()} != \text{rhs_a.egptr()} \]
(4.10) \[ \text{if (pbase()) pbase()} != \text{rhs_a.pbase()} \]
(4.11) \[ \text{if (pptr()) pptr()} != \text{rhs_a.pptr()} \]
(4.12) \[ \text{if (epptr()) epptr()} != \text{rhs_a.epptr()} \]

```
virtual ~basic_filebuf();
```

Effects: Destroys an object of class `basic_filebuf<charT, traits>`. Calls `close()`. If an exception occurs during the destruction of the object, including the call to `close()`, the exception is caught but not rethrown (see 15.5.5.12).

27.9.2.2 Assign and swap

```
basic_filebuf& operator=(basic_filebuf&& rhs);
```

Effects: Calls `close()` then move assigns from `rhs`. After the move assignment `*this` has the observable state it would have had if it had been move constructed from `rhs` (see 27.9.2.1).

Returns: `*this`.

```
void swap(basic_filebuf& rhs);
```

Effects: Exchanges the state of `*this` and `rhs`.

```
template<class charT, class traits>
void swap(basic_filebuf<charT, traits>& x, basic_filebuf<charT, traits>& y);
```

Effects: As if by `x.swap(y)`.

27.9.2.3 Member functions

```
bool is_open() const;
```

Returns: `true` if a previous call to `open` succeeded (returned a non-null value) and there has been no intervening call to close.

```
basic_filebuf* open(const char* s, ios_base::openmode mode);
basic_filebuf* open(const filesystem::path::value_type* s, ios_base::openmode mode); // wide systems only; see 27.9.1
```

Effects: If `is_open()` != `false`, returns a null pointer. Otherwise, initializes the filebuf as required. It then opens a file, if possible, whose name is the NTBS `s` (as if by calling `fopen(s, modstr)`). The NTBS `modstr` is determined from `mode & ~ios_base::ate` as indicated in Table 115. If `mode` is not some combination of flags shown in the table then the open fails.

If the open operation succeeds and `(mode & ios_base::ate) != 0`, positions the file to the end (as if by calling `fseek(file, 0, SEEK_END)`).

If the repositioning operation fails, calls `close()` and returns a null pointer to indicate failure.

Returns: `this` if successful, a null pointer otherwise.

```
basic_filebuf* open(const string& s, ios_base::openmode mode);
basic_filebuf* open(const filesystem::path& s, ios_base::openmode mode);
```

Returns: `open(s.c_str(), mode)`.

```
basic_filebuf* close();
```

Effects: If `is_open()` == `false`, returns a null pointer. If a put area exists, calls `overflow(traits::eof())` to flush characters. If the last virtual member function called on `*this` (between `underflow`, `overflow`, `seekoff`, and `seekpos`) was `overflow` then calls `a_codecvt.unshift` (possibly several

329 The macro `SEEK_END` is defined, and the function signatures `fopen(const char*, const char*)` and `fseek(FILE*, long, int)` are declared, in `<cstdio>` (27.12.1).

</tbody>
</table>

8 Returns: this on success, a null pointer otherwise.
9 Ensures: is_open() == false.

27.9.2.4 Overridden virtual functions  

streamsize showmanyc() override;

1 Effects: Behaves the same as basic_streambuf::showmanyc() (27.6.3.4).
2 Remarks: An implementation might well provide an overriding definition for this function signature if it can determine that more characters can be read from the input sequence.

int_type underflow() override;

3 Effects: Behaves according to the description of basic_streambuf<charT, traits>::underflow(), with the specialization that a sequence of characters is read from the input sequence as if by reading from the associated file into an internal buffer (extern_buf) and then as if by doing:

```cpp
char  extern_buf[XSIZE];
char*  extern_end;
charT interm_buf[ISIZE];
charT* intern_end;
```
```
codecvt_base::result r =
a_codecvt_in(state, extern_buf, extern_buf+XSIZE, extern_end,
  intern_buf, intern_buf+ISIZE, intern_end);
```

This shall be done in such a way that the class can recover the position (fpos_t) corresponding to each character between intern_buf and intern_end. If the value of r indicates that a_codecvt_in() ran out of space in intern_buf, retry with a larger intern_buf.
int_type uflow() override;

Effects: Behaves according to the description of basic_streambuf<charT, traits>::uflow(), with the specialization that a sequence of characters is read from the input with the same method as used by underflow.

int_type pbackfail(int_type c = traits::eof()) override;

Effects: Puts back the character designated by c to the input sequence, if possible, in one of three ways:

1. If traits::eq_int_type(c, traits::eof()) returns false and if the function makes a putback position available and if traits::eq(to_char_type(c), gptr()[-1]) returns true, decrements the next pointer for the input sequence, gptr().
   Returns: c.
2. If traits::eq_int_type(c, traits::eof()) returns false and if the function makes a putback position available and if the function is permitted to assign to the putback position, decrements the next pointer for the input sequence, and stores c there.
   Returns: c.
3. If traits::eq_int_type(c, traits::eof()) returns true, and if either the input sequence has a putback position available or the function makes a putback position available, decrements the next pointer for the input sequence, gptr().
   Returns: traits::not_eof(c).

Returns: As specified above, or traits::eof() to indicate failure.

Remarks: If is_open() == false, the function always fails.

The function does not put back a character directly to the input sequence.

If the function can succeed in more than one of these ways, it is unspecified which way is chosen. The function can alter the number of putback positions available as a result of any call.

int_type overflow(int_type c = traits::eof()) override;

Effects: Behaves according to the description of basic_streambuf<charT, traits>::overflow(c), except that the behavior of “consuming characters” is performed by first converting as if by:

```c
charT* b = pbase();
charT* p = pptr();
charT* end;
char xbuf[XSIZE];
char* xbuf_end;
codecvt_base::result r =
    a_codecvt.out(state, b, p, end, xbuf, xbuf+XSIZE, xbuf_end);
```

and then

1. If r == codecvt_base::error then fail.
2. If r == codecvt_base::noconv then output characters from b up to (and not including) p.
3. If r == codecvt_base::partial then output to the file characters from xbuf up to xbuf_end, and repeat using characters from end to p. If output fails, fail (without repeating).
4. Otherwise output from xbuf to xbuf_end, and fail if output fails. At this point if b != p and b == end (xbuf isn’t large enough) then increase XSIZE and repeat from the beginning.

Returns: traits::not_eof(c) to indicate success, and traits::eof() to indicate failure. If is_open() == false, the function always fails.

basic_streambuf* setbuf(char_type* s, streamsize n) override;

Effects: If setbuf(0, 0) is called on a stream before any I/O has occurred on that stream, the stream becomes unbuffered. Otherwise the results are implementation-defined. “Unbuffered” means that pbase() and pptr() always return null and output to the file should appear as soon as possible.
Effects: Let $width$ denote $a_{codecvt}.encoding()$. If $is\_open() == false$, or $off != 0 \&\& width <= 0$, then the positioning operation fails. Otherwise, if $way != basic\_ios::cur$ or $off != 0$, and if the last operation was output, then update the output sequence and write any unshift sequence. Next, seek to the new position: if $width > 0$, call $fseek(file, width \ast off, whence)$, otherwise call $fseek(file, 0, whence)$.

Remarks: “The last operation was output” means either the last virtual operation was overflow or the put buffer is non-empty. “Write any unshift sequence” means, if $width$ if less than zero then call $a_{codecvt}.unshift(state, xbuf, xbuf+XSIZE, xbuf\_end)$ and output the resulting unshift sequence. The function determines one of three values for the argument $whence$, of type $int$, as indicated in Table 116.

Table 116 — seekoff effects

<table>
<thead>
<tr>
<th>way</th>
<th>Value</th>
<th>stdio Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>basic_ios::beg</td>
<td>SEEK_SET</td>
<td></td>
</tr>
<tr>
<td>basic_ios::cur</td>
<td>SEEK_CUR</td>
<td></td>
</tr>
<tr>
<td>basic_ios::end</td>
<td>SEEK_END</td>
<td></td>
</tr>
</tbody>
</table>

Returns: A newly constructed $pos\_type$ object that stores the resultant stream position, if possible. If the positioning operation fails, or if the object cannot represent the resultant stream position, returns $pos\_type(off\_type(-1))$.

pos_type seekpos(pos_type $sp$, 
    ios_base::openmode $which$
   = ios_base::in | ios_base::out) override;

Alters the file position, if possible, to correspond to the position stored in $sp$ (as described below). Altering the file position performs as follows:
1. if ($om \& ios\_base::out) != 0$, then update the output sequence and write any unshift sequence;
2. set the file position to $sp$ as if by a call to $fsetpos$;
3. if ($om \& ios\_base::in) != 0$, then update the input sequence;
where $om$ is the open mode passed to the last call to $open()$. The operation fails if $is\_open()$ returns $false$.

If $sp$ is an invalid stream position, or if the function positions neither sequence, the positioning operation fails. If $sp$ has not been obtained by a previous successful call to one of the positioning functions ($seekoff$ or $seekpos$) on the same file the effects are undefined.

Returns: $sp$ on success. Otherwise returns $pos\_type(off\_type(-1))$.

int sync() override;

Effects: If a put area exists, calls $filebuf::overflow$ to write the characters to the file, then flushes the file as if by calling $fflush(file)$. If a get area exists, the effect is implementation-defined.

void imbue(const locale& loc) override;

Requires: If the file is not positioned at its beginning and the encoding of the current locale as determined by $a_{codecvt}.encoding()$ is state-dependent (26.4.1.4.2) then that facet is the same as the corresponding facet of $loc$.

Effects: Causes characters inserted or extracted after this call to be converted according to $loc$ until another call of $imbue$.

Remarks: This may require reconversion of previously converted characters. This in turn may require the implementation to be able to reconstruct the original contents of the file.

27.9.3 Class template basic_ifstream

namespace std {

    template<class charT, class traits = char_traits<charT>>
    class basic_ifstream : public basic_istream<charT, traits> {
The class basic_ifstream<charT, traits> supports reading from named files. It uses a basic_filebuf<
charT, traits> object to control the associated sequence. For the sake of exposition, the maintained data
is presented here as:

(1.1) — sb, the filebuf object.

### 27.9.3.1 basic_ifstream constructors

**basic_ifstream();**

*Effects:* Constructs an object of class basic_ifstream<charT, traits>, initializing the base class with
basic_ifstream<charT, traits>::(sb) (27.7.4.1.1) and initializing sb with basic_filebuf<charT,
traits>() (27.9.2.1).

**explicit basic_ifstream(const char* s,**

*Effects:* Constructs an object of class basic_ifstream<charT, traits>, initializing the base class with
basic_ifstream<charT, traits>::(sb) (27.7.4.1.1) and initializing sb with basic_filebuf<charT,
traits>() (27.9.2.1).
traits>() (27.9.2.1), then calls rdbuf()->open(s, mode | ios_base::in). If that function returns a null pointer, calls setstate(failbit).

explicit basic_ifstream(const string& s,
    ios_base::openmode mode = ios_base::in);
explicit basic_ifstream(const filesystem::path& s,
    ios_base::openmode mode = ios_base::in);

Effects: The same as basic_ifstream(s.c_str(), mode).

basic_ifstream(basic_ifstream&& rhs);

Effects: Move constructs from the rvalue rhs. This is accomplished by move constructing the base class, and the contained basic_filebuf. Next basic_istream<charT, traits>::set_rdbuf(&sb) is called to install the contained basic_filebuf.

27.9.3.2 Assign and swap [ifstream.assign]

basic_ifstream& operator=(basic_ifstream&& rhs);

Effects: Move assigns the base and members of *this from the base and corresponding members of rhs.

Returns: *this.

void swap(basic_ifstream& rhs);

Effects: Exchanges the state of *this and rhs by calling basic_istream<charT, traits>::swap(rhs) and sb.swap(rhs.sb).

template<class charT, class traits>
void swap(basic_ifstream<charT, traits>& x,
    basic_ifstream<charT, traits>& y);

Effects: As if by x.swap(y).

27.9.3.3 Member functions [ifstream.members]

basic_filebuf<charT, traits>* rdbuf() const;

Returns: const_cast<basic_filebuf<charT, traits>*(&sb).

bool is_open() const;

Returns: rdbuf()->is_open().

void open(const char* s, ios_base::openmode mode = ios_base::in);
void open(const filesystem::path::value_type* s,
    ios_base::openmode mode = ios_base::in); // wide systems only; see 27.9.1

Effects: Calls rdbuf()->open(s, mode | ios_base::in). If that function does not return a null pointer calls clear(), otherwise calls setstate(failbit) (which may throw ios_base::failure) (27.5.5.4).

void open(const string& s, ios_base::openmode mode = ios_base::in);
void open(const filesystem::path& s, ios_base::openmode mode = ios_base::in);

Effects: Calls open(s.c_str(), mode).

void close();

Effects: Calls rdbuf()->close() and, if that function returns a null pointer, calls setstate(failbit) (which may throw ios_base::failure) (27.5.5.4).

27.9.4 Class template basic_ofstream [ofstream]

namespace std {
    template<class charT, class traits = char_traits<charT>>
        class basic_ofstream : public basic_ostream<charT, traits> {
            public:
                using char_type = charT;
                using int_type = typename traits::int_type;
        }
using pos_type = typename traits::pos_type;
using off_type = typename traits::off_type;
using traits_type = traits;

// 27.9.4.1, constructors
basic_ofstream();
explicit basic_ofstream(const char* s,
    ios_base::openmode mode = ios_base::out);
explicit basic_ofstream(const filesystem::path::value_type* s,
    ios_base::openmode mode = ios_base::out); // wide systems only; see 27.9.1
explicit basic_ofstream(const string& s,
    ios_base::openmode mode = ios_base::out);
explicit basic_ofstream(const filesystem::path& s,
    ios_base::openmode mode = ios_base::out);
basic_ofstream(const basic_ofstream& rhs) = delete;
basic_ofstream(basic_ofstream&& rhs);

// 27.9.4.2, assign and swap
basic_ofstream& operator=(const basic_ofstream& rhs) = delete;
basic_ofstream& operator=(basic_ofstream&& rhs);
void swap(basic_ofstream& rhs);

// 27.9.4.3, members
basic_filebuf<charT, traits>* rdbuf() const;
bool is_open() const;
void open(const char* s, ios_base::openmode mode = ios_base::out);
void open(const filesystem::path::value_type* s,
    ios_base::openmode mode = ios_base::out); // wide systems only; see 27.9.1
void open(const string& s, ios_base::openmode mode = ios_base::out);
void open(const filesystem::path& s, ios_base::openmode mode = ios_base::out);
void close();
private:
    basic_filebuf<charT, traits> sb; // exposition only
};

template<class charT, class traits>
void swap(basic_ofstream<charT, traits>& x,
    basic_ofstream<charT, traits>& y);

The class basic_ofstream<charT, traits> supports writing to named files. It uses a basic_filebuf<charT, traits> object to control the associated sequence. For the sake of exposition, the maintained data is presented here as:

— sb, the filebuf object.

### 27.9.4.1 basic_ofstream constructors

**basic_ofstream();**

*Effects:* Constructs an object of class basic_ofstream<charT, traits>, initializing the base class with basic_ostream<charT, traits>(&sb) (27.7.5.1.1) and initializing sb with basic_filebuf<charT, traits>() (27.9.2.1).

**explicit basic_ofstream(const char* s,**

**    ios_base::openmode mode = ios_base::out);**

**explicit basic_ofstream(const filesystem::path::value_type* s,**

**    ios_base::openmode mode = ios_base::out); // wide systems only; see 27.9.1**

*Effects:* Constructs an object of class basic_ofstream<charT, traits>, initializing the base class with basic_ostream<charT, traits>(&sb) (27.7.5.1.1) and initializing sb with basic_filebuf<charT, traits>() (27.9.2.1), then calls rdbuf() ->open(s, mode | ios_base::out). If that function returns a null pointer, calls setstate(failbit).
explicit basic_ofstream(const string& s,
    ios_base::openmode mode = ios_base::out);
explicit basic_ofstream(const filesystem::path& s,
    ios_base::openmode mode = ios_base::out);

    Effects: The same as basic_ofstream(s.c_str(), mode).

basic_ofstream(basic_ofstream&& rhs);

    Effects: Move constructs from the rvalue rhs. This is accomplished by move constructing the base
    class, and the contained basic_filebuf. Next basic_ostream<charT, traits>::set_rdbuf(&sb)
    is called to install the contained basic_filebuf.

27.9.4.2 Assign and swap

    [ofstream.assign]

basic_ofstream& operator=(basic_ofstream&& rhs);

1    Effects: Move assigns the base and members of *this from the base and corresponding members of
    rhs.

2    Returns: *this.

void swap(basic_ofstream& rhs);

3    Effects: Exchanges the state of *this and rhs by calling basic_ostream<charT, traits>::swap(rhs)
    and sb.swap(rhs.sb).

template<class charT, class traits>
    void swap(basic_ofstream<charT, traits>& x,
        basic_ofstream<charT, traits>& y);

4    Effects: As if by x.swap(y).

27.9.4.3 Member functions

    [ofstream.members]

basic_filebuf<charT, traits>* rdbuf() const;

1    Returns: const_cast<basic_filebuf<charT, traits>*>(&sb).

bool is_open() const;

2    Returns: rdbuf()->is_open().

void open(const char* s, ios_base::openmode mode = ios_base::out);
void open(const filesystem::path::value_type* s,
    ios_base::openmode mode = ios_base::out);  // wide systems only; see 27.9.1

3    Effects: Calls rdbuf()->open(s, mode | ios_base::out). If that function does not return a null
    pointer calls clear(), otherwise calls setstate(failbit) (which may throw ios_base::failure)
    (27.5.5.4).

void close();

4    Effects: Calls rdbuf()->close() and, if that function fails (returns a null pointer), calls setstate(
    failbit) (which may throw ios_base::failure)(27.5.5.4).

void open(const string& s, ios_base::openmode mode = ios_base::out);
void open(const filesystem::path& s, ios_base::openmode mode = ios_base::out);

5    Effects: Calls open(s.c_str(), mode).

27.9.5 Class template basic_fstream

    [fstream]

namespace std {
    template<class charT, class traits = char_traits<charT>>
    class basic_fstream : public basic_iostream<charT, traits> {
        public:
            using char_type = charT;
            using int_type = typename traits::int_type;
            using pos_type = typename traits::pos_type;
            using off_type = typename traits::off_type;
            using traits_type = traits;

§ 27.9.5  1219
/**27.9.5.1**, constructors

```cpp
// 27.9.5.1, constructors
basic_fstream();
explicit basic_fstream(
    const char* s,
    ios_base::openmode mode = ios_base::in | ios_base::out);
explicit basic_fstream(
    const filesystem::path::value_type* s,
    ios_base::openmode mode = ios_base::in | ios_base::out); // wide systems only; see 27.9.1
explicit basic_fstream(
    const string& s,
    ios_base::openmode mode = ios_base::in | ios_base::out);
explicit basic_fstream(
    const filesystem::path& s,
    ios_base::openmode mode = ios_base::in | ios_base::out);
basic_fstream(const basic_fstream& rhs) = delete;
basic_fstream(basic_fstream&& rhs);
```

```cpp
// 27.9.5.2, assign and swap
basic_fstream& operator=(const basic_fstream& rhs) = delete;
basic_fstream& operator=(basic_fstream&& rhs);
void swap(basic_fstream& rhs);
```

```cpp
// 27.9.5.3, members
basic_filebuf<charT, traits>* rdbuf() const;
bool is_open() const;
void open(
    const char* s,
    ios_base::openmode mode = ios_base::in | ios_base::out);
void open(
    const filesystem::path::value_type* s,
    ios_base::openmode mode = ios_base::in | ios_base::out); // wide systems only; see 27.9.1
void open(
    const string& s,
    ios_base::openmode mode = ios_base::in | ios_base::out);
void open(
    const filesystem::path& s,
    ios_base::openmode mode = ios_base::in | ios_base::out);
void close();
```

```cpp
private:
    basic_filebuf<charT, traits> sb; // exposition only
};
```

```cpp
template<class charT, class traits>
void swap(basic_fstream<charT, traits>& x,
    basic_fstream<charT, traits>& y);
```

1 The class template `basic_fstream<charT, traits>` supports reading and writing from named files. It uses a `basic_filebuf<charT, traits>` object to control the associated sequences. For the sake of exposition, the maintained data is presented here as:

1. `sb`, the `basic_filebuf` object.

### 27.9.5.1 basic_fstream constructors

```cpp
// 27.9.5.1 constructors
basic_fstream();
explicit basic_fstream(
    const char* s,
    ios_base::openmode mode = ios_base::in | ios_base::out);
```

**Effects:** Constructs an object of class `basic_fstream<charT, traits>`, initializing the base class with `basic_iostream<charT, traits>(&sb)` (27.7.4.6.1) and initializing `sb` with `basic_filebuf<charT, traits>()`. 
explicit basic_fstream(
    const filesystem::path::value_type* s,
    ios_base::openmode mode = ios_base::in | ios_base::out);  // wide systems only; see 27.9.1

Effects: Constructs an object of class basic_fstream<
    charT, traits>, initializing the base class with
    basic_iosstream<charT, traits>(&sb) (27.7.4.6.1) and initializing sb with basic_filebuf<charT,
    traits>(). Then calls rdbuf()->open(s, mode). If that function returns a null pointer, calls
    setstate(failbit).

explicit basic_fstream(
    const string& s,
    ios_base::openmode mode = ios_base::in | ios_base::out);

explicit basic_fstream(
    const filesystem::path& s,
    ios_base::openmode mode = ios_base::in | ios_base::out);

Effects: The same as basic_fstream(s.c_str(), mode).

basic_fstream(basic_fstream&& rhs);

Effects: Move constructs from the rvalue rhs. This is accomplished by move constructing the base
    class, and the contained basic_filebuf. Next basic_istream<charT, traits>::set_rdbuf(&sb)
    is called to install the contained basic_filebuf.

27.9.5.2 Assign and swap

basic_fstream& operator=(basic_fstream&& rhs);

Effects: Move assigns the base and members of *this from the base and corresponding members of
    rhs.

Returns: *this.

void swap(basic_fstream& rhs);

Effects: Exchanges the state of *this and rhs by calling basic_iosstream<charT, traits>::swap(rhs)
    and sb.swap(rhs.sb).

template<class charT, class traits>
void swap(basic_fstream<charT, traits>& x,
    basic_fstream<charT, traits>& y);

Effects: As if by x.swap(y).

27.9.5.3 Member functions

basic_filebuf<charT, traits>* rdbuf() const;

Returns: const_cast<
    basic_filebuf<charT, traits>*>(&sb).

bool is_open() const;

Returns: rdbuf()->is_open().

void open(
    const char* s,
    ios_base::openmode mode = ios_base::in | ios_base::out);

void open(
    const filesystem::path::value_type* s,
    ios_base::openmode mode = ios_base::in | ios_base::out);  // wide systems only; see 27.9.1

Effects: Calls rdbuf()->open(s, mode). If that function does not return a null pointer calls clear(),
    otherwise calls setstate(failbit) (which may throw ios_base::failure) (27.5.5.4).

void open(
    const string& s,
    ios_base::openmode mode = ios_base::in | ios_base::out);
void open(
    const filesystem::path& s,
    ios_base::openmode mode = ios_base::in | ios_base::out);

Effects: Calls open(s.c_str(), mode).

void close();

Effects: Calls rdbuf()->close() and, if that function returns a null pointer, calls setstate(failbit) (which may throw ios_base::failure) (27.5.5.4).

27.10 Synchronized output streams

27.10.1 Header <syncstream> synopsis

#include <ostream> // see 27.7.2

namespace std {
    template<class charT, class traits, class Allocator>
    class basic_syncbuf;

    using syncbuf = basic_syncbuf<char>;
    using wsyncbuf = basic_syncbuf<wchar_t>;

    template<class charT, class traits, class Allocator>
    class basic_osyncstream;

    using osyncstream = basic_osyncstream<char>;
    using wosyncstream = basic_osyncstream<wchar_t>;
}

The header <syncstream> provides a mechanism to synchronize execution agents writing to the same stream.

27.10.2 Class template basic_syncbuf

27.10.2.1 Overview

namespace std {
    template<class charT, class traits, class Allocator>
    class basic_syncbuf : public basic_streambuf<charT, traits> {
        public:
            using char_type = charT;
            using int_type = typename traits::int_type;
            using pos_type = typename traits::pos_type;
            using off_type = typename traits::off_type;
            using traits_type = traits;
            using allocator_type = Allocator;

            using streambuf_type = basic_streambuf<charT, traits>;

            // 27.10.2.2, construction and destruction
            explicit basic_syncbuf(streambuf_type* obuf = nullptr)
                : basic_syncbuf(obuf, Allocator()) {} 
            basic_syncbuf(streambuf_type*, const Allocator&);
            basic_syncbuf(basic_syncbuf&);
            ~basic_syncbuf();

            // 27.10.2.3, assignment and swap
            basic_syncbuf& operator=(basic_syncbuf&);
            void swap(basic_syncbuf&);

            // 27.10.2.4, member functions
            bool emit();
            streambuf_type* get_wrapped() const noexcept;
            allocator_type get_allocator() const noexcept;
            void set_emit_on_sync(bool) noexcept;

§ 27.10.2.1
protected:
    // 27.10.2.5, overridden virtual functions
    int sync() override;

private:
    streambuf_type* wrapped;    // exposition only
    bool emit_on_sync{};        // exposition only
};

// 27.10.2.6, specialized algorithms
template<class charT, class traits, class Allocator>
void swap(basic_syncbuf<charT, traits, Allocator>&,      
          basic_syncbuf<charT, traits, Allocator>&);

1 Class template basic_syncbuf stores character data written to it, known as the associated output, into internal buffers allocated using the object’s allocator. The associated output is transferred to the wrapped stream buffer object *wrapped when emit() is called or when the basic_syncbuf object is destroyed. Such transfers are atomic with respect to transfers by other basic_syncbuf objects with the same wrapped stream buffer object.

27.10.2.2 Construction and destruction [syncstream.syncbuf.cons]

basic_syncbuf(streambuf_type* obuf, const Allocator& allocator);

Effects: Constructs the basic_syncbuf object and sets wrapped to obuf.
Remarks: A copy of allocator is used to allocate memory for internal buffers holding the associated output.
Throws: Nothing unless an exception is thrown by the construction of a mutex or by memory allocation.
Ensures: get_wrapped() == obuf and get_allocator() == allocator are true.

basic_syncbuf(basic_syncbuf&& other);

Effects: Move constructs from other (Table 25).
Ensures: The value returned by this->get_wrapped() is the value returned by other.get_wrapped() prior to calling this constructor. Output stored in other prior to calling this constructor will be stored in *this afterwards. other.rdbuf()->pbase() == other.rdbuf()->pptr() and other.get_wrapped() == nullptr are true.
Remarks: This constructor disassociates other from its wrapped stream buffer, ensuring destruction of other produces no output.

~basic_syncbuf();

Effects: Calls emit().
Throws: Nothing. If an exception is thrown from emit(), the destructor catches and ignores that exception.

27.10.2.3 Assignment and swap [syncstream.syncbuf.assign]

basic_syncbuf& operator=(basic_syncbuf&& rhs) noexcept;

Effects: Calls emit() then move assigns from rhs. After the move assignment *this has the observable state it would have had if it had been move constructed from rhs (27.10.2.2).
Returns: *this.
Ensures:

(3.1) rhs.get_wrapped() == nullptr is true.
(3.2) this->get_allocator() == rhs.get_allocator() is true when
      allocator_traits<Allocator>::propagate_on_container_move_assignment::value
      is true; otherwise, the allocator is unchanged.
Remarks: This assignment operator disassociates rhs from its wrapped stream buffer, ensuring destruction of rhs produces no output.
void swap(basic_syncbuf& other) noexcept;

Requires: Either allocator_traits<Allocator>::propagate_on_container_swap::value is true or this->get_allocator() == other.get_allocator() is true.

Effects: Exchanges the state of *this and other.

27.10.2.4 Member functions

bool emit();

Effects: Atomically transfers the associated output of *this to the stream buffer *wrapped, so that it appears in the output stream as a contiguous sequence of characters. wrapped->pubsync() is called if and only if a call was made to sync() since the most recent call to emit(), if any.

Returns: true if all of the following conditions hold; otherwise false:

1. wrapped == nullptr is false.
2. All of the characters in the associated output were successfully transferred.
3. The call to wrapped->pubsync() (if any) succeeded.

Ensures: On success, the associated output is empty.

Synchronization: All emit() calls transferring characters to the same stream buffer object appear to execute in a total order consistent with the “happens before” relation (6.8.2.1), where each emit() call synchronizes with subsequent emit() calls in that total order.

Remarks: May call member functions of wrapped while holding a lock uniquely associated with wrapped.

streambuf_type* get_wrapped() const noexcept;

Returns: wrapped.

allocator_type get_allocator() const noexcept;

Returns: A copy of the allocator that was set in the constructor or assignment operator.

void set_emit_on_sync(bool b) noexcept;

Effects: emit_on_sync = b.

27.10.2.5 Overridden virtual functions

int sync() override;

Effects: Records that the wrapped stream buffer is to be flushed. Then, if emit_on_sync is true, calls emit(). [Note: If emit_on_sync is false, the actual flush is delayed until a call to emit(). — end note]

Returns: If emit() was called and returned false, returns -1; otherwise 0.

27.10.2.6 Specialized algorithms

template<class charT, class traits, class Allocator>
void swap(basic_syncbuf<charT, traits, Allocator>& a,
          basic_syncbuf<charT, traits, Allocator>& b) noexcept;

Effects: Equivalent to a.swap(b).

27.10.3 Class template basic_osyncstream

27.10.3.1 Overview

namespace std {
    template<class charT, class traits, class Allocator>
    class basic_osyncstream : public basic_ostream<charT, traits> {
    public:
        using char_type = charT;
        using int_type = typename traits::int_type;
        using pos_type = typename traits::pos_type;
        using off_type = typename traits::off_type;
        using traits_type = traits;
    }
using allocator_type = Allocator;
using streambuf_type = basic_streambuf<charT, traits>;
using syncbuf_type = basic_syncbuf<charT, traits, Allocator>;

// 27.10.3.2, construction and destruction
basic_osyncstream(streambuf_type*, const Allocator&);
explicit basic_osyncstream(streambuf_type* obuf)
    : basic_osyncstream(obuf, Allocator()) {}
basic_osyncstream(basic_ostream<charT, traits>&& os, const Allocator& allocator)
    : basic_osyncstream(os.rdbuf(), allocator) {}
explicit basic_osyncstream(basic_ostream<charT, traits>& os)
    : basic_osyncstream(os, Allocator()) {}
basic_osyncstream(basic_osyncstream&&) noexcept;
~basic_osyncstream();

// 27.10.3.3, assignment
basic_osyncstream& operator=(basic_osyncstream&&) noexcept;

// 27.10.3.4, member functions
void emit();
streambuf_type* get_wrapped() const noexcept;
syncbuf_type* rdbuf() const noexcept { return &sb ; }

private:
syncbuf_type sb; // exposition only
};

1 Allocator shall satisfy the Cpp17Allocator requirements (Table 33).

2 [Example: A named variable can be used within a block statement for streaming.

   { 
     osyncstream bout(cout);
     bout << "Hello, ";
     bout << "World!";
     bout << endl; // flush is noted
     bout << "and more!\n";
   } // characters are transferred and cout is flushed
   —end example]

3 [Example: A temporary object can be used for streaming within a single statement.

   osyncstream(cout) << "Hello, " << "World!" << '\n';

   In this example, cout is not flushed. —end example]

27.10.3.2 Construction and destruction

basic_osyncstream(streambuf_type* buf, const Allocator& allocator);

1 Effects: Initializes sb from buf and allocator. Initializes the base class with basic_ostream(&sb).

2 [Note: The member functions of the provided stream buffer might be called from emit() while a lock
   is held. Care should be taken to ensure that this does not result in deadlock. —end note]

3 Ensures: get_wrapped() == buf is true.

basic_osyncstream(basic_osyncstream&& other) noexcept;

4 Effects: Move constructs the base class and sb from the corresponding subobjects of other, and calls
   basic_ostream<charT, traits>::set_rdbuf(&sb).

5 Ensures: The value returned by get_wrapped() is the value returned by os.get_wrapped() prior to
calling this constructor. nullptr == other.get_wrapped() is true.

~basic_osyncstream();

6 Effects: Calls emit(). If an exception is thrown from emit(), that exception is caught and ignored.
27.10.3.3 Assignment

basic_osyncstream& operator=(basic_osyncstream&& rhs) noexcept;

Effects: First, calls emit(). If an exception is thrown from emit(), that exception is caught and ignored. Move assigns sb from rhs.sb. [Note: This disassociates rhs from its wrapped stream buffer ensuring destruction of rhs produces no output. — end note]

Ensures: nullptr == rhs.get_wrapped() is true. get_wrapped() returns the value previously returned by rhs.get_wrapped().

27.10.3.4 Member functions

void emit();

Effects: Calls sb.emit(). If that call returns false, calls setstate(ios::badbit).

[Example: A flush on a basic_osyncstream does not flush immediately:

```cpp
{  
   osyncstream bout(cout);
   bout << "Hello, " << "World!" << "\n"; // no flush
   bout.emit(); // characters transferred; cout not flushed
   bout << "World!" << endl; // flush noted; cout not flushed
   bout.emit(); // characters transferred; cout flushed
   bout << "Greetings." << "\n"; // no flush
} // characters transferred; cout not flushed

— end example]

Returns: sb.get_wrapped().

[Example: Obtaining the wrapped stream buffer with get_wrapped() allows wrapping it again with an osyncstream. For example,

```cpp
{  
   osyncstream bout1(cout);
   bout1 << "Hello, ";
   {  
      osyncstream(bout1.get_wrapped()) << "Goodbye, " << "Planet!" << "\n";
   }
   bout1 << "World!" << "\n";
}  
produces the uninterleaved output

Goodbye, Planet!
Hello, World!

— end example]

streambuf_type* get_wrapped() const noexcept;

Returns: sb.get_wrapped().

[Example: Obtaining the wrapped stream buffer with get_wrapped() allows wrapping it again with an osyncstream. For example,

```cpp
{  
   osyncstream bout1(cout);
   bout1 << "Hello, ";
   {  
      osyncstream(bout1.get_wrapped()) << "Goodbye, " << "Planet!" << "\n";
   }
   bout1 << "World!" << "\n";
}  
produces the uninterleaved output

Goodbye, Planet!
Hello, World!

— end example]
27.11 File systems

27.11.1 General

1 This subclause describes operations on file systems and their components, such as paths, regular files, and directories.

2 A file system is a collection of files and their attributes.

3 A file is an object within a file system that holds user or system data. Files can be written to, or read from, or both. A file has certain attributes, including type. File types include regular files and directories. Other types of files, such as symbolic links, may be supported by the implementation.

4 A directory is a file within a file system that acts as a container of directory entries that contain information about other files, possibly including other directory files. The parent directory of a directory is the directory that both contains a directory entry for the given directory and is represented by the dot-dot filename (27.11.7.1) in the given directory. The parent directory of other types of files is a directory containing a directory entry for the file under discussion.

5 A link is an object that associates a filename with a file. Several links can associate names with the same file. A hard link is a link to an existing file. Some file systems support multiple hard links to a file. If the last hard link to a file is removed, the file itself is removed. [Note: A hard link can be thought of as a shared-ownership smart pointer to a file. —end note] A symbolic link is a type of file with the property that when the file is encountered during pathname resolution (27.11.7), a string stored by the file is used to modify the pathname resolution. [Note: Symbolic links are often called symlinks. A symbolic link can be thought of as a raw pointer to a file. If the file pointed to does not exist, the symbolic link is said to be a “dangling” symbolic link. —end note]

27.11.2 Conformance

1 Conformance is specified in terms of behavior. Ideal behavior is not always implementable, so the conformance subclauses take that into account.

27.11.2.1 POSIX conformance

1 Some behavior is specified by reference to POSIX (27.11.3). How such behavior is actually implemented is unspecified. [Note: This constitutes an “as if” rule allowing implementations to call native operating system or other APIs. —end note]

2 Implementations should provide such behavior as it is defined by POSIX. Implementations shall document any behavior that differs from the behavior defined by POSIX. Implementations that do not support exact POSIX behavior should provide behavior as close to POSIX behavior as is reasonable given the limitations of actual operating systems and file systems. If an implementation cannot provide any reasonable behavior, the implementation shall report an error as specified in 27.11.6. [Note: This allows users to rely on an exception being thrown or an error code being set when an implementation cannot provide any reasonable behavior. —end note]

3 Implementations are not required to provide behavior that is not supported by a particular file system. [Example: The FAT file system used by some memory cards, camera memory, and floppy disks does not support hard links, symlinks, and many other features of more capable file systems, so implementations are not required to support those features on the FAT file system but instead are required to report an error as described above. —end example]

27.11.2.2 Operating system dependent behavior conformance

1 Behavior that is specified as being operating system dependent is dependent upon the behavior and characteristics of an operating system. The operating system an implementation is dependent upon is implementation-defined.

2 It is permissible for an implementation to be dependent upon an operating system emulator rather than the actual underlying operating system.

27.11.2.3 File system race behavior

1 A file system race is the condition that occurs when multiple threads, processes, or computers interleave access and modification of the same object within a file system. Behavior is undefined if calls to functions provided by this subclause introduce a file system race.
If the possibility of a file system race would make it unreliable for a program to test for a precondition before calling a function described herein, Requires: is not specified for the function. \[Note: As a design practice, preconditions are not specified when it is unreasonable for a program to detect them prior to calling the function. \— end note\]

### 27.11.3 Normative references

This subclause mentions commercially available operating systems for purposes of exposition.\[^{330}\]

### 27.11.4 Requirements

Throughout this subclause, char, wchar_t, char16_t, and char32_t are collectively called **encoded character types**.

Functions with template parameters named EcharT shall not participate in overload resolution unless EcharT is one of the encoded character types.

Template parameters named InputIterator shall satisfy the *Cpp17InputIterator* requirements (22.2.3) and shall have a value type that is one of the encoded character types.

[Note: Use of an encoded character type implies an associated character set and encoding. Since signed char and unsigned char have no implied character set and encoding, they are not included as permitted types. \— end note\]

Template parameters named Allocator shall satisfy the *Cpp17Allocator* requirements (Table 33).

#### 27.11.4.1 Namespaces and headers

Unless otherwise specified, references to entities described in this subclause are assumed to be qualified with `::std::filesystem::`.

### 27.11.5 Header `<filesystem>` synopsis

```cpp
namespace std::filesystem {
    // 27.11.7, paths
class path;

    // 27.11.7.7, path non-member functions
    void swap(path& lhs, path& rhs) noexcept;
    size_t hash_value(const path& p) noexcept;
    bool operator==(const path& lhs, const path& rhs) noexcept;
    bool operator!=(const path& lhs, const path& rhs) noexcept;
    bool operator<(const path& lhs, const path& rhs) noexcept;
    bool operator<=(const path& lhs, const path& rhs) noexcept;
    bool operator>(const path& lhs, const path& rhs) noexcept;
    bool operator>=(const path& lhs, const path& rhs) noexcept;
    path operator/(const path& lhs, const path& rhs);

    // 27.11.7.7.1, path factory functions
    template<class Source>
    path u8path(const Source& source);
    template<class InputIterator>
    path u8path(InputIterator first, InputIterator last);

    // 27.11.8, filesystem errors
class filesystem_error;

    // 27.11.11, directory entries
class directory_entry;

    // 27.11.12, directory iterators
class directory_iterator;
}
```

1 **trivial-clock** is an implementation-defined type that satisfies the Cpp17TrivialClock requirements (25.3) and that is capable of representing and measuring file time values. Implementations should ensure that the resolution and range of file_time_type reflect the operating system dependent resolution and range of file time values.

### 27.11.6 Error reporting

Filesystem library functions often provide two overloads, one that throws an exception to report file system errors, and another that sets an error_code. [Note: This supports two common use cases:

1. Uses where file system errors are truly exceptional and indicate a serious failure. Throwing an exception is an appropriate response.

---

1. **trivial-clock** is an implementation-defined type that satisfies the Cpp17TrivialClock requirements (25.3) and that is capable of representing and measuring file time values. Implementations should ensure that the resolution and range of file_time_type reflect the operating system dependent resolution and range of file time values.

### 27.11.6 Error reporting

Filesystem library functions often provide two overloads, one that throws an exception to report file system errors, and another that sets an error_code. [Note: This supports two common use cases:

1. Uses where file system errors are truly exceptional and indicate a serious failure. Throwing an exception is an appropriate response.

---

© ISO/IEC
Uses where file system errors are routine and do not necessarily represent failure. Returning an error code is the most appropriate response. This allows application specific error handling, including simply ignoring the error.

— end note]

Functions not having an argument of type `error_code&` handle errors as follows, unless otherwise specified:

(2.1) — When a call by the implementation to an operating system or other underlying API results in an error that prevents the function from meeting its specifications, an exception of type `filesystem_error` shall be thrown. For functions with a single path argument, that argument shall be passed to the `filesystem_error` constructor with a single path argument. For functions with two path arguments, the first of these arguments shall be passed to the `filesystem_error` constructor as the `path1` argument, and the second shall be passed as the `path2` argument. The `filesystem_error` constructor’s `error_code` argument is set as appropriate for the specific operating system dependent error.

(2.2) — Failure to allocate storage is reported by throwing an exception as described in 15.5.5.12.

(2.3) — Destructors throw nothing.

Functions having an argument of type `error_code&` handle errors as follows, unless otherwise specified:

(3.1) — If a call by the implementation to an operating system or other underlying API results in an error that prevents the function from meeting its specifications, the `error_code&` argument is set as appropriate for the specific operating system dependent error. Otherwise, `clear()` is called on the `error_code&` argument.

27.11.7 Class `path` [fs.class.path]

1 An object of class `path` represents a path and contains a pathname. Such an object is concerned only with the lexical and syntactic aspects of a path. The path does not necessarily exist in external storage, and the pathname is not necessarily valid for the current operating system or for a particular file system.

2 [Note: Class `path` is used to support the differences between the string types used by different operating systems to represent pathnames, and to perform conversions between encodings when necessary. — end note]

3 A `path` is a sequence of elements that identify the location of a file within a filesystem. The elements are the `root-name_opt`, `root-directory_opt`, and an optional sequence of `filenames` (27.11.7.1). The maximum number of elements in the sequence is operating system dependent (27.11.2.2).

4 An `absolute path` is a path that unambiguously identifies the location of a file without reference to an additional starting location. The elements of a path that determine if it is absolute are operating system dependent. A `relative path` is a path that is not absolute, and as such, only unambiguously identifies the location of a file when resolved relative to an implied starting location. The elements of a path that determine if it is relative are operating system dependent. [Note: Pathnames “.” and “..” are relative paths. — end note]

5 A `pathname` is a character string that represents the name of a path. Pathnames are formatted according to the generic pathname format grammar (27.11.7.1) or according to an operating system dependent `native pathname format` accepted by the host operating system.

6 `Pathname resolution` is the operating system dependent mechanism for resolving a pathname to a particular file in a file hierarchy. There may be multiple pathnames that resolve to the same file. [Example: POSIX specifies the mechanism in section 4.11, Pathname resolution. — end example]

§ 27.11.7
value_type is a typedef for the operating system dependent encoded character type used to represent pathnames.

The value of the preferred_separator member is the operating system dependent preferred-separator character (27.11.7.1).

[Example: For POSIX-based operating systems, value_type is char and preferred_separator is the slash character (’/’). For Windows-based operating systems, value_type is wchar_t and preferred_separator is the backslash character (L'\'). —end example]

### 27.11.7.1 Generic pathname format

pathname:
- root-name\opt root-directory\opt relative-path

root-name:
- operating system dependent sequences of characters
- implementation-defined sequences of characters

root-directory:
- directory-separator

relative-path:
- filename
- directory-separator relative-path
- an empty path

filename:
- non-empty sequence of characters other than directory-separator characters

directory-separator:
- preferred-separator directory-separator\opt
- fallback-separator directory-separator\opt

preferred-separator:
- operating system dependent directory separator character

fallback-separator:
- / if preferred-separator is not /

A filename is the name of a file. The dot and dot-dot filenames, consisting solely of one and two period characters respectively, have special meaning. The following characteristics of filenames are operating system dependent:

- (1.1) The permitted characters. [Example: Some operating systems prohibit the ASCII control characters (0x00 – 0x1F) in filenames. —end example] [Note: For wide portability, users may wish to limit filename characters to the POSIX Portable Filename Character Set:
  A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
  a b c d e f g h i j k l m n o p q r s t u v w x y z
  0 1 2 3 4 5 6 7 8 9 . _ - —end note]

- (1.2) The maximum permitted length.

- (1.3) Filenames that are not permitted.

- (1.4) Filenames that have special meaning.

- (1.5) Case awareness and sensitivity during path resolution.

- (1.6) Special rules that may apply to file types other than regular files, such as directories.

1 Except in a root-name, multiple successive directory-separator characters are considered to be the same as one directory-separator character.

§ 27.11.7.1 1235
The dot filename is treated as a reference to the current directory. The dot-dot filename is treated as a reference to the parent directory. What the dot-dot filename refers to relative to root-directory is implementation-defined. Specific filenames may have special meanings for a particular operating system.

A root-name identifies the starting location for pathname resolution (27.11.7). If there are no operating system dependent root-names, at least one implementation-defined root-name is required. [Note: Many operating systems define a name beginning with two directory-separator characters as a root-name that identifies network or other resource locations. Some operating systems define a single letter followed by a colon as a drive specifier – a root-name identifying a specific device such as a disk drive. — end note]

If a root-name is otherwise ambiguous, the possibility with the longest sequence of characters is chosen. [Note: On a POSIX-like operating system, it is impossible to have a root-name and a relative-path without an intervening root-directory element. — end note]

Normalization of a generic format pathname means:
1. If the path is empty, stop.
2. Replace each slash character in the root-name with a preferred-separator.
3. Replace each directory-separator with a preferred-separator. [Note: The generic pathname grammar (27.11.7.1) defines directory-separator as one or more slashes and preferred-separators. — end note]
4. Remove each dot filename and any immediately following directory-separator.
5. As long as any appear, remove a non-dot-dot filename immediately followed by a directory-separator and a dot-dot filename, along with any immediately following directory-separator.
6. If there is a root-directory, remove all dot-dot filenames and any directory-separators immediately following them. [Note: These dot-dot filenames attempt to refer to nonexistent parent directories. — end note]
7. If the last filename is dot-dot, remove any trailing directory-separator.
8. If the path is empty, add a dot.

The result of normalization is a path in normal form, which is said to be normalized.

27.11.7.2 path conversions

27.11.7.2.1 path argument format conversions

[fs.path.cvt] [fs.path.fmt.cvt]

1 [Note: The format conversions described in this subclause are not applied on POSIX-based operating systems because on these systems:

(1.1) — The generic format is acceptable as a native path.
(1.2) — There is no need to distinguish between native format and generic format in function arguments.
(1.3) — Paths for regular files and paths for directories share the same syntax.
— end note]

Several functions are defined to accept detected-format arguments, which are character sequences. A detected-format argument represents a path using either a pathname in the generic format (27.11.7.1) or a pathname in the native format (27.11.7). Such an argument is taken to be in the generic format if and only if it matches the generic format and is not acceptable to the operating system as a native path.

[Note: Some operating systems may have no unambiguous way to distinguish between native format and generic format arguments. This is by design as it simplifies use for operating systems that do not require disambiguation. An implementation for an operating system where disambiguation is required is permitted to distinguish between the formats. — end note]

Pathnames are converted as needed between the generic and native formats in an operating-system-dependent manner. Let \( G(n) \) and \( N(g) \) in a mathematical sense be the implementation’s functions that convert native-to-generic and generic-to-native formats respectively. If \( g=G(n) \) for some \( n \), then \( G(N(g))=g \); if \( n=N(g) \) for some \( g \), then \( N(G(n))=n \). [Note: Neither \( G \) nor \( N \) need be invertible. — end note]

If the native format requires paths for regular files to be formatted differently from paths for directories, the path shall be treated as a directory path if its last element is a directory-separator, otherwise it shall be treated as a path to a regular file.
[Note: A path stores a native format pathname (27.11.7.4.6) and acts as if it also stores a generic format pathname, related as given below. The implementation may generate the generic format pathname based on the native format pathname (and possibly other information) when requested. — end note]

When a path is constructed from or is assigned a single representation separate from any path, the other representation is selected by the appropriate conversion function (G or N).

When the (new) value p of one representation of a path is derived from the representation of that or another path, a value q is chosen for the other representation. The value q converts to p (by G or N as appropriate) if any such value does so; q is otherwise unspecified. [Note: If q is the result of converting any path at all, it is the result of converting p. — end note]

27.11.7.2.2 path type and encoding conversions  
[fs.path.type.cvt]

The native encoding of a narrow character string is the operating system dependent current encoding for pathnames (27.11.7). The native encoding for wide character strings is the implementation-defined execution wide-character set encoding (5.3).

For member function arguments that take character sequences representing paths and for member functions returning strings, value type and encoding conversion is performed if the value type of the argument or return value differs from path::value_type. For the argument or return value, the method of conversion and the encoding to be converted to is determined by its value type:

1. char: The encoding is the native narrow encoding. The method of conversion, if any, is operating system dependent. [Note: For POSIX-based operating systems path::value_type is char so no conversion from char value type arguments or to char value type return values is performed. For Windows-based operating systems, the native narrow encoding is determined by calling a Windows API function. — end note] [Note: This results in behavior identical to other C and C++ standard library functions that perform file operations using narrow character strings to identify paths. Changing this behavior would be surprising and error prone. — end note]

2. wchar_t: The encoding is the native wide encoding. The method of conversion is unspecified. [Note: For Windows-based operating systems path::value_type is wchar_t so no conversion from wchar_t value type arguments or to wchar_t value type return values is performed. — end note]

3. char16_t: The encoding is UTF-16. The method of conversion is unspecified.

4. char32_t: The encoding is UTF-32. The method of conversion is unspecified.

If the encoding being converted to has no representation for source characters, the resulting converted characters, if any, are unspecified. Implementations should not modify member function arguments if already of type path::value_type.

27.11.7.3 path requirements  
[fs.path.req]

In addition to the requirements (27.11.4), function template parameters named Source shall be one of:

1. basic_string<EcharT, traits, Allocator>. A function argument const Source& source shall have an effective range [source.begin(), source.end()).

2. basic_string_view<EcharT, traits>. A function argument const Source& source shall have an effective range [source.begin(), source.end()).

3. A type meeting the Cpp17InputIterator requirements that iterates over a NTCTS. The value type shall be an encoded character type. A function argument const Source& source shall have an effective range [source, end) where end is the first iterator value with an element value equal to iterator_traits<Source>::value_type().

4. A character array that after array-to-pointer decay results in a pointer to the start of a NTCTS. The value type shall be an encoded character type. A function argument const Source& source shall have an effective range [source, end) where end is the first iterator value with an element value equal to iterator_traits<decay_t<Source>>::value_type().

Functions taking template parameters named Source shall not participate in overload resolution unless either

1. Source is a specialization of basic_string or basic_string_view, or

2. the qualified-id iterator_traits<decay_t<Source>>::value_type is valid and denotes a possibly const encoded character type (12.9.2).
Arguments of type Source shall not be null pointers.

27.11.7.4 path members

27.11.7.4.1 path constructors

path() noexcept;

Effects: Constructs an object of class path.

Ensures: empty() == true.

path(const path& p);
path(path&& p) noexcept;

Effects: Constructs an object of class path having the same pathname in the native and generic formats, respectively, as the original value of p. In the second form, p is left in a valid but unspecified state.

path(string_type&& source, format fmt = auto_format);

Effects: Constructs an object of class path for which the pathname in the detected-format of source has the original value of source (27.11.7.2.1), converting format if required (27.11.7.2.1). source is left in a valid but unspecified state.

template<class Source>
path(const Source& source, format fmt = auto_format);

Requires: The value type of Source is char.

Effects: Let s be the effective range of source or the range [first, last), after converting the encoding as follows:

(7.1) If value_type is wchar_t, converts to the native wide encoding (27.11.7.2.2) using the codecvt<wchar_t, char, mbstate_t> facet of loc.

(7.2) Otherwise a conversion is performed using the codecvt<wchar_t, char, mbstate_t> facet of loc, and then a second conversion to the current narrow encoding.

Finds the detected-format of s (27.11.7.2.1) and constructs an object of class path for which the pathname in that format is s.

[Example: A string is to be read from a database that is encoded in ISO/IEC 8859-1, and used to create a directory:

namespace fs = std::filesystem;
std::string latin1_string = read_latin1_data();
codecvt_8859_1<wchar_t> latin1_facet;
std::locale latin1_locale(std::locale(), latin1_facet);
fs::create_directory(fs::path(latin1_string, latin1_locale));

For POSIX-based operating systems, the path is constructed by first using latin1_facet to convert ISO/IEC 8859-1 encoded latin1_string to a wide character string in the native wide encoding (27.11.7.2.2). The resulting wide string is then converted to a narrow character pathname string in the current native narrow encoding. If the native wide encoding is UTF-16 or UTF-32, and the current native narrow encoding is UTF-8, all of the characters in the ISO/IEC 8859-1 character set will be converted to their Unicode representation, but for other native narrow encodings some characters may have no representation.]
For Windows-based operating systems, the path is constructed by using `latin1_facet` to convert ISO/IEC 8859-1 encoded `latin1_string` to a UTF-16 encoded wide character pathname string. All of the characters in the ISO/IEC 8859-1 character set will be converted to their Unicode representation. — end example

27.11.7.4.2 path assignments

```cpp
path& operator=(const path& p);
```

Effects: If `*this` and `p` are the same object, has no effect. Otherwise, sets both respective pathnames of `*this` to the respective pathnames of `p`.

Returns: `*this`.

```cpp
path& operator=(path& p) noexcept;
```

Effects: If `*this` and `p` are the same object, has no effect. Otherwise, sets both respective pathnames of `*this` to the respective pathnames of `p`. `p` is left in a valid but unspecified state. [Note: A valid implementation is `swap(p)` — end note]

Returns: `*this`.

```cpp
path& operator=(string_type&& source);
path& assign(string_type&& source);
```

Effects: Sets the pathname in the detected-format of `source` to the original value of `source`. `source` is left in a valid but unspecified state.

Returns: `*this`.

```cpp
template<class Source>
path& operator=(const Source& source);
template<class Source>
path& assign(const Source& source);
template<class InputIterator>
path& assign(InputIterator first, InputIterator last);
```

Effects: Let `s` be the effective range of `source` (27.11.7.3) or the range `[first, last)`, with the encoding converted if required (27.11.7.2). Finds the detected-format of `s` (27.11.7.2.1) and sets the pathname in that format to `s`.

Returns: `*this`.

27.11.7.4.3 path appends

```cpp
path& operator/=(const path& p);
```

The append operations use `operator/=` to denote their semantic effect of appending `preferred-separator` when needed.

```
Expression examples:
// On POSIX,
path("foo") / ";";  // yields "foo/"
path("foo") /="/bar";  // yields "/bar"
```

// On Windows, backslashes replace slashes in the above yields

§ 27.11.7.4.3
// On Windows,
path("foo") / "c:/bar"; // yields "c:/bar"
path("foo") / "c:"
path("c:" / ";"; // yields "c:
path("c:foo") / "/bar"; // yields "c:/bar"
path("c:foo") / "c:bar"; // yields "c:foo/bar"

— end example]

Returns: *this.

template<class Source>
path& operator/=(const Source& source);
template<class Source>
path& append(const Source& source);

Effects: Equivalent to: return operator/=(path(source));

template<class InputIterator>
path& append(InputIterator first, InputIterator last);

Effects: Equivalent to: return operator/=(path(first, last));

27.11.7.4.4 path concatenation

path& operator+=(const path& x);
path& operator+=(const string_type& x);
path& operator+=(basic_string_view<value_type> x);
path& operator+=(const value_type* x);
path& operator+=(value_type x);
template<class Source>
path& operator+=(const Source& x);
template<class EcharT>
path& operator+=(EcharT x);
template<class Source>
path& concat(const Source& x);

Effects: Appends path(x).native() to the pathname in the native format. [Note: This directly manipulates the value of native() and may not be portable between operating systems. —end note]

Returns: *this.

template<class InputIterator>
path& concat(InputIterator first, InputIterator last);

Effects: Equivalent to: return *this += path(first, last);

27.11.7.4.5 path modifiers

void clear() noexcept;

Ensures: empty() == true.
path& make_preferred();

Effects: Each directory-separator of the pathname in the generic format is converted to preferred-separator.

Returns: *this.

[Example:
path p("foo/bar");
std::cout << p << 
'\n';
p.make_preferred();
std::cout << p << 
'\n';
On an operating system where preferred-separator is a slash, the output is:
"foo/bar"
"foo/bar"
On an operating system where preferred-separator is a backslash, the output is:]
path& remove_filename();

 Ensures: !has_filename().
 Effects: Remove the generic format pathname of filename() from the generic format pathname.
 Returns: *this.

 [Example:
 path("foo/bar").remove_filename();  // yields "foo/"
 path("foo/").remove_filename();  // yields "foo/"
 path("/foo").remove_filename();  // yields "/"
 path("/").remove_filename();  // yields "/"
 — end example]

path& replace_filename(const path& replacement);

 Effects: Equivalent to:
 remove_filename();
 operator/=(replacement);
 Returns: *this.

 [Example:
 path("/foo").replace_filename("bar");  // yields "/bar" on POSIX
 path("/").replace_filename("bar");  // yields "/bar" on POSIX
 — end example]

path& replace_extension(const path& replacement = path());

 Effects:
 — Any existing extension() (27.11.7.4.9) is removed from the pathname in the generic format, then
 — If replacement is not empty and does not begin with a dot character, a dot character is appended
 to the pathname in the generic format, then
 — operator+=(replacement);
 Returns: *this.

void swap(path& rhs) noexcept;

 Effects: Swaps the contents (in all formats) of the two paths.
 Complexity: Constant time.

27.11.7.4.6 path native format observers

 The string returned by all native format observers is in the native pathname format (27.11.7).

 const string_type& native() const noexcept;
 Returns: The pathname in the native format.

 const value_type* c_str() const noexcept;
 Effects: Equivalent to: return native().c_str();

 operator string_type() const;
 Returns: native().

 [Note: Conversion to string_type is provided so that an object of class path can be given as an
 argument to existing standard library file stream constructors and open functions. — end note]
template<class EcharT, class traits = char_traits<EcharT>,
   class Allocator = allocator<EcharT>>
basic_string<EcharT, traits, Allocator>
   string(const Allocator& a = Allocator()) const;

Returns: native().
Remarks: All memory allocation, including for the return value, shall be performed by a. Conversion, if any, is specified by 27.11.7.2.

std::string string() const;
std::wstring wstring() const;
std::string u8string() const;
std::u16string u16string() const;
std::u32string u32string() const;

Returns: native().
Remarks: All memory allocation, including for the return value, shall be performed by a. Conversion, if any, is specified by 27.11.7.2.

Conversion, if any, is specified by 27.11.7.2. The encoding of the string returned by u8string() is always UTF-8.

27.11.7.4.7 path generic format observers

Generic format observer functions return strings formatted according to the generic pathname format (27.11.7.1). A single slash (`/`) character is used as the directory-separator.

[Example: On an operating system that uses backslash as its preferred-separator, path("foo\bar").generic_string() returns "foo/bar". — end example]

template<class EcharT, class traits = char_traits<EcharT>,
   class Allocator = allocator<EcharT>>
   basic_string<EcharT, traits, Allocator>
   generic_string(const Allocator& a = Allocator()) const;

Returns: The pathname in the generic format.
Remarks: All memory allocation, including for the return value, shall be performed by a. Conversion, if any, is specified by 27.11.7.2.

std::string generic_string() const;
std::wstring generic_wstring() const;
std::string generic_u8string() const;
std::u16string generic_u16string() const;
std::u32string generic_u32string() const;

Returns: The pathname in the generic format.
Remarks: Conversion, if any, is specified by 27.11.7.2. The encoding of the string returned by generic_u8string() is always UTF-8.

27.11.7.4.8 path compare

int compare(const path& p) const noexcept;

Returns:
(1.1) A value less than 0, if native() for the elements of *this are lexicographically less than native() for the elements of p; otherwise,
(1.2) a value greater than 0, if native() for the elements of *this are lexicographically greater than native() for the elements of p; otherwise,
(1.3) 0.

Remarks: The elements are determined as if by iteration over the half-open range [begin(), end()) for *this and p.

int compare(const string_type& s) const
int compare(basic_string_view<value_type> s) const;

Returns: compare(path(s)).
int compare(const value_type* s) const
    Returns: compare(path(s)).

27.11.7.4.9 path decomposition

path root_name() const;
    Returns: root-name, if the pathname in the generic format includes root-name, otherwise path().

path root_directory() const;
    Returns: root-directory, if the pathname in the generic format includes root-directory, otherwise path().

path root_path() const;
    Returns: root_name() / root_directory().

path relative_path() const;
    Returns: A path composed from the pathname in the generic format, if empty() is false, beginning with the first filename after root_path(). Otherwise, path().

path parent_path() const;
    Returns: *this if has_relative_path() is false, otherwise a path whose generic format pathname is the longest prefix of the generic format pathname of *this that produces one fewer element in its iteration.

path filename() const;
    Returns: relative_path().empty() ? path() : *--end().

[Example:
    path("/foo/bar.txt").filename(); // yields "bar.txt"
    path("/foo/bar").filename(); // yields "bar"
    path("/foo/bar/").filename(); // yields ""
    path("/").filename(); // yields ""
    path("//host").filename(); // yields ""
    path(".").filename(); // yields "."
    path("..").filename(); // yields ".."
— end example]

path stem() const;
    Returns: Let f be the generic format pathname of filename(). Returns a path whose pathname in the generic format is
    — f, if it contains no periods other than a leading period or consists solely of one or two periods;
    — otherwise, the prefix of f ending before its last period.

[Example:
    std::cout << path("/foo/bar.txt").stem(); // outputs "bar"
    path p = "foo.bar.baz.tar";
    for (; !p.extension().empty(); p = p.stem())
        std::cout << p.extension() << '\n';
    // outputs: .tar
        // .baz
        // .bar
— end example]

path extension() const;
    Returns: A path whose pathname in the generic format is the suffix of filename() not included in stem().

[Example:
    path("/foo/bar.txt").extension(); // yields ".txt" and stem() is "bar"
    path("/foo/bar").extension(); // yields "" and stem() is "bar"
path("/foo/.profile").extension(); // yields "" and stem() is ".profile"
path(".bar").extension(); // yields "" and stem() is ".bar"
path("../bar").extension(); // yields ".bar" and stem() is ".."

— end example

[Note: The period is included in the return value so that it is possible to distinguish between no extension and an empty extension. — end note]

[Note: On non-POSIX operating systems, for a path p, it may not be the case that p.stem() + p.extension() == p.filename(), even though the generic format pathnames are the same. — end note]

27.11.7.4.10 path query

[[nodiscard]] bool empty() const noexcept;

Returns: true if the pathname in the generic format is empty, else false.

bool has_root_path() const;

Returns: !root_path().empty().

bool has_root_name() const;

Returns: !root_name().empty().

bool has_root_directory() const;

Returns: !root_directory().empty().

bool has_relative_path() const;

Returns: !relative_path().empty().

bool has_parent_path() const;

Returns: !parent_path().empty().

bool has_filename() const;

Returns: !filename().empty().

bool has_stem() const;

Returns: !stem().empty().

bool has_extension() const;

Returns: !extension().empty().

bool is_absolute() const;

Returns: true if the pathname in the native format contains an absolute path (27.11.7), else false.

[Example: path("/").is_absolute() is true for POSIX-based operating systems, and false for Windows-based operating systems. — end example]

bool is_relative() const;

Returns: !is_absolute().

27.11.7.4.11 path generation

path lexically_normal() const;

Returns: A path whose pathname in the generic format is the normal form (27.11.7.1) of the pathname in the generic format of *this.

[Example:
assert(path("foo/./bar/..").lexically_normal() == "foo/");
assert(path("foo/./bar/../").lexically_normal() == "foo/");

The above assertions will succeed. On Windows, the returned path’s directory-separator characters will be backslashes rather than slashes, but that does not affect path equality. — end example]
path lexically_relative(const path& base) const;

3 Returns: *this made relative to base. Does not resolve (27.11.7) symlinks. Does not first normalize (27.11.7.1) *this or base.

Effects: If root_name() != base.root_name() is true or is_absolute() != base.is_absolute() is true or !has_root_directory() & base.has_root_directory() is true, returns path(). Determines the first mismatched element of *this and base as if by:

auto [a, b] = mismatch(begin(), end(), base.begin(), base.end());

Then,

(4.1) — if a == end() and b == base.end(), returns path("."); otherwise

(4.2) — let n be the number of filename elements in [b, base.end()) that are not dot or dot-dot minus the number that are dot-dot. If n<0, returns path(); otherwise

(4.3) — returns an object of class path that is default-constructed, followed by

4.3.1 application of operator/=(path("..")) n times, and then

4.3.2 application of operator/= for each element in [a, end()).

5 [Example:

assert(path("/a/d").lexically_relative("/a/b/c") == "../../d");
assert(path("/a/b/c").lexically_relative("/a/d") == ".../b/c");
assert(path("a/b/c").lexically_relative("a") == "b/c");
assert(path("a/b/c").lexically_relative("a/b/c/x/y") == ".../..");
assert(path("a/b/c").lexically_relative("a/b/c") == ".");
assert(path("a/b").lexically_relative("c/d") == ".../a/b");

The above assertions will succeed. On Windows, the returned path’s directory-separator characters will be backslashes rather than slashes, but that does not affect path equality. — end example]

[Note: If symlink following semantics are desired, use the operational function relative(). — end note]

path lexically_proximate(const path& base) const;

8 Returns: If the value of lexically_relative(base) is not an empty path, return it. Otherwise return *this.

[Note: If symlink following semantics are desired, use the operational function proximate(). — end note]

[Note: If normalization (27.11.7.1) is needed to ensure consistent matching of elements, apply lexically_normal() to *this, base, or both. — end note]

27.11.7.5 path iterators [fs.path.itr]

Path iterators iterate over the elements of the pathname in the generic format (27.11.7.1).

A path::iterator is a constant iterator satisfying all the requirements of a bidirectional iterator (22.2.6) except that, for dereferenceable iterators a and b of type path::iterator with a == b, there is no requirement that *a and *b are bound to the same object. Its value_type is path.

Calling any non-const member function of a path object invalidates all iterators referring to elements of that object.

For the elements of the pathname in the generic format, the forward traversal order is as follows:

4.1 — The root-name element, if present.

4.2 — The root-directory element, if present. [Note: The generic format is required to ensure lexicographical comparison works correctly. — end note]

4.3 — Each successive filename element, if present.

4.4 — An empty element, if a trailing non-root directory-separator is present.

The backward traversal order is the reverse of forward traversal.
iterator begin() const;

Returns: An iterator for the first present element in the traversal list above. If no elements are present, the end iterator.

iterator end() const;

Returns: The end iterator.

27.11.7.6 path inserter and extractor

```cpp
template<class charT, class traits>
friend basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const path& p);

Effects: Equivalent to `os << quoted(p.string<charT, traits>())`. [Note: The quoted function is described in 27.7.8. — end note]

Returns: `os`.
```

```cpp
template<class charT, class traits>
friend basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& is, path& p);

Effects: Equivalent to:
- `basic_string<charT, traits> tmp;`
- `is >> quoted(tmp);`
- `p = tmp;`

Returns: `is`.
```

27.11.7.7 path non-member functions

```cpp
void swap(path& lhs, path& rhs) noexcept;

Effects: Equivalent to `lhs.swap(rhs)`.
```

```cpp
size_t hash_value (const path& p) noexcept;

Returns: A hash value for the path `p`. If for two paths, `p1 == p2` then `hash_value(p1) == hash_value(p2)`.
```

```cpp
bool operator==(const path& lhs, const path& rhs) noexcept;

Returns: !(lhs < rhs) && !(rhs < lhs).
```

[Note: Path equality and path equivalence have different semantics.]

1. Equality is determined by the path non-member `operator==`, which considers the two paths’ lexical representations only. [Example: `path("foo") == "bar"` is never `true`. — end example]
2. Equivalence is determined by the `equivalent()` non-member function, which determines if two paths resolve (27.11.7) to the same file system entity. [Example: `equivalent("foo", "bar")` will be `true` when both paths resolve to the same file. — end example]

Programmers wishing to determine if two paths are “the same” must decide if “the same” means “the same representation” or “resolve to the same actual file”, and choose the appropriate function accordingly. — end note]

```cpp
bool operator!=(const path& lhs, const path& rhs) noexcept;

Returns: `(lhs < rhs) && !(rhs < lhs)`.
```

```cpp
bool operator< (const path& lhs, const path& rhs) noexcept;

Returns: `lhs.compare(rhs) < 0`.
```

```cpp
bool operator<=(const path& lhs, const path& rhs) noexcept;

Returns: `!(rhs < lhs)`.
```

```cpp
bool operator> (const path& lhs, const path& rhs) noexcept;

Returns: `rhs < lhs`.
```
bool operator>=(const path& lhs, const path& rhs) noexcept;

Returns: !(lhs < rhs).

path operator/ (const path& lhs, const path& rhs);

Effects: Equivalent to: return path(lhs) /= rhs;

27.11.7.7.1 path factory functions

template<class Source>
path u8path(const Source& source);

template<class InputIterator>
path u8path(InputIterator first, InputIterator last);

Requires: The source and [first, last) sequences are UTF-8 encoded. The value type of Source
and InputIterator is char.

Returns:

(2.1) — If value_type is char and the current native narrow encoding (27.11.7.2.2) is UTF-8, return
path(source) or path(first, last); otherwise,

(2.2) — if value_type is wchar_t and the native wide encoding is UTF-16, or if value_type is char16_t
or char32_t, convert source or [first, last) to a temporary, tmp, of type string_type and
return path(tmp); otherwise,

(2.3) — convert source or [first, last) to a temporary, tmp, of type u32string and return path(tmp).

Remarks: Argument format conversion (27.11.7.2.1) applies to the arguments for these functions. How
Unicode encoding conversions are performed is unspecified.

[Example: A string is to be read from a database that is encoded in UTF-8, and used to create a
directory using the native encoding for filenames:

```cpp
namespace fs = std::filesystem;
std::string utf8_string = read_utf8_data();
fs::create_directory(fs::u8path(utf8_string));
```

For POSIX-based operating systems with the native narrow encoding set to UTF-8, no encoding or
type conversion occurs.

For POSIX-based operating systems with the native narrow encoding not set to UTF-8, a conversion
to UTF-32 occurs, followed by a conversion to the current native narrow encoding. Some Unicode
characters may have no native character set representation.

For Windows-based operating systems a conversion from UTF-8 to UTF-16 occurs. — end example]

27.11.8 Class filesystem_error

namespace std::filesystem {

class filesystem_error : public system_error {

public:

    filesystem_error(const string& what_arg, error_code ec);
    filesystem_error(const string& what_arg, const path& p1, error_code ec);
    filesystem_error(const string& what_arg, const path& p1, const path& p2, error_code ec);

    const path& path1() const noexcept;
    const path& path2() const noexcept;
    const char* what() const noexcept override;
};
}

The class filesystem_error defines the type of objects thrown as exceptions to report file system errors
from functions described in this subclause.

27.11.8.1 filesystem_error members

Constructors are provided that store zero, one, or two paths associated with an error.
filesystem_error(const string& what_arg, error_code ec);

Ensures:
(2.1) code() == ec,
(2.2) path1().empty() == true,
(2.3) path2().empty() == true, and
(2.4) string_view(what()).find(what_arg) != string_view::npos.

filesystem_error(const string& what_arg, const path& p1, error_code ec);

Ensures:
(3.1) code() == ec,
(3.2) path1() returns a reference to the stored copy of p1,
(3.3) path2().empty() == true, and
(3.4) string_view(what()).find(what_arg) != string_view::npos.

filesystem_error(const string& what_arg, const path& p1, const path& p2, error_code ec);

Ensures:
(4.1) code() == ec,
(4.2) path1() returns a reference to the stored copy of p1,
(4.3) path2() returns a reference to the stored copy of p2, and
(4.4) string_view(what()).find(what_arg) != string_view::npos.

const path& path1() const noexcept;

Returns: A reference to the copy of p1 stored by the constructor, or, if none, an empty path.

const path& path2() const noexcept;

Returns: A reference to the copy of p2 stored by the constructor, or, if none, an empty path.

const char* what() const noexcept override;

Returns: An ntbs that incorporates the what_arg argument supplied to the constructor. The exact format is unspecified. Implementations should include the system_error::what() string and the pathnames of path1 and path2 in the native format in the returned string.

27.11.9 Enumerations

27.11.9.1 Enum path::format

This enum specifies constants used to identify the format of the character sequence, with the meanings listed in Table 117.

Table 117 — Enum path::format

<table>
<thead>
<tr>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>native_format</td>
<td>The native pathname format.</td>
</tr>
<tr>
<td>generic_format</td>
<td>The generic pathname format.</td>
</tr>
<tr>
<td>auto_format</td>
<td>The interpretation of the format of the character sequence is</td>
</tr>
<tr>
<td></td>
<td>implementation-defined. The implementation may inspect the content of</td>
</tr>
<tr>
<td></td>
<td>the character sequence to determine the format. [Note: For POSIX-based</td>
</tr>
<tr>
<td></td>
<td>systems, native and generic formats are equivalent and the character</td>
</tr>
<tr>
<td></td>
<td>sequence should always be interpreted in the same way. — end note]</td>
</tr>
</tbody>
</table>

27.11.9.2 Enum class file_type

This enum class specifies constants used to identify file types, with the meanings listed in Table 118. The values of the constants are distinct.
Table 118 — Enum class file_type

<table>
<thead>
<tr>
<th>Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>The type of the file has not been determined or an error occurred while trying to determine the type.</td>
</tr>
<tr>
<td>not_found</td>
<td>Pseudo-type indicating the file was not found. [Note: The file not being found is not considered an error while determining the type of a file. —end note]</td>
</tr>
<tr>
<td>regular</td>
<td>Regular file</td>
</tr>
<tr>
<td>directory</td>
<td>Directory file</td>
</tr>
<tr>
<td>symlink</td>
<td>Symbolic link file</td>
</tr>
<tr>

<td>Socket file</td>
</tr>
<tr>
<td>implementation-defined</td>
<td>Implementations that support file systems having file types in addition to the above file_type types shall supply implementation-defined file_type constants to separately identify each of those additional file types</td>
</tr>
<tr>
<td>unknown</td>
<td>The file exists but the type could not be determined</td>
</tr>
</tbody>
</table>

27.11.9.3 Enum class copy_options

The enum class type copy_options is a bitmask type (15.4.2.1.4) that specifies bitmask constants used to control the semantics of copy operations. The constants are specified in option groups with the meanings listed in Table 119. The constant none represents the empty bitmask, and is shown in each option group for purposes of exposition; implementations shall provide only a single definition. Every other constant in the table represents a distinct bitmask element.

Table 119 — Enum class copy_options

<table>
<thead>
<tr>
<th>Option group controlling copy_file function effects for existing target files</th>
<th>Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>(Default)</td>
<td>Error; file already exists.</td>
</tr>
<tr>
<td>skip_existing</td>
<td></td>
<td>Do not overwrite existing file, do not report an error.</td>
</tr>
<tr>
<td>overwrite_existing</td>
<td></td>
<td>Overwrite the existing file.</td>
</tr>
<tr>
<td>update_existing</td>
<td></td>
<td>Overwrite the existing file if it is older than the replacement file.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Option group controlling copy function effects for sub-directories</th>
<th>Constant</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
<td>The permissions are not known, such as when a file_status object is created without specifying the permissions</td>
</tr>
</tbody>
</table>

27.11.9.5 Enum class perm_options

1 The enum class type perm_options is a bitmask type (15.4.2.1.4) that specifies bitmask constants used to control the semantics of permissions operations, with the meanings listed in Table 121. The bitmask constants are bitmask elements. In Table 121 perm denotes a value of type perms passed to permissions.

Table 121 — Enum class perm_options

<table>
<thead>
<tr>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>replace</td>
<td>permissions shall replace the file’s permission bits with perm</td>
</tr>
<tr>
<td>add</td>
<td>permissions shall replace the file’s permission bits with the bitwise OR of perm and the file’s current permission bits.</td>
</tr>
<tr>
<td>remove</td>
<td>permissions shall replace the file’s permission bits with the bitwise AND of the complement of perm and the file’s current permission bits.</td>
</tr>
<tr>
<td>nofollow</td>
<td>permissions shall change the permissions of a symbolic link itself rather than the permissions of the file the link resolves to.</td>
</tr>
</tbody>
</table>

27.11.9.6 Enum class directory_options

1 The enum class type directory_options is a bitmask type (15.4.2.1.4) that specifies bitmask constants used to identify directory traversal options, with the meanings listed in Table 122. The constant none represents the empty bitmask; every other constant in the table represents a distinct bitmask element.
Table 122 — Enum class directory_options

<table>
<thead>
<tr>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>(Default) Skip directory symlinks, permission denied is an error.</td>
</tr>
<tr>
<td>follow_directory_symlink</td>
<td>Follow rather than skip directory symlinks.</td>
</tr>
<tr>
<td>skip_permission_denied</td>
<td>Skip directories that would otherwise result in permission denied.</td>
</tr>
</tbody>
</table>

27.11.10 Class file_status

namespace std::filesystem {
  class file_status {
    public:
      // 27.11.10.1, constructors and destructor
      file_status() noexcept : file_status(file_type::none) {}                     
      explicit file_status(file_type ft, perms prms = perms::unknown) noexcept;   
      file_status(const file_status&) noexcept = default;                         
      file_status(file_status&&) noexcept = default;                              
      ~file_status();                                                             
      // assignments
      file_status& operator=(const file_status&) noexcept = default;               
      file_status& operator=(file_status&&) noexcept = default;                    
      // 27.11.10.3, modifiers
      void type(file_type ft) noexcept;                                            
      void permissions(perms prms) noexcept;                                      
      // 27.11.10.2, observers
      file_type type() const noexcept;                                            
      perms permissions() const noexcept;                                         
  };
}

1 An object of type file_status stores information about the type and permissions of a file.

27.11.10.1 file_status constructors

explicit file_status(file_type ft, perms prms = perms::unknown) noexcept;
1 Ensures: type() == ft and permissions() == prms.

27.11.10.2 file_status observers

file_type type() const noexcept;
1 Returns: The value of type() specified by the postconditions of the most recent call to a constructor, operator=, or type(file_type) function.

perms permissions() const noexcept;
2 Returns: The value of permissions() specified by the postconditions of the most recent call to a constructor, operator=, or permissions(perms) function.

27.11.10.3 file_status modifiers

void type(file_type ft) noexcept;
1 Ensures: type() == ft.

void permissions(perms prms) noexcept;
2 Ensures: permissions() == prms.
27.11.11  Class directory_entry

namespace std::filesystem {

    class directory_entry {

        public:

            // 27.11.11.1, constructors and destructor
            directory_entry() noexcept = default;
            directory_entry(const directory_entry&) = default;
            directory_entry(directory_entry&&) noexcept = default;
            explicit directory_entry(const filesystem::path& p);
            directory_entry(const filesystem::path& p, error_code& ec);
            ~directory_entry();

            // assignments
            directory_entry& operator=(const directory_entry&) = default;
            directory_entry& operator=(directory_entry&&) noexcept = default;

            file_status status(error_code& ec) const noexcept;
            file_status symlink_status() const;
            file_status symlink_status(error_code& ec) const noexcept;

            bool operator==(const directory_entry& rhs) const noexcept;
            bool operator!=(const directory_entry& rhs) const noexcept;
            bool operator< (const directory_entry& rhs) const noexcept;
            bool operator> (const directory_entry& rhs) const noexcept;
            bool operator<=(const directory_entry& rhs) const noexcept;
            bool operator>=(const directory_entry& rhs) const noexcept;

        }
    }
}
private:
   filesystem::path pathobject;   // exposition only
   friend class directory_iterator; // exposition only
};

A directory_entry object stores a path object and may store additional objects for file attributes such as hard link count, status, symlink status, file size, and last write time.

Implementations should store such additional file attributes during directory iteration if their values are available and storing the values would allow the implementation to eliminate file system accesses by directory_entry observer functions (27.11.14). Such stored file attribute values are said to be cached.

[Note: For purposes of exposition, class directory_iterator (27.11.12) is shown above as a friend of class directory_entry. Friendship allows the directory_iterator implementation to cache already available attribute values directly into a directory_entry object without the cost of an unneeded call to refresh(). —end note]

[Example:
using namespace std::filesystem;

   // use possibly cached last write time to minimize disk accesses
   for (auto& x : directory_iterator("."))
   {
      std::cout << x.path() << " " << x.last_write_time() << std::endl;
   }

   // call refresh() to refresh a stale cache
   for (auto& x : directory_iterator("."))
   {
      lengthy_function(x.path());  // cache becomes stale
      x.refresh();
      std::cout << x.path() << " " << x.last_write_time() << std::endl;
   }

On implementations that do not cache the last write time, both loops will result in a potentially expensive call to the std::filesystem::last_write_time function. On implementations that do cache the last write time, the first loop will use the cached value and so will not result in a potentially expensive call to the std::filesystem::last_write_time function. The code is portable to any implementation, regardless of whether or not it employs caching. —end example]

27.11.11.1 directory_entry constructors

   explicit directory_entry(const filesystem::path& p);
   directory_entry(const filesystem::path& p, error_code& ec);

   Effects: Constructs an object of type directory_entry, then refresh() or refresh(ec), respectively.
   Ensures: path() == p if no error occurs, otherwise path() == filesystem::path().
   Throws: As specified in 27.11.6.

27.11.11.2 directory_entry modifiers

   void assign(const filesystem::path& p);
   void assign(const filesystem::path& p, error_code& ec);

   Effects: Equivalent to pathobject = p, then refresh() or refresh(ec), respectively. If an error occurs, the values of any cached attributes are unspecified.
   Throws: As specified in 27.11.6.

   void replace_filename(const filesystem::path& p);
   void replace_filename(const filesystem::path& p, error_code& ec);

   Effects: Equivalent to pathobject.replace_filename(p), then refresh() or refresh(ec), respectively. If an error occurs, the values of any cached attributes are unspecified.
   Throws: As specified in 27.11.6.
void refresh();
void refresh(error_code& ec) noexcept;

Effects: Stores the current values of any cached attributes of the file p resolves to. If an error occurs, an error is reported (27.11.6) and the values of any cached attributes are unspecified.

Throws: As specified in 27.11.6.

[Note: Implementations of directory_iterator (27.11.12) are prohibited from directly or indirectly calling the refresh function since it must access the external file system, and the objective of caching is to avoid unnecessary file system accesses. — end note]

27.11.11.3 directory_entry observers [fs.dir.entry.obs]

Unqualified function names in the Returns: elements of the directory_entry observers described below refer to members of the std::filesystem namespace.

const filesystem::path& path() const noexcept;
operator const filesystem::path&() const noexcept;

Returns: pathobject.

bool exists() const;
bool exists(error_code& ec) const noexcept;

Returns: exists(this->status()) or exists(this->status(ec)), respectively.

Throws: As specified in 27.11.6.

bool is_block_file() const;
bool is_block_file(error_code& ec) const noexcept;

Returns: is_block_file(this->status()) or is_block_file(this->status(ec)), respectively.

Throws: As specified in 27.11.6.

bool is_character_file() const;
bool is_character_file(error_code& ec) const noexcept;

Returns: is_character_file(this->status()) or is_character_file(this->status(ec)), respectively.

Throws: As specified in 27.11.6.

bool is_directory() const;
bool is_directory(error_code& ec) const noexcept;

Returns: is_directory(this->status()) or is_directory(this->status(ec)), respectively.

Throws: As specified in 27.11.6.

bool is_fifo() const;
bool is_fifo(error_code& ec) const noexcept;

Returns: is_fifo(this->status()) or is_fifo(this->status(ec)), respectively.

Throws: As specified in 27.11.6.

bool is_other() const;
bool is_other(error_code& ec) const noexcept;

Returns: is_other(this->status()) or is_other(this->status(ec)), respectively.

Throws: As specified in 27.11.6.

bool is_regular_file() const;
bool is_regular_file(error_code& ec) const noexcept;

Returns: is_regular_file(this->status()) or is_regular_file(this->status(ec)), respectively.

Throws: As specified in 27.11.6.

bool is_socket() const;
bool is_socket(error_code& ec) const noexcept;

Returns: is_socket(this->status()) or is_socket(this->status(ec)), respectively.

Throws: As specified in 27.11.6.

bool is_symlink() const;
bool is_symlink(error_code& ec) const noexcept;

Returns: is_symlink(this->symlink_status()) or is_symlink(this->symlink_status(ec)), respectively.

Throws: As specified in 27.11.6.

uintmax_t file_size() const;
uintmax_t file_size(error_code& ec) const noexcept;

Returns: If cached, the file size attribute value. Otherwise, file_size(path()) or file_size(path(), ec), respectively.

Throws: As specified in 27.11.6.

uintmax_t hard_link_count() const;
uintmax_t hard_link_count(error_code& ec) const noexcept;

Returns: If cached, the hard link count attribute value. Otherwise, hard_link_count(path()) or hard_link_count(path(), ec), respectively.

Throws: As specified in 27.11.6.

file_time_type last_write_time() const;
file_time_type last_write_time(error_code& ec) const noexcept;

Returns: If cached, the last write time attribute value. Otherwise, last_write_time(path()) or last_write_time(path(), ec), respectively.

Throws: As specified in 27.11.6.

file_status status() const;
file_status status(error_code& ec) const noexcept;

Returns: If cached, the status attribute value. Otherwise, status(path()) or status(path(), ec), respectively.

Throws: As specified in 27.11.6.

file_status symlink_status() const;
file_status symlink_status(error_code& ec) const noexcept;

Returns: If cached, the symlink status attribute value. Otherwise, symlink_status(path()) or symlink_status(path(), ec), respectively.

Throws: As specified in 27.11.6.

bool operator==(const directory_entry& rhs) const noexcept;

Returns: pathobject == rhs.pathobject.

bool operator!=(const directory_entry& rhs) const noexcept;

Returns: pathobject != rhs.pathobject.

bool operator< (const directory_entry& rhs) const noexcept;

Returns: pathobject < rhs.pathobject.

bool operator> (const directory_entry& rhs) const noexcept;

Returns: pathobject > rhs.pathobject.

bool operator<=(const directory_entry& rhs) const noexcept;

Returns: pathobject <= rhs.pathobject.
bool operator>=(const directory_entry& rhs) const noexcept;

Returns: pathobject >= rhs.pathobject.

### 27.11.12 Class directory_iterator

An object of type `directory_iterator` provides an iterator for a sequence of `directory_entry` elements representing the path and any cached attribute values (27.11.11) for each file in a directory or in an implementation-defined directory-like file type. [Note: For iteration into sub-directories, see class `recursive_directory_iterator` (27.11.13). — end note]

```cpp
namespace std::filesystem {
    class directory_iterator {
        public:
            using iterator_category = input_iterator_tag;
            using value_type = directory_entry;
            using difference_type = ptrdiff_t;
            using pointer = const directory_entry*;
            using reference = const directory_entry&;

            // 27.11.12.1, member functions
            directory_iterator() noexcept;
            explicit directory_iterator(const path& p);
            directory_iterator(const path& p, directory_options options);
            directory_iterator(const path& p, error_code& ec);
            directory_iterator(const path& p, directory_options options,
                                error_code& ec);
            directory_iterator(const directory_iterator& rhs);
            directory_iterator(directory_iterator&& rhs) noexcept;
            ~directory_iterator();

            directory_iterator& operator=(const directory_iterator& rhs);
            directory_iterator& operator=(directory_iterator&& rhs) noexcept;

            const directory_entry& operator*() const;
            const directory_entry* operator->() const;
            directory_iterator& operator++();
            directory_iterator& increment(error_code& ec);

            // other members as required by 22.2.3, input iterators
        }
    }
}
```

2 `directory_iterator` satisfies the `Cpp17InputIterator` requirements (22.2.3).

3 If an iterator of type `directory_iterator` reports an error or is advanced past the last directory element, that iterator shall become equal to the end iterator value. The `directory_iterator` default constructor shall create an iterator equal to the end iterator value, and this shall be the only valid iterator for the end condition.

4 The end iterator is not dereferenceable.

5 Two end iterators are always equal. An end iterator shall not be equal to a non-end iterator.

6 The result of calling the `path()` member of the `directory_entry` object obtained by dereferencing a `directory_iterator` is a reference to a `path` object composed of the directory argument from which the iterator was constructed with filename of the directory entry appended as if by `operator/=`.

7 Directory iteration shall not yield directory entries for the current (dot) and parent (dot-dot) directories.

8 The order of directory entries obtained by dereferencing successive increments of a `directory_iterator` is unspecified.

9 Constructors and non-const `directory_iterator` member functions store the values of any cached attributes (27.11.11) in the `directory_entry` element returned by `operator*()`. `directory_iterator` member functions shall not directly or indirectly call any `directory_entry refresh` function. [Note: The exact mechanism for storing cached attribute values is not exposed to users. For exposition, class `directory_iterator` is shown in 27.11.11 as a friend of class `directory_entry`. — end note]
[Note: Programs performing directory iteration may wish to test if the path obtained by dereferencing a directory iterator actually exists. It could be a symbolic link to a non-existent file. Programs recursively walking directory trees for purposes of removing and renaming entries may wish to avoid following symbolic links. — end note]

[Note: If a file is removed from or added to a directory after the construction of a directory_iterator for the directory, it is unspecified whether or not subsequently incrementing the iterator will ever result in an iterator referencing the removed or added directory entry. See POSIX readdir_r. — end note]

### 27.11.12.1 directory_iterator members

directory_iterator() noexcept;

**Effects:** Constructs the end iterator.

explicit directory_iterator(const path& p);
directory_iterator(const path& p, directory_options options);
directory_iterator(const path& p, error_code& ec);
directory_iterator(const path& p, directory_options options, error_code& ec);

**Effects:** For the directory that `p` resolves to, constructs an iterator for the first element in a sequence of directory_entry elements representing the files in the directory, if any; otherwise the end iterator. However, if

```
(options & directory_options::skip_permission_denied) != directory_options::none
```

and construction encounters an error indicating that permission to access `p` is denied, constructs the end iterator and does not report an error.

**Throws:** As specified in 27.11.6.

[Note: To iterate over the current directory, use directory_iterator(".") rather than directory_iterator("""). — end note]

directory_iterator(const directory_iterator& rhs);
directory_iterator(directory_iterator&& rhs) noexcept;

**Effects:** Constructs an object of class directory_iterator.

**Ensures:** `*this` has the original value of `rhs`.

directory_iterator& operator=(const directory_iterator& rhs);
directory_iterator& operator=(directory_iterator&& rhs) noexcept;

**Effects:** If `*this` and `rhs` are the same object, the member has no effect.

**Ensures:** `*this` has the original value of `rhs`.

**Returns:** `*this`.

directory_iterator& operator++();
directory_iterator& increment(error_code& ec);

**Effects:** As specified for the prefix increment operation of Input iterators (22.2.3).

**Returns:** `*this`.

**Throws:** As specified in 27.11.6.

### 27.11.12.2 directory_iterator non-member functions

These functions enable range access for directory_iterator.

directory_iterator begin(directory_iterator iter) noexcept;

**Returns:** `iter`.

directory_iterator end(const directory_iterator&) noexcept;

**Returns:** directory_iterator().

§ 27.11.12.2
27.11.13 Class recursive_directory_iterator

An object of type recursive_directory_iterator provides an iterator for a sequence of directory_entry elements representing the files in a directory or in an implementation-defined directory-like file type, and its sub-directories.

namespace std::filesystem {
    class recursive_directory_iterator {
    public:
        using iterator_category = input_iterator_tag;
        using value_type = directory_entry;
        using difference_type = ptrdiff_t;
        using pointer = const directory_entry*;
        using reference = const directory_entry&;

        // 27.11.13.1, constructors and destructor
        recursive_directory_iterator() noexcept;
        explicit recursive_directory_iterator(const path& p);
        recursive_directory_iterator(const path& p, directory_options options);
        recursive_directory_iterator(const path& p, directory_options options,
                                       error_code& ec);
        recursive_directory_iterator(const path& p, error_code& ec);
        recursive_directory_iterator(const recursive_directory_iterator& rhs);
        recursive_directory_iterator(recursive_directory_iterator&& rhs) noexcept;
        ~recursive_directory_iterator();

        // 27.11.13.1, observers
        directory_options options() const;
        int depth() const;
        bool recursion_pending() const;

        const directory_entry& operator*() const;
        const directory_entry* operator->() const;

        // 27.11.13.1, modifiers
        recursive_directory_iterator&
        operator=(const recursive_directory_iterator& rhs);
        recursive_directory_iterator&
        operator=(recursive_directory_iterator&& rhs) noexcept;

        recursive_directory_iterator& operator++();
        recursive_directory_iterator& increment(error_code& ec);

        void pop();
        void pop(error_code& ec);
        void disable_recursion_pending();
    } // other members as required by 22.2.3, input iterators
};

2 Calling options, depth, recursion_pending, pop or disable_recursion_pending on an iterator that is not dereferenceable results in undefined behavior.

3 The behavior of a recursive_directory_iterator is the same as a directory_iterator unless otherwise specified.

4 [Note: If the directory structure being iterated over contains cycles then the end iterator may be unreachable. — end note]

27.11.13.1 recursive_directory_iterator members

recursive_directory_iterator() noexcept;

Effects: Constructs the end iterator.

§ 27.11.13.1 1258
explicit recursive_directory_iterator(const path& p);
recursive_directory_iterator(const path& p, directory_options options);
recursive_directory_iterator(const path& p, directory_options options, error_code& ec);
recursive_directory_iterator(const path& p, error_code& ec);

Effects: Constructs an iterator representing the first entry in the directory to which p resolves, if any; otherwise, the end iterator. However, if (options & directory_options::skip_permission_denied) != directory_options::none and construction encounters an error indicating that permission to access p is denied, constructs the end iterator and does not report an error.

Ensures: options() == options for the signatures with a directory_options argument, otherwise options() == directory_options::none.

Throws: As specified in 27.11.6.

[Note: To iterate over the current directory, use recursive_directory_iterator(".") rather than recursive_directory_iterator(""). — end note]

[Note: By default, recursive_directory_iterator does not follow directory symlinks. To follow directory symlinks, specify options as directory_options::follow_directory_symlink — end note]

recursive_directory_iterator(const recursive_directory_iterator& rhs);

Effects: Constructs an object of class recursive_directory_iterator.

Ensures:

(8.1) — options() == rhs.options()
(8.2) — depth() == rhs.depth()
(8.3) — recursion_pending() == rhs.recursion_pending()

recursive_directory_iterator(recursive_directory_iterator& rhs) noexcept;

Effects: Constructs an object of class recursive_directory_iterator.

Ensures: options(), depth(), and recursion_pending() have the values that rhs.options(), rhs.depth(), and rhs.recursion_pending(), respectively, had before the function call.

recursive_directory_iterator& operator=(const recursive_directory_iterator& rhs);

Effects: If *this and rhs are the same object, the member has no effect.

Ensures:

(12.1) — options() == rhs.options()
(12.2) — depth() == rhs.depth()
(12.3) — recursion_pending() == rhs.recursion_pending()

Returns: *this.

recursive_directory_iterator& operator=(recursive_directory_iterator& rhs) noexcept;

Effects: If *this and rhs are the same object, the member has no effect.

Ensures: options(), depth(), and recursion_pending() have the values that rhs.options(), rhs.depth(), and rhs.recursion_pending(), respectively, had before the function call.

Returns: *this.

directory_options options() const;

Returns: The value of the argument passed to the constructor for the options parameter, if present, otherwise directory_options::none.

Throws: Nothing.

int depth() const;

Returns: The current depth of the directory tree being traversed. [Note: The initial directory is depth 0, its immediate subdirectories are depth 1, and so forth. — end note]
20  Throws: Nothing.

bool recursion_pending() const;

21  Returns: true if disable_recursion_pending() has not been called subsequent to the prior construction or increment operation, otherwise false.

22  Throws: Nothing.

recursive_directory_iterator& operator++();
recursive_directory_iterator& increment(error_code& ec);

23  Effects: As specified for the prefix increment operation of Input iterators (22.2.3), except that:

(23.1) — If there are no more entries at the current depth, then if depth() != 0 iteration over the parent directory resumes; otherwise *this = recursive_directory_iterator().

(23.2) — Otherwise if

recursion_pending() && is_directory((*this)->status()) && (!is_symlink((*this)->symlink_status()) || (options() & directory_options::follow_directory_symlink) != directory_options::none)

then either directory (*this)->path() is recursively iterated into or, if

(options() & directory_options::skip_permission_denied) != directory_options::none

and an error occurs indicating that permission to access directory (*this)->path() is denied, then directory (*this)->path() is treated as an empty directory and no error is reported.

24  Returns: *this.

25  Throws: As specified in 27.11.6.

void pop();
void pop(error_code& ec);

26  Effects: If depth() == 0, set *this to recursive_directory_iterator(). Otherwise, cease iteration of the directory currently being iterated over, and continue iteration over the parent directory.

27  Ensures: Any copies of the previous value of *this are no longer required to be dereferenceable nor to be in the domain of ==.

28  Throws: As specified in 27.11.6.

void disable_recursion_pending();

29  Ensures: recursion_pending() == false.

30  [Note: disable_recursion_pending() is used to prevent unwanted recursion into a directory. — end note]

27.11.13.2 recursive_directory_iterator non-member functions [fs.rec.dir.itr.nonmembers]

These functions enable use of recursive_directory_iterator with range-based for statements.

recursive_directory_iterator begin(recursive_directory_iterator iter) noexcept;

2  Returns: iter.

recursive_directory_iterator end(const recursive_directory_iterator&) noexcept;

3  Returns: recursive_directory_iterator().

27.11.14 Filesystem operation functions [fs.op.funcs]

Filesystem operation functions query or modify files, including directories, in external storage.

2  [Note: Because hardware failures, network failures, file system races (27.11.2.3), and many other kinds of errors occur frequently in file system operations, users should be aware that any filesystem operation function, no matter how apparently innocuous, may encounter an error; see 27.11.6. — end note]

27.11.14.1 Absolute [fs.op.absolute]

path absolute(const path& p);
path absolute(const path& p, error_code& ec);

Effects: Composes an absolute path referencing the same file system location as p according to the operating system (27.11.2.2).

Returns: The composed path. The signature with argument ec returns path() if an error occurs.

[Note: For the returned path, rp, rp.is_absolute() is true unless an error occurs. —end note]

Throws: As specified in 27.11.6.

[Note: To resolve symlinks, or perform other sanitization which might require queries to secondary storage, such as hard disks, consider canonical (27.11.14.2). —end note]

[Note: Implementations are strongly encouraged to not query secondary storage, and not consider !exists(p) an error. —end note]

[Example: For POSIX-based operating systems, absolute(p) is simply current_path()/p. For Windows-based operating systems, absolute might have the same semantics as GetFullPathNameW. —end example]

27.11.14.2 Canonical [fs.op.canonical]

path canonical(const path& p);
path canonical(const path& p, error_code& ec);

Effects: Converts p to an absolute path that has no symbolic link, dot, or dot-dot elements in its pathname in the generic format.

Returns: A path that refers to the same file system object as absolute(p). The signature with argument ec returns path() if an error occurs.

Throws: As specified in 27.11.6.

Remarks: !exists(p) is an error.

27.11.14.3 Copy [fs.op.copy]

void copy(const path& from, const path& to);

Effects: Equivalent to copy(from, to, copy_options::none).

void copy(const path& from, const path& to, error_code& ec);

Effects: Equivalent to copy(from, to, copy_options::none, ec).

void copy(const path& from, const path& to, copy_options options);
void copy(const path& from, const path& to, copy_options options, error_code& ec);

Requires: At most one element from each option group (27.11.9.3) is set in options.

Effects: Before the first use of f and t:

(4.1) If

(options & copy_options::create_symlinks) != copy_options::none ||
(options & copy_options::skip_symlinks) != copy_options::none

then auto f = symlink_status(from) and if needed auto t = symlink_status(to).

(4.2) Otherwise, if

(options & copy_options::copy_symlinks) != copy_options::none

then auto f = symlink_status(from) and if needed auto t = status(to).

(4.3) Otherwise, auto f = status(from) and if needed auto t = status(to).

Effects are then as follows:

(4.4) If f.type() or t.type() is an implementation-defined file type (27.11.9.2), then the effects are implementation-defined.

(4.5) Otherwise, an error is reported as specified in 27.11.6 if:

(4.5.1) exists(f) is false, or

(4.5.2) equivalent(from, to) is true, or
is_other(f) || is_other(t) is true, or

is_directory(f) && is_regular_file(t) is true.

Otherwise, if is_symlink(f), then:

- If (options & copy_options::skip_symlinks) != copy_options::none then return.
- Otherwise if !exists(t) && (options & copy_options::copy_symlinks) != copy_options::none then copy_symlink(from, to).

Otherwise report an error as specified in 27.11.6.

Otherwise, if is_regular_file(f), then:

- If (options & copy_options::directories_only) != copy_options::none, then return.
- Otherwise, if (options & copy_options::create_symlinks) != copy_options::none, then create a symbolic link to the source file.
- Otherwise, if (options & copy_options::create_hard_links) != copy_options::none, then create a hard link to the source file.
- Otherwise, if is_directory(t), then copy_file(from, to/from.filename(), options).
- Otherwise, copy_file(from, to, options).

Otherwise, if

is_directory(f) && (options & copy_options::recursive) != copy_options::none || options == copy_options::none

then:

- If exists(t) is false, then create_directory(to, from).
- Then, iterate over the files in from, as if by

  for (const directory_entry& x : directory_iterator(from))
  
  copy(x.path(), to/x.path().filename(),
       options | copy_options::in-recursive-copy);

  where in-recursive-copy is a bitmask element of copy_options that is not one of the elements in 27.11.9.3.

Otherwise, for the signature with argument ec, ec.clear().

Otherwise, no effects.

Throws: As specified in 27.11.6.

Remarks: For the signature with argument ec, any library functions called by the implementation shall have an error_code argument if applicable.

[Example: Given this directory structure:

```
/dir1
  file1
  file2
dir2
  file3
```

Calling copy("/dir1", "/dir3") would result in:

```
/dir1
  file1
  file2
dir2
  file3
/dir3
  file1
  file2
```

Alternatively, calling copy("/dir1", "/dir3", copy_options::recursive) would result in:
27.11.14.4 Copy file

bool copy_file(const path& from, const path& to);
bool copy_file(const path& from, const path& to, error_code& ec);

1 Returns: copy_file(from, to, copy_options::none) or
   copy_file(from, to, copy_options::none, ec), respectively.

2 Throws: As specified in 27.11.6.

bool copy_file(const path& from, const path& to, copy_options options);
bool copy_file(const path& from, const path& to, copy_options options,
               error_code& ec);

3 Requires: At most one element from each option group (27.11.9.3) is set in options.

4 Effects: As follows:

   (4.1) — Report an error as specified in 27.11.6 if:
          — is_regular_file(from) is false, or
          — exists(to) is true and is_regular_file(to) is false, or
          — exists(to) is true and equivalent(from, to) is true, or
          — exists(to) is true and
              (options & (copy_options::skip_existing |
                  copy_options:: overwrite_existing |
                  copy_options::update_existing)) == copy_options::none

   (4.2) — Otherwise, copy the contents and attributes of the file from resolves to, to the file to resolves to, if:
          — exists(to) is false, or
          — (options & copy_options::overwrite_existing) != copy_options::none, or
          — (options & copy_options::update_existing) != copy_options::none and from is more recent than to, determined as if by use of the last_write_time function (27.11.14.25).

   (4.3) — Otherwise, no effects.

5 Returns: true if the from file was copied, otherwise false. The signature with argument ec returns false if an error occurs.

6 Throws: As specified in 27.11.6.

7 Complexity: At most one direct or indirect invocation of status(to).

27.11.14.5 Copy symlink

void copy_symlink(const path& existing_symlink, const path& new_symlink);
void copy_symlink(const path& existing_symlink, const path& new_symlink,
                  error_code& ec) noexcept;

1 Effects: Equivalent to function(read_symlink(existing_symlink), new_symlink) or
function(read_symlink(existing_symlink, ec), new_symlink, ec), respectively, where in each case function is create_symlink or create_directory_symlink as appropriate.

2 Throws: As specified in 27.11.6.
27.11.14.6 Create directories

```cpp
bool create_directories(const path& p);
bool create_directories(const path& p, error_code& ec);
```

**Effects:** Calls `create_directory()` for each element of `p` that does not exist.

**Returns:** `true` if a new directory was created for the directory `p` resolves to, otherwise `false`. The signature with argument `ec` returns `false` if an error occurs.

**Throws:** As specified in 27.11.6.

**Complexity:** $O(n)$ where $n$ is the number of elements of `p`.

27.11.14.7 Create directory

```cpp
bool create_directory(const path& p);
bool create_directory(const path& p, error_code& ec) noexcept;
```

**Effects:** Creates the directory `p` resolves to, as if by POSIX `mkdir()` with a second argument of `static_cast<int>(perms::all)`. Creation failure because `p` already exists is not an error.

**Returns:** `true` if a new directory was created, otherwise `false`. The signature with argument `ec` returns `false` if an error occurs.

**Throws:** As specified in 27.11.6.

27.11.14.8 Create directory symlink

```cpp
void create_directory_symlink(const path& to, const path& new_symlink);
void create_directory_symlink(const path& to, const path& new_symlink,
                             error_code& ec) noexcept;
```

**Effects:** Establishes the postcondition, as if by POSIX `symlink()`.

**Ensures:** `new_symlink` resolves to a symbolic link file that contains an unspecified representation of `to`.

**Throws:** As specified in 27.11.6.

[Note: Some operating systems require symlink creation to identify that the link is to a directory. Portable code should use `create_directory_symlink()` to create directory symlinks rather than `create_symlink()` — end note]

27.11.14.9 Create hard link

```cpp
void create_hard_link(const path& to, const path& new_hard_link);
void create_hard_link(const path& to, const path& new_hard_link,
                      error_code& ec) noexcept;
```

**Effects:** Establishes the postcondition, as if by POSIX `link()`.

**Ensures:**

(2.1) `exists(to) && exists(new_hard_link) && equivalent(to, new_hard_link)`

(2.2) The contents of the file or directory `to` resolves to are unchanged.
Throws: As specified in 27.11.6.

[Note: Some operating systems do not support hard links at all or support them only for regular files. Some file systems (such as the FAT file system) do not support hard links regardless of the operating system. Some file systems limit the number of links per file. — end note]

27.11.14.10 Create symlink [fs.op.create_symlink]

void create_symlink(const path& to, const path& new_symlink);
void create_symlink(const path& to, const path& new_symlink, error_code& ec) noexcept;

Effects: Establishes the postcondition, as if by POSIX symlink().
Ensures: new_symlink resolves to a symbolic link file that contains an unspecified representation of to.
Throws: As specified in 27.11.6.

[Note: Some operating systems do not support symbolic links at all or support them only for regular files. Some file systems (such as the FAT file system) do not support symbolic links regardless of the operating system. — end note]

27.11.14.11 Current path [fs.op.current_path]

path current_path();
path current_path(error_code& ec);

Returns: The absolute path of the current working directory, whose pathname in the native format is obtained as if by POSIX getcwd(). The signature with argument ec returns path() if an error occurs.

Throws: As specified in 27.11.6.

Remarks: The current working directory is the directory, associated with the process, that is used as the starting location in pathname resolution for relative paths.

[Note: The current_path() name was chosen to emphasize that the returned value is a path, not just a single directory name. — end note]

[Note: The current path as returned by many operating systems is a dangerous global variable. It may be changed unexpectedly by third-party or system library functions, or by another thread. — end note]

void current_path(const path& p);
void current_path(const path& p, error_code& ec) noexcept;

Effects: Establishes the postcondition, as if by POSIX chdir().
Ensures: equivalent(p, current_path()).
Throws: As specified in 27.11.6.

[Note: The current path for many operating systems is a dangerous global state. It may be changed unexpectedly by a third-party or system library functions, or by another thread. — end note]

27.11.14.12 Equivalent [fs.op.equivalent]

bool equivalent(const path& p1, const path& p2);
bool equivalent(const path& p1, const path& p2, error_code& ec) noexcept;

Returns: true, if p1 and p2 resolve to the same file system entity, else false. The signature with argument ec returns false if an error occurs.

Two paths are considered to resolve to the same file system entity if two candidate entities reside on the same device at the same location. [Note: On POSIX platforms, this is determined as if by the values of the POSIX stat structure, obtained as if by stat() for the two paths, having equal st_dev values and equal st_ino values. — end note]

Remarks: !exists(p1) || !exists(p2) is an error.

Throws: As specified in 27.11.6.
27.11.14.13  Exists

bool exists(file_status s) noexcept;

1    Returns: status_known(s) && s.type() != file_type::not_found.

bool exists(const path& p);

bool exists(const path& p, error_code& ec) noexcept;

1    Let s be a file_status, determined as if by status(p) or status(p, ec), respectively.
2    Effects: The signature with argument ec calls ec.clear() if status_known(s).
3    Returns: exists(s).
4    Throws: As specified in 27.11.6.

27.11.14  File size

uintmax_t file_size(const path& p);

uintmax_t file_size(const path& p, error_code& ec) noexcept;

1    Effects: If exists(p) is false, an error is reported (27.11.6).
2    Returns:
3        (2.1) — If is_regular_file(p), the size in bytes of the file p resolves to, determined as if by the value of
4            the POSIX stat structure member st_size obtained as if by POSIX stat().
5        (2.2) — Otherwise, the result is implementation-defined.
6            The signature with argument ec returns static_cast<uintmax_t>(-1) if an error occurs.
7    Throws: As specified in 27.11.6.

27.11.15  Hard link count

uintmax_t hard_link_count(const path& p);

uintmax_t hard_link_count(const path& p, error_code& ec) noexcept;

1    Returns: The number of hard links for p. The signature with argument ec returns static_cast<uintmax_t>(-1) if an error occurs.
2    Throws: As specified in 27.11.6.

27.11.16  Is block file

bool is_block_file(file_status s) noexcept;

1    Returns: s.type() == file_type::block.

bool is_block_file(const path& p);

bool is_block_file(const path& p, error_code& ec) noexcept;

1    Returns: is_block_file(status(p)) or is_block_file(status(p, ec)), respectively. The signature with argument ec returns false if an error occurs.
2    Throws: As specified in 27.11.6.

27.11.17  Is character file

bool is_character_file(file_status s) noexcept;

1    Returns: s.type() == file_type::character.

bool is_character_file(const path& p);

bool is_character_file(const path& p, error_code& ec) noexcept;

1    Returns: is_character_file(status(p)) or is_character_file(status(p, ec)), respectively. The signature with argument ec returns false if an error occurs.
2    Throws: As specified in 27.11.6.
27.11.14.18  Is directory

bool is_directory(file_status s) noexcept;

Returns: s.type() == file_type::directory.

bool is_directory(const path& p);
bool is_directory(const path& p, error_code& ec) noexcept;

Returns: is_directory(status(p)) or is_directory(status(p, ec)), respectively. The signature
with argument ec returns false if an error occurs.

Throws: As specified in 27.11.6.

27.11.14.19  Is empty

bool is_empty(const path& p);
bool is_empty(const path& p, error_code& ec);

Effects:

(1.1) — Determine file_status s, as if by status(p) or status(p, ec), respectively.
(1.2) — For the signature with argument ec, return false if an error occurred.
(1.3) — Otherwise, if is_directory(s):

(1.3.1) — Create a variable itr, as if by directory_iterator itr(p) or directory_iterator itr(p,
ec), respectively.
(1.3.2) — For the signature with argument ec, return false if an error occurred.
(1.3.3) — Otherwise, return itr == directory_iterator().

(1.4) — Otherwise:

(1.4.1) — Determine uintmax_t sz, as if by file_size(p) or file_size(p, ec), respectively.
(1.4.2) — For the signature with argument ec, return false if an error occurred.
(1.4.3) — Otherwise, return sz == 0.

Throws: As specified in 27.11.6.

27.11.14.20  Is fifo

bool is_fifo(file_status s) noexcept;

Returns: s.type() == file_type::fifo.

bool is_fifo(const path& p);
bool is_fifo(const path& p, error_code& ec) noexcept;

Returns: is_fifo(status(p)) or is_fifo(status(p, ec)), respectively. The signature with argu-
ment ec returns false if an error occurs.

Throws: As specified in 27.11.6.

27.11.14.21  Is other

bool is_other(file_status s) noexcept;

Returns: exists(s) && !is_regular_file(s) && !is_directory(s) && !is_symlink(s).

bool is_other(const path& p);
bool is_other(const path& p, error_code& ec) noexcept;

Returns: is_other(status(p)) or is_other(status(p, ec)), respectively. The signature with
argument ec returns false if an error occurs.

Throws: As specified in 27.11.6.

27.11.14.22  Is regular file

bool is_regular_file(file_status s) noexcept;

Returns: s.type() == file_type::regular.
bool is_regular_file(const path& p);

Returns: is_regular_file(status(p)).

Throws: filesystem_error if status(p) would throw filesystem_error.

bool is_regular_file(const path& p, error_code& ec) noexcept;

Effects: Sets ec as if by status(p, ec). [Note: file_type::none, file_type::not_found and file_type::unknown cases set ec to error values. To distinguish between cases, call the status function directly. — end note]

Returns: is_regular_file(status(p, ec)). Returns false if an error occurs.

27.11.14.23 Is socket [fs.op.is_socket]

bool is_socket(file_status s) noexcept;

Returns: s.type() == file_type::socket.

bool is_socket(const path& p);
bool is_socket(const path& p, error_code& ec) noexcept;

Returns: is_socket(status(p)) or is_socket(status(p, ec)), respectively. The signature with argument ec returns false if an error occurs.

Throws: As specified in 27.11.6.

27.11.14.24 Is symlink [fs.op.is_symlink]

bool is_symlink(file_status s) noexcept;

Returns: s.type() == file_type::symlink.

bool is_symlink(const path& p);
bool is_symlink(const path& p, error_code& ec) noexcept;

Returns: is_symlink(symlink_status(p)) or is_symlink(symlink_status(p, ec)), respectively. The signature with argument ec returns false if an error occurs.

Throws: As specified in 27.11.6.

27.11.14.25 Last write time [fs.op.last_write_time]

file_time_type last_write_time(const path& p);
file_time_type last_write_time(const path& p, error_code& ec) noexcept;

Returns: The time of last data modification of p, determined as if by the value of the POSIX stat structure member st_mtime obtained as if by POSIX stat(). The signature with argument ec returns file_time_type::min() if an error occurs.

Throws: As specified in 27.11.6.

void last_write_time(const path& p, file_time_type new_time);
void last_write_time(const path& p, file_time_type new_time,
error_code& ec) noexcept;

Effects: Sets the time of last data modification of the file resolved to by p to new_time, as if by POSIX futimens().

Throws: As specified in 27.11.6.

[Note: A postcondition of last_write_time(p) == new_time is not specified since it might not hold for file systems with coarse time granularity. — end note]

27.11.14.26 Permissions [fs.op.permissions]

void permissions(const path& p, perms prms, perm_options opts=perm_options::replace);
void permissions(const path& p, perms prms, error_code& ec) noexcept;
void permissions(const path& p, perms prms, perm_options opts, error_code& ec);

Requires: Exactly one of the perm_options constants replace, add, or remove is present in opts.

Remarks: The second signature behaves as if it had an additional parameter perm_options opts with an argument of perm_options::replace.
Effects: Applies the action specified by \texttt{opts} to the file \texttt{p} resolves to, or to file \texttt{p} itself if \texttt{p} is a symbolic link and \texttt{perm_options::nofollow} is set in \texttt{opts}. The action is applied as if by POSIX \texttt{fchmodat()}. [\textit{Note}: Conceptually permissions are viewed as bits, but the actual implementation may use some other mechanism. — end note]

Throws: As specified in 27.11.6.

27.11.14.27 Proximate [fs.op.proximate]

\begin{verbatim}
path proximate(const path& p, error_code& ec);
\end{verbatim}

\begin{verbatim}
Returns: proximate(p, current_path(), ec).
\end{verbatim}

\begin{verbatim}
Throws: As specified in 27.11.6.
\end{verbatim}

27.11.14.28 Read symlink [fs.op.read_symlink]

\begin{verbatim}
path read_symlink(const path& p);
\end{verbatim}

\begin{verbatim}
path read_symlink(const path& p, error_code& ec);
\end{verbatim}

\begin{verbatim}
Returns: If \texttt{p} resolves to a symbolic link, a \texttt{path} object containing the contents of that symbolic link. The signature with argument \texttt{ec} returns \texttt{path()} if an error occurs.
\end{verbatim}

\begin{verbatim}
Throws: As specified in 27.11.6. [\textit{Note}: It is an error if \texttt{p} does not resolve to a symbolic link. — end note]
\end{verbatim}

27.11.14.29 Relative [fs.op.relative]

\begin{verbatim}
path relative(const path& p, error_code& ec);
\end{verbatim}

\begin{verbatim}
path relative(const path& p, const path& base = current_path());
\end{verbatim}

\begin{verbatim}
path relative(const path& p, const path& base, error_code& ec);
\end{verbatim}

\begin{verbatim}
Returns: For the first form:
weakly_canonical(p).lexically_relative(weakly_canonical(base));
\end{verbatim}

\begin{verbatim}
For the second form:
weakly_canonical(p, ec).lexically_relative(weakly_canonical(base, ec));
or \texttt{path()} at the first error occurrence, if any.
\end{verbatim}

\begin{verbatim}
Throws: As specified in 27.11.6.
\end{verbatim}

27.11.14.30 Remove [fs.op.remove]

\begin{verbatim}
bool remove(const path& p);
\end{verbatim}

\begin{verbatim}
bool remove(const path& p, error_code& ec) noexcept;
\end{verbatim}

\begin{verbatim}
Effects: If \texttt{exists(symlink_status(p, ec))}, the file \texttt{p} is removed as if by POSIX \texttt{remove()}. [\textit{Note}: A symbolic link is itself removed, rather than the file it resolves to. — end note]
\end{verbatim}

\begin{verbatim}
Ensures: \texttt{exists(symlink_status(p))} is \texttt{false}.
\end{verbatim}

\begin{verbatim}
Returns: \texttt{false} if \texttt{p} did not exist, otherwise \texttt{true}. The signature with argument \texttt{ec} returns \texttt{false} if an error occurs.
\end{verbatim}
Throws: As specified in 27.11.6.

27.11.14.31 Remove all

uintmax_t remove_all(const path& p);
uintmax_t remove_all(const path& p, error_code& ec);
1 Effects: Recursively deletes the contents of p if it exists, then deletes file p itself, as if by POSIX remove(). [Note: A symbolic link is itself removed, rather than the file it resolves to. — end note]
2 Ensures: exists(symlink_status(p)) is false.
3 Returns: The number of files removed. The signature with argument ec returns static_cast<uintmax_t>(-1) if an error occurs.
4 Throws: As specified in 27.11.6.

27.11.14.32 Rename

void rename(const path& old_p, const path& new_p);
void rename(const path& old_p, const path& new_p, error_code& ec) noexcept;
1 Effects: Renames old_p to new_p, as if by POSIX rename().
[Note:
(1.1) — If old_p and new_p resolve to the same existing file, no action is taken.
(1.2) — Otherwise, the rename may include the following effects:
(1.2.1) — if new_p resolves to an existing non-directory file, new_p is removed; otherwise,
(1.2.2) — if new_p resolves to an existing directory, new_p is removed if empty on POSIX compliant operating systems but may be an error on other operating systems.
A symbolic link is itself renamed, rather than the file it resolves to. — end note]
2 Throws: As specified in 27.11.6.

27.11.14.33 Resize file

void resize_file(const path& p, uintmax_t new_size);
void resize_file(const path& p, uintmax_t new_size, error_code& ec) noexcept;
1 Effects: Causes the size that would be returned by file_size(p) to be equal to new_size, as if by POSIX truncate().
2 Throws: As specified in 27.11.6.

27.11.14.34 Space

space_info space(const path& p);
space_info space(const path& p, error_code& ec) noexcept;
1 Returns: An object of type space_info. The value of the space_info object is determined as if by using POSIX statvfs to obtain a POSIX struct statvfs, and then multiplying its f_blocks, f_bfree, and f_bavail members by its f_fsize member, and assigning the results to the capacity, free, and available members respectively. Any members for which the value cannot be determined shall be set to static_cast<uintmax_t>(-1). For the signature with argument ec, all members are set to static_cast<uintmax_t>(-1) if an error occurs.
2 Throws: As specified in 27.11.6.
3 Remarks: The value of member space_info::available is operating system dependent. [Note: available may be less than free. — end note]

27.11.14.35 Status

file_status status(const path& p);
1 Effects: As if:
   error_code ec;
   file_status result = status(p, ec);
if (result.type() == file_type::none)
    throw filesystem_error(implementation-supplied-message, p, ec);
return result;

Returns: See above.

Throws: filesystem_error. [Note: result values of file_status(file_type::not_found) and
file_status(file_type::unknown) are not considered failures and do not cause an exception to be
thrown. —end note]

file_status status(const path& p, error_code& ec) noexcept;

Effects: If possible, determines the attributes of the file p resolves to, as if by using POSIX stat()

Let prms denote the result of (m & perms::mask), where m is determined as if by converting the
st_mode member of the obtained struct stat to the type perms.

Returns:

(6.1) — If ec != error_code():

(6.1.1) — If the specific error indicates that p cannot be resolved because some element of the path does
not exist, returns file_status(file_type::not_found).

(6.1.2) — Otherwise, if the specific error indicates that p can be resolved but the attributes cannot be
determined, returns file_status(file_type::unknown).

(6.1.3) — Otherwise, returns file_status(file_type::none).

[Note: These semantics distinguish between p being known not to exist, p existing but not being
able to determine its attributes, and there being an error that prevents even knowing if p exists.
These distinctions are important to some use cases. —end note]

(6.2) — Otherwise,

(6.2.1) — If the attributes indicate a regular file, as if by POSIX S_ISREG, returns file_status(file_type::regular, prms). [Note: file_type::regular implies appropriate <fstream> operations would succeed, assuming no hardware, permission, access, or file system race errors. Lack of file_type::regular does not necessarily imply <fstream> operations would fail on a directory. —end note]

(6.2.2) — Otherwise, if the attributes indicate a directory, as if by POSIX S_ISDIR, returns file_status(file_type::directory, prms). [Note: file_type::directory implies that calling directory_iterator(p) would succeed. —end note]

(6.2.3) — Otherwise, if the attributes indicate a block special file, as if by POSIX S_ISBLK, returns file_status(file_type::block, prms).

(6.2.4) — Otherwise, if the attributes indicate a character special file, as if by POSIX S_ISCHR, returns file_status(file_type::character, prms).

(6.2.5) — Otherwise, if the attributes indicate a fifo or pipe file, as if by POSIX S_ISFIFO, returns file_status(file_type::fifo, prms).

(6.2.6) — Otherwise, if the attributes indicate a socket, as if by POSIX S_ISSOCK, returns file_status(file_type::socket, prms).

(6.2.7) — Otherwise, if the attributes indicate an implementation-defined file type (27.11.9.2), returns file_status(file_type::A, prms), where A is the constant for the implementation-defined file type.

(6.2.8) — Otherwise, returns file_status(file_type::unknown, prms).

Remarks: If a symbolic link is encountered during pathname resolution, pathname resolution continues
using the contents of the symbolic link.
27.11.14.36 Status known

bool status_known(file_status s) noexcept;

Returns: s.type() != file_type::none.

27.11.14.37 Symlink status

file_status symlink_status(const path& p);
file_status symlink_status(const path& p, error_code& ec) noexcept;

Effects: Same as status(), above, except that the attributes of p are determined as if by using POSIX lstat() to obtain a POSIX struct stat.

Let prms denote the result of (m & perms::mask), where m is determined as if by converting the st_mode member of the obtained struct stat to the type perms.

Returns: Same as status(), above, except that if the attributes indicate a symbolic link, as if by POSIX S_ISLNK, returns file_status(file_type::symlink, prms). The signature with argument ec returns file_status(file_type::none) if an error occurs.

Remarks: Pathname resolution terminates if p names a symbolic link.

Throws: As specified in 27.11.6.

27.11.14.38 Temporary directory path

path temp_directory_path();
path temp_directory_path(error_code& ec);

Let p be an unspecified directory path suitable for temporary files.

Effects: If exists(p) is false or is_directory(p) is false, an error is reported (27.11.6).

Returns: The path p. The signature with argument ec returns path() if an error occurs.

Throws: As specified in 27.11.6.

[Example: For POSIX-based operating systems, an implementation might return the path supplied by the first environment variable found in the list TMPDIR, TMP, TEMP, TEMPDIR, or if none of these are found, "/tmp". For Windows-based operating systems, an implementation might return the path reported by the Windows GetTempPath API function. — end example]

27.11.14.39 Weakly canonical

path weakly_canonical(const path& p);
path weakly_canonical(const path& p, error_code& ec);

Returns: p with symlinks resolved and the result normalized (27.11.7.1).

Effects: Using status(p) or status(p, ec), respectively, to determine existence, return a path composed by operator/= from the result of calling canonical() with a path argument composed of the leading elements of p that exist, if any, followed by the elements of p that do not exist, if any. For the first form, canonical() is called without an error_code argument. For the second form, canonical() is called with ec as an error_code argument, and path() is returned at the first error occurrence, if any.

Ensures: The returned path is in normal form (27.11.7.1).

Remarks: Implementations should avoid unnecessary normalization such as when canonical has already been called on the entirety of p.

Throws: As specified in 27.11.6.

§ 27.12.2
The contents and meaning of the header `<cinttypes>` are the same as the C standard library header `<inttypes.h>`, with the following changes:

1. The header `<cinttypes>` includes the header `<cstdint>` instead of `<stdint.h>`, and
2. if and only if the type `intmax_t` designates an extended integer type (6.7.1), the following function signatures are added:
   ```
   intmax_t abs(intmax_t);
   imaxdiv_t div(intmax_t, intmax_t);
   ```
   which shall have the same semantics as the function signatures `intmax_t imaxabs(intmax_t)` and `imaxdiv_t imaxdiv(intmax_t, intmax_t)`, respectively.

28 Regular expressions library

28.1 General

This Clause describes components that C++ programs may use to perform operations involving regular expression matching and searching.

The following subclauses describe a basic regular expression class template and its traits that can handle char-like (20.1) template arguments, two specializations of this class template that handle sequences of char and wchar_t, a class template that holds the result of a regular expression match, a series of algorithms that allow a character sequence to be operated upon by a regular expression, and two iterator types for enumerating regular expression matches, as summarized in Table 123.

28.2 Definitions

The following definitions shall apply to this Clause:

28.2.1 collating element

collating element

a sequence of one or more characters within the current locale that collate as if they were a single character.

28.2.2 finite state machine

finite state machine

an unspecified data structure that is used to represent a regular expression, and which permits efficient matches against the regular expression to be obtained.

28.2.3 format specifier

format specifier

a sequence of one or more characters that is to be replaced with some part of a regular expression match.

28.2.4 matched

matched

a sequence of zero or more characters is matched by a regular expression when the characters in the sequence correspond to a sequence of characters defined by the pattern.

28.2.5 primary equivalence class

primary equivalence class

a set of one or more characters which share the same primary sort key: that is the sort key weighting that depends only upon character shape, and not accents, case, or locale specific tailorings.
regular expression

a pattern that selects specific strings from a set of character strings.

sub-expression

a subset of a regular expression that has been marked by parenthesis.

28.3 Requirements

1. This subclause defines requirements on classes representing regular expression traits. [Note: The class template regex_traits, defined in 28.7, satisfies these requirements. — end note]

2. The class template basic_regex, defined in 28.8, needs a set of related types and functions to complete the definition of its semantics. These types and functions are provided as a set of member typedef-names and functions in the template parameter traits used by the basic_regex class template. This subclause defines the semantics of these members.

3. To specialize class template basic_regex for a character container CharT and its related regular expression traits class Traits, use basic_regex<CharT, Traits>.

4. In Table 124 X denotes a traits class defining types and functions for the character container type charT; u is an object of type X; v is an object of type const X; p is a value of type const charT*; I1 and I2 are input iterators (22.2.3); F1 and F2 are forward iterators (22.2.5); c is a value of type const charT; s is an object of type X::string_type; cs is an object of type const X::string_type; b is a value of type bool; I is a value of type int; cl is an object of type X::char_class_type, and loc is an object of type X::locale_type.

<table>

<td>A bitmask type (15.4.2.1.4).</td>
<td>A bitmask type representing a particular character classification.</td>
</tr>
<tr>
<td>X::length(p)</td>
<td>size_t</td>
<td>Yields the smallest i such that p[i] == 0. Complexity is linear in i.</td>
</tr>
<tr>
<td>v.translate(c)</td>
<td>X::char_type</td>
<td>Returns a character such that for any character d that is to be considered equivalent to c then v.translate(c) == v.translate(d).</td>
</tr>
<tr>
<td>v.translate_nocase(c)</td>
<td>X::char_type</td>
<td>For all characters C that are to be considered equivalent to c when comparisons are to be performed without regard to case, then v.translate_nocase(c) == v.translate_nocase(C).</td>
</tr>
<tr>
<td>v.transform(F1, F2)</td>
<td>X::string_type</td>
<td>Returns a sort key for the character sequence designated by the iterator range [F1, F2) such that if the character sequence [G1, G2) sorts before the character sequence [H1, H2) then v.transform(G1, G2) &lt; v.transform(H1, H2).</td>
</tr>
</tbody>
</table>
Table 124 — Regular expression traits class requirements (continued)

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return type</th>
<th>Assertion/note pre-/post-condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>v.transform_primary(F1, F2)</td>
<td>X::string_type</td>
<td>Returns a sort key for the character sequence designated by the iterator range [F1, F2) such that if the character sequence [G1, G2) sorts before the character sequence [H1, H2) when character case is not considered then v.transform_primary(G1, G2) &lt; v.transform_primary(H1, H2).</td>
</tr>
<tr>
<td>v.lookup_collatename(F1, F2)</td>
<td>X::string_type</td>
<td>Returns a sequence of characters that represents the collating element consisting of the character sequence designated by the iterator range [F1, F2). Returns an empty string if the character sequence is not a valid collating element.</td>
</tr>
<tr>
<td>v.lookup_classname(F1, F2, b)</td>
<td>X::char_class_type</td>
<td>Converts the character sequence designated by the iterator range [F1, F2) into a value of a bitmask type that can subsequently be passed to isctype. Values returned from lookup_classname can be bitwise or’ed together; the resulting value represents membership in either of the corresponding character classes. If b is true, the returned bitmask is suitable for matching characters without regard to their case. Returns 0 if the character sequence is not the name of a character class recognized by X. The value returned shall be independent of the case of the characters in the sequence.</td>
</tr>
<tr>
<td>v.isctype(c, cl)</td>
<td>bool</td>
<td>Returns true if character c is a member of one of the character classes designated by cl, false otherwise.</td>
</tr>
<tr>
<td>v.value(c, I)</td>
<td>int</td>
<td>Returns the value represented by the digit c in base I if the character c is a valid digit in base I; otherwise returns -1. [Note: The value of I will only be 8, 10, or 16. — end note]</td>
</tr>
<tr>
<td>u.imbue(loc)</td>
<td>X::locale_type</td>
<td>Imbues u with the locale loc and returns the previous locale used by u if any.</td>
</tr>
<tr>
<td>v.getloc()</td>
<td>X::locale_type</td>
<td>Returns the current locale used by v, if any.</td>
</tr>
</tbody>
</table>

5 [Note: Class template regex_traits satisfies the requirements for a regular expression traits class when it is specialized for char or wchar_t. This class template is described in the header <regex>, and is described in 28.7. — end note]

28.4 Header <regex> synopsis

28.5 Namespace std::regex_constants

The namespace std::regex_constants holds symbolic constants used by the regular expression library. This namespace provides three types, syntax_option_type, match_flag_type, and error_type, along with several constants of these types.

28.5.1 Bitmask type syntax_option_type

The type syntax_option_type is an implementation-defined bitmask type (15.4.2.1.4). Setting its elements has the effects listed in Table 125. A valid value of type syntax_option_type shall have at most one of the grammar elements ECMAScript, basic, extended, awk, grep, egrep, set. If no grammar element is set, the default grammar is ECMAScript.

28.5.2 Bitmask type match_flag_type
Table 125 — syntax_option_type effects

<table>
<thead>
<tr>
<th>Element</th>
<th>Effect(s) if set</th>
</tr>
</thead>
<tbody>
<tr>
<td>icase</td>
<td>Specifies that matching of regular expressions against a character container sequence shall be performed without regard to case.</td>
</tr>
<tr>
<td>nosubs</td>
<td>Specifies that no sub-expressions shall be considered to be marked, so that when a regular expression is matched against a character container sequence, no sub-expression matches shall be stored in the supplied match_results structure.</td>
</tr>
<tr>
<td>optimize</td>
<td>Specifies that the regular expression engine should pay more attention to the speed with which regular expressions are matched, and less to the speed with which regular expression objects are constructed. Otherwise it has no detectable effect on the program output.</td>
</tr>
<tr>
<td>collate</td>
<td>Specifies that character ranges of the form &quot;[a-b]&quot; shall be locale sensitive.</td>
</tr>
<tr>
<td>ECMAScript</td>
<td>Specifies that the grammar recognized by the regular expression engine shall be that used by ECMAScript in ECMA-262, as modified in 28.13. See also: ECMA-262 15.10</td>
</tr>
<tr>
<td>basic</td>
<td>Specifies that the grammar recognized by the regular expression engine shall be that used by basic regular expressions in POSIX. See also: POSIX, Base Definitions and Headers, Section 9.3</td>
</tr>
<tr>
<td>extended</td>
<td>Specifies that the grammar recognized by the regular expression engine shall be that used by extended regular expressions in POSIX. See also: POSIX, Base Definitions and Headers, Section 9.4</td>
</tr>
<tr>
<td>awk</td>
<td>Specifies that the grammar recognized by the regular expression engine shall be that used by the utility awk in POSIX.</td>
</tr>
<tr>
<td>grep</td>
<td>Specifies that the grammar recognized by the regular expression engine shall be that used by the utility grep in POSIX.</td>
</tr>
<tr>
<td>egrep</td>
<td>Specifies that the grammar recognized by the regular expression engine shall be that used by the utility grep when given the -E option in POSIX.</td>
</tr>
<tr>
<td>multiline</td>
<td>Specifies that ^ shall match the beginning of a line and $ shall match the end of a line, if the ECMAScript engine is selected.</td>
</tr>
</tbody>
</table>

The type match_flag_type is an implementation-defined bitmask type (15.4.2.1.4). The constants of that type, except for match_default and format_default, are bitmask elements. The match_default and format_default constants are empty bitmasks. Matching a regular expression against a sequence of characters (first, last) proceeds according to the rules of the grammar specified for the regular expression object, modified according to the effects listed in Table 126 for any bitmask elements set.

Table 126 — regex_constants::match_flag_type effects when obtaining a match against a character container sequence (first, last).

<table>
<thead>
<tr>
<th>Element</th>
<th>Effect(s) if set</th>
</tr>
</thead>
<tbody>
<tr>
<td>match_not_bol</td>
<td>The first character in the sequence (first, last) shall be treated as though it is not at the beginning of a line, so the character ^ in the regular expression shall not match [first, first].</td>
</tr>
<tr>
<td>match_not_eol</td>
<td>The last character in the sequence (first, last) shall be treated as though it is not at the end of a line, so the character $&quot; in the regular expression shall not match [last, last].</td>
</tr>
<tr>
<td>match_not_bow</td>
<td>The expression \b shall not match the sub-sequence (first, first).</td>
</tr>
<tr>
<td>match_not_eow</td>
<td>The expression \b shall not match the sub-sequence (last, last).</td>
</tr>
<tr>
<td>match_any</td>
<td>If more than one match is possible then any match is an acceptable result.</td>
</tr>
<tr>
<td>match_not_null</td>
<td>The expression shall not match an empty sequence.</td>
</tr>
<tr>
<td>match_continuous</td>
<td>The expression shall only match a sub-sequence that begins at first.</td>
</tr>
</tbody>
</table>
Table 126 — `regex_constants::match_flag_type` effects when obtaining a match against a character container sequence `[first, last)`. (continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Effect(s) if set</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>match_prev_avail</code></td>
<td><code>--first</code> is a valid iterator position. When this flag is set the flags <code>match_not_bol</code> and <code>match_not_bow</code> shall be ignored by the regular expression algorithms (28.11) and iterators (28.12).</td>
</tr>
<tr>
<td><code>format_default</code></td>
<td>When a regular expression match is to be replaced by a new string, the new string shall be constructed using the rules used by the ECMAScript replace function in ECMA-262, part 15.5.4.11 String.prototype.replace. In addition, during search and replace operations all non-overlapping occurrences of the regular expression shall be located and replaced, and sections of the input that did not match the expression shall be copied unchanged to the output string.</td>
</tr>
<tr>
<td><code>format_sed</code></td>
<td>When a regular expression match is to be replaced by a new string, the new string shall be constructed using the rules used by the sed utility in POSIX.</td>
</tr>
<tr>
<td><code>format_no_copy</code></td>
<td>During a search and replace operation, sections of the character container sequence being searched that do not match the regular expression shall not be copied to the output string.</td>
</tr>
<tr>
<td><code>format_first_only</code></td>
<td>When specified during a search and replace operation, only the first occurrence of the regular expression shall be replaced.</td>
</tr>
</tbody>
</table>

28.5.3 Implementation-defined `error_type`

```
namespace std::regex_constants {
    using error_type = T3;
    inline constexpr error_type error_collate = unspecified;
    inline constexpr error_type error_ctype = unspecified;
    inline constexpr error_type error_escape = unspecified;
    inline constexpr error_type error_backref = unspecified;
    inline constexpr error_type error_brack = unspecified;
    inline constexpr error_type error_paren = unspecified;
    inline constexpr error_type error_brace = unspecified;
    inline constexpr error_type error_badbrace = unspecified;
    inline constexpr error_type error_range = unspecified;
    inline constexpr error_type error_space = unspecified;
    inline constexpr error_type error_badrepeat = unspecified;
    inline constexpr error_type error_complexity = unspecified;
    inline constexpr error_type error_stack = unspecified;
}
```

1 The type `error_type` is an implementation-defined enumerated type (15.4.2.1.3). Values of type `error_type` represent the error conditions described in Table 127:

Table 127 — `error_type` values in the C locale

<table>
<thead>
<tr>
<th>Value</th>
<th>Error condition</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>error_collate</code></td>
<td>The expression contained an invalid collating element name.</td>
</tr>
<tr>
<td><code>error_ctype</code></td>
<td>The expression contained an invalid character class name.</td>
</tr>
<tr>
<td><code>error_escape</code></td>
<td>The expression contained an invalid escaped character, or a trailing escape.</td>
</tr>
<tr>
<td><code>error_backref</code></td>
<td>The expression contained an invalid back reference.</td>
</tr>
<tr>
<td><code>error_brack</code></td>
<td>The expression contained mismatched [ and ].</td>
</tr>
<tr>
<td><code>error_paren</code></td>
<td>The expression contained mismatched ( and ).</td>
</tr>
<tr>
<td><code>error_brace</code></td>
<td>The expression contained mismatched { and }.</td>
</tr>
<tr>
<td><code>error_badbrace</code></td>
<td>The expression contained an invalid range in a {} expression.</td>
</tr>
<tr>
<td><code>error_range</code></td>
<td>The expression contained an invalid character range, such as [b-a] in most encodings.</td>
</tr>
<tr>
<td><code>error_space</code></td>
<td>There was insufficient memory to convert the expression into a finite state machine.</td>
</tr>
</tbody>
</table>
Table 127 — error_type values in the C locale (continued)

<table>
<thead>
<tr>
<th>Value</th>
<th>Error condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>error_badrepeat</td>
<td>One of *?+{ was not preceded by a valid regular expression.</td>
</tr>
<tr>

<td>The complexity of an attempted match against a regular expression exceeded a</td>
</tr>
<tr>
<td></td>
<td>pre-set level.</td>
</tr>
<tr>
<td>error_stack</td>
<td>There was insufficient memory to determine whether the regular expression could</td>
</tr>
<tr>
<td></td>
<td>match the specified character sequence.</td>
</tr>
</tbody>
</table>

28.6 Class regex_error

class regex_error : public runtime_error {
  public:
    explicit regex_error(regex_constants::error_type ecode);
    regex_constants::error_type code() const;
};

1 The class regex_error defines the type of objects thrown as exceptions to report errors from the regular expression library.

regex_error(regex_constants::error_type ecode);

2 Effects: Constructs an object of class regex_error.

regex_constants::error_type code() const;

3 Ensures: ecode == code().

regex_constants::error_type code() const;

4 Returns: The error code that was passed to the constructor.

28.7 Class template regex_traits

namespace std {
  template<class charT>
  struct regex_traits {
    using char_type = charT;
    using string_type = basic_string<char_type>;
    using locale_type = locale;
    using char_class_type = bitmask_type;

    regex_traits();
    static size_t length(const char_type* p);
    charT translate(charT c) const;
    charT translate_nocase(charT c) const;
    template<class ForwardIterator>
    string_type transform(ForwardIterator first, ForwardIterator last) const;
    template<class ForwardIterator>
    string_type transform_primary(ForwardIterator first, ForwardIterator last) const;
    template<class ForwardIterator>
    string_type lookup_collatename(ForwardIterator first, ForwardIterator last) const;
    template<class ForwardIterator>
    char_class_type lookup_classname(ForwardIterator first, ForwardIterator last, bool icase = false) const;
    bool isctype(charT c, char_class_type f) const;
    int value(charT ch, int radix) const;
    locale_type imbue(locale_type l);
    locale_type getloc() const;
  };
}

1 The specializations regex_traits<char> and regex_traits<wchar_t> shall be valid and shall satisfy the requirements for a regular expression traits class (28.3).
The type `char_class_type` is used to represent a character classification and is capable of holding an implementation specific set returned by `lookup_classname`.

```cpp
using char_class_type = bitmask_type;
```

```cpp
static size_t length(const char_type* p);
Returns: char_traits<charT>::length(p).
```

```cpp
charT translate(charT c) const;
Returns: c.
```

```cpp
charT translate_nocase(charT c) const;
Returns: use_facet<ctype<charT>>(getloc()).tolower(c).
```

```cpp
template<class ForwardIterator>
string_type transform(ForwardIterator first, ForwardIterator last) const;
Effects: As if by:
string_type str(first, last);
return use_facet<collate<charT>>(getloc()).transform(&*str.begin(), &*str.begin() + str.length());
```

```cpp
template<class ForwardIterator>
string_type transform_primary(ForwardIterator first, ForwardIterator last) const;
Effects: If
typeid(use_facet<collate<charT>>()) == typeid(collate_byname<charT>)
and the form of the sort key returned by collate_byname<charT>::transform(first, last) is known and can be converted into a primary sort key then returns that key, otherwise returns an empty string.
```

```cpp
template<class ForwardIterator>
string_type lookup_collatename(ForwardIterator first, ForwardIterator last) const;
Returns: A sequence of one or more characters that represents the collating element consisting of the character sequence designated by the iterator range `[first, last)`. Returns an empty string if the character sequence is not a valid collating element.
```

```cpp
template<class ForwardIterator>
char_class_type lookup_classname(
    ForwardIterator first, ForwardIterator last, bool icase = false) const;
Returns: An unspecified value that represents the character classification named by the character sequence designated by the iterator range `[first, last)`. If the parameter `icase` is `true` then the returned mask identifies the character classification without regard to the case of the characters being matched, otherwise it does honor the case of the characters being matched.\(^\text{331}\) The value returned shall be independent of the case of the characters in the character sequence. If the name is not recognized then returns `char_class_type()`.
```

```cpp
bool isctype(charT c, char_class_type f) const;
Effects: Determines if the character `c` is a member of the character classification represented by `f`.
Returns: Given the following function declaration:

```
// for exposition only
template<class C>
ctype_base::mask convert(typename regex_traits<C>::char_class_type f);
```
that returns a value in which each `ctype_base::mask` value corresponding to a value in `f` named in Table 128 is set, then the result is determined as if by:

\(^\text{331}\) For example, if the parameter `icase` is `true` then `[:lower:]` is the same as `[:alpha:]`. 

§ 28.7 1288
ctype_base::mask m = convert<charT>(f);
const ctype<charT>& ct = use_facet<ctype<charT>>(getloc());
if (ct.is(m, c)) {
    return true;
} else if (c == ct.widen('_')) {
    charT w[1] = { ct.widen('w') };
    char_class_type x = lookup_classname(w, w+1);
    return (f&x) == x;
} else {
    return false;
}

[Example:
    regex_traits<char> t;
    string d("d");
    string u("upper");
    regex_traits<char>::char_class_type f;
    f = t.lookup_classname(d.begin(), d.end());
    f |= t.lookup_classname(u.begin(), u.end());
    ctype_base::mask m = convert<char>(f); // m == ctype_base::digit|ctype_base::upper
    —end example]

    regex_traits<char> t;
    string w("w");
    regex_traits<char>::char_class_type f;
    f = t.lookup_classname(w.begin(), w.end());
    t.isctype('A', f); // returns true
    t.isctype('_', f); // returns true
    t.isctype(' ', f); // returns false
    —end example]

int value(charT ch, int radix) const;

    Requires: The value of radix shall be 8, 10, or 16.
    Returns: The value represented by the digit ch in base radix if the character ch is a valid digit in base radix; otherwise returns -1.

locale_type imbue(locale_type loc);

    Effects: Imbues this with a copy of the locale loc. [Note: Calling imbue with a different locale than the one currently in use invalidates all cached data held by *this. —end note]
    Returns: If no locale has been previously imbued then a copy of the global locale in effect at the time of construction of *this, otherwise a copy of the last argument passed to imbue.
    Ensures: getloc() == loc.

locale_type getloc() const;

    Returns: If no locale has been imbued then a copy of the global locale in effect at the time of construction of *this, otherwise a copy of the last argument passed to imbue.

28.8 Class template basic_regex

    [re.regex]

1 For a char-like type charT, specializations of class template basic_regex represent regular expressions constructed from character sequences of charT characters. In the rest of 28.8, charT denotes a given char-like type. Storage for a regular expression is allocated and freed as necessary by the member functions of class basic_regex.

2 Objects of type specialization of basic_regex are responsible for converting the sequence of charT objects to an internal representation. It is not specified what form this representation takes, nor how it is accessed by algorithms that operate on regular expressions. [Note: Implementations will typically declare some function templates as friends of basic_regex to achieve this —end note]

3 The functions described in this Clause report errors by throwing exceptions of type regex_error.

28.8.1 basic_regex constructors
[re.regex.construct]
basic_regex();

Effects: Constructs an object of class basic_regex that does not match any character sequence.

explicit basic_regex(const charT* p, flag_type f = regex_constants::ECMAScript);

Requires: p shall not be a null pointer.

Throws: regex_error if p is not a valid regular expression.

Effects: Constructs an object of class basic_regex; the object’s internal finite state machine is
constructed from the regular expression contained in the array of charT of length char_traits<charT>::length(p) whose
first element is designated by p, and interpreted according to the flags f.

Ensures: flags() returns f. mark_count() returns the number of marked sub-expressions within the
expression.

basic_regex(const charT* p, size_t len, flag_type f = regex_constants::ECMAScript);

Requires: p shall not be a null pointer.

Throws: regex_error if p is not a valid regular expression.

Effects: Constructs an object of class basic_regex; the object’s internal finite state machine is
constructed from the regular expression contained in the sequence of characters [p, p+len), and
interpreted according to the flags specified in f.
Ensures: flags() returns \( f \). mark_count() returns the number of marked sub-expressions within the expression.

\[
\text{basic_regex(const basic_regex& } e);\]

Effects: Constructs an object of class basic_regex as a copy of the object \( e \).

Ensures: flags() and mark_count() return \( e.\text{flags()} \) and \( e.\text{mark_count()} \), respectively.

\[
\text{basic_regex(basic_regex&& } e) \text{ noexcept;}\]

Effects: Move constructs an object of class basic_regex from \( e \).

Ensures: flags() and mark_count() return the values that \( e.\text{flags()} \) and \( e.\text{mark_count()} \), respectively, had before construction. \( e \) is in a valid state with unspecified value.

\[
\text{template<class ST, class SA> }\]
\[
\text{explicit basic_regex(const basic_string<charT, ST, SA>& } s, \quad \text{flag_type } f = \text{regex_constants::ECMAScript});\]

\[
\text{Throws: regex_error if } s \text{ is not a valid regular expression.}\]

Effects: Constructs an object of class basic_regex: the object’s internal finite state machine is constructed from the regular expression contained in the string \( s \), and interpreted according to the flags specified in \( f \).

Ensures: flags() returns \( f \). mark_count() returns the number of marked sub-expressions within the expression.

\[
\text{template<class ForwardIterator> }\]
\[
\text{basic_regex(ForwardIterator first, ForwardIterator last, } \quad \text{flag_type } f = \text{regex_constants::ECMAScript});\]

\[
\text{Throws: regex_error if the sequence } \text{[first, last)} \text{ is not a valid regular expression.}\]

Effects: Constructs an object of class basic_regex: the object’s internal finite state machine is constructed from the regular expression contained in the sequence of characters \( \text{[first, last)} \), and interpreted according to the flags specified in \( f \).

Ensures: flags() returns \( f \). mark_count() returns the number of marked sub-expressions within the expression.

\[
\text{basic_regex(initializer_list<charT> il, flag_type } f = \text{regex_constants::ECMAScript});\]

Effects: Same as basic_regex(il.begin(), il.end(), \( f \)).

\[
\text{28.8.2 basic_regex assign } \quad [\text{re.regex.assign}]\]

\[
\text{basic_regex& operator=(const basic_regex& } e);\]

Effects: Copies \( e \) into *this and returns *this.

Ensures: flags() and mark_count() return \( e.\text{flags()} \) and \( e.\text{mark_count()} \), respectively.

\[
\text{basic_regex& operator=(basic_regex&& } e) \text{ noexcept;}\]

Effects: Move assigns from \( e \) into *this and returns *this.

Ensures: flags() and mark_count() return the values that \( e.\text{flags()} \) and \( e.\text{mark_count()} \), respectively, had before assignment. \( e \) is in a valid state with unspecified value.

\[
\text{basic_regex& operator=(const charT* } ptr);\]

Requires: \( ptr \) shall not be a null pointer.

Effects: Returns assign(ptr).

\[
\text{basic_regex& operator=(initializer_list<charT> } il);\]

Effects: Returns assign(il.begin(), il.end()).

\[
\text{template<class ST, class SA> }\]
\[
\text{basic_regex& operator=(const basic_string<charT, ST, SA>& } p);\]

Effects: Returns assign(p).
basic_regex& assign(const basic_regex& that);

Effects: Equivalent to: return *this = that;

basic_regex& assign(basic_regex&& that) noexcept;

Effects: Equivalent to: return *this = std::move(that);

basic_regex& assign(const charT* ptr, flag_type f = regex_constants::ECMAScript);

Returns: assign(string_type(ptr), f).

basic_regex& assign(const charT* ptr, size_t len, flag_type f = regex_constants::ECMAScript);

Returns: assign(string_type(ptr, len), f).

template<class string_traits, class A>
basic_regex& assign(const basic_string<charT, string_traits, A>& s,
                    flag_type f = regex_constants::ECMAScript);

Throws: regex_error if s is not a valid regular expression.

Returns: *this.

Effects: Assigns the regular expression contained in the string s, interpreted according the flags specified in f. If an exception is thrown, *this is unchanged.

Ensures: If no exception is thrown, flags() returns f and mark_count() returns the number of marked sub-expressions within the expression.

template<class InputIterator>
basic_regex& assign(InputIterator first, InputIterator last,
                    flag_type f = regex_constants::ECMAScript);

Requires: InputIterator shall satisfy the Cpp17InputIterator requirements (22.2.3).

Returns: assign(string_type(first, last), f).

basic_regex& assign(initializer_list<charT> il,
                    flag_type f = regex_constants::ECMAScript);

Effects: Same as assign(il.begin(), il.end(), f).

Returns: *this.

28.8.3 basic_regex constant operations

unsigned mark_count() const;

Effects: Returns the number of marked sub-expressions within the regular expression.

flag_type flags() const;

Effects: Returns a copy of the regular expression syntax flags that were passed to the object’s constructor or to the last call to assign.

28.8.4 basic_regex locale

locale_type imbue(locale_type loc);

Effects: Returns the result of traits_inst.imbue(loc) where traits_inst is a (default-initialized) instance of the template type argument traits stored within the object. After a call to imbue the basic_regex object does not match any character sequence.

locale_type getloc() const;

Effects: Returns the result of traits_inst.getloc() where traits_inst is a (default-initialized) instance of the template parameter traits stored within the object.

28.8.5 basic_regex swap

void swap(basic_regex& e);

Effects: Swaps the contents of the two regular expressions.
**Ensures:** *this contains the regular expression that was in e, e contains the regular expression that was in *this.

**Complexity:** Constant time.

### 28.8.6 basic_regex non-member functions

**28.8.6.1 basic_regex non-member swap**

```cpp
template<class charT, class traits>
void swap(basic_regex<charT, traits>& lhs, basic_regex<charT, traits>& rhs);
```

**Effects:** Calls lhs.swap(rhs).

### 28.9 Class template sub_match

Class template `sub_match` denotes the sequence of characters matched by a particular marked sub-expression.

```cpp
namespace std {
    template<class BidirectionalIterator>
    class sub_match : public pair<BidirectionalIterator, BidirectionalIterator> {
        public:
            using value_type = typename iterator_traits<BidirectionalIterator>::value_type;
            using difference_type = typename iterator_traits<BidirectionalIterator>::difference_type;
            using iterator = BidirectionalIterator;
            using string_type = basic_string<value_type>;
            bool matched;

            constexpr sub_match();

            difference_type length() const;
            operator string_type() const;
            string_type str() const;

            int compare(const sub_match& s) const;
            int compare(const string_type& s) const;
            int compare(const value_type* s) const;
    };
}
```

### 28.9.1 sub_match members

```cpp
constexpr sub_match();
```

**Effects:** Value-initializes the pair base class subobject and the member matched.

```cpp
difference_type length() const;
```

**Returns:** matched ? distance(first, second) : 0.

```cpp
operator string_type() const;
```

**Returns:** matched ? string_type(first, second) : string_type().

```cpp
string_type str() const;
```

**Returns:** matched ? string_type(first, second) : string_type().

```cpp
int compare(const sub_match& s) const;
```

**Returns:** str().compare(s.str()).

```cpp
int compare(const string_type& s) const;
```

**Returns:** str().compare(s).

```cpp
int compare(const value_type* s) const;
```

**Returns:** str().compare(s).
§ 28.9.2  sub_match non-member operators

```
// re.submatch.op

template<class BiIter>
bool operator==(const sub_match<BiIter>& lhs, const sub_match<BiIter>& rhs);

    Returns: lhs.compare(rhs) == 0.

template<class BiIter>
bool operator!=(const sub_match<BiIter>& lhs, const sub_match<BiIter>& rhs);

    Returns: lhs.compare(rhs) != 0.

template<class BiIter>
bool operator<(const sub_match<BiIter>& lhs, const sub_match<BiIter>& rhs);

    Returns: lhs.compare(rhs) < 0.

template<class BiIter>
bool operator>(const sub_match<BiIter>& lhs, const sub_match<BiIter>& rhs);

    Returns: lhs.compare(rhs) > 0.

template<class BiIter>
bool operator<=(const sub_match<BiIter>& lhs, const sub_match<BiIter>& rhs);

    Returns: lhs.compare(rhs) <= 0.

template<class BiIter>
bool operator>=(const sub_match<BiIter>& lhs, const sub_match<BiIter>& rhs);

    Returns: lhs.compare(rhs) >= 0.

template<class BiIter, class ST, class SA>
bool operator==(const basic_string<typename iterator_traits<BiIter>::value_type, ST, SA>& lhs, const sub_match<BiIter>& rhs);

    Returns: rhs.compare(typename sub_match<BiIter>::string_type(lhs.data(), lhs.size())) == 0.

template<class BiIter, class ST, class SA>
bool operator!=(const basic_string<typename iterator_traits<BiIter>::value_type, ST, SA>& lhs, const sub_match<BiIter>& rhs);

    Returns: !(lhs == rhs).

template<class BiIter, class ST, class SA>
bool operator<(const basic_string<typename iterator_traits<BiIter>::value_type, ST, SA>& lhs, const sub_match<BiIter>& rhs);

    Returns: rhs.compare(typename sub_match<BiIter>::string_type(lhs.data(), lhs.size())) > 0.

template<class BiIter, class ST, class SA>
bool operator>(const basic_string<typename iterator_traits<BiIter>::value_type, ST, SA>& lhs, const sub_match<BiIter>& rhs);

    Returns: rhs < lhs.

template<class BiIter, class ST, class SA>
bool operator<=(const basic_string<typename iterator_traits<BiIter>::value_type, ST, SA>& lhs, const sub_match<BiIter>& rhs);

    Returns: !(rhs < lhs).
```
template<class BiIter, class ST, class SA>
bool operator>=(
    const basic_string<typename iterator_traits<BiIter>::value_type, ST, SA>& lhs,
    const sub_match<BiIter>& rhs);

\textit{Returns:} !(lhs < rhs).

template<class BiIter, class ST, class SA>
bool operator==(const typename iterator_traits<BiIter>::value_type* lhs,
               const sub_match<BiIter>& rhs);

\textit{Returns:} rhs.compare(lhs) == 0.

template<class BiIter, class ST, class SA>
bool operator!=(const typename iterator_traits<BiIter>::value_type* lhs,
               const sub_match<BiIter>& rhs);

\textit{Returns:} !(lhs == rhs).

template<class BiIter, class ST, class SA>
bool operator<(const typename iterator_traits<BiIter>::value_type* lhs,
               const sub_match<BiIter>& rhs);

\textit{Returns:} rhs.compare(lhs) > 0.
template<class BiIter>
bool operator>(const typename iterator_traits<BiIter>::value_type* lhs,
const sub_match<BiIter>& rhs);

Returns: rhs < lhs.

template<class BiIter>
bool operator<=(const typename iterator_traits<BiIter>::value_type* lhs,
const sub_match<BiIter>& rhs);

Returns: !(rhs < lhs).

template<class BiIter>
bool operator>=(const typename iterator_traits<BiIter>::value_type* lhs,
const sub_match<BiIter>& rhs);

Returns: !(lhs < rhs).

template<class BiIter>
bool operator==(const sub_match<BiIter>& lhs,
const typename iterator_traits<BiIter>::value_type* rhs);

Returns: rhs.compare(rhs) == 0.

template<class BiIter>
bool operator!=(const sub_match<BiIter>& lhs,
const typename iterator_traits<BiIter>::value_type* rhs);

Returns: !(lhs == rhs).

template<class BiIter>
bool operator<(const sub_match<BiIter>& lhs,
const typename iterator_traits<BiIter>::value_type& rhs);

Returns: rhs.compare(lhs) < 0.

§ 28.9.2 1297
```cpp
template<class BiIter>
bool operator>(const typename iterator_traits<BiIter>::value_type& lhs,
const sub_match<BiIter>& rhs);

Returns: rhs < lhs.

template<class BiIter>
bool operator<=(const typename iterator_traits<BiIter>::value_type& lhs,
const sub_match<BiIter>& rhs);

Returns: !(rhs < lhs).

template<class BiIter>
bool operator>=(const typename iterator_traits<BiIter>::value_type& lhs,
const sub_match<BiIter>& rhs);

Returns: !(lhs < rhs).

template<class BiIter>
bool operator==(const sub_match<BiIter>& lhs,
const typename iterator_traits<BiIter>::value_type& rhs);

Returns: lhs.compare(typename sub_match<BiIter>::string_type(1, rhs)) == 0.

template<class BiIter>
bool operator!=(const sub_match<BiIter>& lhs,
const typename iterator_traits<BiIter>::value_type& rhs);

Returns: !(lhs == rhs).

template<class BiIter>
bool operator<(const sub_match<BiIter>& lhs,
const typename iterator_traits<BiIter>::value_type& rhs);

Returns: rhs < lhs.

template<class BiIter>
bool operator<=(const sub_match<BiIter>& lhs,
const typename iterator_traits<BiIter>::value_type& rhs);

Returns: !(rhs < lhs).

template<class BiIter>
bool operator>=(const sub_match<BiIter>& lhs,
const typename iterator_traits<BiIter>::value_type& rhs);

Returns: !(lhs < rhs).

template<class BiIter, class charT, class ST, class BiIter>
basic_ostream<charT, ST>&
operator<<(basic_ostream<charT, ST>& os, const sub_match<BiIter>& m);

Returns: os << m.str().
```

# 28.10 Class template match_results

Class template `match_results` denotes a collection of character sequences representing the result of a regular expression match. Storage for the collection is allocated and freed as necessary by the member functions of class template `match_results`.

The class template `match_results` satisfies the requirements of an allocator-aware container and of a sequence container (21.2.1, 21.2.3) except that only operations defined for const-qualified sequence containers are supported and that the semantics of comparison functions are different from those required for a container.

A default-constructed `match_results` object has no fully established result state. A match result is `ready` when, as a consequence of a completed regular expression match modifying such an object, its result state...
becomes fully established. The effects of calling most member functions from a `match_results` object that is not ready are undefined.

4 The `sub_match` object stored at index 0 represents sub-expression 0, i.e., the whole match. In this case the `sub_match` member `matched` is always `true`. The `sub_match` object stored at index n denotes what matched the marked sub-expression n within the matched expression. If the sub-expression n participated in a regular expression match then the `sub_match` member `matched` evaluates to `true`, and members `first` and `second` denote the range of characters ([`first`, `second`]) which formed that match. Otherwise `matched` is `false`, and members `first` and `second` point to the end of the sequence that was searched. [Note: The `sub_match` objects representing different sub-expressions that did not participate in a regular expression match need not be distinct. — end note]

```
namespace std {
    template<class BidirectionalIterator,
             class Allocator = allocator<sub_match<BidirectionalIterator>>>  
    class match_results {
public:
    using value_type = sub_match<BidirectionalIterator>; 
    using const_reference = const value_type&; 
    using reference = value_type&; 
    using const_iterator = implementation-defined; 
    using iterator = const_iterator; 
    using difference_type = 
        typename iterator_traits<BidirectionalIterator>::difference_type; 
    using size_type = typename allocator_traits<Allocator>::size_type; 
    using allocator_type = Allocator; 
    using char_type = 
        typename iterator_traits<BidirectionalIterator>::value_type; 
    using string_type = basic_string<char_type>; 

    // 28.10.1, construct/copy/destroy
    match_results() : match_results(Allocator()) {} 
    explicit match_results(const Allocator&); 
    match_results(const match_results& m); 
    match_results(match_results&& m) noexcept; 
    match_results& operator=(const match_results& m); 
    match_results& operator=(match_results&& m); 
    ~match_results();

    // 28.10.2, state
    bool ready() const; 

    // 28.10.3, size
    size_type size() const; 
    size_type max_size() const; 
    [[nodiscard]] bool empty() const; 

    // 28.10.4, element access
    difference_type length(size_type sub = 0) const; 
    difference_type position(size_type sub = 0) const; 
    string_type str(size_type sub = 0) const; 
    const_reference operator[](size_type n) const; 
    const_reference prefix() const; 
    const_reference suffix() const; 
    const_iterator begin() const; 
    const_iterator end() const; 
    const_iterator cbegin() const; 
    const_iterator cend() const; 

    // 28.10.5, format
    template<class OutputIter>
    OutputIter
    format(OutputIter out,
```
const char_type* fmt_first, const char_type* fmt_last,
regex_constants::match_flag_type flags = regex_constants::format_default) const;

-template<class OutputIter, class ST, class SA>
OutputIter
format(OutputIter out,
const basic_string<char_type, ST, SA>& fmt,
regex_constants::match_flag_type flags = regex_constants::format_default) const;

template<class ST, class SA>
basic_string<char_type, ST, SA>
format(const basic_string<char_type, ST, SA>& fmt,
regex_constants::match_flag_type flags = regex_constants::format_default) const;

string_type
format(const char_type* fmt,
regex_constants::match_flag_type flags = regex_constants::format_default) const;

// 28.10.6, allocator
allocator_type get_allocator() const;

// 28.10.7, swap
void swap(match_results& that);
});// 28.10.1 1300

28.10.1 match_results constructors

In all match_results constructors, a copy of the Allocator argument shall be used for any memory allocation performed by the constructor or member functions during the lifetime of the object.

explicit match_results(const Allocator& a);

Effects: Constructs an object of class match_results.

Ensures: ready() returns false. size() returns 0.

match_results(const match_results& m);

Effects: Constructs an object of class match_results, as a copy of m.

match_results(match_results&& m) noexcept;

Effects: Move constructs an object of class match_results from m satisfying the same postconditions as Table 129. Additionally, the stored Allocator value is move constructed from m.get_allocator().

Throws: Nothing.

match_results& operator=(const match_results& m);

Effects: Assigns m to *this. The postconditions of this function are indicated in Table 129.

match_results& operator=(match_results&& m);

Effects: Move-assigns m to *this. The postconditions of this function are indicated in Table 129.

<tr>
<td>position(n)</td>
<td>m.position(n) for all integers n &lt; m.size()</td>
</tr>
</tbody>
</table>
28.10.2 match_results state

bool ready() const;  
Returns: true if *this has a fully established result state, otherwise false.

28.10.3 match_results size

size_type size() const;  
Returns: One plus the number of marked sub-expressions in the regular expression that was matched if *this represents the result of a successful match. Otherwise returns 0. [Note: The state of a match_results object can be modified only by passing that object to regex_match or regex_search. Subclauses 28.11.2 and 28.11.3 specify the effects of those algorithms on their match_results arguments. —end note]

size_type max_size() const;  
Returns: The maximum number of sub_match elements that can be stored in *this.

[[nodiscard]] bool empty() const;  
Returns: size() == 0.

28.10.4 match_results element access

difference_type length(size_type sub = 0) const;  
Requires: ready() == true.  
Returns: (*this)[sub].length().

difference_type position(size_type sub = 0) const;  
Requires: ready() == true.  
Returns: The distance from the start of the target sequence to (*this)[sub].first.

string_type str(size_type sub = 0) const;  
Requires: ready() == true.  
Returns: string_type((*this)[sub]).

const_reference operator[](size_type n) const;  
Requires: ready() == true.  
Returns: A reference to the sub_match object representing the character sequence that matched marked sub-expression n. If n == 0 then returns a reference to a sub_match object representing the character sequence that matched the whole regular expression. If n >= size() then returns a sub_match object representing an unmatched sub-expression.

const_reference prefix() const;  
Requires: ready() == true.  
Returns: A reference to the sub_match object representing the character sequence from the start of the string being matched/searched to the start of the match found.

const_reference suffix() const;  
Requires: ready() == true.  
Returns: A reference to the sub_match object representing the character sequence from the end of the match found to the end of the string being matched/searched.

const_iterator begin() const;  
const_iterator cbegin() const;  
Returns: A starting iterator that enumerates over all the sub-expressions stored in *this.

const_iterator end() const;
const_iterator cend() const;

14 Returns: A terminating iterator that enumerates over all the sub-expressions stored in *this.

28.10.5 match_results formatting

template<class OutputIter>
OutputIter format(OutputIter out,
    const char_type* fmt_first, const char_type* fmt_last,
    regex_constants::match_flag_type flags = regex_constants::format_default) const;

Requires: ready() == true and OutputIter shall satisfy the requirements for a Cpp17OutputIterator (22.2.4).

Effects: Copies the character sequence [fmt_first, fmt_last) to OutputIter out. Replaces each format specifier or escape sequence in the copied range with either the character(s) it represents or the sequence of characters within *this to which it refers. The bitmasks specified in flags determine which format specifiers and escape sequences are recognized.

Returns: out.

template<class OutputIter, class ST, class SA>
OutputIter format(OutputIter out,
    const basic_string<char_type, ST, SA>& fmt,
    regex_constants::match_flag_type flags = regex_constants::format_default) const;

Effects: Equivalent to:
    return format(out, fmt.data(), fmt.data() + fmt.size(), flags);

template<class ST, class SA>
basic_string<char_type, ST, SA> format(const basic_string<char_type, ST, SA>& fmt,
    regex_constants::match_flag_type flags = regex_constants::format_default) const;

Requires: ready() == true.

Effects: Constructs an empty string result of type basic_string<char_type, ST, SA> and calls:
    format(back_inserter(result), fmt, flags);

Returns: result.

string_type format(const char_type* fmt,
    regex_constants::match_flag_type flags = regex_constants::format_default) const;

Requires: ready() == true.

Effects: Constructs an empty string result of type string_type and calls:
    format(back_inserter(result), fmt, fmt + char_traits<char_type>::length(fmt), flags);

Returns: result.

28.10.6 match_results allocator

allocator_type get_allocator() const;

Returns: A copy of the Allocator that was passed to the object’s constructor or, if that allocator has been replaced, a copy of the most recent replacement.

28.10.7 match_results swap

void swap(match_results& that);

Effects: Swaps the contents of the two sequences.

Ensures: *this contains the sequence of matched sub-expressions that were in that, that contains the sequence of matched sub-expressions that were in *this.

Complexity: Constant time.
template<class BidirectionalIterator, class Allocator>
void swap(match_results<BidirectionalIterator, Allocator>& m1,
          match_results<BidirectionalIterator, Allocator>& m2);

Effects: As if by m1.swap(m2).

28.10.8 match_results non-member functions

template<class BidirectionalIterator, class Allocator>
bool operator==(const match_results<BidirectionalIterator, Allocator>& m1,
                const match_results<BidirectionalIterator, Allocator>& m2);

Returns: true if neither match result is ready, false if one match result is ready and the other is not.
If both match results are ready, returns true only if:

1. m1.empty() && m2.empty(), or
2. !m1.empty() && !m2.empty(), and the following conditions are satisfied:
3. m1.prefix() == m2.prefix(),
4. m1.size() == m2.size() && equal(m1.begin(), m1.end(), m2.begin()), and
5. m1.suffix() == m2.suffix().

[Note: The algorithm equal is defined in Clause 23. — end note]

template<class BidirectionalIterator, class Allocator>
bool operator!=(const match_results<BidirectionalIterator, Allocator>& m1,
                const match_results<BidirectionalIterator, Allocator>& m2);

Returns: !(m1 == m2).

28.11 Regular expression algorithms

28.11.1 Exceptions

The algorithms described in this subclause may throw an exception of type regex_error. If such an
exception e is thrown, e.code() shall return either regex_constants::error_complexity or regex_-
constants::error_stack.

28.11.2 regex_match

template<class BidirectionalIterator, class Allocator, class charT, class traits>
bool regex_match(BidirectionalIterator first, BidirectionalIterator last,
                 match_results<BidirectionalIterator, Allocator>& m,
                 const basic_regex<charT, traits>& e,
                 regex_constants::match_flag_type flags = regex_constants::match_default);

Requires: The type BidirectionalIterator shall satisfy the Cpp17BidirectionalIterator requirements
(22.2.6).

Effects: Determines whether there is a match between the regular expression e, and all of the character
sequence [first, last). The parameter flags is used to control how the expression is matched
against the character sequence. When determining if there is a match, only potential matches that
match the entire character sequence are considered. Returns true if such a match exists, false
otherwise. [Example:

std::regex re("Get|GetValue");
std::cmatch m;
regex_search("Get\x20\x20Get\x20Value", m, re); // returns true, and m[0] contains "Get"
regex_search("Get\x20\x20Value", m, re); // returns true, and m[0] contains "GetValue"
regex_search("Get\x20\x20Values", m, re); // returns true, and m[0] contains "Get"
regex_search("Get\x20\x20Values", m, re); // returns false

— end example]

Ensures: m.ready() == true in all cases. If the function returns false, then the effect on parameter
m is unspecified except that m.size() returns 0 and m.empty() returns true. Otherwise the effects on
parameter m are given in Table 130.
### Table 130 — Effects of `regex_match` algorithm

</tr>
<tr>
<td><code>m[n].second</code></td>
<td>For all integers (0 &lt; n &lt; m.size()), the end of the sequence that matched sub-expression (n). Alternatively, if sub-expression (n) did not participate in the match, then last.</td>
</tr>
<tr>
<td><code>m[n].matched</code></td>
<td>For all integers (0 &lt; n &lt; m.size()), true if sub-expression (n) participated in the match, false otherwise.</td>
</tr>
</tbody>
</table>

#### Effects

- Behaves “as if” by constructing an instance of `match_results<BidirectionalIterator>` `what`, and then returning the result of `regex_match(first, last, what, e, flags)`.

```cpp
template<class BidirectionalIterator, class charT, class traits>
bool regex_match(BidirectionalIterator first, BidirectionalIterator last,
    const basic_regex<charT, traits>& e,
    regex_constants::match_flag_type flags = regex_constants::match_default);
```

#### Returns

- `regex_match(str, str + char_traits<charT>::length(str), m, e, flags)`.  

```cpp
template<class charT, class Allocator, class traits>
bool regex_match(const charT* str,
    match_results<const charT*, Allocator>& m,
    const basic_regex<charT, traits>& e,
    regex_constants::match_flag_type flags = regex_constants::match_default);
```

#### Returns

- `regex_match(str, str + char_traits<charT>::length(str), m, e, flags)`.  

```cpp
template<class ST, class SA, class charT, class traits>
bool regex_match(const basic_string<charT, ST, SA>& s,
    match_results<typename basic_string<charT, ST, SA>::const_iterator,
        Allocator>& m,
    const basic_regex<charT, traits>& e,
    regex_constants::match_flag_type flags = regex_constants::match_default);
```

#### Returns

- `regex_match(s.begin(), s.end(), m, e, flags)`.  

```cpp
template<class charT, class traits>
bool regex_match(const charT* str,
    const basic_regex<charT, traits>& e,
    regex_constants::match_flag_type flags = regex_constants::match_default);
```

#### Returns

- `regex_match(str, str + char_traits<charT>::length(str), e, flags)`.  

```cpp
template<class ST, class SA, class charT, class traits>
bool regex_match(const basic_string<charT, ST, SA>& s,
    const basic_regex<charT, traits>& e,
    regex_constants::match_flag_type flags = regex_constants::match_default);
```

#### Returns

- `regex_match(s.begin(), s.end(), e, flags)`.  

§ 28.11.2
28.11.3 regex_search

```
template<class BidirectionalIterator, class Allocator, class charT, class traits>
bool regex_search(BidirectionalIterator first, BidirectionalIterator last,
                 match_results<BidirectionalIterator, Allocator>& m,
                 const basic_regex<charT, traits>& e,
                 regex_constants::match_flag_type flags = regex_constants::match_default);
```

1 Requires: Type BidirectionalIterator shall satisfy the Cpp17BidirectionalIterator requirements (22.2.6).

2 Effects: Determines whether there is some sub-sequence within [first, last) that matches the regular expression e. The parameter flags is used to control how the expression is matched against the character sequence. Returns true if such a sequence exists, false otherwise.

3 Ensures: m.ready() == true in all cases. If the function returns false, then the effect on parameter m is unspecified except that m.size() returns 0 and m.empty() returns true. Otherwise the effects on parameter m are given in Table 131.

Table 131 — Effects of regex_search algorithm

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>m.size()</td>
<td>1 + e.mark_count()</td>
</tr>
<tr>

<tr>
<td>m[0].first</td>
<td>The start of the sequence of characters that matched the regular expression</td>
</tr>
<tr>
<td>m[0].second</td>
<td>The end of the sequence of characters that matched the regular expression</td>
</tr>
<tr>
<td>m[0].matched</td>
<td>true</td>
</tr>
<tr>
<td>m[n].first</td>
<td>For all integers 0 &lt; n &lt; m.size(), the start of the sequence that matched sub-expression n. Alternatively, if sub-expression n did not participate in the match, then last.</td>
</tr>
<tr>
<td>m[n].second</td>
<td>For all integers 0 &lt; n &lt; m.size(), the end of the sequence that matched sub-expression n. Alternatively, if sub-expression n did not participate in the match, then last.</td>
</tr>
<tr>
<td>m[n].matched</td>
<td>For all integers 0 &lt; n &lt; m.size(), true if sub-expression n participated in the match, false otherwise.</td>
</tr>
</tbody>
</table>

```
template<class charT, class Allocator, class traits>
bool regex_search(const charT* str, match_results<const charT*, Allocator>& m,
                   const basic_regex<charT, traits>& e,
                   regex_constants::match_flag_type flags = regex_constants::match_default);
```

4 Returns: regex_search(str, str + char_traits<charT>::length(str), m, e, flags).

```
template<class ST, class SA, class Allocator, class charT, class traits>
bool regex_search(const basic_string<charT, ST, SA>& s,
                  match_results<typename basic_string<charT, ST, SA>::const_iterator, Allocator>& m,
                  const basic_regex<charT, traits>& e,
                  regex_constants::match_flag_type flags = regex_constants::match_default);
```

5 Returns: regex_search(s.begin(), s.end(), m, e, flags).
template<class BidirectionalIterator, class charT, class traits>
bool regex_search(BidirectionalIterator first, BidirectionalIterator last,
const basic_regex<charT, traits>& e,
regex_constants::match_flag_type flags = regex_constants::match_default);

Effects: Behaves "as if" by constructing an object what of type match_results<BidirectionalIterator> and returning regex_search(first, last, what, e, flags).

template<class charT, class traits>
bool regex_search(const charT* str,
const basic_regex<charT, traits>& e,
regex_constants::match_flag_type flags = regex_constants::match_default);

Returns: regex_search(str, str + char_traits<charT>::length(str), e, flags).

template<class ST, class SA, class charT, class traits>
bool regex_search(const basic_string<charT, ST, SA>& s,
const basic_regex<charT, traits>& e,
regex_constants::match_flag_type flags = regex_constants::match_default);

Returns: regex_search(s.begin(), s.end(), e, flags).

28.11.4 regex_replace
[re.alg.replace]

template<class OutputIterator, class BidirectionalIterator, class traits, class charT, class ST, class SA>
OutputIterator
regex_replace(OutputIterator out,
BidirectionalIterator first, BidirectionalIterator last,
const basic_regex<charT, traits>& e,
const basic_string<charT, ST, SA>& fmt,
regex_constants::match_flag_type flags = regex_constants::match_default);

Effects: Constructs a regex_iterator object i as if by
regex_iterator<BidirectionalIterator, charT, traits> i(first, last, e, flags)
and uses i to enumerate through all of the matches m of type match_results<BidirectionalIterator>
that occur within the sequence [first, last). If no such matches are found and !(flags & regex CONSTANTS::format_no_copy), then calls
out = copy(first, last, out)
If any matches are found then, for each such match:
(1.1) If !(flags & regex_constants::format_no_copy), calls
out = copy(m.prefix().first, m.prefix().second, out)
(1.2) Then calls
out = m.format(out, fmt, flags)
for the first form of the function and
out = m.format(out, fmt, fmt + char_traits<charT>::length(fmt), flags)
for the second.
Finally, if such a match is found and !(flags & regex_constants::format_first_only)
is nonzero, then only the first match found is replaced.

Returns: out.
template<class traits, class charT, class ST, class SA, class FST, class FSA>
  basic_string<charT, ST, SA>
  regex_replace(const basic_string<charT, ST, SA>& s,
                const basic_regex<charT, traits>& e,
                const basic_string<charT, FST, FSA>& fmt,
                regex_constants::match_flag_type flags = regex_constants::match_default);

template<class traits, class charT, class ST, class SA>
  basic_string<charT, ST, SA>
  regex_replace(const basic_string<charT, ST, SA>& s,
                const basic_regex<charT, traits>& e,
                const charT* fmt,
                regex_constants::match_flag_type flags = regex_constants::match_default);

Effects: Constructs an empty string result of type basic_string<charT, ST, SA> and calls:
regex_replace(back_inserter(result), s.begin(), s.end(), e, fmt, flags);

Returns: result.

template<class traits, class charT, class ST, class SA>
  basic_string<charT>
  regex_replace(const charT* s,
                const basic_regex<charT, traits>& e,
                const basic_string<charT, ST, SA>& fmt,
                regex_constants::match_flag_type flags = regex_constants::match_default);

Effects: Constructs an empty string result of type basic_string<charT> and calls:
regex_replace(back_inserter(result), s, s + char_traits<charT>::length(s), e, fmt, flags);

Returns: result.

28.12 Regular expression iterators
28.12.1 Class template regex_iterator

The class template regex_iterator is an iterator adaptor. It represents a new view of an existing iterator sequence, by enumerating all the occurrences of a regular expression within that sequence. A regex_iterator uses regex_search to find successive regular expression matches within the sequence from which it was constructed. After the iterator is constructed, and every time operator++ is used, the iterator finds and stores a value of match_results<BidirectionalIterator>. If the end of the sequence is reached (regex_search returns false), the iterator becomes equal to the end-of-sequence iterator value. The default constructor constructs an end-of-sequence iterator object, which is the only legitimate iterator to be used for the end condition. The result of operator* on an end-of-sequence iterator is not defined. For any other iterator value a const match_results<BidirectionalIterator>& is returned. The result of operator-> on an end-of-sequence iterator is not defined. For any other iterator value a const match_results<BidirectionalIterator>* is returned. It is impossible to store things into regex_iterators. Two end-of-sequence iterators are always equal. An end-of-sequence iterator is not equal to a non-end-of-sequence iterator. Two non-end-of-sequence iterators are equal when they are constructed from the same arguments.

namespace std {
  template<class BidirectionalIterator,
           class charT = typename iterator_traits<BidirectionalIterator>::value_type,
           class traits = regex_traits<charT>>
  class regex_iterator {
    public:
      using regex_type = basic_regex<charT, traits>;
      using iterator_category = forward_iterator_tag;
      using value_type = match_results<BidirectionalIterator>;
      using difference_type = ptrdiff_t;
      using pointer = const value_type*;
      using reference = const value_type&;
  }

§ 28.12.1
regex_iterator();
regex_iterator(BidirectionalIterator a, BidirectionalIterator b,
    const regex_type& re,
    regex_constants::match_flag_type m = regex_constants::match_default);
regex_iterator(BidirectionalIterator, BidirectionalIterator,
    const regex_type&&,
    regex_constants::match_flag_type = regex_constants::match_default) = delete;
regex_iterator(const regex_iterator&);
regex_iterator& operator=(const regex_iterator&);
bool operator==(const regex_iterator&) const;
bool operator!=(const regex_iterator&) const;
const value_type& operator*() const;
const value_type* operator->() const;
regex_iterator& operator++();
regex_iterator operator++(int);

private:
    BidirectionalIterator begin; // exposition only
    BidirectionalIterator end; // exposition only
    const regex_type* pregex; // exposition only
    regex_constants::match_flag_type flags; // exposition only
    match_results<BidirectionalIterator> match; // exposition only
};

2 An object of type regex_iterator that is not an end-of-sequence iterator holds a zero-length match if match[0].matched == true and match[0].first == match[0].second. [Note: For example, this can occur when the part of the regular expression that matched consists only of an assertion (such as '^', '$', '\b', '\B'). — end note]

28.12.1.1 regex_iterator constructors [re.regexiter.cnstr]

regex_iterator();

Effects: Constructs an end-of-sequence iterator.

regex_iterator(BidirectionalIterator a, BidirectionalIterator b,
    const regex_type& re,
    regex_constants::match_flag_type m = regex_constants::match_default);

Effects: Initializes begin and end to a and b, respectively, sets pregex to &re, sets flags to m, then calls regex_search(begin, end, match, *pregex, flags). If this call returns false the constructor sets *this to the end-of-sequence iterator.

28.12.1.2 regex_iterator comparisons [re.regexiter.comp]

bool operator==(const regex_iterator& right) const;

Returns: true if *this and right are both end-of-sequence iterators or if the following conditions all hold:

(1.1) begin == right.begin,
(1.2) end == right.end,
(1.3) pregex == right.pregex,
(1.4) flags == right.flags, and
(1.5) match[0] == right.match[0]; otherwise false.

bool operator!=(const regex_iterator& right) const;

Returns: !(this == right).
28.12.1.3 regex_iterator indirection

const value_type& operator*() const;

Returns: match.

const value_type* operator->() const;

Returns: &match.

28.12.1.4 regex_iterator increment

regex_iterator& operator++();

Effects: Constructs a local variable start of type BidirectionalIterator and initializes it with the value of match[0].second.

If the iterator holds a zero-length match and start == end the operator sets *this to the end-of-sequence iterator and returns *this.

Otherwise, if the iterator holds a zero-length match, the operator calls:

regex_search(start, end, match, *pregex, flags | regex_constants::match_not_null | regex_constants::match_continuous)

If the call returns true the operator returns *this. Otherwise the operator increments start and continues as if the most recent match was not a zero-length match.

If the most recent match was not a zero-length match, the operator sets flags to flags | regex_constants::match_prev_avail and calls regex_search(start, end, match, *pregex, flags). If the call returns false the iterator sets *this to the end-of-sequence iterator. The iterator then returns *this.

In all cases in which the call to regex_search returns true, match.prefix().first shall be equal to the previous value of match[0].second, and for each index i in the half-open range [0, match.size()) for which match[i].matched is true, match.position(i) shall return distance(begin, match[i].first).

[Note: This means that match.position(i) gives the offset from the beginning of the target sequence, which is often not the same as the offset from the sequence passed in the call to regex_search. — end note]

It is unspecified how the implementation makes these adjustments.

[Note: This means that a compiler may call an implementation-specific search function, in which case a program-defined specialization of regex_search will not be called. — end note]

regex_iterator operator++(int);

Effects: As if by:

regex_iterator tmp = *this;
++(*this);
return tmp;

28.12.2 Class template regex_token_iterator

The class template regex_token_iterator is an iterator adaptor; that is to say it represents a new view of an existing iterator sequence, by enumerating all the occurrences of a regular expression within that sequence, and presenting one or more sub-expressions for each match found. Each position enumerated by the iterator is a sub_match class template instance that represents what matched a particular sub-expression within the regular expression.

When class regex_token_iterator is used to enumerate a single sub-expression with index -1 the iterator performs field splitting: that is to say it enumerates one sub-expression for each section of the character container sequence that does not match the regular expression specified.

After it is constructed, the iterator finds and stores a value regex_iterator<BidirectionalIterator> position and sets the internal count N to zero. It also maintains a sequence subs which contains a list of the sub-expressions which will be enumerated. Every time operator++ is used the count N is incremented; if N exceeds or equals subs.size(), then the iterator increments member position and sets count N to zero.
If the end of sequence is reached (position is equal to the end of sequence iterator), the iterator becomes equal to the end-of-sequence iterator value, unless the sub-expression being enumerated has index -1, in which case the iterator enumerates one last sub-expression that contains all the characters from the end of the last regular expression match to the end of the input sequence being enumerated, provided that this would not be an empty sub-expression.

The default constructor constructs an end-of-sequence iterator object, which is the only legitimate iterator to be used for the end condition. The result of operator* on an end-of-sequence iterator is not defined. For any other iterator value a const sub_match<BidirectionalIterator>& is returned. The result of operator-> on an end-of-sequence iterator is not defined. For any other iterator value a const sub_match<BidirectionalIterator>* is returned.

It is impossible to store things into regex_token iterators. Two end-of-sequence iterators are always equal. An end-of-sequence iterator is not equal to a non-end-of-sequence iterator. Two non-end-of-sequence iterators are equal when they are constructed from the same arguments.

```cpp
namespace std {
    template<class BidirectionalIterator,
             class charT = typename iterator_traits<BidirectionalIterator>::value_type,
             class traits = regex_traits<charT>>
    class regex_token_iterator {
        public:
            using regex_type = basic_regex<charT, traits>;
            using iterator_category = forward_iterator_tag;
            using value_type = sub_match<BidirectionalIterator>;
            using difference_type = ptrdiff_t;
            using pointer = const value_type*;
            using reference = const value_type&;

            regex_token_iterator();
            regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b,
                                 const regex_type& re,
                                 int submatch = 0,
                                 regex_constants::match_flag_type m =
                                 regex_constants::match_default);
            regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b,
                                 const regex_type& re,
                                 const vector<int>& submatches,
                                 regex_constants::match_flag_type m =
                                 regex_constants::match_default);
            regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b,
                                 const regex_type& re,
                                 initializer_list<int> submatches,
                                 regex_constants::match_flag_type m =
                                 regex_constants::match_default);
            template<size_t N>
            regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b,
                                 const regex_type& re,
                                 const int (&submatches)[N],
                                 regex_constants::match_flag_type m =
                                 regex_constants::match_default);
            regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b,

                                 int submatch = 0,
                                 regex_constants::match_flag_type m =
                                 regex_constants::match_default) = delete;
            regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b,
                                 const regex_type& re,
                                 const vector<int>& submatches,
                                 regex_constants::match_flag_type m =
                                 regex_constants::match_default) = delete;
            regex_token_iterator(BidirectionalIterator a, BidirectionalIterator b,
                                 const regex_type& re,
                                 initializer_list<int> submatches,
                                 regex_constants::match_flag_type m =
                                 regex_constants::match_default) = delete;
    }
}
```
A suffix iterator is a regex_token_iterator object that points to a final sequence of characters at the end of the target sequence. In a suffix iterator the member result holds a pointer to the data member suffix, the value of the member suffix.match is true, suffix.first points to the beginning of the final sequence, and suffix.second points to the end of the final sequence.

[Note: For a suffix iterator, data member suffix.first is the same as the end of the last match found, and suffix.second is the same as the end of the target sequence — end note]

The current match is (*position).prefix() if subs[N] == -1, or (*position)[subs[N]] for any other value of subs[N].

### 28.12.2.1 regex_token_iterator constructors

regex_token_iterator();

**Effects:** Constructs the end-of-sequence iterator.

**Requires:** Each of the initialization values of submatches shall be >= -1.
Effects: The first constructor initializes the member subs to hold the single value submatch. The second constructor initializes the member subs to hold a copy of the argument submatches. The third and fourth constructors initialize the member subs to hold a copy of the sequence of integer values pointed to by the iterator range [submatches.begin(), submatches.end()) and [submatches, &submatches + N), respectively.

Each constructor then sets N to 0, and position to position_iterator(a, b, re, m). If position is not an end-of-sequence iterator the constructor sets result to the address of the current match. Otherwise if any of the values stored in subs is equal to -1 the constructor sets *this to a suffix iterator that points to the range [a, b), otherwise the constructor sets *this to an end-of-sequence iterator.

28.12.2.2 regex_token_iterator comparisons [re.tokiter.comp]

bool operator==(const regex_token_iterator& right) const;

Returns: true if *this and right are both end-of-sequence iterators, or if *this and right are both suffix iterators and suffix == right.suffix; otherwise returns false if *this or right is an end-of-sequence iterator or a suffix iterator. Otherwise returns true if position == right.position, N == right.N, and subs == right.subs. Otherwise returns false.

bool operator!=(const regex_token_iterator& right) const;

Returns: !(*this == right).

28.12.2.3 regex_token_iterator indirection [re.tokiter.deref]

const value_type& operator*() const;

Returns: *result.

const value_type* operator->() const;

Returns: result.

28.12.2.4 regex_token_iterator increment [re.tokiter.incr]

regex_token_iterator& operator++();

Effects: Constructs a local variable prev of type position_iterator, initialized with the value of position.

If *this is a suffix iterator, sets *this to an end-of-sequence iterator.

Otherwise, if N + 1 < subs.size(), increments N and sets result to the address of the current match.

Otherwise, sets N to 0 and increments position. If position is not an end-of-sequence iterator the operator sets result to the address of the current match.

Otherwise, if any of the values stored in subs is equal to -1 and prev->suffix().length() is not 0 the operator sets *this to a suffix iterator that points to the range [prev->suffix().first, prev->suffix().second).

Otherwise, sets *this to an end-of-sequence iterator.

Returns: *this

regex_token_iterator& operator++(int);

Effects: Constructs a copy tmp of *this, then calls ++(*this).

Returns: tmp.

28.13 Modified ECMAScript regular expression grammar [re.grammar]

The regular expression grammar recognized by basic_regex objects constructed with the ECMAScript flag is that specified by ECMAScript, except as specified below.

Objects of type specialization of basic_regex store within themselves a default-constructed instance of their traits template parameter, henceforth referred to as traits_inst. This traits_inst object is used to support localization of the regular expression; basic_regex member functions shall not call any locale dependent C or C++ API, including the formatted string input functions. Instead they shall call the appropriate traits member function to achieve the required effect.
3 The following productions within the ECMAScript grammar are modified as follows:

ClassAtom ::
   - ClassAtomNoDash
   ClassAtomExClass
   ClassAtomCollatingElement
   ClassAtomEquivalence

IdentityEscape ::
   SourceCharacter but not c

4 The following new productions are then added:

ClassAtomExClass ::
   [: ClassName :]

ClassAtomCollatingElement ::
   [. ClassName .]

ClassAtomEquivalence ::
   [= ClassName =]

ClassName ::
   ClassNameCharacter
   ClassNameCharacter ClassName

ClassNameCharacter ::
   SourceCharacter but not one of "," "=" ":"

5 The productions ClassAtomExClass, ClassAtomCollatingElement and ClassAtomEquivalence provide functionality equivalent to that of the same features in regular expressions in POSIX.

6 The regular expression grammar may be modified by any \regex_constants::syntax_option_type flags specified when constructing an object of type specialization of \basic_regex according to the rules in Table 125.

7 A ClassName production, when used in ClassAtomExClass, is not valid if traits_inst.lookup_classname returns zero for that name. The names recognized as valid ClassNames are determined by the type of the traits class, but at least the following names shall be recognized: alnum, alpha, blank, cntrl, digit, graph, lower, print, punct, space, upper, xdigit, d, s, w. In addition the following expressions shall be equivalent:

\d and [[[:digit:]]]
\D and [^[[:digit:]]]
\s and [[[:space:]]]
\S and [^[[:space:]]]
\w and [^[[:alnum:]]]
\W and [^[[:alnum:]]]

8 A ClassName production when used in a ClassAtomCollatingElement production is not valid if the value returned by traits_inst.lookup_collatename for that name is an empty string.

9 The results from multiple calls to traits_inst.lookup_classname can be bitwise OR’ed together and subsequently passed to traits_inst.isctype.

10 A ClassName production when used in a ClassAtomEquivalence production is not valid if the value returned by traits_inst.lookup_collatename for that name is an empty string or if the value returned by traits_inst.transform_primary for the result of the call to traits_inst.lookup_collatename is an empty string.

11 When the sequence of characters being transformed to a finite state machine contains an invalid class name the translator shall throw an exception object of type \regex_error.
If the \( CV \) of a \textit{UnicodeEscapeSequence} is greater than the largest value that can be held in an object of type \texttt{charT} the translator shall throw an exception object of type \texttt{regex_error}. \[\textit{Note: This means that values of the form "uxxxx" that do not fit in a character are invalid. — end note}\]

Where the regular expression grammar requires the conversion of a sequence of characters to an integral value, this is accomplished by calling \texttt{traits_inst.value}.

The behavior of the internal finite state machine representation when used to match a sequence of characters is as described in ECMA-262. The behavior is modified according to any \texttt{match_flag_type flags (28.5.2)} specified when using the regular expression object in one of the regular expression algorithms (28.11). The behavior is also localized by interaction with the \texttt{traits} class template parameter as follows:

\[\text{(14.1)}\] — During matching of a regular expression finite state machine against a sequence of characters, two characters \( c \) and \( d \) are compared using the following rules:

\[\text{(14.1.1)}\] — if \( \text{flags()} \& \text{regex_constants::icase} \) the two characters are equal if \( \text{traits\_inst\_translate\_nocase}(c) == \text{traits\_inst\_translate\_nocase}(d) \);

\[\text{(14.1.2)}\] — otherwise, if \( \text{flags()} \& \text{regex_constants::collate} \) the two characters are equal if \( \text{traits\_inst\_translate}(c) == \text{traits\_inst\_translate}(d) \);

\[\text{(14.1.3)}\] — otherwise, the two characters are equal if \( c == d \).

\[\text{(14.2)}\] — During matching of a regular expression finite state machine against a sequence of characters, comparison of a collating element range \( c_1-c_2 \) against a character \( c \) is conducted as follows: if \( \text{flags()} \& \text{regex\_constants::collate} \) is false then the character \( c \) is matched if \( c_1 <= c && c <= c_2 \), otherwise \( c \) is matched in accordance with the following algorithm:

\[\text{string\_type str1 = string\_type(1, flags() \& icase ? traits\_inst\_translate\_nocase(c1) : traits\_inst\_translate(c1);}\]
\[\text{string\_type str2 = string\_type(1, flags() \& icase ? traits\_inst\_translate\_nocase(c2) : traits\_inst\_translate(c2);}\]
\[\text{string\_type str = string\_type(1, flags() \& icase ? traits\_inst\_translate\_nocase(c) : traits\_inst\_translate(c);}\]
\[\text{return traits\_inst\_transform(str1.begin(), str1.end()) <= traits\_inst\_transform(str.begin(), str.end()) && traits\_inst\_transform(str2.begin(), str2.end());}\]

\[\text{(14.3)}\] — During matching of a regular expression finite state machine against a sequence of characters, testing whether a collating element is a member of a primary equivalence class is conducted by first converting the collating element and the equivalence class to sort keys using \texttt{traits::transform\_primary}, and then comparing the sort keys for equality.

\[\text{(14.4)}\] — During matching of a regular expression finite state machine against a sequence of characters, a character \( c \) is a member of a character class designated by an iterator range \( \text{[first, last)} \) if \( \text{traits\_inst\_isctype}(c, \text{traits\_inst\_lookup\_classname}(\text{first, last, flags()} \& \text{icase})) \) is true.

29 Atomic operations library

29.1 General

This Clause describes components for fine-grained atomic access. This access is provided via operations on atomic objects.

The following subclauses describe atomics requirements and components for types and operations, as summarized below.

// 29.10, fences
extern "C" void atomic_thread_fence(memory_order) noexcept;<br>extern "C" void atomic_signal_fence(memory_order) noexcept;
29.3 Type aliases

The type aliases `atomic_int_t`, `atomic_uint_t`, `atomic_intptr_t`, and `atomic_uintptr_t` are defined if and only if `int_t`, `uint_t`, `intptr_t`, and `uintptr_t` are defined, respectively.

29.4 Order and consistency

```
namespace std {
    enum class memory_order : unspecified {
        relaxed, consume, acquire, release, acq_rel, seq_cst
    };

    inline constexpr memory_order memory_order_reached = memory_order::relaxed;
    inline constexpr memory_order memory_order_consume = memory_order::consume;
    inline constexpr memory_order memory_order_acquire = memory_order::acquire;
    inline constexpr memory_order memory_order_release = memory_order::release;
    inline constexpr memory_order memory_order_acq_rel = memory_order::acq_rel;
    inline constexpr memory_order memory_order_seq_cst = memory_order::seq_cst;
}
```

The enumeration `memory_order` specifies the detailed regular (non-atomic) memory synchronization order as defined in 6.8.2 and may provide for operation ordering. Its enumerated values and their meanings are as follows:

1. `memory_order::relaxed`: no operation orders memory.
2. `memory_order::release`, `memory_order::acq_rel`, and `memory_order::seq_cst`: a store operation performs a release operation on the affected memory location.
3. `memory_order::consume`: a load operation performs a consume operation on the affected memory location. *[Note: Prefer `memory_order::acquire`, which provides stronger guarantees than `memory_order::consume`. Implementations have found it infeasible to provide performance better than that of `memory_order::acquire`. Specification revisions are under consideration. — end note]*
4. `memory_order::acquire`, `memory_order::acq_rel`, and `memory_order::seq_cst`: a load operation performs an acquire operation on the affected memory location.

```
namespace std {
    enum class memory_order : unspecified {
        relaxed, consume, acquire, release, acq_rel, seq_cst
    };

    inline constexpr memory_order memory_order_reached = memory_order::relaxed;
    inline constexpr memory_order memory_order_consume = memory_order::consume;
    inline constexpr memory_order memory_order_acquire = memory_order::acquire;
    inline constexpr memory_order memory_order_release = memory_order::release;
    inline constexpr memory_order memory_order_acq_rel = memory_order::acq_rel;
    inline constexpr memory_order memory_order_seq_cst = memory_order::seq_cst;
}
```

An atomic operation $A$ that performs a release operation on an atomic object $M$ synchronizes with an atomic operation $B$ that performs an acquire operation on $M$ and takes its value from any side effect in the release sequence headed by $A$.

There shall be a single total order $S$ on all `memory_order::seq_cst` operations, consistent with the “happens before” order and modification orders for all affected locations, such that each `memory_order::seq_cst` operation $B$ that loads a value from an atomic object $M$ observes one of the following values:

```
namespace std {
    enum class memory_order : unspecified {
        relaxed, consume, acquire, release, acq_rel, seq_cst
    };

    inline constexpr memory_order memory_order_reached = memory_order::relaxed;
    inline constexpr memory_order memory_order_consume = memory_order::consume;
    inline constexpr memory_order memory_order_acquire = memory_order::acquire;
    inline constexpr memory_order memory_order_release = memory_order::release;
    inline constexpr memory_order memory_order_acq_rel = memory_order::acq_rel;
    inline constexpr memory_order memory_order_seq_cst = memory_order::seq_cst;
}
```

```
namespace std {
    enum class memory_order : unspecified {
        relaxed, consume, acquire, release, acq_rel, seq_cst
    };

    inline constexpr memory_order memory_order_reached = memory_order::relaxed;
    inline constexpr memory_order memory_order_consume = memory_order::consume;
    inline constexpr memory_order memory_order_acquire = memory_order::acquire;
    inline constexpr memory_order memory_order_release = memory_order::release;
    inline constexpr memory_order memory_order_acq_rel = memory_order::acq_rel;
    inline constexpr memory_order memory_order_seq_cst = memory_order::seq_cst;
}
```

```
namespace std {
    enum class memory_order : unspecified {
        relaxed, consume, acquire, release, acq_rel, seq_cst
    };

    inline constexpr memory_order memory_order_reached = memory_order::relaxed;
    inline constexpr memory_order memory_order_consume = memory_order::consume;
    inline constexpr memory_order memory_order_acquire = memory_order::acquire;
    inline constexpr memory_order memory_order_release = memory_order::release;
    inline constexpr memory_order memory_order_acq_rel = memory_order::acq_rel;
    inline constexpr memory_order memory_order_seq_cst = memory_order::seq_cst;
}
```

```
namespace std {
    enum class memory_order : unspecified {
        relaxed, consume, acquire, release, acq_rel, seq_cst
    };

    inline constexpr memory_order memory_order_reached = memory_order::relaxed;
    inline constexpr memory_order memory_order_consume = memory_order::consume;
    inline constexpr memory_order memory_order_acquire = memory_order::acquire;
    inline constexpr memory_order memory_order_release = memory_order::release;
    inline constexpr memory_order memory_order_acq_rel = memory_order::acq_rel;
    inline constexpr memory_order memory_order_seq_cst = memory_order::seq_cst;
}
```

```
namespace std {
    enum class memory_order : unspecified {
        relaxed, consume, acquire, release, acq_rel, seq_cst
    };

    inline constexpr memory_order memory_order_reached = memory_order::relaxed;
    inline constexpr memory_order memory_order_consume = memory_order::consume;
    inline constexpr memory_order memory_order_acquire = memory_order::acquire;
    inline constexpr memory_order memory_order_release = memory_order::release;
    inline constexpr memory_order memory_order_acq_rel = memory_order::acq_rel;
    inline constexpr memory_order memory_order_seq_cst = memory_order::seq_cst;
}
```

```
namespace std {
    enum class memory_order : unspecified {
        relaxed, consume, acquire, release, acq_rel, seq_cst
    };

    inline constexpr memory_order memory_order_reached = memory_order::relaxed;
    inline constexpr memory_order memory_order_consume = memory_order::consume;
    inline constexpr memory_order memory_order_acquire = memory_order::acquire;
    inline constexpr memory_order memory_order_release = memory_order::release;
    inline constexpr memory_order memory_order_acq_rel = memory_order::acq_rel;
    inline constexpr memory_order memory_order_seq_cst = memory_order::seq_cst;
}
```

```
namespace std {
    enum class memory_order : unspecified {
        relaxed, consume, acquire, release, acq_rel, seq_cst
    };

    inline constexpr memory_order memory_order_reached = memory_order::relaxed;
    inline constexpr memory_order memory_order_consume = memory_order::consume;
    inline constexpr memory_order memory_order_acquire = memory_order::acquire;
    inline constexpr memory_order memory_order_release = memory_order::release;
    inline constexpr memory_order memory_order_acq_rel = memory_order::acq_rel;
    inline constexpr memory_order memory_order_seq_cst = memory_order::seq_cst;
}
```

For an atomic operation $B$ that reads the value of an atomic object $M$, if there is a `memory_order::seq_cst` fence $X$ sequenced before $B$, then $B$ observes either the last `memory_order::seq_cst` modification of $M$ preceding $X$ in the total order $S$ or a later modification of $M$ in its modification order.

For atomic operations $A$ and $B$ on an atomic object $M$, where $A$ modifies $M$ and $B$ takes its value, if there is a `memory_order::seq_cst` fence $X$ such that $A$ is sequenced before $X$ and $B$ follows $X$ in $S$, then $B$ observes either the effects of $A$ or a later modification of $M$ in its modification order.

For atomic operations $A$ and $B$ on an atomic object $M$, where $A$ modifies $M$ and $B$ takes its value, if there are `memory_order::seq_cst` fences $X$ and $Y$ such that $A$ is sequenced before $X$, $Y$ is sequenced before $B$, and $X$ precedes $Y$ in $S$, then $B$ observes either the effects of $A$ or a later modification of $M$ in its modification order.
For atomic modifications $A$ and $B$ of an atomic object $M$, $B$ occurs later than $A$ in the modification order of $M$ if:

- there is a `memory_order::seq_cst` fence $X$ such that $A$ is sequenced before $X$, and $X$ precedes $B$ in $S$, or
- there is a `memory_order::seq_cst` fence $Y$ such that $Y$ is sequenced before $B$, and $A$ precedes $Y$ in $S$, or
- there are `memory_order::seq_cst` fences $X$ and $Y$ such that $A$ is sequenced before $X$, $Y$ is sequenced before $B$, and $X$ precedes $Y$ in $S$.

[Note: `memory_order::seq_cst` ensures sequential consistency only for a program that is free of data races and uses exclusively `memory_order::seq_cst` operations. Any use of weaker ordering will invalidate this guarantee unless extreme care is used. In particular, `memory_order::seq_cst` fences ensure a total order only for the fences themselves. Fences cannot, in general, be used to restore sequential consistency for atomic operations with weaker ordering specifications. —end note]

Implementations should ensure that no “out-of-thin-air” values are computed that circularly depend on their own computation.

[Note: For example, with $x$ and $y$ initially zero,

```c
// Thread 1:
r1 = y.load(memory_order::relaxed);
x.store(r1, memory_order::relaxed);
// Thread 2:
r2 = x.load(memory_order::relaxed);
y.store(r2, memory_order::relaxed);
```

should not produce $r1 == r2 == 42$, since the store of 42 to $y$ is only possible if the store to $x$ stores 42, which circularly depends on the store to $y$ storing 42. Note that without this restriction, such an execution is possible. —end note]

Atomic read-modify-write operations shall always read the last value (in the modification order) written before the write associated with the read-modify-write operation.

Implementations should make atomic stores visible to atomic loads within a reasonable amount of time.

```c
template<class T>
T kill_dependency(T y) noexcept;
```

Effects: The argument does not carry a dependency to the return value (6.8.2).

Returns: $y$.

### 29.5 Lock-free property

```c
#define ATOMIC_BOOL_LOCK_FREE unspecified
#define ATOMIC_CHAR_LOCK_FREE unspecified
#define ATOMIC_CHAR16_T_LOCK_FREE unspecified
#define ATOMIC_CHAR32_T_LOCK_FREE unspecified
#define ATOMIC_WCHAR_T_LOCK_FREE unspecified
#define ATOMIC_SHORT_LOCK_FREE unspecified
#define ATOMIC_INT_LOCK_FREE unspecified
#define ATOMIC_LONG_LOCK_FREE unspecified
#define ATOMIC_LLONG_LOCK_FREE unspecified
#define ATOMIC_POINTER_LOCK_FREE unspecified
```

[atomics.lockfree]
The \texttt{ATOMIC\_\ldots\_LOCK\_FREE} macros indicate the lock-free property of the corresponding atomic types, with the signed and unsigned variants grouped together. The properties also apply to the corresponding (partial) specializations of the \texttt{atomic} template. A value of 0 indicates that the types are never lock-free. A value of 1 indicates that the types are sometimes lock-free. A value of 2 indicates that the types are always lock-free.

The function \texttt{atomic\_is\_lock\_free} (29.7.1) indicates whether the object is lock-free. In any given program execution, the result of the lock-free query shall be consistent for all pointers of the same type.

Atomic operations that are not lock-free are considered to potentially block (6.8.2.2).

[\textit{Note:} Operations that are lock-free should also be address-free. That is, atomic operations on the same memory location via two different addresses will communicate atomically. The implementation should not depend on any per-process state. This restriction enables communication by memory that is mapped into a process more than once and by memory that is shared between two processes. — end note]

## 29.6 Class template \texttt{atomic\_ref} [atomics.ref.generic]

```cpp
class std::atomic_ref {
    private:
        T* ptr; // exposition only
    public:
        using value_type = T;
        static constexpr bool is_always_lock_free = implementation-defined;
        static constexpr size_t required_alignment = implementation-defined;
        atomic_ref() = delete;
        atomic_ref(const atomic_ref&) = delete;
        explicit atomic_ref(T&); // exposition only
        atomic_ref(atomic_ref&&) noexcept;
        T operator=(T) const noexcept;
        operator T() const noexcept;
        bool is_lock_free() const noexcept;
        void store(T, memory_order = memory_order_seq_cst) const noexcept;
        T load(memory_order = memory_order_seq_cst) const noexcept;
        T exchange(T, memory_order = memory_order_seq_cst) const noexcept;
        bool compare_exchange_weak(T&, T,
            memory_order, memory_order) const noexcept;
        bool compare_exchange_strong(T&, T,
            memory_order, memory_order) const noexcept;
        bool compare_exchange_weak(T&, T,
            memory_order = memory_order_seq_cst) const noexcept;
        bool compare_exchange_strong(T&, T,
            memory_order = memory_order_seq_cst) const noexcept;
};
```

1. An \texttt{atomic\_ref} object applies atomic operations (29.1) to the object referenced by \texttt{*ptr} such that, for the lifetime (6.6.3) of the \texttt{atomic\_ref} object, the object referenced by \texttt{*ptr} is an atomic object (6.8.2.1).
2. The template argument for \texttt{T} shall be trivially copyable (6.7).
3. The lifetime (6.6.3) of an object referenced by \texttt{*ptr} shall exceed the lifetime of all \texttt{atomic\_ref}s that reference the object. While any \texttt{atomic\_ref} instances exist that reference the \texttt{*ptr} object, all accesses to that object shall exclusively occur through those \texttt{atomic\_ref} instances. No subobject of the object referenced by \texttt{atomic\_ref} shall be concurrently referenced by any other \texttt{atomic\_ref} object.
4. Atomic operations applied to an object through a referencing \texttt{atomic\_ref} are atomic with respect to atomic operations applied through any other \texttt{atomic\_ref} referencing the same object. [\textit{Note:} Atomic operations or the \texttt{atomic\_ref} constructor could acquire a shared resource, such as a lock associated with the referenced object, to enable atomic operations to be applied to the referenced object. — end note]
29.6.1 Operations

static constexpr bool is_always_lock_free;

The static data member is_always_lock_free is true if the atomic_ref type’s operations are always lock-free, and false otherwise.

static constexpr size_t required_alignment;

The alignment required for an object to be referenced by an atomic reference, which is at least alignof(T).

[Note: Hardware could require an object referenced by an atomic_ref to have stricter alignment (6.6.5) than other objects of type T. Further, whether operations on an atomic_ref are lock-free could depend on the alignment of the referenced object. For example, lock-free operations on std::complex<double> could be supported only if aligned to 2*alignof(double). — end note]

atomic_ref(T& obj);

Requires: The referenced object shall be aligned to required_alignment.
Effects: Constructs an atomic reference that references the object.
Throws: Nothing.

atomic_ref(const atomic_ref&amp; ref) noexcept;
Effects: Constructs an atomic reference that references the object referenced by ref.

T operator=(T desired) const noexcept;
Effects: Equivalent to:
store(desired);
return desired;

operator T() const noexcept;
Effects: Equivalent to: return load();

bool is_lock_free() const noexcept;
Returns: true if the object’s operations are lock-free, false otherwise.

void store(T desired, memory_order order = memory_order_seq_cst) const noexcept;
Requires: The order argument shall not be memory_order_consume, memory_order_acquire, nor memory_order_acq_rel.
Effects: Atomically replaces the value referenced by *ptr with the value of desired. Memory is affected according to the value of order.

T load(memory_order order = memory_order_seq_cst) const noexcept;
Requires: The order argument shall not be memory_order_release nor memory_order_acq_rel.
Effects: Memory is affected according to the value of order.
Returns: Atomically returns the value referenced by *ptr.

T exchange(T desired, memory_order order = memory_order_seq_cst) const noexcept;
Effects: Atomically replaces the value referenced by *ptr with desired. Memory is affected according to the value of order. This operation is an atomic read-modify-write operation (6.8.2).
Returns: Atomically returns the value referenced by *ptr immediately before the effects.

bool compare_exchange_weak(T&amp; expected, T desired,
memory_order success, memory_order failure) const noexcept;

bool compare_exchange_strong(T&amp; expected, T desired,
memory_order success, memory_order failure) const noexcept;

bool compare_exchange_weak(T&amp; expected, T desired,
memory_order order = memory_order_seq_cst) const noexcept;
bool compare_exchange_strong(T& expected, T desired,
    memory_order order = memory_order_seq_cst) const noexcept;

18  Requires: The failure argument shall not be memory_order_release nor memory_order_acq_rel.

19  Effects: Retrieves the value in expected. It then atomically compares the value referenced by *ptr for equality with that previously retrieved from expected, and if true, replaces the value referenced by *ptr with that in desired. If and only if the comparison is true, memory is affected according to the value of success, and if the comparison is false, memory is affected according to the value of failure. When only one memory_order argument is supplied, the value of success is order, and the value of failure is order except that a value of memory_order_acquire shall be replaced by the value memory_order_acquire and a value of memory_order_release shall be replaced by the value memory_order_relaxed. If and only if the comparison is false then, after the atomic operation, the contents of the memory in expected are replaced by the value read from the value referenced by *ptr during the atomic comparison. If the operation returns true, these operations are atomic read-modify-write operations (6.8.2.1) on the value referenced by *ptr. Otherwise, these operations are atomic load operations on that memory.

20  Returns: The result of the comparison.

21  Remarks: A weak compare-and-exchange operation may fail spuriously. That is, even when the contents of memory referred to by expected and ptr are equal, it may return false and store back to expected the same memory contents that were originally there. [Note: This spurious failure enables implementation of compare-and-exchange on a broader class of machines, e.g., load-locked store-conditional machines. A consequence of spurious failure is that nearly all uses of weak compare-and-exchange will be in a loop. When a compare-and-exchange is in a loop, the weak version will yield better performance on some platforms. When a weak compare-and-exchange would require a loop and a strong one would not, the strong one is preferable. —end note]

29.6.2 Specializations for integral types

[atomics.ref.int] There are specializations of the atomic_ref class template for the integral types char, signed char, unsigned char, short, unsigned short, int, unsigned int, long, unsigned long, long long, unsigned long long, char16_t, char32_t, and wchar_t, and any other types needed by the typedefs in the header <cstdint>. For each such type integral, the specialization atomic_ref<integral> provides additional atomic operations appropriate to integral types. [Note: For the specialization atomic_ref<bool>, see 29.6. —end note]

namespace std {
    template<> struct atomic_ref<integral> {
private:
    integral* ptr;  // exposition only

public:
    using value_type = integral;
    using difference_type = value_type;
    static constexpr bool is_always_lock_free = implementation-defined;
    static constexpr size_t required_alignment = implementation-defined;

    atomic_ref() = delete;
    atomic_ref& operator=(const atomic_ref&) = delete;

    explicit atomic_ref(integral&);
    atomic_ref(const atomic_ref&) noexcept;

    integral operator=(integral) const noexcept;
    operator integral() const noexcept;

    bool is_lock_free() const noexcept;
    void store(integral, memory_order = memory_order_seq_cst) const noexcept;
    integral load(memory_order = memory_order_seq_cst) const noexcept;
    integral exchange(integral,
        memory_order = memory_order_seq_cst) const noexcept;
    bool compare_exchange_weak(integral&, integral,
        memory_order, memory_order) const noexcept;

§ 29.6.2  1323
bool compare_exchange_strong(integral& l, integral, memory_order, memory_order) const noexcept;
bool compare_exchange_weak(integral& l, integral, memory_order = memory_order_seq_cst) const noexcept;
bool compare_exchange_strong(integral& l, integral, memory_order = memory_order_seq_cst) const noexcept;

integral fetch_add(integral, memory_order = memory_order_seq_cst) const noexcept;
integral fetch_sub(integral, memory_order = memory_order_seq_cst) const noexcept;
integral fetch_and(integral, memory_order = memory_order_seq_cst) const noexcept;
integral fetch_or(integral, memory_order = memory_order_seq_cst) const noexcept;
integral fetch_xor(integral, memory_order = memory_order_seq_cst) const noexcept;

integral operator++(int) const noexcept;
integral operator--(int) const noexcept;
integral operator++() const noexcept;
integral operator--() const noexcept;
integral operator+=(integral) const noexcept;
integral operator-=(integral) const noexcept;
integral operator&=(integral) const noexcept;
integral operator|=(integral) const noexcept;
integral operator^=(integral) const noexcept;

§ 29.6.3 1324

2 Descriptions are provided below only for members that differ from the primary template.
3 The following operations perform arithmetic computations. The key, operator, and computation correspondence is identified in Table 133.

integral fetch_key(integral operand, memory_order order = memory_order_seq_cst) const noexcept;

4 Effects: Atomically replaces the value referenced by *ptr with the result of the computation applied to the value referenced by *ptr and the given operand. Memory is affected according to the value of order. These operations are atomic read-modify-write operations (6.8.2.1).
5 Returns: Atomically, the value referenced by *ptr immediately before the effects.
6 Remarks: For signed integer types, arithmetic is defined to use two’s complement representation. There are no undefined results.

integral operator op=(integral operand) const noexcept;

7 Effects: Equivalent to: return fetch_key(operand) op operand;

29.6.3 Specializations for floating-point types

There are specializations of the atomic_ref class template for the floating-point types float, double, and long double. For each such type floating-point, the specialization atomic_ref<floating-point> provides additional atomic operations appropriate to floating-point types.

namespace std {
    template<> struct atomic_ref<floating-point> {
        private:
            floating-point* ptr; // exposition only
        public:
            using value_type = floating-point;
            using difference_type = value_type;
            static constexpr bool is_always_lock_free = implementation-defined;
            static constexpr size_t required_alignment = implementation-defined;

            atomic_ref() = delete;
            atomic_ref& operator=(const atomic_ref&) = delete;
    };
}
explicit atomic_ref(floating-point);
atomic_ref(const atomic_ref&) noexcept;

floating-point operator=(floating-point) noexcept;
operator floating-point() const noexcept;

bool is_lock_free() const noexcept;
void store(floating-point, memory_order = memory_order_seq_cst) const noexcept;
floating-point load(memory_order = memory_order_seq_cst) const noexcept;
floating-point exchange(floating-point,
    memory_order = memory_order_seq_cst) const noexcept;
bool compare_exchange_weak(floating-point&, floating-point,
    memory_order, memory_order) const noexcept;
bool compare_exchange_strong(floating-point&, floating-point,
    memory_order = memory_order_seq_cst) const noexcept;
bool compare_exchange_weak(floating-point&, floating-point,
    memory_order, memory_order) const noexcept;
bool compare_exchange_strong(floating-point&, floating-point,
    memory_order = memory_order_seq_cst) const noexcept;

floating-point fetch_add(floating-point,
    memory_order = memory_order_seq_cst) const noexcept;

floating-point fetch_sub(floating-point,
    memory_order = memory_order_seq_cst) const noexcept;

floating-point operator+=((floating-point) const noexcept;
floating-point operator-=((floating-point) const noexcept;
}

2 Descriptions are provided below only for members that differ from the primary template.
3 The following operations perform arithmetic computations. The key, operator, and computation correspondence are identified in Table 133.

floating-point fetch_key(floating-point operand,
    memory_order order = memory_order_seq_cst) const noexcept;

Effects: Atomically replaces the value referenced by *ptr with the result of the computation applied to the value referenced by *ptr and the given operand. Memory is affected according to the value of order. These operations are atomic read-modify-write operations (6.8.2.1).

Returns: Atomically, the value referenced by *ptr immediately before the effects.

Remarks: If the result is not a representable value for its type (7.1), the result is unspecified, but the operations otherwise have no undefined behavior. Atomic arithmetic operations on floating-point should conform to the std::numeric_limits<floating-point> traits associated with the floating-point type (16.3.2). The floating-point environment (24.4) for atomic arithmetic operations on floating-point may be different than the calling thread's floating-point environment.

floating-point operator op=(floating-point operand) const noexcept;

Effects: Equivalent to: return fetch_key(operand) op operand;

29.6.4 Partial specialization for pointers

namespace std {
    template<class T> struct atomic_ref<T*> {
    private:
        T** ptr; // exposition only
    public:
        using value_type = T*;
        using difference_type = ptrdiff_t;
        static constexpr bool is_always_lock_free = implementation-defined;
        static constexpr size_t required_alignment = implementation-defined;
    };
}
atomic_ref() = delete;
atomic_ref& operator=(const atomic_ref&) = delete;

explicit atomic_ref(T*);
atomic_ref(const atomic_ref&) noexcept;
T* operator=(T*) const noexcept;
operator T*() const noexcept;

bool is_lock_free() const noexcept;
void store(T*, memory_order = memory_order_seq_cst) const noexcept;
T* exchange(T*, memory_order = memory_order_seq_cst) const noexcept;
bool compare_exchange_weak(T*&, T*,
    memory_order, memory_order) const noexcept;
bool compare_exchange_strong(T*&, T*,
    memory_order = memory_order_seq_cst) const noexcept;
bool compare_exchange_weak(T*&, T*,
    memory_order, memory_order) const noexcept;
bool compare_exchange_strong(T*&, T*,
    memory_order = memory_order_seq_cst) const noexcept;
T* fetch_add(difference_type, memory_order = memory_order_seq_cst) const noexcept;
T* fetch_sub(difference_type, memory_order = memory_order_seq_cst) const noexcept;
T* operator++(int) const noexcept;
T* operator--(int) const noexcept;
T* operator++() const noexcept;
T* operator--() const noexcept;
T* operator+=(difference_type) const noexcept;
T* operator-=(difference_type) const noexcept;

1 Descriptions are provided below only for members that differ from the primary template.

2 The following operations perform arithmetic computations. The key, operator, and computation correspondence is identified in Table 134.

T* fetch_key(difference_type operand, memory_order_order = memory_order_seq_cst) const noexcept;

3 Requires: T shall be an object type, otherwise the program is ill-formed.

4 Effects: Atomically replaces the value referenced by *ptr with the result of the computation applied to the value referenced by *ptr and the given operand. Memory is affected according to the value of order. These operations are atomic read-modify-write operations (6.8.2.1).

5 Returns: Atomically, the value referenced by *ptr immediately before the effects.

6 Remarks: The result may be an undefined address, but the operations otherwise have no undefined behavior.

T* operator op=(difference_type operand) const noexcept;

7 Effects: Equivalent to: return fetch_key(operand) op operand;

29.6.5 Member operators common to integers and pointers to objects
[atomics.ref.memop]

T* operator++(int) const noexcept;

8 Effects: Equivalent to: return fetch_add(1);

T* operator--(int) const noexcept;

9 Effects: Equivalent to: return fetch_sub(1);

T* operator++() const noexcept;

10 Effects: Equivalent to: return fetch_add(1) + 1;
T* operator--(int) const noexcept;

Effects: Equivalent to: return fetch_sub(1) - 1;

29.7 Class template atomic

namespace std {
    template<class T> struct atomic {
        using value_type = T;
        static constexpr bool is_always_lock_free = implementation-defined;
        bool is_lock_free() const volatile noexcept;
        bool is_lock_free() const noexcept;
        void store(T, memory_order = memory_order::seq_cst) volatile noexcept;
        void store(T, memory_order = memory_order::seq_cst) noexcept;
        T load(memory_order = memory_order::seq_cst) const volatile noexcept;
        T load(memory_order = memory_order::seq_cst) const noexcept;
        operator T() const volatile noexcept;
        operator T() const noexcept;
        T exchange(T, memory_order = memory_order::seq_cst) volatile noexcept;
        T exchange(T, memory_order = memory_order::seq_cst) noexcept;
        bool compare_exchange_weak(T&, T, memory_order, memory_order) volatile noexcept;
        bool compare_exchange_weak(T&, T, memory_order, memory_order) noexcept;
        bool compare_exchange_strong(T&, T, memory_order, memory_order) volatile noexcept;
        bool compare_exchange_strong(T&, T, memory_order, memory_order) noexcept;
        bool compare_exchange_weak(T&, T, memory_order = memory_order::seq_cst) volatile noexcept;
        bool compare_exchange_weak(T&, T, memory_order = memory_order::seq_cst) noexcept;
        bool compare_exchange_strong(T&, T, memory_order = memory_order::seq_cst) volatile noexcept;
        bool compare_exchange_strong(T&, T, memory_order = memory_order::seq_cst) noexcept;
        atomic() noexcept = default;
        constexpr atomic(T) noexcept;
        atomic(const atomic&) = delete;
        atomic& operator=(const atomic&) = delete;
        atomic& operator=(const atomic&) volatile = delete;
        T operator=(T) volatile noexcept;
        T operator=(T) noexcept;
    }
};

The template argument for T shall be trivially copyable (6.7). [Note: Type arguments that are not also statically initializable may be difficult to use. —end note]

2 The specialization atomic<bool> is a standard-layout struct.

3 [Note: The representation of an atomic specialization need not have the same size as its corresponding argument type. Specializations should have the same size whenever possible, as this reduces the effort required to port existing code. —end note]

29.7.1 Operations on atomic types

[atomics.types.operations]

1 [Note: Many operations are volatile-qualified. The “volatile as device register” semantics have not changed in the standard. This qualification means that volatility is preserved when applying these operations to volatile objects. It does not mean that operations on non-volatile objects become volatile. —end note]

atomic() noexcept = default;

2 Effects: Leaves the atomic object in an uninitialized state. [Note: These semantics ensure compatibility with C. —end note]

constexpr atomic(T desired) noexcept;

3 Effects: Initializes the object with the value desired. Initialization is not an atomic operation (6.8.2). [Note: It is possible to have an access to an atomic object A race with its construction, for example by communicating the address of the just-constructed object A to another thread via memory_order::relaxed operations on a suitable atomic pointer variable, and then immediately accessing A in the receiving thread. This results in undefined behavior. —end note]
#define ATOMIC_VAR_INIT(value) see below

The macro expands to a token sequence suitable for constant initialization of an atomic variable of static storage duration of a type that is initialization-compatible with value. [Note: This operation may need to initialize locks. — end note] Concurrent access to the variable being initialized, even via an atomic operation, constitutes a data race. [Example:

```c
atomic<int> v = ATOMIC_VAR_INIT(5);
```
—end example]

static constexpr bool is_always_lock_free = implementation-defined;

The static data member is_always_lock_free is true if the atomic type’s operations are always lock-free, and false otherwise. [Note: The value of is_always_lock_free is consistent with the value of the corresponding ATOMIC_.LOCK_FREE macro, if defined. — end note]

bool is_lock_free() const volatile noexcept;
bool is_lock_free() const noexcept;

Returns: true if the object’s operations are lock-free, false otherwise. [Note: The return value of the is_lock_free member function is consistent with the value of is_always_lock_free for the same type. — end note]

void store(T desired, memory_order order = memory_order::seq_cst) volatile noexcept;
void store(T desired, memory_order order = memory_order::seq_cst) noexcept;

Requires: The order argument shall not be memory_order::consume, memory_order::acquire, nor memory_order::acq_rel.

Effects: Atomically replaces the value pointed to by this with the value of desired. Memory is affected according to the value of order.

T operator=(T desired) volatile noexcept;
T operator=(T desired) noexcept;

Effects: Equivalent to store(desired).

Returns: desired.

T load(memory_order order = memory_order::seq_cst) const volatile noexcept;
T load(memory_order order = memory_order::seq_cst) const noexecept;

Requires: The order argument shall not be memory_order::release nor memory_order::acq_rel.

Effects: Memory is affected according to the value of order.

Returns: Atomically returns the value pointed to by this.

operator T() const volatile noexcept;
operator T() const noexcept;

Effects: Equivalent to: return load();

T exchange(T desired, memory_order order = memory_order::seq_cst) volatile noexecept;
T exchange(T desired, memory_order order = memory_order::seq_cst) noexecept;

Effects: Atomically replaces the value pointed to by this with desired. Memory is affected according to the value of order. These operations are atomic read-modify-write operations (6.8.2).

Returns: Atomically returns the value pointed to by this immediately before the effects.

bool compare_exchange_weak(T& expected, T desired,
memory_order success, memory_order failure) volatile noexecept;
bool compare_exchange_weak(T& expected, T desired,
memory_order success, memory_order failure) noexecept;
bool compare_exchange_strong(T& expected, T desired,
memory_order success, memory_order failure) volatile noexecept;
bool compare_exchange_strong(T& expected, T desired,
memory_order success, memory_order failure) noexecept;
bool compare_exchange_weak(T& expected, T desired,
memory_order order = memory_order::seq_cst) volatile noexecept;
bool compare_exchange_weak(T& expected, T desired,
               memory_order order = memory_order::seq_cst) noexcept;
bool compare_exchange_strong(T& expected, T desired,
               memory_order order = memory_order::seq_cst) volatile noexcept;
bool compare_exchange_strong(T& expected, T desired,
               memory_order order = memory_order::seq_cst) noexcept;

Requires: The failure argument shall not be memory_order::release nor memory_order::acq_rel.

Effects: Retrieves the value in expected. It then atomically compares the value representation of
the value pointed to by this for equality with that previously retrieved from expected, and if true,
replaces the value pointed to by this with that in desired. If and only if the comparison is true, memory is affected according to the value of success, and if the comparison is false, memory is affected according to the value of failure. When only one memory_order argument is supplied, the value of
success is order, and the value of failure is order except that a value of memory_order::acq_rel
shall be replaced by the value memory_order::acquire and a value of memory_order::release shall be replaced by the value memory_order::relaxed. If and only if the comparison is false then, after the atomic operation, the value in expected is replaced by the value pointed to by this during the atomic comparison. If the operation returns true, these operations are atomic read-modify-write operations (6.8.2) on the memory pointed to by this. Otherwise, these operations are atomic load operations on that memory.

Returns: The result of the comparison.

[Note: For example, the effect of compare_exchange_strong on objects without padding bits (6.7) is
if (memcmp(this, &expected, sizeof(*this)) == 0)
    memcpy(this, &desired, sizeof(*this));
else
    memcpy(expected, this, sizeof(*this));
— end note] [Example: The expected use of the compare-and-exchange operations is as follows. The compare-and-exchange operations will update expected when another iteration of the loop is needed.
expected = current.load();
do {
    desired = function(expected);
} while (!current.compare_exchange_weak(expected, desired));
— end example] [Example: Because the expected value is updated only on failure, code releasing the memory containing the expected value on success will work. E.g. list head insertion will act atomically and would not introduce a data race in the following code:
do {
    p->next = head; // make new list node point to the current head
} while (!head.compare_exchange_weak(p->next, p)); // try to insert
— end example]

Implementations should ensure that weak compare-and-exchange operations do not consistently return
false unless either the atomic object has value different from expected or there are concurrent modifications to the atomic object.

Remarks: A weak compare-and-exchange operation may fail spuriously. That is, even when the contents of memory referred to by expected and this are equal, it may return false and store back to expected the same memory contents that were originally there. [Note: This spurious failure enables implementation of compare-and-exchange on a broader class of machines, e.g., load-locked store-conditional machines. A consequence of spurious failure is that nearly all uses of weak compare-and-exchange will be in a loop. When a compare-and-exchange is in a loop, the weak version will yield better performance on some platforms. When a weak compare-and-exchange would require a loop and a strong one would not, the strong one is preferable. — end note]

[Note: Under cases where the memcpy and memcmp semantics of the compare-and-exchange operations apply, the outcome might be failed comparisons for values that compare equal with operator== if the value representation has trap bits or alternate representations of the same value. Notably, on implementations conforming to ISO/IEC/IEEE 60559, floating-point -0.0 and +0.0 will not compare equal with memcmp but will compare equal with operator==, and NaNs with the same payload will compare equal with memcmp but will not compare equal with operator==. — end note] [Note: Because
compare-and-exchange acts on an object’s value representation, padding bits that never participate in the object’s value representation are ignored. As a consequence, the following code is guaranteed to avoid spurious failure:

```c
struct padded {
    char clank = 0x42;
    // Padding here.
    unsigned biff = 0xCODEFEFE;
};
atomic<padded> pad = ATOMIC_VAR_INIT({});

bool zap() {
    padded expected, desired{0, 0};
    return pad.compare_exchange_strong(expected, desired);
}
```

—end note] [Note: For a union with bits that participate in the value representation of some members but not others, compare-and-exchange might always fail. This is because such padding bits have an indeterminate value when they do not participate in the value representation of the active member. As a consequence, the following code is not guaranteed to ever succeed:

```c
union pony {
    double celestia = 0.;
    short luna; // padded
};
atomic<pony> princesses = ATOMIC_VAR_INIT({});

bool party(pony desired) {
    pony expected;
    return princesses.compare_exchange_strong(expected, desired);
}
```

—end note]

### 29.7.2 Specializations for integers

There are specializations of the `atomic` class template for the integral types `char`, `signed char`, `unsigned char`, `short`, `unsigned short`, `int`, `unsigned int`, `long`, `unsigned long`, `long long`, `unsigned long long`, `char16_t`, `char32_t`, and `wchar_t`, and any other types needed by the typedefs in the header `<cstdint>`. For each such type `integral`, the specialization `atomic<integral>` provides additional atomic operations appropriate to integral types. [Note: For the specialization `atomic<bool>`, see 29.7. — end note]

```c
namespace std {
    template<> struct atomic<integral> {
        using value_type = integral;
        using difference_type = value_type;
        static constexpr bool is_always_lock_free = implementation-defined;
        bool is_lock_free() const volatile noexcept;
        bool is_lock_free() const noexcept;
        void store(integral, memory_order = memory_order::seq_cst) volatile noexcept;
        void store(integral, memory_order = memory_order::seq_cst) noexcept;
        integral load(memory_order = memory_order::seq_cst) const volatile noexcept;
        integral load(memory_order = memory_order::seq_cst) const noexcept;
        operator integral() const volatile noexcept;
        operator integral() const noexcept;
        integral exchange(integral, memory_order = memory_order::seq_cst) volatile noexcept;
        integral exchange(integral, memory_order = memory_order::seq_cst) noexcept;
        bool compare_exchange_weak(integral&, integral,
            memory_order, memory_order) volatile noexcept;
        bool compare_exchange_weak(integral&, integral,
            memory_order, memory_order) noexcept;
        bool compare_exchange_strong(integral&, integral,
            memory_order, memory_order) volatile noexcept;
        bool compare_exchange_strong(integral&, integral,
            memory_order, memory_order) noexcept;
    }
}
```
bool compare_exchange_weak(integral&, integral, 
    memory_order = memory_order::seq_cst) volatile noexcept;
bool compare_exchange_weak(integral&, integral, 
    memory_order = memory_order::seq_cst) noexcept;
bool compare_exchange_strong(integral&, integral, 
    memory_order = memory_order::seq_cst) volatile noexcept;
bool compare_exchange_strong(integral&, integral, 
    memory_order = memory_order::seq_cst) noexcept;

integral fetch_add(integral, memory_order = memory_order::seq_cst) volatile noexcept;
integral fetch_add(integral, memory_order = memory_order::seq_cst) noexcept;
integral fetch_sub(integral, memory_order = memory_order::seq_cst) volatile noexcept;
integral fetch_sub(integral, memory_order = memory_order::seq_cst) noexcept;
integral fetch_and(integral, memory_order = memory_order::seq_cst) volatile noexcept;
integral fetch_and(integral, memory_order = memory_order::seq_cst) noexcept;
integral fetch_or(integral, memory_order = memory_order::seq_cst) volatile noexcept;
integral fetch_or(integral, memory_order = memory_order::seq_cst) noexcept;
integral fetch_xor(integral, memory_order = memory_order::seq_cst) volatile noexcept;
integral fetch_xor(integral, memory_order = memory_order::seq_cst) noexcept;

atomic() noexcept = default;
constexpr atomic(integral) noexcept;
atomic(const atomic&) = delete;
atomic& operator=(const atomic&) = delete;
atomic& operator=(const atomic&) volatile = delete;

integral operator=(integral) volatile noexcept;
integral operator=(integral) noexcept;
integral operator++(int) volatile noexcept;
integral operator++(int) noexcept;
integral operator--(int) volatile noexcept;
integral operator--(int) noexcept;
integral operator++() volatile noexcept;
integral operator++() noexcept;
integral operator--() volatile noexcept;
integral operator--() noexcept;
integral operator+=(integral) volatile noexcept;
integral operator+=(integral) noexcept;
integral operator-=(integral) volatile noexcept;
integral operator-=(integral) noexcept;
integral operator&=(integral) volatile noexcept;
integral operator&=(integral) noexcept;
integral operator|=(integral) volatile noexcept;
integral operator|=(integral) noexcept;
integral operator^=(integral) volatile noexcept;
integral operator^=(integral) noexcept;

T fetch_key(T operand, memory_order order = memory_order::seq_cst) volatile noexcept;

2 The atomic integral specializations are standard-layout structs. They each have a trivial default constructor and a trivial destructor.

3 Descriptions are provided below only for members that differ from the primary template.

4 The following operations perform arithmetic computations. The key, operator, and computation correspondence is:

<table>
<thead>
<tr>
<th>key</th>
<th>Op</th>
<th>Computation</th>
</tr>
</thead>
<tbody>
<tr>
<td>add</td>
<td>+</td>
<td>addition</td>
</tr>
<tr>
<td>or</td>
<td></td>
<td>bitwise inclusive or</td>
</tr>
<tr>

<td>-</td>
<td>subtraction</td>
</tr>
<tr>
<td>xor</td>
<td>^</td>
<td>bitwise exclusive or</td>
</tr>
</tbody>
</table>

§ 29.7.2
T fetch_key(T operand, memory_order order = memory_order::seq_cst) noexcept;

Effects: Atomically replaces the value pointed to by this with the result of the computation applied to the value pointed to by this and the given operand. Memory is affected according to the value of order. These operations are atomic read-modify-write operations (6.8.2).

Returns: Atomically, the value pointed to by this immediately before the effects.

Remarks: For signed integer types, arithmetic is defined to use two’s complement representation. There are no undefined results.

T operator op=(T operand) volatile noexcept;
T operator op=(T operand) noexcept;

Effects: Equivalent to: return fetch_key(operand) op operand;

29.7.3 Specializations for floating-point types [atomics.types.float]

There are specializations of the atomic class template for the floating-point types float, double, and long double. For each such type floating-point, the specialization atomic<floating-point> provides additional atomic operations appropriate to floating-point types.

namespace std {
  template<> struct atomic<floating-point> {
    using value_type = floating-point;
    using difference_type = value_type;
    static constexpr bool is_always_lock_free = implementation-defined;
    bool is_lock_free() const volatile noexcept;
    bool is_lock_free() const noexcept;
    void store(float, memory_order = memory_order_seq_cst) volatile noexcept;
    void store(float, memory_order = memory_order_seq_cst) noexcept;
    float load(memory_order = memory_order_seq_cst) volatile noexcept;
    float load(memory_order = memory_order_seq_cst) noexcept;
    operator float() volatile noexcept;
    operator float() noexcept;
    float exchange(float, memory_order = memory_order_seq_cst) volatile noexcept;
    float exchange(float, memory_order = memory_order_seq_cst) noexcept;
    bool compare_exchange_weak(float&, float, memory_order, memory_order) volatile noexcept;
    bool compare_exchange_weak(float&, float, memory_order, memory_order) noexcept;
    bool compare_exchange_strong(float&, float, memory_order, memory_order) volatile noexcept;
    bool compare_exchange_strong(float&, float, memory_order, memory_order) noexcept;
    bool compare_exchange_weak(float&, float, memory_order = memory_order_seq_cst) volatile noexcept;
    bool compare_exchange_weak(float&, float, memory_order = memory_order_seq_cst) noexcept;
    bool compare_exchange_strong(float&, float, memory_order = memory_order_seq_cst) volatile noexcept;
    bool compare_exchange_strong(float&, float, memory_order = memory_order_seq_cst) noexcept;
    float fetch_add(float, memory_order = memory_order_seq_cst) volatile noexcept;
    float fetch_add(float, memory_order = memory_order_seq_cst) noexcept;
    float fetch_sub(float, memory_order = memory_order_seq_cst) volatile noexcept;
    float fetch_sub(float, memory_order = memory_order_seq_cst) noexcept;
  }
}
The atomic floating-point specializations are standard-layout structs. They each have a trivial default constructor and a trivial destructor.

Descriptions are provided below only for members that differ from the primary template.

The following operations perform arithmetic addition and subtraction computations. The key, operator, and computation correspondence are identified in Table 133.

Operator |
--- |
T A::fetch_key(T operand, memory_order order = memory_order_seq_cst) volatile noexcept; |
T A::fetch_key(T operand, memory_order order = memory_order_seq_cst) noexcept; |

Effects: Atomically replaces the value pointed to by \texttt{this} with the result of the computation applied to the value pointed to by \texttt{this} and the given \texttt{operand}. Memory is affected according to the value of \texttt{order}. These operations are atomic read-modify-write operations (6.8.2).

Returns: Atomically, the value pointed to by \texttt{this} immediately before the effects.

Remarks: If the result is not a representable value for its type (7.1) the result is unspecified, but the operations otherwise have no undefined behavior. Atomic arithmetic operations on \texttt{floating-point} should conform to the \texttt{std::numeric_limits<floating-point>} traits associated with the floating-point type (16.3.2). The floating-point environment (24.4) for atomic arithmetic operations on \texttt{floating-point} may be different than the calling thread’s floating-point environment.

Operator |
--- |
T operator op=(T operand) volatile noexcept; |
T operator op=(T operand) noexcept; |

Effects: Equivalent to: \texttt{return fetch_key(operand) op operand;}

Remarks: If the result is not a representable value for its type (7.1) the result is unspecified, but the operations otherwise have no undefined behavior. Atomic arithmetic operations on \texttt{floating-point} should conform to the \texttt{std::numeric_limits<floating-point>} traits associated with the floating-point type (16.3.2). The floating-point environment (24.4) for atomic arithmetic operations on \texttt{floating-point} may be different than the calling thread’s floating-point environment.

29.7.4 Partial specialization for pointers

```cpp
namespace std {
    template<class T> struct atomic<T*> { 
        using value_type = T*; 
        using difference_type = ptrdiff_t; 
        static constexpr bool is_always_lock_free = implementation-defined; 
        bool is_lock_free() const volatile noexcept; 
        bool is_lock_free() const noexcept; 
        void store(T*, memory_order = memory_order::seq_cst) volatile noexcept; 
        void store(T*, memory_order = memory_order::seq_cst) noexcept; 
        T* load(memory_order = memory_order::seq_cst) const volatile noexcept; 
        T* load(memory_order = memory_order::seq_cst) const noexcept; 
        operator T*() const volatile noexcept; 
        operator T*() const noexcept; 
        T* exchange(T*, memory_order = memory_order::seq_cst) volatile noexcept; 
        T* exchange(T*, memory_order = memory_order::seq_cst) noexcept; 
        bool compare_exchange_weak(T*& T, T*, memory_order, memory_order) volatile noexcept; 
        bool compare_exchange_weak(T*& T, T*, memory_order, memory_order) noexcept; 
        bool compare_exchange_strong(T*& T, T*, memory_order, memory_order) volatile noexcept; 
        bool compare_exchange_strong(T*& T, T*, memory_order, memory_order) noexcept; 
    };
}
```
bool compare_exchange_weak(T*&, T*,
    memory_order = memory_order::seq_cst) volatile noexcept;
bool compare_exchange_weak(T*&, T*,
    memory_order = memory_order::seq_cst) noexcept;
bool compare_exchange_strong(T*&, T*,
    memory_order = memory_order::seq_cst) volatile noexcept;
bool compare_exchange_strong(T*&, T*,
    memory_order = memory_order::seq_cst) noexcept;
T* fetch_add(ptrdiff_t, memory_order = memory_order::seq_cst) volatile noexcept;
T* fetch_add(ptrdiff_t, memory_order = memory_order::seq_cst) noexcept;
T* fetch_sub(ptrdiff_t, memory_order = memory_order::seq_cst) volatile noexcept;
T* fetch_sub(ptrdiff_t, memory_order = memory_order::seq_cst) noexcept;
atomic() noexcept = default;
constexpr atomic(T*) noexcept;
atomic(const atomic&) = delete;
atomic& operator=(const atomic&) = delete;
atomic& operator=(const atomic&) volatile = delete;
T* operator=(T*) volatile noexcept;
T* operator=(T*) noexcept;
T* operator++(int) volatile noexcept;
T* operator++(int) noexcept;
T* operator--(int) volatile noexcept;
T* operator--(int) noexcept;
T* operator++() volatile noexcept;
T* operator++() noexcept;
T* operator--() volatile noexcept;
T* operator--() noexcept;
T* operator+=(ptrdiff_t) volatile noexcept;
T* operator+=(ptrdiff_t) noexcept;
T* operator-=(ptrdiff_t) volatile noexcept;
T* operator-=(ptrdiff_t) noexcept;

1 There is a partial specialization of the atomic class template for pointers. Specializations of this partial specialization are standard-layout structs. They each have a trivial default constructor and a trivial destructor.
2 Descriptions are provided below only for members that differ from the primary template.
3 The following operations perform pointer arithmetic. The key, operator, and computation correspondence is:

<table>
<thead>
<tr>
<th>Key Op</th>
<th>Computation</th>
<th>Key Op</th>
<th>Computation</th>
</tr>
</thead>
<tbody>
<tr>
<td>add +</td>
<td>addition</td>
<td>sub -</td>
<td>subtraction</td>
</tr>
</tbody>
</table>

T* fetch_key(ptrdiff_t operand, memory_order order = memory_order::seq_cst) volatile noexcept;
T* fetch_key(ptrdiff_t operand, memory_order order = memory_order::seq_cst) noexcept;
4 Requires: T shall be an object type, otherwise the program is ill-formed. [Note: Pointer arithmetic on void* or function pointers is ill-formed. —end note]
5 Effects: Atomically replaces the value pointed to by this with the result of the computation applied to the value pointed to by this and the given operand. Memory is affected according to the value of order. These operations are atomic read-modify-write operations (6.8.2).
6 Returns: Atomically, the value pointed to by this immediately before the effects.
7 Remarks: The result may be an undefined address, but the operations otherwise have no undefined behavior.

T* operator op=(ptrdiff_t operand) volatile noexcept;
T* operator op=(ptrdiff_t operand) noexcept;
8 Effects: Equivalent to: return fetch_key(operand) op operand;
29.7.5 Member operators common to integers and pointers to objects

[atomics.types.memop]

T operator++(int) volatile noexcept;
T operator++(int) noexcept;

Effects: Equivalent to: return fetch_add(1);

T operator--(int) volatile noexcept;
T operator--(int) noexcept;

Effects: Equivalent to: return fetch_sub(1);

T operator++() volatile noexcept;
T operator++() noexcept;

Effects: Equivalent to: return fetch_add(1) + 1;

T operator--() volatile noexcept;
T operator--() noexcept;

Effects: Equivalent to: return fetch_sub(1) - 1;

29.8 Non-member functions

[atomics.nonmembers]

A non-member function template whose name matches the pattern atomic_f or the pattern atomic_f_explicit invokes the member function f, with the value of the first parameter as the object expression and the values of the remaining parameters (if any) as the arguments of the member function call, in order. An argument for a parameter of type atomic<T>::value_type* is dereferenced when passed to the member function call. If no such member function exists, the program is ill-formed.

template<class T>
void atomic_init(volatile atomic<T>* object, typename atomic<T>::value_type desired) noexcept;

Effects: Non-atomically initializes *object with value desired. This function shall only be applied to objects that have been default constructed, and then only once. [Note: These semantics ensure compatibility with C. — end note] [Note: Concurrent access from another thread, even via an atomic operation, constitutes a data race. — end note]

3 [Note: The non-member functions enable programmers to write code that can be compiled as either C or C++, for example in a shared header file. — end note]

29.9 Flag type and operations

[atomics.flag]

namespace std {

struct atomic_flag {
    bool test_and_set(memory_order = memory_order::seq_cst) volatile noexcept;
    bool test_and_set(memory_order = memory_order::seq_cst) noexcept;
    void clear(memory_order = memory_order::seq_cst) volatile noexcept;
    void clear(memory_order = memory_order::seq_cst) noexcept;

    atomic_flag() noexcept = default;
    atomic_flag(const atomic_flag&) = delete;
    atomic_flag& operator=(const atomic_flag&) volatile = delete;
};

bool atomic_flag_test_and_set(volatile atomic_flag*) noexcept;
bool atomic_flag_test_and_set(atomic_flag*) noexcept;
bool atomic_flag_test_and_set_explicit(volatile atomic_flag*, memory_order) noexcept;
bool atomic_flag_test_and_set_explicit(atomic_flag*, memory_order) noexcept;
void atomic_flag_clear(volatile atomic_flag*) noexcept;
void atomic_flag_clear(atomic_flag*) noexcept;
void atomic_flag_clear_explicit(volatile atomic_flag*, memory_order) noexcept;
void atomic_flag_clear_explicit(atomic_flag*, memory_order) noexcept;
}
#define ATOMIC_FLAG_INIT see below
}

The atomic_flag type provides the classic test-and-set functionality. It has two states, set and clear.

Operations on an object of type atomic_flag shall be lock-free. [Note: Hence the operations should also be address-free. — end note]

The atomic_flag type is a standard-layout struct. It has a trivial default constructor and a trivial destructor.

The macro ATOMIC_FLAG_INIT shall be defined in such a way that it can be used to initialize an object of type atomic_flag to the clear state. The macro can be used in the form:

    atomic_flag guard = ATOMIC_FLAG_INIT;

It is unspecified whether the macro can be used in other initialization contexts. For a complete static-duration object, that initialization shall be static. Unless initialized with ATOMIC_FLAG_INIT, it is unspecified whether an atomic_flag object has an initial state of set or clear.

bool atomic_flag_test_and_set(volatile atomic_flag* object) noexcept;
bool atomic_flag_test_and_set(atomic_flag* object) noexcept;
bool atomic_flag_test_and_set_explicit(volatile atomic_flag* object, memory_order order) noexcept;
bool atomic_flag_test_and_set_explicit(atomic_flag* object, memory_order order) noexcept;
bool atomic_flag::test_and_set(memory_order order = memory_order::seq_cst) volatile noexcept;
bool atomic_flag::test_and_set(memory_order order = memory_order::seq_cst) noexcept;

Effects: Atomically sets the value pointed to by object or by this to true. Memory is affected according to the value of order. These operations are atomic read-modify-write operations (6.8.2).

Returns: Atomically, the value of the object immediately before the effects.

void atomic_flag_clear(volatile atomic_flag* object) noexcept;
void atomic_flag_clear(atomic_flag* object) noexcept;
void atomic_flag_clear_explicit(volatile atomic_flag* object, memory_order order) noexcept;
void atomic_flag_clear_explicit(atomic_flag* object, memory_order order) noexcept;
void atomic_flag::clear(memory_order order = memory_order::seq_cst) volatile noexcept;
void atomic_flag::clear(memory_order order = memory_order::seq_cst) noexcept;

Requires: The order argument shall not be memory_order::consume, memory_order::acquire, nor memory_order::acq_rel.

Effects: Atomically sets the value pointed to by object or by this to false. Memory is affected according to the value of order.

29.10 Fences [atomics.fences]

This subclause introduces synchronization primitives called fences. Fences can have acquire semantics, release semantics, or both. A fence with acquire semantics is called an acquire fence. A fence with release semantics is called a release fence.

A release fence A synchronizes with an acquire fence B if there exist atomic operations X and Y, both operating on some atomic object M, such that A is sequenced before X, X modifies M, Y is sequenced before B, and Y reads the value written by X or a value written by any side effect in the hypothetical release sequence X would head if it were a release operation.

A release fence A synchronizes with an atomic operation B that performs an acquire operation on an atomic object M if there exists an atomic operation X such that A is sequenced before X, X modifies M, and B reads the value written by X or a value written by any side effect in the hypothetical release sequence X would head if it were a release operation.

An atomic operation A that is a release operation on an atomic object M synchronizes with an acquire fence B if there exists some atomic operation X on M such that X is sequenced before B and reads the value written by A or a value written by any side effect in the release sequence headed by A.

extern "C" void atomic_thread_fence(memory_order order) noexcept;

Effects: Depending on the value of order, this operation:

(5.1) — has no effects, if order == memory_order::relaxed;
(5.2) — is an acquire fence, if order == memory_order::acquire or order == memory_order::consume;
(5.3) — is a release fence, if `order` == `memory_order::release`;
(5.4) — is both an acquire fence and a release fence, if `order` == `memory_order::acq_rel`;
(5.5) — is a sequentially consistent acquire and release fence, if `order` == `memory_order::seq_cst`.

```c
extern "C" void atomic_signal_fence(memory_order order) noexcept;
```

6 Effects: Equivalent to `atomic_thread_fence(order)`, except that the resulting ordering constraints are established only between a thread and a signal handler executed in the same thread.

7 [Note: `atomic_signal_fence` can be used to specify the order in which actions performed by the thread become visible to the signal handler. Compiler optimizations and reorderings of loads and stores are inhibited in the same way as with `atomic_thread_fence`, but the hardware fence instructions that `atomic_thread_fence` would have inserted are not emitted. — end note]
30 Thread support library
[thread]

30.1 General
[thread.general]
The following subclauses describe components to create and manage threads (6.8.2), perform mutual exclusion, and communicate conditions and values between threads, as summarized in Table 135.

Table 135 — Thread support library summary

<td>&lt;future&gt;</td>
</tr>
</tbody>
</table>

30.2 Requirements
[thread.req]

30.2.1 Template parameter names
[thread.req.paramname]
Throughout this Clause, the names of template parameters are used to express type requirements. If a template parameter is named `Predicate`, `operator()` applied to the template argument shall return a value that is convertible to `bool`. If a template parameter is named `Clock`, the corresponding template argument shall be a type `C` for which `is_clock_v<C>` is `true`; otherwise the program is ill-formed.

30.2.2 Exceptions
[thread.req.exception]
Some functions described in this Clause are specified to throw exceptions of type `system_error` (18.5.7). Such exceptions shall be thrown if any of the function’s error conditions is detected or a call to an operating system or other underlying API results in an error that prevents the library function from meeting its specifications. Failure to allocate storage shall be reported as described in 15.5.5.12.

[Example: Consider a function in this clause that is specified to throw exceptions of type `system_error` and specifies error conditions that include `operation_not_permitted` for a thread that does not have the privilege to perform the operation. Assume that, during the execution of this function, an `errno` of `EPERM` is reported by a POSIX API call used by the implementation. Since POSIX specifies an `errno` of `EPERM` when “the caller does not have the privilege to perform the operation”, the implementation maps `EPERM` to an `error_condition` of `operation_not_permitted` (18.5) and an exception of type `system_error` is thrown. —end example]

The `error_code` reported by such an exception’s `code()` member function shall compare equal to one of the conditions specified in the function’s `error condition` element.

30.2.3 Native handles
[thread.req.native]
Several classes described in this Clause have members `native_handle_type` and `native_handle`. The presence of these members and their semantics is implementation-defined. [Note: These members allow implementations to provide access to implementation details. Their names are specified to facilitate portable compile-time detection. Actual use of these members is inherently non-portable. —end note]

30.2.4 Timing specifications
[thread.req.timing]
Several functions described in this Clause take an argument to specify a timeout. These timeouts are specified as either a `duration` or a `time_point` type as specified in Clause 25.

Implementations necessarily have some delay in returning from a timeout. Any overhead in interrupt response, function return, and scheduling induces a “quality of implementation” delay, expressed as duration \(D_i\). Ideally, this delay would be zero. Further, any contention for processor and memory resources induces a “quality of
The resolution of timing provided by an implementation depends on both operating system and hardware. The finest resolution provided by an implementation is called the native resolution. Implementation-provided clocks that are used for these functions shall satisfy the Cpp17TrivialClock requirements (25.3).

A function that takes an argument which specifies a timeout will throw if, during its execution, a clock, time point, or time duration throws an exception. Such exceptions are referred to as timeout-related exceptions. [Note: Instantiations of clock, time point and duration types supplied by the implementation as specified in 25.7 do not throw exceptions. —end note]

### 30.2.5 Requirements for Cpp17Lockable types

#### 30.2.5.1 In general

An execution agent is an entity such as a thread that may perform work in parallel with other execution agents. [Note: Implementations or users may introduce other kinds of agents such as processes or thread-pool tasks. —end note] The calling agent is determined by context, e.g., the calling thread that contains the call, and so on.

[Note: Some lockable objects are “agent oblivious” in that they work for any execution agent model because they do not determine or store the agent’s ID (e.g., an ordinary spin lock). —end note]

The standard library templates unique_lock (30.4.4.3), shared_lock (30.4.4.4), scoped_lock (30.4.4.2), lock_guard (30.4.4.1), lock, try_lock (30.4.5), and condition_variable_any (30.5.4) all operate on user-supplied lockable objects. The Cpp17BasicLockable requirements, the Cpp17Lockable requirements, and the Cpp17TimedLockable requirements list the requirements imposed by these library types in order to acquire or release ownership of a lock by a given execution agent. [Note: The nature of any lock ownership and any synchronization it may entail are not part of these requirements. —end note]

#### 30.2.5.2 Cpp17BasicLockable requirements

A type L meets the Cpp17BasicLockable requirements if the following expressions are well-formed and have the specified semantics (m denotes a value of type L).

---
332) All implementations for which standard time units are meaningful must necessarily have a steady clock within their hardware implementation.
m.lock()

Effects: Blocks until a lock can be acquired for the current execution agent. If an exception is thrown then a lock shall not have been acquired for the current execution agent.

m.unlock()

Requires: The current execution agent shall hold a lock on m.

Effects: Releases a lock on m held by the current execution agent.

Throws: Nothing.

### 30.2.5.3 Cpp17Lockable requirements

A type L meets the Cpp17Lockable requirements if it meets the Cpp17BasicLockable requirements and the following expressions are well-formed and have the specified semantics (m denotes a value of type L).

m.try_lock()

Effects: Attempts to acquire a lock for the current execution agent without blocking. If an exception is thrown then a lock shall not have been acquired for the current execution agent.

Return type: bool.

Returns: true if the lock was acquired, false otherwise.

### 30.2.5.4 Cpp17TimedLockable requirements

A type L meets the Cpp17TimedLockable requirements if it meets the Cpp17Lockable requirements and the following expressions are well-formed and have the specified semantics (m denotes a value of type L, rel_time denotes a value of an instantiation of duration (25.5), and abs_time denotes a value of an instantiation of time_point (25.6)).

m.try_lock_for(rel_time)

Effects: Attempts to acquire a lock for the current execution agent within the relative timeout (30.2.4) specified by rel_time. The function shall not return within the timeout specified by rel_time unless it has obtained a lock on m for the current execution agent. If an exception is thrown then a lock shall not have been acquired for the current execution agent.

Return type: bool.

Returns: true if the lock was acquired, false otherwise.

m.try_lock_until(abs_time)

Effects: Attempts to acquire a lock for the current execution agent before the absolute timeout (30.2.4) specified by abs_time. The function shall not return before the timeout specified by abs_time unless it has obtained a lock on m for the current execution agent. If an exception is thrown then a lock shall not have been acquired for the current execution agent.

Return type: bool.

Returns: true if the lock was acquired, false otherwise.

### 30.2.6 decay_copy

In several places in this Clause the operation DECAY_COPY(x) is used. All such uses mean call the function decay_copy(x) and use the result, where decay_copy is defined as follows:

```cpp
template<class T> decay_t<T> decay_copy(T&& v)
{ return std::forward<T>(v); }
```

### 30.3 Threads

30.3 describes components that can be used to create and manage threads. [Note: These threads are intended to map one-to-one with operating system threads. — end note]
void swap(thread& x, thread& y) noexcept;

namespace this_thread {
  thread::id get_id() noexcept;
  void yield() noexcept;
  template<class Clock, class Duration>
  void sleep_until(const chrono::time_point<Clock, Duration>& abs_time);
  template<class Rep, class Period>
  void sleep_for(const chrono::duration<Rep, Period>& rel_time);
}

30.3.2 Class thread

The class thread provides a mechanism to create a new thread of execution, to join with a thread (i.e., wait for a thread to complete), and to perform other operations that manage and query the state of a thread. A thread object uniquely represents a particular thread of execution. That representation may be transferred to other thread objects in such a way that no two thread objects simultaneously represent the same thread of execution. A thread of execution is detached when no thread object represents that thread. Objects of class thread can be in a state that does not represent a thread of execution. [Note: A thread object does not represent a thread of execution after default construction, after being moved from, or after a successful call to detach or join. — end note]

namespace std {
  class thread {
  public:
    // types
    class id;
    using native_handle_type = implementation-defined; // see 30.2.3
    // construct/copy/destroy
    thread() noexcept;
    template<class F, class... Args> explicit thread(F&& f, Args&&... args);
    ~thread();
    thread(const thread&) = delete;
    thread(thread&&) noexcept;
    thread& operator=(const thread&) = delete;
    thread& operator=(thread&&) noexcept;
    // members
    void swap(thread&) noexcept;
    bool joinable() const noexcept;
    void join();
    void detach();
    id get_id() const noexcept;
    native_handle_type native_handle(); // see 30.2.3
    // static members
    static unsigned int hardware_concurrency() noexcept;
  }
}

30.3.2.1 Class thread::id

namespace std {
  class thread::id {
  public:
    id() noexcept;
  
    bool operator==(thread::id x, thread::id y) noexcept;
    bool operator!=(thread::id x, thread::id y) noexcept;
    bool operator<(thread::id x, thread::id y) noexcept;
    bool operator>(thread::id x, thread::id y) noexcept;
  
  }
}
bool operator<=(thread::id x, thread::id y) noexcept;
bool operator>=(thread::id x, thread::id y) noexcept;

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& out, thread::id id);

// hash support
template<class T> struct hash;
template<> struct hash<thread::id>;

An object of type `thread::id` provides a unique identifier for each thread of execution and a single distinct value for all `thread` objects that do not represent a thread of execution (30.3.2). Each thread of execution has an associated `thread::id` object that is not equal to the `thread::id` object of any other thread of execution and that is not equal to the `thread::id` object of any `thread` object that does not represent threads of execution.

`thread::id` is a trivially copyable class (Clause 10). The library may reuse the value of a `thread::id` of a terminated thread that can no longer be joined.

[Note: Relational operators allow `thread::id` objects to be used as keys in associative containers. — end note]

`id()` noexcept;

`Effects`: Constructs an object of type `id`.

`Ensures`: The constructed object does not represent a thread of execution.

bool operator==(thread::id x, thread::id y) noexcept;

`Returns`: `true` only if `x` and `y` represent the same thread of execution or neither `x` nor `y` represents a thread of execution.

bool operator!=(thread::id x, thread::id y) noexcept;

`Returns`: `!(x == y)`

bool operator<(thread::id x, thread::id y) noexcept;

`Returns`: A value such that `operator<` is a total ordering as described in 23.7.

bool operator>(thread::id x, thread::id y) noexcept;

`Returns`: `y < x`.

bool operator<=(thread::id x, thread::id y) noexcept;

`Returns`: `!(y < x)`.

bool operator>=(thread::id x, thread::id y) noexcept;

`Returns`: `!(x < y)`.

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& out, thread::id id);

`Effects`: Inserts an unspecified text representation of `id` into `out`. For two objects of type `thread::id` `x` and `y`, if `x == y` the `thread::id` objects have the same text representation and if `x != y` the `thread::id` objects have distinct text representations.

`Returns`: `out`.

The specialization is enabled (19.14.16).
30.3.2.2 thread constructors

thread() noexcept;
   Effects: Constructs a thread object that does not represent a thread of execution.
   Ensures: get_id() == id().

template<class F, class... Args> explicit thread(F&& f, Args&&... args);
   Requires: F and each T_i in Args shall satisfy the Cpp17MoveConstructible requirements. INVOKE(
   DECAY_COPY(std::forward<F>(f)), DECAY_COPY(std::forward<Args>(args))...) (19.14.3) shall be a valid expression.
   Remarks: This constructor shall not participate in overload resolution if remove_cvref_t<F> is the same type as std::thread.
   Effects: Constructs an object of type thread. The new thread of execution executes INVOKE(
   DECAY_COPY(std::forward<F>(f)), DECAY_COPY(std::forward<Args>(args))...) with the calls to DECAY_COPY being evaluated in the constructing thread. Any return value from this invocation is ignored. [Note: This implies that any exceptions not thrown from the invocation of the copy of f will be thrown in the constructing thread, not the new thread. — end note] If the invocation of INVOKE(DECAY_COPY(std::forward<F>(f)), DECAY_COPY(std::forward<Args>(args))...) terminates with an uncaught exception, terminate shall be called.
   Synchronization: The completion of the invocation of the constructor synchronizes with the beginning of the invocation of the copy of f.
   Ensures: get_id() != id(). *this represents the newly started thread.
   Throws: system_error if unable to start the new thread.
   Error conditions:
   — resource_unavailable_try_again — the system lacked the necessary resources to create another thread, or the system-imposed limit on the number of threads in a process would be exceeded.

thread(thread&& x) noexcept;
   Effects: Constructs an object of type thread from x, and sets x to a default constructed state.
   Ensures: x.get_id() == id() and get_id() returns the value of x.get_id() prior to the start of construction.

30.3.2.3 thread destructor

~thread();
   If joinable(), calls terminate(). Otherwise, has no effects. [Note: Either implicitly detaching or joining a joinable() thread in its destructor could result in difficult to debug correctness (for detach) or performance (for join) bugs encountered only when an exception is thrown. Thus the programmer must ensure that the destructor is never executed while the thread is still joinable. — end note]

30.3.2.4 thread assignment

thread& operator=(thread&& x) noexcept;
   Effects: If joinable(), calls terminate(). Otherwise, assigns the state of x to *this and sets x to a default constructed state.
   Ensures: x.get_id() == id() and get_id() returns the value of x.get_id() prior to the assignment.
   Returns: *this.

30.3.2.5 thread members

void swap(thread& x) noexcept;
   Effects: Swaps the state of *this and x.
   bool joinable() const noexcept;
   Returns: get_id() != id().
void join();

3   Effects: Blocks until the thread represented by *this has completed.

4   Synchronization: The completion of the thread represented by *this synchronizes with (6.8.2) the corresponding successful join() return. [Note: Operations on *this are not synchronized. — end note]

5   Ensures: The thread represented by *this has completed. get_id() == id().

6   Throws: system_error when an exception is required (30.2.2).

7   Error conditions:

    (7.1) — resource_deadlock_would_occur — if deadlock is detected or get_id() == this_thread::get_id().

    (7.2) — no_such_process — if the thread is not valid.

    (7.3) — invalid_argument — if the thread is not joinable.

void detach();

8   Effects: The thread represented by *this continues execution without the calling thread blocking. When detach() returns, *this no longer represents the possibly continuing thread of execution. When the thread previously represented by *this ends execution, the implementation shall release any owned resources.

9   Ensures: get_id() == id().

10  Throws: system_error when an exception is required (30.2.2).

11  Error conditions:

    (11.1) — no_such_process — if the thread is not valid.

    (11.2) — invalid_argument — if the thread is not joinable.

id get_id() const noexcept;

12  Returns: A default constructed id object if *this does not represent a thread, otherwise this_thread::get_id() for the thread of execution represented by *this.

§ 30.3.3 1344
void this_thread::yield() noexcept;

Effects: Offers the implementation the opportunity to reschedule.

Synchronization: None.

template<class Clock, class Duration>
void sleep_until(const chrono::time_point<Clock, Duration>& abs_time);

Effects: Blocks the calling thread for the absolute timeout (30.2.4) specified by abs_time.

Synchronization: None.

Throws: Timeout-related exceptions (30.2.4).

template<class Rep, class Period>
void sleep_for(const chrono::duration<Rep, Period>& rel_time);

Effects: Blocks the calling thread for the relative timeout (30.2.4) specified by rel_time.

Synchronization: None.

Throws: Timeout-related exceptions (30.2.4).

30.4 Mutual exclusion

This subclause provides mechanisms for mutual exclusion: mutexes, locks, and call once. These mechanisms ease the production of race-free programs (6.8.2).

30.4.1 Header <mutex> synopsis

namespace std {
    class mutex;
    class recursive_mutex;
    class timed_mutex;
    class recursive_timed_mutex;

    struct defer_lock_t { explicit defer_lock_t() = default; };
    struct try_to_lock_t { explicit try_to_lock_t() = default; };
    struct adopt_lock_t { explicit adopt_lock_t() = default; };

    inline constexpr defer_lock_t defer_lock { };
    inline constexpr try_to_lock_t try_to_lock { };
    inline constexpr adopt_lock_t adopt_lock { };

    template<class Mutex> class lock_guard;
    template<class... MutexTypes> class scoped_lock;
    template<class Mutex> class unique_lock;

    template<class Mutex> void swap(unique_lock<Mutex>& x, unique_lock<Mutex>& y) noexcept;

    template<class L1, class L2, class... L3> int try_lock(L1&, L2&, L3&...);
    template<class L1, class L2, class... L3> void lock(L1&, L2&, L3&...);

    struct once_flag;

    template<class Callable, class... Args>
    void call_once(once_flag& flag, Callable& func, Args&... args);
}

30.4.2 Header <shared_mutex> synopsis

namespace std {
    class shared_mutex;
    class shared_timed_mutex;
    template<class Mutex> class shared_lock;

    template<class Mutex>
    void swap(shared_lock<Mutex>& x, shared_lock<Mutex>& y) noexcept;
}

§ 30.4.2
30.4.3 Mutex requirements

30.4.3.1 In general

A mutex object facilitates protection against data races and allows safe synchronization of data between execution agents (30.2.5). An execution agent owns a mutex from the time it successfully calls one of the lock functions until it calls unlock. Mutexes can be either recursive or non-recursive, and can grant simultaneous ownership to one or many execution agents. Both recursive and non-recursive mutexes are supplied.

30.4.3.2 Mutex types

The mutex types are the standard library types mutex, recursive_mutex, timed_mutex, recursive_timed_mutex, shared_mutex, and shared_timed_mutex. They shall satisfy the requirements set out in this subclause. In this description, m denotes an object of a mutex type.

The mutex types shall satisfy the Cpp17Lockable requirements (30.2.5.3).

The mutex types shall be Cpp17DefaultConstructible and Cpp17Destructible. If initialization of an object of a mutex type fails, an exception of type system_error shall be thrown. The mutex types shall not be copyable or movable.

The error conditions for error codes, if any, reported by member functions of the mutex types shall be:

1. resource_unavailable_try_again — if any native handle type manipulated is not available.
2. operation_not_permitted — if the thread does not have the privilege to perform the operation.
3. invalid_argument — if any native handle type manipulated as part of mutex construction is incorrect.

The implementation shall provide lock and unlock operations, as described below. For purposes of determining the existence of a data race, these behave as atomic operations (6.8.2). The lock and unlock operations on a single mutex shall appear to occur in a single total order. [Note: This can be viewed as the modification order (6.8.2) of the mutex. —end note] [Note: Construction and destruction of an object of a mutex type need not be thread-safe; other synchronization should be used to ensure that mutex objects are initialized and visible to other threads. —end note]

The expression m.lock() shall be well-formed and have the following semantics:

Requires: If m is of type mutex, timed_mutex, shared_mutex, or shared_timed_mutex, the calling thread does not own the mutex.

Effects: Blocks the calling thread until ownership of the mutex can be obtained for the calling thread.

Ensures: The calling thread owns the mutex.

Return type: void.

Synchronization: Prior unlock() operations on the same object shall synchronize with (6.8.2) this operation.

Throws: system_error when an exception is required (30.2.2).

Error conditions:

1. operation_not_permitted — if the thread does not have the privilege to perform the operation.
2. resource_deadlock_would_occur — if the implementation detects that a deadlock would occur.

The expression m.try_lock() shall be well-formed and have the following semantics:

Requires: If m is of type mutex, timed_mutex, shared_mutex, or shared_timed_mutex, the calling thread does not own the mutex.

Effects: Attempts to obtain ownership of the mutex for the calling thread without blocking. If ownership is not obtained, there is no effect and try_lock() immediately returns. An implementation may fail to obtain the lock even if it is not held by any other thread. [Note: This spurious failure is normally uncommon, but allows interesting implementations based on a simple compare and exchange (Clause 29). —end note] An implementation should ensure that try_lock() does not consistently return false in the absence of contending mutex acquisitions.

Return type: bool.

Returns: true if ownership of the mutex was obtained for the calling thread, otherwise false.

Synchronization: If try_lock() returns true, prior unlock() operations on the same object synchronize with (6.8.2) this operation. [Note: Since lock() does not synchronize with a failed subsequent try_—
lock(), the visibility rules are weak enough that little would be known about the state after a failure, even in the absence of spurious failures. — end note]

Throws: Nothing.

The expression m.unlock() shall be well-formed and have the following semantics:

Requires: The calling thread shall own the mutex.
Effects: Releases the calling thread's ownership of the mutex.
Return type: void.
Synchronization: This operation synchronizes with (6.8.2) subsequent lock operations that obtain ownership on the same object.
Throws: Nothing.

30.4.3.2.1 Class mutex

namespace std {
    class mutex {
        public:
            constexpr mutex() noexcept;
            ~mutex();
            mutex(const mutex&) = delete;
            mutex& operator=(const mutex&) = delete;
            void lock();
            bool try_lock();
            void unlock();

            using native_handle_type = implementation-defined;  // see 30.2.3
            native_handle_type native_handle();  // see 30.2.3
    };
}

The class mutex provides a non-recursive mutex with exclusive ownership semantics. If one thread owns a mutex object, attempts by another thread to acquire ownership of that object will fail (for try_lock()) or block (for lock()) until the owning thread has released ownership with a call to unlock().

[Note: After a thread A has called unlock(), releasing a mutex, it is possible for another thread B to lock the same mutex, observe that it is no longer in use, unlock it, and destroy it, before thread A appears to have returned from its unlock call. Implementations are required to handle such scenarios correctly, as long as thread A doesn't access the mutex after the unlock call returns. These cases typically occur when a reference-counted object contains a mutex that is used to protect the reference count. — end note]

The class mutex shall satisfy all of the mutex requirements (30.4.3). It shall be a standard-layout class (Clause 10).

[Note: A program may deadlock if the thread that owns a mutex object calls lock() on that object. If the implementation can detect the deadlock, a resource_deadlock_would_occur error condition may be observed. — end note]

The behavior of a program is undefined if it destroys a mutex object owned by any thread or a thread terminates while owning a mutex object.

30.4.3.2.2 Class recursive_mutex

namespace std {
    class recursive_mutex {
        public:
            recursive_mutex();
            ~recursive_mutex();
            recursive_mutex(const recursive_mutex&) = delete;
            recursive_mutex& operator=(const recursive_mutex&) = delete;

§ 30.4.3.2.2
# 30.4.3.3 Timed mutex types

The timed mutex types are the standard library types `timed_mutex`, `recursive_timed_mutex`, and `shared_timed_mutex`. They shall meet the requirements set out below. In this description, `m` denotes an object of a mutex type, `rel_time` denotes an object of an instantiation of `duration` (25.5), and `abs_time` denotes an object of an instantiation of `time_point` (25.6).

The timed mutex types shall satisfy the `Cpp17TimedLockable` requirements (30.2.5.4).

The expression `m.try_lock_for(rel_time)` shall be well-formed and have the following semantics:

- **Requires:** If `m` is of type `timed_mutex` or `shared_timed_mutex`, the calling thread does not own the mutex.

- **Effects:** The function attempts to obtain ownership of the mutex within the relative timeout (30.2.4) specified by `rel_time`. If the time specified by `rel_time` is less than or equal to `rel_time.zero()`, the function attempts to obtain ownership without blocking (as if by calling `try_lock()`). The function shall return within the timeout specified by `rel_time` only if it has obtained ownership of the mutex object. [Note: As with `try_lock()`, there is no guarantee that ownership will be obtained if the lock is available, but implementations are expected to make a strong effort to do so. — end note]

- **Return type:** `bool`.

- **Returns:** `true` if ownership was obtained, otherwise `false`.

- **Synchronization:** If `try_lock_for()` returns `true`, prior `unlock()` operations on the same object synchronize with (6.8.2) this operation.

- **Throws:** Timeout-related exceptions (30.2.4).

The expression `m.try_lock_until(abs_time)` shall be well-formed and have the following semantics:

- **Requires:** If `m` is of type `timed_mutex` or `shared_timed_mutex`, the calling thread does not own the mutex.

- **Effects:** The function attempts to obtain ownership of the mutex. If `abs_time` has already passed, the function attempts to obtain ownership without blocking (as if by calling `try_lock()`). The function shall return before the absolute timeout (30.2.4) specified by `abs_time` only if it has obtained ownership of the mutex object. [Note: As with `try_lock()`, there is no guarantee that ownership will be obtained if the lock is available, but implementations are expected to make a strong effort to do so. — end note]

- **Return type:** `bool`. 

--end note--
Returns: true if ownership was obtained, otherwise false.

Synchronization: If try_lock_until() returns true, prior unlock() operations on the same object synchronize with (6.8.2) this operation.

Throws: Timeout-related exceptions (30.2.4).

30.4.3.3.1 Class timed_mutex

namespace std {
    class timed_mutex {
        public:
            timed_mutex();
            ~timed_mutex();

            timed_mutex(const timed_mutex&) = delete;
            timed_mutex& operator=(const timed_mutex&) = delete;

            void lock(); // blocking
            bool try_lock();
            template<class Rep, class Period>
                bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);
            template<class Clock, class Duration>
                bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);

            void unlock();

            using native_handle_type = implementation-defined; // see 30.2.3
            native_handle_type native_handle(); // see 30.2.3
        }
    } // namespace std

1 The class timed_mutex provides a non-recursive mutex with exclusive ownership semantics. If one thread owns a timed_mutex object, attempts by another thread to acquire ownership of that object will fail (for try_lock() or block (for lock(), try_lock_for(), and try_lock_until()) until the owning thread has released ownership with a call to unlock() or the call to try_lock_for() or try_lock_until() times out (having failed to obtain ownership).

2 The class timed_mutex shall satisfy all of the timed mutex requirements (30.4.3.3). It shall be a standard-layout class (Clause 10).

3 The behavior of a program is undefined if:
   (3.1) — it destroys a timed_mutex object owned by any thread,
   (3.2) — a thread that owns a timed_mutex object calls lock(), try_lock(), try_lock_for(), or try_lock_until() on that object, or
   (3.3) — a thread terminates while owning a timed_mutex object.

30.4.3.3.2 Class recursive_timed_mutex

namespace std {
    class recursive_timed_mutex {
        public:
            recursive_timed_mutex();
            ~recursive_timed_mutex();

            recursive_timed_mutex(const recursive_timed_mutex&) = delete;
            recursive_timed_mutex& operator=(const recursive_timed_mutex&) = delete;

            void lock(); // blocking
            bool try_lock() noexcept;
            template<class Rep, class Period>
                bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);
            template<class Clock, class Duration>
                bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);

            void unlock();

§ 30.4.3.3.2
The class `recursive_timed_mutex` provides a recursive mutex with exclusive ownership semantics. If one thread owns a `recursive_timed_mutex` object, attempts by another thread to acquire ownership of that object will fail (for `try_lock()`) or block (for `lock()`, `try_lock_for()`, and `try_lock_until()`) until the owning thread has completely released ownership or the call to `try_lock_for()` or `try_lock_until()` times out (having failed to obtain ownership).

The class `recursive_timed_mutex` shall satisfy all of the timed mutex requirements (30.4.3.3). It shall be a standard-layout class (Clause 10).

A thread that owns a `recursive_timed_mutex` object may acquire additional levels of ownership by calling `lock()`, `try_lock()`, `try_lock_for()`, or `try_lock_until()` on that object. It is unspecified how many levels of ownership may be acquired by a single thread. If a thread has already acquired the maximum level of ownership for a `recursive_timed_mutex` object, additional calls to `try_lock()`, `try_lock_for()`, or `try_lock_until()` shall fail, and additional calls to `lock()` shall throw an exception of type `system_error`. A thread shall call `unlock()` once for each level of ownership acquired by calls to `lock()`, `try_lock()`, `try_lock_for()`, and `try_lock_until()`. Only when all levels of ownership have been released may ownership of the object be acquired by another thread.

The behavior of a program is undefined if:

1. it destroys a `recursive_timed_mutex` object owned by any thread, or
2. a thread terminates while owning a `recursive_timed_mutex` object.

### 30.4.3.4 Shared mutex types

The standard library types `shared_mutex` and `shared_timed_mutex` are `shared` mutex types. Shared mutex types shall satisfy the requirements of mutex types (30.4.3.2), and additionally shall satisfy the requirements set out below. In this description, `m` denotes an object of a shared mutex type.

In addition to the exclusive lock ownership mode specified in 30.4.3.2, shared mutex types provide a `shared` lock ownership mode. Multiple execution agents can simultaneously hold a shared lock ownership of a shared mutex type. But no execution agent shall hold a shared lock while another execution agent holds an exclusive lock on the same shared mutex type, and vice-versa. The maximum number of execution agents which can share a shared lock on a single shared mutex type is unspecified, but shall be at least 10000. If more than the maximum number of execution agents attempt to obtain a shared lock, the excess execution agents shall block until the number of shared locks are reduced below the maximum amount by other execution agents releasing their shared lock.

The expression `m.lock_shared()` shall be well-formed and have the following semantics:

- **Requires:** The calling thread has no ownership of the mutex.
- **Effects:** Blocks the calling thread until shared ownership of the mutex can be obtained for the calling thread. If an exception is thrown then a shared lock shall not have been acquired for the current thread.
- **Ensures:** The calling thread has a shared lock on the mutex.
- **Return type:** void.
- **Synchronization:** Prior `unlock()` operations on the same object shall synchronize with (6.8.2) this operation.
- **Throws:** `system_error` when an exception is required (30.2.2).

**Error conditions:**

- operation_not_permitted — if the thread does not have the privilege to perform the operation.
- resource_deadlock_would_occur — if the implementation detects that a deadlock would occur.

The expression `m.unlock_shared()` shall be well-formed and have the following semantics:

- **Requires:** The calling thread shall hold a shared lock on the mutex.
- **Effects:** Releases a shared lock on the mutex held by the calling thread.
- **Return type:** void.
Synchronization: This operation synchronizes with (6.8.2) subsequent \texttt{lock()} operations that obtain ownership on the same object.

Throws: Nothing.

The expression \texttt{m\textunderscore try\_lock\_shared()} shall be well-formed and have the following semantics:

Requires: The calling thread has no ownership of the mutex.

Effects: Attempts to obtain shared ownership of the mutex for the calling thread without blocking. If shared ownership is not obtained, there is no effect and \texttt{try\_lock\_shared()} immediately returns. An implementation may fail to obtain the lock even if it is not held by any other thread.

Return type: \texttt{bool}.

Returns: \texttt{true} if the shared ownership lock was acquired, \texttt{false} otherwise.

Synchronization: If \texttt{try\_lock\_shared()} returns \texttt{true}, prior \texttt{unlock()} operations on the same object synchronize with (6.8.2) this operation.

Throws: Nothing.

\textbf{30.4.3.4.1} Class \texttt{shared\_mutex} [thread.sharedmutex.class]

```cpp
namespace std {
    class shared_mutex {
    public:
        shared_mutex();
        ~shared_mutex();
        shared_mutex(const shared_mutex&) = delete;
        shared_mutex& operator=(const shared_mutex&) = delete;

        // exclusive ownership
        void lock(); // blocking
        bool try_lock();
        void unlock();

        // shared ownership
        void lock_shared(); // blocking
        bool try_lock_shared();
        void unlock_shared();

        using native_handle_type = implementation-defined; // see 30.2.3
        native_handle_type native_handle(); // see 30.2.3
    };
}
```

1 The class \texttt{shared\_mutex} provides a non-recursive mutex with shared ownership semantics.

2 The class \texttt{shared\_mutex} shall satisfy all of the shared mutex requirements (30.4.3.4). It shall be a standard-layout class (Clause 10).

3 The behavior of a program is undefined if:
   \begin{itemize}
   \item[(3.1)] it destroys a \texttt{shared\_mutex} object owned by any thread,
   \item[(3.2)] a thread attempts to recursively gain any ownership of a \texttt{shared\_mutex}, or
   \item[(3.3)] a thread terminates while possessing any ownership of a \texttt{shared\_mutex}.
   \end{itemize}

4 \texttt{shared\_mutex} may be a synonym for \texttt{shared\_timed\_mutex}.

\textbf{30.4.3.5} Shared timed mutex types [thread.sharedtimedmutex.requirements]

1 The standard library type \texttt{shared\_timed\_mutex} is a \texttt{shared timed mutex type}. Shared timed mutex types shall satisfy the requirements of timed mutex types (30.4.3.3), shared mutex types (30.4.3.4), and additionally shall satisfy the requirements set out below. In this description, \texttt{m} denotes an object of a shared timed mutex type, \texttt{rel\_type} denotes an object of an instantiation of \texttt{duration} (25.5), and \texttt{abs\_time} denotes an object of an instantiation of \texttt{time\_point} (25.6).
The expression `m.try_lock_shared_for(rel_time)` shall be well-formed and have the following semantics:

**Requires:** The calling thread has no ownership of the mutex.

**Effects:** Attempts to obtain shared lock ownership for the calling thread within the relative timeout (30.2.4) specified by `rel_time`. If the time specified by `rel_time` is less than or equal to `rel_time.zero()`, the function attempts to obtain ownership without blocking (as if by calling `try_lock_shared()`). The function shall return within the timeout specified by `rel_time` only if it has obtained shared ownership of the mutex object. [Note: As with `try_lock()`, there is no guarantee that ownership will be obtained if the lock is available, but implementations are expected to make a strong effort to do so. — end note] If an exception is thrown then a shared lock shall not have been acquired for the current thread.

**Return type:** `bool`.

**Returns:** `true` if the shared lock was acquired, `false` otherwise.

**Synchronization:** If `try_lock_shared_for()` returns `true`, prior `unlock()` operations on the same object synchronize with (6.8.2) this operation.

**Throws:** Timeout-related exceptions (30.2.4).

The expression `m.try_lock_shared_until(abs_time)` shall be well-formed and have the following semantics:

**Requires:** The calling thread has no ownership of the mutex.

**Effects:** The function attempts to obtain shared ownership of the mutex. If `abs_time` has already passed, the function attempts to obtain shared ownership without blocking (as if by calling `try_lock_shared()`). The function shall return before the absolute timeout (30.2.4) specified by `abs_time` only if it has obtained shared ownership of the mutex object. [Note: As with `try_lock()`, there is no guarantee that ownership will be obtained if the lock is available, but implementations are expected to make a strong effort to do so. — end note] If an exception is thrown then a shared lock shall not have been acquired for the current thread.

**Return type:** `bool`.

**Returns:** `true` if the shared lock was acquired, `false` otherwise.

**Synchronization:** If `try_lock_shared_until()` returns `true`, prior `unlock()` operations on the same object synchronize with (6.8.2) this operation.

**Throws:** Timeout-related exceptions (30.2.4).

---

30.4.3.5.1 **Class shared_timed_mutex**

```cpp
namespace std {
    class shared_timed_mutex {
    public:
        shared_timed_mutex(); // exclusive ownership
        shared_timed_mutex(const shared_timed_mutex&); // shared ownership
        ~shared_timed_mutex();
        void lock(); // blocking
        bool try_lock();
        template<class Rep, class Period> // blocking
        bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);
        template<class Clock, class Duration> // blocking
        bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);
        void unlock();
    } // shared ownership
    // exclusive ownership
    void lock(); // blocking
    bool try_lock();
    template<class Rep, class Period> // blocking
    bool try_lock_shared_for(const chrono::duration<Rep, Period>& rel_time);
    template<class Clock, class Duration> // blocking
    bool try_lock_shared_until(const chrono::time_point<Clock, Duration>& abs_time);
}
```

---

§ 30.4.3.5.1 1352
The class `shared_timed_mutex` provides a non-recursive mutex with shared ownership semantics.

The class `shared_timed_mutex` shall satisfy all of the shared timed mutex requirements (30.4.3.5). It shall be a standard-layout class (Clause 10).

The behavior of a program is undefined if:

1. it destroys a `shared_timed_mutex` object owned by any thread,
2. a thread attempts to recursively gain any ownership of a `shared_timed_mutex`, or
3. a thread terminates while possessing any ownership of a `shared_timed_mutex`.

30.4.4 Locks

1. A lock is an object that holds a reference to a lockable object and may unlock the lockable object during the lock’s destruction (such as when leaving block scope). An execution agent may use a lock to aid in managing ownership of a lockable object in an exception safe manner. A lock is said to own a lockable object if it is currently managing the ownership of that lockable object for an execution agent. A lock does not manage the lifetime of the lockable object it references. [Note: Locks are intended to ease the burden of unlocking the lockable object under both normal and exceptional circumstances. —end note]

2. Some lock constructors take tag types which describe what should be done with the lockable object during the lock’s construction.

```cpp
namespace std {
    struct defer_lock_t {};// do not acquire ownership of the mutex
    struct try_to_lock_t {};// try to acquire ownership of the mutex
    struct adopt_lock_t {};// assume the calling thread has already
    // obtained mutex ownership and manage it

    inline constexpr defer_lock_t defer_lock {};
    inline constexpr try_to_lock_t try_to_lock {};
    inline constexpr adopt_lock_t adopt_lock {};
}
```

30.4.4.1 Class template lock_guard

```cpp
namespace std {
    template<class Mutex>
    class lock_guard {
    public:
        using mutex_type = Mutex;
        explicit lock_guard(mutex_type& m);
        lock_guard(mutex_type m, adopt_lock_t);
        lock_guard();
        lock_guard(const lock_guard&); = delete;
        lock_guard& operator=(const lock_guard&); = delete;

    private:
        mutex_type& pm; // exposition only
    }
}
```

1. An object of type `lock_guard` controls the ownership of a lockable object within a scope. A `lock_guard` object maintains ownership of a lockable object throughout the `lock_guard` object’s lifetime (6.6.3). The behavior of a program is undefined if the lockable object referenced by `pm` does not exist for the entire lifetime of the `lock_guard` object. The supplied `Mutex` type shall satisfy the `Cpp17BasicLockable` requirements (30.2.5.2).

```cpp
explicit lock_guard(mutex_type& m);
```

2. Requires: If `mutex_type` is not a recursive mutex, the calling thread does not own the mutex `m`. 

§ 30.4.4.1 1353
3  Effects: As if by m.lock().
4  Ensures: &pm == &m
5  lock_guard(mutex_type& m, adopt_lock_t);
6  Requires: The calling thread owns the mutex m.
7  Ensures: &pm == &m
8  Throws: Nothing.

~lock_guard();
9  Effects: As if by pm.unlock().

30.4.4.2 Class template scoped_lock [thread.lock.scoped]

namespace std {
    template<class... MutexTypes>
    class scoped_lock {
    public:
        using mutex_type = Mutex; // If MutexTypes... consists of the single type Mutex

        explicit scoped_lock(MutexTypes&... m);
        explicit scoped_lock(adopt_lock_t, MutexTypes&... m);
        ~scoped_lock();

        scoped_lock(const scoped_lock&) = delete;
        scoped_lock& operator=(const scoped_lock&) = delete;

    private:
        tuple<MutexTypes&...> pm; // exposition only
    };
}

1 An object of type scoped_lock controls the ownership of lockable objects within a scope. A scoped_lock object maintains ownership of lockable objects throughout the scoped_lock object’s lifetime (6.6.3). The behavior of a program is undefined if the lockable objects referenced by pm do not exist for the entire lifetime of the scoped_lock object. When sizeof...(MutexTypes) is 1, the supplied Mutex type shall satisfy the Cpp17BasicLockable requirements (30.2.5.2). Otherwise, each of the mutex types shall satisfy the Cpp17Lockable requirements (30.2.5.3).

explicit scoped_lock(MutexTypes&... m);
2  Requires: If a MutexTypes type is not a recursive mutex, the calling thread does not own the corresponding mutex element of m.
3  Effects: Initializes pm with tie(m...). Then if sizeof...(MutexTypes) is 0, no effects. Otherwise if sizeof...(MutexTypes) is 1, then m.lock(). Otherwise, lock(m...).

explicit scoped_lock(adopt_lock_t, MutexTypes&... m);
4  Requires: The calling thread owns all the mutexes in m.
5  Effects: Initializes pm with tie(m...).
6  Throws: Nothing.

~scoped_lock();
7  Effects: For all i in [0, sizeof...(MutexTypes)), get<i>(pm).unlock().

30.4.4.3 Class template unique_lock [thread.lock.unique]

namespace std {
    template<class Mutex>
    class unique_lock {
    public:
        using mutex_type = Mutex;

§ 30.4.4.3 1354
```cpp
// 30.4.4.3.1, construct/copy/destroy
unique_lock() noexcept;
explicit unique_lock(mutex_type& m);
unique_lock(mutex_type& m, defer_lock_t) noexcept;
unique_lock(mutex_type& m, try_to_lock_t);
unique_lock(mutex_type& m, adopt_lock_t);
template<class Clock, class Duration>
unique_lock(mutex_type& m, const chrono::time_point<Clock, Duration>& abs_time);
template<class Rep, class Period>
unique_lock(mutex_type& m, const chrono::duration<Rep, Period>& rel_time);
~unique_lock();
unique_lock(const unique_lock&) = delete;
unique_lock& operator=(const unique_lock&) = delete;
unique_lock(unique_lock&& u) noexcept;
unique_lock& operator=(unique_lock&& u);

// 30.4.4.3.2, locking
void lock();
bool try_lock();
template<class Rep, class Period>
bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);
template<class Clock, class Duration>
bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);
void unlock();

// 30.4.4.3.3, modifiers
void swap(unique_lock& u) noexcept;
mutex_type* release() noexcept;

// 30.4.4.3.4, observers
bool owns_lock() const noexcept;
explicit operator bool () const noexcept;
mutex_type* mutex() const noexcept;

private:
mutex_type* pm;  // exposition only
bool owns;       // exposition only
};

template<class Mutex>
void swap(unique_lock<Mutex>& x, unique_lock<Mutex>& y) noexcept;
```

1. An object of type `unique_lock` controls the ownership of a lockable object within a scope. Ownership of the lockable object may be acquired at construction or after construction, and may be transferred, after acquisition, to another `unique_lock` object. Objects of type `unique_lock` are not copyable but are movable. The behavior of a program is undefined if the contained pointer `pm` is null and the lockable object pointed to by `pm` does not exist for the entire remaining lifetime (6.6.3) of the `unique_lock` object. The supplied `Mutex` type shall satisfy the `Cpp17BasicLockable` requirements (30.2.5.2).

2. [Note: `unique_lock<Mutex>` meets the `Cpp17BasicLockable` requirements. If `Mutex` meets the `Cpp17Lockable` requirements (30.2.5.3), `unique_lock<Mutex>` also meets the `Cpp17Lockable` requirements; if `Mutex` meets the `Cpp17TimedLockable` requirements (30.2.5.4), `unique_lock<Mutex>` also meets the `Cpp17TimedLockable` requirements. — end note]

### 30.4.4.3.1 unique_lock constructors, destructor, and assignment  [thread.lock.unique.cons]

**unique_lock()** noexcept;

**Effects:** Constructs an object of type `unique_lock`.

**Ensures:** `pm == 0` and `owns == false`.
explicit unique_lock(mutex_type& m);

Requires: If mutex_type is not a recursive mutex the calling thread does not own the mutex.
Effects: Constructs an object of type unique_lock and calls m.lock().
Ensures: pm == addressof(m) and owns == true.

unique_lock(mutex_type& m, defer_lock_t) noexcept;
Effects: Constructs an object of type unique_lock.
Ensures: pm == addressof(m) and owns == false.

unique_lock(mutex_type& m, try_to_lock_t);
Requires: The supplied Mutex type shall satisfy the Cpp17Lockable requirements (30.2.5.3). If mutex_type is not a recursive mutex the calling thread does not own the mutex.
Effects: Constructs an object of type unique_lock and calls m.try_lock().
Ensures: pm == addressof(m) and owns == res, where res is the value returned by the call to m.try_lock().

unique_lock(mutex_type& m, adopt_lock_t);
Requires: The calling thread owns the mutex.
Effects: Constructs an object of type unique_lock.
Ensures: pm == addressof(m) and owns == true.

template<class Clock, class Duration>
unique_lock(mutex_type& m, const chrono::time_point<Clock, Duration>& abs_time);
Requires: If mutex_type is not a recursive mutex the calling thread does not own the mutex. The supplied Mutex type shall satisfy the Cpp17TimedLockable requirements (30.2.5.4).
Effects: Constructs an object of type unique_lock and calls m.try_lock_until(abs_time).
Ensures: pm == addressof(m) and owns == res, where res is the value returned by the call to m.try_lock_until(abs_time).

template<class Rep, class Period>
unique_lock(mutex_type& m, const chrono::duration<Rep, Period>& rel_time);
Requires: If mutex_type is not a recursive mutex the calling thread does not own the mutex. The supplied Mutex type shall satisfy the Cpp17TimedLockable requirements (30.2.5.4).
Effects: Constructs an object of type unique_lock and calls m.try_lock_for(rel_time).
Ensures: pm == addressof(m) and owns == res, where res is the value returned by the call to m.try_lock_for(rel_time).

unique_lock(unique_lock&& u) noexcept;
Ensures: pm == u_p.pm and owns == u_p.owns (where u_p is the state of u just prior to this construction), u.pm == 0 and u.owns == false.

unique_lock& operator=(unique_lock&& u);
Effects: If owns calls pm->unlock().
Ensures: pm == u_p.pm and owns == u_p.owns (where u_p is the state of u just prior to this construction), u.pm == 0 and u.owns == false.
[Note: With a recursive mutex it is possible for both *this and u to own the same mutex before the assignment. In this case, *this will own the mutex after the assignment and u will not. — end note]
Throws: Nothing.

~unique_lock();
Effects: If owns calls pm->unlock().
30.4.4.3.2  unique_lock locking

```cpp
void lock();
  Effects: As if by pm->lock().
  Ensures: owns == true.
  Throws: Any exception thrown by pm->lock(). system_error when an exception is required (30.2.2).
Error conditions:
(4.1)  — operation_not_permitted — if pm is nullptr.
(4.2)  — resource_deadlock_would_occur — if on entry owns is true.

bool try_lock();
  Requires: The supplied Mutex shall satisfy the Cpp17Lockable requirements (30.2.5.3).
  Effects: As if by pm->try_lock().
  Returns: The value returned by the call to try_lock().
  Ensures: owns == res, where res is the value returned by the call to try_lock().
  Throws: Any exception thrown by pm->try_lock(). system_error when an exception is required (30.2.2).
Error conditions:
(10.1) — operation_not_permitted — if pm is nullptr.
(10.2) — resource_deadlock_would_occur — if on entry owns is true.

template<class Clock, class Duration>
bool try_lock_until(const std::chrono::time_point<Clock, Duration>& abs_time);
  Requires: The supplied Mutex type shall satisfy the Cpp17TimedLockable requirements (30.2.5.4).
  Effects: As if by pm->try_lock_until(abs_time).
  Returns: The value returned by the call to try_lock_until(abs_time).
  Ensures: owns == res, where res is the value returned by the call to try_lock_until(abs_time).
  Throws: Any exception thrown by pm->try_lock_until(). system_error when an exception is required (30.2.2).
Error conditions:
(16.1) — operation_not_permitted — if pm is nullptr.
(16.2) — resource_deadlock_would_occur — if on entry owns is true.

template<class Rep, class Period>
bool try_lock_for(const std::chrono::duration<Rep, Period>& rel_time);
  Requires: The supplied Mutex type shall satisfy the Cpp17TimedLockable requirements (30.2.5.4).
  Effects: As if by pm->try_lock_for(rel_time).
  Returns: The value returned by the call to try_lock_until(rel_time).
  Ensures: owns == res, where res is the value returned by the call to try_lock_for(rel_time).
  Throws: Any exception thrown by pm->try_lock_for(). system_error when an exception is required (30.2.2).
Error conditions:
(22.1) — operation_not_permitted — if pm is nullptr.
(22.2) — resource_deadlock_would_occur — if on entry owns is true.

void unlock();
  Effects: As if by pm->unlock().
  Ensures: owns == false.
  Throws: system_error when an exception is required (30.2.2).
```
Error conditions:
— operation_not_permitted — if on entry owns is false.

30.4.4.3.3  unique_lock modifiers

void swap(unique_lock& u) noexcept;
  
  Effects: Swaps the data members of *this and u.

mutex_type* release() noexcept;
  
  Returns: The previous value of pm.
  
  Ensures: pm == 0 and owns == false.

template<class Mutex>
  void swap(unique_lock<Mutex>& x, unique_lock<Mutex>& y) noexcept;
  
  Effects: As if by x.swap(y).

30.4.4.3.4  unique_lock observers

bool owns_lock() const noexcept;
  
  Returns: owns.

explicit operator bool() const noexcept;
  
  Returns: owns.

mutex_type *mutex() const noexcept;
  
  Returns: pm.

30.4.4.4  Class template shared_lock

namespace std {
  template<class Mutex>
  class shared_lock {
    public:
      using mutex_type = Mutex;

      // 30.4.4.4.1, construct/copy/destroy
      shared_lock() noexcept;
      explicit shared_lock(mutex_type& m);  // blocking
      shared_lock(mutex_type& m, defer_lock_t) noexcept;
      shared_lock(mutex_type& m, try_to_lock_t);
      shared_lock(mutex_type& m, adopt_lock_t);
      template<class Clock, class Duration>
        shared_lock(mutex_type& m, const chrono::time_point<Clock, Duration>& abs_time);
      template<class Rep, class Period>
        shared_lock(mutex_type& m, const chrono::duration<Rep, Period>& rel_time);
      ~shared_lock();

      shared_lock(const shared_lock&) = delete;
      shared_lock& operator=(const shared_lock&) = delete;
      shared_lock(shared_lock&& u) noexcept;
      shared_lock& operator=(shared_lock&& u) noexcept;

      // 30.4.4.4.2, locking
      void lock();  // blocking
      bool try_lock();
      template<class Rep, class Period>
        bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);
      template<class Clock, class Duration>
        bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);
      void unlock();
  }
}
// 30.4.4.4.3, modifiers
void swap(shared_lock& u) noexcept;
mutex_type* release() noexcept;

// 30.4.4.4.4, observers
bool owns_lock() const noexcept;
explicit operator bool () const noexcept;
mutex_type* mutex() const noexcept;

private:
mutex_type* pm; // exposition only
bool owns; // exposition only
};

template<class Mutex>
void swap(shared_lock<Mutex>& x, shared_lock<Mutex>& y) noexcept;

An object of type shared_lock controls the shared ownership of a lockable object within a scope. Shared ownership of the lockable object may be acquired at construction or after construction, and may be transferred, after acquisition, to another shared_lock object. Objects of type shared_lock are not copyable but are movable. The behavior of a program is undefined if the contained pointer pm is not null and the lockable object pointed to by pm does not exist for the entire remaining lifetime (6.6.3) of the shared_lock object. The supplied Mutex type shall satisfy the shared mutex requirements (30.4.3.5).

[Note: shared_lock<Mutex> meets the Cpp17TimedLockable requirements (30.2.5.4). —end note]

30.4.4.4.1 shared_lock constructors, destructor, and assignment  [thread.lock.shared.cons]

shared_lock() noexcept;

Effects: Constructs an object of type shared_lock.

Ensures: pm == nullptr and owns == false.

explicit shared_lock(mutex_type& m);

Requires: The calling thread does not own the mutex for any ownership mode.

Effects: Constructs an object of type shared_lock and calls m.lock_shared().

Ensures: pm == addressof(m) and owns == true.

shared_lock(mutex_type& m, defer_lock_t) noexcept;

Effects: Constructs an object of type shared_lock.

Ensures: pm == addressof(m) and owns == false.

shared_lock(mutex_type& m, try_to_lock_t);

Requires: The calling thread does not own the mutex for any ownership mode.

Effects: Constructs an object of type shared_lock and calls m.try_lock_shared().

Ensures: pm == addressof(m) and owns == res where res is the value returned by the call to m.try_lock_shared().

shared_lock(mutex_type& m, adopt_lock_t);

Requires: The calling thread has shared ownership of the mutex.

Effects: Constructs an object of type shared_lock.

Ensures: pm == addressof(m) and owns == true.

template<class Clock, class Duration>
shared_lock(mutex_type& m,
    const chrono::time_point<Clock, Duration>& abs_time);

Requires: The calling thread does not own the mutex for any ownership mode.

Effects: Constructs an object of type shared_lock and calls m.try_lock_shared_until(abs_time).
Ensures: pm == addressof(m) and owns == res where res is the value returned by the call to m.try_lock_shared_until(abs_time).

```cpp
template<class Rep, class Period>
shared_lock(mutex_type& m,
    const chrono::duration<Rep, Period>& rel_time);
```

Requires: The calling thread does not own the mutex for any ownership mode.

Effects: Constructs an object of type shared_lock and calls m.try_lock_shared_for(rel_time).

Ensures: pm == addressof(m) and owns == res where res is the value returned by the call to m.try_lock_shared_for(rel_time).

~shared_lock();

Effects: If owns calls pm->unlock_shared().

shared_lock(shared_lock&& sl) noexcept;

Ensures: pm == sl_p.pm and owns == sl_p.owns (where sl_p is the state of sl just prior to this construction), sl.pm == nullptr and sl.owns == false.

shared_lock& operator=(shared_lock&& sl) noexcept;

Effects: If owns calls pm->unlock_shared().

Ensures: pm == sl_p.pm and owns == sl_p.owns (where sl_p is the state of sl just prior to this assignment), sl.pm == nullptr and sl.owns == false.

30.4.4.4.2 shared_lock locking

void lock();

Effects: As if by pm->lock_shared().

Ensures: owns == true.

Throws: Any exception thrown by pm->lock_shared(). system_error when an exception is required (30.2.2).

Error conditions:

(4.1) operation_not_permitted — if pm is nullptr.

(4.2) resource_deadlock_would_occur — if on entry owns is true.

bool try_lock();

Effects: As if by pm->try_lock_shared().

Returns: The value returned by the call to pm->try_lock_shared().

Ensures: owns == res, where res is the value returned by the call to pm->try_lock_shared().

Throws: Any exception thrown by pm->try_lock_shared(). system_error when an exception is required (30.2.2).

Error conditions:

(9.1) operation_not_permitted — if pm is nullptr.

(9.2) resource_deadlock_would_occur — if on entry owns is true.

template<class Clock, class Duration>
bool try_lock_until(const chrono::time_point<Clock, Duration>& abs_time);

Effects: As if by pm->try_lock_shared_until(abs_time).

Returns: The value returned by the call to pm->try_lock_shared_until(abs_time).

Ensures: owns == res, where res is the value returned by the call to pm->try_lock_shared_until(abs_time).

Throws: Any exception thrown by pm->try_lock_shared_until(abs_time). system_error when an exception is required (30.2.2).

Error conditions:
template<class Rep, class Period>
bool try_lock_for(const chrono::duration<Rep, Period>& rel_time);

Effects: As if by pm->try_lock_shared_for(rel_time).

Returns: The value returned by the call to pm->try_lock_shared_for(rel_time).

Ensures: owns == res, where res is the value returned by the call to pm->try_lock_shared_for(rel_time).

Throws: Any exception thrown by pm->try_lock_shared_for(rel_time). system_error when an exception is required (30.2.2).

Error conditions:
— operation_not_permitted — if pm is nullptr.
— resource_deadlock_would_occur — if on entry owns is true.

void unlock();

Effects: As if by pm->unlock_shared().

Ensures: owns == false.

Throws: system_error when an exception is required (30.2.2).

Error conditions:
— operation_not_permitted — if pm is nullptr.
— resource_deadlock_would_occur — if on entry owns is true.

30.4.4.4.3 shared_lock modifiers

void swap(shared_lock& sl) noexcept;

Effects: Swaps the data members of this and sl.

mutex_type* release() noexcept;

Returns: The previous value of pm.

Ensures: pm == nullptr and owns == false.

template<class Mutex>
void swap(shared_lock<Mutex>& x, shared_lock<Mutex>& y) noexcept;

Effects: As if by x.swap(y).

30.4.4.4 shared_lock observers

bool owns_lock() const noexcept;

Returns: owns.

explicit operator bool() const noexcept;

Returns: owns.

mutex_type* mutex() const noexcept;

Returns: pm.

30.4.5 Generic locking algorithms

template<class L1, class L2, class... L3> int try_lock(L1& l1, L2& l2, L3&...);

Requires: Each template parameter type shall satisfy the Cpp17Lockable requirements. [Note: The unique_lock class template meets these requirements when suitably instantiated. — end note]

Effects: Calls try_lock() for each argument in order beginning with the first until all arguments have been processed or a call to try_lock() fails, either by returning false or by throwing an exception. If a call to try_lock() fails, unlock() is called for all prior arguments with no further calls to try_lock().
Returns: -1 if all calls to `try_lock()` returned `true`, otherwise a zero-based index value that indicates the argument for which `try_lock()` returned `false`.

```cpp
template<class L1, class L2, class... L3> void lock(L1&, L2&, L3&...);
```

Requires: Each template parameter type shall satisfy the `Cpp17Lockable` requirements, [Note: The `unique_lock` class template meets these requirements when suitably instantiated. —end note]

Effects: All arguments are locked via a sequence of calls to `lock()`, `try_lock()`, or `unlock()` on each argument. The sequence of calls does not result in deadlock, but is otherwise unspecified. [Note: A deadlock avoidance algorithm such as try-and-back-off must be used, but the specific algorithm is not specified to avoid over-constraining implementations. —end note] If a call to `lock()` or `try_lock()` throws an exception, `unlock()` is called for any argument that had been locked by a call to `lock()` or `try_lock()`.

### 30.4.6 Call once

#### 30.4.6.1 Struct `once_flag`

```cpp
namespace std {
    struct once_flag {
        constexpr once_flag() noexcept;
        once_flag(const once_flag&) = delete;
        once_flag& operator=(const once_flag&) = delete;
    };
}
```

The class `once_flag` is an opaque data structure that `call_once` uses to initialize data without causing a data race or deadlock.

```cpp
constexpr once_flag() noexcept;
```

Effects: Constructs an object of type `once_flag`.

Synchronization: The construction of a `once_flag` object is not synchronized.

Ensures: The object’s internal state is set to indicate to an invocation of `call_once` with the object as its initial argument that no function has been called.

#### 30.4.6.2 Function `call_once`

```cpp
template<class Callable, class... Args>
void call_once(once_flag& flag, Callable&& func, Args&&... args);
```

Requires:

```
INVOKE(std::forward<Callable>(func), std::forward<Args>(args)...) (see 19.14.3) shall be a valid expression.
```

Effects: An execution of `call_once` that does not call its `func` is a passive execution. An execution of `call_once` that calls its `func` is an active execution. An active execution shall call `INVOKE(std::forward<Callable>(func), std::forward<Args>(args)...)`. If such a call to `func` throws an exception the execution is exceptional, otherwise it is returning. An exceptional execution shall propagate the exception to the caller of `call_once`. Among all executions of `call_once` for any given `once_flag`: at most one shall be a returning execution; if there is a returning execution, it shall be the last active execution; and there are passive executions only if there is a returning execution. [Note: Passive executions allow other threads to reliably observe the results produced by the earlier returning execution. —end note]

Synchronization: For any given `once_flag`: all active executions occur in a total order; completion of an active execution synchronizes with (6.8.2) the start of the next one in this total order; and the returning execution synchronizes with the return from all passive executions.

Throws: `system_error` when an exception is required (30.2.2), or any exception thrown by `func`.

[Example:

```cpp
// global flag, regular function
void init();
std::once_flag flag;
```]
void f() {
    std::call_once(flag, init);
}

// function static flag, function object
struct initializer {
    void operator()();
};

void g() {
    static std::once_flag flag2;
    std::call_once(flag2, initializer());
}

// object flag, member function
class information {
    std::once_flag verified;
    void verifier();
    public:
        void verify() { std::call_once(verified, &information::verifier, *this); }
};

—end example

30.5 Condition variables

1 Condition variables provide synchronization primitives used to block a thread until notified by some other thread that some condition is met or until a system time is reached. Class condition_variable provides a condition variable that can only wait on an object of type unique_lock<mutex>, allowing maximum efficiency on some platforms. Class condition_variable_any provides a general condition variable that can wait on objects of user-supplied lock types.

2 Condition variables permit concurrent invocation of the wait, wait_for, wait_until, notify_one and notify_all member functions.

3 The execution of notify_one and notify_all shall be atomic. The execution of wait, wait_for, and wait_until shall be performed in three atomic parts:
   1. the release of the mutex and entry into the waiting state;
   2. the unblocking of the wait; and
   3. the reacquisition of the lock.

4 The implementation shall behave as if all executions of notify_one, notify_all, and each part of the wait, wait_for, and wait_until executions are executed in a single unspecified total order consistent with the 'happens before' order.

5 Condition variable construction and destruction need not be synchronized.

30.5.1 Header <condition_variable> synopsis

namespace std {
    class condition_variable;
    class condition_variable_any;

    void notify_all_at_thread_exit(condition_variable& cond, unique_lock<mutex> lk);

    enum class cv_status { no_timeout, timeout };
}

30.5.2 Non-member functions

void notify_all_at_thread_exit(condition_variable& cond, unique_lock<mutex> lk);

1 Requires: lk is locked by the calling thread and either
   (1.1) — no other thread is waiting on cond, or
lk.mutex() returns the same value for each of the lock arguments supplied by all concurrently waiting (via wait, wait_for, or wait_until) threads.

**Effects:** Transfers ownership of the lock associated with lk into internal storage and schedules cond to be notified when the current thread exits, after all objects of thread storage duration associated with the current thread have been destroyed. This notification shall be as if:

```cpp
lk.unlock();
cond.notify_all();
```

**Synchronization:** The implied lk.unlock() call is sequenced after the destruction of all objects with thread storage duration associated with the current thread.

**[Note:]** The supplied lock will be held until the thread exits, and care should be taken to ensure that this does not cause deadlock due to lock ordering issues. After calling notify_all_at_thread_exit it is recommended that the thread should be exited as soon as possible, and that no blocking or time-consuming tasks are run on that thread. — end note]

**[Note:]** It is the user’s responsibility to ensure that waiting threads do not erroneously assume that the thread has finished if they experience spurious wakeups. This typically requires that the condition being waited for is satisfied while holding the lock on lk, and that this lock is not released and reacquired prior to calling notify_all_at_thread_exit. — end note]

### 30.5.3 Class condition_variable

```cpp
namespace std {
    class condition_variable {
        public:
            condition_variable();
            ~condition_variable();
            condition_variable(const condition_variable&) = delete;
            condition_variable& operator=(const condition_variable&) = delete;
            void notify_one() noexcept;
            void notify_all() noexcept;
            void wait(unique_lock<mutex>& lock);
            template<class Predicate>
                void wait(unique_lock<mutex>& lock, Predicate pred);
            template<class Clock, class Duration>
                cv_status wait_until(unique_lock<mutex>& lock,
                    const chrono::time_point<Clock, Duration>& abs_time);
            template<class Clock, class Duration, class Predicate>
                bool wait_until(unique_lock<mutex>& lock,
                    const chrono::time_point<Clock, Duration>& abs_time,
                    Predicate pred);
            template<class Rep, class Period>
                cv_status wait_for(unique_lock<mutex>& lock,
                    const chrono::duration<Rep, Period>& rel_time);
            template<class Rep, class Period, class Predicate>
                bool wait_for(unique_lock<mutex>& lock,
                    const chrono::duration<Rep, Period>& rel_time,
                    Predicate pred);

            using native_handle_type = implementation-defined; // see 30.2.3
            native_handle_type native_handle(); // see 30.2.3
        }
    }
}
```

1 The class condition_variable shall be a standard-layout class (Clause 10).

condition_variable();

**Effects:** Constructs an object of type condition_variable.

**Throws:** system_error when an exception is required (30.2.2).

**Error conditions:**
resource_unavailable_try_again — if some non-memory resource limitation prevents initialization.

~condition_variable();

5

Requires: There shall be no thread blocked on *this. [Note: That is, all threads shall have been notified; they may subsequently block on the lock specified in the wait. This relaxes the usual rules, which would have required all wait calls to happen before destruction. Only the notification to unblock the wait needs to happen before destruction. The user should take care to ensure that no threads wait on *this once the destructor has been started, especially when the waiting threads are calling the wait functions in a loop or using the overloads of wait, wait_for, or wait_until that take a predicate. —end note]

Effects: Destroys the object.

void notify_one() noexcept;

7

Effects: If any threads are blocked waiting for *this, unblocks one of those threads.

void notify_all() noexcept;

8

Effects: Unblocks all threads that are blocked waiting for *this.

void wait(unique_lock<mutex>& lock);

9

Requires: lock.owns_lock() is true and lock.mutex() is locked by the calling thread, and either

(9.1) no other thread is waiting on this condition_variable object or

(9.2) lock.mutex() returns the same value for each of the lock arguments supplied by all concurrently waiting (via wait, wait_for, or wait_until) threads.

Effects:

(10.1) Atomically calls lock.unlock() and blocks on *this.

(10.2) When unblocked, calls lock.lock() (possibly blocking on the lock), then returns.

(10.3) The function will unblock when signaled by a call to notify_one() or a call to notify_all(), or spuriously.

Remarks: If the function fails to meet the postcondition, terminate() shall be called (13.5.1). [Note: This can happen if the re-locking of the mutex throws an exception. —end note]

Ensures: lock.owns_lock() is true and lock.mutex() is locked by the calling thread.

Throws: Nothing.

template<class Predicate>

void wait(unique_lock<mutex>& lock, Predicate pred);

14

Requires: lock.owns_lock() is true and lock.mutex() is locked by the calling thread, and either

(14.1) no other thread is waiting on this condition_variable object or

(14.2) lock.mutex() returns the same value for each of the lock arguments supplied by all concurrently waiting (via wait, wait_for, or wait_until) threads.

Effects: Equivalent to:

while (!pred())

wait(lock);

Remarks: If the function fails to meet the postcondition, terminate() shall be called (13.5.1). [Note: This can happen if the re-locking of the mutex throws an exception. —end note]

Ensures: lock.owns_lock() is true and lock.mutex() is locked by the calling thread.

Throws: Any exception thrown by pred.

template<class Clock, class Duration>

cv_status wait_until(unique_lock<mutex>& lock,

const chrono::time_point.Clock, Duration>& abs_time);

19

Requires: lock.owns_lock() is true and lock.mutex() is locked by the calling thread, and either

(19.1) no other thread is waiting on this condition_variable object or
lock.mutex() returns the same value for each of the lock arguments supplied by all concurrently waiting (via wait, wait_for, or wait_until) threads.

**Effects:**

- Atomically calls lock.unlock() and blocks on *this.
- When unblocked, calls lock.lock() (possibly blocking on the lock), then returns.
- The function will unblock when signaled by a call to notify_one(), a call to notify_all(), expiration of the absolute timeout (30.2.4) specified by abs_time, or spuriously.
- If the function exits via an exception, lock.lock() shall be called prior to exiting the function.

**Remarks:** If the function fails to meet the postcondition, terminate() shall be called (13.5.1). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

**Ensures:** lock.owns_lock() is true and lock.mutex() is locked by the calling thread.

**Returns:** cv_status::timeout if the absolute timeout (30.2.4) specified by abs_time expired, otherwise cv_status::no_timeout.

**Throws:** Timeout-related exceptions (30.2.4).

```cpp
template<class Rep, class Period>
cv_status wait_for(unique_lock<mutex>& lock,  
const chrono::duration<Rep, Period>& rel_time);
```

**Requires:** lock.owns_lock() is true and lock.mutex() is locked by the calling thread, and either
- no other thread is waiting on this condition_variable object or
- lock.mutex() returns the same value for each of the lock arguments supplied by all concurrently waiting (via wait, wait_for, or wait_until) threads.

**Effects:** Equivalent to:

```
return wait_until(lock, chrono::steady_clock::now() + rel_time);
```

**Returns:** cv_status::timeout if the relative timeout (30.2.4) specified by rel_time expired, otherwise cv_status::no_timeout.

**Remarks:** If the function fails to meet the postcondition, terminate() shall be called (13.5.1). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

**Ensures:** lock.owns_lock() is true and lock.mutex() is locked by the calling thread.

**Throws:** Timeout-related exceptions (30.2.4).

```cpp
template<class Clock, class Duration, class Predicate>
bool wait_until(unique_lock<mutex>& lock,  
const chrono::time_point<Clock, Duration>& abs_time,  
Predicate pred);
```

**Requires:** lock.owns_lock() is true and lock.mutex() is locked by the calling thread, and either
- no other thread is waiting on this condition_variable object or
- lock.mutex() returns the same value for each of the lock arguments supplied by all concurrently waiting (via wait, wait_for, or wait_until) threads.

**Effects:** Equivalent to:

```
while (!pred())
  if (wait_until(lock, abs_time) == cv_status::timeout)  
    return pred();
return true;
```

**Remarks:** If the function fails to meet the postcondition, terminate() shall be called (13.5.1). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

**Ensures:** lock.owns_lock() is true and lock.mutex() is locked by the calling thread.

[Note: The returned value indicates whether the predicate evaluated to true regardless of whether the timeout was triggered. — end note]

**Throws:** Timeout-related exceptions (30.2.4) or any exception thrown by pred.
template<class Rep, class Period, class Predicate>
bool wait_for(unique_lock<mutex>& lock,
    const chrono::duration<Rep, Period>& rel_time,
    Predicate pred);

Requires: lock.owns_lock() is true and lock.mutex() is locked by the calling thread, and either
— no other thread is waiting on this condition_variable object or
— lock.mutex() returns the same value for each of the lock arguments supplied by all concurrently
waiting (via wait, wait_for, or wait_until) threads.

Effects: Equivalent to:
return wait_until(lock, chrono::steady_clock::now() + rel_time, std::move(pred));

[Note: There is no blocking if pred() is initially true, even if the timeout has already expired. — end
note]

Remarks: If the function fails to meet the postcondition, terminate() shall be called (13.5.1). [Note:
This can happen if the re-locking of the mutex throws an exception. — end note]

Ensures: lock.owns_lock() is true and lock.mutex() is locked by the calling thread.

[Note: The returned value indicates whether the predicate evaluates to true regardless of whether the
timeout was triggered. — end note]

Throws: Timeout-related exceptions (30.2.4) or any exception thrown by pred.

30.5.4 Class condition_variable_any
A Lock type shall satisfy the Cpp17BasicLockable requirements (30.2.5.2). [Note: All of the standard
mutex types meet this requirement. If a Lock type other than one of the standard mutex types or a
unique_lock wrapper for a standard mutex type is used with condition_variable_any, the user should
ensure that any necessary synchronization is in place with respect to the predicate associated with the
condition_variable_any instance. — end note]
	namespace std {
    class condition_variable_any {
    public:
        condition_variable_any();
        ~condition_variable_any();

        condition_variable_any(const condition_variable_any&) = delete;
        condition_variable_any& operator=(const condition_variable_any&) = delete;

        void notify_one() noexcept;
        void notify_all() noexcept;

template<class Lock>
    void wait(Lock& lock);

template<class Lock, class Predicate>
    void wait(Lock& lock, Predicate pred);

template<class Lock, class Clock, class Duration>
    cv_status wait_until(Lock& lock, const chrono::time_point<Clock, Duration>& abs_time);

template<class Lock, class Clock, class Duration, class Predicate>
    bool wait_until(Lock& lock, const chrono::time_point<Clock, Duration>& abs_time,
        Predicate pred);

template<class Lock, class Rep, class Period>
    cv_status wait_for(Lock& lock, const chrono::duration<Rep, Period>& rel_time);

template<class Lock, class Rep, class Period, class Predicate>
    bool wait_for(Lock& lock, const chrono::duration<Rep, Period>& rel_time, Predicate pred);
    }
}

condition_variable_any();

Effects: Constructs an object of type condition_variable_any.

Throws: bad_alloc or system_error when an exception is required (30.2.2).
Error conditions:

— resource_unavailable_try_again — if some non-memory resource limitation prevents initialization.

— operation_not_permitted — if the thread does not have the privilege to perform the operation.

~condition_variable_any();

Requires: There shall be no thread blocked on *this. [Note: That is, all threads shall have been notified; they may subsequently block on the lock specified in the wait. This relaxes the usual rules, which would have required all wait calls to happen before destruction. Only the notification to unblock the wait needs to happen before destruction. The user should take care to ensure that no threads wait on *this once the destructor has been started, especially when the waiting threads are calling the wait functions in a loop or using the overloads of wait, wait_for, or wait_until that take a predicate.
— end note]

Effects: Destroys the object.

void notify_one() noexcept;

Effects: If any threads are blocked waiting for *this, unblocks one of those threads.

void notify_all() noexcept;

Effects: Unblocks all threads that are blocked waiting for *this.

template<class Lock>
void wait(Lock& lock);

Effects:

(9.1) Atomically calls lock.unlock() and blocks on *this.
(9.2) When unblocked, calls lock.lock() (possibly blocking on the lock) and returns.
(9.3) The function will unblock when signaled by a call to notify_one(), a call to notify_all(), or spuriously.

Remarks: If the function fails to meet the postcondition, terminate() shall be called (13.5.1). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

Ensures: lock is locked by the calling thread.

Throws: Nothing.

template<class Lock, class Predicate>
void wait(Lock& lock, Predicate pred);

Effects: Equivalent to:

while (!pred())
    wait(lock);

template<class Lock, class Clock, class Duration>
    cv_status wait_until(Lock& lock, const chrono::time_point<Clock, Duration>& abs_time);

Effects:

(14.1) Atomically calls lock.unlock() and blocks on *this.
(14.2) When unblocked, calls lock.lock() (possibly blocking on the lock) and returns.
(14.3) The function will unblock when signaled by a call to notify_one(), a call to notify_all(), expiration of the absolute timeout (30.2.4) specified by abs_time, or spuriously.
(14.4) If the function exits via an exception, lock.lock() shall be called prior to exiting the function.

Remarks: If the function fails to meet the postcondition, terminate() shall be called (13.5.1). [Note: This can happen if the re-locking of the mutex throws an exception. — end note]

Ensures: lock is locked by the calling thread.

Returns: cv_status::timeout if the absolute timeout (30.2.4) specified by abs_time expired, otherwise cv_status::no_timeout.

Throws: Timeout-related exceptions (30.2.4).
template<class Lock, class Rep, class Period>
    cv_status wait_for(Lock& lock, const chrono::duration<Rep, Period>& rel_time);

    Effects: Equivalent to:
        return wait_until(lock, chrono::steady_clock::now() + rel_time);
    Returns: cv_status::timeout if the relative timeout (30.2.4) specified by rel_time expired, otherwise
        cv_status::no_timeout.
    Remarks: If the function fails to meet the postcondition, terminate() shall be called (13.5.1). [Note:
        This can happen if the re-locking of the mutex throws an exception. — end note]
    Ensures: lock is locked by the calling thread.
    Throws: Timeout-related exceptions (30.2.4).

template<class Lock, class Clock, class Duration, class Predicate>
    bool wait_until(Lock& lock, const chrono::time_point<Clock, Duration>& abs_time, Predicate pred);

    Effects: Equivalent to:
        while (!pred())
            if (wait_until(lock, abs_time) == cv_status::timeout)
                return pred();
        return true;
    [Note: There is no blocking if pred() is initially true, or if the timeout has already expired. — end note]
    [Note: The returned value indicates whether the predicate evaluates to true regardless of whether the
        timeout was triggered. — end note]

template<class Lock, class Rep, class Period, class Predicate>
    bool wait_for(Lock& lock, const chrono::duration<Rep, Period>& rel_time, Predicate pred);

    Effects: Equivalent to:
        return wait_until(lock, chrono::steady_clock::now() + rel_time, std::move(pred));

### 30.6 Futures

#### 30.6.1 Overview
30.6 describes components that a C++ program can use to retrieve in one thread the result (value or exception)
from a function that has run in the same thread or another thread. [Note: These components are not
restricted to multi-threaded programs but can be useful in single-threaded programs as well. — end note]

#### 30.6.2 Header <future> synopsis

namespace std {
    enum class future_errc {
        broken_promise = implementation-defined,
        future_already_retrieved = implementation-defined,
        promise_already_satisfied = implementation-defined,
        no_state = implementation-defined
    };

    enum class launch : unspecified {
        async = unspecified,
        deferred = unspecified,
        implementation-defined
    };

    enum class future_status {
        ready,
        timeout,
        deferred
    };

§ 30.6.2
template<> struct is_error_code_enum<future_errc> : public true_type {
};

error_code make_error_code(future_errc e) noexcept;

error_condition make_error_condition(future_errc e) noexcept;

const error_category& future_category() noexcept;

class future_error;

template<class R> class promise;
template<class R> class promise<R&>;
template<> class promise<void>;

template<class R>
void swap(promise<R>& x, promise<R>& y) noexcept;

template<class R, class Alloc>
struct uses_allocator<promise<R>, Alloc>;

template<class R> class future;
template<class R> class future<R&>;
template<> class future<void>;

template<class R> class shared_future;
template<class R> class shared_future<R&>;
template<> class shared_future<void>;

template<class> class packaged_task;
// not defined

template<class R, class... ArgTypes>
class packaged_task<R(ArgTypes...)>;

template<class R, class... ArgTypes>
void swap(packaged_task<R(ArgTypes...)>&, packaged_task<R(ArgTypes...)>&) noexcept;

template<class F, class... Args>
[[nodiscard]] future<invoke_result_t<decay_t<F>, decay_t<Args>...>>
async(F&& f, Args&&... args);

template<class F, class... Args>
[[nodiscard]] future<invoke_result_t<decay_t<F>, decay_t<Args>...>>
async(launch policy, F&& f, Args&&... args);

The enum type launch is a bitmask type (15.4.2.1.4) with elements launch::async and launch::deferred. [Note: Implementations can provide bitmasks to specify restrictions on task interaction by functions launched by async() applicable to a corresponding subset of available launch policies. Implementations can extend the behavior of the first overload of async() by adding their extensions to the launch policy under the “as if” rule. — end note]

2 The enum values of future_errc are distinct and not zero.

30.6.3 Error handling

const error_category& future_category() noexcept;

Returns: A reference to an object of a type derived from class error_category.

1 The object’s default_error_condition and equivalent virtual functions shall behave as specified for the class error_category. The object’s name virtual function shall return a pointer to the string "future".

error_code make_error_code(future_errc e) noexcept;

Returns: error_code(static_cast<int>(e), future_category()).

error_condition make_error_condition(future_errc e) noexcept;

Returns: error_condition(static_cast<int>(e), future_category()).
30.6.4 Class future_error

namespace std {
    class future_error : public logic_error {
        public:
            explicit future_error(future_errc e);
            
            const error_code& code() const noexcept;
            const char* what() const noexcept;

        private:
            error_code ec_; // exposition only
    };

    explicit future_error(future_errc e);

    Effects: Constructs an object of class future_error and initializes ec_ with make_error_code(e).

    const error_code& code() const noexcept;

    Returns: ec_.

    const char* what() const noexcept;

    Returns: An NTBS incorporating code().message().

30.6.5 Shared state

Many of the classes introduced in this subclause use some state to communicate results. This shared state consists of some state information and some (possibly not yet evaluated) result, which can be a (possibly void) value or an exception. [Note: Futures, promises, and tasks defined in this clause reference such shared state. — end note]

[Note: The result can be any kind of object including a function to compute that result, as used by async when policy is launch::deferred. — end note]

An asynchronous return object is an object that reads results from a shared state. A waiting function of an asynchronous return object is one that potentially blocks to wait for the shared state to be made ready. If a waiting function can return before the state is made ready because of a timeout (30.2.5), then it is a timed waiting function, otherwise it is a non-timed waiting function.

An asynchronous provider is an object that provides a result to a shared state. The result of a shared state is set by respective functions on the asynchronous provider. [Note: Such as promises or tasks. — end note]

The means of setting the result of a shared state is specified in the description of those classes and functions that create such a state object.

When an asynchronous return object or an asynchronous provider is said to release its shared state, it means:

(5.1) — if the return object or provider holds the last reference to its shared state, the shared state is destroyed; and

(5.2) — the return object or provider gives up its reference to its shared state; and

(5.3) — these actions will not block for the shared state to become ready, except that it may block if all of the following are true: the shared state was created by a call to std::async, the shared state is not yet ready, and this was the last reference to the shared state.

When an asynchronous provider is said to make its shared state ready, it means:

(6.1) — first, the provider marks its shared state as ready; and

(6.2) — second, the provider unblocks any execution agents waiting for its shared state to become ready.

When an asynchronous provider is said to abandon its shared state, it means:

(7.1) — first, if that state is not ready, the provider

(7.1.1) — stores an exception object of type future_error with an error condition of broken_promise within its shared state; and then

(7.1.2) — makes its shared state ready;

(7.2) — second, the provider releases its shared state.
A shared state is \textit{ready} only if it holds a value or an exception ready for retrieval. Waiting for a shared state to become ready may invoke code to compute the result on the waiting thread if so specified in the description of the class or function that creates the state object.

Calls to functions that successfully set the stored result of a shared state synchronize with (6.8.2) calls to functions successfully detecting the ready state resulting from that setting. The storage of the result (whether normal or exceptional) into the shared state synchronizes with (6.8.2) the successful return from a call to a waiting function on the shared state.

Some functions (e.g., \texttt{promise::set_value\_at\_thread\_exit}) delay making the shared state ready until the calling thread exits. The destruction of each of that thread’s objects with thread storage duration (6.6.4.2) is sequenced before making that shared state ready.

Access to the result of the same shared state may conflict (6.8.2). [\textit{Note}: This explicitly specifies that the result of the shared state is visible in the objects that reference this state in the sense of data race avoidance (15.5.5.9). For example, concurrent accesses through references returned by \texttt{shared\_future::get()} (30.6.8) must either use read-only operations or provide additional synchronization. — end note]

### 30.6.6 Class template promise

```cpp
namespace std {
    template<class R>
    class promise {
        public:
            promise();
            template<class Allocator>
                promise(allocator\_arg\_t, const Allocator& a);
            promise(promise\&\& rhs) noexcept;
            promise(const promise& rhs) = delete;
            ~promise();

            // assignment
            promise\&\& operator=(promise\&\& rhs) noexcept;
            promise\&\& operator=(const promise& rhs) = delete;
            void swap(promise\&\& other) noexcept;

            // retrieving the result
            future<R> get\_future();

            // setting the result
            void set\_value(see below);
            void set\_exception(exception\_ptr p);

            // setting the result with deferred notification
            void set\_value\_at\_thread\_exit(see below);
            void set\_exception\_at\_thread\_exit(exception\_ptr p);
        }

        template<class R>
            void swap(promise<R\& x, promise<R\& y) noexcept;

    template<class R, class Alloc>
        struct uses\_allocator<promise<R>, Alloc>;
    }
```

1. The implementation shall provide the template \texttt{promise} and two specializations, \texttt{promise<R\&>} and \texttt{promise<void>}. These differ only in the argument type of the member functions \texttt{set\_value} and \texttt{set\_value\_at\_thread\_exit}, as set out in their descriptions, below.

2. The \texttt{set\_value}, \texttt{set\_exception}, \texttt{set\_value\_at\_thread\_exit}, and \texttt{set\_exception\_at\_thread\_exit} member functions behave as though they acquire a single mutex associated with the promise object while updating the promise object.
§ 30.6.6

: true_type { };

Requires: Alloc shall satisfy the Cpp17Allocator requirements (Table 33).

promise();

template<class Allocator>
 promise(const Allocator& a);

Effects: Constructs a promise object and a shared state. The second constructor uses the allocator a to allocate memory for the shared state.

promise(promise&& rhs) noexcept;

Effects: Constructs a new promise object and transfers ownership of the shared state of rhs (if any) to the newly-constructed object.

Ensures: rhs has no shared state.

~promise();

Effects: Abandons any shared state (30.6.5).

promise& operator=(promise&& rhs) noexcept;

Effects: Abandons any shared state (30.6.5) and then as if promise(std::move(rhs)).swap(*this).

Returns: *this.

void swap(promise& other) noexcept;

Effects: Exchanges the shared state of *this and other.

Ensures: *this has the shared state (if any) that other had prior to the call to swap. other has the shared state (if any) that *this had prior to the call to swap.

future<R> get_future();

Returns: A future<R> object with the same shared state as *this.

Throws: future_error if *this has no shared state or if get_future has already been called on a promise with the same shared state as *this.

Error conditions:

— future_already_retrieved if get_future has already been called on a promise with the same shared state as *this.

— no_state if *this has no shared state.

void promise::set_value(const R& r);
void promise::set_value(R&& r);
void promise<R&>::set_value(R& r);
void promise<void>::set_value();

Effects: Atomically stores the value r in the shared state and makes that state ready (30.6.5).

Throws:

— future_error if its shared state already has a stored value or exception, or

— for the first version, any exception thrown by the constructor selected to copy an object of R, or

— for the second version, any exception thrown by the constructor selected to move an object of R.

Error conditions:

— promise_already_satisfied if its shared state already has a stored value or exception.

— no_state if *this has no shared state.

void set_exception(exception_ptr p);

Requires: p is not null.

Effects: Atomically stores the exception pointer p in the shared state and makes that state ready (30.6.5).

Throws: future_error if its shared state already has a stored value or exception.

Error conditions:
promise_already_satisfied if its shared state already has a stored value or exception.

no_state if *this has no shared state.

```cpp
void promise::set_value_at_thread_exit(const R& r);
void promise::set_value_at_thread_exit(R&& r);
void promise<R&>::set_value_at_thread_exit(R& r);
void promise<void>::set_value_at_thread_exit();
```

Effects: Stores the value \( r \) in the shared state without making that state ready immediately. Schedules that state to be made ready when the current thread exits, after all objects of thread storage duration associated with the current thread have been destroyed.

Throws:

- future_error if its shared state already has a stored value or exception, or
- for the first version, any exception thrown by the constructor selected to copy an object of \( R \), or
- for the second version, any exception thrown by the constructor selected to move an object of \( R \).

Error conditions:

- promise_already_satisfied if its shared state already has a stored value or exception.
- no_state if *this has no shared state.

```cpp
void set_exception_at_thread_exit(exception_ptr p);
```

Requires: \( p \) is not null.

Effects: Stores the exception pointer \( p \) in the shared state without making that state ready immediately. Schedules that state to be made ready when the current thread exits, after all objects of thread storage duration associated with the current thread have been destroyed.

Throws: future_error if an error condition occurs.

Error conditions:

- promise_already_satisfied if its shared state already has a stored value or exception.
- no_state if *this has no shared state.

```cpp
template<class R>
void swap(promise<R>& x, promise<R>& y) noexcept;
```

Effects: As if by \( x.swap(y) \).

### 30.6.7 Class template future

The class template `future` defines a type for asynchronous return objects which do not share their shared state with other asynchronous return objects. A default-constructed `future` object has no shared state. A `future` object with shared state can be created by functions on asynchronous providers (30.6.5) or by the move constructor and shares its shared state with the original asynchronous provider. The result (value or exception) of a `future` object can be set by calling a respective function on an object that shares the same shared state.

[Note: Member functions of `future` do not synchronize with themselves or with member functions of `shared_future`. — end note]

The effect of calling any member function other than the destructor, the move-assignment operator, `share`, or `valid` on a `future` object for which `valid() == false` is undefined. [Note: It is valid to move from a future object for which `valid() == false`. — end note] [Note: Implementations should detect this case and throw an object of type `future_error` with an error condition of `future_errc::no_state`. — end note]

```cpp
namespace std {
    template<class R>
    class future {
        public:
            future() noexcept;
            future(future&&) noexcept;
            ~future();
```
future& operator=(const future& rhs) = delete;
future& operator=(future&&) noexcept;
shared_future<R> share() noexcept;

// retrieving the value
see below get();

// functions to check state
bool valid() const noexcept;

void wait() const;
template<class Rep, class Period>
  future_status wait_for(const chrono::duration<Rep, Period>& rel_time) const;
template<class Clock, class Duration>
  future_status wait_until(const chrono::time_point<Clock, Duration>& abs_time) const;
}

4 The implementation shall provide the template `future` and two specializations, `future<R&>` and `future<void>`. These differ only in the return type and return value of the member function `get`, as set out in its description, below.

future() noexcept;
5 Effects: Constructs an empty `future` object that does not refer to a shared state.
6 Ensures: `valid()` == false.

future(future&& rhs) noexcept;
7 Effects: Move constructs a `future` object that refers to the shared state that was originally referred to by `rhs` (if any).
8 Ensures:
   (8.1) — `valid()` returns the same value as `rhs.valid()` prior to the constructor invocation.
   (8.2) — `rhs.valid()` == false.

~future();
9 Effects:
   (9.1) — Releases any shared state (30.6.5);
   (9.2) — destroys *this.

future& operator=(future&& rhs) noexcept;
10 Effects:
   (10.1) — Releases any shared state (30.6.5).
   (10.2) — move assigns the contents of `rhs` to *this.
11 Ensures:
   (11.1) — `valid()` returns the same value as `rhs.valid()` prior to the assignment.
   (11.2) — `rhs.valid()` == false.

shared_future<R> share() noexcept;
12 Returns: `shared_future<R>(std::move(*this))`.
13 Ensures: `valid()` == false.

R future::get();
R& future<R&>::get();
void future<void>::get();
14 [Note: As described above, the template and its two required specializations differ only in the return type and return value of the member function `get`. — end note]
15 Effects:
(15.1) \( \text{wait}() \) s until the shared state is ready, then retrieves the value stored in the shared state;
(15.2) releases any shared state (30.6.5).

Returns:
(16.1) \( \text{future::get()} \) returns the value \( v \) stored in the object’s shared state as \( \text{std::move}(v) \).
(16.2) \( \text{future<R&>::get()} \) returns the reference stored as value in the object’s shared state.
(16.3) \( \text{future<void>::get()} \) returns nothing.

Throws: The stored exception, if an exception was stored in the shared state.

Ensures: \( \text{valid()} == \text{false} \).

\[
\text{bool \text{valid()} const 
}\]
\[
\text{Returns: true only if \*this refers to a shared state.}
\]

\[
\text{void \text{wait()} const;}
\]
\[
\text{Effects: Blocks until the shared state is ready.}
\]

\[
\text{template<class Rep, class Period>}
\]
\[
\text{future_status \text{wait_for(const chronogram::duration<Rep, Period>& rel_time) const;}
}\]
\[
\text{Effects: None if the shared state contains a deferred function (30.6.9), otherwise blocks until the shared state is ready or until the relative timeout (30.2.4) specified by rel_time has expired.}
\]

Returns:
(22.1) \( \text{future_status::deferred} \) if the shared state contains a deferred function.
(22.2) \( \text{future_status::ready} \) if the shared state is ready.
(22.3) \( \text{future_status::timeout} \) if the function is returning because the relative timeout (30.2.4) specified by rel_time has expired.

Throws: timeout-related exceptions (30.2.4).

\[
\text{template<class Clock, class Duration>}
\]
\[
\text{future_status \text{wait_until(const chronogram::time_point<Clock, Duration>& abs_time) const;}
}\]
\[
\text{Effects: None if the shared state contains a deferred function (30.6.9), otherwise blocks until the shared state is ready or until the absolute timeout (30.2.4) specified by abs_time has expired.}
\]

Returns:
(25.1) \( \text{future_status::deferred} \) if the shared state contains a deferred function.
(25.2) \( \text{future_status::ready} \) if the shared state is ready.
(25.3) \( \text{future_status::timeout} \) if the function is returning because the absolute timeout (30.2.4) specified by abs_time has expired.

Throws: timeout-related exceptions (30.2.4).

30.6.8 Class template \text{shared_future} 
[\text{futures.shared_future}]

The class template \text{shared_future} defines a type for asynchronous return objects which may share their shared state with other asynchronous return objects. A default-constructed \text{shared_future} object has no shared state. A \text{shared_future} object with shared state can be created by conversion from a \text{future} object and shares its shared state with the original asynchronous provider (30.6.5) of the shared state. The result (value or exception) of a \text{shared_future} object can be set by calling a respective function on an object that shares the same shared state.

[Note: Member functions of \text{shared_future} do not synchronize with themselves, but they synchronize with the shared state. —end note]

The effect of calling any member function other than the destructor, the move-assignment operator, the copy-assignment operator, or \text{valid()} on a \text{shared_future} object for which \text{valid()} == \text{false} is undefined.

[Note: It is valid to copy or move from a \text{shared_future} object for which \text{valid()} is \text{false}. —end note]

[Note: Implementations should detect this case and throw an object of type \text{future_error} with an error condition of \text{future_errc::no_state}. —end note]
namespace std {
    template<class R>
    class shared_future {
public:
    shared_future() noexcept;
    shared_future(const shared_future& rhs) noexcept;
    shared_future(future<R>&& rhs) noexcept;
    shared_future(shared_future&& rhs) noexcept;
    ~shared_future();
    shared_future& operator=(const shared_future& rhs) noexcept;
    shared_future& operator=(shared_future&& rhs) noexcept;

    // retrieving the value
    see below get() const;

    // functions to check state
    bool valid() const noexcept;
    void wait() const;
    template<class Rep, class Period>
    future_status wait_for(const chrono::duration<Rep, Period>& rel_time) const;
    template<class Clock, class Duration>
    future_status wait_until(const chrono::time_point<Clock, Duration>& abs_time) const;
    
};

The implementation shall provide the template shared_future and two specializations, shared_future<R&> and shared_future<void>. These differ only in the return type and return value of the member function get, as set out in its description, below.

shared_future() noexcept;
Effects: Constructs an empty shared_future object that does not refer to a shared state.
Ensures: valid() == false.

shared_future(const shared_future& rhs) noexcept;
Effects: Constructs a shared_future object that refers to the same shared state as rhs (if any).
Ensures: valid() returns the same value as rhs.valid().

shared_future(future<R>&& rhs) noexcept;
shared_future(shared_future&& rhs) noexcept;
Effects: Move constructs a shared_future object that refers to the shared state that was originally referred to by rhs (if any).
Ensures:
(10.1) valid() returns the same value as rhs.valid() returned prior to the constructor invocation.
(10.2) rhs.valid() == false.

shared_future& operator=(shared_future&& rhs) noexcept;
Effects:
(11.1) Releases any shared state (30.6.5); 
(11.2) destroys *this.

shared_future& operator=(const shared_future& rhs) noexcept;
Effects:
(12.1) Releases any shared state (30.6.5);
(12.2) move assigns the contents of rhs to *this.
Ensures:
(13.1) valid() returns the same value as rhs.valid() returned prior to the assignment.
shared_future& operator=(const shared_future& rhs) noexcept;

Effects:
— Releases any shared state (30.6.5);
— assigns the contents of rhs to this. [Note: As a result, this refers to the same shared state as rhs (if any). — end note]

Ensures: valid() == rhs.valid().

const R& shared_future::get() const;
R& shared_future<R&>::get() const;
void shared_future<void>::get() const;

[Note: As described above, the template and its two required specializations differ only in the return type and return value of the member function get. — end note]

[Note: Access to a value object stored in the shared state is unsynchronized, so programmers should apply only those operations on R that do not introduce a data race (6.8.2). — end note]

Effects: wait()s until the shared state is ready, then retrieves the value stored in the shared state.

Returns:
— shared_future::get() returns a const reference to the value stored in the object’s shared state.
[Note: Access through that reference after the shared state has been destroyed produces undefined behavior; this can be avoided by not storing the reference in any storage with a greater lifetime than the shared_future object that returned the reference. — end note]
— shared_future<R&>::get() returns the reference stored as value in the object’s shared state.
— shared_future<void>::get() returns nothing.

Throws: The stored exception, if an exception was stored in the shared state.

bool valid() const noexcept;

Returns: true only if this refers to a shared state.

void wait() const;

Effects: Blocks until the shared state is ready.

template<class Rep, class Period>
future_status wait_for(const chrono::duration<Rep, Period>& rel_time) const;

Effects: None if the shared state contains a deferred function (30.6.9), otherwise blocks until the shared state is ready or until the relative timeout (30.2.4) specified by rel_time has expired.

Returns:
— future_status::deferred if the shared state contains a deferred function.
— future_status::ready if the shared state is ready.
— future_status::timeout if the function is returning because the relative timeout (30.2.4) specified by rel_time has expired.

Throws: timeout-related exceptions (30.2.4).

template<class Clock, class Duration>
future_status wait_until(const chrono::time_point<Clock, Duration>& abs_time) const;

Effects: None if the shared state contains a deferred function (30.6.9), otherwise blocks until the shared state is ready or until the absolute timeout (30.2.4) specified by abs_time has expired.

Returns:
— future_status::deferred if the shared state contains a deferred function.
— future_status::ready if the shared state is ready.
— future_status::timeout if the function is returning because the absolute timeout (30.2.4) specified by abs_time has expired.
30.6.9 Function template async

The function template async provides a mechanism to launch a function potentially in a new thread and provides the result of the function in a future object with which it shares a shared state.

```
// futures.async

template<class F, class... Args>
[[nodiscard]] future<invoke_result_t<decay_t<F>, decay_t<Args>...>>
async(F&& f, Args&&... args);
```

1. **Requires:** F and each Ti in Args shall satisfy the Cpp17MoveConstructible requirements, and

\[
\text{INVOKE}(\text{DECAY\_COPY}(\text{std}::\text{forward}<F>(f)),
\text{DECAY\_COPY}(\text{std}::\text{forward}<Args>(\text{args}))...) \quad \text{// see 19.14.3, 30.3.2.2}
\]

shall be a valid expression.

2. **Effects:** The first function behaves the same as a call to the second function with a policy argument of `launch::async | launch::deferred` and the same arguments for F and Args. The second function creates a shared state that is associated with the returned future object. The further behavior of the second function depends on the policy argument as follows (if more than one of these conditions applies, the implementation may choose any of the corresponding policies):

- If launch::async is set in policy, calls \(\text{INVOKE}(\text{DECAY\_COPY}(\text{std}::\text{forward}<F>(f)), \text{DECAY\_COPY}(\text{std}::\text{forward}<\text{Args}>(\text{args})))\) (19.14.3, 30.3.2.2) as if in a new thread of execution represented by a thread object with the calls to \(\text{DECAY\_COPY}\) being evaluated in the thread that called async. Any return value is stored as the result in the shared state. Any exception propagated from the execution of \(\text{INVOKE}(\text{DECAY\_COPY}(\text{std}::\text{forward}<F>(f)), \text{DECAY\_COPY}(\text{std}::\text{forward}<\text{Args}>(\text{args})))\) is stored as the exceptional result in the shared state. The thread object is stored in the shared state and affects the behavior of any asynchronous return objects that reference that state.

- If launch::deferred is set in policy, stores \(\text{DECAY\_COPY}(\text{std}::\text{forward}<F>(f))\) and \(\text{DECAY\_COPY}(\text{std}::\text{forward}<\text{Args}>(\text{args}))\) in the shared state. These copies of f and args constitute a deferred function. Invocation of the deferred function evaluates \(\text{INVOKE}(\text{std}::\text{move}(g), \text{std}::\text{move}(xyz))\) where g is the stored value of \(\text{DECAY\_COPY}(\text{std}::\text{forward}<F>(f))\) and xyz is the stored copy of \(\text{DECAY\_COPY}(\text{std}::\text{forward}<\text{Args}>(\text{args}))\) ... Any return value is stored as the result in the shared state. Any exception propagated from the execution of the deferred function is stored as the exceptional result in the shared state. The shared state is not made ready until the function has completed. The first call to a non-timed waiting function (30.6.5) on an asynchronous return object referring to this shared state shall invoke the deferred function in the thread that called the waiting function. Once evaluation of \(\text{INVOKE}(\text{std}::\text{move}(g), \text{std}::\text{move}(xyz))\) begins, the function is no longer considered deferred. [Note: If this policy is specified together with other policies, such as when using a policy value of launch::async | launch::deferred, implementations should defer invocation or the selection of the policy when no more concurrency can be effectively exploited. — end note]

- If no value is set in the launch policy, or a value is set that is neither specified in this document nor by the implementation, the behavior is undefined.

3. **Returns:** An object of type future<invoke_result_t<decay_t<F>, decay_t<Args>...>> that refers to the shared state created by this call to async. [Note: If a future obtained from async is moved outside the local scope, other code that uses the future should be aware that the future’s destructor may block for the shared state to become ready. — end note]

4. **Synchronization:** Regardless of the provided policy argument,

- the invocation of async synchronizes with (6.8.2) the invocation of f. [Note: This statement applies even when the corresponding future object is moved to another thread. — end note] ; and

- the completion of the function f is sequenced before (6.8.2) the shared state is made ready. [Note: f might not be called at all, so its completion might never happen. — end note]
If the implementation chooses the `launch::async` policy,

(5.3) — a call to a waiting function on an asynchronous return object that shares the shared state created by this `async` call shall block until the associated thread has completed, as if joined, or else time out (30.3.2.5);

(5.4) — the associated thread completion synchronizes with (6.8.2) the return from the first function that successfully detects the ready status of the shared state or with the return from the last function that releases the shared state, whichever happens first.

Throws: `system_error` if `policy == launch::async` and the implementation is unable to start a new thread, or `std::bad_alloc` if memory for the internal data structures could not be allocated.

Error conditions:

(7.1) — `resource_unavailable_try_again` — if `policy == launch::async` and the system is unable to start a new thread.

Example:

```cpp
int work1(int value);
int work2(int value);
int work(int value) {
    auto handle = std::async([=]{ return work2(value); });
    int tmp = work1(value);
    return tmp + handle.get();  // #1
}
```

[Note: Line #1 might not result in concurrency because the `async` call uses the default policy, which may use `launch::deferred`, in which case the lambda might not be invoked until the `get()` call; in that case, `work1` and `work2` are called on the same thread and there is no concurrency. — end note] — end example]

### 30.6.10 Class template `packaged_task`

The class template `packaged_task` defines a type for wrapping a function or callable object so that the return value of the function or callable object is stored in a future when it is invoked.

When the `packaged_task` object is invoked, its stored task is invoked and the result (whether normal or exceptional) stored in the shared state. Any futures that share the shared state will then be able to access the stored result.

```cpp
namespace std {
    template<class> class packaged_task; // not defined

template<class R, class... ArgTypes>
class packaged_task<R(ArgTypes...)> {  
    public:
    // construction and destruction
    packaged_task() noexcept;
    template<class F>
    explicit packaged_task(F&& f);
    ~packaged_task();

    // no copy
    packaged_task(const packaged_task&) = delete;
    packaged_task& operator=(const packaged_task&) = delete;

    // move support
    packaged_task(packaged_task&& rhs) noexcept;
    packaged_task& operator=(packaged_task&& rhs) noexcept;
    void swap(packaged_task& other) noexcept;

    bool valid() const noexcept;

    // result retrieval
    future<R> get_future();

    // execution
    void operator()(ArgTypes...);
}  

§ 30.6.10 1380
void make_ready_at_thread_exit(ArgTypes...);
void reset();

template<class R, class... ArgTypes>
void swap(packaged_task<R(ArgTypes...)>& x, packaged_task<R(ArgTypes...)>& y) noexcept;

30.6.10.1 packaged_task member functions

packed_task() noexcept;
Effects: Constructs a packaged_task object with no shared state and no stored task.

template<class F>
packed_task(F&& f);
Requires: INVOKE<R>(f, t_1, t_2, ..., t_N) (19.14.3), where t_1, t_2, ..., t_N are values of the corresponding types in ArgTypes..., shall be a valid expression. Invoking a copy of f shall behave the same as invoking f.
Remarks: This constructor shall not participate in overload resolution if remove_cvref_t<F> is the same type as packaged_task<R(ArgTypes...)>
Effects: Constructs a new packaged_task object with a shared state and initializes the object’s stored task with std::forward<F>(f).
Throws: Any exceptions thrown by the copy or move constructor of f, or bad_alloc if memory for the internal data structures could not be allocated.

documented_task(packaged_task&& rhs) noexcept;
Effects: Constructs a new packaged_task object and transfers ownership of rhs’s shared state to *this, leaving rhs with no shared state. Moves the stored task from rhs to *this.
Ensures: rhs has no shared state.

packed_task& operator=(packaged_task&& rhs) noexcept;
Effects:
— (8.1) Releases any shared state (30.6.5);
— (8.2) calls packaged_task(std::move(rhs)).swap(*this).

packed_task();
Effects: Abandons any shared state (30.6.5).

void swap(packaged_task& other) noexcept;
Effects: Exchanges the shared states and stored tasks of *this and other.
Ensures: *this has the same shared state and stored task (if any) as other prior to the call to swap.
other has the same shared state and stored task (if any) as *this prior to the call to swap.

bool valid() const noexcept;
Returns: true only if *this has a shared state.

future<R> get_future();
Returns: A future object that shares the same shared state as *this.
Throws: A future_error object if an error occurs.
Error conditions:
— future_already_retrieved if get_future has already been called on a packaged_task object with the same shared state as *this.
— no_state if *this has no shared state.
void operator()(ArgTypes... args);

Effects: As if by `INVOKE\langle R\rangle(f, t_1, t_2, ..., t_N)` (19.14.3), where `f` is the stored task of `*this` and `t_1, t_2, ..., t_N` are the values in `args...`. If the task returns normally, the return value is stored as the asynchronous result in the shared state of `*this`, otherwise the exception thrown by the task is stored. The shared state of `*this` is made ready, and any threads blocked in a function waiting for the shared state of `*this` to become ready are unblocked.

Throws: A `future_error` exception object if there is no shared state or the stored task has already been invoked.

Error conditions:

(18.1) — `promise_already_satisfied` if the stored task has already been invoked.
(18.2) — `no_state` if `*this` has no shared state.

void make_ready_at_thread_exit(ArgTypes... args);

Effects: As if by `INVOKE\langle R\rangle(f, t_1, t_2, ..., t_N)` (19.14.3), where `f` is the stored task and `t_1, t_2, ..., t_N` are the values in `args...`. If the task returns normally, the return value is stored as the asynchronous result in the shared state of `*this`, otherwise the exception thrown by the task is stored. In either case, this shall be done without making that state ready (30.6.5) immediately. Schedules the shared state to be made ready when the current thread exits, after all objects of thread storage duration associated with the current thread have been destroyed.

Throws: `future_error` if an error condition occurs.

Error conditions:

(21.1) — `promise_already_satisfied` if the stored task has already been invoked.
(21.2) — `no_state` if `*this` has no shared state.

void reset();

Effects: As if `*this = packaged_task(std::move(f))`, where `f` is the task stored in `*this`. [Note: This constructs a new shared state for `*this`. The old state is abandoned (30.6.5). — end note]

Throws:

(23.1) — `bad_alloc` if memory for the new shared state could not be allocated.
(23.2) — any exception thrown by the move constructor of the task stored in the shared state.
(23.3) — `future_error` with an error condition of `no_state` if `*this` has no shared state.

§ 30.6.10.2 packaged_task globals

```cpp
template<class R, class... ArgTypes>
void swap(packaged_task<R(ArgTypes...)>& x, packaged_task<R(ArgTypes...)>& y) noexcept;
```

Effects: As if by `x.swap(y)`. 

© ISO/IEC N4762
Annex A  (informative)
Grammar summary

This summary of C++ grammar is intended to be an aid to comprehension. It is not an exact statement of the language. In particular, the grammar described here accepts a superset of valid C++ constructs. Disambiguation rules (8.8, 9.1, 10.7) must be applied to distinguish expressions from declarations. Further, access control, ambiguity, and type rules must be used to weed out syntactically valid but meaningless constructs.

A.1 Keywords

New context-dependent keywords are introduced into a program by typedef (9.1.3), namespace (9.7.1), class (Clause 10), enumeration (9.6), and template (Clause 12) declarations.

typedef-name:
   identifier

namespace-name:
   identifier
   namespace-alias

namespace-alias:
   identifier

class-name:
   identifier
   simple-template-id

enum-name:
   identifier

template-name:
   identifier

Note that a typedef-name naming a class is also a class-name (10.2).

A.2 Lexical conventions

hex-quad:
   hexadecimal-digit hexadecimal-digit hexadecimal-digit hexadecimal-digit

universal-character-name:
   \u hex-quad
   \U hex-quad hex-quad

Annex B  (informative)
Implementation quantities

Because computers are finite, C++ implementations are inevitably limited in the size of the programs they can successfully process. Every implementation shall document those limitations where known. This documentation may cite fixed limits where they exist, say how to compute variable limits as a function of available resources, or say that fixed limits do not exist or are unknown.

The limits may constrain quantities that include those described below or others. The bracketed number following each quantity is recommended as the minimum for that quantity. However, these quantities are only guidelines and do not determine compliance.

1. Nesting levels of compound statements (8.3), iteration control structures (8.5), and selection control structures (8.4) [256].

2. Nesting levels of conditional inclusion (14.1) [256].

3. Pointer (9.2.3.1), array (9.2.3.4), and function (9.2.3.5) declarators (in any combination) modifying a class, arithmetic, or incomplete type in a declaration [256].

4. Nesting levels of parenthesized expressions (7.5.3) within a full-expression [256].

5. Number of characters in an internal identifier (5.10) or macro name (14.3) [1024].

6. Number of characters in an external identifier (5.10, 6.5) [1024].

7. External identifiers (6.5) in one translation unit [65536].

8. Identifiers with block scope declared in one block (6.3.3) [1024].

9. Structured bindings (9.5) introduced in one declaration [256].

10. Macro identifiers (14.3) simultaneously defined in one translation unit [65536].

11. Parameters in one function definition (9.4.1) [256].

12. Arguments in one function call (7.6.1.2) [256].

13. Parameters in one macro definition (14.3) [256].

14. Arguments in one macro invocation (14.3) [256].

15. Characters in one logical source line (5.2) [65536].

16. Characters in a string literal (5.13.5) (after concatenation (5.2)) [65536].

17. Size of an object (6.6.2) [262144].

18. Nesting levels for #include files (14.2) [256].

19. Case labels for a switch statement (8.4.2) (excluding those for any nested switch statements) [16384].

20. Non-static data members (including inherited ones) in a single class (10.3) [16384].

21. Lambda-captures in one lambda-expression (7.5.5.2) [256].

22. Enumeration constants in a single enumeration (9.6) [4096].

23. Levels of nested class definitions (10.3.11) in a single member-specification [256].

24. Functions registered by atexit() (16.5) [32].

25. Functions registered by at_quick_exit() (16.5) [32].

26. Direct and indirect base classes (10.6) [16384].

27. Direct base classes for a single class (10.6) [1024].

28. Class members declared in a single member-specification (including member functions) (10.3) [4096].

29. Final overriding virtual functions in a class, accessible or not (10.6.2) [16384].

30. Direct and indirect virtual bases of a class (10.6.1) [1024].
— Static data members of a class (10.3.9.2) [1024].
— Friend declarations in a class (10.8.3) [4096].
— Access control declarations in a class (10.8.1) [4096].
— Member initializers in a constructor definition (10.9.2) [6144].
— **initializer-clauses** in one braced-init-list (9.3) [16384].
— Scope qualifications of one identifier (7.5.4.2) [256].
— Nested **linkage-specifications** (9.10) [1024].
— Recursive constexpr function invocations (9.1.5) [512].
— Full-expressions evaluated within a core constant expression (7.7) [1 048 576].
— Template parameters in a template declaration (12.1) [1 024].
— Recursively nested template instantiations (12.8.1), including substitution during template argument deduction (12.9.2) [1 024].
— Handlers per try block (13.3) [256].
— Number of placeholders (19.14.12.4) [10].
Annex C  (informative)

Compatibility

C.1  C++ and ISO C

This subclause lists the differences between C++ and ISO C, by the chapters of this document.

C.1.1  Clause 5: lexical conventions

1 Affected subclause: 5.11
Change: New Keywords
New keywords are added to C++; see 5.11.
Rationale: These keywords were added in order to implement the new semantics of C++.
Effect on original feature: Change to semantics of well-defined feature. Any ISO C programs that used any of these keywords as identifiers are not valid C++ programs.
Difficulty of converting: Syntactic transformation. Converting one specific program is easy. Converting a large collection of related programs takes more work.
How widely used: Common.

2 Affected subclause: 5.13.3
Change: Type of character literal is changed from int to char.
Rationale: This is needed for improved overloaded function argument type matching. For example:

```c
int function( int i );
int function( char c );
function( 'x' );
```

It is preferable that this call match the second version of function rather than the first.
Effect on original feature: Change to semantics of well-defined feature. ISO C programs which depend on `sizeof('x') == sizeof(int)` will not work the same as C++ programs.
Difficulty of converting: Simple.
How widely used: Programs which depend upon `sizeof('x')` are probably rare.

3 Affected subclause: 5.13.5
Change: String literals made const.
The type of a string literal is changed from “array of char” to “array of const char”. The type of a char16_t string literal is changed from “array of some-integer-type” to “array of const char16_t”. The type of a char32_t string literal is changed from “array of some-integer-type” to “array of const char32_t”. The type of a wide string literal is changed from “array of wchar_t” to “array of const wchar_t”.
Rationale: This avoids calling an inappropriate overloaded function, which might expect to be able to modify its argument.
Effect on original feature: Change to semantics of well-defined feature.
Difficulty of converting: Syntactic transformation. The fix is to add a cast:

```c
char* p = "abc";  // valid in C, invalid in C++
void f(char*) {
    char* p = (char*)"abc";  // OK: cast added
    f(p);
    f((char*)"def");  // OK: cast added
}
```

How widely used: Programs that have a legitimate reason to treat string literals as pointers to potentially modifiable memory are probably rare.
C.1.2 Clause 6: basic concepts [diff.basic]

1 Affected subclause: 6.1
Change: C++ does not have “tentative definitions” as in C.
E.g., at file scope,

```c
int i;
int i;
```

is valid in C, invalid in C++. This makes it impossible to define mutually referential file-local static objects, if initializers are restricted to the syntactic forms of C. For example,

```c
struct X { int i; struct X* next; };
static struct X a;
static struct X b = { 0, &a };
static struct X a = { 1, &b };
```

Rationale: This avoids having different initialization rules for fundamental types and user-defined types.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Semantic transformation. In C++, the initializer for one of a set of mutually-referential file-local static objects must invoke a function call to achieve the initialization.
How widely used: Seldom.

2 Affected subclause: 6.3
Change: A struct is a scope in C++, not in C.
Rationale: Class scope is crucial to C++, and a struct is a class.
Effect on original feature: Change to semantics of well-defined feature.
Difficulty of converting: Semantic transformation.
How widely used: C programs use struct extremely frequently, but the change is only noticeable when struct, enumeration, or enumerator names are referred to outside the struct. The latter is probably rare.

3 Affected subclause: 6.5 [also 9.1.7]
Change: A name of file scope that is explicitly declared const, and not explicitly declared extern, has internal linkage, while in C it would have external linkage.
Rationale: Because const objects may be used as values during translation in C++, this feature urges programmers to provide an explicit initializer for each const object. This feature allows the user to put const objects in source files that are included in more than one translation unit.
Effect on original feature: Change to semantics of well-defined feature.
Difficulty of converting: Semantic transformation.
How widely used: Seldom.

4 Affected subclause: 6.8.3.1
Change: The main function cannot be called recursively and cannot have its address taken.
Rationale: The main function may require special actions.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Trivial: create an intermediary function such as mymain(argc, argv).
How widely used: Seldom.

5 Affected subclause: 6.7
Change: C allows “compatible types” in several places, C++ does not.
For example, otherwise-identical struct types with different tag names are “compatible” in C but are distinctly different types in C++.
Rationale: Stricter type checking is essential for C++.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Semantic transformation. The “typesafe linkage” mechanism will find many, but not all, of such problems. Those problems not found by typesafe linkage will continue to function properly, according to the “layout compatibility rules” of this document.
How widely used: Common.

C.1.3 7.3: standard conversions [diff.conv]

1 Affected subclause: 7.3.11
Change: Converting void* to a pointer-to-object type requires casting.
```c
char a[10];
```
ISO C will accept this usage of pointer to void being assigned to a pointer to object type. C++ will not.

**Rationale:** C++ tries harder than C to enforce compile-time type safety.

**Effect on original feature:** Deletion of semantically well-defined feature.

**Difficulty of converting:** Could be automated. Violations will be diagnosed by the C++ translator. The fix is to add a cast. For example:

```c
char* c = (char*) b;
```

**How widely used:** This is fairly widely used but it is good programming practice to add the cast when assigning pointer-to-void to pointer-to-object. Some ISO C translators will give a warning if the cast is not used.

### C.1.4 Clause 7: expressions

1. **Affected subclause:** 7.6.1.2

   **Change:** Implicit declaration of functions is not allowed.

   **Rationale:** The type-safe nature of C++.

   **Effect on original feature:** Deletion of semantically well-defined feature. Note: the original feature was labeled as “obsolescent” in ISO C.

   **Difficulty of converting:** Syntactic transformation. Facilities for producing explicit function declarations are fairly widespread commercially.

   **How widely used:** Common.

2. **Affected subclauses:** 7.6.1.6, 7.6.2.2

   **Change:** Decrement operator is not allowed with `bool` operand.

   **Rationale:** Feature with surprising semantics.

   **Effect on original feature:** A valid ISO C expression utilizing the decrement operator on a `bool` lvalue (for instance, via the C typedef in `<stdbool.h>`) is ill-formed in this International Standard.

3. **Affected subclauses:** 7.6.2.3, 7.6.3

   **Change:** Types must be defined in declarations, not in expressions.

   In C, a sizeof expression or cast expression may define a new type. For example,

   ```c
   p = (void*)(struct x {int i;} *)0;
   ```

   defines a new type, struct x.

   **Rationale:** This prohibition helps to clarify the location of definitions in the source code.

   **Effect on original feature:** Deletion of semantically well-defined feature.

   **Difficulty of converting:** Syntactic transformation.

   **How widely used:** Seldom.

4. **Affected subclauses:** 7.6.16, 7.6.18, 7.6.19

   **Change:** The result of a conditional expression, an assignment expression, or a comma expression may be an lvalue.

   **Rationale:** C++ is an object-oriented language, placing relatively more emphasis on lvalues. For example, function calls may yield lvalues.

   **Effect on original feature:** Change to semantics of well-defined feature. Some C expressions that implicitly rely on lvalue-to-rvalue conversions will yield different results. For example,

   ```c
   char arr[100];
   sizeof(0, arr)
   ```

   yields 100 in C++ and `sizeof(char*)` in C.

   **Difficulty of converting:** Programs must add explicit casts to the appropriate rvalue.

   **How widely used:** Rare.

### C.1.5 Clause 8: statements

1. **Affected subclauses:** 8.4.2, 8.6.4

   **Change:** It is now invalid to jump past a declaration with explicit or implicit initializer (except across entire block not entered).

§ C.1.5
Rationale: Constructors used in initializers may allocate resources which need to be de-allocated upon leaving the block. Allowing jump past initializers would require complicated runtime determination of allocation. Furthermore, any use of the uninitialized object could be a disaster. With this simple compile-time rule, C++ assures that if an initialized variable is in scope, then it has assuredly been initialized.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Semantic transformation.

How widely used: Seldom.

Affected subclause: 8.6.3

Change: It is now invalid to return (explicitly or implicitly) from a function which is declared to return a value without actually returning a value.

Rationale: The caller and callee may assume fairly elaborate return-value mechanisms for the return of class objects. If some flow paths execute a return without specifying any value, the implementation must embody many more complications. Besides, promising to return a value of a given type, and then not returning such a value, has always been recognized to be a questionable practice, tolerated only because very-old C had no distinction between void functions and int functions.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Semantic transformation. Add an appropriate return value to the source code, such as zero.

How widely used: Seldom. For several years, many existing C implementations have produced warnings in this case.

C.1.6 Clause 9: declarations

Affected subclause: 9.1.1

Change: In C++, the static or extern specifiers can only be applied to names of objects or functions. Using these specifiers with type declarations is illegal in C++. In C, these specifiers are ignored when used on type declarations.

Example:

```c
static struct S {
    int i;
};
```

Rationale: Storage class specifiers don’t have any meaning when associated with a type. In C++, class members can be declared with the static storage class specifier. Allowing storage class specifiers on type declarations could render the code confusing for users.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Syntactic transformation.

How widely used: Seldom.

Affected subclause: 9.1.1

Change: In C++, register is not a storage class specifier.

Rationale: The storage class specifier had no effect in C++.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Syntactic transformation.

How widely used: Common.

Affected subclause: 9.1.3

Change: A C++ typedef name must be different from any class type name declared in the same scope (except if the typedef is a synonym of the class name with the same name). In C, a typedef name and a struct tag name declared in the same scope can have the same name (because they have different name spaces).

Example:

```c
typedef struct namel { /* ... */ } namel; // valid C and C++
struct name { /* ... */ }; // valid C, invalid C++
typedef int name; // valid C, invalid C++
```

Rationale: For ease of use, C++ doesn’t require that a type name be prefixed with the keywords class, struct or union when used in object declarations or type casts.

Example:
class name { /* ... */ };  // i has type class name

Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Semantic transformation. One of the 2 types has to be renamed.
How widely used: Seldom.

4 Affected subclause: 9.1.7 [see also 6.5]
Change: const objects must be initialized in C++ but can be left uninitialized in C.
Rationale: A const object cannot be assigned to so it must be initialized to hold a useful value.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Semantic transformation.
How widely used: Seldom.

5 Affected subclause: 9.1.7
Change: Banning implicit int.
In C++ a decl-specifier-seq must contain a type-specifier, unless it is followed by a declarator for a constructor, a destructor, or a conversion function. In the following example, the left-hand column presents valid C; the right-hand column presents equivalent C++:

```c
void f(const parm);
const n = 3;
main()
  /* ... */
```  
```c++
void f(const int parm);
const int n = 3;
int main()
  /* ... */
```  
Rationale: In C++, implicit int creates several opportunities for ambiguity between expressions involving function-like casts and declarations. Explicit declaration is increasingly considered to be proper style. Liaison with WG14 (C) indicated support for (at least) deprecating implicit int in the next revision of C.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Syntactic transformation. Could be automated.
How widely used: Common.

6 Affected subclause: 9.1.7.4
Change: The keyword auto cannot be used as a storage class specifier.
```c
  auto int x;  // valid C, invalid C++
```  
Rationale: Allowing the use of auto to deduce the type of a variable from its initializer results in undesired interpretations of auto as a storage class specifier in certain contexts.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Syntactic transformation.
How widely used: Rare.

7 Affected subclause: 9.6
Change: C++ objects of enumeration type can only be assigned values of the same enumeration type. In C, objects of enumeration type can be assigned values of any integral type.
Example:
```c
enum color { red, blue, green };
enum color c = 1;  // valid C, invalid C++
```  
Rationale: The type-safe nature of C++.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Syntactic transformation. (The type error produced by the assignment can be automatically corrected by applying an explicit cast.)
How widely used: Common.

8 Affected subclause: 9.6
Change: In C++, the type of an enumerator is its enumeration. In C, the type of an enumerator is int.
Example:
enum e { A };

// in C
sizeof(A) == sizeof(int)

// in C++
sizeof(A) == sizeof(e)

/* and sizeof(int) is not necessarily equal to sizeof(e) */

Rationale: In C++, an enumeration is a distinct type.
Effect on original feature: Change to semantics of well-defined feature.
Difficulty of converting: Semantic transformation.
How widely used: Seldom. The only time this affects existing C code is when the size of an enumerator is taken. Taking the size of an enumerator is not a common C coding practice.

C.1.7 9.2: declarators

Affected subclause: [diff.decl]

Change: In C++, a function declared with an empty parameter list takes no arguments. In C, an empty parameter list means that the number and type of the function arguments are unknown.

Example:

int f();
// means int f(void) in C++
// int f( unknown ) in C

Rationale: This is to avoid erroneous function calls (i.e., function calls with the wrong number or type of arguments).
Effect on original feature: Change to semantics of well-defined feature. This feature was marked as “obsolescent” in C.
Difficulty of converting: Syntactic transformation. The function declarations using C incomplete declaration style must be completed to become full prototype declarations. A program may need to be updated further if different calls to the same (non-prototype) function have different numbers of arguments or if the type of corresponding arguments differed.
How widely used: Common.

2 Affected subclause: 9.2.3.5 [see 7.6.2.3]

Change: In C++, types may not be defined in return or parameter types. In C, these type definitions are allowed.

Example:

void f( struct S { int a; } arg ) {} // valid C, invalid C++
enum E { A, B, C } f() {} // valid C, invalid C++

Rationale: When comparing types in different translation units, C++ relies on name equivalence when C relies on structural equivalence. Regarding parameter types: since the type defined in a parameter list would be in the scope of the function, the only legal calls in C++ would be from within the function itself.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Semantic transformation. The type definitions must be moved to file scope, or in header files.
How widely used: Seldom. This style of type definition is seen as poor coding style.

3 Affected subclause: 9.4

Change: In C++, the syntax for function definition excludes the “old-style” C function. In C, “old-style” syntax is allowed, but deprecated as “obsolescent”.
Rationale: Prototypes are essential to type safety.
Effect on original feature: Deletion of semantically well-defined feature.
Difficulty of converting: Syntactic transformation.
How widely used: Common in old programs, but already known to be obsolescent.

4 Affected subclause: 9.3.1

Change: In C++, designated initialization support is restricted compared to the corresponding functionality in C. In C++, designators for non-static data members must be specified in declaration order, designators for array elements and nested designators are not supported, and designated and non-designated initializers cannot be mixed in the same initializer list.

Example:
struct A { int x, y; }
struct B { struct A a; }
struct A a = {.y = 1, .x = 2}; // valid C, invalid C++
int arr[3] = {{1} = 5}; // valid C, invalid C++
struct B b = {.a.x = 0}; // valid C, invalid C++
struct A c = {.x = 1, 2}; // valid C, invalid C++

Rationale: In C++, members are destroyed in reverse construction order and the elements of an initializer list are evaluated in lexical order, so field initializers must be specified in order. Array designators conflict with lambda-expression syntax. Nested designators are seldom used.

Effect on original feature: Deletion of feature that is incompatible with C++.

Difficulty of converting: Syntactic transformation.

How widely used: Out-of-order initializers are common. The other features are seldom used.

5

Affected subclause: 9.3.2
Change: In C++, when initializing an array of character with a string, the number of characters in the string (including the terminating ‘\0’) must not exceed the number of elements in the array. In C, an array can be initialized with a string even if the array is not large enough to contain the string-terminating ‘\0’.

Example:
```
char array[4] = "abcd"; // valid C, invalid C++
```

Rationale: When these non-terminated arrays are manipulated by standard string functions, there is potential for major catastrophe.

Effect on original feature: Deletion of semantically well-defined feature.

Difficulty of converting: Semantic transformation. The arrays must be declared one element bigger to contain the string terminating ‘\0’.

How widely used: Seldom. This style of array initialization is seen as poor coding style.

C.1.8 Clause 10: classes

1

Affected subclause: 10.2 [see also 9.1.3]
Change: In C++, a class declaration introduces the class name into the scope where it is declared and hides any object, function or other declaration of that name in an enclosing scope. In C, an inner scope declaration of a struct tag name never hides the name of an object or function in an outer scope.

Example:
```
int x[99];
void f() {
    struct x { int a; };
    sizeof(x); /* size of the array in C */
    /* size of the struct in C++ */
}
```

Rationale: This is one of the few incompatibilities between C and C++ that can be attributed to the new C++ name space definition where a name can be declared as a type and as a non-type in a single scope causing the non-type name to hide the type name and requiring that the keywords class, struct, union or enum be used to refer to the type name. This new name space definition provides important notational conveniences to C++ programmers and helps making the use of the user-defined types as similar as possible to the use of fundamental types. The advantages of the new name space definition were judged to outweigh by far the incompatibility with C described above.

Effect on original feature: Change to semantics of well-defined feature.

Difficulty of converting: Semantic transformation. If the hidden name that needs to be accessed is at global scope, the :: C++ operator can be used. If the hidden name is at block scope, either the type or the struct tag has to be renamed.

How widely used: Seldom.

2

Affected subclause: 10.3.10
Change: Bit-fields of type plain int are signed.

Rationale: Leaving the choice of signedness to implementations could lead to inconsistent definitions of template specializations. For consistency, the implementation freedom was eliminated for non-dependent
types, too.

**Effect on original feature:** The choice is implementation-defined in C, but not so in C++.

**Difficulty of converting:** Syntactic transformation.

**How widely used:** Seldom.

### 3. Affected subclause: 10.3.11

**Change:** In C++, the name of a nested class is local to its enclosing class. In C the name of the nested class belongs to the same scope as the name of the outermost enclosing class.

**Example:**
```c
struct X {
    struct Y { /* ... */ } y;
};
struct Y yy; // valid C, invalid C++
```

**Rationale:** C++ classes have member functions which require that classes establish scopes. The C rule would leave classes as an incomplete scope mechanism which would prevent C++ programmers from maintaining locality within a class. A coherent set of scope rules for C++ based on the C rule would be very complicated and C++ programmers would be unable to predict reliably the meanings of nontrivial examples involving nested or local functions.

**Effect on original feature:** Change to semantics of well-defined feature.

**Difficulty of converting:** Semantic transformation. To make the struct type name visible in the scope of the enclosing struct, the struct tag could be declared in the scope of the enclosing struct, before the enclosing struct is defined. Example:
```c
struct Y;
// struct Y and struct X are at the same scope
struct X {
    struct Y { /* ... */ } y;
};
```

All the definitions of C struct types enclosed in other struct definitions and accessed outside the scope of the enclosing struct could be exported to the scope of the enclosing struct. Note: this is a consequence of the difference in scope rules, which is documented in 6.3.

**How widely used:** Seldom.

### 4. Affected subclause: 10.3.12

**Change:** In C++, a typedef name may not be redeclared in a class definition after being used in that definition.

**Example:**
```c
typedef int I;
struct S {
    I i;
    int I; // valid C, invalid C++
};
```

**Rationale:** When classes become complicated, allowing such a redefinition after the type has been used can create confusion for C++ programmers as to what the meaning of I really is.

**Effect on original feature:** Deletion of semantically well-defined feature.

**Difficulty of converting:** Semantic transformation. Either the type or the struct member has to be renamed.

**How widely used:** Seldom.

### C.1.9 10.3.3: special member functions

**Affected subclause:** 10.3.5

**Change:** Copying volatile objects.

The implicitly-declared copy constructor and implicitly-declared copy assignment operator cannot make a copy of a volatile lvalue. For example, the following is valid in ISO C:
```c
struct X { int i; };
volatile struct X x1 = {0};
struct X x2 = x1; // invalid C++
struct X x3;
```
x3 = x1;  // also invalid C++

**Rationale:** Several alternatives were debated at length. Changing the parameter to `volatile const X&` would greatly complicate the generation of efficient code for class objects. Discussion of providing two alternative signatures for these implicitly-defined operations raised unanswered concerns about creating ambiguities and complicating the rules that specify the formation of these operators according to the bases and members.

**Effect on original feature:** Deletion of semantically well-defined feature.

**Difficulty of converting:** Semantic transformation. If volatile semantics are required for the copy, a user-declared constructor or assignment must be provided. If non-volatile semantics are required, an explicit `const_cast` can be used.

**How widely used:** Seldom.

### C.1.10 Clause 14: preprocessing directives

**Affected subclause:** 14.8

**Change:** Whether `__STDC__` is defined and if so, what its value is, are implementation-defined.

**Rationale:** C++ is not identical to ISO C. Mandating that `__STDC__` be defined would require that translators make an incorrect claim. Each implementation must choose the behavior that will be most useful to its marketplace.

**Effect on original feature:** Change to semantics of well-defined feature.

**Difficulty of converting:** Semantic transformation.

**How widely used:** Programs and headers that reference `__STDC__` are quite common.

### C.2 C++ and ISO C++ 2003

This subclause lists the differences between C++ and ISO C++ 2003 (ISO/IEC 14882:2003, Programming Languages — C++), by the chapters of this document.

### C.2.1 Clause 5: lexical conventions

**Affected subclause:** 5.4

**Change:** New kinds of string literals.

**Rationale:** Required for new features.

**Effect on original feature:** Valid C++ 2003 code may fail to compile or produce different results in this International Standard. Specifically, macros named `R`, `u8`, `u8R`, `u`, `uR`, `U`, `UR`, or `LR` will not be expanded when adjacent to a string literal but will be interpreted as part of the string literal. For example:

```cpp
#define u8 "abc"
const char* s = u8"def";  // Previously "abcdef", now "def"
```

**Affected subclause:** 5.4

**Change:** User-defined literal string support.

**Rationale:** Required for new features.

**Effect on original feature:** Valid C++ 2003 code may fail to compile or produce different results in this International Standard. For example:

```cpp
#define _x "there"
"hello"_x  // #1
```

Previously, #1 would have consisted of two separate preprocessing tokens and the macro `_x` would have been expanded. In this International Standard, #1 consists of a single preprocessing token, so the macro is not expanded.

**Affected subclause:** 5.11

**Change:** New keywords.

**Rationale:** Required for new features.

**Effect on original feature:** Added to Table 5, the following identifiers are new keywords: `alignas`, `alignof`, `char16_t`, `char32_t`, `constexpr`, `decltype`, `decltype`, `noexcept`, `nullptr`, `static_assert`, and `thread_local`. Valid C++ 2003 code using these identifiers is invalid in this International Standard.

**Affected subclause:** 5.12

**Change:** Type of integer literals.

**Rationale:** C99 compatibility.
Effect on original feature: Certain integer literals larger than can be represented by `long` could change from an unsigned integer type to `signed long long`.

C.2.2 7.3: standard conversions

Affected subclause: 7.3.11
Change: Only literals are integer null pointer constants.
Rationale: Removing surprising interactions with templates and constant expressions.
Effect on original feature: Valid C++ 2003 code may fail to compile or produce different results in this International Standard. For example:

```cpp
void f(void *);  // #1
void f(...);    // #2
template<int N> void g() {
    f(0*N);    // calls #2; used to call #1
}
```

C.2.3 Clause 7: expressions

Affected subclause: 7.6.5
Change: Specify rounding for results of integer `/` and `%`.
Rationale: Increase portability, C99 compatibility.
Effect on original feature: Valid C++ 2003 code that uses integer division rounds the result toward 0 or toward negative infinity, whereas this International Standard always rounds the result toward 0.

Affected subclause: 7.6.14
Change: `&&` is valid in a `type-name`.
Rationale: Required for new features.
Effect on original feature: Valid C++ 2003 code may fail to compile or produce different results in this International Standard. For example:

```cpp
bool b1 = new int && false;       // previously false, now ill-formed
struct S { operator int() {}; };  
bool b2 = &S::operator int && false; // previously false, now ill-formed
```

C.2.4 Clause 9: declarations

Affected subclause: 9.1
Change: Remove `auto` as a storage class specifier.
Rationale: New feature.
Effect on original feature: Valid C++ 2003 code that uses the keyword `auto` as a storage class specifier may be invalid in this International Standard. In this International Standard, `auto` indicates that the type of a variable is to be deduced from its initializer expression.

C.2.5 9.2: declarators

Affected subclause: 9.3.4
Change: Narrowing restrictions in aggregate initializers.
Rationale: Catches bugs.
Effect on original feature: Valid C++ 2003 code may fail to compile in this International Standard. For example, the following code is valid in C++ 2003 but invalid in this International Standard because `double` to `int` is a narrowing conversion:

```cpp
int x[] = { 2.0 };  
```

C.2.6 10.3.3: special member functions

Affected subclauses: 10.3.4, 10.3.7, 10.3.5, 10.3.6
Change: Implicitly-declared special member functions are defined as deleted when the implicit definition would have been ill-formed.
Rationale: Improves template argument deduction failure.
Effect on original feature: A valid C++ 2003 program that uses one of these special member functions in a context where the definition is not required (e.g., in an expression that is not potentially evaluated) becomes ill-formed.

Affected subclause: 10.3.7
Change: User-declared destructors have an implicit exception specification.
Rationale: Clarification of destructor requirements.
Effect on original feature: Valid C++ 2003 code may execute differently in this International Standard. In particular, destructors that throw exceptions will call `std::terminate` (without calling `std::unexpected`) if their exception specification is non-throwing.

C.2.7 Clause 12: templates

1 Affected subclause: 12.1
   Change: Remove `export`.
   Rationale: No implementation consensus.
Effect on original feature: A valid C++ 2003 declaration containing `export` is ill-formed in this International Standard.

2 Affected subclause: 12.3
   Change: Remove whitespace requirement for nested closing template right angle brackets.
   Rationale: Considered a persistent but minor annoyance. Template aliases representing non-class types would exacerbate whitespace issues.
Effect on original feature: Change to semantics of well-defined expression. A valid C++ 2003 expression containing a right angle bracket (“>”) followed immediately by another right angle bracket may now be treated as closing two templates. For example, the following code is valid in C++ 2003 because “>>>” is a right-shift operator, but invalid in this International Standard because “>>>” closes two templates.

```cpp
template <class T> struct X { };
template <int N> struct Y { };
X< Y< 1 >> 2 > > x;
```

3 Affected subclause: 12.7.4.2
   Change: Allow dependent calls of functions with internal linkage.
   Rationale: Overly constrained, simplify overload resolution rules.
Effect on original feature: A valid C++ 2003 program could get a different result than this International Standard.

C.2.8 Clause 15: library introduction

1 Affected: Clause 15 – Clause 30
   Change: New reserved identifiers.
   Rationale: Required by new features.
Effect on original feature: Valid C++ 2003 code that uses any identifiers added to the C++ standard library by this International Standard may fail to compile or produce different results in this International Standard. A comprehensive list of identifiers used by the C++ standard library can be found in the Index of Library Names in this International Standard.

2 Affected subclause: 15.5.1.2
   Change: New headers.
   Rationale: New functionality.
Effect on original feature: The following C++ headers are new: `<array>`, `<atomic>`, `<chrono>`, `<codecvt>`, `<condition_variable>`, `<forward_list>`, `<future>`, `<initializer_list>`, `<mutex>`, `<random>`, `<ratio>`, `<regex>`, `<scoped_allocator>`, `<system_error>`, `<thread>`, `<tuple>`, `<typeindex>`, `<type_traits>`, `<unordered_map>`, and `<unordered_set>`. In addition the following C compatibility headers are new: `<cfenv>`, `<cinttypes>`, `<cstdint>`, and `<cuchar>`. Valid C++ 2003 code that #includes headers with these names may be invalid in this International Standard.

3 Affected subclause: 15.5.3.2
   Effect on original feature: Function `swap` moved to a different header
   Rationale: Remove dependency on `<algorithm>` for `swap`.
Effect on original feature: Valid C++ 2003 code that has been compiled expecting swap to be in `<algorithm>` may have to instead include `<utility>`.

4 Affected subclause: 15.5.4.2.2
   Change: New reserved namespace.
   Rationale: New functionality.
Effect on original feature: The global namespace `posix` is now reserved for standardization. Valid C++ 2003 code that uses a top-level namespace `posix` may be invalid in this International Standard.
Affected subclause: 15.5.5.3
Change: Additional restrictions on macro names.
Rationale: Avoid hard to diagnose or non-portable constructs.
Effect on original feature: Names of attribute identifiers may not be used as macro names. Valid C++ 2003 code that defines `override`, `final`, `carries_dependency`, or `noreturn` as macros is invalid in this International Standard.

C.2.9 Clause 16: language support library

Affected subclause: 16.6.2.1
Change: `operator new` may throw exceptions other than `std::bad_alloc`.
Rationale: Consistent application of `noexcept`.
Effect on original feature: Valid C++ 2003 code that assumes that global `operator new` only throws `std::bad_alloc` may execute differently in this International Standard. Valid C++ 2003 code that replaces the global replaceable `operator new` is ill-formed in this International Standard, because the exception specification of `throw(std::bad_alloc)` was removed.

C.2.10 Clause 18: diagnostics library

Affected subclause: 18.4
Change: Thread-local error numbers.
Rationale: Support for new thread facilities.
Effect on original feature: Valid but implementation-specific C++ 2003 code that relies on `errno` being the same across threads may change behavior in this International Standard.

C.2.11 Clause 19: general utilities library

Affected subclause: 19.10.5
Change: Minimal support for garbage-collected regions.
Rationale: Required by new feature.
Effect on original feature: Valid C++ 2003 code, compiled without traceable pointer support, that interacts with newer C++ code using regions declared reachable may have different runtime behavior.

Change: Standard function object types no longer derived from `std::unary_function` or `std::binary_function`.
Rationale: Superseded by new feature; `unary_function` and `binary_function` are no longer defined.
Effect on original feature: Valid C++ 2003 code that depends on function object types being derived from `unary_function` or `binary_function` may fail to compile in this International Standard.

C.2.12 Clause 20: strings library

Affected subclause: 20.3
Change: `basic_string` requirements no longer allow reference-counted strings.
Rationale: Invalidation is subtly different with reference-counted strings. This change regularizes behavior for this International Standard.
Effect on original feature: Valid C++ 2003 code may execute differently in this International Standard.

Affected subclause: 20.3.2.1
Change: Loosen `basic_string` invalidation rules.
Rationale: Allow small-string optimization.
Effect on original feature: Valid C++ 2003 code may execute differently in this International Standard. Some `const` member functions, such as `data` and `c_str`, no longer invalidate iterators.

C.2.13 Clause 21: containers library

Affected subclause: 21.2
Change: Complexity of `size()` member functions now constant.
Rationale: Lack of specification of complexity of `size()` resulted in divergent implementations with inconsistent performance characteristics.
Effect on original feature: Some container implementations that conform to C++ 2003 may not conform to the specified `size()` requirements in this International Standard. Adjusting containers such as `std::list` to the stricter requirements may require incompatible changes.
2 **Affected subclause:** 21.2  
**Change:** Requirements change: relaxation.  
**Rationale:** Clarification.  
**Effect on original feature:** Valid C++ 2003 code that attempts to meet the specified container requirements may now be over-specified. Code that attempted to be portable across containers may need to be adjusted as follows:

(2.1) — not all containers provide `size()`; use `empty()` instead of `size() == 0`;  
(2.2) — not all containers are empty after construction (`array`);  
(2.3) — not all containers have constant complexity for `swap()` (`array`).

3 **Affected subclause:** 21.2  
**Change:** Requirements change: default constructible.  
**Rationale:** Clarification of container requirements.  
**Effect on original feature:** Valid C++ 2003 code that attempts to explicitly instantiate a container using a user-defined type with no default constructor may fail to compile.

4 **Affected subclauses:** 21.2.3, 21.2.6  
**Change:** Signature changes: from `void` return types.  
**Rationale:** Old signature threw away useful information that may be expensive to recalculate.  
**Effect on original feature:** The following member functions have changed:

(4.1) — `erase(iter)` for `set`, `multiset`, `map`, `multimap`  
(4.2) — `erase(begin, end)` for `set`, `multiset`, `map`, `multimap`  
(4.3) — `insert(pos, num, val)` for `vector`, `deque`, `list`, `forward_list`  
(4.4) — `insert(pos, beg, end)` for `vector`, `deque`, `list`, `forward_list`  

Valid C++ 2003 code that relies on these functions returning `void` (e.g., code that creates a pointer to member function that points to one of these functions) will fail to compile with this International Standard.

5 **Affected subclauses:** 21.2.3, 21.2.6  
**Change:** Signature changes: from `iterator` to `const_iterator` parameters.  
**Rationale:** Overspecification.  
**Effect on original feature:** The signatures of the following member functions changed from taking an `iterator` to taking a `const_iterator`:

(5.1) — `insert(iter, val)` for `vector`, `deque`, `list`, `set`, `multiset`, `map`, `multimap`  
(5.2) — `insert(pos, beg, end)` for `vector`, `deque`, `list`, `forward_list`  
(5.3) — `erase(begin, end)` for `set`, `multiset`, `map`, `multimap`  
(5.4) — all forms of `list::splice`  
(5.5) — all forms of `list::merge`  

Valid C++ 2003 code that uses these functions may fail to compile with this International Standard.

6 **Affected subclauses:** 21.2.3, 21.2.6  
**Change:** Signature changes: `resize`.  
**Rationale:** Performance, compatibility with move semantics.  
**Effect on original feature:** For `vector`, `deque`, and `list` the fill value passed to `resize` is now passed by reference instead of by value, and an additional overload of `resize` has been added. Valid C++ 2003 code that uses this function may fail to compile with this International Standard.

### C.2.14 Clause 23: algorithms library

1 **Affected subclause:** 23.1  
**Change:** Result state of inputs after application of some algorithms.  
**Rationale:** Required by new feature.  
**Effect on original feature:** A valid C++ 2003 program may detect that an object with a valid but unspecified state has a different valid but unspecified state with this International Standard. For example, `std::remove` and `std::remove_if` may leave the tail of the input sequence with a different set of values than previously.
C.2.15 Clause 24: numerics library

Affected subclause: 24.5
Change: Specified representation of complex numbers.
Rationale: Compatibility with C99.
Effect on original feature: Valid C++ 2003 code that uses implementation-specific knowledge about the binary representation of the required template specializations of std::complex may not be compatible with this International Standard.

C.2.16 Clause 27: input/output library

Affected subclauses: 27.7.4.1.3, 27.7.5.1.3, 27.5.5.4
Change: Specify use of explicit in existing boolean conversion functions.
Rationale: Clarify intentions, avoid workarounds.
Effect on original feature: Valid C++ 2003 code that relies on implicit boolean conversions will fail to compile with this International Standard. Such conversions occur in the following conditions:

1. passing a value to a function that takes an argument of type bool;
2. using operator== to compare to false or true;
3. returning a value from a function with a return type of bool;
4. initializing members of type bool via aggregate initialization;
5. initializing a const bool& which would bind to a temporary object.

C.3 C++ and ISO C++ 2011

This subclause lists the differences between C++ and ISO C++ 2011 (ISO/IEC 14882:2011, Programming Languages — C++), by the chapters of this document.

C.3.1 Clause 5: lexical conventions

Affected subclause: 5.9
Change: pp-number can contain one or more single quotes.
Rationale: Necessary to enable single quotes as digit separators.
Effect on original feature: Valid C++ 2011 code may fail to compile or may change meaning in this International Standard. For example, the following code is valid both in C++ 2011 and in this International Standard, but the macro invocation produces different outcomes because the single quotes delimit a character literal in C++ 2011, whereas they are digit separators in this International Standard:

```cpp
#define M(x, ...) __VA_ARGS__
int x[2] = { M(1'2, 3'4, 5) }; // C++ 2011
// int x[2] = { 5 }; — this International Standard
```
N4762

© ISO/IEC

C.3.2
1

Clause 6: basic concepts

[diff.cpp11.basic]

Affected subclause: 6.6.4.4.2
Change: New usual (non-placement) deallocator.
Rationale: Required for sized deallocation.
Effect on original feature: Valid C++ 2011 code could declare a global placement allocation function and
deallocation function as follows:
void* operator new(std::size_t, std::size_t);
void operator delete(void*, std::size_t) noexcept;

In this International Standard, however, the declaration of operator delete might match a predefined usual
(non-placement) operator delete (6.6.4.4). If so, the program is ill-formed, as it was for class member
allocation functions and deallocation functions (7.6.2.4).

C.3.3
1

Clause 7: expressions

[diff.cpp11.expr]

Affected subclause: 7.6.16
Change: A conditional expression with a throw expression as its second or third operand keeps the type
and value category of the other operand.
Rationale: Formerly mandated conversions (lvalue-to-rvalue (7.3.1), array-to-pointer (7.3.2), and functionto-pointer (7.3.3) standard conversions), especially the creation of the temporary due to lvalue-to-rvalue
conversion, were considered gratuitous and surprising.
Effect on original feature: Valid C++ 2011 code that relies on the conversions may behave differently in
this International Standard:
struct S {
int x = 1;
void mf() { x = 2; }
};
int f(bool cond) {
S s;
(cond ? s : throw 0).mf();
return s.x;
}

In C++ 2011, f(true) returns 1. In this International Standard, it returns 2.
sizeof(true ? "" : throw 0)

In C++ 2011, the expression yields sizeof(const char*).
sizeof(const char[1]).

C.3.4
1

Clause 9: declarations

In this International Standard, it yields

[diff.cpp11.dcl.dcl]

Affected subclause: 9.1.5
Change: constexpr non-static member functions are not implicitly const member functions.
Rationale: Necessary to allow constexpr member functions to mutate the object.
Effect on original feature: Valid C++ 2011 code may fail to compile in this International Standard. For
example, the following code is valid in C++ 2011 but invalid in this International Standard because it declares
the same member function twice with different return types:
struct S {
constexpr const int &f();
int &f();
};

C.3.5
1

9.2: declarators

[diff.cpp11.dcl.decl]

Affected subclause: 9.3.1
Change: Classes with default member initializers can be aggregates.
Rationale: Necessary to allow default member initializers to be used by aggregate initialization.
Effect on original feature: Valid C++ 2011 code may fail to compile or may change meaning in this
International Standard. For example:
struct S { // Aggregate in C++ 2014 onwards.
int m = 1;
};

§ C.3.5

1419


struct X {
    operator int();
    operator S();
};
X a{};
S b{a}; // uses copy constructor in C++ 2011,
// performs aggregate initialization in this International Standard

C.3.6 Clause 15: library introduction

Affected subclause: 15.5.1.2
Change: New header.
Rationale: New functionality.
Effect on original feature: The C++ header <shared_mutex> is new. Valid C++ 2011 code that #includes a header with that name may be invalid in this International Standard.

C.3.7 Clause 27: input/output library

Affected subclause: 27.12
Change: gets is not defined.
Rationale: Use of gets is considered dangerous.
Effect on original feature: Valid C++ 2011 code that uses the gets function may fail to compile in this International Standard.

C.4 C++ and ISO C++ 2014

This subclause lists the differences between C++ and ISO C++ 2014 (ISO/IEC 14882:2014, Programming Languages — C++), by the chapters of this document.

C.4.1 Clause 5: lexical conventions

Affected subclause: 5.2
Change: Removal of trigraph support as a required feature.
Rationale: Prevents accidental uses of trigraphs in non-raw string literals and comments.
Effect on original feature: Valid C++ 2014 code that uses trigraphs may not be valid or may have different semantics in this International Standard. Implementations may choose to translate trigraphs as specified in C++ 2014 if they appear outside of a raw string literal, as part of the implementation-defined mapping from physical source file characters to the basic source character set.

Affected subclause: 5.9
Change: pp-number can contain p sign and P sign.
Rationale: Necessary to enable hexadecimal floating literals.
Effect on original feature: Valid C++ 2014 code may fail to compile or produce different results in this International Standard. Specifically, character sequences like 0p+0 and 0e1_p+0 are three separate tokens each in C++ 2014, but one single token in this International Standard. For example:

```cpp
#define F(a) b ## a
int b0p = F(0p+0); // ill-formed; equivalent to "int b0p = b0p + 0;" in C++ 2014
```

C.4.2 Clause 7: expressions

Affected subclauses: 7.6.1.6, 7.6.2.2
Change: Remove increment operator with bool operand.
Rationale: Obsolete feature with occasionally surprising semantics.
Effect on original feature: A valid C++ 2014 expression utilizing the increment operator on a bool lvalue is ill-formed in this International Standard. Note that this might occur when the lvalue has a type given by a template parameter.

Affected subclauses: 7.6.2.4, 7.6.2.5
Change: Dynamic allocation mechanism for over-aligned types.
Rationale: Simplify use of over-aligned types.
Effect on original feature: In C++ 2014 code that uses a new-expression to allocate an object with an over-aligned class type, where that class has no allocation functions of its own, ::operator new(std::size_t) is used to allocate the memory. In this International Standard, ::operator new(std::size_t, std::align_val_t) is used instead.
C.4.3 Clause 9: declarations

1 Affected subclause: 9.1.1

Change: Removal of register storage-class-specifier.

Rationale: Enable repurposing of deprecated keyword in future revisions of this International Standard.

Effect on original feature: A valid C++ 2014 declaration utilizing the register storage-class-specifier is ill-formed in this International Standard. The specifier can simply be removed to retain the original meaning.

2 Affected subclause: 9.1.7.4

Change: auto deduction from braced-init-list.

Rationale: More intuitive deduction behavior.

Effect on original feature: Valid C++ 2014 code may fail to compile or may change meaning in this International Standard. For example:

```cpp
auto x1{1};  // was std::initializer_list<int>, now int
auto x2{1, 2};  // was std::initializer_list<int>, now ill-formed
```

C.4.4 9.2: declarators

1 Affected subclause: 9.2.3.5

Change: Make exception specifications be part of the type system.

Rationale: Improve type-safety.

Effect on original feature: Valid C++ 2014 code may fail to compile or change meaning in this International Standard. For example:

```cpp
void g1() noexcept;
void g2();
template<class T> int f(T *, T *);
int x = f(g1, g2);  // ill-formed; previously well-formed
```

2 Affected subclause: 9.3.1

Change: Definition of an aggregate is extended to apply to user-defined types with base classes.

Rationale: To increase convenience of aggregate initialization.

Effect on original feature: Valid C++ 2014 code may fail to compile or produce different results in this International Standard; initialization from an empty initializer list will perform aggregate initialization instead of invoking a default constructor for the affected types. For example:

```cpp
struct derived;
struct base {
  friend struct derived;
private:
  base();
};
struct derived : base {};

derived d1;  // error; the code was well-formed in C++ 2014
derived d2;  // still OK
```

C.4.5 10.3.3: special member functions

1 Affected subclause: 10.9.3

Change: Inheriting a constructor no longer injects a constructor into the derived class.

Rationale: Better interaction with other language features.

Effect on original feature: Valid C++ 2014 code that uses inheriting constructors may not be valid or may have different semantics. A using-declaration that names a constructor now makes the corresponding base class constructors visible to initializations of the derived class rather than declaring additional derived class constructors.

```cpp
struct A {
  template<typename T> A(T, typename T::type = 0);
  A(int);
};
struct B : A {
  using A::A;
  B(int);
};
B b(42L);  // now calls B(int), used to call B<long>(long).
```
C.4.6 Clause 12: templates  [diff.cpp14.temp]

1 Affected subclause: 12.9.2.5
Change: Allowance to deduce from the type of a non-type template argument.
Rationale: In combination with the ability to declare non-type template arguments with placeholder types, allows partial specializations to decompose from the type deduced for the non-type template argument.
Effect on original feature: Valid C++ 2014 code may fail to compile or produce different results in this International Standard. For example:

```cpp
template <int N> struct A;
template <typename T, T N> int foo(A<N> *) = delete;
void foo(void *);
void bar(A<0> *p) {
    foo(p); // ill-formed; previously well-formed
}
```

C.4.7 Clause 13: exception handling  [diff.cpp14.except]

1 Affected subclause: 13.4
Change: Remove dynamic exception specifications.
Rationale: Dynamic exception specifications were a deprecated feature that was complex and brittle in use. They interacted badly with the type system, which became a more significant issue in this International Standard where (non-dynamic) exception specifications are part of the function type.
Effect on original feature: A valid C++ 2014 function declaration, member function declaration, function pointer declaration, or function reference declaration, if it has a potentially throwing dynamic exception specification, will be rejected as ill-formed in this International Standard. Violating a non-throwing dynamic exception specification will call `terminate` rather than `unexpected` and might not perform stack unwinding prior to such a call.

C.4.8 Clause 15: library introduction  [diff.cpp14.library]

1 Affected subclause: 15.5.1.2
Change: New headers.
Rationale: New functionality.
Effect on original feature: The following C++ headers are new: `<any>`, `<charconv>`, `<execution>`, `<filesystem>`, `<memory_resource>`, `<optional>`, `<string_view>`, and `<variant>`. Valid C++ 2014 code that includes headers with these names may be invalid in this International Standard.

2 Affected subclause: 15.5.4.2.3
Change: New reserved namespaces.
Rationale: Reserve namespaces for future revisions of the standard library that might otherwise be incompatible with existing programs.
Effect on original feature: The global namespaces `std` followed by an arbitrary sequence of digits is reserved for future standardization. Valid C++ 2014 code that uses such a top-level namespace, e.g., `std2`, may be invalid in this International Standard.

C.4.9 Clause 19: general utilities library  [diff.cpp14.utilities]

1 Affected subclause: 19.14.14
Change: Constructors taking allocators removed.
Rationale: No implementation consensus.
Effect on original feature: Valid C++ 2014 code may fail to compile or may change meaning in this International Standard. Specifically, constructing a `std::function` with an allocator is ill-formed and uses-allocator construction will not pass an allocator to `std::function` constructors in this International Standard.

2 Affected subclause: 19.11.3
Change: Different constraint on conversions from `unique_ptr`.
Rationale: Adding array support to `shared_ptr`, via the syntax `shared_ptr<T[]>` and `shared_ptr<T[N]>`.
Effect on original feature: Valid C++ 2014 code may fail to compile or may change meaning in this International Standard. For example:
`#include <memory>`
`std::unique_ptr<int[]> arr(new int[1]);`
`std::shared_ptr<int> ptr(std::move(arr));`  // error: `int(*)[]` is not compatible with `int*`

### C.4.10 Clause 20: strings library

- **Affected subclause:** 20.3.2
- **Change:** Non-const `.data()` member added.
- **Rationale:** The lack of a non-const `.data()` differed from the similar member of `std::vector`. This change regularizes behavior for this International Standard.
- **Effect on original feature:** Overloaded functions which have differing code paths for `char*` and `const char*` arguments will execute differently when called with a non-const string’s `.data()` member in this International Standard.

```cpp
int f(char *) = delete;
int f(const char *);
string s;
int x = f(s.data());`  // ill-formed; previously well-formed```

### C.4.11 Clause 21: containers library

- **Affected subclause:** 21.2.6
- **Change:** Requirements change.
- **Rationale:** Increase portability, clarification of associative container requirements.
- **Effect on original feature:** Valid C++ 2014 code that attempts to use associative containers having a comparison object with non-const function call operator may fail to compile in this International Standard:

```cpp
#include <set>
struct compare {
    bool operator()(int a, int b) {
        return a < b;
    }
};
int main() {
    const std::set<int, compare> s;
    s.find(0);
}
```

### C.4.12 Annex D: compatibility features

- **Change:** The class templates `auto_ptr`, `unary_function`, and `binary_function`, the function templates `random_shuffle`, and the function templates (and their return types) `ptr_fun`, `mem_fun`, `mem_fun_ref`, `bind1st`, and `bind2nd` are not defined.
- **Rationale:** Superseded by new features.
- **Effect on original feature:** Valid C++ 2014 code that uses these class templates and function templates may fail to compile in this International Standard.

- **Change:** Remove old iostreams members [depr.ios.members].
- **Rationale:** Redundant feature for compatibility with pre-standard code has served its time.
- **Effect on original feature:** A valid C++ 2014 program using these identifiers may be ill-formed in this International Standard.

### C.5 C++ and ISO C++ 2017

- **This subclause lists the differences between C++ and ISO C++ 2017 (ISO/IEC 14882:2017, Programming Languages — C++), by the chapters of this document.**

### C.5.1 Clause 5: lexical conventions

- **Affected subclause:** 5.11
- **Change:** New keywords.
- **Rationale:** Required for new features. The `requires` keyword is added to introduce constraints through a `requires-clause` or a `requires-expression`. The `concept` keyword is added to enable the definition of
concepts (12.6.8).

**Effect on original feature:** Valid ISO C++ 2017 code using `concept` or `requires` as an identifier is not valid in this International Standard.

2 **Affected subclause:** 5.12  
**Change:** New operator `<=>`.  
**Rationale:** Necessary for new functionality.  
**Effect on original feature:** Valid C++ 2017 code that contains a `<=` token immediately followed by a `>` token may be ill-formed or have different semantics in this International Standard:

```cpp
namespace N {
  struct X {}
  bool operator<=(X, X);
  template<bool(X, X)> struct Y '{};
  Y<operator<=> y;  // ill-formed; previously well-formed
}
```

C.5.2 Clause 7: expressions  
[diff.cpp17.expr]

1 **Affected subclause:** 7.5.5.2  
**Change:** Implicit lambda capture may capture additional entities.  
**Rationale:** Rule simplification, necessary to resolve interactions with constexpr if.  
**Effect on original feature:** Lambdas with a `capture-default` may capture local entities that were not captured in C++ 2017 if those entities are only referenced in contexts that do not result in an odr-use.

C.5.3 9.2: declarators  
[diff.cpp17.dcl.decl]

1 **Affected subclause:** 9.3.1  
**Change:** A class that has user-declared constructors is never an aggregate.  
**Rationale:** Remove potentially error-prone aggregate initialization which may apply notwithstanding the declared constructors of a class.  
**Effect on original feature:** Valid C++ 2017 code that aggregate-initializes a type with a user-declared constructor may be ill-formed or have different semantics in this International Standard.

```cpp
struct A {  // not an aggregate; previously an aggregate
  A() = delete;
};

struct B {  // not an aggregate; previously an aggregate
  B() = default;
  int i = 0;
};

struct C {  // not an aggregate; previously an aggregate
  C(C&&) = default;
  int a, b;
};

A a{};  // ill-formed; previously well-formed
B b = {1};  // ill-formed; previously well-formed
auto* c = new C{2, 3};  // ill-formed; previously well-formed

struct Y;

struct X {  
  operator Y();
};

struct Y {  // not an aggregate; previously an aggregate
  Y(const Y&) = default;
  X x;
};

Y y{x{}};  // copy constructor call; previously aggregate-initialization
```
C.5.4 10.3.3: special member functions

1 Affected subclauses: 10.3.4, 10.3.8.2
Change: The class name can no longer be used parenthesized immediately after an explicit decl-specifier in a constructor declaration. The conversion-function-id can no longer be used parenthesized immediately after an explicit decl-specifier in a conversion function declaration.
Rationale: Necessary for new functionality.
Effect on original feature: Valid C++ 2017 code may fail to compile in this International Standard. For example:

```cpp
struct S {
    explicit (S)(const S&);  // ill-formed; previously well-formed
    explicit (operator int)();  // ill-formed; previously well-formed
    explicit(true) (S)(int);  // OK
};
```

2 Affected subclauses: 10.3.4, 10.3.7
Change: A simple-template-id is no longer valid as the declarator-id of a constructor or destructor.
Rationale: Remove potentially error-prone option for redundancy.
Effect on original feature: Valid C++ 2017 code may fail to compile in this International Standard. For example:

```cpp
template<class T>
struct A {
    A<T>();  // error: simple-template-id not allowed for constructor
    A(int);  // OK, injected-class-name used
    ~A<T>();  // error: simple-template-id not allowed for destructor
};
```

C.5.5 Clause 12: templates

1 Affected subclause: 12.2
Change: An unqualified-id that is followed by a < and for which name lookup finds nothing or finds a function will be treated as a template-name in order to potentially cause argument dependent lookup to be performed.
Rationale: It was problematic to call a function template with an explicit template argument list via argument dependent lookup because of the need to have a template with the same name visible via normal lookup.
Effect on original feature: Previously valid code that uses a function name as the left operand of a < operator would become ill-formed.

```cpp
struct A {};
bool operator<(void (*fp)(), A);  
void f() {}
int main() {
    A a;
    f < a;  // ill-formed; previously well-formed
    (f) < a;  // still well formed
}
```

C.5.6 Clause 13: exception handling

1 Affected subclause: 13.4
Change: Remove throw() exception specification.
Rationale: Removal of obsolete feature that has been replaced by noexcept.
Effect on original feature: A valid C++ 2017 function declaration, member function declaration, function pointer declaration, or function reference declaration that uses throw() for its exception specification will be rejected as ill-formed in this International Standard. It should simply be replaced with noexcept for no change of meaning since C++ 2017. [Note: There is no way to write a function declaration that is non-throwing in this International Standard and is also non-throwing in C++ 2003 except by using the preprocessor to generate a different token sequence in each case. — end note]

C.5.7 Clause 15: library introduction

1 Affected subclause: 15.5.1.2
Change: New headers.
Rationale: New functionality.
Effect on original feature: The following C++ headers are new: `<bit>`, `<compare>`, `<concepts>`, `<contract>`, `<span>`, `<synostream>`, and `<version>`. Valid C++ 2017 code that #includes headers with these names may be invalid in this International Standard.

2 Affected subclause: 15.5.1.2

Change: Remove vacuous C++ header files.
Rationale: The empty headers implied a false requirement to achieve C compatibility with the C++ headers.
Effect on original feature: A valid C++ 2017 program that #includes any of the following headers may fail to compile: `<complex>`, `<ciso646>`, `<cstdlib>`, `<cstring>`, and `<ctgmath>`. To retain the same behavior:

(2.1) — a #include of `<ccomplex>` can be replaced by a #include of `<complex>` (24.5.1),
(2.2) — a #include of `<ctgmath>` can be replaced by a #include of `<cmath>` (24.9.1) and a #include of `<complex>`, and
(2.3) — a #include of `<ciso646>`, `<cstdlib>`, or `<cstring>` can simply be removed.

C.5.8 Clause 21: containers library [diff.cpp17.containers]

1 Affected subclauses: 21.3.9, 21.3.10

Change: Return types of remove, remove_if, and unique changed from void to container::size_type.
Rationale: Improve efficiency and convenience of finding number of removed elements.
Effect on original feature: Code that depends on the return types might have different semantics in this International Standard. Translation units compiled against this version of C++ may be incompatible with translation units compiled against C++ 2017, either failing to link or having undefined behavior.

C.5.9 Annex D: compatibility features [diff.cpp17.depr]

1 Change: Remove uncaught_exception.
Rationale: The function did not have a clear specification when multiple exceptions were active, and has been superseded by uncaught_exceptions.
Effect on original feature: A valid C++ 2017 program that calls std::uncaught_exception may fail to compile. It might be revised to use std::uncaught_exceptions instead, for clear and portable semantics.

2 Change: Remove support for adaptable function API.
Rationale: The deprecated support relied on a limited convention that could not be extended to support the general case or new language features. It has been superseded by direct language support with decltype, and by the std::bind and std::not_fn function templates.
Effect on original feature: A valid C++ 2017 program that relies on the presence of result_type, argument_type, first_argument_type, or second_argument_type in a standard library class may fail to compile. A valid C++ 2017 program that calls not1 or not2, or uses the class templates unary_negate or binary_negate, may fail to compile.

3 Change: Remove redundant members from std::allocator.
Rationale: std::allocator was overspecified, encouraging direct usage in user containers rather than relying on std::allocator_traits, leading to poor containers.
Effect on original feature: A valid C++ 2017 program that directly makes use of the pointer, const_pointer, reference, const_reference, rebind, address, construct, destroy, or max_size members of std::allocator, or that directly calls allocate with an additional hint argument, may fail to compile.

4 Change: Remove raw_storage_iterator.
Rationale: The iterator encouraged use of algorithms that might throw exceptions, but did not return the number of elements successfully constructed that might need to be destroyed in order to avoid leaks.
Effect on original feature: A valid C++ 2017 program that uses this iterator class may fail to compile.

5 Change: Remove temporary buffers API.
Rationale: The temporary buffer facility was intended to provide an efficient optimization for small memory requests, but there is little evidence this was achieved in practice, while requiring the user to provide their own exception-safe wrappers to guard use of the facility in many cases.
Effect on original feature: A valid C++ 2017 program that calls get_temporary_buffer or return_temporary_buffer may fail to compile.

6 Change: Remove shared_ptr::unique.
Rationale: The result of a call to this member function is not reliable in the presence of multiple threads.
and weak pointers. The member function \texttt{use\_count} is similarly unreliable, but has a clearer contract in such cases, and remains available for well defined use in single-threaded cases.

\textbf{Effect on original feature:} A valid C++ 2017 program that calls \texttt{unique} on a \texttt{shared\_ptr} object may fail to compile.

7 Affected subclause: D.9

\textbf{Change:} Remove deprecated type traits.

\textbf{Rationale:} The traits had unreliable or awkward interfaces. The \texttt{is\_literal\_type} trait provided no way to detect which subset of constructors and member functions of a type were declared \texttt{constexpr}. The \texttt{result\_of} trait had a surprising syntax that could not report the result of a regular function type. It has been superseded by the \texttt{invoke\_result} trait.

\textbf{Effect on original feature:} A valid C++ 2017 program that relies on the \texttt{is\_literal\_type} or \texttt{result\_of} type traits, on the \texttt{is\_literal\_type\_v} variable template, or on the \texttt{result\_of\_t} alias template may fail to compile.

C.6 C standard library

This subclause summarizes the explicit changes in headers, definitions, declarations, or behavior between the C standard library in the C standard and the parts of the C++ standard library that were included from the C standard library.

C.6.1 Modifications to headers

For compatibility with the C standard library, the C++ standard library provides the C headers enumerated in D.6, but their use is deprecated in C++.

There are no C++ headers for the C standard library’s headers \texttt{<stdatomic.h>}, \texttt{<stdnoreturn.h>}, and \texttt{<threads.h>}, nor are these headers from the C standard library headers themselves part of C++.

The C headers \texttt{<complex.h>} and \texttt{<tgmath.h>} do not contain any of the content from the C standard library and instead merely include other headers from the C++ standard library.

C.6.2 Modifications to definitions

C.6.2.1 Types \texttt{char16\_t} and \texttt{char32\_t}

The types \texttt{char16\_t} and \texttt{char32\_t} are distinct types rather than typedefs to existing integral types. The tokens \texttt{char16\_t} and \texttt{char32\_t} are keywords in this International Standard (5.11). They do not appear as macro names defined in \texttt{<cuchar> (20.5.5)}.

C.6.2.2 Type \texttt{wchar\_t}

The type \texttt{wchar\_t} is a distinct type rather than a typedef to an existing integral type. The token \texttt{wchar\_t} is a keyword in this International Standard (5.11). It does not appear as a type name defined in any of \texttt{<cwchar> (20.5.4)}.

C.6.2.3 Header \texttt{<assert.h>}

The token \texttt{static\_assert} is a keyword in this International Standard (5.11). It does not appear as a macro name defined in \texttt{<cassert> (18.3.1)}.

C.6.2.4 Header \texttt{<iso646.h>}

The tokens \texttt{and}, \texttt{and\_eq}, \texttt{bitand}, \texttt{bitor}, \texttt{compl}, \texttt{not\_eq}, \texttt{not}, \texttt{or\_eq}, \texttt{xor}, and \texttt{xor\_eq} are keywords in this International Standard (5.11), and are not introduced as macros by \texttt{<iso646.h> (D.6.2)}.

C.6.2.5 Header \texttt{<stdalign.h>}

The token \texttt{alignas} is a keyword in this International Standard (5.11), and is not introduced as a macro by \texttt{<stdalign.h> (D.6.3)}.

C.6.2.6 Header \texttt{<stdbool.h>}

The tokens \texttt{bool}, \texttt{true}, and \texttt{false} are keywords in this International Standard (5.11), and are not introduced as macros by \texttt{<stdbool.h> (D.6.4)}.

§ C.6.2.6 1427
C.6.2.7 Macro NULL

The macro NULL, defined in any of `<clocale>` (26.5), `<cstdint>` (16.2.1), `<cstddef>` (16.2.2), `<cstring>` (20.5.3), `<cstdlib>` (16.2.2), `<cstring>` (20.5.3), `<ctime>` (25.13), or `<cwchar>` (20.5.4), is an implementation-defined C++ null pointer constant in this International Standard (16.2).

C.6.3 Modifications to declarations

1 Header `<cstring>` (20.5.3): The following functions have different declarations:

- `strchr`
- `strpbrk`
- `strrchr`
- `strstr`
- `memchr`

Subclause 20.5.3 describes the changes.

2 Header `<cwchar>` (20.5.4): The following functions have different declarations:

- `wcschr`
- `wcspbrk`
- `wcsrchr`
- `wcsstr`
- `wmemchr`

Subclause 20.5.4 describes the changes.

3 Header `<cstdint>` (16.2.1) declares the name `nullptr_t` in addition to the names declared in `<stddef.h>` in the C standard library.

C.6.4 Modifications to behavior

1 Header `<cstdlib>` (16.2.2): The following functions have different behavior:

- `atexit`
- `exit`
- `abort`

Subclause 16.5 describes the changes.

2 Header `<csetjmp>` (16.12.2): The following functions have different behavior:

- `longjmp`

Subclause 16.12.2 describes the changes.

C.6.4.1 Macro offsetof(type, member-designator)

The macro `offsetof`, defined in `<cstdint>` (16.2.1), accepts a restricted set of `type` arguments in this International Standard. Subclause 16.2.4 describes the change.

C.6.4.2 Memory allocation functions

The functions `aligned_alloc`, `calloc`, `malloc`, and `realloc` are restricted in this International Standard. Subclause 19.10.12 describes the changes.
Annex D  (normative)  
Compatibility features  [depr]

1 This Clause describes features of the C++ Standard that are specified for compatibility with existing implementations.

2 These are deprecated features, where deprecated is defined as: Normative for the current edition of this International Standard, but having been identified as a candidate for removal from future revisions. An implementation may declare library names and entities described in this Clause with the deprecated attribute (9.11.5).

D.1 Arithmetic conversion on enumerations  [depr.arith.conv.enum]

1 The ability to apply the usual arithmetic conversions (7.4) on operands where one is of enumeration type and the other is of a different enumeration type or a floating-point type is deprecated. [Note: Three-way comparisons (7.6.8) between such operands are ill-formed. — end note]  [Example:

```cpp
enum E1 { e }
enum E2 { f }
bool b = e <= 3.7; // deprecated
int k = f - e; // deprecated
auto cmp = e <=> f; // ill-formed
```
—end example]

D.2 Implicit capture of *this by reference  [depr.capture.this]

1 For compatibility with prior C++ International Standards, a lambda-expression with capture-default = (7.5.5.2) may implicitly capture *this by reference. [Example:

```cpp
struct X {
    int x;
    void foo(int n) {
        auto f = [=]() { x = n; }; // deprecated: x means this->x, not a copy thereof
        auto g = [=, this]() { x = n; }; // recommended replacement
    }
};
```
—end example]

D.3 Array comparisons  [depr.array.comp]

1 Equality and relational comparisons (7.6.10, 7.6.9) between two operands of array type are deprecated. [Note: Three-way comparisons (7.6.8) between such operands are ill-formed. — end note]  [Example:

```cpp
int arr1[5];
itarr2[5];
bool same = arr1 == arr2; // deprecated, same as &arr[0] == &arr[1],
auto cmp = arr1 <=> arr2; // ill-formed
```
—end example]

D.4 Redeclaration of static constexpr data members  [depr.staticconstexpr]

1 For compatibility with prior C++ International Standards, a constexpr static data member may be redundantly redeclared outside the class with no initializer. This usage is deprecated. [Example:

```cpp
struct A {
    static constexpr int n = 5; // definition (declaration in C++ 2014)
};

constexpr int A::n; // redundant declaration (definition in C++ 2014)
```
—end example]
D.5 Implicit declaration of copy functions

1 The implicit definition of a copy constructor (10.3.5) as defaulted is deprecated if the class has a user-declared copy assignment operator or a user-declared destructor (10.3.7). The implicit definition of a copy assignment operator (10.3.6) as defaulted is deprecated if the class has a user-declared copy constructor or a user-declared destructor. In a future revision of this International Standard, these implicit definitions could become deleted (9.4).

D.6 C standard library headers

1 For compatibility with the C standard library, the C++ standard library provides the C headers shown in Table 136.

Table 136 — C headers

| <assert.h> | <inttypes.h> | <signal.h> | <stdio.h> | <wchar.h> |
| <complex.h> | <iso646.h> | <stdalign.h> | <stdlib.h> | <wctype.h> |
| <ctype.h> | <limits.h> | <stdarg.h> | <stdbool.h> | <stddef.h> |
| <errno.h> | <locale.h> | <stdlib.h> | <stddef.h> | <string.h> |
| <fenv.h> | <math.h> | <stdio.h> | <string.h> | <tgmath.h> |
| <float.h> | <setjmp.h> | <stdlib.h> | <string.h> | <time.h> |
| <uchar.h> | <setjmp.h> | <stdlib.h> | <string.h> | <time.h> |
| <wchar.h> | <setjmp.h> | <stdlib.h> | <string.h> | <time.h> |
| <wctype.h> | <setjmp.h> | <stdlib.h> | <string.h> | <time.h> |

D.6.1 Header <complex.h> synopsis

#include <complex>

1 The header <complex.h> behaves as if it simply includes the header <complex> (24.5.1).

2 [Note: Names introduced by <complex> in namespace std are not placed into the global namespace scope by <complex.h>. — end note]

D.6.2 Header <iso646.h> synopsis

1 The C++ header <iso646.h> is empty. [Note: and, and_eq, bitand, bitor, compl, not_eq, not, or, or_eq, xor, and xor_eq are keywords in this International Standard (5.11). — end note]

D.6.3 Header <stdalign.h> synopsis

#define __alignas_is_defined 1

1 The contents of the C++ header <stdalign.h> are the same as the C standard library header <stdalign.h>, with the following changes: The header <stdalign.h> does not define a macro named alignas.

See also: ISO C 7.15

D.6.4 Header <stdbool.h> synopsis

#define __bool_true_false_are_defined 1

1 The contents of the C++ header <stdbool.h> are the same as the C standard library header <stdbool.h>, with the following changes: The header <stdbool.h> does not define macros named bool, true, or false.

See also: ISO C 7.18

D.6.5 Header <tgmath.h> synopsis

#include <cmath>
#include <complex>

1 The header <tgmath.h> behaves as if it simply includes the headers <cmath> (24.9.1) and <complex> (24.5.1).

2 [Note: The overloads provided in C by type-generic macros are already provided in <complex> and <cmath> by “sufficient” additional overloads. — end note]

3 [Note: Names introduced by <cmath> or <complex> in namespace std are not placed into the global namespace scope by <tgmath.h>. — end note]
D.6.6 Other C headers

1 Every C header other than `<complex.h>`, `<iso646.h>`, `<stdalign.h>`, `<stdbool.h>`, and `<tgmath.h>`, each of which has a name of the form `<name>.h>`, behaves as if each name placed in the standard library namespace by the corresponding `<name>` header is placed within the global namespace scope, except for the functions described in 24.9.5, the declaration of `std::byte (16.2.1)`, and the functions and function templates described in 16.2.5. It is unspecified whether these names are first declared or defined within namespace scope (6.3.6) of the namespace `std` and are then injected into the global namespace scope by explicit `using-declarations` (9.8).

2 [Example: The header `<cstdlib>` assuredly provides its declarations and definitions within the namespace `std`. It may also provide these names within the global namespace. The header `<stdlib.h>` assuredly provides the same declarations and definitions within the global namespace, much as in the C Standard. It may also provide these names within the namespace `std` — end example]

D.7 Relational operators

1 The header `<utility>` has the following additions:

```cpp
namespace std::rel_ops {
    template<class T> bool operator!=(const T&, const T&);
    template<class T> bool operator>(const T&, const T&);
    template<class T> bool operator<=(const T&, const T&);
    template<class T> bool operator>=(const T&, const T&);
}
```

2 To avoid redundant definitions of `operator!=` out of `operator==` and operators `>`, `<`, and `>=` out of `operator<`, the library provides the following:

```cpp
template<class T> bool operator!=(const T& x, const T& y);
```

3 Requires: Type `T` is `Cpp17EqualityComparable` (Table 22).

4 Returns: `!(x == y)`.

```cpp
template<class T> bool operator>(const T& x, const T& y);
```

5 Requires: Type `T` is `Cpp17LessThanComparable` (Table 23).

6 Returns: `y < x`.

```cpp
template<class T> bool operator<=(const T& x, const T& y);
```

7 Requires: Type `T` is `Cpp17LessThanComparable` (Table 23).

8 Returns: `!(y < x)`.

```cpp
template<class T> bool operator>=(const T& x, const T& y);
```

9 Requires: Type `T` is `Cpp17LessThanComparable` (Table 23).

10 Returns: `!(x < y)`.

D.8 char* streams

D.8.1 Header `<strstream>` synopsis

1 The header `<strstream>` defines types that associate stream buffers with character array objects and assist reading and writing such objects.

```cpp
namespace std {
    class strstreambuf;
    class istrstream;
    class ostrstream;
    class strstream;
}
```

D.8.2 Class strstreambuf

```cpp
namespace std {
    class strstreambuf : public basic_streambuf<char> {
        public:
            strstreambuf() : strstreambuf(0) {};
    }
```
explicit strstreambuf(streamsize alsize_arg);
strstreambuf(void* (*palloc_arg)(size_t), void (*pfree_arg)(void*));
strstreambuf(char* gnext_arg, streamsize n, char* pbeg_arg = nullptr);
strstreambuf(const char* gnext_arg, streamsize n);
strstreambuf(signed char* gnext_arg, streamsize n,
    signed char* pbeg_arg = nullptr);
strstreambuf(const signed char* gnext_arg, streamsize n);
strstreambuf(unsigned char* gnext_arg, streamsize n,
    unsigned char* pbeg_arg = nullptr);
strstreambuf(const unsigned char* gnext_arg, streamsize n);
virtual ~strstreambuf();

void freeze(bool freezefl = true);
char* str();
int pcount();

protected:
    int_type overflow (int_type c = EOF) override;
    int_type pbackfail(int_type c = EOF) override;
    int_type underflow() override;
    pos_type seekoff(off_type off, ios_base::seekdir way,
        ios_base::openmode which = ios_base::in | ios_base::out) override;
    pos_type seekpos(pos_type sp,
        ios_base::openmode which = ios_base::in | ios_base::out) override;
    streambuf* setbuf(char* s, streamsize n) override;

private:
    using strstate = T1;  // exposition only
    static const strstate allocated;  // exposition only
    static const strstate constant;  // exposition only
    static const strstate dynamic;  // exposition only
    static const strstate frozen;  // exposition only
    strstate strmode;  // exposition only
    streamsize alsize;
    void* (*palloc)(size_t);  // exposition only
    void (*pfree)(void*);  // exposition only
};

1 The class strstreambuf associates the input sequence, and possibly the output sequence, with an object of some character array type, whose elements store arbitrary values. The array object has several attributes.

2 [Note: For the sake of exposition, these are represented as elements of a bitmask type (indicated here as T1) called strstate. The elements are:

(2.1) — allocated, set when a dynamic array object has been allocated, and hence should be freed by the destructor for the strstreambuf object;

(2.2) — constant, set when the array object has const elements, so the output sequence cannot be written;

(2.3) — dynamic, set when the array object is allocated (or reallocated) as necessary to hold a character sequence that can change in length;

(2.4) — frozen, set when the program has requested that the array object not be altered, reallocated, or freed.

— end note]

3 [Note: For the sake of exposition, the maintained data is presented here as:

(3.1) — strstate strmode, the attributes of the array object associated with the strstreambuf object;

(3.2) — int alsize, the suggested minimum size for a dynamic array object;

(3.3) — void* (*palloc)(size_t), points to the function to call to allocate a dynamic array object;

(3.4) — void (*pfree)(void*), points to the function to call to free a dynamic array object.
Each object of class `strstreambuf` has a *seekable area*, delimited by the pointers `seeklow` and `seekhigh`. If `gnext` is a null pointer, the seekable area is undefined. Otherwise, `seeklow` equals `gbeg` and `seekhigh` is either `pend`, if `pend` is not a null pointer, or `gend`.

### D.8.2.1 strstreambuf constructors

#### 1 explicit strstreambuf(streamsize alsize_arg);

*Effects:* Constructs an object of class `strstreambuf`, initializing the base class with `streambuf()`. The postconditions of this function are indicated in Table 137.

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>strmode</td>
<td>dynamic</td>
</tr>
<tr>
<td>alsize</td>
<td>alsize_arg</td>
</tr>
<tr>
<td>palloc</td>
<td>a null pointer</td>
</tr>
<tr>
<td>pfree</td>
<td>a null pointer</td>
</tr>
</tbody>
</table>

#### 2 strstreambuf(void* (*palloc_arg)(size_t), void (*pfree_arg)(void*));

*Effects:* Constructs an object of class `strstreambuf`, initializing the base class with `streambuf()`. The postconditions of this function are indicated in Table 138.

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

#### 3 strstreambuf(char* gnext_arg, streamsize n, char* pbeg_arg = nullptr);

*Effects:* Constructs an object of class `strstreambuf`, initializing the base class with `streambuf()`. The postconditions of this function are indicated in Table 139.

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>strmode</td>
<td>0</td>
</tr>
<tr>
<td>alsize</td>
<td>an unspecified value</td>
</tr>
<tr>
<td>palloc</td>
<td>a null pointer</td>
</tr>
<tr>
<td>pfree</td>
<td>a null pointer</td>
</tr>
</tbody>
</table>

`gnext_arg` shall point to the first element of an array object whose number of elements \(N\) is determined as follows:

\[
\begin{align*}
& \text{(4.1)} & \text{If } n > 0, \text{ then } N = n. \\
& \text{(4.2)} & \text{If } n == 0, \text{ then } N = \text{std::strlen(gnext_arg)}. \\
& \text{(4.3)} & \text{If } n < 0, \text{ then } N = \text{INT_MAX}.\quad\text{333}
\end{align*}
\]

---

333 The function signature `strlen(const char*)` is declared in `<cstring>` (20.5.3). The macro `INT_MAX` is defined in `<climits>` (16.3.5).
If `pbeg_arg` is a null pointer, the function executes:

```c
setg(gnext_arg, gnext_arg, gnext_arg + N);
```

Otherwise, the function executes:

```c
setg(gnext_arg, gnext_arg, pbeg_arg);
setp(pbeg_arg, pbeg_arg + N);
```

`strstreambuf(const char* gnext_arg, streamsize n);`
`strstreambuf(const signed char* gnext_arg, streamsize n);`
`strstreambuf(const unsigned char* gnext_arg, streamsize n);`

**Effects:** Behaves the same as `strstreambuf((char*)gnext_arg,n)`, except that the constructor also sets `constant` in `strmode`.

```c
virtual ~strstreambuf();
```

**Effects:** Destroys an object of class `strstreambuf`. The function frees the dynamically allocated array object only if `(strmode & allocated) != 0 and (strmode & frozen) == 0`. (D.8.2.3 describes how a dynamically allocated array object is freed.)

### D.8.2.2 Member functions

```c
void freeze(bool freezefl = true);
```

**Effects:** If `strmode & dynamic` is nonzero, alters the freeze status of the dynamic array object as follows:

1. If `freezefl` is `true`, the function sets `frozen` in `strmode`.
2. Otherwise, it clears `frozen` in `strmode`.

```c
char* str();
```

**Effects:** Calls `freeze()`, then returns the beginning pointer for the input sequence, `gbeg`.

**Remarks:** The return value can be a null pointer.

```c
int pcount() const;
```

**Effects:** If the next pointer for the output sequence, `pnext`, is a null pointer, returns zero. Otherwise, returns the current effective length of the array object as the next pointer minus the beginning pointer for the output sequence, `pnext - pbeg`.

### D.8.2.3 strstreambuf overridden virtual functions

```c
int_type overflow(int_type c = EOF) override;
```

**Effects:** Appends the character designated by `c` to the output sequence, if possible, in one of two ways:

1. If `c != EOF` and if either the output sequence has a write position available or the function makes a write position available (as described below), assigns `c` to `*pnext++`.
   Returns `(unsigned char)c`.
2. If `c == EOF`, there is no character to append.
   Returns a value other than `EOF`.

**Remarks:** The function can alter the number of write positions available as a result of any call.

To make a write position available, the function reallocates (or initially allocates) an array object with a sufficient number of elements `n` to hold the current array object (if any), plus at least one additional write position. How many additional write positions are made available is otherwise unspecified. If `palloc` is not a null pointer, the function calls `(*palloc)(n)` to allocate the new dynamic array object. Otherwise, it evaluates the expression `new charT[n]`. In either case, if the allocation fails, the function returns `EOF`. Otherwise, it sets `allocated` in `strmode`.

To free a previously existing dynamic array object whose first element address is `p`: If `pfree` is not a null pointer, the function calls `(*pfree)(p)`. Otherwise, it evaluates the expression `delete[]p`.

An implementation should consider `alsize` in making this decision.
If \((\text{strmode} \& \text{dynamic}) \neq 0\), or if \((\text{strmode} \& \text{frozen}) \neq 0\), the function cannot extend the array (reallocate it with greater length) to make a write position available.

```c
int_type pbackfail(int_type c = EOF) override;
```

Puts back the character designated by \(c\) to the input sequence, if possible, in one of three ways:

1. If \(c \neq EOF\), if the input sequence has a putback position available, and if \((\text{char})c \neq \text{gnext}[-1]\), assigns \(\text{gnext} - 1\) to \(\text{gnext}\).
   - Returns \(c\).

2. If \(c \neq EOF\), if the input sequence has a putback position available, and if \(\text{strmode} \& \text{constant}\) is zero, assigns \(c\) to \(*--\text{gnext}\).
   - Returns \(c\).

3. If \(c == EOF\) and if the input sequence has a putback position available, assigns \(\text{gnext} - 1\) to \(\text{gnext}\).
   - Returns a value other than EOF.

Returns EOF to indicate failure.

Remarks: If the function can succeed in more than one of these ways, it is unspecified which way is chosen. The function can alter the number of putback positions available as a result of any call.

```c
int_type underflow() override;
```

Effects: Reads a character from the input sequence, if possible, without moving the stream position past it, as follows:

1. If the input sequence has a read position available, the function signals success by returning \((\text{unsigned char})*\text{gnext}\).
2. Otherwise, if the current write next pointer \(\text{pnext}\) is not a null pointer and is greater than the current read end pointer \(\text{gend}\), makes a read position available by assigning to \(\text{gend}\) a value greater than \(\text{gnext}\) and no greater than \(\text{pnext}\).
   - Returns \((\text{unsigned char})*\text{gnext}\).

Returns EOF to indicate failure.

Remarks: The function can alter the number of read positions available as a result of any call.

```c
pos_type seekoff(off_type off, seekdir way, openmode which = in | out) override;
```

Effects: Alters the stream position within one of the controlled sequences, if possible, as indicated in Table 140.

<table>
<thead>
<tr>
<th>Conditions</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>((\text{which} &amp; \text{ios::in}) \neq 0)</td>
<td>positions the input sequence</td>
</tr>
<tr>
<td>((\text{which} &amp; \text{ios::out}) \neq 0)</td>
<td>positions the output sequence</td>
</tr>
<tr>
<td>((\text{which} &amp; (\text{ios::in \mid ios::out})) == (\text{ios::in \mid ios::out}))) and (\text{way} == \text{either}) (\text{ios::beg}) or (\text{ios::end})</td>
<td>positions both the input and the output sequences</td>
</tr>
<tr>
<td>Otherwise</td>
<td>the positioning operation fails.</td>
</tr>
</tbody>
</table>

For a sequence to be positioned, if its next pointer is a null pointer, the positioning operation fails. Otherwise, the function determines \(\text{newoff}\) as indicated in Table 141.

If \((\text{newoff} + \text{off}) < (\text{seeklow} - \text{xbeg})\) or \((\text{seekhigh} - \text{xbeg}) < (\text{newoff} + \text{off})\), the positioning operation fails. Otherwise, the function assigns \(\text{xbeg} + \text{newoff} + \text{off}\) to the next pointer \(\text{xnext}\).

\[\text{§ D.8.2.3}\]
Table 141 — newoff values

<table>
<thead>
<tr>
<th>Condition</th>
<th>newoff Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>way == ios::beg</td>
<td>0</td>
</tr>
<tr>
<td>way == ios::cur</td>
<td>the next pointer minus the beginning pointer (xnext - xbeg).</td>
</tr>
<tr>
<td>way == ios::end</td>
<td>seekhigh minus the beginning pointer (seekhigh - xbeg).</td>
</tr>
</tbody>
</table>

Returns: pos_type(newoff), constructed from the resultant offset newoff (of type off_type), that stores the resultant stream position, if possible. If the positioning operation fails, or if the constructed object cannot represent the resultant stream position, the return value is pos_type(off_type(-1)).

\[
pos_type \text{ seekpos}(pos_type \, sp, \text{ios_base::openmode which} = \text{ios_base::in} | \text{ios_base::out}) \text{ override;}
\]

Effects: Alters the stream position within one of the controlled sequences, if possible, to correspond to the stream position stored in \( sp \) (as described below).

- If (which & ios::in) != 0, positions the input sequence.
- If (which & ios::out) != 0, positions the output sequence.
- If the function positions neither sequence, the positioning operation fails.

For a sequence to be positioned, if its next pointer is a null pointer, the positioning operation fails. Otherwise, the function determines newoff from \( sp.\text{offset()} \):

- If newoff is an invalid stream position, has a negative value, or has a value greater than (seekhigh - seeklow), the positioning operation fails
- Otherwise, the function adds newoff to the beginning pointer xbeg and stores the result in the next pointer xnext.

Returns: pos_type(newoff), constructed from the resultant offset newoff (of type off_type), that stores the resultant stream position, if possible. If the positioning operation fails, or if the constructed object cannot represent the resultant stream position, the return value is pos_type(off_type(-1)).

streambuf<char*> setbuf(char* s, streamsize n) \text{ override;}

Effects: Implementation defined, except that setbuf(0, 0) has no effect.

D.8.3 Class istrstream

namespace std {
    class istrstream : public basic_istream<char> {
    public:
        explicit istrstream(const char* s);
        explicit istrstream(char* s);
        istrstream(const char* s, streamsize n);
        istrstream(char* s, streamsize n);
        virtual ~istrstream();

        strstreambuf* rdbuf() const;
        char* str();

        private:
        strstreambuf sb; // exposition only
    };
}

1 The class istrstream supports the reading of objects of class strstreambuf. It supplies a strstreambuf object to control the associated array object. For the sake of exposition, the maintained data is presented here as:

- sb, the strstreambuf object.
D.8.3.1 istrstream constructors

explicit istrstream(const char* s);
explicit istrstream(char* s);

Effects: Constructs an object of class istrstream, initializing the base class with istream(&sb) and initializing sb with strstreambuf(s,0). s shall designate the first element of an NTBS.

istrstream(const char* s, streamsize n);
istrstream(char* s, streamsize n);

Effects: Constructs an object of class istrstream, initializing the base class with istream(&sb) and initializing sb with strstreambuf(s,n). s shall designate the first element of an array whose length is n elements, and n shall be greater than zero.

D.8.3.2 Member functions

strstreambuf* rdbuf() const;
char* str();

D.8.4 Class ostrstream

namespace std {
class ostrstream : public basic_ostream<char> {
public:
    ostrstream();
ostrstream(char* s, int n, ios_base::openmode mode = ios_base::out);
    virtual ~ostrstream();

    strstreambuf* rdbuf() const;
    void freeze(bool freezefl = true);
    char* str();
    int pcount() const;
private:
    strstreambuf sb; // exposition only
};
}

The class ostrstream supports the writing of objects of class strstreambuf. It supplies a strstreambuf object to control the associated array object. For the sake of exposition, the maintained data is presented here as:

— sb, the strstreambuf object.

D.8.4.1 ostrstream constructors

ostrstream();

Effects: Constructs an object of class ostrstream, initializing the base class with ostream(&sb) and initializing sb with strstreambuf().

ostrstream(char* s, int n, ios_base::openmode mode = ios_base::out);

Effects: Constructs an object of class ostrstream, initializing the base class with ostream(&sb), and initializing sb with one of two constructors:

— If (mode & app) == 0, then s shall designate the first element of an array of n elements.

The constructor is strstreambuf(s, n, s).

— If (mode & app) != 0, then s shall designate the first element of an array of n elements that contains an NTBS whose first element is designated by s. The constructor is strstreambuf(s, n, s + std::strlen(s)).335

335) The function signature strlen(const char*) is declared in <cstring> (20.5.3).
D.8.4.2 Member functions

strstreambuf* rdbuf() const;
1
Returns: (strstreambuf*)&sb.

void freeze(bool freezeFl = true);
2
Effects: Calls rdbuf()->freeze(freezeFl).

char* str();
3
Returns: rdbuf()->str().

int pcount() const;
4
Returns: rdbuf()->pcount().

D.8.5 Class strstream

namespace std {
    class strstream : public basic_iostream<char> {
public:
    // types
    using char_type = char;
    using int_type = char_traits<char>::int_type;
    using pos_type = char_traits<char>::pos_type;
    using off_type = char_traits<char>::off_type;

    // constructors/destructor
    strstream();
    strstream(char* s, int n,
             ios_base::openmode mode = ios_base::in|ios_base::out);
    virtual ~strstream();

    // members
    strstreambuf* rdbuf() const;
    void freeze(bool freezeFl = true);
    int pcount() const;
    char* str();
private:
    strstreambuf sb; // exposition only
    }
}

The class strstream supports reading and writing from objects of class strstreambuf. It supplies a strstreambuf object to control the associated array object. For the sake of exposition, the maintained data is presented here as:

— sb, the strstreambuf object.

D.8.5.1 strstream constructors

strstream();
1
Effects: Constructs an object of class strstream, initializing the base class with iostream(&sb).

strstream(char* s, int n,
         ios_base::openmode mode = ios_base::in|ios_base::out);
2
Effects: Constructs an object of class strstream, initializing the base class with iostream(&sb) and initializing sb with one of the two constructors:

(2.1) — If (mode & app) == 0, then s shall designate the first element of an array of n elements. The constructor is strstreambuf(s,n,s).

(2.2) — If (mode & app) != 0, then s shall designate the first element of an array of n elements that contains an NTBS whose first element is designated by s. The constructor is strstreambuf(s,n,s + std::strlen(s)).
D.8.5.2  `strstream` destructor

```cpp
virtual ~strstream();
```

**Effects:** Destroys an object of class `strstream`.

D.8.5.3  `strstream` operations

```cpp
strstreambuf* rdbuf() const;
void freeze(bool freezefl = true);
char* str();
int pcount() const;
```

**Returns:** &sb.

**Effects:** Calls rdbuf()->freeze(freezefl).

**Returns:** rdbuf()->str().

**Returns:** rdbuf()->pcount().

D.9  Deprecated type traits

The header `<type_traits>` has the following addition:

```cpp
namespace std {
  template<class T> struct is_pod;
  template<class T> inline constexpr bool is_pod_v = is_pod<T>::value;
}
```

**Requires:** remove_all_extents_t<T> shall be a complete type or cv void.

**is_pod<T>** is a `Cpp17UnaryTypeTrait` (19.15.1) with a base characteristic of `true_type` if T is a POD type, and `false_type` otherwise. A POD class is a class that is both a trivial class and a standard-layout class, and has no non-static data members of type non-POD class (or array thereof). A POD type is a scalar type, a POD class, an array of such a type, or a cv-qualified version of one of these types.

**Note:** It is unspecified whether a closure type (7.5.5.1) is a POD type. —end note

D.10  Deprecated iterator primitives

D.10.1  Basic iterator

The header `<iterator>` has the following addition:

```cpp
namespace std {
  template<class Category, class T, class Distance = ptrdiff_t,
  class Pointer = T*, class Reference = T&>
  struct iterator {
    using iterator_category = Category;
    using value_type = T;
    using difference_type = Distance;
    using pointer = Pointer;
    using reference = Reference;
  };
}
```

The iterator template may be used as a base class to ease the definition of required types for new iterators.

**Example:** If a C++ program wants to define a bidirectional iterator for some data structure containing `double` and such that it works on a large memory model of the implementation, it can do so with:
class MyIterator :
    public iterator<bidirectional_iterator_tag, double, long, T*, T&> {
        // code implementing ++, etc.
    }

—end example]

D.11 Deprecated shared_ptr atomic access [depr.util.smartptr.shared.atomic]

1 The header <memory> has the following additions:

    namespace std {
        template<class T>
            bool atomic_is_lock_free(const shared_ptr<T>* p);
        template<class T>
            shared_ptr<T> atomic_load(const shared_ptr<T>* p);
        template<class T>
            shared_ptr<T> atomic_load_explicit(const shared_ptr<T>* p, memory_order mo);
        template<class T>
            void atomic_store( shared_ptr<T>* p, shared_ptr<T> r);
        template<class T>
            void atomic_store_explicit( shared_ptr<T>* p, shared_ptr<T> r, memory_order mo);
        template<class T>
            shared_ptr<T> atomic_exchange( shared_ptr<T>* p, shared_ptr<T> r);
        template<class T>
            shared_ptr<T> atomic_exchange_explicit( shared_ptr<T>* p, shared_ptr<T> r, memory_order mo);
        template<class T>
            bool atomic_compare_exchange_weak( shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w);
        template<class T>
            bool atomic_compare_exchange_strong( shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w);
        template<class T>
            bool atomic_compare_exchange_weak_explicit( shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w, memory_order success, memory_order failure);
        template<class T>
            bool atomic_compare_exchange_strong_explicit( shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w, memory_order success, memory_order failure);
    }

2 Concurrent access to a shared_ptr object from multiple threads does not introduce a data race if the access
does not employ the functions in this subclause and the instance is passed as their first argument.

3 The meaning of the arguments of type memory_order is explained in 29.4.

    template<class T> bool atomic_is_lock_free(const shared_ptr<T>* p);
    Requires: p shall not be null.
    Returns: true if atomic access to *p is lock-free, false otherwise.
    Throws: Nothing.

    template<class T> shared_ptr<T> atomic_load(const shared_ptr<T>* p);
    Requires: p shall not be null.
    Returns: atomic_load_explicit(p, memory_order_seq_cst).
    Throws: Nothing.

    template<class T> shared_ptr<T> atomic_load_explicit(const shared_ptr<T>* p, memory_order mo);
    Requires: p shall not be null.
    Requires: mo shall not be memory_order_release or memory_order_acq_rel.
    Returns: *p.
template<class T> void atomic_store(shared_ptr<T>* p, shared_ptr<T> r);

Requires: p shall not be null.
Effects: As if by atomic_store_explicit(p, r, memory_order_seq_cst).
Throws: Nothing.

template<class T> void atomic_store_explicit(shared_ptr<T>* p, shared_ptr<T> r, memory_order mo);

Requires: p shall not be null.
Requires: mo shall not be memory_order_acquire or memory_order_acq_rel.
Effects: As if by p->swap(r).
Throws: Nothing.

template<class T> shared_ptr<T> atomic_exchange(shared_ptr<T>* p, shared_ptr<T> r);

Requires: p shall not be null.
Returns: atomic_exchange_explicit(p, r, memory_order_seq_cst).
Throws: Nothing.

template<class T>
shared_ptr<T> atomic_exchange_explicit(shared_ptr<T>* p, shared_ptr<T> r, memory_order mo);

Requires: p shall not be null.
Effects: As if by p->swap(r).
Returns: The previous value of *p.
Throws: Nothing.

template<class T>
bool atomic_compare_exchange_weak(shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w);

Requires: p shall not be null and v shall not be null.
Returns: atomic_compare_exchange_weak_explicit(p, v, w, memory_order_seq_cst, memory_order_seq_cst)
Throws: Nothing.

template<class T>
bool atomic_compare_exchange_strong(shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w);

Returns: atomic_compare_exchange_strong_explicit(p, v, w, memory_order_seq_cst, memory_order_seq_cst)

template<class T>
bool atomic_compare_exchange_strong_explicit(
    shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w,
    memory_order success, memory_order failure);

template<class T>
bool atomic_compare_exchange_weak_explicit(
    shared_ptr<T>* p, shared_ptr<T>* v, shared_ptr<T> w,
    memory_order success, memory_order failure);

Requires: p shall not be null and v shall not be null. The failure argument shall not be memory_order_release nor memory_order_acq_rel.
Effects: If *p is equivalent to *v, assigns w to *p and has synchronization semantics corresponding to the value of success, otherwise assigns *p to *v and has synchronization semantics corresponding to the value of failure.
Returns: true if *p was equivalent to *v, false otherwise.
Throws: Nothing.
Remarks: Two `shared_ptr` objects are equivalent if they store the same pointer value and share ownership. The weak form may fail spuriously. See 29.7.1.

D.12 Deprecated basic_string capacity  

The following member is declared in addition to those members specified in 20.3.2.4:

```cpp
namespace std {
    template<class charT, class traits = char_traits<charT>,
             class Allocator = allocator<charT>>
    class basic_string {
        public:
            void reserve();
    };
}
```

`void reserve();`

Effects: After this call, `capacity()` has an unspecified value greater than or equal to `size()`. [Note: This is a non-binding shrink to fit request. — end note]

D.13 Deprecated standard code conversion facets  

The header `<codecvt>` provides code conversion facets for various character encodings.

D.13.1 Header `<codecvt>` synopsis  

```cpp
namespace std {
    enum codecvt_mode {
        consume_header = 4,
        generate_header = 2,
        little_endian = 1
    };

    template<class Elem, unsigned long Maxcode = 0x10ffff, codecvt_mode Mode = (codecvt_mode)0>
    class codecvt_utf8 : public codecvt<Elem, char, mbstate_t> {
        public:
            explicit codecvt_utf8(size_t refs = 0);
            ~codecvt_utf8();
    };

    template<class Elem, unsigned long Maxcode = 0x10ffff, codecvt_mode Mode = (codecvt_mode)0>
    class codecvt_utf16 : public codecvt<Elem, char, mbstate_t> {
        public:
            explicit codecvt_utf16(size_t refs = 0);
            ~codecvt_utf16();
    };

    template<class Elem, unsigned long Maxcode = 0x10ffff, codecvt_mode Mode = (codecvt_mode)0>
    class codecvt_utf8_utf16 : public codecvt<Elem, char, mbstate_t> {
        public:
            explicit codecvt_utf8_utf16(size_t refs = 0);
            ~codecvt_utf8_utf16();
    };
}
```

D.13.2 Requirements  

For each of the three code conversion facets `codecvt_utf8`, `codecvt_utf16`, and `codecvt_utf8_utf16`:  

1. `Elem` is the wide-character type, such as `wchar_t`, `char16_t`, or `char32_t`.  
2. `Maxcode` is the largest wide-character code that the facet will read or write without reporting a conversion error.  
3. If `(Mode & consume_header)`, the facet shall consume an initial header sequence, if present, when reading a multibyte sequence to determine the endianness of the subsequent multibyte sequence to be read.

§ D.13.2
(1.4) If (Mode & generate_header), the facet shall generate an initial header sequence when writing a multibyte sequence to advertise the endianness of the subsequent multibyte sequence to be written.

(1.5) If (Mode & little_endian), the facet shall generate a multibyte sequence in little-endian order, as opposed to the default big-endian order.

For the facet codecvt_utf8:

(2.1) The facet shall convert between UTF-8 multibyte sequences and UCS-2 or UTF-32 (depending on the size of Elem) within the program.

(2.2) Endianness shall not affect how multibyte sequences are read or written.

(2.3) The multibyte sequences may be written as either a text or a binary file.

For the facet codecvt_utf16:

(3.1) The facet shall convert between UTF-16 multibyte sequences and UCS-2 or UTF-32 (depending on the size of Elem) within the program.

(3.2) Multibyte sequences shall be read or written according to the Mode flag, as set out above.

(3.3) The multibyte sequences may be written only as a binary file. Attempting to write to a text file produces undefined behavior.

For the facet codecvt_utf8_utf16:

(4.1) The facet shall convert between UTF-8 multibyte sequences and UTF-16 (one or two 16-bit codes) within the program.

(4.2) Endianness shall not affect how multibyte sequences are read or written.

(4.3) The multibyte sequences may be written as either a text or a binary file.

The encoding forms UTF-8, UTF-16, and UTF-32 are specified in ISO/IEC 10646. The encoding form UCS-2 is specified in ISO/IEC 10646-1:1993.

D.14 Deprecated convenience conversion interfaces

The header <locale> has the following additions:

\begin{verbatim}
namespace std {
    template<class Codecvt, class Elem = wchar_t,
             class Wide_alloc = allocator<Elem>,
             class Byte_alloc = allocator<char>>
    class wstring_convert;

    template<class Codecvt, class Elem = wchar_t,
             class Tr = char_traits<Elem>>
    class wbuffer_convert;
}
\end{verbatim}

D.14.1 Class template wstring_convert

Class template wstring_convert performs conversions between a wide string and a byte string. It lets you specify a code conversion facet (like class template codecvt) to perform the conversions, without affecting any streams or locales. [Example: If you want to use the code conversion facet codecvt_utf8 to output to cout a UTF-8 multibyte sequence corresponding to a wide string, but you don’t want to alter the locale for cout, you can write something like:

\begin{verbatim}
wstring_convert<std::codecvt_utf8<wchar_t>> myconv;
std::string mbstring = myconv.to_bytes(L"Hello\n");
std::cout << mbstring;
\end{verbatim}

—end example]

\begin{verbatim}
namespace std {
    template<class Codecvt, class Elem = wchar_t,
             class Wide_alloc = allocator<Elem>,
             class Byte_alloc = allocator<char>>
    class wstring_convert {
        public:
            using byte_string = basic_string<char, char_traits<char>, Byte_alloc>;
            using wide_string = basic_string<Elem, char_traits<Elem>, Wide_alloc>;
    }
\end{verbatim}
using state_type = typename Codecvt::state_type;
using int_type = typename wide_string::traits_type::int_type;

wstring_convert() : wstring_convert(new Codecvt) {}  
explicit wstring_convert(Codecvt* pcvt);
wstring_convert(Codecvt* pcvt, state_type state);
explicit wstring_convert(const byte_string& byte_err,  
    const wide_string& wide_err = wide_string());
~wstring_convert();

wstring_convert(const wstring_convert&) = delete;
wstring_convert& operator=(const wstring_convert&) = delete;

wide_string from_bytes(char byte);
wide_string from_bytes(const char* ptr);
wide_string from_bytes(const byte_string& str);
wide_string from_bytes(const char* first, const char* last);

byte_string to_bytes(Elem wchar);
byte_string to_bytes(const Elem* wptr);
byte_string to_bytes(const wide_string& wstr);
byte_string to_bytes(const Elem* first, const Elem* last);

size_t converted() const noexcept;
state_type state() const;

private:
    byte_string byte_err_string; // exposition only  
    wide_string wide_err_string; // exposition only  
    Codecvt* cvtptr; // exposition only  
    state_type cvtstate; // exposition only  
    size_t cvtcount; // exposition only  
};

The class template describes an object that controls conversions between wide string objects of class basic_string<Elem, char_traits<Elem>, Wide_alloc> and byte string objects of class basic_string<char, char_traits<char>, Byte_alloc>. The class template defines the types wide_string and byte_string as synonyms for these two types. Conversion between a sequence of Elem values (stored in a wide_string object) and multibyte sequences (stored in a byte_string object) is performed by an object of class Codecvt, which meets the requirements of the standard code-conversion facet codecvt<Elem, char, mbstate_t>.

An object of this class template stores:

(3.1) — byte_err_string — a byte string to display on errors

(3.2) — wide_err_string — a wide string to display on errors

(3.3) — cvtptr — a pointer to the allocated conversion object (which is freed when the wstring_convert object is destroyed)

(3.4) — cvtstate — a conversion state object

(3.5) — cvtcount — a conversion count

using byte_string = basic_string<char, char_traits<char>, Byte_alloc>;

The type shall be a synonym for basic_string<char, char_traits<char>, Byte_alloc>.

size_t converted() const noexcept;

Returns: cvtcount.

wide_string from_bytes(char byte);
wide_string from_bytes(const char* ptr);
wide_string from_bytes(const byte_string& str);
wide_string from_bytes(const char* first, const char* last);

Effects: The first member function shall convert the single-element sequence byte to a wide string. The second member function shall convert the null-terminated sequence beginning at ptr to a wide string. The third member function shall convert the sequence stored in str to a wide string. The fourth member function shall convert the sequence defined by the range [first, last) to a wide string.

In all cases:

(7.1) If the cvtstate object was not constructed with an explicit value, it shall be set to its default value (the initial conversion state) before the conversion begins. Otherwise it shall be left unchanged.

(7.2) The number of input elements successfully converted shall be stored in cvtcount.

Returns: If no conversion error occurs, the member function shall return the converted wide string. Otherwise, if the object was constructed with a wide-error string, the member function shall return the wide-error string. Otherwise, the member function throws an object of class range_error.

using int_type = typename wide_string::traits_type::int_type;

The type shall be a synonym for wide_string::traits_type::int_type.

state_type state() const;
returns cvtstate.

using state_type = typename Codecvt::state_type;

The type shall be a synonym for Codecvt::state_type.

byte_string to_bytes(Elem wchar);
byte_string to_bytes(const Elem* wptr);
byte_string to_bytes(const wide_string& wstr);
byte_string to_bytes(const Elem* first, const Elem* last);

Effects: The first member function shall convert the single-element sequence wchar to a byte string. The second member function shall convert the null-terminated sequence beginning at wptr to a byte string. The third member function shall convert the sequence stored in wstr to a byte string. The fourth member function shall convert the sequence defined by the range [first, last) to a byte string.

In all cases:

(13.1) If the cvtstate object was not constructed with an explicit value, it shall be set to its default value (the initial conversion state) before the conversion begins. Otherwise it shall be left unchanged.

(13.2) The number of input elements successfully converted shall be stored in cvtcount.

Returns: If no conversion error occurs, the member function shall return the converted byte string. Otherwise, if the object was constructed with a byte-error string, the member function shall return the byte-error string. Otherwise, the member function shall throw an object of class range_error.

using wide_string = basic_string<Elem, char_traits<Elem>, Wide_alloc>;

The type shall be a synonym for basic_string<Elem, char_traits<Elem>, Wide_alloc>.

explicit wstring_convert(Codecvt* pcvt);
wstring_convert(Codecvt* pcvt, state_type state);
explicit wstring_convert(const byte_string& byte_err, const wide_string& wide_err, const wide_string& wide_err = wide_string());

Requires: For the first and second constructors, pcvt != nullptr.

Effects: The first constructor shall store pcvt in cvtptr and default values in cvtstate, byte_err_string, and wide_err_string. The second constructor shall store pcvt in cvtptr, state in cvtstate, and default values in byte_err_string and wide_err_string; moreover the stored state shall be retained between calls to from_bytes and to_bytes. The third constructor shall store new Codecvt in cvtptr, state_type() in cvtstate, byte_err in byte_err_string, and wide_err in wide_err_string.
D.14.2 Class template \texttt{wbuffer\_convert} \hfill [depr.conversions.buffer]

Class template \texttt{wbuffer\_convert} looks like a wide stream buffer, but performs all its I/O through an underlying byte stream buffer that you specify when you construct it. Like class template \texttt{wstring\_convert}, it lets you specify a code conversion facet to perform the conversions, without affecting any streams or locales.

\begin{verbatim}
namespace std {
    template<class Codecvt, class Elem = wchar_t, class Tr = char_traits<Elem>>
    class wbuffer_convert : public basic_streambuf<Elem, Tr> {
        public:
            using state_type = typename Codecvt::state_type;

            wbuffer_convert() : wbuffer_convert(nullptr) {} 
            explicit wbuffer_convert(streambuf* bytebuf, 
                Codecvt* pcvt = new Codecvt, 
                state_type state = state_type());

            ~wbuffer_convert();

            wbuffer_convert(const wbuffer_convert&) = delete;
            wbuffer_convert& operator=(const wbuffer_convert&) = delete;

            streambuf* rdbuf() const;
            streambuf* rdbuf(streambuf* bytebuf);

            state_type state() const;

        private:
            streambuf* bufptr;   // exposition only
            Codecvt* cvtptr;     // exposition only
            state_type cvtstate; // exposition only
        };
    }
\end{verbatim}

2 The class template describes a stream buffer that controls the transmission of elements of type \texttt{Elem}, whose character traits are described by the class \texttt{Tr}, to and from a byte stream buffer of type \texttt{streambuf}. Conversion between a sequence of \texttt{Elem} values and multibyte sequences is performed by an object of class \texttt{Codecvt}, which shall satisfy the requirements of the standard code-conversion facet \texttt{codecvt<Elem, char, mbstate_t>}.

3 An object of this class template stores:
   \begin{enumerate}
   \item \texttt{bufptr} — a pointer to its underlying byte stream buffer
   \item \texttt{cvtptr} — a pointer to the allocated conversion object (which is freed when the \texttt{wbuffer\_convert} object is destroyed)
   \item \texttt{cvtstate} — a conversion state object
   \end{enumerate}

4 \texttt{state\_type state() const;}

5 \texttt{streambuf* rdbuf() const;}

6 \texttt{streambuf* rdbuf(streambuf* bytebuf);} 
\hspace{1em} \textit{Effects:} Stores \texttt{bytebuf} in \texttt{bufptr}.

7 \texttt{Returns:} The previous value of \texttt{bufptr}.

8 \texttt{using state\_type = typename Codecvt::state\_type;}

9 The type shall be a synonym for \texttt{Codecvt::state\_type}.
explicit wbuffer_convert(
    streambuf* bytebuf,
    Codecvt* pcvt = new Codecvt,
    state_type state = state_type());

9  Requires: pcvt != nullptr.
10  Effects: The constructor constructs a stream buffer object, initializes bufptr to bytebuf, initializes cvtptr to pcvt, and initializes cvtstate to state.

~wbuffer_convert();
11  Effects: The destructor shall delete cvtptr.
The following documents are cited informatively in this document:

— ISO 4217:2015, *Codes for the representation of currencies*

The arithmetic specification described in ISO/IEC 10967-1:2012 is called *LIA-1* in this document.

**Note:** The above text provides an index of library names and related functions or operators, such as `operator bool`, `operator!=`, `operator<`, `operator<<`, `operator=`, `operator==`, `value`, `error_condition`, `assign`, `category`, `clear`, `constructor`, `message`, `operator bool`, `operator!=`, `operator<`, `operator=`, `operator==`, `value`, `error_type`, and many others. Each entry is followed by a page number indicating its location in the document. This index serves as a reference to quickly locate specific library names across the document. Additionally, there are descriptions of exceptions and their related terms, such as `exception`, `exception_ptr`, `exceptions`, `exchange`, `atomic`, `atomic<floating-point>`, `atomic<integral>`, `atomic<shared_ptr<T>`, `atomic<T>`, `atomic<weak_ptr<T>`, `atomic_ref`, `atomic_ref<floating-point>`, `atomic_ref<integral>`, `atomic_ref<T>`, `exclusive_scan`, `EXDEV`, `EXIT_FAILURE`, `EXIT_SUCCESS`, `exp`, `exp2`, `exp2f`, `exp2l`, `expf`, `expint`, `expintf`, `expintl`, `expired`, `weak_ptr`, `expl`, `expm1`, `expm1f`, `expm1l`, `exponential_distribution`, `constructor`, `lambda`, `extension`, `path`, `extent`, `extreme_value_distribution`, `a`, `b`, `constructor`, `fabs`, `fabsf`, `fabsl`, `facet`, `locale`, `fail`, `basic_ios`, `failed`, `ostreambuf_iterator`, `false_type`, `false_name`, `numpunct`, `fclose`, `fdim`, `fdimf`, `fdiml`, `FE_ALL_EXCEPT`, `FE_DFL_ENV`, `FE_DIVBYZERO`, `FE_DOWNWARD`, `FE_INEXACT`, `FE_INVALID`, `FE_OVERFLOW`, `FE_TONEAREST`, `FE_TOWARDZERO`, `FE_UNDERFLOW`, `fclearexcept`, `fegetenv`, `fegetexceptflag`, and `fegetround`. Each term is followed by a page number indicating its location in the document. This index is essential for quickly locating specific library names or terms across the document. **Index of library names**

Index of implementation-defined behavior

The entries in this index are rough descriptions; exact specifications are at the indicated page in the general text.

#define, 414
additional execution policies supported by parallel algorithms, 672, 867
additional file_type enumerators for file systems supporting additional types of file, 1249
additional formats for time_get::do_get_date, 1138
additional supported forms of preprocessing directive, 405
algorithms for producing the standard random number distributions, 964
alignment, 57
alignment additional values, 57
alignment of bit-fields within a class object, 243
allocation of bit-fields within a class object, 243
any use of an invalid pointer other than to perform indirection or deallocate, 54
argument for violation handler, 216
argument values to construct basic_ios::failure, 1166
assignability of placeholder objects, 636
behavior of iostream classes when traits::pos_type is not streampos or when traits::off_type is not streamoff, 1150
behavior of non-standard attributes, 210
bits in a byte, 48
choice of larger or smaller value of floating literal, 19
concatenation of some types of string literals, 20
consistency of build level and violation continuation mode, 29
conversions between pointers and integers, 110
converting characters from source character set to execution character set, 9
converting function pointer to object pointer and vice versa, 110
default configuration of a pool, 615
default next_buffer_size for a monotonic_buffer_resource, 616
default number of buckets in unordered_map, 808
default number of buckets in unordered_multimap, 813, 814
default number of buckets in unordered_multiset, 821, 822
default number of buckets in unordered_set, 818
defining main in freestanding environment, 74
definition and meaning of __STDC__, 416, 1413
definition and meaning of __STDC_VERSION__, 416
definition of NULL, 450, 1428
derived type for typeid, 107
diagnostic message, 3
dynamic initialization of static inline variables before main, 76
dynamic initialization of static variables before main, 75, 76
dynamic initialization of thread-local variables before entry, 76
effect of calling associated Laguerre polynomials with n >= 128 or m >= 128, 1009
effect of calling associated Legendre polynomials with l >= 128, 1010
effect of calling basic_filebuf::setbuf with nonzero arguments, 1214
effect of calling basic_filebuf::sync when a get area exists, 1215
effect of calling basic_streambuf::setbuf with nonzero arguments, 1205
effect of calling cylindrical Bessel functions of the first kind with nu >= 128, 1011
effect of calling cylindrical Neumann functions with nu >= 128, 1012
effect of calling Hermite polynomials with n >= 128, 1013
effect of calling ios_base::sync_with_stdio after any input or output operation on standard streams, 1160
effect of calling irregular modified cylindrical Bessel functions with nu >= 128, 1011
effect of calling Laguerre polynomials with n >= 128, 1013
effect of calling Legendre polynomials with l >= 128, 1013
effect of calling regular modified cylindrical Bessel functions with nu >= 128, 1011
effect of calling spherical associated Legendre functions with l >= 128, 1014
effect of calling spherical Bessel functions with n >= 128, 1014
effect of calling spherical Neumann functions with n >= 128, 1014
effect of filesystem::copy, 1261
effect on C locale of calling locale::global, 1116
encoding of universal character name not in execution character set, 18
**error_category** for errors originating outside the operating system, 446

exception type when `random_device` constructor fails, 962

exception type when `random_device::operator()` fails, 962

exception type when `shared_ptr` constructor fails, 593

exceptions thrown by standard library functions that have a potentially-throwing exception specification, 446

execution character set and execution wide-character set, 10

exit status, 464

extended signed integer types, 63

file type of the file argument of `filesystem::status`, 1271

formatted character sequence generated by `time_put::do_put` in C locale, 1140

forward progress guarantees for implicit threads of parallel algorithms (if not defined for `thread`), 866

growth factor for `monotonic_buffer_resource`, 616, 617

headers for freestanding implementation, 429

how `random_device::operator()` generates values, 962

interactive device, 7

interpretation of the path character sequence with format `path::auto_format`, 1248

largest supported value to configure the largest allocation satisfied directly by a pool, 614

largest supported value to configure the maximum number of blocks to replenish a pool, 614

linkage of `main`, 74

linkage of names from C standard library, 430

linkage of objects between C++ and other languages, 209

locale names, 1114

lvalue-to-rvalue conversion of an invalid pointer value, 83

manner of search for included source file, 408

mapping from name to catalog when calling `messages::do_open`, 1146

mapping from physical source file characters to basic source character set, 10, 1420

mapping header name to header or external source file, 13

mapping of pointer to integer, 110

mapping physical source file characters to basic source character set, 9

mapping to message when calling `messages::do_get`, 1147

maximum depth of recursive template instantiations, 367

maximum size of an allocated object, 115, 470

meaning of ‘\’, ‘\n’, ‘/’, ‘\*/’, or ‘//’ in a q-char-sequence or an h-char-sequence, 13

meaning of `asm` declaration, 207

meaning of attribute declaration, 144

meaning of dot-dot in `root-directory`, 1236

mechanism for selecting the build level, 216

negative value of character literal in preprocessor, 407

nesting limit for `#include` directives, 408

NTCTS in `basic_ostream<charT, traits>& operator<<(nullptr_t)`, 1194

number of placeholders for bind expressions, 1194, 636

number of threads in a program under a freestanding implementation, 69

numeric values of character literals in `#if` directives, 407

operating system on which implementation depends, 1227

parameters to `main`, 74

passing argument of class type through ellipsis, 104

physical source file characters, 9

presence and meaning of `native_handle_type` and `native_handle`, 1338

range defined for character literals, 18

rank of extended signed integer type, 66

representation of `char`, 62

required alignment for `atomic_ref` type’s operations, 1321, 1323–1325

required libraries for freestanding implementation, 6

resource limits on a message catalog, 1147

result of `filesystem::file_size`, 1266

result of inexact floating-point conversion, 85

result of right shift of negative value, 123

return value of `bad_alloc::what`, 469

return value of `bad_any_cast::what`, 558

return value of `bad_array_new_length::what`, 470

return value of `bad_cast::what`, 472

return value of `bad_exception::what`, 475

return value of `bad_function_call::what`, 637

return value of `bad_optional_access::what`, 544

return value of `bad_typeid::what`, 473

return value of `bad_variant_access::what`, 557

return value of `bad_weak_ptr::what`, 591

return value of `char_traits<char16_t>::eof`, 680

return value of `char_traits<char32_t>::eof`, 680

Index of implementation-defined behavior
return value of `exception::what`, 475
return value of `type_info::name()`, 472

search locations for " header, 408
search locations for <> header, 408
semantics of an access through a volatile glvalue, 153
semantics of linkage specification on templates, 314
semantics of linkage specifiers, 207
semantics of non-standard escape sequences, 18
semantics of parallel algorithms invoked with implementation-defined execution policies, 867
semantics of `token` parameter and default token value used by `random_device` constructors, 962
sequence of places searched for a header, 408
set of character types that iostreams templates can be instantiated for, 1113, 1150
signedness of `char`, 62, 154
`sizeof` applied to fundamental types other than `char`, `signed char`, and `unsigned char`, 113
source location of precondition violation, 216
specification of violation handler, 216
stack unwinding before call to `std::terminate`, 399, 402
start-up and termination in freestanding environment, 74
string resulting from `_func_`, 189
support for extended alignment, 664
support for extended alignments, 57
supported multibyte character encoding rules, 679, 681
supported `root-names` in addition to any operating system dependent `root-names`, 1235, 1236
text of `__DATE__` when date of translation is not available, 415
text of `__TIME__` when time of translation is not available, 415
threads and program points at which deferred dynamic initialization is performed, 75, 76
type of a directory-like file, 1256, 1258
type of `array::const_iterator`, 762
type of `array::iterator`, 762
type of `basic_string::const_iterator`, 685
type of `basic_string::iterator`, 685
type of `basic_string_view::const_iterator`, 713, 715
type of `default_random_engine`, 961
type of `deque::const_iterator`, 764
type of `deque::iterator`, 764
type of filesystem trivial clock, 1231
type of `forward_list::const_iterator`, 768
type of `forward_list::iterator`, 768
type of `list::const_iterator`, 774
type of `list::iterator`, 774
type of `map::const_iterator`, 788
type of `map::iterator`, 788
type of `multimap::const_iterator`, 793
type of `multimap::iterator`, 793
type of `multiset::const_iterator`, 799
type of `multiset::iterator`, 799
type of `ptdiff_t`, 122, 451
type of `regex_constants::error_type`, 1286
type of `regex_constants::match_flag_type`, 1285
type of `set::const_iterator`, 796
type of `set::iterator`, 796
type of `size_t`, 451
type of `span::const_iterator`, 830
type of `span::iterator`, 830
type of `streamoff`, 679
type of `streampos`, 679
syntax resulting from `__func__`, 189
threads and program points at which deferred dynamic initialization is performed, 75, 76
underlying type for enumeration, 194
value of bit-field that cannot represent
assigned value, 129
incremented value, 106
initializer, 177
value of character literal outside range of corresponding type, 18
value of ctype<char>::table_size, 1121
value of has-attribute-expression for non-standard attributes, 406
value of multicharacter literal, 17
value of pow(0,0), 941
value of result of inexact integer to floating-point conversion, 85
value of result of unsigned to signed conversion, 84
value of wide-character literal containing multiple characters, 18
value of wide-character literal with single c-char that is not in execution wide-character set, 17
value representation of floating-point types, 63
value representation of pointer types, 65
values of a trivially copyable type, 61
values of various ATOMIC_..._LOCK_FREE macros, 1320
whether <cfenv> functions can be used to manage floating-point status, 934
whether a given atomic type’s operations are always lock free, 604, 606, 1327, 1328, 1330, 1332, 1333
whether a given atomic_ref type’s operations are always lock free, 1321, 1323–1325
whether an implementation has relaxed or strict pointer safety, 57
whether functions from Annex K of the C standard library are declared when C++ headers are included, 429
whether get_pointer_safety returns pointer_safety::relaxed or pointer_safety::preferred if the implementation has relaxed pointer safety, 575
whether locale object is global or per-thread, 1112
whether pragma FENV_ACCESS is supported, 934
whether rand may introduce a data race, 981
whether sequence pointers are copied by basic_filebuf move constructor, 1211
whether sequence pointers are copied by basic_stringbuf move constructor, 1202
whether source of translation units must be available to locate template definitions, 10
whether stack is unwound before calling the function std::terminate when a noexcept specification is violated, 402
whether the lifetime of a parameter ends when the callee returns or at the end of the enclosing full-expression, 103

whether the thread that executes main and the threads created by std::thread provide concurrent forward progress guarantees, 73
whether time_get::do_get_year accepts two-digit year numbers, 1139
whether values are rounded or truncated to the required precision when converting between time_t values and time_point objects, 1043
whether variant supports over-aligned types, 549
which functions in the C++ standard library may be recursively reentered, 445
which non-standard-layout objects containing no data are considered empty, 50
which scalar types have unique object representations, 658

Index of implementation-defined behavior 1571
